What will you do with your life here? You have been wise in coming, for supreme advantages are in the gift of this great place. While we rejoice that these are more and more decentralized, and that in different parts of the country facilities for improvement have been created, London presents them in such infinite variety as still to remain the wished-for haven of the student. Then, contact with this mass of people, with its innumerable interests, aspirations, and necessities, and the provision made for their promotion, is in itself an education. Men under such influences learn to estimate themselves aright; to make large allowances for others, and to drop the pettiness of spirit almost inseparable from a contracted sphere.

But we must not lose ourselves in generalities, and there is distinctly before my mind that to-night my business is with young men who have accepted Pharmacy as a vocation. Some have finished their first campaign and have been openly rewarded by the chief. Let me as myself an old student, congratulate them on their success. Let them take the good the Gods provide, without reserve or afterthought; and let the remembrance of past triumphs nerve them for fresh victories. Others are entering on the contest, overshadowed by the fond wishes of their relatives, and the earnest hopes in their behalf of every true-hearted pharmacist.

London has its splendid openings, but also its fell temptations—these have made or marred countless generations. What will you do with your life here? is a question we are bound to ask. Will you trim the lamp of science and keep it brightly burning; or will you kindle the unhallowed fire of passion, and run riot in its lurid light? One thing hold fast in your memory, and treasure it in your heart of hearts, that the time must come sooner or later when each one of us knows either in the joy of his soul, or in the bitterness of his disappointment, conduct is fate.

Fifty years ago Pharmacy as a corporate body had no existence. Here and there was an isolated light shining: such was William Allen in the hermitage of Plough Court; John Savory in the West End; midway between both, Thomas Morson; and my own father dwelling under the shadow of the Phenix; and there were a very great number of respectable individuals who honestly kept shop and aspired to nothing more.

A common danger drove the scattered ranks together, as a storm sends the most disunited to seek a common shelter. But no sooner was there a Society of some sort, a distinct and recognized community, than it was found imperative to have a stronger bond of union than mere aggregation of numbers. The grains of sand upon the seashore are numerous and form a distinctive class, but there is no cohesion among the particles; and from the first it was seen that numerical strength alone was destitute of vital power. Moreover provision had to be made for future exigencies, and it was vain for pharmacists to claim respect from the world outside, unless it were discovered that the claimants were men of trained intelligence and education. Hence necessity completed what threatened danger had begun: and so rose the School of the Pharmaceutical Society of Great Britain.

I have diligently searched the records of the period but I can discover no other English sources of instruction open at that date to the chemist and druggist, than the courses at our London and Provincial Hospitals in which Materia Medica, Botany, and Chemistry formed part of the curriculum. I learn from credible witnesses that none of these three branches were held in high estimation, but that they were subservient to purely medical studies, and tinctured with professional reference and allusion. The one subject that promised usefulness was that of Therapeutics which was not treated so as to be understood by the non-medical student. Pharmacy as a separate science had not risen into sufficient importance to have a teaching of its own or to rank as a distinct study, and I have listened to sorrowful details from druggists then engaged in business of the hopelessness of educational improvement.

At this crisis there appeared one who revolutionized the manner in which the once dry details of Materia Medica were elucidated: this was Jonathan Pereira. Endowed with a handsome person and commanding presence; having the gift of speech and a singularly buoyant temperament: clear in statement, and brilliant in illustration; he inspired his audience with enthusiasm for a theme which its nature hardly seemed to warrant. The dry bones lived—and from that moment an era in pharmaceutical education was begun. The genius of Mr. Jacob Bell saw at a glance that he had hit upon the right man with whose aid he should develop a new order of instruction.

Nearly as fortunate was the choice of Anthony Todd Thomson who was called to fill the chair of Botany. It would be difficult to find one who showed more unwearied diligence in a professional career. I have often been astonished whilst reading the acccount of his laborious activities; and it was no slight compliment that when our Society was in its infancy it should have been so effectually countenanced by men of a higher faculty, supposed sometimes, but erroneously to be antagonistic to the pharmacist. We had just acquired the right to be respected; a right which was immediately conceded.

Next in order came a young man, of keen susceptibilities and retiring habit; who wrote a successful essay for which he was publicly rewarded, and who had already begun to teach Chemistry not so much from books as by direct experiment and laboratory demonstration. This was George Fownes whose services it was no small gain to have enlisted. Lastly appeared upon the scene our own Professor, Dr. Redwood, of whom an old pupil can say nothing in his immediate presence. These were the pioneer exponents of the theory that education must be the lever by which to raise the druggist; to give him the command of circumstances, and to enable him worthily to fill the station which the framework of wise regulations and law might secure. So rose this School; and it was a bright day for British Pharmacy, and for the British public; for from that hour the reign of intelligence dethroned the rule of thumb.

Such amongst you as are the heirs of modern progress, are hereby informed that the word "rose" is metaphorical. Pharmacy like the bird of song had its nest upon the ground, from which like that bird it has risen skywards.

We were literally a foundation school, situated in the basement, which less euphoniously might have been termed the kitchen. From these subterranean regions evil smells ascended which discomfited the Council; and not unfrequently the students underground would receive visits from the powers above who expressed their sentiments in language which was not always guarded. A liberal bequest allowed more convenient arrangements to be provided; and it is clear that the conditions under which laboratory work was undertaken, were justified only by necessity. Sooner or later a change must have been made, for with increasing numbers those conditions had becoming impossible.

I believe that it is entirely due to the Professor whose praises have been left unsaid, that the school was shifted bodily to the topmost story, and was reconstructed according to the plans and with the appliances now open to your inspection.

As time presses, this brief historical sketch must end, and I propose with your permission, to say a few words to a beginner about the manner in which he may best pursue his studies.

Probably there is no time when encouragement, and even advice is less essential than at the commencement of a career of study. All is new, and novelty is a strong stimulant. There are fresh faces pursuits and associations; there is actual contact with persons whose names have been long familiar; and with places that have been known intimately by report. The dreams of imagination have become realities, and now they are clothed with visible shape and presence.

For a brief space there is no outward difference between one student and another: all alike are eager, confident and industrious. The tares are not distinguishable from the wheat.

But novelty must cease, and with it the influence of excitement, good in itself but evanescent. Here is the rock on which many a brave ship has foundered. When the sun shines it is easy sailing; and when the storm blows, every man is on the alert; but the calm is a perilous condition, for where there is little apparent progress, the most persevering are tempted to grow weary of well-doing.

This is doubly the student's danger,—his surroundings are no longer strange and no sooner has the stimulus of acquiring leading facts diminished, than a sense of lassitude springs up: the calm, most of all things to be dreaded, has set in.

At this critical point begins the differentiation between the good and the bad student. The first is sorely tried; but the second yields—unconsciously; to a great degree, imperceptibly; until a fatal carelessness becomes habit: until regret merges into apathy: until apathy itself runs through the transformations of inattention, recklessness and despair.

No man is suddenly a bad student—the phases of a downward path are generally as just described.

He who would win the race and wear the crown is warned that this period of stagnation will supervene. The better the student, the more quickly will it arrive; but it is the fourth month which frequently decides success or failure.

The student in chemistry knows his gases, acids, salts, metallic and non-metallic bodies, and theories of combination. In Pharmacy he knows the run of the preparations of the British Pharmacopœia; in Botany, the book-teaching of the subject, and he can both recognize and is acquainted with the history of the various products of Materia Medica. Then, either seeing the immensity of the field before him;

or far worse, not seeing it, and beginning to be content, the warmth of his ardour cools, and the fresh vigour of his energy decays. Would that he would allow an old student to be taken into his confidence, and listen while he tells him, that this state of passivity has afflicted countless generations of men who have triumphed over the narcotic influence; who have aroused themselves from a slumber fatal as the snow-sleep; and who have attained to what theologians call, final perseverance. Happy is the student, who feeling no pleasure in his work; with loss of appetite for study, and for a season indifferent to success; realizes that this is an illness of the mind produced by natural causes; and who quietly goes on his accustomed way certain that the fit will pass.

Poor humanity is not always in a crisis, nor exposed to overstrained emotion; three quarters of the student's work is of an equable and regular description. On an average it is all the better, should he be fortunate enough not to read alone. Two congenial friends having sympathies in common, and passing through the same curriculum, form a splendid mutual aid society. One cheers the other, and chaffs him pleasantly when inclined to loiter. Two, can talk over their mutual difficulties and question each other on the various subjects: two can examine each other's notes and point out deficiencies in the manuscript of either: two, to make the matter brief, are stated on high authority to be better far than one.

But should circumstances render this impossible, the best substitute is to read aloud, and unless this plan be adopted, a very large portion of the knowledge to be gained from books will escape the reader. Understandest thou what thou readest? is an ancient question; but the student who reads always to himself is not in a position to discover whether he understands or not. Forgive me if I insist upon this point. In cases innumerable an abstruse sentence becomes intelligible solely by this method; and it is the daily experience of every constant reader that words travelling through the air and coming back upon him as a listener acquire a meaning and a distinctness which previously they did not possess.

May I to-night repeat what I have insisted on for more than twenty years, that the regular consecration of a fixed portion of time, to any branch of learning, pharmaceutical or otherwise, will surmount whatever difficulties may be presented. Thus the enforced, consecutive and continuous devotion of one hour a day to a given purpose, is omnipotent. I know full well that the idea has been deemed romantic, but it never will be by those who venture on the attempt.

We read of genius—and in truth there is a species of divine intuition vouchsafed to a few. A street boy takes a piece of chalk and with it traces lines which command the admiration of the world; a rude miner in the bowels of the earth solves problems in mathematics; and an untaught lad makes music out of pots and pans—music destined to be the delight of after ages. For this there is no law—but next to genius there is something which marvellously simulates its effects, and that is uninterrupted perseverance. So great is its power that some have even mistaken its identity and declared that genius itself was but the faculty of unremitted application. Let us not quarrel about definitions—try it under whatever name; and should you inadvertently turn out a genius, your friends will be quite pleased.

The wise king said that of making books there was no end, and in the days of Solomon there were no second editions. There are now more books than ever, but it must be granted that many of them are extremely good. No man need hunt for an admirable treatise on any technical subject; and it is specially characteristic of the age that professors of acknowledged excellence devote their full powers to the literary explanation of their own science. Their works are correct, lucid and arranged with charming simplicity. They are no longer written to display the profundity of personal erudition, but lovingly, as if to beg the student to understand the contents of the manual.

He acts wisely therefore who is not a man of one book, but who is catholic in his selection, and who consults two or more standard authorities in each department of information.

But whatever text-books be adopted, they should not be blindly followed, or be permitted to supplant original thought. An author himself is the first to condemn such *literatim* study, for his wish is to instruct others in the lore which he has himself acquired, and to lead those who accept his services, into fresh fields and pastures new.

I am bound most unwillingly to advert to a peculiar cause of weakness which should not be suffered to continue. It has been to myself and others a matter of astonishment that there should exist in young Pharmacy such a dread of examinations. I am not alluding to those prescribed by law, for I have rigidly set myself the task of speaking only of the School of Pharmacy as such. I have designedly left untouched the broader questions of education, such as the proposed curriculum; the creation of recognized official centres, and the politics of our Society. We turn to the pages of the Journal and see that at the end of a session one student enters into competition (if the term can then be permissible,) for a prize: or two present themselves for an examination. Reports of former years confirm the statement that often the number of candidates is in inverse proportion to the number of the class. Some possibly argue that the reward is likely to pass into other hands, and it is therefore useless for them to compete, a notion which is confusion worse confounded as to the whole bearing of the subject.

If the value of the teaching here is represented by the medals, prizes and certificates which can only fall into the hands of a restricted few, the sooner the place shuts its doors the better. The expenditure, and the machinery employed would both be infinitely out of keeping with results. The system of giving prizes is the best at our disposal, and it contemplates two objects;—first, it directly promotes the activity of study, and is a public sign on the part of the authorities that certain students have distinguished themselves in a more than ordinary manner. Secondly, it is an inducement to persuade young men to accustom themselves to an examination, and thus to ascertain for themselves from time to time the exact position in which they stand. They will find no plan more useful, or more satisfactory: and, just as a merchant undergoes a perpetual examination of his affairs by consulting his accounts, and thus sees where he is weak, and where he is strong: where the source of failure by being anticipated may be prevented; and also sees the exact moment when he may stand before the world with confidence; so the student may both ascertain his deficiencies, and know when calmly to rely upon his strength.

I implore the students of the opening session to be guided in these matters by common sense; and I ask them to court every chance of class examination—a process salutary beyond description, and one which will rob the official compulsory examinations of all their terrors.

Having reached this pleasant elevation let me not close my note-book without showing you a little sketch which I have made of a flower by the wayside: it is hardy in character; indigenous to Great Britain, and should be carefully cultivated by every student: the flower is called, Cheerfulness. You may think it a minor virtue, and an anti-climax to other gifts, but it is wonderful what it will do for a man as a mental, physical and moral safeguard. A cheerful heart doeth good as a medicine and puts its possessor in full pleasurable exercise of all his faculties. Cheerfulness will dissipate a thousand grievances real and supposed; it will smooth the rough angles of many an awkward corner, and it will open a myriad avenues of contentment.

It is so invaluable to the student: so tinges and changes the current of his life: makes him such a fine companion, and centre of happiness to others, that I cannot omit the gift from the catalogue of things essential.

And I knew once upon a time a master spirit of the art of cheerfulness, dear to Michael Carteighe, and to an examiner from Newcastle-upon-Tyne—in the person of John Cargill Brough.

It would be treason to long friendship not to bear one in loving memory this evening, who took so deep an interest in the establishment of these inaugural addresses.

There was within him a never-ending spring of pleasantry which rippled and bubbled over his correspondence, his conversation, and his life. His cheerfulness was contagious and found expression in quaint fancies and exquisite turns of thought. I am thankful to have been under such an influence, and many amongst us can make the same confession.

In his companionship our President would sometimes forget his bye-laws; and even the strictest of the sect of the students resident at Plough Court, remarked, "I like to hear Jack talk."

These are some hints which may aid you in turning to the best account your London life. I would have you bear in mind that you can make or mar the reputation of this historic School. From its walls have gone forth men whose success while here has added lustre to the place; and whose after-career has exalted British Pharmacy. Most of these continue to this hour to endow Pharmacy in a way which no Government, no grant of money, and no patronage, can do.

May I ask you to join their ranks and to hand down to your successors the fair fame which you have inherited. There is joy in harvest when the yellow sheaves are gathered; joy in the vintage when the grape is pressed; and there will be joy in many a near and distant household when you return laden with the spoils of successful learning. Well may the home be glad, when he who came to this great city as a trembling student, has finished his course bravely, and goes back—a man.

The Pharmaceutical Journal.

SATURDAY, OCTOBER 7, 1882.

THE OPENING OF THE SESSION.

It will be admitted by all who have been privileged to attend an Evening Meeting of the Pharmaceutical Society in October that it constitutes one of the most pleasant of *réunions*. The students of the past session, with their hearty greetings of their former professors as well as of their successful fellow pupils; the new students, just buckling on the harness; the presence of ladies; the distribution of prizes; and last, but not least, the words of wise counsel which on such occasions are spoken by some one held in honour by pharmacists;—all conspire to create an enthusiasm which may be expected to produce good effects reaching far beyond the immediate occasion. We are glad to be able to report that the meeting on Wednesday last proved no exception to the general rule.

The reports of the Professors were, as they have been for many years past, eulogistic of the intelligence, application, and conduct of the students, and it was satisfactory to hear that, although the number of students in the School of Pharmacy had been rather smaller than usual, there were among them those who are likely to become men of mark in the future. Once more the silver medals of all three classes have been carried off by the same student, and the awards of the Professors have found confirmation in the decision of Dr. CLARK and Mr. GIBSON that this gentleman was also entitled to the Pereira Medal. In distributing the prizes the President spoke a few kindly words of encouragement to each recipient, and in handing the "blue riband of pharmacy" to Mr. SHORT, he appropriately reminded the audience that he also is a Pereira medallist.

Not the least successful event of the evening was the delivery of the Introductory Sessional Address by Mr. JOSEPH INCE. Mr. INCE's piquant literary style is now well known to pharmacists, and it may be fairly said that the address was most characteristic and one of his best efforts. A brief historic sketch of the origin and object of the "Annual Sessional Address," and an enumeration of the honoured names of those to whom in successive years the delivery of it has been confided, led up to a hearty welcome to the new students. Once more becoming historical he went back to the period, little more than forty years since, when pharmacy was not represented by a corporate body in this country, and recounted the steps by which the School of Pharmacy rose from the basement of the Society's premises to its present lofty quarters, interspersing here and there personal sketches of the early professors, and raising a frequent laugh by sly quips which gained in point by the dryness with which they were delivered.

Then turning to the real task of his address he cautioned students against giving way to the stagnation of the fourth month, advised them not to be men of one book, to cultivate companionship in their studies and gave them other advice which commanded the approval of all who heard it. When at the close of the address a vote of thanks was passed with acclamation it was felt that seldom had such a compliment been more richly deserved.

ELECTION OF BENEVOLENT FUND ANNUITANTS.

It is a subject for congratulation to learn from the official report that the Council at its meeting on Wednesday last, acting upon the recommendation of the Benevolent Fund Committee, decided that six annuitants shall be elected in December next. This will raise the amount disbursed annually in annuities to nearly £1400, a sum more than twice the income derived from funded property, which theoretically regulates the amount of responsibility incurred in this direction. It will be seen, therefore, that the Council relies upon the continued liberality of the subscribers and donors to the Fund, and it is hoped that a large proportion of those who have not yet renewed their subscriptions for the present year will be induced to do so at once by this action of the Council. That the relief afforded, great as it is, is unfortunately not yet commensurate with the distress existing, is evident from statements made by members of the Committee, as well as by the fact that for the six fresh annuities there are already nine approved candidates.

SUSPECTED LEAD POISONING.

The case of suspected poisoning by water contaminated with lead, reported in this week's Journal, has excited considerable interest in the neighbourhood where it occurred, and it is to be regretted that the circumstances connected with it have not been more clearly made known and less eclipsed by opinions tending to support opposing views. Thus as regards the cause to which the presence of lead in the water is ascribed, we only find it referred to incidentally, without any statement as to what mineral acid was present in the water in a free state. The account of the medical evidence given to disprove the alleged poisoning is equally unsatisfactory. It is difficult to understand on what grounds Dr. Tidy stated that though lead poisoning had preceded death it was not the actual cause of death in this case, but that the probable cause was granular disease of the kidneys, that being, however, as he admitted, a consequence of lead poisoning. We are not surprised to learn that the condition of the water in question is to be thoroughly investigated, for the doubts raised by this case are such as to make inquiry indispensable.

AUSTRIAN PHARMACEUTICAL SOCIETY.

The twenty-first General Meeting of the Austrian Pharmaceutical Society was held on the 17th of September, in the large building of the National Museum in Agram. The "Directorium" was represented by Messrs. Schiffner, Waldheim and Kwisda, from Vienna; the Pharmaceutical Gremium of Croatia by all the pharmaceutical chemists of Agram and some visitors and guests from Croatia, Slavonia, Istria, Styria, Moravia and Bosnia.

After the regular business affairs of the Society had been transacted, different motions proposed by the Directorium came on for discussion, the most important, brought forward by Mr. v. Waldheim, in reference to pharmaceutical education, was adopted unanimously. Mr. v. Waldheim also made a statement as to the progress made in carrying out the "International Pharmacopœia." It is only necessary to add to our recent note on this subject (before, p. 247), that the Italian representatives have now sent in their revised and amended lists to the President of the Commission.

For the guests and visitors of this meeting the Pharmaceutical Gremium of Agram and Croatia arranged a splendid banquet in the Hotel "Kaiser von Oestreich," which the Burgermeister (Lord Mayor) from Agram, Dr. Hofman, the President of the Police in Agram (Stadthauptman), the Landes Sanitals Referent, Dr. Rakovan, and Mr. Dezelic, Senator of the Municipium of Agram, honoured with their presence. The project to pay a visit to Banjaenka, in Bosnia, was not carried out, the weather not being favourable.

EARLY CLOSING.

A vigorous attempt is being made in different districts in the South of London to promote what is known as the Thursday half-holiday movement. A meeting has recently been held in the Masonic Hall, Camberwell New Road, under the presidency of Mr. W. Dodd, chemist and druggist, when a resolution was passed in favour of closing shops at five o'clock on Thursday afternoons. We hope that this movement may, as far as possible, receive the countenance of chemists and druggists, and would recommend those in the district of Camberwell desiring concerted action to communicate with Mr. Dodd, whose address is 169, Southampton Street.

CHEMISTS' ASSISTANTS' ASSOCIATION.

The first meeting of the above Association will be held at 32a, George Street, Hanover Square, W., on Wednesday, October 11, at 9 p.m. precisely, when the President, Mr. W. A. Wrenn, will deliver his inaugural address. We understand that a complete and attractive programme is ready for circulation, and a most successful session is confidently anticipated.

EDINBURGH CHEMISTS' ASSISTANTS' ASSOCIATION.

The Edinburgh Chemists' Assistants' Association will commence a new session on Wednesday next, when an address will be delivered by the President, Mr. Peter Boa. We notice that in connection with this Association two prizes are offered to apprentice members for competition in the form of a written examination in Latin, English, Arithmetic, Elementary Chemistry and Pharmacy.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, October 4, 1882.

MR. MICHAEL CARTEIGHE, PRESIDENT.

MR. SAMUEL RALPH ATKINS, VICE-PRESIDENT.

Present—Messrs. Andrews, Borland, Bottle, Butt, Churchill, Gostling, Hampson, W. Hills, Radley, Richardson, Robbins, Savage, Schacht, Symes, Williams, Woolley and Young.

The minutes of the previous meeting (August) were read and confirmed.

The PRESIDENT said the instructions given by the Council in August, with reference to the repairs and alterations, had been carried out, as far as practicable; but there were one or two alterations still incomplete, and he must ask for indulgence if the ventilation in some of the rooms was not yet as perfect as he hoped it would be.

ELECTIONS.

ASSOCIATES IN BUSINESS.

The following, having passed their respective examination, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:—

Minor.

Loam, James Gilbert ....Reading.

Modified.

Hulbert, Samuel James ....Glastonbury.

ASSOCIATES.

The following, having passed the Minor examination, and tendered (or paid as Apprentices or Students) their subscriptions for the current year, were elected "Associates" of the Society:—

Gaskin, John Henry ....Wolverhampton.
Gatward, Oswald ....Hitchin.
Jackson, William Moses.........Ayr.
Longtoft, William ....Bedale.
Ransom, Francis ....Hitchin.
Reade, John Edmonds............Wolverhampton.
Weddle, William ....Gateshead.

APPRENTICES OR STUDENTS.

The following, having passed the Preliminary examination and tendered their subscriptions for the current year, were elected "Apprentices or Students" of the Society :—

Bing, Charles ....Canterbury.
Cooper, George Thomas ....Market Bosworth.
Dyer, William Bury ....Halifax.
Evans, Robert ....Bala.
Gilbert, Joseph Anthony.........Manchester.
Greenhalgh, William Henry ...Rotherham.
Lamplough, James William ...London.
Notcutt, William Brighty ......London.
Oxen, David Hunter ....Tynemouth.
Powell, Samuel R. ....Scarborough.
Rees, Charles Joseph ....Swansea.
Rigden, George.....................Folkestone.
Smith, Arthur Llewellyn ......Sidcup.
Topham, Thomas ....Mirfield.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a fine.

RESTORATIONS TO THE REGISTER.

The names of the following persons, who had made the required declarations and paid a fine of one guinea, were restored to the Register of Chemists and Druggists:—

Robert Coulson, 3, Vicar Terrace, Cranmer Road, Forest Gate, Essex.
Francis Charles Rawlings, Barmouth, Merionethshire.

APPOINTMENT OF SECRETARY TO THE NORTH BRITISH BRANCH.

Mr. Peter MacEwan was reappointed Secretary to the North British Branch until June next, it being considered desirable that in future the appointment of this officer should be made at the same time as that of the other officers of the Society.

Mr. RICHARDSON, having recently visited Scotland, had great pleasure in saying that he heard everywhere a most excellent account of the present Secretary, showing that he was thoroughly appreciated in Scotland.

Mr. BORLAND was very pleased to hear such an expression from a gentleman south of the Tweed. He might add on behalf of the Members of the Board of Examiners in Edinburgh, that they were thoroughly satisfied with the manner in which the work of the office was conducted.

ADDITIONS TO THE REGISTER.

The Registrar reported that the following:—

James Coley, 5, Chapel Terrace, Derby Road, Bootle, Liverpool,
Ebenezer Gibb, New Byth by Turriff, N.B., and
Henry Thompson, 105, Hither Green Lane, Lewisham,

having made statutory declarations that they were in business before the passing of the Pharmacy Act, 1868, and these declarations having been supported by duly qualified medical practitioners, their names had been placed on the Register. In each case he had made inquiries and was satisfied that these persons were entitled to have their names put on the Register.

Mr. ROBBINS inquired if the chemists in the neighbourhood were satisfied also.

The SECRETARY said he could not say; he had adopted the usual course of writing to the medical gentlemen who had given the certificates.

Mr. SYMES said that as a matter of fact inquiries had been made of him, by the office, with regard to the gentlemen in the neighbourhood of Liverpool.

REPORTS OF COMMITTEES.

FINANCE.

The report and recommendations of this Committee were received and adopted, and several accounts were ordered to be paid.

BENEVOLENT FUND.

The report of this Committee included a recommendation of the following grants :—

£20 to a member from 1853 to 1878, and also a subscriber to the Benevolent Fund. Applicant is now paralysed.

£20 to the widow of a former member and subscriber to the Fund.

£15 to the widow of a member and subscriber to the Fund. Applicant has had a former grant of the like amount.

£10 to a former member, aged 69.

£10 to a registered chemist and druggist, aged 72.

£5 to the widow of a former member.

One case had been postponed, and another application the Committee had declined to entertain.

The SECRETARY had presented the following statement for the current year:—

Income.

	£ s. d.	£ s. d.
Dividend on £18,600 . . .	556 10 0	
Subscriptions to end of September	1421 17 4	
		1978 7 4
Donations to end of September		377 11 0
		2355 18 4

On deposit . . . . . £500.

Expenditure.

	£ s. d.	£ s. d.
Annuitants:—		
22 at £35	770 0 0	
14 „ £30	420 0 0	
		1190 0 0
Casual grants up to October, inclusive		396 0 0
		1586 0 0

Thirty-six annuitants now on list:—

4 over 80.
14 „ 70 under 80.
14 „ 60 „ 70.
4 „ 50 „ 60.

The Committee recommended that certain names be placed on the list of approved candidates for annuities, and that six annuitants be elected on Friday, December 15.

The Secretary reported that three hundred and twenty four persons had not renewed their subscriptions during the present year.

The Council went into committee to consider the details of the report.

On resuming, it was moved that the report and recommendations of the Committee be received and adopted.

Mr. Bottle said it quite accorded with the views he had previously expressed that the Council would be perfectly safe in electing annuitants on the money coming from subscriptions, as well as on the interest of the invested capital. He found that prior to the election in 1872 only fourteen annuitants had been elected, thirteen of whom were alive at that time. The Benevolent Fund was not then in the condition in which it was now, for he did not know that in all his experience at that Council table he had heard anything more satisfactory than the statement now made. Up to the present moment there had been received something like £200 more in subscriptions than in the previous year, and on the previous evening the Committee had had an unexampled list of applicants for relief. He did not know that he ever remembered applications from people whom the Committee had felt so much desire to relieve,—persons who had been in good circumstances, and who, from causes beyond their own control, had come to poverty. He had much pleasure in supporting the election of six annuitants, believing that the subscriptions would come in amply sufficient to make the required payments.

Mr. Richardson desired it to go forth that continued efforts should be made to increase the Fund, so that more might be distributed in casual grants as well as in annuities. He had no doubt that if some energy were shown, not merely by members of the Council, but by influential chemists in every centre of Great Britain, the amount raised could be increased considerably. He feared that in future years there would be a painful accession of numbers in the applicants and of a character which all must much deplore. There had been several instances on the previous evening of persons who had lived in affluence, but who had been brought to poverty. As had been said, in nine months there had been an increase of subscriptions amounting to £210, and he believed if the year were taken it would be considerably more.

Mr. Hampson said he occasionally got letters from members of the Society objecting to the want of the spirit of adventure at the Council table in the distribution of the Fund. It had been said that there were two ideas as to the distribution, one being that only the interest on the money invested should be expended. But these correspondents objected to contribute to the Fund, because they felt that their money was not likely to be used in the way in which they wished. If they thought it would be spent almost to the utmost farthing it would give that kind of impetus that would compensate for any want of caution in the distribution. He thoroughly sympathized with that spirit and believed it only needed a statement that the Council was almost absolutely without funds in order to get an ample response. He was extremely gratified to find that new spirit had been infused into the administration of this Fund and he hoped next year it would evoke a hearty response throughout the trade, and lead to many more contributions being received. He felt sure there was plenty of money amongst chemists in the country, notwithstanding their poverty, to support all the poverty incident to the trade; it only required to be got at.

Mr. Robbins said it was very gratifying to see the present state of the Fund. He remembered when he first made the proposal that four candidates should be elected it aroused almost a consternation at the board, and it was said it could not possibly be done, because there was no money to pay for it. At that time the whole expenditure of the Benevolent Fund was something under £600, although there was an income of more than double that sum. The Council was then funding all that it could, but was only able to put by a small sum annually. Happily the Council was persuaded to add more annuitants, trusting to the benevolence of the general body, and from that time the funds had been increasing, whilst the sum expended annually had been doubled, trebled, and was now almost quadrupled. There were at that time thirteen annuitants on the books, and in a few weeks there would be forty-two, which was more than he, at that time, anticipated. He was also pleased to see the names selected as approved candidates, for he had never seen a a better list. Many of them were persons who had been members and had subscribed to the Society; who had held a good position and by some misfortune had been brought to seek help of this kind. He was quite sure it was a wise policy to spend the greater part of the money which was subscribed, and he hoped, before long, to see fifty annuitants on the list.

The Vice-President said he believed the necessity for the Fund was not likely to decrease but to increase, but he also believed in the statement made by Mr. Hampson, that the money was somewhere if it could only be got at. It appeared to him some sort of organization was wanted for getting at this money, some better devised system of collecting. The extra support that had recently been given was simply the result of extra efforts which had been made in various parts of the country, but he did not think that London had yet grappled with the problem. There was a huge population of four millions in the Metropolis, amongst whom there must be a large number of chemists who did not contribute, and it seemed to him that what was needed was a method of organization for going round and asking for contributions, and in that way he believed that a large revenue could be obtained. It was very seldom that charitable contributions were sent; they were always called for. He should be very glad if the Council would put its shoulder to the wheel and take up this matter.

Mr. Symes had no wish to damp the spirit of satisfaction which seemed to pervade the Council in regard to the state of the Funds, but he should like to call attention to the fact that, although the Committee was then in the proud position of proposing to elect six candidates, there were nine down on the list, all of whom were eligible, and he should like it to be recorded that notwithstanding the special efforts made this year, still three hundred and twenty-four persons had not subscribed this year who did last. Putting those facts together, it showed that whatever satisfaction might be felt there was still room for considerable accession to the Fund, and still a large number of cases which could not receive the amount of aid the Council would like to give.

Mr. WILLIAMS said he had just glanced through the books and he was quite certain that of the three hundred and twenty-four persons who had been mentioned as not having yet paid the subscriptions for this year, a large number only required to be reminded of it; he was sure a great deal of that money was not lost to the Fund.

Mr. BOTTLE could not allow the discussion to close without expressing his dissent from the view which the Vice-President seemed to entertain, that London had not been properly attacked, if by that it was intended that London did not subscribe as it ought to do. He found that out of fifty columns of names of subscribers to the fund for the whole Great Britain nine were filled by London, which was, he thought, a very fair proportion.

Mr. SAVAGE asked if any efforts were made to remind those who had not paid the subscriptions that were due.

The SECRETARY said that two written applications had been sent and another would be.

Mr. SAVAGE suggested that if someone in a locality, well acquainted with the subscribers, would call it would be more likely to be efficacious. If there were any in his neighbourhood he should be happy to call upon them.

Mr. ANDREWS said he had said the same with regard to any gentleman in his district.

Mr. ROBBINS thought it would not be advisable to pester too much.

The SECRETARY said he did not think there were many subscriptions lost for want of their being asked for.

Mr. HAMPSON thought the residue of the London subscriptions might be gathered in if a list were furnished to a clerk for collection; it would be better than merely sending a circular.

The report and recommendations of the Committee were then received and adopted.

Legacy from the late Mr. Howden.

The SECRETARY announced that since the last meeting of the Council, Mr. Robert Howden, of Gracechurch Street, who had been a subscriber and also donor to the Fund, had died. A communication had been received from one of the executors, saying that Mr. Howden had left a bequest of £100 free of legacy duty to the Benevolent Fund, which he should have the pleasure of forwarding as soon as probate was granted.

GENERAL PURPOSES.

The report of this Committee was, as usual, considered in committee. It included the usual letter from the Solicitor giving particulars of cases which had been placed in his hands. It stated that in the case of Sinton Michael Honan, 90, King Street, Hammersmith, the defendant had confessed judgment, and judgment had been entered for the penalty and costs.

Several other cases had been considered by the Committee, and in some cases it was recommended that the Solicitor be instructed to commence proceedings.

A memorial had been received from a person at Derby, praying that his name be restored to the register; but after going at length into all the circumstances of the case, the Committee had seen no reason for altering the decision arrived at in May, 1881.

The report and recommendations were received and adopted.

COMMUNICATION FROM THE PRIVY COUNCIL.

THE SOCIETY'S EXAMINATIONS.

The following communication from the Privy Council Office was received:—

"Council Office,
"16th August, 1882.

"Sir,—I am directed by the Lords of the Council to transmit to you, to be laid before the Pharmaceutical Society for their information, a copy of the report upon the examinations held by the London Board of Examiners of the Society in 1881, by Dr. Greenhow, the officer appointed by their Lordships to attend such examinations.

"I am, Sir,
"Your obedient Servant,
(Signed) "C. L. PEEL.

"The Secretary,
"The Pharmaceutical Society,
"17, Bloomsbury Square."

"*Report on the Examinations held by the London Board of Examiners of the Pharmaceutical Society during the Year* 1881.

"During the year 1881, the London Board of Examiners of the Pharmaceutical Society held twenty-five meetings for the examination of candidates for registration under the Pharmacy Act, 1868. This is exclusive of the first or Preliminary examination, which continues to be conducted by the College of Preceptors.

"*Preliminary Examination.*—During the year 1881, 1187 candidates offered themselves for the Preliminary examination in English, Latin and arithmetic, 512 of whom passed and 675 were rejected, being at the rate of 56·8 per cent. The proportion of failures was, therefore, unusually large.

"Of the rejected candidates 20 who had obtained the minimum passing number of marks, viz., four-tenths of the allotted number, in each of the three subjects of examination, failed because they did not obtain half the aggregate number of marks on the whole examination; 86 failed in all the subjects; 77 in English; 53 in Latin; 195 in arithmetic; and 244 in two of the subjects.

"*Major Examination.*—Only 100 candidates presented themselves for the Major examination during last year, 51 of whom passed and were registered as pharmaceutical chemists, and 49, being at the rate of 49 per cent., were rejected. Of these 7 failed, although they had gained the minimum number of marks in each separate subject, because they did not obtain half the number of marks allotted to the whole examination; 32 failed in chemistry and practical work, and 10 in botany or in botany and either materia medica or chemistry.

"*Minor Examination.*—During last year 567 candidates for the Minor qualification were examined, 278 of whom passed and were registered as chemists and druggists, and 289, or in the proportion of 50·6 per cent., failed; of the latter, 51 failed in the whole examination, although they had gained the minimum passing number of marks in each separate subject; 81 failed in chemistry; 44 in materia medica; 13 in botany; 25 in reading Latin prescriptions; 18 in practical dispensing; 23 in pharmacy, and 34 in two of these subjects.

"*Modified Examination.*—Only 9 candidates came up for the Modified examination last year, 3 of whom passed, and 6 were found incompetent.

"I have, on former occasions, pointed out the probable causes of the very large number of rejected candidates at the pharmaceutical examinations. They are, as regards the first or Preliminary examination, the very inadequate early education of the large majority of the candidates; and, as regards the technical examinations, their very defective training during the three years passed in a chemist's shop previous to admission for the Minor examination.

"I learn that many of the candidates for this examination have had only scanty opportunities for practically learning to read prescriptions written in Latin, or to dispense and compound medicines; as a rule, it is only in large towns that there is much demand for dispensing physicians' prescriptions, and when a young man is apprenticed to a master who has not much dispensing work, he can neither acquire the intimate acquaintance with the physical characters of drugs and chemicals, nor the practical skill in dispensing, which he requires to fit him for carrying on business on his own account, and which he is expected to manifest in the examination room.

"The large number of rejections at the examinations of the Pharmaceutical Society has naturally attracted much attention on the part of the Council of the Society. A Special Committee was accordingly appointed by that body in 1882 to inquire into and consider the relation to each other of pharmaceutical education and pharmaceutical examinations.

"A first report was presented to the Council in August, 1881, and being generally approved, was referred back to the Committee for the consideration of details.

"The final report was brought up in April of the present year and, with the exception of a clause recommending that the Minor examination should be divided into two parts, with an interval of not less than six months between the first and second portions, was adopted by the Council, and subsequently by the Annual Meeting of the Society.

"As, however, the recommendations contained in that report will still need some consideration before they are carried out, and further, as it is not proposed that they shall come into force until January, 1886, I defer offering any detailed comments upon them until further steps have been taken by the Council with a view to their practical adoption. I may, nevertheless, say that the two first recommendations are accordant with views I have expressed in previous reports.

"They are, first, that candidates for examination be required to produce evidence of having passed an apprenticeship or pupilage of not less than three years with some duly registered chemist and druggist; and, secondly, that the Preliminary examination or its equivalent be passed prior to apprenticeship or pupilage.

"In conclusion, I am glad to be able to express my opinion that the examinations of the Pharmaceutical Society held in London, as at present conducted, afford a sufficient guarantee that the candidates who pass them are competent to be registered under the Pharmacy Act, 1868.

"(Signed) E. H. Greenhow."

Mr. Hills said he considered the Preliminary examination one of the most important parts of the qualifying process, and he was disappointed to find the percentage of failures was on the increase. He had obtained from the office the percentages for the last five years. He found in 1877 there were 46·7; in 1878, 52·4; 1879, 46·88; in 1880, 48, and in this Report there were 56·87 failures. One point which especially struck him as very disappointing was that in such a subject as arithmetic about one in six failed to pass. He did not think the arithmetical questions were of such a nature as to cause this result, for in a chemist's daily business questions quite as difficult often occurred, so that one unable to pass in arithmetic would scarcely be fit to dispense prescriptions. He saw, moreover, that only half the full number of marks were required to pass, and it would be very interesting to know how many of those who did pass obtained 70 or 80 per cent., for after all those were the men to whom they should look for the future. It could not be too strongly insisted upon, that this Preliminary examination was very important, and it was very desirable that parents and guardians and those interested in the future of young men should make it a subject of thought, and see that those under their care came up in some way fitted for their future career.

Mr. Richardson quite agreed with Mr. Hills, and said the results now shown entirely bore out the arguments he had adduced before, that the young men, before being apprenticed, had not had a sufficient education; in fact he thought that the young men now coming forward were not of the same calibre as were those some time ago. It was all very well to say that parents should be told of this, but he was afraid that, in country places especially, chemists were induced to take young men as apprentices without having sufficient regard to the future requirements of their position, and it had been his duty frequently to advise parents and guardians on this point that the better plan would be to see that the candidate was tested as to his educational powers before being apprenticed. He hoped that as soon as possible that portion of the curriculum would become law.

Mr. Symes said the greater part of this Report was very properly a historical record of the facts connected with the examination, and it was only towards the conclusion that Dr. Greenhow drew any deductions. The paragraph which interested him most was the final one, which seemed to him to cut at the foundation of much of the work the Council had been doing. Whether Dr. Greenhow was under a misapprehension or not he did not know, but reading the Report a person not conversant with the discussions in the Council would say that an exceedingly good case was proved for this concluding remark. The Report showed that a large number had been examined, and that a large proportion was rejected, and if the examinations were sufficiently stringent to sift out a large proportion who presented themselves they accomplished all that could be desired at the present moment. If that were so the inference might also be drawn that the direction in which the Council was working was the making of examinations more stringent, or placing further difficulties in the way, and, therefore, it was a pity the paragraph should pass without some notice being taken of it. It could not be too frequently stated that the sole object of the Council was to increase the facilities for passing the examinations, and to reduce the percentage of failures. So that when future reports were presented it would be found that properly trained young men would come up so thoroughly prepared that, instead of there being 60 or 65 per cent. of failures, there would be only 10 or 20 per cent. That was really the object of the changes it was proposed to introduce. The deduction which appeared to be drawn was that if a young man passed the examination as at present conducted it was in itself a guarantee that he was a thoroughly qualified young man, but in certain cases it was thought some passed the examinations who were not thoroughly qualified.

Mr. Williams said the statement was that the candidates who passed were competent to be registered under the Pharmacy Act. He thought Mr. Symes was rather misreading the paragraph.

Mr. Symes said if that was the statement of a simple fact he could only say that what the Council was doing was something which was undesirable.

The Vice-President hardly thought that was so. He agreed with Mr. Symes that it was a matter of regret that there was such a large percentage of failures, and no doubt the action of the special Committee on the subject was to endeavour to reduce the percentage. But he differed with him on the interpretation of this last clause of the Report. It seemed to him that Dr. Greenhow, in representing the public interest, had simply stated what was important as an endorsement of their work—that he believed the examination was a true and honest one, and that the men who passed it were competent to go into pharmacy. To come back to the important matters raised by Mr. Hills, it could not be too much impressed on all young men's minds, that to succeed well in the future they must start well. This matter of the Preliminary examination, although it might seem to some but the smaller matter, because it was a scholastic examination and not a technical or scientific one, was of the highest importance. It was very desirable to start with an educated class of men, and he had always urged that the qualification should exist before the apprenticeship commenced. He held the strongest convictions on that point, as he did ten years ago; but the awkward fact constantly came up that a very large number of young men entered the calling who were perfectly incompetent, from the want of an early education, to pass the examination. In fact children who were successful in the sixth standard under the Elementary Education Act were far better prepared than a large number of young men who entered the trade. But having entered it a man naturally said, "What am I to do? I have been at it some time, and I cannot turn to anything else." Without raising the question of elevating the standard, it ought to be insisted that those who commenced work should come in with a good sound liberal education.

Mr. Robbins agreed with the views of several speakers that these rejections were not a small question. It was important in many respects, not only to the young men who were rejected and the Society, but to the public also. All young men who went into the trade should by proper perseverance be able to pass the examinations, but the great objection to the present state of things was that about half of the candidates were rejected after they had commenced to be pharmacists and had learnt something of the business, and then what could they do? He understood that a great number of them went to grocers and introduced the chemists' business into the grocery shop, and this it was which had caused so much mischief throughout the country. The great object of the Society should be to get young men to pass the Preliminary before learning any of the technicalities of the trade. If they were not up to the proper standard they would not enter the trade, but if they were they would be able afterwards to pass the subsequent examination if they only properly applied themselves.

Mr. Savage thought on the whole this was a very satisfactory Report. It was not only the Preliminary examination that had to be looked to, but the paragraph which related more particularly to the masters ought to be strongly impressed upon them. Dr. Greenhow said that he learnt that many of the candidates had had only scanty opportunities for practically learning to read prescriptions or to dispense and compound medicines, and that as a rule it was only in large towns there was much demand for dispensing physicians' prescriptions. These were really important matters which were not so much dependent on the Preliminary as they were on the masters themselves. He knew that many masters much neglected to impart that information which they themselves possessed to the young men under their care.

Mr. Hampson said the difficulty in this respect, which was no doubt very unfortunate, was almost insurmountable in the present condition of pharmacy. The majority of chemists in this country really did not get prescriptions to dipense; the dispensing was done by the medical practitioner, and that was the key to the whole question with respect to the pharmacy of the future. If pharmacists had the pharmacy of the country in their hands they would have no difficulty in training the young men, because during their apprenticeship they would be brought into contact with prescriptions and would have to dispense them and handle drugs, and in many cases would have to make preparations themselves, and thus pharmacy would be constantly progressing. But what was the prevailing state of affairs? Even in London, which was supposed to be the centre of the universe, dispensing was not done by chemists and druggists, and yet it was expected at the same time that young men would enter the profession with zeal and almost with acclamation; and that they would feel a deep interest in their own education. They did not do so, and the reason was quite palpable. They saw that the prescriptions did not come into the shop of the chemist, who was already qualified and established, and perhaps a member of the Society, and consequently there was little or no interest taken in pharmacy. In other countries there was no difficulty. In France, Germany, and even in democratic America, there was no difficulty about the educational question, because the prescriptions gravitated in the proper direction. They reached the chemist's shop, and the student of pharmacy was interested, because he was surrounded with pharmaceutical matter. Until that matter was settled and pharmacists had the dispensing of the country in their hands there would be always this difficulty with respect to education. When even the highest qualification of the Society was obtained, the student knew he had to begin business under most adverse circumstances; he had to establish a business or join another and to deal in all kinds of things to make a living. But unfortunately all this miscellaneous trade was gravitating away from him and there was nothing but bare pharmacy, which unfortunately scarcely existed at all, left to him to depend upon.

Mr. Schacht wished to express his gratification that this Report, to a great extent, coincided with the results arrived at by the Committee which had devoted a large portion of time and consideration to this subject. The Report itself and the tone of the discussion had gone to show the wisdom at any rate of the first two of the recommendations submitted to and adopted by the Council; so distinctly and deliberately was that done that, although he was pleased to hear the repetition of the same opinions, he hardly thought it was necessary. But he could not help thinking that Mr. Symes was to a great extent correct, when he said that if this last paragraph was absolutely true there was no occasion for a large portion of the labours through which the Committee had been going. That was how he understood him; not that he objected to the expression as a legal opinion, but that it did not contain what he should like to have seen Dr. Greenhow finish his Report with. He should endorse that view exactly, for, although it might be perfectly true that the Society only registered such persons as were legally qualified to be registered, and, in that sense come up the legal requirements, still he was bold to say that many of those who were placed on the list were not up to the standard of pharmaceutical requirements that he should like to see them arrive at; and what was more, he thought that the examiners felt that in the present condition of affairs, they were not themselves quite competent to gauge the qualifications of the candidates. It was for that reason the Council had come to a unanimous conclusion that, in addition to an examination test of a man's qualifications, there should be a curriculum established. All educationalists had pretty well come to the conclusion that an examination test was not in itself sufficient. No examination test, applied in the fashion in which the Society's examinations were applied, could possibly be a real test of the qualifications of the candidate, and, therefore, the Council had come to the conclusion that the examination must be supplemented by a curriculum, in order to secure the registration of only those who were competent to conduct a responsible occupation. The last part of the Report seemed to assume that the examination alone had been proved to be sufficient to guarantee all that was required; but all agreed that it was not, and that, in addition to a curriculum which should train a man to pass the examination, the examiner should be strengthened in declaring a candidate to be competent because he knew that he had been trained up to the examination by a certain course, and that he had carefully followed the course of instruction prescribed by the Council before he came up for the final test of the examination. He thought the Council was quite justified in expressing a regret that no allusion was made to this point by Dr. Greenhow.

Mr. Young said he came to the conclusion, reading this Report, that the last paragraph merely referred to the opinion entertained by Dr. Greenhow as to the high character of the gentlemen who conducted the examinations, and expressed his satisfaction as to the manner in which they were carried out. He quite agreed with what had been said with reference to the importance of preparation for the Preliminary examination. Beyond that Dr. Greenhow referred to the defective training of the candidates during the three years passed in the chemist's shop, and so on, and further down where he reported as to what had been done by the Council, he adverted merely to the first two resolutions, omitting altogether any reference to the curriculum, as Mr. Schacht had pointed out. That appeared to be the one thing which was wanting in order to give some kind of indication as to what his views were, and so far he thought it was a defect, because without that it appeared to him the Council would be left much in the present condition of things. The candidate had merely to show that he had been apprenticed for three years, and unless the curriculum was brought to bear, matters might go on just as they did now.

Mr. WILLIAMS said he disagreed entirely with Mr. Schacht's remarks on one point, namely, that the Council had unanimously agreed on certain questions which had been brought before it on more than one occasion. On one occasion the Council was so far from being unanimous that it was the casting vote of the President which carried the proposition, and in other cases there was certainly a majority against the Committee's recommendations. Therefore he could not see, himself, that there was any right to assume unanimity on the part of the Council at present, until these matters had been further considered, for he denied that they had as yet been fully considered. There had been certain reports presented which the Council could not understand, and which were rejected on some occasions; on another occasion, the Council agreed to the principle. On the last occasion another report was agreed to, not unanimously, but simply under protest, it being referred to another Committee for further investigation.

The PRESIDENT said that the three resolutions referred to in the Report were passed unanimously on the motion of Mr. Williams.

Mr. WILLIAMS said the resolution was carried under such circumstances and conditions as made it very different from what was assumed. He thought Dr. Greenhow in this paper really gave the proper and right view of the matter.

Mr. SYMES said he in no way complained of the Report, which he had no right to do. In fact, when he first read it he thought it was almost intended as a compliment. Mr. Schacht had thoroughly interpreted his meaning. What he wished to point out was, what the Council had already agreed to, that certain young men neglected their training and got posted up in examiners' questions rather than got educated, and then came there to pass the examinations. The fact broadly stated in the Report was that the man was qualified, whilst the Council by its action had said that many of these men, although legally qualified, were not properly qualified for the business they went into. That was the ground of the action of the Council. First, to reduce the number of failures, and secondly, to secure that all those who passed the examination were thoroughly qualified. The question of the curriculum was before the country and presented itself in different aspects to different people; in some cases no doubt it met with opposition, and he feared this Report might be used as an argument that no curriculum and no further restrictions were required. He should be sorry if such were the effect produced.

The PRESIDENT said that he thought this discussion might now terminate. This Report was a very important document, but he thought more weight had been attached to the last paragraph than the writer intended, and he feared some of his colleagues looked at it partially, as members of the Education Committee. Looking at it as an individual he saw nothing whatever to find fault with, and he believed he had as much interest in the subject referred to as anyone. He considered this was a strictly accurate report; there was not even a tacit disapproval of certain of the recommendations, which might be said to be more or less incomplete at present. With regard to the curriculum, the Council had not yet laid down the basis on which to act with regard to the recognition of schools; and with regard to the examination itself, it had not yet decided what form that should take. He was not sure that Dr. Greenhow, in reporting as he had, was not quite right in taking those two resolutions which were clear and decided, and making his comments on them, and leaving the other matter for further information and consideration. This Report was for the year 1881, and he took it to be distinctly encouraging to the views held by that Council. He believed the writer simply intended to mean what he said, that those who passed the examination were competent to be registered under the Act. Dr. Greenhow had had large experience in every department of the medical profession; he knew the wants of pharmacists extremely well, and simply required to have all the facts put before him and to consider his own experience in connection therewith before coming to a conclusion. He believed that when the proper time came Dr. Greenhow would be found to agree entirely with the views of the practical men who had been consulted on this subject.

LEEDS CHEMISTS' ASSOCIATION.

The SECRETARY reported the receipt of a letter of thanks from the Leeds Chemists' Association for copies of the Journal.

PHARMACY IN GUERNSEY.

The PRESIDENT said Mr. Crossley, of Guernsey, an Associate of the Society, had written to inform the Council that an Act had been passed for one year placing the law in that island on a moderately satisfactory basis with regard to the sale of poisons and enclosing a copy of the following "Ordonnance" which had been passed:—

"*Ordonnance provisoire au Sujet du Débit de Poisons.*

"Vu les dispositions des lois du Royaume Uni à l'égard du débit de poisons attendu qu'il est expédient que des provisions analogues à ces dispositions soient introduites en cette Ile:—La Cour en amendant les provisions de l'Ordonnance provisoire à ce sujet passée aux Chefs-Plaids d'après Noël, tenus le 17 Janvier, 1881, ouïes les conclusions des officiers de la Reine, a ordonné et ordonne.

"I. Il est défendu à qui que ce soit autres que les pharmaciens et chimistes dûment autorisés à exercer leur profession dans cette Ile de débiter des poisons.

"Il est défendu aux dits pharmaciens et chimistes de débiter des poisons sans que la bouteille, boîte ou enveloppe contenant le poison débité ne soit marquée avec le nom du poison—le mot 'poison' en grandes lettres—et le nom et l'addresse du vendeur.

"III. Il leur est défendu de garder les poisons dont les noms sont insérés dans la première partie de la liste contenue dans l'article 6 de la présente Ordonnance à moins que les dits poisons ne soient déposés dans des armoires, boîtes ou autres lieux fermés à clef.

"IV. Il leur est aussi défendu de débiter les dits poisons insérés dans la première partie de la dite liste à des mineurs âgés d'au-dessous de quatorze ans ou à des personnes inconnues au vendeur.

"V. Ils sont tenus de garder un livre spécial dans la forme suivante:—Nom de l'acheteur; Nom et quantité de poison vendu; Pour quel objet; Signature de l'acheteur; Date.

"Et d'y insérer ou faire insérer le faits ci-dessus applicable à chaque vente de poisons dénommés dans la première partie de la dite liste.

"VI. Sont comprises sous le nom de poisons les substances suivantes leur désignation dans la langue Anglaise.

"Partie I.

"Arsenic and its preparations.
"Prussic acid and its preparations.
"KCy and all metallic cyanides and preparations.

"Strychnia and all poisonous vegetable alkaloids and their salts and preparations.
"Atropine and preparations.
"Aconite and preparations.
"Emetic tartar.
"Corrosive sublimate.
"Cantharides.
"Savin and its oil.
"Ergot of rye and its preparations.
"Chloral hydrate.
"Essential oil of almonds undeprived of prussic acid.
"Opium.
"Corrosive sublimate, sol. of.
"Corrosive sublimate, yellow potion of.
"Morphia acet., sol. of.
"Morphia hydrochlor., sol of.
"Morphia.

"Part II.

"Oxalic acid.
"Chloroform.
"Belladonna and preparations.
"Opium, the preparations of.
"Poppies, the preparations of.
"Red oxide of mercury (red precipitate of Hg).
"Ammoniated mercury (white precipitate of Hg).

"Every compound containing any of the poisons above mentioned, when prepared or sold for the destruction of vermin.

"The tincture and all vesicating liquid preparations of cantharides.

"VII. Toute personne, qui enfreindra un des articles ci-dessus sera passible d'une amende qui ne sera pas moins de £2 stg. et n'excédera pas £20 stg., la dite amende applicable moitié à Sa Majesté et moitié au délateur.

"VIII. Sera rappelée l'Ordonnance des Chefs-Plaids d'après Noël, tenus le 18 Janvier, 1730, au sujet de l'arsenic.

"IX. Et sera cette Ordonnance en force jusqu'aux Chefs-Plaids d'après Noël prochain."

Mr. Radley said he knew one case of a young man who had failed to pass the examination here who had gone to Guernsey to set up in business, and he believed that had not been an uncommon occurrence.

The Council then went into committee to consider a complaint with regard to the appointment of a deputy superintendent of written examinations in the country, and upon resuming adjourned.

EVENING MEETING.

Wednesday, October 4, 1882.

The first Evening Meeting of the Session was held on October 4, the chair being taken at 8·30 by the President, Mr. Michael Carteighe.

After a few words from the President, explanatory of the programme of the proceedings, Professor Redwood was called upon to give his—

Report on the Chemistry and Pharmacy Class.

Professor Redwood said his report was not less satisfactory than it had usually been on previous occasions. Although the attendance of students in the School might not have been so numerous as could be desired, there was distinct evidence of an improvement in that respect, and both he and his colleagues could give a very good account of the way in which the students had acquitted themselves during the last session, not only with regard to their general conduct, but to the proficiency in the prosecution of their studies, of which they had given evidence. Acting in accordance with the desire and intention of the Council, the Professors had endeavoured to make the system of education there the means of laying a solid foundation for the qualification of those who were about to engage in the practice of pharmacy. Their programme was, as it had been for years past, that which the Council, aided by the best advice and assistance it could obtain, had recently given its approval of, and even intimated its intention of making ultimately compulsory as a curriculum. They had no faith in and did not encourage in any way the lath-and-plaster system of giving a semblance of a qualification, which, although it might sometimes pass current at a review, nevertheless lacked that solidity which alone would give it permanence and enable those who had it to bear the brunt of what was required in a professional life. One of the most important and encouraging features of the last session of the School was that a large proportion of those who entered as students did so at once for the whole session, thus giving palpable evidence that they at least were not advocates of the lath-and-plaster system. It was only natural to expect that students of such a class would prove to be a good sort, and this expectation had not been disappointed. They had been regular and punctual in attendance, well conducted and assiduous in their attention during the lectures, and had, moreover, given evidence at the after lecture examinations, that they were carrying away and digesting that which had been supplied to them. The result had been that when they came to the final examinations for the distribution of prizes and certificates, it was found that a goodly number had acquitted themselves with very great credit, and he must briefly submit the names of those in his class whom he had recommended to the Council for distinction. The session was divided into two courses of five months each. At the end of the first course an examination took place, when he who had acquitted himself most creditably was awarded a bronze medal, whilst others who reached a certain standard received certificates of merit, it being necessary for the candidates to give answers equivalent to 75 per cent. of the total number possible in order to obtain these certificates. At the end of the second course, a sessional examination was held, when a silver medal and certificates of honour and of merit were awarded. Having mentioned in complimentary terms the names of the successful candidates, which will be found below, Professor Redwood concluded by expressing his entire conviction that all these gentlemen were fully entitled to the honours which were about to be conferred upon them.

The President then presented the prizes and certificates awarded to members of this class, as follows:—

Five Months' Courses.

first course.

Bronze Medal ....Fredk. Wm. Short.

Certificates of Merit .... Thos. Goddard Nicholson. Richd. Augustus Cripps. Edward Marsh. Walter Clark Drew.

second course.

No award made.

Session. Ten Months.

Silver Medal ....Fredk. Wm. Short.

Certificates of Honour .... Walter Clark Drew. Edward Marsh.

Certificates of Merit .... Richd. Augustus Cripps. Thos. Goddard Nicholson.

The following are the questions which were set for these examinations:—

FIRST COURSE.

BRONZE MEDAL AND CERTIFICATES.

Hours—Eleven till Three.

1. Describe the forces of *cohesion* and *adhesion*, showing the difference in the meaning of these terms, and the essential characters of the forces to which the terms are applied. Give illustrations of the action of these forces.

2. Describe the physical condition of gases as distinguished from liquids and solids, and explain the meaning of the term "critical condition" in relation to gases.

3. Give examples of good and of bad conductors, radiators, absorbers, and reflectors, of heat.

4. Describe the hydraulic press, the principle of its action, its advantages, and also its defects.

5. Describe the production of oxygen gas, and point out any precautions that you think ought to be observed in conducting the process.

6. Give the formulæ for representing the compositions of hypochlorite and hypophosphite of calcium.

7. Describe the composition and mode of production of chromic acid, and point out a possible source of failure in conducting the process for its production.

8. Point out the distinction between the atomicity and basicity of the organic acids derivable from alcohols of the fatty group, and show their relation to the respective aldehydes.

9. Give the formulæ for representing *cane sugar, grape sugar, alcohol, aldehyde, lactic acid, oxalic acid, natural salt of sorrel, artificial salt of sorrel.*

SECOND COURSE.

BRONZE MEDAL AND CERTIFICATES.

Hours—Ten till Two.

1. Describe the construction, the mode of action, and the principles involved in the action, of the syphon.

2. Describe the essential characters and properties of an emulsion, and the conditions most favourable for the formation of emulsions of oils, resins, and oleo-resins.

3. What is the mode of action of charcoal as a decolorizing and also as a deodorizing agent?

4. Explain the term "dimorphous."

5. What are the principal sources of iodine, the method by which it is obtained in a free state, and finally purified?

6. What are the distinctive characters of the metals?

7. Describe cyanogen, its production, properties, and some of its compounds.

8. What are the conditions under which alcohol may be obtained from cane sugar? Describe the various changes that occur, and the means by which the alcohol may finally be rendered anhydrous.

SESSION.

EXAMINATION FOR SILVER MEDAL AND CERTIFICATES.

Time allowed, 3 *hours.*

1. What is the weight of an ounce of *spirit of nitrous ether* of the Pharmacopœia?

2. Explain the principle of action of the *hydraulic press,* and the means by which Bramah succeeded in rendering the application of this principle available in the production of great pressure.

3. What is the physical condition of the luminiferous ether in the production of light, both as common light and as polarized light? How is polarized light produced, and what are its peculiar properties? What is a *Nicol's prism,* and how is it constructed?

4. Describe the Pharmacopœia process for the production of hydrochloric acid, and explain the objects for which the several parts of the process have been adopted.

Time allowed, 3 *hours.*

5. Describe Lablanc's process for the production of carbonate of soda. Point out the impurities usually present in the product obtained by this process, and means by which it may be freed from such impurities.

6. What are the natural sources of zinc, and the method by which the metal is obtained from its ores in this country? What is the melting point of zinc, and what are its properties at temperatures below its melting point?

7. Describe the constitutions of alcohols, aldehydes and ketones; their respective relations and their sources.

8. What are the natural and artificial sources of benzoic and salicylic acids, their compositions, and the methods by which they are prepared?

Professor Bentley was then called upon to give his—

REPORT ON THE BOTANY AND MATERIA MEDICA CLASS.

Professor BENTLEY said his senior colleague always relieved him of a great deal of that which he could not say half so well, and his observations would therefore be as brief as possible, but it would not be doing justice to the Council or to the students if he did not cordially reiterate that which had been said by Professor Redwood, in saying that on no previous occasion had he ever been able to speak in higher terms of the regularity, diligence, and progress generally, than he could with regard to the past session. It might be said that this was the tale which was always told, and so it was, for he had never had occasion to speak otherwise, but that which he had said in former years he might repeat with still greater emphasis on the present occasion. Professor Bentley concluded by mentioning the names of the successful candidates in his class.

The PRESIDENT then presented the prizes and certificates awarded to the members of this class as follows:—

BOTANY AND MATERIA MEDICA CLASS.

FIVE MONTHS' COURSES.

FIRST COURSE.

Bronze Medal .... Thos. Goddard Nicholson.

Certificates of Merit .... Fredk. Wm. Short. / Richd. Augustus Cripps. / T. Staddon Waymouth. / Walter Clark Drew.

SECOND COURSE.

Bronze Medal .... Henry Hamilton.

SESSION. TEN MONTHS.

Silver Medal .... Frederick Wm. Short.

Certificates of Honour .... Equal: George F. Callaway. / Thos. G. Nicholson. — Walter Clark Drew. — Equal: Rd. Augustus Cripps. / Fredk. Jas. Yeatman.

Certificates of Merit .... Edward Marsh. / T. Staddon Waymouth. / Edgar Haward.

The following are the questions which were set for these examinations:—

FIRST COURSE.

BRONZE MEDAL AND CERTIFICATES OF MERIT.

Hours from 10.30 *till* 2.

1. Describe the structure of pitted vessels, scalariform vessels, sieve tubes, and laticiferous vessels.

2. Describe the structure of the bark in a Dicotyledonous plant.

3. Explain the terms superior, inferior, simple, and

compound, as applied to the ovary. Define the following terms as applied to fruits:—Apocarpous, syncarpous, legume, follicle, drupe, achenium, capsule, and cremocarp.

4. Give a general sketch of the changes which the crude sap undergoes in the leaves. What is metastasis, and what are degradation products?

5. What are the botanical and geographical sources of Cusparia bark? Describe its physical and chemical characteristics, and mention what barks have been substituted for it, and how they may be distinguished.

6. Describe the botanical and geographical sources of Asafœtida. Describe its chemical characters, and enumerate its official preparations.

7. Describe the botanical characters of chamomiles. Show how they may be distinguished from the capitula of other plants. What are their chemical characters, and what are the official preparations of chamomiles?

SECOND COURSE.

BRONZE MEDAL AND CERTIFICATES OF MERIT.

Hours from 10.30 *till* 2.

1. Distinguish between parenchyma, prosenchyma, and vascular tissue.

2. Define the following:—Epiphyte, parasite, saprophyte, rootcap, rhizome, tuber, corm and bulb. What are the distinctive characters between roots and leaves?

3. Define the following terms as applied to leaves:—Primordial, decussate, fascicled, palmate, pinnatifid, crenate, runcinate, pedate, retuse, ovate, cordate, reniform.

4. What is an acropetal inflorescence? Define an amentum, corymb, panicle, umbel, capitulum, and verticillaster.

5. Enumerate the official plants of the Menispermaceæ. Describe the botanical and geographical sources of Calumba Root, its general characters and chemical composition, and enumerate its official preparations.

6. What are the botanical and geographical sources of Colocynth Pulp? Describe its mode of preparation, general and chemical characters, and enumerate its official preparations.

7. What are the geographical and botanical sources of Balsam of Peru? How is it obtained, and what are its general and chemical characters? Enumerate its official preparations.

SILVER MEDAL AND CERTIFICATES.

Hours from 10 *till* 1.

BOTANY.

1. What is a Primordial cell? Describe the chemical and general characters of the cell-wall and of Protoplasm.

2. Give a sketch of the general distinctive characters between Plants and Animals.

3. Define the following terms as applied to leaves:—Amplexicaul, decurrent, verticillate, equitant, pinnate, palmatifid, serrate, hastate, decompound, pulvinus, tendril, and phyllode, and illustrate by examples.

4. What do you understand by Determinate and Indeterminate Inflorescences? Define a cyme, fascicle, spike, raceme, spadix, and locusta, and illustrate by examples.

5. Define the following terms as applied to the andrœcium and gynœcium:—Innate, versatile, gynandrous, exserted, synantherous, didynamous, simple pistil, gynophore, apocarpous, and syncarpous, and illustrate by examples.

6. Give the essential characters of the following natural orders, and enumerate their official plants:—Cruciferæ, Rosaceæ, Labiatæ, Solanaceæ, Polygonaceæ, and Liliaceæ.

Hours from 2 *till* 5.

MATERIA MEDICA.

1. Mention the botanical and geographical sources of Guaiacum Resin. Describe how it is obtained, its physical and chemical characteristics, and the means of detecting it when employed to adulterate Scammony.

2. Describe the general and chemical characters of official Myrrh; mention its botanical and geographical sources, the substances used to adulterate it or which are substituted for it, and enumerate its official preparations.

3. What do you understand by Balsam? Describe the botanical and geographical sources, and the general and chemical characters of Benzoin, and enumerate its official preparations.

4. What are the botanical and geographical sources of Nux Vomica? Describe the general and chemical characters of these seeds, and give the doses of Nux Vomica and Strychnia, and of the official preparations in which they are contained.

5. Describe the characters of the Mealy and Non-Mealy Sarsaparillas of Pereira. What kind of Sarsaparilla is official, and what are its botanical and geographical sources, and official preparations?

6. What is Saffron? Describe its characters, and mention the substances which are used in its adulteration, and the means by which they may be detected.

The PRESIDENT then called upon Professor Attfield for his—

REPORT ON THE PRACTICAL CHEMISTRY CLASS.

Professor ATTFIELD said his report respecting the Class of Practical Chemistry would, as usual, be based on the two reports which it was his duty to present to the Council at the close of the session, one giving the general statistics of the class, and the other setting forth the result of the examination for prizes. With regard to the former he might condense all that he had said to the Council in one sentence, and that was, that comparing the session with perhaps the last five previous years, they had had, as regards numbers and period of study, a good average session. He was happy to report that of the whole number of students fully 40 per cent. were with him for the whole of every day of the whole session of ten months. The attendance was very good, the diligence of the students was unquestionable, and their progress very satisfactory, whilst with regard to their general behaviour it was, as he had been glad to say on every occasion, that of gentlemen. At the close of the session an examination was held, extending over two days, when fourteen students competed, six of whom obtained sufficient marks to qualify them for medals or certificates. The standard number was 100, and the gentleman who stood first on the list obtained the full number, whilst the next in order obtained 85, 80, 65 and 60. Before sitting down he should like to allude to two incidents which had given him great pleasure, and which would, he felt sure, please the Council, under whose supervision the School of Pharmacy was conducted, and his colleagues and the assistants in the School. The first was the receipt of a letter from one of the past year's students, a gentleman who had taken several prizes, a portion of which he would read. He said, "By the spirit which is infused into the students at the Society's school, one feels as if knowledge is introduced to us not as a mere acquaintance who will be forgotten after having carried us over the examination, but as a friend who will accompany us along the path of life, always ready to bring willing aid in professional and other difficulties, and perhaps coming to help us unawares by introducing us to her colleague, discovery. A mere acquaintance is soon forgotten, but if we are taught to love knowledge we generally remain faithful to her, and are sure to receive the reward in after life. Thus the true object of education is gained. Believing these to be the feelings not only of myself, but of my fellow students, I remain," etc. And then followed the name, which he was asked not to mention. The other matter he wished to allude to related to the present session, and it was that they had a larger number of students than had entered in October for several years; in the laboraties there were very few benches to spare.

The PRESIDENT then presented the prizes and certificates awarded to members of this class as follows.—

SESSION. TEN MONTHS.

Silver Medal	Frederick Wm. Short.
Bronze Medals	Fredk. Jas. Yeatman. Richd. Augustus Cripps.
Certificates of Merit	Edgar Haward. Walter Clark Drew.

The President also handed to Mr. Frederick William Short a copy of the 'Pharmacographia,' and one of 'Science Papers,' presented by Mr. Thomas Hanbury, in memory of his brother, Mr. Daniel Hanbury, to students taking a silver medal.

The following are the questions which were set for this examination:—

PRACTICAL CHEMISTRY.

July 17th and 18th, 1882.

Hours 10 to 5 each day.

(*Books and Memoranda permitted.*)

Standard number of Marks, 100.

FIRST DAY.

1. Ascertain what salts are present in the "Saline" medicine handed to you.
2. How much real Hydrocyanic Acid is present in the "Diluted Hydrocyanic Acid" supplied to you?

SECOND DAY.

3. Examine the accompanying sample of "Urine" and state the results.
4. In the specimen of "Reduced Iron" given to you how much free iron is present?

NOTE—*Manipulation as well as results will be scrutinized.*

Professor Bentley was then requested to report with respect to the result of his examination of the herbaria sent in by competitors for—

THE HERBARIUM PRIZE.

Professor BENTLEY said if time had permitted he should have liked to say a good deal on the advantage of the study of practical botany which the Herbarium prizes offered by the Council were intended to stimulate, because the time for studying practical botany was when students were engaged in the country during their apprenticeship. He was very pleased to report that this year there had been a very good competition; last year there was only one collection sent in, but he was glad to notice that the gentleman who forwarded it had won several honorary distinctions during the past session. This year there were five collections, all of which were worthy of notice. It entailed a good deal of labour to examine them, but it was a labour of love. The first one, which obtained the silver medal, contained over six hundred specimens, and he thought the best thing he could say about it was to ask everyone present to go and look at it and judge for themselves. The next two, to which bronze medals were awarded, were also very good, and the next two well deserved the certificates of merit which were awarded to them. He hoped that many of those who inspected these collections would be stimulated to do similar work on a future occasion.

The PRESIDENT then presented the prizes and certificates awarded in this competition as follows:—

HERBARIUM PRIZE.

Silver Medal	Henry Hamilton.
Bronze Medals	Equal. F. V. Butterfield. Thos. G. Nicholson.
Certificates of Merit	Henry Edward Skyrme. Edward Henry Farr.

THE COUNCIL EXAMINATION PRIZES.

The PRESIDENT next stated the result of the competition for the Council Prizes, which were awarded to those who passed the best examination for the higher qualification in each year in the three subjects of Pharmacy, Botany, and Practical Chemistry, irrespective of where they had studied. The first and highest award was the silver Pereira medal, with books value £5, presented by Mr. Hyde Hills; the second was the Council medal, with books value £3; and the third a bronze medal, and books value £2. The examination was conducted in July last by Mr. Gibson and Dr. William Inglis Clark, members of the Edinburgh Board of Examiners, and as neither of these gentlemen was present, he would briefly state the result. The standard number of marks for the three subjects was 1000, and the first candidate obtained 829, the second 756, and the third 689. It was satisfactory to find that, although this examination was conducted by two gentlemen residing north of the Tweed, their report was confirmatory of the conclusions arrived at by the Professors in London, since Mr. Short, who had already taken the silver medal in each class, had been recommended as most worthy to receive the Pereira medal. He might remind the meeting that Mr. Short had been the "Bell Scholar" for the past year.

The President then presented the Council Examination Prizes as follows:—

Pereira Medal (*Silver*); *and Books value £5, presented by Mr. T. H. Hills.*

Frederick William Short.

Pharmaceutical Society's Medal (*Silver*); *and Books value £3, presented by Mr. T. H. Hills.*

William Kirkby.

Pharmaceutical Society's Medal (*Bronze*); *and Books value £2, presented by Mr. T. H. Hills.*

Frederick James Yeatman.

The following are the questions which were set for this examination:—

BOTANY AND MATERIA MEDICA.

Time: 10 *a.m. to* 1 *p.m.*

In framing Answers, Candidates should not enlarge upon the Questions, but should confine themselves to giving, as briefly and clearly as they can, the information required.

BOTANY.

1. Describe the processes of Cell formation, and show how these processes are involved in the reproduction of the lower Cryptogams.
2. What gases commonly exist in Plants? Describe the circulation process, and how it is affected by external influences.

3. Describe the inflorescence of the Oat; and explain how fertilization is effected.

4. Mention the official orders of the sub-class Calycifloræ, and give the distinguishing characters of such of them as yield indigenous medicinal plants.

MATERIA MEDICA.

1. What are the botanical sources and distinguishing characteristics of true and false Pareira Root? Name the principle of true Pareira, and mention any other plants in which an analogous substance is to be found.

2. State the official process for the preparation of Morphia and give the tests for its recognition and purity. What is Apomorphia? How does it differ from Morphia in constitution, and in physiological action?

3. What is Araroba? State its composition, and in what tissues of the plant it occurs, and give your opinion as to how it may be formed.

4. What is the botanical source, and natural order of the plant yielding Papaw-Juice? State clearly what you know regarding its properties, and how the active principle may be isolated.

CHEMISTRY.

Time: 2 *to* 5 *p.m.*

In framing answers, candidates should not enlarge upon the questions, but should confine themselves to giving, as briefly and clearly as they can, the information required.

1. Explain what is meant by the ortho, meta, and para series of Benzol compounds, and give the relations of Salicylic and Benzoic Acids.

2. A mixture contains Aldehyde, Alcohol, Cane Sugar and Glycerine. How would you (1) detect the presence of these substances, and (2) approximately estimate the proportions present?

3. A sample of vinegar contains Sulphuric and Hydrochloric Acids, Sodium Carbonate has been added so as to neutralize these acids and part of the Acetic Acid. How would you estimate the Acids present, free and in combination? Working details should be given.

4. What is dissociation? How is it proved,

a. In the case of Water,

b. In the case of Ammonium Chloride?

5. Syr. Ferri Iodidi is suspected to contain Hydrochloric and Phosphoric Acids. How would you prove this?

6. Explain (by means of equations) the action of (1) Nitrous Acid on Ammonia, (2) Zinc on dilute Nitric acid, (3) Ammonia on Chlorine, (4) Chlorine on a cold solution of Caustic Potash.

The Bell Memorial Scholarships.

Mr. Ekin, being called upon to state the result of the competition for the Bell Scholarships, said that twenty candidates had presented themselves, eight from London and twelve from other centres, and he was glad to state that the papers generally were decidedly satisfactory. The Council had fixed the proportion of the total marks as being necessary for the award, and six of the candidates obtained that number; the papers of the two successful men being eminently satisfactory. These were—

William Edward Crow.
Edward Baily.

The President congratulated the new "Bell Scholars," and handed to each books of the value of £2 10*s.* presented by Mr. Thomas Hyde Hills.

The following are the questions which were set for this examination:—

Time allowed: Three hours (12 *to* 3).

In awarding marks the neatness and legibility of the writing will be taken into account.

LATIN.

1. Translate into English:—

"Diverso interea miscentur mœnia luctu;
Et magis atque magis, quanquam secreta parentis
Anchisæ domus arboribusque obtecta recessit,
Clarescunt sonitus, armorumque ingruit horror.
Excutior somno, et summi fastigia tecti
Ascensu supero, atque arrectis auribus adsto;
In segetem veluti quum flamma furentibus Austris
Incidit, aut rapidus montano flumine torrens
Sternit agros, sternit sata læta boumque labores.
Præcipitesque trahit silvas; stupet inscius alto
Accipiens sonitum saxi de vertice pastor.
Tum vero manifesta fides, Danaumque patescunt
Insidiæ."

2. Parse the concluding sentence of the above quotation.

3. Translate the following prescription into full Latin:—

"Take of—
Strychnia, one grain.
Disulphate of quina, two scruples.
Dilute hydrochloric acid, fifty minims.
Tincture of orange peel, one ounce and a half.
Compound infusion of gentian to one pint.

Mix and make a mixture. Let the patient take two tablespoonfuls three or four times a day."

4. Decline the Latin substantives employed in your translation of the above prescription.

ENGLISH.

1. Write a short essay on Courage.

2. Parse the following lines:—

"I wish thy lot, now bad, still worse, my friend;
For when at worst, they say, things always mend."

ARITHMETIC.

1. Divide the product of $5\frac{2}{7}$ and $4\frac{6}{9}$ successively by their sum and their difference.

2. What weight added to ·278 of a pound will equal ·729 of a kilogramme? Express the weight in grammes.

3. A collier working ·645 of the week and spending $\frac{13}{14}$ of his earnings, saves 2*s.* $10\frac{1}{2}$*d.* per week. What will be the sum of his annual savings should he work $\frac{6}{7}$ of every week, and spend ·562 of his earnings?

4. The melting point of stearic acid is 69·2° C. Convert this into degrees Fahrenheit and Réaumur; and also state how many degrees C. and R. correspond with +52° F. and −17° F.

FRENCH OR GERMAN.

The candidate is at liberty to choose either French or German, and is not required to show a knowledge of both. Marks will only be awarded for one.

FRENCH.

Translate into English:—

"A quelque temps de là, un pêcheur qui avait tendu ses filets non loin du pied de cette tour, fut tout étonné, en les retirant, d'y trouver quelque chose de lourd: c'était le plat d'argent du Masque de fer; comme cet homme simple ne savait pas lire, il pensa que ce plat était tombé par megardé dans les flots, et se hâta de le reporter au gouverneur, dans l'espoir d'une récompense."

And:—

"Mettez l'huile dans un flacon d'une capacité telle qu'il en soit presque entièrement rempli; introduisez le phosphore, et faites chauffer pendant quinze à vingt minutes, au bain-marie, en ayant soin d'agiter vivement de temps en temps."

GERMAN.

Translate into English:—

"Der Freiheitskampf der Deutschen gegen Napoleon.

"Diese Geschichte umfasst einen Zeitraum von nicht mehr als drei Jahren; aber das Gemüth fühlt sich wunderbar gehoben, wenn es die Ereignisse berschaut, die sich in der Spanne von Zeit zutrugen. Wir sahen ganz Europa und einen grossen Theil Asiens in Bewegung für die Sache der Freiheit. Deutschlands Fürsten, durch der Ränke des Auslandes auf immer, wie man meinte aus einander gerissen, boten sich von neuem redlich die Hand. In den Völkern erwachte eine Begeisterung wie in den Tagen der Kreuzzüge."

Time allowed: Two hours (4 to 6).

In awarding marks, the neatness and legibility of the writing will be taken into account.

CHEMISTRY AND PHARMACY.

1. In making Extract of Henbane, the directions are to heat the juice to 130° and filter, and again heat to 200° and filter. What is the nature of the substances left on the filter in each case, and why are they separated?

2. Give the composition and mode of preparation of Glacial Acetic and Glacial Phosphoric Acids, and explain the meaning of the word Glacial.

3. Why is Sodium Acetate used in making Syrup of Phosphate of Iron and Chloride of Ammonium in making Solution of Perchloride of Mercury?

4. How much Iron is required to make 100 grammes of Ferrous Sulphate?

5. Give the formulæ for Sodium Hydrate, Arseniate, Bicarbonate, Carbonate, Nitrate, Phosphate, Chloride, and Sulphate.

BOTANY.

1. Describe from memory, as nearly as you can, the flower, leaves, etc., of the common Buttercup, and enumerate other plants belonging to the same family.

2. Describe an Apple, Strawberry, and Gooseberry.

Inaugural Sessional Address.

Mr. Joseph Ince then delivered an address to the students, which will be found on p. 281, *et seq.* At the conclusion of the Address—

Professor Chandler Roberts, F.R.S., proposed a vote of thanks to Mr. Ince for the instructive address and rich literary effort all had heard with so much pleasure. At first he was at loss to see why a metallurgist was permitted to propose this motion; but he thought he saw the reason for the President's selection. Metallurgy and pharmacy certainly had a common origin, for at the time when Paracelsus was attempting to introduce order into medicine, Biringuccio was building up the science of metallurgy. Perhaps another reason was that an early volume of the 'Philosophical Transactions of the Royal Society' contained an admirable paper giving a description of work done by Mr. Carteighe, not in pharmacy, but in metallurgy. Mr. Ince had told them that conduct was fate, and the whole public must feel very strongly that the fate of every one must depend in great measure on the accuracy of the chemist's knowledge. Any body of students was very fortunate in beginning its career under such sympathetic influences as those of Mr. Ince, and he had much pleasure in proposing a vote of thanks to him.

The Vice-President (Mr. Atkins) seconded the motion with very great pleasure. He thought this address was the crown of all Mr. Ince's previous performances, and he could not find a phrase which would more aptly express the perfection and beauty and the exquisite symmetry of that address than the one applied by Mr. Ince to Dr. Pereira, where he said that "having the gift of speech and a singularly buoyant temperament, he was clear in statement and brilliant in illustration." No words of his own could so fully express the beauty of the historical *résumé* of pharmacy and the admirable advice given to those who were entering on their studies. His own feeling, as one who had passed the meridian, was, "Oh! that he were just entering on his career, looking forwards instead of looking backwards, and that it had been his privilege as a young man to have been inspired, as he felt he should have been, and go forward on the path of work, he trusted successfully."

The vote of thanks having been carried by acclamation,

Mr. Ince, in reply, expressed his appreciation of the compliment, and said it was often a matter of regret with him that he was separated so much from the public work of pharmacy, and he was therefore very glad of this opportunity of renewing his connection with it.

Parliamentary and Law Proceedings.

Prosecution under the 17th Section of the Pharmacy Act.

At the Borough Police Court, Halifax, on Friday, September 22, before Messrs. Barstow and Buller, John Gledhill, of 90, Gibbett Street, was charged with having unlawfully sold to George Revill Templeman, of 23, Burlington Chambers, New Street, Birmingham, Assistant Secretary to the Chemists and Druggists' Trade Association of Great Britain, a certain poison, to wit, laudanum, the same being a preparation of opium, and not labelled with the name and address of the seller, contrary to the statute in such cases made and provided.

Mr. Henry Glaisyer, Solicitor of the Association, conducted the prosecution, and Mr. Storey appeared for the defence.

Mr. Glaisyer said this was a case under the 17th section of the Pharmacy Act, 1868, which enacts that it shall be unlawful to sell any poison, either by wholesale or by retail, unless the box, bottle, parcel or wrapper, in which the poison is contained, be distinctly labelled with the name of the article, the word "poison," together with the name and address of the seller of the same. He then proceeded to quote from the case of Templeman *v.* Trafford, which was heard before Mr. Justice Grove and Mr. Justice Lopes, in October last, who held that the seller within the meaning of the Act was the person who had actual control of the business where the sale took place. At the time of such sale the defendant was not a registered chemist, and had no right to sell poison at all.

Mr. G. R. Templeman said he was Assistant Secretary of the Chemists and Druggists' Trade Association, and resided in Birmingham. On Monday last he went to the shop of the defendant, at 90, Gibbett Street, and there purchased from him personally twopennyworth of laudanum; the bottle containing the laudanum was labelled, "Charles Brierly, Chemist, Raglan Street and Gibbett Street, Halifax. Poison. Laudanum." He saw several other parcels in the window labelled with the name and address of the defendant; the defendant's name also appears on a sign over the front of the shop.

Cross-examined by Mr. Storey: He purchased a halfpennyworth of linseed meal at the same time, and stated that he required it to make a poultice, and the laudanum was required to sprinkle on it and not to be taken inwardly.

Mr. Storey said his client would plead guilty. He had never sold any poison previous to this case; he was a young man about twenty years of age, who had purchased the business in question, and was endeavouring to pass his examination as a chemist, and it was not until he had ascertained from the complainant that he required it for an outward application, and from his appearance he thought him a person whom he might safely trust with that quantity of poison that he had sold it; after taking these facts into consideration he trusted the bench would deal very leniently with him, and only inflict a small fine, and he would promise not to again repeat the offence.

The Chairman of the Bench: The sale of poisons to the public by unqualified persons was a very serious offence, as they could never tell what consequences might ensue; they had decided to deal very leniently with him this time, and trusted he would take care not to offend again. He would be fined 20*s.* and costs 7*s.* 6*d.*

Alleged Death from Lead Poisoning.

The adjourned inquest touching the circumstances attending the death of Wilson Riley, mechanic, of Keighley, who died on August 26, from the supposed effects of lead poisoning, was held on Tuesday, September 26, in the Keighley Police Court, before Mr. J. P. Brown, Coroner.

Considerable interest was manifested in the inquiry.

The Keighley Local Board was represented by Mr. Tindal Atkinson, barrister, of Leeds (instructed by Mr. George Burr, clerk to the board).

There were also present Messrs. R. L. Hattersley (Chairman of the Board), B. S. Brigg, John Gledhill, Dr. A. Roberts (Medical Officer of Health), Dr. Dobie, Dr. Jack, and a number of other medical gentlemen.

Mr. Tindal Atkinson, on behalf of the Local Board, said he had a very important witness whom he should like to call—that was Professor Tidy, of London, who had considerable experience in chemistry and cases of the kind they were inquiring into. He was, however, away in Scotland, and he should ask for a further adjournment after the additional witnesses had been examined.

The viscera of the deceased and a sample of the town's water from the mains and tap of the deceased's late residence had been submitted to Mr. Alfred H. Allen, of Sheffield, for analysis, and following is an extract from his report supplied to the Coroner:—

"A doubtful trace of lead was found in the kidneys, but in the liver and spleen a notable quantity of lead and copper was found. There was $\frac{1}{8}$ of a grain of lead in one-half of the liver. That amount was smaller than they might expect to find in the liver of a person who was poisoned by lead, but he had not unfrequently noticed very insignificant amounts of lead in the viscera of cows and other animals that had undoubtedly met their death by lead poisoning. He attached no importance to the finding of copper, as he had met with it in several other instances. He had examined a sample of water from the tap in the deceased's dwelling-house, and found that it contained $\frac{3}{5}$ of a grain of metallic lead per gallon. The proportion was amply sufficient to produce poisonous effects, but some persons appeared to be more sensitive to the influence of lead than others. Speaking generally, anything over $\frac{1}{10}$ of a grain of metallic lead per gallon of water was a dangerous contamination. He had known $\frac{1}{5}$ of a grain of lead produce severe symptoms of lead poisoning. On examining a sample of the water taken direct from the mains he did not find any trace of lead, but it contained a distinct trace of mineral acid. The water, by remaining in contact eighteen hours with a strip of clean lead, became contaminated with lead to the extent of 0·56, or over $\frac{1}{2}$ a grain per gallon. A repetition of the experiment showed that 0·45 of a grain of lead was taken up in fourteen hours. Those proportions of lead would render the water highly injurious to a person who drank it regularly. When the water in question was rendered faintly alkaline with lime water, and left in contact with lead over one night, it took up the smaller quantity of 0·14 grain of lead per gallon. From the experiments he considered it was the free acid in the water that gave it so great a tendency to act on the lead. He found that Sheffield water took up a small trace of lead during one night, but Rotherham water took up no trace of lead after two nights' contact with metal."

Mr. Allen was called, and said he arrived at the conclusion, when he found no lead in the heart, that it had been eliminated by medical treatment. On good authority he believed that a person under medical treatment could be freed from lead in a fortnight, but the organs would show deterioration.

By Mr. Tindal Atkinson: One-fifth of a grain was not sufficient to cause death, but it would cause paralysis.

Dr. William Dobie was then called. In examination by Mr. Atkinson, he said that disease of the kidneys generally accompanied lead poisoning. They might find symptoms of paralysis without lead poisoning, but in aggravated cases of lead poisoning paralysis was generally found.

By the Foreman: The deceased might have died from granular disease, caused by lead poisoning. (1) Lead poisoning was a very common cause of granular disease. (2) During life there were unmistakable signs of lead poisoning. (3) Lead was found in the tissues after death.

By Mr. Atkinson: Witness had treated deceased for lead poisoning about two years ago. Lead might be eliminated from the system after ten days of medical treatment. He accounted for the absence of lead in other organs of the deceased from the fact that it was being rapidly eliminated from the system by medical treatment.

Dr. William Jack, who attended deceased up to the time of death, gave his opinion that the cause of death was lead poisoning.

Further evidence having been given, the case was adjourned for a week to allow Professor Tidy, of London to be present to give evidence as to the quality of the water supplied by the Local Board.

The adjourned inquest was held on Tuesday last at the Court House, Keighley, before Mr. T. P. Brown, Coroner.

Charles Meymott Tidy, M.B., Master of Surgery, and medical adviser to the Home Office, was examined. He said he had had great experience in cases of poisoning. He had been called upon to make analyses in several cases of lead poisoning. He had never had before him a case of death resulting from chronic lead poisoning. Lead poisoning was not the actual cause of death, but it had preceded death. Deaths caused by lead poisoning were very rare occurrences. When lead poisoning was very advanced, he invariably found paralysis of the muscles—especially the muscles of the wrist. He did not know of any case of lead poisoning but what was attended by paralysis of some kind, but during his experience he never knew of an actual death from lead poisoning. Granular disease of the kidneys resulted in some cases from lead poisoning. He had read Mr. Allen's report, and he was astonished to see the small amount of lead found in the system, for in one case, which had not resulted in death, he found 5 grains of lead in the spleen and 4 grains in the liver. Iodide of potassium was a remedy against lead poisoning, but it was difficult to get it from the system. The effect of iodide of potassium on the system was to render the lead insoluble and inert. It was very difficult to say in this case what was the cause of death, because he was not present when the *post-mortem* examination was made. There was very little lead found, and that led him to suppose that death had probably been caused by granular degeneration of the kidneys. There was no evidence of disease of the nerve centre.

Dr. Jack, who attended the deceased, was recalled and make additional remarks. He said the deceased vomited, but the vomit had not the appearance of being caused by disease of the kidneys. The deceased was never above the natural heat. The temperature always rose from inflammation. The deceased's breath had a peculiar fetid odour, which he had never noticed before except in cases of severe lead poisoning. He also complained of pains in the arms and legs, which constantly shifted. Shortly before death convulsions set in, and the deceased was attacked by severe pains. All the medical men were of opinion at the *post-mortem* examination that the deceased had died from lead poisoning.

The Coroner, in summing up, said the jury need not attach any importance to the small quantity of lead found in the deceased.

Mr. Atkinson, addressing the jury, said whatever the result of the inquiry might be, he was instructed by the Local Board to say that the most searching investigations would be made with regard to the town's water.

The Jury retired to consider their verdict, and after being absent for two hours, the Foreman handed in the following verdict:—"We are of opinion that the deceased, Wilson Riley, died from granular disease of the kidneys, but how caused we are unable positively to say; but death was accelerated by lead poisoning."—*Leeds Mercury.*

Poisoning of a Chemist and Druggist by Prussic Acid.

Mr. Carttar, West Kent Coroner, held an inquest on Tuesday, October 3, at New Cross, on the body of Joseph Quinlan, aged 43, chemist, 457, New Cross Road.

Annie Quinlan, the widow, identified the body, and said deceased for twelve months had suffered from depression and nervous debility. On Sunday morning last he left home, and returned with some chloroform, which he was in the habit of taking. He went upstairs, and finding him taking some she tried to take the bottle from him, but could not. He went out again twice, but returned without any chloroform, and went upstairs. She again followed him on his knocking on the floor with his foot, and found him drinking something from a bottle, which she knocked out of his hand, and he then fell backwards. She then sent for Dr. Gordon, who immediately attended, but her husband shortly afterwards expired. She had never seen him take any drug as an antidote to chloroform, or heard him threaten to commit suicide.

Dr. Gordon, of 10, Amersham Road, New Cross, said he spoke to Mr. Quinlan professionally on Friday last, when he was suffering from the effects of chloroform and intoxication. About four years ago witness discovered him insensible in his own shop from chloroform. When he recovered witness found he had been in the habit of taking chloroform to produce oblivion and drown care. Witness had attended him professionally, but within the last year he took chloroform to such an extent, and became so violent under its influence, that witness declined to have anything more to do with his case. Witness told him he would be one day found dead, and there would be a coroner's inquest, and he replied that he did not care how he died. He took enough chloroform to kill an ordinary person over and over again, and witness believed at times he took as much as a pound in twenty-four hours. On Sunday morning witness was called to his house, and found him lying down, and Mrs. Quinlan with him. She said "Oh, Mr. Quinlan has taken prussic acid," and added that when she went upstairs, he said "I have done it at last." The bottle produced had contained prussic acid three times as strong as the Pharmacopœia solution.

After some further evidence, the Jury returned a verdict that he died from an overdose of prussic acid taken by misadventure to produce relief.—*Standard.*

Correspondence.

Liq. Ferri Iodidi.

Sir,—I have just received this day's Journal and note the discussion on my paper on the above subject. I do not wish to make any personal defence of the position I took or of the correctness of any of my observations. My position was sufficiently indicated in the paper itself, where, towards the end I say, "I do not suggest the propriety of adding any foreign matter as a preservative. I have not even suggested the impropriety of such a course," but the pharmacist "had better at least know what he is doing." And regarding the correctness of my observations, I have no respect for an argumentative reply; those who are interested in the subject can very easily try the reactions, and if my reputation suffers, scientific pharmacy at least will be benefited.

Perhaps it is due to scientific accuracy that I should state that the solution of iodide of iron, which I spoke of as pure and free from acid, was of that degree of purity which the B.P. process readily yields, and that degree of freedom from acidity which is indicated by the testing which I describe. The B.P. sample, which was accepted as a standard, was made by one of my apprentices in the ordinary course of trade, and I do not think that any manufacturing chemist can complain that he "had not had a very good time of it at the Conference" (as Mr. Fletcher expresses it), if his preparations have a less close approximation to purity than those made by the pharmacist's apprentice.

I do not think the specific gravity an important test, if purity is doubted. If the gravity were not correct the preparation must be at fault, but if the gravity were all right the preparation might still be all wrong.

I do not know that sulphurous acid makes a muddle of ferrous salts, and I do not know that phosphoric acid always precipitates ferric salts, though the manuals of analysis tell us how to throw down phosphoric acid as ferric phosphate.

It must not be supposed that I suggest adding iron wire to syr. iod. iron. I spoke of liquor and did not recommend anything being added. The iron wire is a very old suggestion, as pointed out by Mr. Fletcher, and I believe often used in preserving the liquor, though I was not aware of its being used in the syrup. If the discussion leads to the more general following of the pharmacopœial process, with attention to the points emphasized by Professor Tichborne (which are not deviations from the official formula), my object will have been attained. I may just add that, though it formed no part of ths object of my paper, I do recommend the exclusion of air as the most important point to be adopted by the pharmacist towards the preservation of the liquor or the syrup of the iodide of iron.

Grey Street, Newcastle. Barnard S. Proctor.

Erratum.—In "The Month," p. 265, col. i., line 20, *for* "$\frac{1}{100}$ gram" *read* "$\frac{1}{100}$ grain."

Inquirer.—The quantity of borax is too great for solution. Shake the mixture until a saturated solution is produced and leave the excess in the bottle.

W.—Mixtures containing quinine and iodide of potassium have on several occasions been the subject of comment under "Dispensing Memoranda."

N. M. G.—*Funkia subcordata.*

Country Chemist.—We do not think that the subject is quite suited for discussion in these pages. It must be evident that, to say the least, the so-called "system" is open to a great deal of abuse.

J. G. F.—Any person whose name is on the Register may carry on the business of a chemist and druggist, whether he is a member of the Society or not. A person who has passed the Preliminary and Minor examinations is entitled to have his name placed on the Register and may then be elected an Associate of the Society. If in addition he passes the Major examination he is registered as a Pharmaceutical Chemist and is then eligible as a Member.

Communications, Letters, etc., have been received from Messrs. Dodd, Abraham, Bedford, Mason, Wilkes, Hall, Bennett, Richardson, Dyer, Baines, Elliott, Minor, Guerra al Cuetiella, F. W. E. S., W. J. S.

THE "TAMBOR," A TREE YIELDING A PURGATIVE OIL, WITH DESCRIPTIONS OF TWO SPECIES OF OMPHALEA.

BY W. BOTTING HEMSLEY, A.L.S.

Some twenty years ago, Dr. Dorat, of Sonsonate, San Salvador, Central America, sent to the late Daniel Hanbury dried specimens of a tree called tambor, that was said to yield a valuable purgative oil resembling castor oil in its properties, with the advantage of having a more agreeable flavour. Mr. Hanbury sent one specimen to Kew Herbarium, where it was recognized as a species of *Omphalea*, near, if not identical with specimens collected by Sutton Hayes, at Acajutla, not far from Sonsonate, but apparently different from any described species. Nothing further seems to have been done with the plant. Having to deal with it for the botany of Godman and Salvin's *Biologia Centrali-Americana*, I lately wrote to Mr. E. M. Holmes, the Curator of the Pharmaceutical Society's Museum, asking whether the specimens in the collection under his charge afforded any information beyond those at Kew. He obligingly communicated a copy of a note by Dr. Dorat, together with some particulars of the specimens which were found in the Hanbury Herbarium. Although the material is by no means so complete as one could wish, it is sufficient to show that the plant does not belong to any described species. I have, therefore, described it as far as it goes, as well as Sutton Hayes's specimen alluded to above, which I take to be a second species; and the publication of these descriptions and what is known of the plants, in this Journal, may serve to draw attention to them and be the means of eliciting further information. The genus *Omphalea* comprises about eight known species, one of which is endemic in Madagascar, whilst all the others are restricted to tropical America. This peculiarity in distribution is shared by some other genera of plants, *Ravenala* for example; and it also finds a parallel in the animal kingdom, according to Wallace. The most striking distinctive character of the genus is in the male flowers, or rather in the stamens, of which there are two or three in each flower. They are united and form together a body shaped like a mushroom. The columnar portion is short, and the cap consists of the thickened dilated connectives of the two or three stamens, so that the two cells of each anther are distant from each other, and two cells of different anthers close to each other. In my *O. cardiophylla* the number of stamens is usually two, but there were three in one flower that I examined. All the flowers I examined, both male and female, had a calyx of four decussate sepals, yet it is likely that in these species, as in the others, the number may vary from four to five.

Concerning the "Tambor," Dr. Dorat sent the following note to Mr. D. Hanbury:—"The fruit about the size of a pear, contains three beans, jet black, which, by pressure, yield a very fine oil in large quantity, rather pleasant to the taste, and resembling castor oil in its purgative effect, with the advantage that it does not gripe. The leaf is large (I send a small one), and is used here for packing cheese, on account of its strength. Flowers in December; fruit ripe in February or March. The seeds are covered with an exceedingly hard, black, thin epidermis, with a white soft pulp containing the oil, which, besides its purgative quality, burns well. Seeds [seed-vessels] grow in large bunches."

This I propose naming *Omphalea oleifera*, and the following is a description of the species as far as the material will permit:—

OMPHALEA OLEIFERA, Hemsley, species nova. *O. foliis amplis fere orbicularibus profunde cordatis stellato puberulis, paniculis brevibus ramosis, bracteis paucis infra pollicaribus, ovario glabro.*

Arbor? ramulis ultimis inflorescentias gerentibus crassocarnosis. Folia (*unicum circiter* 5 *poll. diametro a nobis tantum visum*) *petiolata, tenuia, papyracea, sparse stellatopuberula* (*pilis deciduis*), *suborbicularia, profunde cordata* ("*ampla, lenta*" *Doratius*), *venis primariis lateralibus utrinque* 5 *vel* 6 *conspicuis; petiolus in spec. Kewens. omnino deest. Flores monoici, paniculati; paniculæ terminales, latæ, ramosæ, puberulæ; bracteæ paucæ, petiolatæ, angustæ, oblongæ, vix* 1 *poll. longæ, venosæ, puberulæ; calycis sepala in fl.* ♂ *ut in fl.* ♀ 4, *decussata, orbicularia, ciliolata; antheræ* 2; *ovarium glabrum.* "*Fructus magnitudine pyri,* 3-*spermus; semina nigra, oleam gratam purgativam copiose præbentia.*" —Dorat.

This and the following differ from all the previously described species in having thin, strong, papery leaves, and perhaps also in their very stout ultimate branchlets. This differs too from the common *Omphalea diandra* in having a glabrous, not hairy, ovary; and it differs from *O. cardiophylla* in its leaves being sparsely furnished with stellate hairs, in its short branching, narrow panicles, and in its smaller bracts. These differences are possibly all due to different conditions under which the plants grow; but rather than confuse two species under one name, I will risk making a bad species.

Here is a description of Sutton Hayes's plant numbered 617:—

OMPHALEA CARDIOPHYLLA, Hemsley, species nova, *O. foliis amplis fere orbicularibus profunde cordatis glaberrimis, paniculis angustis elongatis, bracteis oblanceolatis ad* 2 *poll. longis.*

Arbor 30—40 *pedalis* (*fide Hayesii*), *ramulis* . . . *Folia* (2 *tantum visa*) *longe petiolata, tenuia, papyracea* (*in vivis subcarnosa?*), *glaberrima, suborbicularia, basi profunde cordata, apice acuminata, obtusa* (*majus fere pedem diametro*), *undulata; venis primariis lateralibus utrinque* 5 *vel* 6, *conspicuis; petiolus* (*perfectus deest*) *saltem* 4 *poll. longus, apice* 2-*glandulosus, crassus, carnosus, in siccis infra medium crassior. Flores* (♂ *tantum visi*) *paniculati; paniculæ angustæ, graciles, terminales* (*pendulæ?*), *pedem vel ultra longæ, obsolete puberulæ; bracteæ oblanceolatæ ad* 2 *poll. longæ, venosæ, graciliter petiolatæ, petiolo* 2—4 *lineas longo, apice* 2-*glanduloso; calycis sepala* 4, *decussata, orbicularia, ciliolata; antheræ* 2 *vel interdum* 3.

THE INFLUENCE OF GUM ARABIC IN CERTAIN CHEMICAL REACTIONS.*

BY J. LEFORT AND P. THIBAULT.

It is known that the presence of certain organic substances in saline solutions may prevent the formation of a large number of precipitates. In this respect, the influence of tartaric acid is familiar to chemists. The researches it is proposed to describe warrant the statement that some neutral bodies, and gum arabic in particular, also enjoy this property.

* *Journ. de Pharmacie et de Chimie*, [5], vi., 169.

Upon this principle is based the therapeutic employment of soluble sulphide of mercury, as described by M. Lambron in a communication to the French Academy of Medicine. M Lambron pointed out that when an aqueous solution of bichloride of mercury is added to the ulphuretted Luchon water a precipitate of sulphide of mercury is rapidly formed which falls to the bottom of the vessel as a black powder. But if instead of introducing the bichloride of mercury directly it be previously mixed with syrup of gum or sarsaparilla, beef tea, albumen or apple jelly, and then poured into the Luchon water, in proportion a little in excess of the sulphur strength of the water, no precipitate is formed even after several weeks of contact. This observation induced M. Lambron to suppose that when bichloride of mercury is dissolved and mixed with gummy and albuminous substances and then poured into the sulphuretted Luchon water, the chemical action is suspended, *i.e.*, no sulphide of mercury is formed. The authors believe that although the experiments of M. Lambron may be correct his interpretation is not admissible.

At first, it might be supposed that the viscosity of the solution was the cause of the non-precipitation. But this is not the case, for if the syrup of gum be replaced by simple syrup or glycerine a precipitate is formed. It would therefore appear that the prevention of the formation of the precipitate is due to the gum or vegetable extract contained in the precipitate, and this was confirmed by the authors' experiments. The reaction is not peculiar to Luchon water and solutions of sulphuretted hydrogen or monosulphide of sodium may be substituted without sensibly modifying the results.

The authors therefore thought it would be interesting to ascertain whether gum equally prevented the precipitation of the different metallic sulphides, using solutions suitably diluted. For this purpose a titrated solution of monosulphide of sodium was prepared containing 1·7 gram of sulphydric acid per litre; on the other hand, a certain number of solutions each also containing a corresponding quantity of a metallic salt per litre; finally, a clear solution of 1 part of gum arabic in 2 parts of water. The observations were made in the following manner:—

Two quantities of 10 c.c. of the solution to be examined were run from a graduated pipette into two glasses of equal volume; with one of these 3 c.c. of solution of gum was incorporated by stirring and to the other 3 c.c. of distilled water was added; finally 10 c.c. of sulphuretted solution was added to each and rapidly mixed. The following table represents what was observed both after a few minutes and some weeks:—

	Without Gum.	With Gum.
Lead acetate	Black precipitate.	Clear brown solution.
Silver nitrate	Black precipitate.	Clear black solution.
Ferrous sulphate	Black precipitate.	Clear black solution.
Manganous sulphate.	Rosy flesh-coloured precipitate.	Clear light-brown solution.
Mercuric chloride	Black precipitate.	Clear dark-brown solution.
Copper sulphate	Black precipitate.	Clear dark-brown solution.
Zinc sulphate	White precipitate.	Clear colourless solution.
Antimonous chloride in solution acidified by HCl.	Orange precipitate.	Clear orange solution.
Arsenous acid	Citron-yellow precipitate.	Clear citron-yellow solution.

It will be seen, therefore, that under the conditions stated gum prevented the precipitation of metallic sulphides. In concentrated solutions, or when the proportion of gum was very small, more or less incomplete precipitations were observed.

It next appeared interesting to ascertain whether gum has also the power to stop the precipitation of metallic oxides and of alkaloids by the ordinary reagents. The following were the results obtained.

As to the metallic oxides it is unnecessary to enter into details of the experiments, it will be sufficient to say that they behaved like the sulphides in the presence of solution of gum. But since the oxides are, as a rule, much more soluble in water than the corresponding sulphides, metallic solutions of double the strength were used, and a corresponding solution of caustic soda.

The action of gum upon the formation of certain other precipitates was also studied, the following being the results observed:—

	With Gum.	Without Gum.
Neutral phosphate of ammonia and calcium chloride.	White gelatinous precipitate.	Clear colourless solution.
Uranium nitrate and potassium ferrocyanide.	Chocolate brown precipitate.	Clear brown solution.
Very dilute solution of ferric chloride and ammonia.	Brown gelatinous precipitate.	Clear light brown solution.

In a like manner no precipitates were produced in the presence of gum in solutions of 1 in 1000 of the following alkaloids, quinine, cinchonine, morphia, strychnia, brucia, and veratria, by the usual alkaloidal reagents,—phosphomolybdate of ammonia, double iodide of mercury and potassium and tannin. If it be remembered that the separation of alkaloids by their reagents has to be effected in the presence of various organic matters that accompany them either naturally or accidentally, these researches acquire for toxicology an unmistakable importance.

It is necessary also to note that certain vegetable infusions—among others, that of tea—are opposed to the precipitation of sulphide of mercury. The liquid only acquires a darker colour, consequent upon the presence of sulphide of mercury formed; this, however, is the same as happens with gum solutions.

Notwithstanding the numerous instances that have been quoted the non-precipitation of dilute solutions in the presence of gum is not absolutely general. The iodides of lead and mercury, sulphate of barium and carbonate of lead are precipitated in solutions containing gum more slowly, but nearly as completely as in distilled water.

The question arises whether in the presence of these facts it is necessary to conclude that the ordinary reactions undergo modification. Contrary to the opinion of M. Lambron, the authors think it is not. Although precipitation does not take place, it is evident from the intense coloration of most of the gummy liquids, as compared with that of the liquids floating above the precipitates, that the compounds are formed, but that they remain, if not in solution, at least in such a state of division that they pass through any filter; and the microscope, even with the strongest powers, does not reveal any trace of solid matter in suspension. Under these conditions it might be asked whether gum does not possess the property of dissolving metallic sulphides and oxides. Such an interpretation would be inexact, because recently formed precipitates are not redissolved when submitted to the action of a very concentrated solution of gum.

Although the phenomenon has not the generality that might be expected, the authors publish these results as affecting not only therapeutics, but also analytical chemistry and toxicology. It is also suggested that they are worthy of the attention of physiologists, since most of the organic liquids contain gum or analogous substances, and it is therefore possible to conceive the simultaneous existence in the soluble state in animal or vegetable cells of compounds reacting chemically upon each other.

THE OLEATES AND OLEO-PALMITATES IN SKIN DISEASES.*

At the thirty-third annual session of the Medical Society of the State of Pennsylvania, Dr. J. V. Shoemaker, of Philadelphia, read a paper on the above subject, which is reported in full in the *Med. and Surg. Reporter*, May 13, 1882. Dr. Shoemaker claims to have introduced, for the first time, the use of *chemically true* oleates, in contradistinction to those introduced by Mr. John Marshall in this country, which are here described as simply solutions and not true oleated compounds. Shoemaker's oleates are prepared by the double decomposition of sodium oleate with solutions of neutral salts, the former being prepared by saponification of oleic acid, with a solution of sodium hydrate. A solution of the sodium oleate in eight parts of water is precipitated by a neutral salt, and the precipitate, washed and dried, is the oleate required. The oleates of mercury, atropia, quinia and antimony, with their therapeutical action, were considered, and Dr. Shoemaker claimed to have first introduced the oleates of lead and bismuth in 1879, before the Society. The following oleates were also brought forward and shown for the first time.

1. *Oleate of Zinc*, made by decomposing a sodium oleate with a saturated solution of zinc sulphate, boiling out and drying the precipitate and reducing it to an impalpable powder. One part of this powder, melted with three of a fatty vehicle, makes a suitable ointment. Zinc oleate is a fine pearl-coloured powder, with a soft soapy feel, very much like powdered French chalk. The very best results are obtained from using it simply as a dusting powder, as in cases of excessive sweating of the feet, hands, or other parts, and in seborrhœa oleosa affecting the face; it is the most reliable remedy in eczema vesiculosum, in erythema about the groins and axillæ, and in herpes.

2. *Oleate of Copper*, obtained by double decomposition with a saturated solution of copper sulphate. The washed precipitate melted with either 4 or 9 parts of cosmoline, fat, or lard, gives respectively a 20 or a 10 per cent. of oleate of copper ointment. Applied to the unbroken skin the oleate of copper rapidly penetrates deeply into the parts, particularly into the follicles, and will produce slight stimulation; applied to the broken skin it acts as a stimulant, and an insoluble albuminate is formed, which coats over the surface and supplies the place of the abraded skin. This oleate is specially useful in cases of ringworm, the ointment being lightly rubbed in night and morning; the parts should be well washed with soap and water to start with, but afterwards only every ten or twelve days. Epilation is not always necessary in this method of treatment. This ointment is also a useful application for indolent ulcers, warts, corns, and bunions.

3. *Oleate of Aluminum*, prepared by decomposing sodium oleate with aluminum sulphate; the washed precipitate mixed with equal parts of lard gives the ointment the author uses. This ointment is semi-solid, dark brown in colour, and has a most powerful astringent action. It very rapidly checks mucopurulent discharges in eczema. The author also recommends it as a dressing in foul ulcers, abscesses, sinuses, burns, and scalds; in these cases it coagulates albumen, constringes the vessels, and has an antiseptic action.

4. *Oleate of Iron*; the precipitate thrown down on adding ferrous sulphate to sodium oleate is converted, by boiling, into ferric oleate, and this may either be used pure or made into an ointment with an equal part of a fatty base. "When prepared in the above manner it occurs in a reddish-brown paste, inodorous, leaving a styptic taste and readily soluble in fats, which hold in combination about 30 per cent. of oxide of iron, forming a powerful and important therapeutic remedy." Used topically it is non-irritating; applied to an ulcerating surface it is mildly astringent. The author recommends it for its constitutional, as well as its local effects, advising that a small piece should be rubbed into the axillæ and inguinal regions two or three times a day; from its use in this way he reports "excellent constitutional (systemic) results" in those who had a weak pulse, a pale and flabby condition of skin, and deranged digestive organs, unable to bear the ordinary chalybeates. In scrofula also he has used it with marked effect.

5. *Oleate of Arsenic* obtained by making arsenious chloride by the cautious saturation of hydrochloric acid with metallic arsenic; the solution thus obtained precipitates the oleate required from the sodium oleate. Twenty grains of this with 1 ounce of a fatty base form the author's ointment, which is soft, yellowish, having no action on the skin except when this is abraded, or in wounds, ulcerating and granulating surfaces, in which conditions it will excite active inflammation and destroy the tissues to some depth. It is of value in lupus, especially the ulcerating variety, and also in the tubercular variety after the parts have been thoroughly scraped. It may be applied also in ulcerating epithelioma, in warts, condylomata, nævi, corns, etc.; opium, belladonna, hyoscyamus, and arnica may be combined with it.

6. *Oleate of Silver* is prepared by precipitating sodium oleate with a saturated solution of silver nitrate, washing the precipitate with boiling water, drying it, and reducing it to fine powder. Of this an ointment may be made; strength, one drachm to the ounce. The salt is brownish-yellow in colour, the ointment dark brown, soft and pliable. The simple oleate may be sprinkled over old chronic ulcers, old sores, and exuberant granulations, when it will set up a healthy condition in the parts. The ointment coats over an abraded surface by combining with the albumen, and causes contraction of the blood-vessels; it is valuable, in the strength 10–20 grains to the ounce, as an application in erysipelas, a stronger ointment being used at the margin to prevent extension of the disease. It has been used also in superficial lupus, boils, and carbuncles.

The oleates of magnesium, lithium, calcium, antimony, tin, and others, have been prepared by similar processes, but are at present of little therapeutic value.

The author claims for these oleates the following advantages: their deep penetration; their freedom from rancidity; their cleanliness of application; their great economy; and their antiseptic action.

* From the *Glasgow Medical Journal*, October, 1882.

SPICES OF THE STRAITS SETTLEMENTS.*

Cloves and the Clove Tree.—People that labour under the opinion that cloves do well only in the Moluccas and on the island of Zanzibar are simply mistaken. It thrives splendidly in the Straits Settlement—this wonderful, lovely tree. Many years ago enterprising men on the island of Penang introduced and cultivated the clove tree, and it proved a decided success. It is to be found in some of the gardens of Europeans and wealthy Chinese in the Straits Settlements, producing flowers liberally; and it is a subject for wonder why no one cultivates it more largely, not to serve as an ornament only, but to derive benefit from it. In Penang it was planted for that purpose, and "Penang cloves" have the reputation, like the nutmegs, to be the best in the market, commanding a higher price than Amboyna (Moluccas) and Zanzibar cloves. But the consumption of this spice among the natives throughout the colony (and all India and the East in fact) is so large that the quantity left for export is very limited. It is the bud of the flower just before

* From the *Weekly Drug News*, Aug. 11, 1882

opening that constitutes the spice, and in this lies the difficulty that prevents many from planting cloves for export. One having a quantity of trees will find himself busy about the time the buds (white in colour, and strongly resembling snowdrops) begin to made their appearance. It must not be gathered before it, the bud, is well formed, just before opening; and as on a full-g own tree the number of buds is exceedingly large, the planter must have plenty of hands ready to gather them as quickly as possible, because the bud after opening—becoming a flower—loses much of its strength. Boys and girls from ten to fourteen years old answer best for this purpose. The bud-gathering time lasts a few days only, and whoever does not "make hay while the sun shines" will lose his crop of buds. The buds after being gathered are spread on large sieves or mats of loose texture, and dried under the shade of trees, or in sheds with palm-leaf covered roofs, and are then ready for the market. To dry them in the sun causes them to turn black and shrivelled, and to evaporate much of their strength. A properly dried clove is of light-brown or tan colour. The shipments of cloves from Singapore to the United States have, last year excepted, never amounted to much, and supplies were obtained chiefly from Amboyna.

Pepper Cultivation.—Black and white pepper grow on the same vine; the green pepper-berries, just before maturity, after gathering, turn black and make "black pepper," while "white pepper" is obtained by gathering the berries—fire-red in colour—when fully ripe, and through long soaking in water and subsequent stirring and shaking, relieving the berries of the outer skin; after which, on being dried, they become "white." In what country the pepper-vine originated, the writer is unable to say; but Eastern history shows that the northern half of Sumatra, the once mighty old sultanate of Acheen, when the Portuguese, Dutch and British (in rotation) came to that country, was far famed for that spice, which drew, at Acheen Busar, in North Sumatra (near the entrance of the Straits of Malacca), the native traders from many Eastern countries and islands, who there exchanged the products of their countries or purchased for cash. After the British East India Company, during the last century, acquired the island of Penang from the Rajah of Quedah, a Siamese souzerain, so favourably situated for commercial purposes, and made it a very important factory and place of residence for a sub-governor, the great Acheen trade gradually drifted to Pulo-Penang (Prince of Wales Islands), and with it the pepper trade principally. At that time Singapore had not been acquired by the British, and not before 1819, when the island was covered with a dense trackless jungle. After the acquisition of Penang the natives on the peninsula of Malacca, especially in the province of Frang, a Siamese souzerain province, commenced to plant pepper, and with excellent success; and now it is extensively planted by Malays and Chinese in many places on the peninsula of Malacca, also in Siam, Cochin-China, and in Sarawak, Borneo. That grown in the southern part of the peninsula and on the island of Singapore, known in the market as "Singapore pepper," is by far the best, commanding a higher price than Acheen pepper. Penang maintained the Acheen pepper trade until the Dutch commenced their war of conquest in Acheen in 1873, blockading the coast and preventing the exports of all Acheenese products. At that time, owing to the spread of wild rumours about the destruction of the pepper gardens in Acheen, etc., pepper reached the figure of 14 dollars per cwt., for a short time. It was feared, the supplies from Acheen being cut off, that the spice would become scarce, and as a consequence many Chinese planters increased its cultivation; in fact, to such extent that the Acheen war was no longer looked upon as the cause of influence in prices. Later some of the chiefs of certain Acheenese provinces having submitted to Dutch rule, were allowed to send pepper to Penang on vessels having a permit from the Dutch Consul in Penang to supply them with rice and other needed goods. Then it appeared that some of the Rajahs who had submitted to the Dutch, after having been pretty well supplied with the necessaries of life, turned truant again, and, as a consequence, their coasts were again blockaded. The Dutch are now making efforts to make "Ole-Seh," the old port of Acheen Busar, in fact well protected by a fort and man-of-war, a trading port, and to export "Acheen pepper from Acheen" themselves. As to the pepper-vine it presents a very handsome appearance; a pepper garden at a distance looks like a "hop-yard." Some planters, however, trellis the vine, and the writer thinks that is the best plan. It grows everywhere round about Singapore very easily and luxuriantly on fair upland soil, not liking low heavy soil, and, like the grape-vine, needs occasional pruning, weeding and fertilizing. With a little care and attention it yields abundantly and proves a good source of income. The quantity of pepper exported annually from the Malay peninsula and ports in Dutch India is simply immense, and is almost exclusively planted, gathered, and brought to market by natives, Malays and Chinamen chiefly.

Nutmegs and Mace.—Nutmegs and mace belong together, the latter being the inner covering of the nut. This most interesting, and, in its natural fresh state, lovely spice, seems to be an especial favourite with the American people, since the export thereof, of the nut especially, to the United States, exceeds that to all Europe combined. The home of the nutmeg in reality is New Guinea (Papua), where it grows wild, and it is possible that in times past (and now) the famous and daring Bugistraders, who alone obtained the most noted products, by way of barter with the extremely barbarous and hostile inhabitants, brought away certain quantities thereof. The most reliable place of production of obtaining them, agreeably with the demands of the market, has ever been the island of Banda and probably other islands, among or near the Moluccas, while the island of Penang and the Straits Settlements furnished also their quota, the quantity increasing gradually. The nutmeg thrives well, also, with a little care, on certain parts of the peninsula, and if the Colonial Government had given hitherto a little more fostering care to its cultivation, a much larger quantity might have been produced. In Deli, Sumatra, nearly opposite Penang, where the tobacco planters labour under the idea that their rich soil, after having produced one crop of tobacco will not produce a second sufficiently good to pay, and that the land must lie fallow for six years (grow up in jungle again), some of them a few years ago became happily possessed of the idea whether during those six long years the tobacco lands might not possibly produce something else "that would pay," and a few of these intelligent tropical husbandmen concluded to plant nutmegs. Six good coolies, at 20 cents wages per day each, with a hand cart, could soon plant a large piece of fallow tobacco land in nutmegs. In the meantime, the tobacco planters, who looked upon this as an experiment that would not cost them much, and paying little attention to it, went on tobacco planting, looking upon that as their object and actual source of profit, as it takes about five years until the nutmeg trees commenced to bear. Some of the planters had crops of fine nutmegs to send to market at the end of that time, in addition to all the tobacco they produced and shipped during the same period. The nutmegs being good and large could enter the market as "Penang nutmegs"—an innocent, cheap enterprise that turned out well, the nutmegs being worth about 70 dollars per picul, unselected, and mace, if slowly and neatly dried, not scorched, about from 40 dollars to 50 dollars per picul. It takes 110 fair-sized nutmegs to make one pound (1 picul = $133\frac{1}{3}$ pounds at 80 dollars) worth 60 cents; and since a good full-grown nutmeg tree in full bearing can produce several bushels of nuts with the hulls on, it can be easily seen that the "experiment" turned out well. Such of the planters as had their wits about them, the price of Deli tobacco having fallen during the last two or three years nearly 50 per cent. against former years, and yielding little or no profit at the present time, can now stop tobacco planting and find old tobacco prices in their nutmeg groves until the price of tobacco rises again. The number of the "successful," however, is not large; but will, after such a demonstration, become larger, it is supposed. The nutmeg tree will grow well on the coast of Borneo and adjacent islands, as well as in the Malayan States on the peninsula, under British and Siamese rule; and, as we have very advantageous treaties with both countries, the United States buying more nutmegs than the whole of Europe taken together, some of our enterprising young men might perhaps spend some time profitably in reflecting upon this.

ARALIA SPINOSA.*

BY JOSIAH KIRBY LILLY, PH.G.

Noticing the great differences in the results of former investigations of aralia bark, the writer performed a series of experiments, in hopes of determining the nature of the principles to which the drug owes its slightly aromatic odour, bitterish and acrid taste.

The odour of the bark proved to be due to a volatile oil, present in very minute quantity. By distilling 8 ounces of the ground drug with water a few yellowish-green globules of the oil were separated. It possessed an aromatic, somewhat camphoraceous odour, and gave with litmus an acid reaction.

On continuing the distillation, with the addition of solution of potassa, no other volatile principles were observed.

The bitter taste resides in an amorphous, extract-like mass, soluble in ether, alcohol and water, insoluble in petroleum benzin, and not precipitated by neutral or subacetate of lead. The process by which it was obtained is as follows:—The drug was exhausted with alcohol, this removed by distillation until the residue assumed the consistence of syrup; this residue was then precipitated in water, the resinous precipitate separated by filtering, and the filtrate evaporated to a soft extract, which was treated repeatedly with stronger ether. The ether solution on being allowed to evaporate spontaneously left a yellow mass, which, when dissolved in water and allowed to stand, separated crystals; the mother-water from the crystals, upon being evaporated, yielded the bitter mass already described.

It was also separated from an extract, resulting from the evaporation of a decoction, by treating it with stronger ether, and proceeding with this ether solution as with the one above.

The crystals that were separated from the bitter principle possessed a taste which was at first saline, then developing a slight astringency; they were freely soluble in ether and alcohol, less so in water, and were entirely volatilized at a red heat.

The acrid principle is a resin, which I obtained in the form of a grey powder, possessing a strong and persistently acrid taste, insoluble in ether, soluble in alcohol. It is the resin remaining after treating with stronger ether the resinous precipitate yielded by the alcoholic extract in water.

The portion of this resinous precipitate which was soluble in ether consisted of a tasteless resin and much green colouring matter, undoubtedly chlorophyll.

In distilling for volatile oil, preparing decoctions, infusions, etc., much trouble was experienced through the formation of a dense and persistent froth. Steps were taken to separate this saponaceous principle with the result of obtaining it in the form of a nearly white powder, inodorous, possessing a slightly acrid taste, freely soluble in water and dilute alcohol, almost insoluble in alcohol, and entirely insoluble in ether and chloroform. A process by which it was isolated is as follows:—The extract procured by evaporating a cold infusion was treated with stronger ether to remove the bitter principle, and the residue thoroughly washed with dilute alcohol; this solution was evaporated to an extract and dissolved in water. The aqueous solution yielded with a solution of lead acetate a scanty precipitate, which was separated by filtration. The filtrate gave with solution of subacetate of lead a copious precipitate, which was collected, well washed, the lead removed by suspending in water and passing hydrosulphuric acid through the solution, and the filtrate evaporated. The product of this evaporation proved to be this saponin-like substance; it was much improved in colour by dissolving in a small quantity of hot alcohol, from which it reprecipitated upon cooling, the alcohol holding much of the coloring matter in solution. This principle may also be obtained by exhausting the ground drug with boiling alcohol, from which it separates upon cooling. On boiling this body in a very dilute solution of hydrochloric acid it proved to be a glucoside, yielding glucose and an insoluble white substance.

To this principle I think the name "araliin" could be very properly applied. The araliin of Holden (*Am. Journ. Pharm.*, August, 1880) is described as "a yellowish substance in scale, foaming excessively upon agitation," and is very probably this substance incorporated with some foreign matter.

The alkaloid announced by Elkin (*Am. Journ. Pharm.*, August, 1880) as existing in aralia bark could not be found. No precipitates were formed when Mayer's test, or a solution of iodine in iodide of potassium, was added to an acidulated infusion or decoction, nor to the solution resulting after treating an alcoholic extract with acidulated water.

No reactions were given indicating the presence of tannin. A green colour was produced by ferric chloride, but a solution of gelatin caused no precipitate with a somewhat concentrated decoction. Glucose was indicated by Trommer's and Fehling's tests, as was starch by iodine. Milk of lime precipitated pectin from an acid decoction. Albumen was not coagulated upon boiling a cold infusion.

* From the *American Journal of Pharmacy*, September, 1882.

THE LACQUER INDUSTRY OF JAPAN

BY JOHN J. QUIN,

Her Majesty's Acting Consul at Hakodate.

(*Continued from page* 268.)

Various Kinds of Lacquer and Mixtures used.

(*a.*) *For Plain Work.*

Ki-urushi (crude lacquer) is the generic name by which all lacquer obtained from the trunks of live trees is known. It forms the basis of nearly all the various mixtures used in making lacquer ware.

Seshime (branch lacquer).—This kind is obtained from the branches of the trees, as described above; but the yield is only about 1 per cent. in comparison with other lacquer. As, however, in working the proportion of nearly 90 per cent. is required, the lacquer manufacturers sell a mixture which is stated to be a compound of true branch lacquer, the best crude lacquer, *Ura-me* and *Tomê* lacquer, *funori* (seaweed jelly), and sweet potatoes grated fine, the whole coloured, as may be necessary, with soot. The proportions in which these materials are used cannot be ascertained, and, indeed, each manufacturer uses his own special mixture, but the extraneous additions are believed not to injure the quality of the whole.

True branch lacquer becomes extremely hard when once dry, but used alone will not dry under some twenty days, so that now, when time is an object, the pure sap is but little used. Previous to the Revolution of 1868, branch lacquer of a very superior quality, and which would dry quickly, was obtained by using the young shoots which sprouted yearly from the roots after the trees had been cut down. This kind was called *Ki-seshime* (crude branch lacquer), and was made under directions from the Government, who received it as taxes; but the practice has been discontinued of late. The price of pure branch lacquer is, owing to the difficulty in drying, only 70 per cent. of ordinary good lacquer.

Rō-urushi (black lacquer).—This is made by adding to crude or branch lacquer about 5 per cent. of the tooth-dye used by women (*Haguro*), a liquor formed by boiling iron filings in rice vinegar, and exposing it to the sun for several days, stirring the mixture frequently till it becomes a deep black.

In preparing all lacquer, from the crude lacquer to the various mixtures, the principal object is to get rid of the water that exudes from the tree with the sap. To effect this, it is exposed in broad flat wooden dishes, and stirred in the sun. This, however, alone will not cause the original water to evaporate, so from time to time—ordinarily about three times in the day—a small portion of clean water is stirred in, say 1 per cent. each time, for a couple or three days, according to the heat of the sun. All the water then evaporates together. No lacquer will dry until this process has been gone through. If the lacquer is old, *i.e.*, has been tapped a long time before using, it is much more difficult to dry. In such cases a portion of fresh lacquer is added to the old by the wholesale dealers, or else the manufacturers, instead of water, sometimes mix *saké* (rice beer) or alcohol to "quicken" it.

A very remarkable property of lacquer should be mentioned. If crude lacquer, which is originally of the colour and consistency of cream, is exposed to the sun for a few days without adding water, it loses its creamy colour, and becomes quite black, or nearly so, but also becomes thinner and transparent, or rather translucent, as can be seen when it is smeared on a white board. It will not now, however, dry if appplied to an article, even if kept a month or more in the damp press. But if water is mixed with the lacquer which has thus been exposed and become black, it at once loses the black colour and its transparency, and becomes again of a creamy colour, though slightly darker, as if some coffee had been added, than at first. After evaporating this water, it can then be used like any ordinary lacquer, either alone or in mixtures, and will dry in the damp press, during which process it again turns black. What lacquer workers have found their greatest stumbling-block is the difficulty of obtaining a clear transparent varnish. What is called transparent varnish is really black to the eye, and requires grinding and polishing after application before it presents a brilliant surface, becoming also much lighter after a little time. It would be a new era in the manufacture of lacquer ware if a method could be discovered of rendering the lacquer varnish perfectly clear and light coloured when so desired, without depriving it of its drying qualities, and also if colours could be used with it other than those hereafter mentioned.

Nakanuri-urushi (middle painting varnish).—This is merely the crude lacquer. After having been exposed for some time to the sun to darken it and to get rid of all water, it is used for under coats in making first-class lacquer ware.

Nuritate-urushi (finishing lacquer).—This is a mixture of crude lacquer and a little terpentine with *Tō-midzu* (whetstone water)—being the mixture obtained from whetstones on which blades have been sharpened. In it there is some 7 to 8 per cent. of iron, and after mixing, the whole is exposed to the sun, both for the purpose of getting rid of all the water and to darken the colour. This is used for final coats of cheap lacquer, which is not polished afterwards.

Jō-hana-urushi.—This is a mixture of the above kind. with oil obtained from the *Ye* plant (*Perilla ocymoides*), This is used for still more common kinds requiring no after polishing, and the lacquer does not present a hard surface.

Jō-chiu, called in Kioto *Chiu-hana; Jō-tame*, called in Kioto *Ge-hana.*

These contain more and more oil, and are used for the commonest articles, such as for varnishing clogs, clothes baskets, etc. These three last kinds give a high polish, but the lacquer does not last.

Shu-urushi (vermilion lacquer).—This is the best crude or transparent varnish mixed with *Ye* oil (*Perilla ocymoides*), sometimes as much as 50 per cent. being added. It is then exposed to the sun and water added, which is afterwards evaporated. This kind is only used for red (whence its name) and coloured lacquers, the colours being added at the time of application. It requires no after polishing.

(*b.*) *For Lacquering with Gold.*

Nashiji-urushi (pear basis lacquer), or *Suki-urushi* (transparent lacquer).—The first name is that best known in the trade, as indicating that it is required for using over gold, silver or tin powdering. It consists of the finest crude lacquer obtained from old trees. As stated previously, the lacquer is allowed to stand till all dirt and foreign matter has sunk to the bottom, when the best is skimmed off, and after being exposed to the sun to evaporate the water in the usual manner, and carefully filtered, it is ready for use. Except when used for the highest class of gold powdering, a certain proportion of gamboge is mixed with the lacquer to give the dust a fine yellow colour.

N.B.—The above ten kinds are all bought by the lacquer workers ready prepared from the manufacturers. Any further mixtures used by them are made as required, colours added, etc.

Seshime-urushi (branch lacquer) and *Rō-urushi* are used also in making gold lacquer.

Yoshino-urushi.—This is crude lacquer from the district of Yoshino in the Province of Yamato. It dries quickly, and closely resembles transparent varnish. It is used when giving the final coats before polishing.

Yoshino-nobe-urushi (Yoshino spreading lacquer).—Same as above, with the addition of about one-third of camphor to render the lacquer thinner and more easy to spread.

Seshime-nobe-urushi (spreading branch lacquer).—This is merely branch lacquer with the same proportion of camphor as above; when cheap work is required more camphor is used till the proportions are reversed. This renders the mixture very soft, and a small quantity can be spread over a large surface.

Shita-maki-urushi (under coat lacquer).—A mixture of branch lacquer and *Benigara* (red oxide of iron) in equal parts by weight.

Ke-uchi-urushi (inside line lacquer).—This is the same as above, but it is allowed to stand for about six months after mixing before it is used. By this time it has got thicker, and the very finest lines can be drawn without fear of their running, and they moreover stand out better.

Shita-maki-nobe-urushi (under coat spreading lacquer).—Same composition as above, with the addition of a little camphor to make the lacquer thin. It thus goes much farther, and causes a great saving when lacquering with powdered gold-leaf (*keshi-fun*), for which it is best suited. As in the other mixtures, the more camphor is used the thinner it renders the lacquer, and less gold is required.

Taka-maki-urushi (raised lacquer).—To make this a certain quantity of *Rō* or *Nuritate* is taken and divided into three parts. To one part is added lampblack and camphor in equal portions of bulk. These, after being well mixed, are boiled together; then the other two portions are added, and the whole stirred together, and afterwards filtered through paper. It is boiled more or less according to the season. In summer when lacquer dries quickly, it is boiled for a longer period, while in winter, or during cold weather, when lacquer naturally takes longer to dry, the mixture is boiled for a shorter time. The reason why *Takamaki* is thus purposely rendered soft is explained by the fact that otherwise the upper surface would harden at once, while the under portion (*Takamaki* being applied thickly) being excluded from the upper air, would not be able to dry, and later the top surface would crack and show fissures, whereas the introduction of camphor renders it soft and much slower to dry, and the whole has thus time to harden equally. Camphor being volatile is gradually lost, and the composition becomes quite hard.

Ro-se-urushi (a mixture of black and branch lacquer).—This is used for the lacquer coating upon which gold, silver, or tin powder is scattered, except in such cases when the grain of the wood is to be shown, when *nashiji* lacquer is used instead.

Kuma-urushi (shading lacquer).—A mixture of *Johana* lacquer and lampblack, used for final shading in the feathers of birds or animals, or for drawing hair, etc., on flat and raised gold lacquer.

It should be noted that whenever lampblack is mentioned as a mixture it is used for the superior kinds, wood or coal soot being used for inferior articles.

Implements and Materials used in the Manufacture of Plain Lacquered Ware.

Hera.—A spatula made of *Hinoki* (*Chamæcyparis obtusa*), used for applying the under or priming coats and for mixing the lacquer.

Haké.—A flat brush made from human hair, used for laying on the lacquer.

Kokuso.—Finely chopped hemp. Mixed with lacquer it is used for covering joints.

Nuno.—Hempen cloth, used for pasting over the wood to prevent it splitting and to strengthen corners, etc. For very fine work and small articles silk is used.

Ji-no-ko (burnt clay).—Afterwards reduced to a very fine powder. Pounded bricks are often used.

To-no-ko.—A fine kind of clay, which is procured from Mount Mari, near Kioto. This is likewise burnt, and reduced to a fine powder.

Sumi.—Charcoal made of *Hōnoki* (*Magnolia hypoleuca*), used for smoothing down the under coats; it has rather a rough grain. Also charcoal made from *Hiyakujikkō* (*Lagerstrœmia indica*). This is very soft and of a fine grain, and is used for the final smoothing before hand polishing. This kind is called by the trade *Rō-iro-sumi* (black coloured charcoal).

To-ishi.—Whetstones of four different qualities of fineness: *Ara-to* (rough), *shiro-to* (white), *awo-to* (green), and *nagura*, the last being the finest. These are used for smoothing down the priming coats.

Tsuno-ko (horn powder).—This is made of calcined deer's-horns, reduced to a fine powder, and is used for the final polishing with the finger.

To-kusa (*Equisetum*).—A kind of scouring rush, used for smoothing the lacquer.

Kaki-no-shibu (Persimmon juice).—This is used when no ground lacquer is required, as in the Aidzu lacquer, or when the grain of the wood is shown.

Nikawa (glue).—This is used to mix with the groundwork for cheap kinds of ware, instead of lacquer.

Yuyen-sumi (lampblack).—Used for groundwork of cheap articles, mixed with Persimmon juice. For still more common ware, soot of any kind is used.

Gofun (whiting).—Made from burning old shells, such as are obtained from the ancient kitchen middens; used for mixing with glue to make the groundwork of common lacquer.

Shō-no (camphor).—Used for mixing with lacquer, to make it thinner and spread more easily.

Hōchō (knife).—Used for scraping off all inequalities of the hempen cloth after it is pasted on the article, etc.

Yoshino-gami.—A very thin kind of paper, made at Yoshino; used for filtering the lacquer before using it.

Jō-ban.—A box with a very hard lacquered lid, usually containing drawers for the various pencils, etc. The lid is used for mixing the lacquer on while working.

Tsuno-ko-ban.—Board for mixing and powdering the deer's horn ashes before using: generally made of cherry wood or oak.

Muro.—A cave or cellar underground is used, where practicable; otherwise, an air-tight case, made of wood, with rough unplaned planks inside. These are thoroughly wetted before the lacquered article is put in to dry, which occupies a period varying from six to fifty hours, according to the time of the year or style of the lacquer. Lacquer will not dry or harden properly in the open air; it absolutely requires a damp closed atmosphere to do so, otherwise it would run and always remain sticky.

The following are mixtures made by the workman as required:—

Kokuso.—A mixture of finely chopped hemp, with rice starch and branch lacquer sufficient to make a thick paste.

Jino-ko (No. 1).—Powdered burnt clay and branch lacquer, mixed together in the proportion of 1 part of clay to 2 parts of lacquer.

Jino-ko (No. 2).—The same, mixed in the proportion of 10 parts of clay to 13 of lacquer, and a little water.

Jino-ko (No. 3).—The same, mixed in the proportion of 10 parts of clay to 8 parts of lacquer and 2 parts of thin rice starch. This mixture is known in the trade as *Han-dan-ji* (half-step basis).

Jino-ko (No. 4).—The burnt clay powder mixed with liquid glue only in such proportions as will resemble the consistency of lacquer.

Kiri-ko.—A mixture of *Jino-ko* and *Tōno-ko* in equal portions with 1½ of branch lacquer. This becomes very hard.

Sabi.—A mixture of 2 parts of the burnt clay from Mount Mari to 1½ of branch lacquer, with just sufficient water to mix the clay into a paste.

An inferior class of *Sabi* is made by putting in less lacquer—as little as 8 parts of lacquer being used to 20 parts of the clay. Less lacquer cannot be used, as it would not stand polishing after having been dried.

Mugi-urushi.—Wheat lacquer; being a portion of wheaten flour mixed with branch lacquer to such consistency as may be required. It is used to paste the hempen cloth on to the wood.

Shin.—A mixture of rice flour with branch lacquer, used for the same purpose as wheat lacquer. Wheaten flour is the best, but being more difficult to blend with lacquer it is not so much used.

Ka-no-ji.—A mixture of whiting and liquid glue, used for under coats or cheap articles.

Shibu-ji.—A mixture of lampblack and Persimmon juice, used for under coats in inferior ware.

The following are the modes of applying the lacquer:

(*a.*) *Honji* (real basis). The article to be lacquered is first carefully smoothed, and the wood is slightly hollowed away along each joint, so as to form a circular depression. The surface of the whole article is then given a coating of branch lacquer (this is called *Ki-ji-gatame*—hardening the wooden basis), and the article set to dry in the damp press, or *Muro*, for about twelve hours. The hollowed portions are filled with prepared *Kokuso*, which is well rubbed in with a spatula made of the wood of the *Chamæcyparis obtusa*, and the article is enclosed in the drying press for a period of at least forty hours. Over the *Kokuso* a coating of *Sabi* is applied, and set to dry for twelve hours. The next process is to smooth off with a white whetstone any roughness or inequalities of the *Kokuso* and *Sabi*. The article is then given a coating of wheaten lacquer, over which is stretched hempen cloth, great care being taken to spread it smoothly and leave no wrinkles or perceptible joinings, and it is then again enclosed in the drying press for about twenty-four hours. After taking the article out of the press all inequalities in the cloth—which has now under the influence of the lacquer become harder than wood—are smoothed down with a knife or with a plane. Next, a coating of *Sabi* is applied with the spatula, to hide the texture of the hempen cloth, and the article is again put in the press for twenty-four hours. Next, a coating is given of No. 1, *Jino-ko*, applied with the spatula, after which the article is enclosed in the drying press for twenty-four hours, and this process repeated. Next, the article is given a coating of *Kiriko*, likewise applied with the spatula, and the drying process is repeated for twenty-four hours; there is then a repetition of the same process, after which the article is set to dry for at least three days. The surface is next ground smooth with a fine white whetstone, and a hardening coat of branch lacquer is given with a spatula, and set to dry for twenty-four hours. A fresh coat of *Sabi* is applied with the spatula, and the article is put to dry in the press for twenty-four hours. When thoroughly hardened the surface is ground smooth with a white whetstone, as before. Next, a thin coating of branch laquer is applied with the spatula, and the article is set to dry in the press for twelve hours. A coating of *Naka-nuri* is then applied with a flat brush (*Haké*), and the article set to dry again for twenty-four hours. On being taken out the surface is ground smooth with charcoal made from *Hōnoki* (*Magnolia hypoleuca*). A thin coating of branch lacquer is given with cotton wool—old wool being chosen because less likely to leave hairs behind it—and rubbed off again with soft paper, after which the article is set to dry for twelve hours. A coating of *Rō* (black lacquer) is then applied, and the article is set to dry for twenty-four hours. The surface is rubbed smooth with a piece of charcoal made from *Hiyakujikko* (*Lagerstrœmia indica*). The surface is partly polished with finely-powdered *Lagerstrœmia* charcoal, applied with a cotton cloth. A coating of *Rō* is applied very thinly with cotton wool, and this is rubbed off again with soft paper, after which the article is enclosed in the drying press for twenty-four hours. The surface is now polished with an equal mixture of powdered burnt clay from Mount Mari (*To-no-ko*) and calcined deer's-horn ashes, applied with a cotton cloth and a little oil (made from *Sesamum orientale*), till a fine polish is obtained. A coating of branch lacquer is next given, applied with cotton wool very thinly, and the article is enclosed in the drying press for twelve hours. The workman dips his finger in oil and rubs a small quantity of it over the surface, which he then polishes with deer's-horn ashes, applied with a cotton cloth, till a bright surface is obtained. A coating of branch lacquer is applied thinly with cotton wool, wiped off with soft paper, and set to dry for twelve hours. Oil is again applied, and then a final polishing with deer's-horn ashes given with the finger to the surface, which now assumes the most brilliant polish of which it is capable.

For articles that are liable to get rubbed, such as scabbards, these last two processes are repeated seven or eight times, the surface getting harder at each repetition, but this is not necessary for other articles even of the best quality. In describing the above processes the *minimum* time for drying has in each case been given, but for the first twenty-five processes the longer the article is kept in the press the better. From the twenty-eighth process to the finish it is better not to greatly exceed the times mentioned.

(*b.*) *Kata-ji* (hard basis); (*c.*) *Handan-ji* (half-step basis); and (*d.*) *Manzo* (after a lacquer worker of that name), modifications of the first process.

(*e.*) *Ka-no-ji* (inferior basis). In this class the joints of the article to be lacquered are frequently not hollowed away, a strip of paper being merely pasted over them, and even this precaution being often omitted. A coating of *Ka-no-ji* (whiting and glue) is applied with a spatula twice or thrice, and dried in the sun. The article is then wiped over with a wet brush and rubbed smooth with a white whetstone, and afterwards given an extra smoothing with the spatula. Sometimes a thin coating of *Nakanuri* or of branch lacquer is given to the article, but more frequently a coating of glue and lampblack, or of glue and soot mixed together, is applied. A final coating of either *Jō-hana* or *Jōchiu* finishes the process without any subsequent polishing.

(*f.*) *Shibu-ji* (*Persimmon*)—(juice basis). The joints of the article are prepared in the same manner as for (*e*), but, instead of *Ka-no-ji*, four or five coats of *Shibu-ji* (Persimmon juice and lampblack) are applied with a brush; these dry very rapidly and the last coating is smoothed with *To-kusa* (*Equisetum*). A final coating of either *Jō-hana* or *Jō-chiu* is given. This kind of article is chiefly made in Aidzu, and, indeed, goes by the name of "Aidzu Ware." It has not such a good appearance as *Ka-no-ji*, for the grain of the wood is easily traceable under the lacquer, but being made without glue, it stands water much better, and is in general request for rice bowls and *zen* (small dinner trays with legs, one of which is set before each guest).

(*g.*) *Sabi-Sabi* (double Sabi). In this class of goods the joints are generally hollowed out, and a basis-hardening coat of branch lacquer given. Paper is also pasted over the work after filling in the joints with *Koku-so*. Three coats of inferior *Sabi* are then applied, and after drying for about twelve hours in the press, the article is ground smooth with a white whetstone. Next comes a coating of branch lacquer, applied with cotton wool, and then one of *Nakanuri*, which is ground smooth with *Magnolia* charcoal. Another coating of branch lacquer is followed by one of *Jō-hana* or *Jō-chiu*, and the article is finished without further polishing. Drying in the damp press is requisite between each process for this class of lacquer. It is manufactured only in Tôkiô, though the processes for the under coats of *Wakasa* lacquer are identical. Rice bowels, drinking cups, and luncheon boxes, etc., are the usual articles manufactured. In this, as in Aidzu ware, the grain of the wood is traceable, and its common appearance constitutes the reason for classing it so low, but in actual excellence and durability it ought to rank fourth next to *Handan-ji*.

(*h.*) *Kaki-awase* (mixture), or *Kuro-shunkei* (black Shunkei), from the name of its inventors. In this class of goods the wood is given a basis-hardening coat of branch lacquer mixed with lamblack, over which is laid a final single application of *Jō-hana* or *Jō-chiu*. This ware is made at Tôkiô, and is used for cheap rice bowls and boxes. For the commonest kind of work a mixture of glue and lampblack or Persimmon juice and lampblack is used, instead of branch lacquer, as a ground coat.

(*i.*) *Aka-shunkei* (red Shunkei).—This kind also derives its name from the inventor. For making articles of this class, which show the natural grain of the wood, a mixture of *Yoshino* lacquer and gamboge is rubbed on with a hard brush, after which they are inclosed for a day in the press to dry, and then a coating of *Shu-urushi* (transparent lacquer, containing a proportion of *Perilla ocymoides* oil) is applied. When dry it presents a polished surface, and it appears dark when at first finished, but in a few months becomes much lighter. A cheaper quality of *Shunkei* is made by using glue and gamboge or Persimmon juice and oxide of iron for the under coat, but though the colour has a better appearance at first, it gradually deteriorates. The best is made in the Province of Dewa, at Akita. For the most part soft woods are used in making this ware.

(*j.*) *Kiji-ro* (colour of the grain of wood). Well seasoned wood is selected, and the article having been carefully smoothed, a thin coating of *Yoshino* lacquer is applied with a brush, after which it is set to dry in the press for twelve hours. A coating of best *Sabi* is then applied with the spatula, and set to dry in the press as usual. This is ground completely away with a green whetstone. A coating of *Nashiji* (pure transparent lacquer) is now given, and the article is inclosed in the press for twenty-four hours. It is again ground with a green whetstone till no remains of the lacquer coating are apparent. Then follows a second coat of transparent lacquer, which, after drying as before, is ground smooth with a piece of *Hiyakujikko* (*Lagerstrœmia indica*) charcoal. Transparent lacquer is again applied with a piece of cotton wool, and wiped off with soft paper, and the article is set to dry for twelve hours. Afterwards it is given a primary polish with an equal mixture of *To-no-ko* and deer's-horn ashes applied with a cotton cloth and a little oil. Next, a coating of *Yoshino* lacquer is applied with cotton wool, wiped off with paper, and set to dry as before. At this stage only deer's-horn ashes, with a trifle of oil, are used for polishing. This process is repeated three times, and results in an exceedingly brilliant polish. Only hard woods are used for this kind of ware.

(*k*.) *Red and Coloured Lacquers*. For making best red and other coloured lacquers the first twenty-two processes are the same as in *Honji* (*a*). Next a mixture of *Nashiji* (pure transparent lacquer) and vermilion, or the colour desired, is given to the article, which is thereupon set to dry. The remainder of the processes are identical with (*a*), except that *Yoshino* lacquer is substituted for "branch lacquer," and transparent varnish is used instead of *Rō* (black lacquer). For extra high-class work, instead of the thin coating of lacquer which is wiped off again, a thick coating of transparent varnish is given, applied with a brush, and set to dry for about thirty-five hours, the remaining processes remaining unchanged. For second-rate articles the colour is mixed with *Shu-urushi* (transparent lacquer containing oil), and no after polishing takes place. The article presents a brilliant surface, and the colour is better and brighter than in the best kind, but the surface much less hard. Many processes are omitted for cheaper articles, as is the case in black lacquer, and less lacquer and more oil is used.

(*To be continued.*)

SELECTIONS FROM THE NON-OFFICIAL FORMULARY OF THE DUTCH SOCIETY FOR THE ADVANCEMENT OF PHARMACY.*

(*Continued from page* 186.)

TINCTURA KAMALÆ (*Tincture of Kamala*).

Kamala	3
Stronger alcohol	8

Macerate during three days, and filter.

TINCTURA GUARANÆ (*Tincture of Guarana*).

Extract of guarana	1
Alcohol	16

Dissolve the extract in the alcohol, and, if necessary, filter.

EXTRACTUM GUARANÆ (*Extract of Guarana*).

Guarana	1
Stronger alcohol	3
Water	q.s.

Mix the guarana with 2 parts of the alcohol and 3 parts of water, and let it stand three days, occasionally shaking. Then express and treat the residue with a mixture of 1 part of the alcohol and 2 parts of water. Let stand during one day, express, unite, and filter the strained liquids, and evaporate them, on a water-bath, to a thick extract.

TINCTURA PUCHURY (*Tincture of Puchury*).

Puchury beans (from *Nectandra Puchury*, Nees), in coarse powder	1
Stronger alcohol	8

Macerate during seven days, express and filter.

TINCTURA PYRETHRI COMPOSITA (*Compound Tincture of Pellitory*).

Walker's Toothache Tincture.

(Commonly called, in Dutch, "woordhoulder" = "word-keeper.")

Pellitory root (*Anacyclus Pyrethrum*), finely cut	1
Guaiac resin, in powder	4
Stronger alcohol	24

Macerate during seven days, express and filter.

* From *New Remedies*, August, 1882.

TRIMETHYLAMINA (*Trimethylamine*).

(Propylamine, improperly so called.)

A liquid obtained from herring-brine [or, more abundantly, from beet-root molasses.—ED. N. R.], containing 20 per cent. of pure trimethylamine. It is a clear, colourless liquid, of an alkaline reaction, the specific gravity 1·124, and having a peculiar odour, recalling that of ammonia and herring brine. It is miscible with water and alcohol in all proportions.

One part of hydrochloric acid of specific gravity 1·170 should neutralize 3 parts of trimethylamine. The salt, obtained by evaporating this solution, should be completely soluble in absolute alcohol.

TROCHISCI IODOFORMI (*Troches of Iodoform*).

	Grams.
Iodoform	50
Sugar, in powder	1000
Oil of peppermint	1·5
Tragacanth, powdered	2·5
Glycerin	10
Water	q.s.

Mix the first four ingredients with the glycerin and enough water to form a mass, and divide this into 1000 troches.

Each troche contains 0·05 gm. or nearly $\frac{3}{4}$ of a grain of iodoform.

TROCHISCI CETRARIÆ (*Troches of Iceland Moss*).

Iceland moss sugar (see vol. xii., p. 827)	q.s.
Orange-flower water	q.s.

Make troches, weighing 1 gm. (15½ grains) each. Dry them, and keep them in a stopped bottle.

UNGUENTUM LENIENS (*Cold Cream*).

(Unguentum Aquæ Rosæ.)

Olive oil	360
White wax	36
Spermaceti	60
Rose water	120
Tincture of benzoin	24
Oil of rose	1

Melt the first three ingredients together on a water-bath, allow the mixture to become nearly cold, then add to it, under constant stirring, the other three ingredients.

UNGUENTUM ARGENTI NITRATIS COMPOSITUM (*Compound Nitrate of Silver Ointment*).

(Unguentum Nigrum.)

Nitrate of silver	1
Oxide of zinc	3
Balsam of Peru	3
Lard (unsalted)	24

Dissolve the nitrate of silver in a few drops of distilled water and mix the solution with 12 parts of suet. Then, having mixed the oxide of zinc with the remainder of the suet, incorporate it with the first prepared mixture, and finally add the balsam of Peru.

UNGUENTUM OPHTHALMICUM COMPOSITUM (*St. Yves' Compound Eye Salve*).

Red oxide of mercury	15
Oxide of zinc	6
Camphor	5
Oil of almonds	10
Lard	140
Yellow wax	24

Mix the oxides and the camphor intimately with the oil of almonds, then incorporate with the lard and wax previously melted together and allowed to cool.

VASELINUM (*Vaseline*).

Vaseline is a product obtained from the residue left after the distillation of petroleum.

American Vaseline is a semi-transparent, orange-yellow, odourless and tasteless mass, melting at 32°–33° C. (89·6°–91·4° F.), and having the spec. grav. 0·860. It is insoluble in water, very little soluble in cold or boiling alcohol, but is easily soluble in ether, chloroform, benzol, fixed or volatile oils.

When heated in an atmosphere of oxygen, it absorbs much of this gas, acquiring a sharp odour, and yielding, when dissolved in ether, a solution having an acid reaction.

Austrian Vaseline is almost identical, in properties, with American vaseline.

Virginia Vaseline is a greenish-yellow, odourless and tasteless mass, melting at 40°–41° C. (104°–105·8° F.), having the spec. grav. 0·900, and a denser consistence than American vaseline. Towards ether, water, benzol, etc., it behaves like the American. In strong alcohol it is somewhat more soluble.

This variety of vaseline absorbs but little oxygen, when heated in an atmosphere of the gas. Its odour is scarcely affected thereby, and if shaken, after cooling, with ether, it yields a liquid of not more than a faintly acid reaction.

Vinum Amarum Alkalisatum (*Alkaline Bitter Wine*).

(Elixir Aurantiorum Compositum.)

Tincture of orange peel (1 of orange p. and 6 alcohol	2
Carbonate of potassium	1
Sherry wine	46
Extract of gentian	1
„ centaury (lesser)	1
„ wormwood	1
„ Carduus Benedictus	1

Dissolve the carbonate of potassium in the sherry wine; add the extracts, and let the mixture stand for one day, occasionally agitating. Finally add the tincture of orange peel.

Vinum Amarum cum Spiritu (*Bitter Wine with Alcohol*).

Gentian, finely cut	4
Red bark (Indian or Javanese), in coarse powder	8
Orange peel, deprived of the white layer, and finely cut	1
Canella, in coarse powder	1
Alcohol	30
Sherry wine	200

Macerate the solids with the alcohol for twenty-four hours, then add the sherry, macerate for four days, strain, express, and filter.

Vinum Camphoratum (*Camphor Wine*).

Camphor, in powder	1
Acacia, in powder	1
White wine	44
Stronger alcohol	4

Mix them. It forms a white, turbid liquid.

Vinum Cinchonæ (*Wine of Cinchona*).

(Laroche's Cinchona Wine.)

Red bark (Javanese or Indian) containing at least 6 per cent. of alkaloid, and powdered	1
Stronger alcohol	4
Sherry wine	20
Sugar	16
Water	q.s.

Macerate the red bark with twenty parts of water, for half an hour, then strain, transfer the residue to a displacement apparatus, and pour upon it the sherry wine. Allow the percolate to pass slowly, and, when the wine has disappeared from the surface, follow it by a mixture of four parts of stronger alcohol and six parts of water. Finally percolate with water until the volume of the whole liquid amounts to fifty parts. Let this stand for a few weeks until it has completely settled, then dissolve in it the sugar, and filter.

Vinum Cinchonæ Ferratum (*Wine of Cinchona and Iron*).

(Laroche's Ferrated Wine of Iron.)

Pyrophosphate of iron (soluble)	2
Citric acid	1
Water	3
Wine of cinchona	200

Dissolve the pyrophosphate of iron and the citric acid in the water, add the wine of cinchona, and filter, if necessary.

Vinum Quineti (*Wine of Quinetum*).

Quinetum	1
Stronger alcohol	20
Sherry wine	180

Dissolve the quinetum in the alcohol and add the wine.

Vinum Pepsini (*Wine of Pepsin*).

Mucuous membrane of the stomach of the hog (or of the fourth stomach of the calf or ox) scraped off with a bone knife	20
Glycerin	10
Water	10
White wine	200
Hydrochloric acid	1

Mix the mucous membrane with the glycerin and water, and then add the wine and acid. Shake the mixture well, macerate it for three days at 20° C. (68° F.), occasionally shaking, and filter.

The product should be clear, of a yellowish colour, and should have a vinous, slightly acid taste.

Ten grams of the wine, when mixed with 10 gm. of distilled water and 24 drops of diluted hydrochloric acid, should dissolve 3·5 gm. of egg-albumen (coagulated at 80°–90° C. = 176°–194° F.), after being digested with it for ten hours at a temperature of 30° to 40° C. (86°–104° F.).

MORAVIAN RHUBARB.*

The culture of *Rheum compactum* in Moravia was commenced, in the beginning of the present century, by Prikryl, apothecary in Austerlitz. Until about twenty-five or thirty years ago the root was largely exported to Lyons and Milan, where it was used for dyeing silk. With the use of chemicals for dyeing, the price of this rhubarb receded to about 10 florins per hundredweight, but more recently has advanced again, and is about 1 florin per pound for triennial roots. This rhubarb is again largely exported, chiefly to Russia, whence it is exported again as Asiatic rhubarb. Professor Dr. A. Vogl has pointed out histological differences by which this article may be distinguished from Chinese rhubarb; but a correspondent insists that even in this respect it will resemble the latter much more closely if permitted to remain in the ground for five or six years. The commercial article is said to yield extracts, tinctures and infusions, which, not only in colour, odour and taste, but likewise in activity, compare favourably with the corresponding preparations of Chinese rhubarb. The author urges the employment of this rhubarb, partly for patriotic reasons as far as Austria-Hungary is concerned, but chiefly on account of its low price and its good effects, these being fully secured if 5 parts of Moravian rhubarb be used in place of 4 parts of the Chinese root, as was pointed out already, in 1808, by Trommsdorff.

CHLORODYNE.†

Dr. John H. Gilman, of Lowell, Mass., gives the following formula for chlorodyne, in which the ingredients are so combined as to form a perfect solution, and which can be diluted with 10 parts of water without separation.

Chloroform	fl. oz.	2
Ether (stronger)	„	½
Alcohol ("95" per cent.)	„	8
Oil of peppermint	min.	24
Tincture of capsicum	fl. dr.	6
„ cardam., comp.	fl. oz.	2
Fl. ext. of licorice root	„	2
Diluted hydrocyanic acid	„	1
Glycerin	„	16
Sulphate of morphia	grains	40

Mix in the order quoted, and shake until dissolved. Dose: 10 to 30 drops.

The Pharmaceutical Journal.

SATURDAY, OCTOBER 14, 1882.

Communications for the Editorial department of the Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed* "*Pharm. Journ.*"

FREDERICK WÖHLER.

ON the last Wednesday in September there passed away at Göttingen, in his eighty-third year, one of the most illustrious chemists that the present century has yet seen, and one who in the length of his life seemed almost to form a connecting link with a time when the science of chemistry was, comparatively speaking, still in swaddling clothes. FREDERICK WÖHLER was born in the year 1800 in Frankfort-on-the-Maine. He first studied medicine and chemistry at Marburg and afterwards at Heidelberg, where upon the advice of GMELIN he gave up the idea of practising medicine and decided to devote himself to chemistry. In 1823 he went to Stockholm and became a pupil of BERZELIUS. Famous as was the master, WÖHLER was at that time his only scholar. As to the school, two common rooms with some simple accommodation, though without furnace, ventilation or water supply, constituted a not very pretentious laboratory; but WÖHLER had been preceded there by such men as MITSCHERLICH and HENRY and GUSTAVUS ROSE and was followed by MAGNUS. One long pine bench for the master and another for the pupil; some cases against the wall to hold reagents; a mercury trough, a glass-blowing table, a sink, and a pail used in common by the household servant, constituted the furniture of one room, and the balances and other apparatus that of the other, whilst the sand-bath was found in the kitchen. Such were the surroundings where the Swedish chemist did most of his famous work and where his German pupil learned to follow in his footsteps. Late in life WÖHLER loved to recall the memories of his earlier years, and some other interesting autobiographical details of his connection with BERZELIUS have already appeared in this Journal.*

In the first few years after WÖHLER'S return to Germany he obtained some minor posts; but in the year 1836 he succeeded STROMEYER as Professor of Chemistry in the University of Göttingen and Director of the Chemical Institute; and he was also appointed inspector-general of pharmacies in the Kingdom of Hanover. His university appointments he retained until his death; the inspectorship he eventually resigned, Dr. WIGGERS being chosen as his successor. But of greater importance even than his professorial work were the numerous memoirs, reporting the results of most important and diverse researches, with which he enriched chemical literature. No less than two hundred and sixty-eight communications of which he was the sole author are enumerated in the Royal Society's Catalogue, besides thirty or forty written in conjunction with such men as JUSTUS VON LIEBIG, HENRI STE.-CLAIRE DEVILLE and others. His first paper appeared in 1821 and was upon the occurrence of selenium in oil of vitriol prepared from a Bohemian mineral. Other papers followed pretty quickly, and in 1827 he announced that he had succeeded in isolating the metal aluminum by igniting the chloride in the presence of potassium. For thirty years this work appeared without adequate result, and it was DEVILLE'S successful researches upon the preparation of sodium and aluminum that first brought this metal within the reach of the manufacturer. M. DUMAS, at a recent meeting of the Academy of Sciences, speaking of the joint work of WÖHLER and DEVILLE, said, "United by a rivalry that would have caused division between less elevated minds, these two great chemists pursued in common their researches in mineral chemistry, utilized their respective labours to elucidate points still obscure in the history of boron, silicium and the platinum metals, and remained closely bound in a friendship which increased every year." WÖHLER'S early connection with BERZELIUS would appear to have influenced the direction of his work to a considerable extent, as is shown by his numerous papers on the isolation of elemental bodies—such as aluminum, glucinium, tungsten, boron, iridium, osmium, silicium, vanadium, etc.—and on various points of mineralogical chemistry.

But, perhaps, WÖHLER'S most famous communication was that upon the artificial formation of urea, published in 1828, in which he took up the position of pioneer in the synthesis of organic compounds. Before that time the apparently distinctive peculiarity of the compounds found in or eliminated from animal or vegetable organisms had given rise to the idea that their formation was due to some special agency, to which the term "vital force" was applied, and the chemistry of organic compounds was treated as a branch of chemical science distinct from the chemistry of inorganic compounds. But the discovery by WÖHLER, that the highly nitrogenous body, urea, could be produced by the molecular rearrangement of cyanate of ammonium made the first breach in this wall of partition, and when FOWNES subsequently showed that cyanogen could be formed by the direct combination of its elements, the steps in the passage from the simple inorganic substance to the "organic" compound were complete. Since that time many other compounds occurring in animal and plant organisms have been formed synthetically, but in the words of a competent judge, M. DUMAS, "la formation artificielle

* *Pharmaceutical Journal,* [3], vi., 65.

de l'urée reste encore l'exemple le plus net et le plus élégant de ce genre de créations."

Mention might be made of Wöhler's researches in conjunction with Liebig on the benzoic compounds and on the derivatives of uric acid, as well as a number of papers on essential oils; but it would be evidently impossible to attempt in these columns to analyse the subjects of all his memoirs, and enough has been said to give some indication of their importance. Before concluding, however, a few words must be devoted to another phase of his literary and scientific work. Many of his memoirs first saw the light in the famous *Annalen der Chemie und Pharmacie,* and of that journal he was one of the principal editors from the year 1838 until the time of his death. He was also the author of several larger works, such as 'Elements of Organic Chemistry' (1831), 'Examples in Mineral Analysis' (1840), and 'Practical Exercises in Chemical Analysis' (1853), and was co-editor of the 'Handworterbuch der Chemie.'

Notwithstanding his great age, Dr. Wöhler appears to have taken outdoor exercise within a week of his death, his final illness only lasting four days.

A DENTISTS' BILL FOR VICTORIA.

A Bill for the regulation of the practice of dentistry in Victoria has been introduced into the colonial legislature. Like the British Act it is based upon the reservation of the title of "dentist" to registered persons; but although providing for the registration of persons who have practised dentistry for three years continuously immediately before its passing it contains no provision for the registration of those who have *bonâ fide* practised it "in conjunction with the practice of medicine, surgery and pharmacy," similar to that which was introduced into the British Act at the instance of the Council of the Pharmaceutical Society and has been found so useful. The Victoria pharmacists are, however, alive to the importance of the omission.

A LARGE DOSE OF EXTRACT OF MALE FERN.

The *Ceylon Observer* reports an interesting case in which a death, following the administration of an unusually large dose of liquid extract of male fern, has been the subject of a magisterial inquiry. It appears that the deceased had been for some time under treatment for tape worm, and had urged his medical adviser to relieve him as quickly as possible, so as not to interfere with his business arrangements. The prescription given, which appears in the exhibits of the case, was as follows :—

℞ Ext. Æth. Filic. Mas.		1½ oz.
Pulv. Kamalæ		3 drms.
Pulv. Granati Rad.		3 drms.
Mucil. Acac.,		
Syrup. Simp.		q. s.
Aquæ Cinnam.	ad	4 oz.

Fl. Half to be taken at bedtime and half at 2 a.m.

The dispenser left out the pomegranate root, signifying that he done so to the prescriber. After taking the first dose the patient was so distressed that he sent to the prescriber to know whether he should take the remainder and received an answer in the affirmative. He did so and the worm was expelled, but the patient became worse with vomiting and purging and died in a few hours. A certificate of death from choleraic diarrhœa was given; but in consequence of the circumstances a *post-mortem* examination of the body was made, and as a result the doctor was charged with "homicide by imprudence." The prescription as actually dispensed closely resembles one attributed in Naphey's 'Medical Therapeutics' (6th edit., p. 331) to the late Dr. William Brinton, who it is there said, "believes this superior to all other combinations for the ejection of teniæ." The dose of male fern ordered is precisely the same in both cases, but in the book it is possibly a misprint for 1½ drachms. This fact was mentioned during the inquiry and eventually the charge was dismissed.

GLUCOSE MANUFACTURE IN THE UNITED STATES.

The manufacture and consumption of glucose in the United States is assuming enormous proportions. According to Mr. Consul-General Archibald, the present production is estimated at not less than ten thousand tons daily. The product is chiefly used by brewers, but it is also largely used as a substitute for cane sugar in the manufacture of confectionery and the mixing of syrups. A product known under the name of "new process" sugar is said to be coming into increasing demand; it contains 20 per cent. of glucose, and is with difficulty distinguished from genuine cane sugar, for which it is probably sold to a considerable extent.

"CAUTIONS TO CHEMISTS."

Under the above heading we continually receive communications which have for their subject the victimization of the writers by more or less plausible impostors. In some of these the statements are so diffuse and vague that it is difficult to gather what is the exact ground of the complaints, whilst on the other hand in some the indications are so precise that it would be unwise to undertake the responsibility of publishing them without a fuller acquaintance with the facts, especially as in these cases the writers generally desire to retain their anonymity. Whilst willing to render all reasonable service to the trade, we think it will be seen that it is undesirable, except in extreme cases, for us to undertake the task of publishing such statements, and the more so because as a rule immunity from impositions can, after all, be only secured by the exercise of a proper amount of carefulness in dealing with strangers.

Pharmaceutical Society of Ireland.

ANNUAL MEETING.

The seventh annual meeting of this Society was held in the College of Physicians, Dublin, on Monday, October 2, at 4 o'clock.

The chair was taken by the President, Professor R. C. Tichborne, Ph.D.

The other members of the Society present were:—Dr. Aquilla Smith, Vice-President; Messrs. Allen, Brunker, Dr. Collins, Messrs. Doran, Grindley, Hayes, Hodgson, Holmes, Dr. Montgomery, Sir George Owens, Messrs. Simpson, Wells, Batt, Bernard, Beggs, Whitby, and McIlwaine.

The first business was the election of seven members of Council to replace the outgoing seven. Messrs. Doran, Batt, and Beggs were appointed scrutineers of the voting papers.

The President said while they were waiting for the report of the scrutineers he would say a few words as to the progress of the Society. They might congratulate themselves on having, generally speaking, a quiet and steady success. On January 1, 1881, they had 187 licentiates. On January 1, 1882, they had 201, being an increase of 14, notwithstanding that they had lost two or three by death. That increase he believed had since gone on. As regarded the number of members, there had been a slight decrease, the numbers having been 96 in 1881, and 92 in 1882. He did not attach much importance to that, because in new societies a certain number of members often put down their names at first and did not continue them afterwards. As to the Preliminary examination, the result was most satisfactory. At the present moment it appeared by the list that 275 candidates had passed the Preliminary examination, and most of those gentlemen he presumed would hereafter come forward at the examination for the licence. Besides this, the Society having agreed to accept the Preliminary examinations of other licensing bodies, the number of those who had passed their own Preliminary examination did not represent all that would ultimately seek to become licentiates of the Society. Their Treasurer would no doubt place a more or less satisfactory account before them. He understood that they had been able to lodge £100, which was a satisfactory circumstance. With respect to illegal compounding, the Society had been doing their best to put a stop to it. He firmly believed every member of the Council was of opinion that the success of the Society depended on the determination with which they carried out the law as it existed in the country. Frequently there were great difficulties in the way of carrying out these prosecutions, but they had been successful in the two they had tried this year. No doubt one of them had cost a considerable sum of money, but they did not look on the matter as one of merely pounds, shillings, and pence. They prosecuted not from any animus against individuals, but to show that they were determined, if possible, to put an end to illegal compounding. One prize had been given this year by a member of the Council to a young licentiate who competed for it. He (the President) had not seen the prize essay, but the examiner in chemistry and another gentlemen who read it had reported that it was one of the cleverest essays they had seen for many years. This was in itself a mark of progress, showing that they had amongst them young men who were likely to make a name in the scientific world.

Mr. Hodgson, Treasurer to the Society, in submitting the balance sheet for the year, said it showed that they commenced with a balance in the Bank of Ireland of £133 4*s.* 2*d.* The amount received during the year was £289 19*s.* 2*d.* That included £68 5*s.* for the subscriptions of sixty-five members. The total income for the year was £432 2*s.* 4*d.* The cost of prosecutions amounted to £29 3*s.* 2*d.*; while they received £3 for a fine imposed on one party prosecuted. He was aware that the feeling of the Society was that it was most desirable to put down illegal compounding, and there was no doubt whatever that the Council was the proper body to move in the matter; but their income was limited and law was an expensive luxury; and although many members might think that if the Council did their duty they would have had even more prosecutions, there was no doubt that if they repeated these prosecutions very often it would cost a very considerable sum of money indeed. It might, therefore, be desirable to consider whether some arrangement could not be come to by which the parties who would be benefited in the towns or districts in which the prosecutions took place would recoup the Society for the expenditure thus incurred. A sum of £100 10*s.* 5*d.* had been invested in 3 per cents. The cost of printing had been £44 7*s.* 3*d.*, and he had requested Mr. Fennell to get some estimates in connection with that department. There was an item of £42 9*s.* 2*d.* for the *Pharmaceutical Journal.* As a member of the Council he had always had the strongest possible objection to that. It was absurd to spend such a sum as a bonus in order to get £68 5*s.* for sixty-five subscribers. The final result of the present account was that they had only £17 5*s.* 11*d.* in bank, together with about £400 invested in the Funds.

The President stated that the account had been duly audited by Messrs. Allen and Hayes.

Dr. Collins moved the adoption of the account.

Mr. Wells seconded the motion, which was agreed to.

The President then announced that the report of the scrutineers of the ballot was as follows:—Dr. Aquilla Smith, 50 votes; Mr. H. Bennett, 46; Mr. J. C. C. Payne, 45; Mr. Minchin, 40; Dr. Henry Whitaker, 38; Mr. McIlwaine, 36; Sir George Owens, 31; Mr. Holmes, 29 votes; and Mr. Goulding, 20.

The President declared the first seven gentlemen duly elected to serve on the Council for the ensuing three years.

Sir George Owens said he had great pleasure in moving that Dr. Charles Tichborne be re-elected President of the Society. They were much indebted to him, and he was well entitled to any compliment that they could pay. It added honour and prestige to the Society to have for their President a gentleman whose writings were so well known.

Dr. Collins said he had much pleasure in seconding the motion, which was put by the Vice-President and carried unanimously.

Dr. Tichborne said he almost forgot how many times he had to thank them for re-electing him. He could conscientiously say as regarded whatever he did, whether it met their approval or not, that it was done with but one object and that was the benefit of the Pharmaceutical Society of Ireland. For reasons which it was not necessary to mention he accepted the Presidentship now; but he thought the time was come when they should consider whether it was not desirable to change the occupant of the office, so that it might not be a permanent position for one person. In fact, it was his intention before the next election to bring forward a notice of motion on the subject. He thanked them very much for their kindness.

Dr. Collins said he had great pleasure in proposing that Dr. Aquilla Smith be re-elected Vice-President. The same reasons applied to his re-election as to that of the President. They could not possibly have a better man, if he would do them the honour of accepting reappointment.

Mr. Hodgson said he had much pleasure in seconding the motion. They all knew how much they owed to Dr. Smith. At the time of the inauguration of the Society no one gave more talent, acumen and attention to the working out of details than he did.

The President said he had much pleasure in putting the motion. He looked on Dr. Smith as a tower of strength to the Society, and he hoped he would long remain with them.

The motion having been unanimously agreed to,

Dr. Smith said he accepted his reappointment with pleasure. He had always entertained an earnest desire to promote the interests of the Society and would willingly continue his efforts with that object.

Mr. Hayes moved:—

"That Mr. Hodgson be re-elected Treasurer."

And the motion was seconded by Mr. Simpson, and unanimously agreed to.

Mr. Hodgson said he was much obliged to them for re-electing him. It was his most anxious desire to conserve the funds of the Society with one special object, namely, that they might as soon as possible obtain for themselves a "local habitation." This object he had long had before him. Of course the Society were greatly indebted to the College of Physicians for their kindness in allowing them to meet there; but still they should remember that they were only there on sufferance and that they might at any time receive an intimation that the room was required for other purposes. If once their funds attained a certain amount he did not think subscriptions would be wanting from members in order to make up the balance of what would be required to provide its own rooms for the Society.

Mr. Holmes: I think such an arrangement would soon become self-supporting.

Mr. Brunker moved:—

"That Mr. Fennell be re-elected Registrar."

They all knew how efficiently that gentlemen discharged his duties.

Mr. Hodgson seconded the motion, which was agreed to; and Mr. Fennell returned thanks.

On the motion of Mr. Holmes, seconded by Mr. Doran, Mr. Allen and Mr. Hayes were re-elected Auditors.

On the motion of Mr. Grindley, seconded by Mr. Simpson, the Law Committee were re-elected.

On the motion of Mr. Beggs, seconded by Mr. Holmes, the Committee to visit Examinations for the Licence were re-elected.

On the motion of Mr. Brunker, seconded by Mr. Collins, the following were elected the Committee for examining certificates of candidates for the licence:—Dr. Collins, and Messrs. Brunker, Allen, Payne, Hayes and Lester.

The following were re-elected the Pharmacy Act Amendment Committee:—Messrs. Allen, Draper, Hayes, Collins, Payne and Brunker.

Mr. Hatchell Whitby moved the following resolution:—

"That a Committee of twelve members, or such other number as shall be agreed on, of whom not less than one-third or more than one-half shall be members of the Council of the Society, be appointed with a view (*a*) to inquire into and report to the Council on the best means of rendering the Society more attractive to its members; and (*b*) to consider and recommend for adoption alterations calculated to induce licentiates to become members and to improve the prospects of the Society generally."

No one could hold the opinion that the Society was in a satisfactory condition. In the year 1880 they had 187 licentiates, 78 members, and seventy-two subscriptions. In 1881 they had 197 licentiates, 74 members, and fifty-three subscriptions. Their balance to credit in 1880 was £430, while in 1881 it was only £404. The members of the Society should be offered some advantages, such as a library and room in which they could meet for the purpose of consultation. He thought some money could be saved in connection with the printing of the Calendar. From 1878 to 1880 they paid £51 for printed matter, a large part of which he supposed consisted of the cost of printing the Calendar.

The President: We have a library here which is accessible to members. It is not very extensive at present, but we hope it will grow bigger. It contains some very valuable and useful books, of which one alone is worth £10, and the value of all is about £50.

Mr. Beggs seconded the motion.

Mr. Grindley supported it, and considered that much assistance in the promotion of the objects of the resolution could be given by outsiders.

Mr. Hodgson observed that the necessity of having a nice library was an additional reason for conserving their funds. When they had £1000 in bank they would be in a position to invite subscriptions for the purpose of getting a place of their own.

In the course of discussion, Mr. Brunker remarked that the fact that prosecutions for breach of the law had been so few, was due, not to any neglect on the part of the Law Committee, but to the difficulty of getting evidence. Several places had been reported as suspected, but the Committee could not get evidence against them. Still they knew that illegal dispensing was going on. Unless members of the Society and licentiates came forward openly and above board and gave evidence, it would be utterly impossible to have prosecutions. In several houses in that city it was known that the law was broken, but they were wide-awake enough not to afford evidence of it.

The resolution was put and carried unanimously, and it was agreed that the Committee should consist of eight members, viz., the mover and seconder of the resolution, Messrs. Bernard and Batt, and four members of the Council to be named by that body.

This terminated the proceedings.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The annual meeting of the above Association was held at the Royal Institution on Septemper 28.

The members having as usual partaken of tea and coffee, the President, Mr. Michael Conroy, took the chair at 8 o'clock.

The minutes of the last general meeting were read and confirmed and the following donations announced:—'The Smithsonian Report,' from the Association; 'Report of the Alumni Association of Philadelphia,' from the Association; The *Pharmaceutical Journal*, from the Society; The *Canadian Pharmaceutical Journal*, from the Editor; and the following Reports and Transactions of local societies from the respective societies:—Liverpool Naturalists' Field Club, Liverpool Philomathic Society, Liverpool Science Students' Association, Birkenhead Literary and Scientific Society.

The Hon. Secretary then read the following report of the Council for the past year:—

Annual Report.

"Your Council, in presenting to the Association this, the Thirty-third Annual Report, trust that it may show that the Association has maintained its satisfactory position among the societies of the city.

"Ten new members have been elected; three members and one associate have resigned; but owing to the Council having removed from the list of members and associates the names of several gentlemen whose membership has, from various causes, lapsed, the totals have slightly diminished, and are—honorary members 19, ordinary members 99, associates 18; total 136.

"There have been thirteen general meetings during the session, at which papers and communications upon important and interesting subjects were read.

"The Associated Soirée, in which the Association again participated, was in every way a success. Messrs. A. C. Abraham, Conroy and Mason have been appointed delegates from the Association to the General Committee for the forthcoming soirée.

"An insufficient number of students having come forward to attend the Organic Chemistry Class, usually conducted by Mr. Davies, that class was not held, and the customary examination for the President's prize did not, therefore, take place. The attendance at the Inorganic Chemistry Class was, however, good.

"At the meeting of the British Pharmaceutical Conference, recently held at Southampton, the Association was represented by Messrs. Symes and Mason.

"Several valuable additions have been made to the Library during the session. The various periodicals have been bound up to a recent date. Three series of the reports of the Association, as complete as possible, have also been bound. One of these has been forwarded to the Pharmaceutical Society, at their request; one to the Liverpool Free Library, at the request of the Librarian; and one retained for our own Library. The number of volumes, etc., issued from the Library has been 423, and the references have been numerous.

"At the last general meeting Mr. Joseph Woodcock was elected President in succession to Mr. Conroy, who desired not to be again put in nomination, his time being too fully occupied to allow him to fill the office to his satisfaction.

"Messrs. E. Davies, R. M. Sumner, Alex. Watt, and Thomas Williams retire from your Council, their term of office expiring this evening; they are, however, with the exception of Mr. Alex. Watt (who has retired), eligible for re-election, and have signified their willingness to continue their services.

"The Hon. Treasurer's Financial Statement ashows balance in favour of the Association of £4 18*s.* 8*d.*"

The Hon. Treasurer, Mr. R. M. Sumner, then read the annual statement of the financial position of the Association, from which it appeared that although the balance in hand was not large, the condition of the Association was pecuniarily satisfactory.

On the motion of the President, seconded by Mr. Joseph Woodcock, it was resolved:—"That the report as read be adopted, and, together with a list of members and abstract of proceedings of the past session, be printed and circulated among the members."

Mr. R. M. Sumner then moved:—"That the best thanks of this meeting be given to the donors to the Library, and to the authors of papers during the session." Mr. H. O. Dutton seconded this motion, which was carried unanimously.

The following motion, proposed by Mr. Parkinson, seconded by Mr. Samuel, was also carried:—"That the best thanks of this meeting be given to the officers and Council for their services during the past session."

The election of four members of Council then took place, and Messrs. E. Davies, R. M. Sumner, T. Williams and R. Parkinson were duly elected.

There being no further business brought forward the proceedings terminated.

LEEDS CHEMISTS' ASSOCIATION.

The annual meeting was held in the Library, Church Institute, Leeds, on Wednesday, September 20, 1882. Mr. E. Yewdall, Vice-President, in the chair.

The Honorary Secretary, Mr. Hellowell, read the following reports:—

"The Committee meet you to-day under exceptional circumstances and regret to have to state that since the last meeting of the society our President, Mr. T. B. Stead, has passed away from us. In all matters connected with the trade, Mr. Stead, by his regular attendance at the meetings, unostentatious manners and judicious remarks, did much to forward its interests. Several members of the society attended his funeral, and the Committee, at a special meeting convened for the purpose, passed a resolution of condolence with Mrs. Stead and her family.

"The great depression which has affected our trade for some time and still presses upon us, having produced a feeling of dissatisfaction in the minds of some, has no doubt been the cause of the society not making any addition to the list of members and associates during the past year; but as there are indications of an improvement it is hoped that there will be more interest shown in our work and a consequent desire to join our ranks.

"The Committee have carefully considered the desirability of affording an opportunity to all those not connected with us to do so by lowering the membership fee, and the subject will be brought before you in a formal manner at this meeting.

"The society is greatly indebted to J. J. Humel, Esq., F.C.S., for a very interesting lecture 'On the Chemistry of Dye Materials used in Pharmacy,' given by the kind permission of the Governors of the Yorkshire College, in the new Technical Schools, College Road, at which there was a good attendance.

"The Library has been thoroughly cleaned, the walls and ceiling have been recoloured and whitewashed, affording a comfortable room for any of the associates wishing to consult the various excellent books of reference or to examine the specimens of materia medica in the cabinet. It has also been regularly supplied with periodicals, including the *Pharmaceutical Journal*, *Chemist and Druggist*, *Chemical News*, *Nature*, and *Science Gossip*.

"The Committee hope the associates will make a greater use of the advantages offered by such a good library so centrally situated.

"The lectures upon chemistry at the Mechanics' Institution and Yorkshire College, to which associates of this Society are admitted without any extra charge beyond the lecture fee, afford opportunities for the systematic study of this science in its various branches, and to those youths who wish to thoroughly learn the Committee strongly recommend them.

"The botany class at the College is another means by which associates can make themselves well acquainted with this subject, and if masters will allow their apprentices and assistants, wishful to attend these lectures, the opportunity of doing so, they need not ask for better opportunities of acquiring the knowledge required for them to pass their examinations."

The Treasurer's report showed a balance in favour of the Society of £8 5*s.*

The following gentlemen were unanimously elected officers for the ensuing year:—President, Mr. S. Taylor; Vice-President, Mr. J. Abbott; Honorary Secretary, Mr. J. Hellowell; Treasurer, Mr. J. A. Hirst; Committee, Messrs. T. Barrowclough, P. Jefferson, W. Manfield, R. Reynolds, F.C.S., W. Smeeton, E. Yewdall.

Mr. Yewdall proposed the best thanks of the Association be given to the Pharmaceutical Society for the gift of the Journal, also to the British Pharmaceutical Conference for the gift of the Year-Book of Pharmacy.

Mr. P. Jefferson, gave notice of alteration of a rule:—"That the annual subscription be reduced from 10*s.* to 5*s.* per annum."

BOLTON DISTRICT ASSOCIATION OF CHEMISTS AND DRUGGISTS.

The annual meeting of the above Association was held at the Commercial Hotel, Town Hall Square, at 7·30 p.m. on Tuesday evening, September 19, when upwards of twenty-five members with a few friends sat down to an excellent dinner. After the removal of the cloth the usual loyal and patriotic toasts were given, and the following report of the Committee was read by the Secretary, Mr. W. B. Mason, F.C.S.—

"In presenting the members of the Association with a report of the work done during the past session, your Committee congratulate the Association on the increase of the numbers now on the books. During the year the rules have been revised, and assistants and apprentices are now admitted on payment of a small annual subscription. By this slight alteration the numbers of the Association have been increased by ten, making a total of forty members. In consequence of the Association not meeting until March of the present year, there have been no general unions for the discussion of trade topics, but your Committee trust that during the winter a series of evening meetings will be held as often as is deemed convenient. The wants of the younger members of the trade have not been neglected, the room kindly placed at the disposal of the Association by Mr. Priestley having been furnished with a very complete collection of materia medica and botanical specimens, which your Committee hope ere long will be materially augmented by a donation from the Pharmaceutical Society. Arrangements have been made for a series of classes during the winter months in the subjects of the Minor examination to which your Committee hope the attention of the apprentices will be directed."

The report having been received and adopted, the meeting then proceeded to the election of officers for the ensuing session, after which Mr. W. Blain, the President-elect delivered his annual address, urging upon chemists the necessity of united action, more especially with regard to the education of apprentices. After pointing out to the members the courses of lectures arranged for the coming winter, especially thanking the wholesale houses who so kindly contributed to the materia medica collection, the President concluded by appealing to the members of the Association on behalf of Mr. Buott, a gentleman who formerly greatly interested himself in Bolton chemists, but who now unfortunately is in great distress.

As a direct result of this appeal it may be stated the sum of 24*s.* 6*d.* was subscribed, and has since been forwarded to Mr. R. Hampson.

The remainder of the evening was occupied with recitations and songs, and a most successful meeting brought to a close with the National Anthem.

YORK CHEMISTS' ASSOCIATION.

A meeting of the above Association was held at 9, High Ousegate, on Friday evening the 29th ult.

Mr. Councillor Dawson presided, and the following officers were elected:—President, Mr. Dawson; Secretary, Mr. Scruton; Treasurer, Mr. Sawray.

A committee was appointed to make arrangements for meetings and lectures during the winter months.

It was also decided that a room should be engaged at the above address where the books and specimens belonging to the Society will be available for the use of the assistants and apprentices connected with the trade.

PRESTON CHEMISTS' ASSOCIATION.

At a meeting of this Association, the prizes and certificates gained by the students in the science classes last session were distributed by Mr. J. Scott, Vice-President, who congratulated the students on their success, and hoped the ensuing session would be equally satisfactory.

Proceedings of Scientific Societies.

BRITISH ASSOCIATION.

Gas Burners.*

BY WILLIAM SUGG, A.I.C.E.

Coal gas, as now supplied to the public, consists of hydrogen and marsh gas to the extent of about 80 per cent., and the remainder consists of luminous hydrocarbons of various qualities, with traces of sulphur in the form of disulphide.

The gas supply of London is watched over by a Commission, appointed by the Board of Trade, called gas referees, who are Professor Tyndall, Professo Vernon Harcourt, and Mr. Pole. They are empowered to prescribe the manner of verifying the illuminating power and purity of the gas, and they have also authority to act in cases of dispute in public lighting. Their prescriptions, as emanating from the only legal body of the kind in the kingdom, are accepted as the proper methods, so that in effect, though they are appointed in London, they may be said to be gas referees for the whole kingdom. But the use that is made of gas is a matter which is altogether out of the control of gas companies and their engineers, and here the proverb about food and bad cooks may be paraphrased. The great hindrance to the improvements in the use of gas has been the general public themselves, who have not taken sufficient interest in the kinds of apparatus employed, but have, as a rule, supplied themselves with the cheapest burners, stoves, and other apparatus, utterly regardless of the waste and annoyance which this system entailed; and when they have complained, they have always attributed the causes of failure to the quality or pressure of the gas, instead of ascribing it to the true cause.

In 1871, the gas referees made an examination of a number of gas-burners which they had collected from various large establishments, newspaper offices, warehouses, shops, and dwelling-houses, and they found that those burners (samples of those generally employed by the public) would only give about one-half the light that the gas was capable of yielding per cubic foot consumed, and several of the burners tested by them gave only one-fourth of the proper light of the gas.

They say in their report to Parliament:—"The economy to the public, arising from the use of good gas-burners instead of bad ones, is so obvious as hardly to need remark. The gas rental of London amounts annually to more than two millions sterling. Taking a very moderate estimate, upwards of one-fourth of this sum (£500,000 per annum) might be saved by the use of good burners. This is the saving which might be made in London alone; how much vaster the sum thus economized if good gas burners were to come into general use throughout England."

Now, the quantity of gas used in London last year, according to the analysis of the London Gas Companies' accounts, prepared by Mr. John Field, was in round numbers, 20,230,000,000 cubic feet, which is equal to a bulk of 1 mile square × 726 feet high, and its cost to the public was £2,911,000.

The result of careful trials, made with a number of burners taken lately from private houses and shops, shows that, as a rule, the amount of light obtained by the general public, from five cubic feet of gas, is less than one half of that which it is capable of giving. The iron and metal burners, of which a great many are used, give the best result in light when they are worn out, although the shape of the flame is bad. The reason why, is that in order to obtain from what is a compound of hydrogen, marsh gas, and carbon, its best effect in light, the burner must be so made that the quantity of gas required to be consumed is proportionate to the size of the burner, so that it cannot exceed the maximum quantity which the burner is made for. Then the outlet of the burner itself, whether it be of the Argand or the flat-flame form, must be so arranged that the gas issues forth at a sufficiently low rate of velocity, so that it has time to get heated to a proper degree by the hydrogen and marsh gas before it comes into combustion with the oxygen of the atmosphere. When this rate of velocity is obtained in an Argand burner, the pressure at the point of ignition is almost *nil*. In flat-flame burners the pressure of the gas must be raised to a point sufficient to blow out the flame to a fan-like shape, but it must only be sufficient to do this if it is desired to obtain a good result per cubic foot of gas consumed.

One more point is of great importance in the construction of a gas-burner—that is, that the gas should

* Abstracted from a paper read before the Mechanical Section of the British Association, at Southampton. Reprinted from the *Journal of the Society of Arts.*

not be heated until it arrives at the point of ignition. The body of the chamber below the point of ignition must therefore be made of material which is a bad conductor of heat; so as not only to prevent the undue expansion of the gas before it arrives at the point of ignition, but also to maintain the heat in the flame.

Sir Frederick Bramwell very ingeniously pointed out, some time since, that the important point in the proper combustion of gas is not so much to keep the gas cool as to keep the flame hot. The distinction is extremely subtle; but, nevertheless, a non-conducting gas-chamber performs both these important functions. If a gas-chamber made of metal or any good conductor of heat is used, then the gas becomes expanded in bulk, and the velocity of the issuing gas is greatly increased; less time being given for chemical combinations necessary to produce a proper amount of light from it. In addition to this, as Sir Frederick Bramwell has pointed out, the heat which should remain in the flame is conducted away from it into the lower fittings of the burner, where it may burn the fingers of the incautious consumer, but it is of no manner of use in the evolution of light.

You will, perhaps, say it is not possible to conceive how the flame can be kept hot without keeping the gas cool at the same time, because if the heat is to be kept in the flame, and not conducted away down the stem of the burner, the gas must be kept cool by the means employed. But, nevertheless, there is a difference in the effects produced, and the ingenious definition of Sir Frederick is scientifically accurate. As an explanation of the expansion theory, it may be stated that if 1 cubic foot of gas is heated to about 500° F., it will occupy the same bulk that 2 cubic feet do at the mean temperature of the atmosphere. Now, supposing it is issuing in a cool state from the aperture of the burner at a velocity equal to 1½ mile per hour, it must then issue at 3 miles per hour, if the rate of consumption is equal in both cases. Therefore it has only half the time in the heated state to combine with the oxygen of the air that it had in the cooler state, and a loss of illuminating power is the result. Again, as regards the maintenance of the heat in the flame; supposing the chamber from which the gas issues is a conductor of heat. In this case the heat from the flame is conducted away from it down the stem of the burner, expanding the gas and leaving the flame so relatively cooled, as to require more gas to raise it to the necessary state of incandescence to allow the oxygen to combine with it in the proper proportions. In this case, as the two operations are simultaneous, it is difficult to apportion the effect produced. But that the effect is produced is proved by the following experiments, made some time since by the late Mr. F. J. Evans.

Two Argand burners were made precisely alike in every respect, except that one had a combustion chamber made in steatite, and the other in brass. The same quantity of gas was consumed through both of these, the result being that the burner with the non-conducting chamber gave more light per 5 cubic feet of gas consumed than the other, the proportion being as 15 candles to 13. The burner with a non-conducting chamber was quite cool immediately below the chamber, while the other was so hot that it could not be touched without burning the hand. The metal burners which are now used in enormous quantities in London and the provinces become exceedingly hot, so much so as to communicate the heat to a considerabe distance down the fittings. The velocity of the issue of 5 cubic feet per hour of gas from these burners, varies from 10 to 60 miles per hour. The worn-out burners generally give the lowest velocity. As a rule, the metal burners give the lowest result in light per cubic foot of gas consumed.

For example, a metal burner of the flat-flame type, which has been stated in the columns of the *Journal of Gas Lighting* to be identical with the steatite hollow-top burner, invented in 1868, gives the following results:—A large-sized burner, No. 8, burning 5 cubic feet per hour, gave a result equal to 11·5 candles, whilst the result obtained with a like quantity of gas from a steatite burner of corresponding size, which has a non-conducting gas-chamber, was 14·6 candles, a difference in favour of the steatite of 3·1 candles, or nearly 25 per cent. more light. Another metal burner, of a size more generally in use by the public, only gave 6·2 candles for the 5 cubic feet, or considerably less than half the latent value of the gas, which was 16 candles.

The fact of the difference of illuminating power, with like quantities of gas, clearly shows that the two burners are not the same by any means. The statement gravely made in the columns of the *Journal of Gas Lighting* that they are identically the same, clearly shows that if this is the belief of the gas trade generally with respect to these two burners, it is no wonder that the public, who rely on the recommendations of the trade, continue still to waste their gas in the manner pointed out by the gas referees in 1870 and 1871.

As before stated, careful tests of a collection of burners, bought from different gas-fitters and ironmongers in various towns in England, and from their recommendations, prove that the knowledge of the proper use of gas possessed by those persons is still most incomplete, and, therefore, the general public continue still to burn gas in the same wasteful manner as they did when the gas referees made their report.

The remedy for this enormous waste of gas is in the hands of the public only. Gas producers whether they are corporate bodies or public companies, are almost powerless to oppose the vested interest which derives large profits from the sale of gas-burners constructed with a view to require frequent renewals. It is only fair to say that the producers of gas have always shown the greatest interest in the improved use of gas in every way; but the speculating builder and his colleague, the local plumber and gas-fitter, hold a final power for evil over the employment of gas, which, till very lately, has been paramount.

Happily for the gas interest, the general public are beginning to take a deep interest in gas, and are acquiring a great amount of information concerning it, through the numerous gas exhibitions which have been held under the auspices of gas companies and corporate gas committees throughout the kingdom, and it is to be hoped that the forthcoming exhibition at the Crystal Palace, in October next, will very largely aid the good work of instructing the public how to use gas to the best advantage. Thus we may hope that soon the ring of interests inimical to the progress of gas will be broken through, and fresh encouragement given to the inventors of improvements in the use of gas. It will be impossible, in the limits of this paper, to give you a complete idea of all the improvements which have been, and are still being made; but I propose to indicate the direction they are taking, and give you a general idea of what they are.

It has been found that a comparatively large quantity of gas, about four to six times that ordinarily used, will give a much better result from one burner per cubic foot of gas consumed than can be obtained from four or six separate burners consuming the aggregate quantity of gas equal to that consumed by the large one; and this is true of both Argand and flat-flame burners. This is by no means a new idea; it was known to Faraday and others before him. I have in my possession an old burner made many years ago; it has several rings and a silver top drilled with very fine holes. The quantity of gas used is large—the effect is small—in fact, it is more useful for boiling water than for giving light. But this old burner is a type of the large Argands of twenty or thirty years ago. They did not succeed, because although they produce a great amount of light, it was at the cost of too much gas. Modern Argands will produce just double the amount of light for the same quantity of gas.

There is also incorporated in some of the newest burners now before the public an idea which was originated by Professor Frankland more than ten years ago, viz., that if the air for combustion supplied to a burner be heated before it arrives at the point of ignition, a much better result per cubic foot of gas consumed can be realized. This you will perceive is a mode of carrying out Sir Frederick Bramwell's idea of keeping the flame hot, and undoubtedly a better result can be obtained. This burner, although it did not come much into use, has very lately been repeated, and is now being sold on the Continent. The burner is so much like Dr. Frankland's that there is no difficulty in recognizing it at once.

Of the modern Argands, there are now several kinds; one is made with two or three concentric rings of flame and a glass chimney, and is made with non-conducting steatite gas-chambers, and apertures permitting the gas to issue under an almost inappreciable pressure at the point of ignition, the velocity per hour being only about 1½ mile. In this kind of burner the gas is kept cool and the flame hot. These were first used in the public lighting of Waterloo Road, in 1879, and in Waterloo Place and Queen Victoria Street.

Another kind, of newer type, is made on the theory of keeping the flame hot by making use of the products of combustion to heat the air-supply. This also combines the low velocity of emission theory, and likewise heats the gas itself. It is made by inverting the flame of the burner, the heat generated by the products of combustion being carried away by a concentric flue, fastened round the burner, through which metallic tubes convey the air necessary to produce combustion, which thus becomes heated.

A third is constructed on the principle of keeping the flame hot and the gas cool, but has besides an arrangement for admitting separate currents of cold air round the flame, for the purpose of keeping the chimney cool. It was important to observe that, although this burner does not warm the air admitted to it for promoting combustion, yet the results per cubic foot of gas consumed are stated to be as high as any of the others, showing clearly that there is no advantage in heating the gas before combustion. As to the advantage obtained by heating the air, the practical effect upon an Argand suitable for use by such ordinary unskilled labour as is usually employed to look after gaslights, has not yet been clearly demonstrated; although it is without doubt a great advantage to burners of the flat-flame type, because these have always too much cold air supplied to them.

The Argand, with its more complete regulation of air and its immunity from the effect of surrounding cold air, is able to evolve from 15 to 30 per cent. more light per cubic foot of gas consumed than can be obtained from the best flat-flame burner; but, although the general public have no objection to glass chimneys in paraffin and other oil lamps, they do not appear to look with favour upon the general employment of glass chimneys for gas-burners, no matter how much better the result to be obtained. I need not say that the cordial support of the ring inimical to the true interests of gas is given to the public on this point, and a great deal of very strong literature condemnatory of the Argand burners has been widely disseminated. But it is impossible, in the face of the improvements which are continually being made in gas-burners of the Argand type, to believe otherwise than that they are destined to play an important part in the gas-lighting arrangements of the future. The improvements in the flat-flame burners, though not producing such high results as those obtained from large Argands, are great, and, concurrently with improved lanterns, have placed the lighting of the public streets on a much improved footing. Here, again, about three times the amount of light per cubic foot of gas is obtained from the use of large burners than with the old-fashioned small ones. The consumption of gas by the large ones is only equal to the aggregate consumption of four or six smaller burners. In addition to this, the improvements in the reflecting tops of the lanterns make the new lamps still more effective, and may fairly be said to double the effective power. In internal lighting, the progress of gas has been very considerable of late years. Small burners for rooms have been greatly improved. For large rooms and theatres new kinds of sun-burners are made, to give three times the amount of light obtainable from the old ones, and to ventilate the buildings at the same time.

One of the greatest advantages of gas is that the heat generated by the combustion can, if properly applied, be made to do the work of ventilation, and it is in this direction that the future progress of gas-lighting lies. There are many ways of utilizing this heat; some are extremely easy to put into practice, others require more preparation. Among the simplest, is the method of ventilating rooms by the fish-gill ventilator, invented by the late Goldsworthy Gurney. It consists simply in covering an opening made in the wall with strips of calico fastened across the hole by tacks put into the two upper corners of each band. The bands are made just long enough for the lower part of the superior band to cover the top part of the inferior one. When fixed properly, they open like the gill of a fish, hence the name. They can be used to let in fresh air, or carry off heated air from the top of a room.

These useful and simple ventilators, if employed in rooms where gas is used, would tend greatly to the comfort of the public who require a good light, but complain of the resulting heat. They work when closed by diffusion, the heated air passing through the porous medium of the calico, and the cooler air from outside the rooms passing in without draught. For the ventilation of ballrooms it is very easy to put into the windows a frame fitted with muslin or washed calico of half or even the full size of the window. Ventilation will thus take place by diffusion, and the draughts and danger resulting from incautiously-opened windows will be avoided. If the wind blows hard on this opening, it may be protected by a loose curtain of muslin or calico hanging in front of it.

You will perceive, therefore, from what I have said, that the progress of invention in gas lighting is great and continuous, and that in the future, if the public will only interest themselves just sufficiently to obtain a moderate amount of information on the subject of gas, they will be enabled to use it with great economy and comfort to themselves in every way. The facile manner in which gas can be employed to produce the light of a rushlight or the blaze of a thousand candles by the mere turn of the wrist, joined to the readiness with which it can be conveyed to great distances without any practical loss, will always ensure a large and growing demand for it everywhere.

But it must be remembered that its extreme adaptability renders it capable of being used with the most crude apparatus as well as the most perfect; and when we see in the public streets the blazing pipe and shovel, a rough but powerful burner of from 100 to 600 candles power, rigged up in a few minutes by a navvy, we must not be surprised at the prevalence of crude apparatus of smaller dimensions put into practice by the public, who are not aware that they can do better with a more perfect burner.

Parliamentary and Law Proceedings.

Suicide of a Chemist and Druggist.

On Saturday, October 7, the Deputy Coroner for Bristol, Mr. E. M. Harwood, held an inquest at 51, White Ladies Road, on the body of John Facey, aged 42. Deceased, who had been carrying on business as a chemist and druggist at the above address, was found dead in a bathroom early on Saturday morning, under circumstances which led to the belief that he had committed suicide.

John William Newhill, an assistant to the deceased, said that he had known him for about two months, and during that period he had noticed that he appeared very ill at times. Witness did not think he was satisfied with his business with regard to the amount of money he had paid for it and the returns. Any person who understood the business could be of no other opinion. Deceased was married on September 6, and witness had every reason to believe that he lived very happily with his wife. He had at times spoken to witness about his business affairs, and complained that his returns were not in proportion to the money he had paid for the concern. Witness believed that he paid £750 for the business, but there was a stipulation that he was to pay £26 in addition to that sum if the returns came up to £800 in the first year. As Mr. Facey's assistant, witness was satisfied that the returns were not adequate, and that if the deceased had kept the establishment up and conducted it as it should be he would lose £150 a year by it. For the first few weeks when witness was there deceased was very irritable, and complained very much about the price he had paid; but latterly, although he complained occasionally, he did not appear so much irritated. Deceased left the shop about half-past six o'clock on Friday evening, and witness did not see him again alive.

William Player, brother-in-law to the deceased, said that on going into the bath-room he found the deceased laying on the floor quite dead, with a little bottle by his side.

Mr. Player, M.R.C.S., said that he was called in by the last witness to see the deceased, who was then dead, death having taken place some hours previously. The bottle produced, which smelt strongly of chloroform, was found by his side and on making inquiries in the shop witness found that about an ounce was missing. A handkerchief which had been saturated with chloroform was spread over his face, the effects of which would alone, he thought, have been sufficient to cause death. That afternoon he found in the left hand pocket of his coat a small bottle perfectly empty, which had contained about an ounce of prussic acid. Deceased smelt very strongly of prussic acid, and witness's theory of the affair was that he took the prussic acid first and then threw the handkerchief saturated with chloroform over his face to deaden the pain.

The Jury were of opinion that deceased was not in his right mind at the time, and returned a verdict to the effect that he committed suicide whilst in a state of temporary insanity.—*Western Daily Press.*

Review.

Pharmakognosie des Pflanzenreiches. [Pharmacognosy of the Vegetable Kingdom.] By F. A. Flückiger. Second Edition. Parts I and II. Berlin: Rudolf Gaertner.

Any work on pharmacognosy by the surviving author of the classic 'Pharmacographia' demands and is sure to secure the attention of all interested in materia medica. The work which is the subject of the present notice is a portion of what is nominally a second edition of a manual dealing with the natural history of the more important medicinal substances of vegetable origin, published by Professor Flückiger in 1867. But it is in reality a new book. Since 1867 'Pharmacographia' has appeared, and an enormous number of books and scattered memoirs upon allied subjects have been published, which required to be taken into account in order to bring such a work abreast of the times. How thoroughly this has been done is proved by the fact that the second part contains in several places information that has only been published since the issue of the first. Naturally the 'Pharmakognosie' has points of resemblance to the 'Pharmacographia,' and it includes most of the information contained in that work; but it is not merely 'Pharmacographia' in a German dress and indeed it presents some striking differences.

Probably the first feature that will catch the eye is the arrangement. As is known, in Flückiger and Hanbury's work the different articles of materia medica are arranged under the botanical orders to which the plants belong from which they are derived. In the 'Pharmakognosie,' however, this arrangement does not obtain, and, for reasons hinted at in the preface, the plan is adopted of classifying mainly in respect to the physical characters of the crude drug. As the whole of this scheme of classification will not be disclosed before the appearance of the third and concluding part, it will be premature to criticize it now, further than to say that as far as it goes the different substances described fall fairly well into the different classes and sub-classes in which they are found, though some curiosity is justifiable respecting the ultimate lot of some that are not yet dealt with. This feature is sufficiently interesting and important to justify a brief indication of its character.

The *First Class* includes "Vegetable Substances without Organic Structure," and it is subdivided into—"varieties of gum," "sweet exudations," "resin mixed with gum," "resins mixed with ethereal oils and gums," "resins with ethereal oils," "resins," "balsams" (aromatic acids, alcohols and ethers mixed with resin), "ethereal oils," "milky juices," and "extracts." The *Second Class* includes "Organized Substances," and is subdivided into—"substances in powder," "galls," and "vegetable organs not in the powder form," the last being an important subdivision, commencing towards the end of the first part and going entirely through the second.

In the subdivision of the First Class devoted to gums there are articles on gum arabic, Senegal gum, and tragacanth gum, and one in which the less important varieties of gums are briefly summarized. This subdivision well illustrates one of the features in which this work differs from 'Pharmacographia,' that it is written more specially for the German pharmacist, the article on Senegal gum, which in the English work only extends to ten lines, extending over three pages in the 'Pharmakognosie,' in accordance with the relatively greater importance of that gum on the Continent. Manna is the only representative of the "sweet exudations," and gamboge of the gum resins. The "resins mixed with ethereal oils and gum" are myrrh, olibanum, asafœtida, galbanum, and ammoniacum. The oleo-resins described are common, Venetian and Strassburg turpentines, Canada balsam, Burgundy pitch, elemi, and copaiba and gurjun balsams. Chian turpentine, which in 'Pharmacographia' occupies two pages, is, notwithstanding its recent resuscitation, left out in the cold, being only casually mentioned. Then come the "resins," which are colophony, sandarac, dragon's blood, guaiacum, mastic, and benzoin; but jalap and scammony resins are dealt with under their respective roots, and podophyllum resin and root are omitted. Next come the true "balsams," liquid storax, Peru and Tolu balsams. A subdivision of "essential oils" follows, but this only includes camphor and oils of cajeput and rose. By the way, in 'Pharmacographia' it is said that rose oil itself is no longer exported from Persia, and this is also implied in a statement in the 'Pharmakognosie' that it is only prepared for purposes of export in the districts south of the Balkans. But according to Douglas (*Pharm. Journ.*, [3], viii., 811), who is quoted as an authority by Professor Flückiger, "the greater part of the large quantities of rose oil consumed in Western and Northern India is imported to Bombay from Persia." The last two subdivisions in this class are tho "milky juices" (opium, euphorbium, and lactucarium) and the "extracts" (aloes, liquorice, kino, catechu, and gambier).

It will be seen from this outline of one of the principal divisions that although the arrangement has some disadvantages,—as, for instance, sometimes the wide separation of drugs derived from the same plant or closely allied plants,—it has the merit of bringing together substances resembling each other in some of their characters, and thus facilitating their study by comparison.

As previously mentioned, the whole of the second par- is taken up with a portion of the "non-pulverulent" subdivision of the Second Class ("Organized Substances"); this includes "roots," "rhizomes," "stems," "barks," and "bulbs." But the series of "subterraneous or partially subterraneous parts of plants" does not include the roots of *Actæa racemosa*, *Cochlearia Armoracia*, *Atropa Belladonna*, *Helleborus niger*, *Hemidesmus indicus*, *Chondodendron tomentosum* (or *pareira brava*), or *Ferula Sumbul*, or the corms of *Colchicum autumnale*. The woods are guaiacum, quassia, and red sandal (neither the wood nor the oil of *Santalum album* appears). In the subdivision devoted to barks the most important article is that on cinchona bark, which might indeed aspire to the position of a monograph on the subject. It is carefully brought up to date, including the latest information as to the origin of cuprea bark. We notice, however, that Professor Flückiger states that it is not established whether quinine sulphate crystallizes with 7 or 8 molecules of water, or a quantity lying between; in this he ignores the work done upon this subject by Cownley in 1876 (*Pharm. Journ.*, [3], vii., 189), from which it appeared that the freshly prepared quinine sulphate contains 7½ molecules of water of crystallization, but that when freely exposed to the air it effloresces rapidly until the proportion is reduced to 2 molecules, when it remains constant.

Although the possession of 'Pharmacographia' renders English students of materia medica practically independent of the work under notice, its publication is decidedly a valuable acquisition to German literature on the subject.

The Poison of the Stinging Nettle.

Sir,—In his lecture on the "Irritating Effects of Stings," reported in your last issue, Professor Vogel says:—"The irritating action of stinging nettles and other similar vegetables depends on formic acid." The same statement is frequently made in botanical textbooks. Can any of your readers refer to definite analyses from which it is deduced? Is it not a fact that the irritant fluid of the common stinging nettle always has an alkaline reaction? If this is so, it is difficult to reconcile with the presence of free formic acid.

The Keeping of Leeches.

Sir,—In reply to Mr. Baker, permit me to say that although both *Planorbis* and *Limnea* were present in my tank as well as *Paludina*, I have no hesitation in saying that the ova was that of the leech. A friend who is a noted naturalist, was of opinion, when first he saw them, that they were the ova of *Limnea*; but they agreed so very minutely with the description of the leech ova, in the original edition of Pereira, that I felt convinced my friend was wrong, and after watching every stage of their development, I had the satisfaction of proving to him that my opinion was the correct one, and for months I had a supply of leeches in every stage of development; they were seen by several gentlemen who were well qualified to form an opinion, so that there can be no possible doubt about the matter. I shall be glad to know if any other "keeper of leeches" has previously noticed this; those who are interested will find a very full and interesting account of the leech in the original edition of Pereira, vol. ii., part ii., pp. 2185, *et seq.*

Presence of Organisms in Solutions of Inorganic Salts.

Sir,—The interesting paper on this subject communicated to the Pharmaceutical Conference by Mr. Bothamley reminds me of a discussion on the same subject, which took place here and which may be of some interest in conjunction with Mr. Bothamley's paper.

In November last Mr. C. A. McPherson, of this city, brought before the Assistants' Association several samples of fluid magnesia containing a green deposit; this was shown by Mr. Boa to be composed of unicellular organisms, spherical in form and containing chlorophyll granules. It appeared identical with an alga which I had seen in laboratory magnesic sulphate solution. Mr. McPherson mentioned that it had developed in fluid magnesia obtained from various houses, and that the development took place in white flint glass bottles and not in those of blue glass. I have three of the samples still beside me; all of them have a heavy deposit of magnesic carbonate, in one bottle the crystalline mass is quite green, and the others show the organisms round the edge of the bottom. This is the only instance I have yet observed of the development of the organism in fluid magnesia.

One of the samples contains traces of ammonia and phosphoric acid. Sulphuric acid is also present to a small extent.

I agree with Mr. Bothamley that the organism is more like a species of *Chroococcus* than *Protococcus*; those which I have observed are non-ciliated and appear to multiply by cell division.

Should Mr. Bothamley continue his investigations it would be advantageous were he to direct his attention to the influence which blue light rays may have in retarding the development of the organism.

PETER MACEWAN.

Pharmaceutical Society's Rooms, Edinburgh.

G. E. Post.—We hope you will be able to renew your work eventually, and do not propose to make any alteration in the supply of the Journal at present.

T. J. Wilkes is recommended to devote his attention to the study of the principles underlying chemical reactions rather than to attempts to represent what takes place by diagrams.

F. W. Richardson.—*The Rainband in the Spectroscope.*—A very interesting communication upon this subject, from Professor Piazzi Smyth, will be found in *Nature*, October 5, p. 551. After premising that the slit should be narrowed down almost to extinction, and the eye-piece focussed carefully, Professor Smyth gives the following instructions:—"Observe always low down near the horizon, for atmospheric effects in the spectroscope are there nearly twenty times as strong as in the zenith. Get an opening between clouds if you can to observe through. Prefer that the sun itself shall be angularly distant from your observing direction; and behind a cloud also, if possible, at the instant, so as not to illumine the motes in the air of your neighbourhood with its high altitude light. Especially avoid the minutes of sun-rising or setting, for that act, or rather position, brings certain of the dry gas bands into a short-lived maximum of intensity, without any other signification than that the sun *is* then on the horizon. But good observations may often be taken through falling rain, though not through falling snow, and also between the earth and the under sides of the clouds, if they entirely shut out all view of the air of the heavens beyond them."

J. D. Lawton.—Probably *Solanum Dulcamara*; send a flower.

X. Y. Z.—(1) *Achillea ptarmica*; (2) *Artemisia Dracunculus*; (3) *Scrophularia*: send leaves if you wish to know the species.

H. S. C.—See *Pharm. Journ.*, [3], x., 603.

"*Minor.*"—The employment of iodoform in what appears to be large quantities has been advocated recently by several medical writers. We do not think that the propriety of such treatment can be advantageously discussed in these columns. But it may be remarked that it would be as well for prescribers to remember that the intensity of the action would probably depend to some extent upon whether the compound is brought into contact with the diseased surface in a finely divided condition or in scales.

An Associate.—Your question can only be answered by the result of experiments which you are recommended to carry out for yourself.

J. T. Hall.—(1) *Galium verum*; (2) *Ulva latissima*; (3) *Gigartina mammillosa*; (5) *Porphyra vulgaris*.

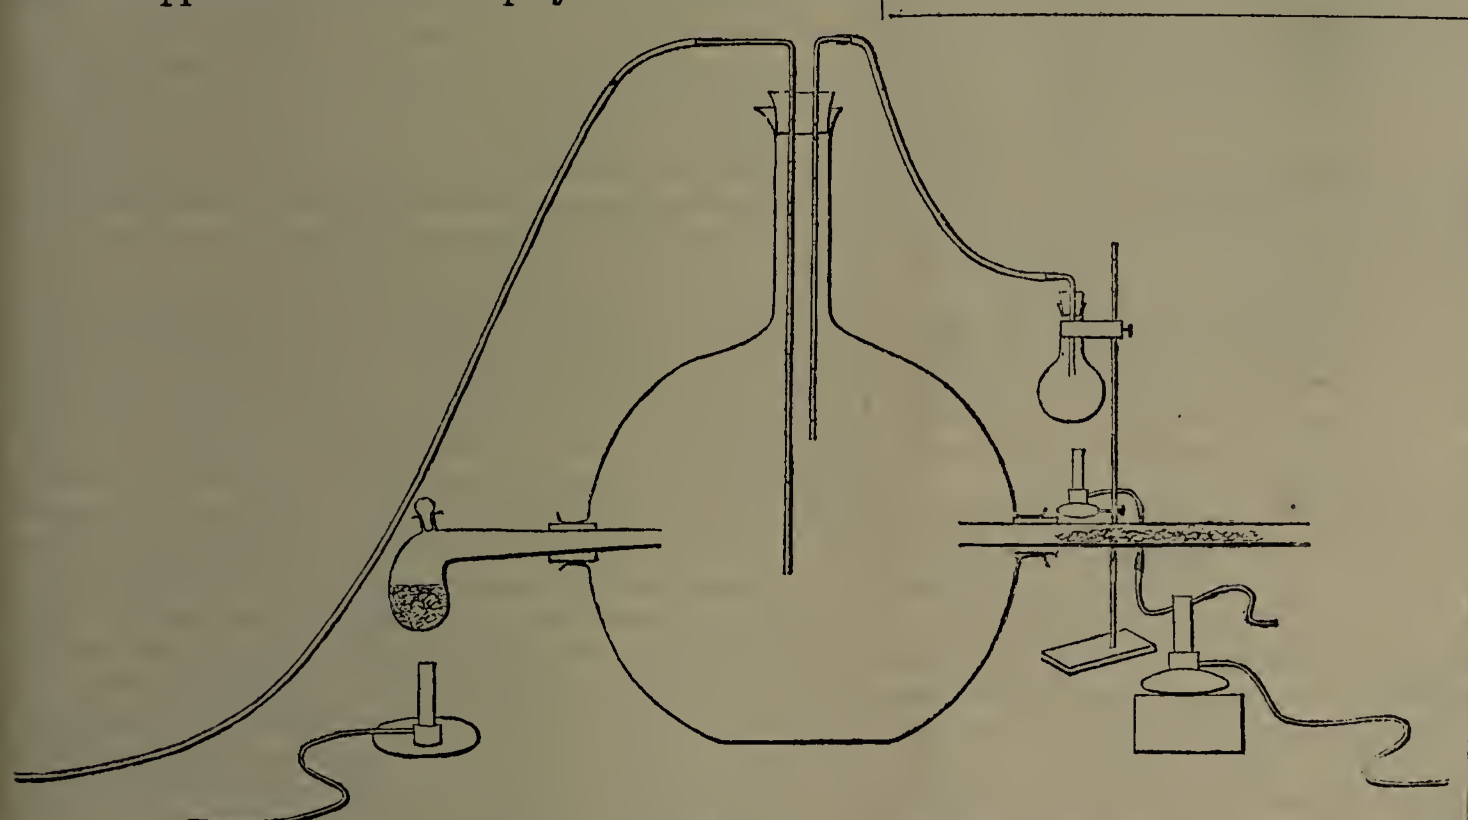
COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Lawton, Modlen, Candy, Woodland, Ward, Agricola, Fritz.

AN IMPROVED APPARATUS FOR ILLUSTRATING THE MANUFACTURE OF SULPHURIC ACID.

BY ALFRED SENIER,
Lecturer on Chemistry in St. John's Training College, Battersea.

The forms of apparatus described in chemical works for the purpose of illustrating the sulphuric acid manufacture experimentally very generally involve the logical error of taking the full quantity of sulphuric acid to begin with. This is to be avoided for educational reasons. There are, however, some exceptions to this general rule, and notably the apparatus recommended by Roscoe and Schorlemmer,* in which they employ sulphur burned in a current of air as the source of sulphurous anhydride. The apparatus here suggested is simpler and more easily constructed than that of Roscoe and Schorlemmer, and employs burning sulphur as a source of sulphurous anhydride. While, therefore, it is to be preferred to the best form of apparatus hitherto suggested, it is an important advance upon the methods generally recommended and employed in teaching. I have myself used the apparatus for several years.

The following drawing illustrates, in outline, the form of apparatus which I employ:—



Through a cork in one neck of the flask (of about a gallon capacity) is passed the neck of a small retort, containing nitre and sulphuric acid; through a similar cork in the opposite neck is passed one end of a piece of combustion tube, containing fragments of sulphur, and open at both ends; through the cork at the mouth of the flask are passed two tubes, one connected with a small flask, in which water is boiled, and the other connected with an aspirator,—preferably a gasholder full of water. Some of the sulphur in the combustion tube is heated to just above its melting point, when it ignites on a gentle current of air being caused to flow over the sulphur into the flask by means of the aspirator. Once started, the sulphur continues to burn by the heat of its own combustion, so long as the current of air is maintained. If it is wanted to introduce air it can be done easily without an extra tube, by stopping the aspirator a minute, when the burning sulphur is extinguished, and cooling below its ignition point, a flow of air passes over it through the combustion tube when the aspirator is again turned on. The sulphur can again be raised to the ignition point by momentary application of the Bunsen flame. In other respects, the mode of working is sufficiently obvious.

* 'Treatise on Chemistry,' vol. i., 322.

THE EXAMINATION OF BALSAM OF PERU.*

BY O. SCHLICKUM.

The author reports the results of a number of experiments having for their object the facilitating of the examination of balsam of peru for adulterants and the quantitative determination of these when present. As materials he used five guaranteed samples of balsam obtained at different times from different sources. The possible adulterants particularly investigated were castor oil, copaiba balsam, purified storax, an alcoholic solution of benzoin brought to the consistence of a balsam, and a similar solution of colophony. Before proceeding to methods of investigation the author makes the following remarks on the specific gravity and the free acids of peru balsam.

The specific gravity is a very important criterion of unsophisticated balsam. All the other substances above mentioned possess a lower specific gravity than the true peru balsam. The highest of the five specimens examined by the author was 1·148 and the lowest 1·142. Any sample of peru balsam having a specific gravity lower than 1·135 may therefore be regarded as adulterated. The specific gravity of castor oil and of copaiba balsam is in each case under 1·00, that of the former varying between 0·95 and 0·97, and that of the latter between 0·94 and 0·99. The specific gravity of the purified storax, which was obtained as a brown transparent balsam by extracting liquid storax with alcoholic ether and evaporating the clear filtrate, was determined as 1·090; that of the colophony solution as 1·016; and that of the benzoin solution as 1·080. These are all considerably below the specific gravity of the true peru balsam, so that an addition of one of them would markedly lower its specific gravity. For instance, an addition of 15 per cent. of benzoin solution to peru balsam, specific gravity 1·146, lowered the specific gravity to 1·135. The author prefers to use the pycnometer in determining the specific gravity of the balsam. The plan recommended by Hager, of observing whether a drop of balsam floats or sinks in a saline solution of known density, he considers to be defective, as the behaviour of the drop is affected by the conditions under which it reaches the surface of the solution.

The author does not consider that the estimation of the free acid constitutes such a good criterion as the specific gravity. The five genuine samples of peru

* Abstract of a paper in the *Archiv der Pharmacie*, [3], xx., 498.

balsam required from 5·1 to 7·2 per cent. of soda crystals for their exact neutralization. The purified storax corresponded to 4·5 to 5·1 per cent.; the copaiba balsam to 5·1 per cent.; the colophony solution to 7·5 per cent.; the benzoin solution to 14 per cent. of soda; only the castor oil was devoid of free acid. The estimation of free acid would therefore only be of use in conjunction with other tests, chiefly in the determination of admixture with benzoin or castor oil, the former increasing and the latter diminishing the acidity.

A. Behaviour of Balsam of Tolu towards Solvents.

(1). Spirit of wine dissolves half its weight of peru balsam almost clear; a further addition of spirit, however, renders the solution turbid, through separation of a small quantity of resin. Ether behaves similarly; it mixes clear with an equal quantity of balsam, but the solution becomes turbid upon the addition of more ether, resin separating equal to about 6 per cent. of the peru balsam.

As ether and alcohol easily form clear solutions with both castor oil and the colophony solution, they do not furnish a means for detecting admixtures of these substances. Purified storax and copaiba balsam give with alcohol very turbid and with ether clear solutions; benzoin solution mixes clear with alcohol, and turbid with ether, about 10 per cent. of resin separating. Consequently these solvents give no decisive indication of adulteration of peru balsam with the last three substances.

(2). Carbon bisulphide dissolves peru balsam with the exception of 11 to 16 per cent. of resin, which adheres so fast to the sides of the vessel that the light coloured solution can be poured off clear. Benzoin resin is almost insoluble in carbon bisulphide, giving up only the benzoic acid present, so that carbon bisulphide furnishes a good means for detecting a large admixture of benzoin. The following table shows the behaviour of one part of the substance tested in two parts of carbon bisulphide.

One part of	In two parts of Carbon Bisulphide.
Peru balsam	At most 16 per cent. of resinous residue. The genuine samples varied from 11 to 16 per cent.
Purified storax . . .	Dissolved completely; clear solution.
Colophony solution . .	Entirely soluble; perfectly clear.
Copaiba balsam . . .	Dissolved completely; quite clear.
Castor oil	Dissolved completely; quite clear.
Benzoin solution . .	60 per cent. of resinous residue.

Consequently if a sample of peru balsam, when shaken with double its weight of carbon bisulphide, yields more than 16 per cent. of undissolved resinous residue, an admixture of solution of benzoin is probable.

(3). Petroleum spirit takes up from peru balsam a light yellowish balsam, probably consisting principally of cinnamein (benzyl cinnamate). Upon saponifying this with alcoholic solution of caustic soda, besides sodium cinnamate, benzyl alcohol is obtained, easily recognized by its intense hyacinth odour. By repeatedly shaking peru balsam with three or four times its quantity of petroleum spirit half of it is dissolved and half remains undissolved. The following shows the relative behaviour of the other substances:—

	Shaken with Petroleum Spirit.
Peru balsam	Half dissolved.
Purified storax . . .	About one-third dissolved.
Benzoin solution . .	Only 12 per cent. dissolved.
Colophony solution . .	More than half dissolved (40 per cent. of resin).
Copaiba balsam . . .	All dissolved.
Castor oil	All dissolved.

Consequently if a sample of balsam gives up more than 50 per cent. to petroleum spirit an admixture of copaiba balsam or castor oil is indicated.

B. Behaviour of Peru Balsam towards Caustic Lime.

When peru balsam is mixed with dried calcic hydrate, no saponification or decomposition of the cinnamein contained in it results; neither does this take place if water or alcohol be added. The cinnamein can be extracted from the mixture by means of petroleum spirit, and in a large number of experiments with peru balsam the proportion was found to remain constant at 41 per cent. of the balsam used. From the residue undissolved by petroleum spirit ether dissolves out about 14 per cent. of styracin, which differs from cinnamein in being difficultly soluble in cold alcohol, and in yielding upon saponification with alcoholic soda solution not benzyl alcohol, but cinnamyl alcohol, together with sodium cinnamate.

Purified storax behaves similarly, but gives up somewhat less cinnamein to petroleum spirit and about as much more styracin to ether. Colophony and benzoin solutions, when macerated with calcic hydrate, combine with it so that petroleum spirit extracts scarcely anything from the mass. On the other hand castor oil can be completely removed with petroleum spirit as long as there has been no addition of water; but if castor oil be digested in a water-bath for several hours with calcic hydrate and successive additions of water, saponification takes place, and petroleum spirit no longer dissolves out oil from the mass. Copaiba balsam behaves similarly, its resin eventually combining with the lime, after which petroleum spirit only dissolves out the essential oil of the balsam.

After several hours' digestion with caustic lime and water, petroleum spirit removes from—

Peru balsam	41 per cent.
Purified storax.	35 per cent.
Copaiba balsam	Its essential oil.
Castor oil	Almost nothing.
Benzoin solution	Almost nothing.
Colophony solution	Almost nothing.

This method is not very suitable for the recognition of the substances used for sophistication, but it is of great value in their quantitative determination.

C. Behaviour of Peru Balsam towards Caustic Ammonia

When an ethereal solution of peru balsam is shaken with ammonia solution, sp. gr. 0·960, two yellowish-brown layers are formed, between which brownish flocks swim. The upper layer is the ethereal solution of the balsam, and leaves when separated and evaporated about 80 per cent. of the quantity used as a brown balsam. The inconsiderable resinous mass swimming between the two layers adheres partially to the side of the vessel. The lower ammoniacal layer, when separated and rendered acid with acetic acid, shows a whitish turbidity, but becomes almost clear on boiling and again turbid on cooling through separation of cinnamic acid, without, however, forming a solid deposit at the bottom. The ammonia solution withdraws the free cinnamic acid from the balsam, without affecting its other constituents.

Benzoin solution behaves similarly. It gives up to the ethereal layer the greater part of its resin, whilst the watery layer takes up the benzoic acid, and upon supersaturation with acetic acid and boiling becomes only slightly turbid.

Castor oil passes so completely into the upper ethereal layer that the ammoniacal layer upon being acidified scarcely separates a single oil globule.

In the case of colophony solution and copaiba balsam the resin combines with the ammonia, so that when the lower layer is rendered acid and boiled a considerable separation of solid resin takes place.

With purified storax there is scarcely any separation into two layers, but it yields a stiff homogeneous jelly that will hardly flow from the glass.

This holds nearly good for a mixture of equal quantities of peru balsam and purified storax; if less storax be present there is a separation into layers, but gelatinous lumps are to be seen swimming in the ethereal solution. Whilst also with pure peru balsam the lower ammoniacal layer, when separated and supersaturated with acetic acid, appears only slightly turbid upon boiling, the lower liquid layer from a balsam adulterated with copaiba balsam or colophony, when similarly treated, shows a separation of more or less solid resin.

D. Action of Strong Sulphuric Acid on Balsam of Peru.

If peru balsam be mixed with at least an equal quantity of concentrated sulphuric acid, the mass becomes hot, blackened and thickened. Upon washing it with hot and afterwards with cold water, it is at first plastic, but after cooling becomes solid and brittle. If it be spread out smooth, dried superficially with blotting paper, crushed and placed in a test tube with several times its quantity of ether, complete solution takes place in a short time. When a small quantity (1 to 2 grams) of peru balsam is used no smell or frothing or evolution of vapour is observed when the mixing takes place; but with larger quantities these phenomena are manifested, sulphurous acid being set free. When the test is used with the adulterants mentioned, their behaviour in small quantities—1 gram—exactly resembles that of genuine peru balsam; except in the case of copaiba balsam with which, even in the smallest quantity, there is strong frothing and an evolution of white vapour and sulphurous acid. With colophony, benzoin, storax and castor oil these appearances are first manifested with a quantity exceeding 2 grams. Consequently, if frothing and evolution of sulphurous acid commences when the quantity is limited to 1 gram, the presence of copaiba balsam may be concluded.

The washed resinous mass is completely soluble in ether, as before mentioned, so long as it contains neither benzoin nor storax. But if only a small quantity has been taken for the experiments, so that no reduction of sulphuric acid has taken place (1 gram of balsam and 1 gram concentrated sulphuric acid), a sample containing storax or benzoin yields a mass that when washed and superficially dried is only partially soluble in ether. Upon mixing 1 gram of substance with 1 gram of concentrated sulphuric acid, and subsequently washing with hot and afterwards with cold water, there was obtained with peru balsam, copaiba balsam, or colophony, a solid brittle mass completely soluble in ether; with purified storax or benzoin a solid brittle mass, only partially soluble in ether; and with castor oil a smeary greasy mass completely soluble in ether.

The smeary property which castor oil imparts to the sulphuric resinous mass indicates with certainty the presence of this oil. In the case of all the other substances the washed residue possessed a plastic or even crumbling character, and became quite hard on cooling.

If the insoluble residue be well washed on a filter with ether and then treated with alcohol any portion of it derived from benzoin dissolves completely. If it owes its origin to storax a small white residue is left, consisting of a substance first observed by the author in 1881 and which E. Mylius has named styrogenin, and represented by the formula $C_{26}H_{40}O_3$. Styrogenin is still better isolated by treating the residue left by ether with acetone, which dissolves any portion of the residue derived from benzoin completely and that from storax all except the styrogenin. Styrogenin is insoluble in water, alcohol, acetone and alkalies, but is easily soluble in chloroform. It can therefore be readily got pure by treating with a little chloroform the white powder left after washing the ether residue with acetone or spirit, and allowing the chloroformic solution to evaporate in a watch glass. The styrogenin is thus obtained in microscopic crystals partly tabular and partly more pointed, but always prismatic.

If larger quantities of storax be used no styrogenin is obtained, since the reduction of the sulphuric acid thus set up involves the decomposition of the storax in other ways. But with quantities not exceeding 1 to 2 grams storax always yielded the author styrogenin. It is also requisite that the quantity of sulphuric acid used should not be less than that of the balsam. Storax yields from 6 to 7 per cent. of styrogenin.

If therefore a sample of peru balsam treated with sulphuric acid is not entirely soluble in ether, the residue if completely soluble in acetone or alcohol indicates an adulteration with benzoin; but if a white powder insoluble in acetone or alcohol be left, it shows an adulteration with storax. This powder may then be dissolved in chloroform and left to crystallize.

Scheme for the Qualitative Examination of Balsam of Peru.

(1). The specific gravity should be determined. It should never fall below 1·135.

(2). Upon shaking 1 gram of balsam three or four times with several grams of petroleum spirit, not more than 0·5 gram should be taken up, so as to be left behind upon evaporation. Otherwise an admixture of castor oil or copaiba balsam would be probable. The latter would be recognizable by the odour of the essential oil.

(3). Dissolve 1 gram of balsam in several grams of carbon bisulphide and estimate the undissolved portion, dried at 140° C. This should not amount to more than 0·16 gram, otherwise an admixture of benzoin is probable.

(4) *a.* Mix 1 gram of balsam with 1 to 1·2 gram of concentrated sulphuric acid. If frothing and a smell of burning sulphur be observed an admixture of copaiba balsam is probable. (Confirm by tests 2 and 5.)

b. After the mixture has cooled wash it first with hot and then with cold water. The residue should be at first plastic and afterwards hard and brittle. A smeary character indicates an admixture with castor oil. (Confirm by test 2.)

c. Dry the washed resinous mass superficially with blotting-paper and dissolve it in several grams of ether. It should dissolve completely; if an insoluble residue be left it indicates an admixture of benzoin or storax. Treat this insoluble residue with strong alcohol, or preferably with acetone. If it dissolves completely, the adulterant is benzoin, in cases where carbon bisulphide leaves more than 16 per cent. of the balsam undissolved (test 3). If after treatment with alcohol (or acetone) there remains a white powder, easily soluble in chloroform and separating in microscopic crystals upon evaporation of the solvent, storax is present. (Confirm by test 5.)

(5). Dissolve 1 gram of balsam in 3 grams of ammonia solution, specific gravity ·960. No gelatinization of the mixture should take place, or appearance of gelatinous fragments swimming in the ethereal layer; otherwise storax is present. (Confirm by test 4.) The mixture should separate readily into two layers, the lower of which when separated, supersaturated with acetic acid and heated to boiling, should only present a slight turbidity. The separation of solid resin shows copaiba balsam or colophony. The former gives the reaction mentioned under test 4; further, the extract obtained by evaporation of the petroleum spirit solution (test 2) has clearly the smell of oil of copaiba, whilst a colophony residue has no special odour.

Quantitative Estimation of Adulterants.

(1). Estimation of Benzoin Admixture.

a. An admixture of solution of benzoin increases the amount insoluble in carbon bisulphide, which in the case of genuine peru balsam was never found by the author to exceed 16 per cent., to the extent of the whole of the benzoin resin, exclusive of the benzoic acid by which it is accompanied, and this may be used as the basis of one method of estimating the extent of adulteration with benzoin.

Example.—1 gram of a mixture of equal parts of peru balsam and an alcoholic solution of benzoin containing 75 per cent. of resin, when treated with carbon bisulphide, left a residue which, dried at 100° C., weighed 0·38 gram.

Of this 0·08 gram is reckoned as belonging to the half gram of peru balsam and the remaining 0·30 gram as the amount of resin in the half gram of benzoin solution.

b. A second method of estimating added benzoin is based upon the amount of residue insoluble in ether after the sample of balsam has been heated with sulphuric acid. The undissolved residue amounts to about half the benzoin resin or one-third of the benzoin solution.

Example.—1 gram of a peru balsam containing 14 per cent. of benzoin solution, after treatment with sulphuric acid, left a residue of 0·05 gram insoluble in ether, which represented 10 per cent. of benzoin.

c. The direct estimation of the peru balsam in a sample adulterated with benzoin may be effected by repeatedly shaking it with petroleum spirit, which dissolves out nearly half the peru balsam as well as the benzoic acid of the benzoin. If 1 gram of the balsam be mixed with 0·30 gram of calcic hydrate and allowed to stand an hour the petroleum spirit then dissolves only 41 per cent. of the balsam of peru present, so that the quantity of this may easily be calculated.

Example.—From a balsam mixed with 14 per cent. of benzoin solution, after maceration with calcic hydrate, petroleum spirit dissolved 35 per cent. (cinnamein), which, according to the proportion $41 : 100 = 35 : x$, indicated 85 per cent. of peru balsam.

(2). Estimation of Admixture of Purified Storax.

As purified storax consists, like peru balsam, mainly of styracin, cinnamein and cinnamic acid, though with a greater preponderance of styracin, the estimation of added storax is difficult, and can only be effected by preparation of the crystalline styrogenin as before described. The quantity of styrogenin left after evaporation of the chloroform amounts to about 7 per cent. of the storax present in the balsam.

Example.—1 gram of a mixture of equal parts of peru balsam and purified storax yielded 0·04 gram of styrogenin.

(3). Estimation of Admixture of Colophony.

a. The direct estimation of colophony is effected by shaking the ethereal solution of balsam with ammonia solution, sp. gr. ·960, as before described, and separating the resin taken up by supersaturating with an acid. The solid resin dried at 100° C. amounts to seven-eighths of the colophony present.

Example.—One gram of balsam mixed with 23 per cent. of a 60 per cent. solution of colophony yielded 0·115 gram of solid resin from the ammoniacal layer of liquid.

b. The direct estimation of the peru balsam present may be made by macerating the sample with caustic lime and exhausting with petroleum, as in the estimation of benzoin.

Example.—1 gram of balsam containing 23 per cent. of solution of colophony, macerated with caustic lime, gave up to petroleum spirit 0·32 gram (cinnamein), corresponding, according to the proportion, 41 : 100, to 0·78 gram of peru balsam.

(4). Estimation of Admixture of Castor Oil.

The author was unable to accomplish the direct estimation of the castor oil, being unable to separate it from the balsam by any suitable solvent; nor was he more successful in saponifying it with an alcoholic solution of an alkali. An attempt was also made to remove the oil from the resinous mass resulting from treatment with sulphuric acid, but it was found that the castor oil was so much decomposed by the strong acid as to be no longer soluble in petroleum spirit.

a. The amount of admixture may, however, be estimated by first ascertaining the amount of cinnamein and castor oil dissolved out by petroleum spirit, and then the amount of cinnamein alone. 1 gram of the mixture of balsam and castor oil is first macerated for an hour with 0·30 gram of caustic lime, without the addition of water, and then exhausted with petroleum spirit, which dissolves the cinnamein (41 per cent.) of the balsam together with all the castor oil. A second quantity, with the addition of water, is macerated in a water-bath for several hours, by which the saponification of the oil, but not of the balsam, is induced. Petroleum spirit then dissolves only the cinnamein of the balsam. The difference in the two results gives the amount of castor oil, whilst the quantity of peru balsam can be easily calculated from the cinnamein. Of course the exactitude of the result is dependent upon the complete saponification of the oil.

b. A more simple plan is to exhaust the sample by three or four shakings with petroleum spirit, and then to estimate the soluble constituents by evaporating the solution, and the insoluble by drying the residue. The former include nearly one-half of the peru balsam together with castor oil; the latter more than one-half of the peru balsam present. By subtracting the amount undissolved from that dissolved an approximation to the quantity of castor oil is obtained.

Example.—1 gram of balsam containing 23 per cent. of added castor oil, left after four shakings with petroleum spirit 0·40 gram undissolved, which indicated approximately 80 per cent. of peru balsam. The petroleum spirit left upon evaporation 0·60 gram of oily residue, which quantity indicated somewhat more than 20 per cent. of castor oil ($0·60 - 0·40 = 0·20$).

(5). Estimation of Admixture of Copaiba Balsam.

a. The proportion of peru balsam is estimated directly by digesting the sample for several hours with caustic lime and water, exhausting the mass completely with petroleum spirit and leaving the filtered liquid to evaporate. In this way there is at first obtained 41 per cent. of the peru balsam, together with the essential oil of copaiba. To volatilize the latter the residue is heated in a water-bath until it no longer perceptibly loses weight. What is now left represents 41 per cent. of peru balsam, whilst the loss in weight gives the amount of essential oil of copaiba.

b. The amount of copaiba resin is found by means of the caustic ammonia test, as described for colophony. If to this be added the amount of essential oil, as obtained in the preceding experiment, the total will represent the amount of copaiba balsam present.

Example.—One gram of peru balsam containing 30 per cent. of added copaiba balsam after being digested with lime and water gave up to petroleum spirit 0·38 gram, which in the water-bath decreased to 0·27 gram, representing 0·11 gram of essential oil. The 0·27 gram of residue indicated 66 per cent. of peru balsam. (41 : 100.) One gram of the same sample gave when treated with ammonia solution 0·17 gram of solid resin, which added to the 0·11 gram of essential oil made a total of 0·28 gram, or 28 per cent. of copaiba balsam.

b. A more simple and sufficiently exact method is to shake the sample repeatedly with petroleum spirit, and to weigh the undissolved portion after drying at 100° C., and the dissolved portion after evaporation of the spirit at the ordinary temperature. The undissolved portion amounts to a good half of the peru balsam, and by subtracting the amount from that of the evaporation residue, an approximation to the quantity of copaiba balsam is obtained.

Example.—One gram of peru balsam containing 30 per cent. of added peru balsam left after shaking with petroleum spirit 0·35 gram undissolved, or equal to 70 per cent. of peru balsam. The petroleum spirit left upon evaporation 0·65 gram. Consequently $0·65 - 0·35 = 30$ gram (30 per cent.) of copaiba balsam.

PRECIPITATES IN FLUID EXTRACTS.*

BY J. U. LLOYD.

In considering the formation of precipitates or sediments in fluid extracts and tinctures, I have previously presented a line of experiments to show that, to a greater or less extent, they result from the mixing of various solutions whereby a new solvent is formed, and which is incapable of retaining in solution the matters extracted from the crude material by each section of the original percolate, hence a line of precipitates. As this act of precipitation progresses, the solvent power of the menstruum changes, in consequence of deposition of material which formed a part of the previous liquid; therefore the deposition of one precipitate led to the formation of others. If this phase alone were to be considered, after a certain length of time, varying perhaps from months to years, the menstruum would arrive at a point where it could hold in solution all of the material then dissolved, and at this point the act of precipitation would cease. This view of the case must be accepted, even if we assume that none of the constituents in solution are soluble, after purification in the original menstruum; for, after a certain time under such conditions, a pure menstruum would remain, and all of the dissolved matter would have settled to the bottom of the vessel.

Now we know that this point is never reached. Fluid extracts and tinctures often precipitate to a very great extent, and sometimes become much lighter in colour, but never reach a point where all of the dissolved matters become insoluble. Upon the other hand, under ordinary conditions, changes usually follow as long as we may keep a specimen of fluid extract, and the result of these changes is a continuous precipitation. In taking up this phase of the subject, it may seem that the two preceding statements contradict each other. However, such is not the case, for continuous precipitation may be taking place without depleting the liquid of dissolved matters, and may continue for an indefinite period. Let me introduce the proposition with the following experiment, which, although apparently foreign to our subject, will illustrate phenomena which follow with the tinctures and fluid extracts upon our shelves.

Into a glass vial from six to twelve inches in length and an inch in diameter, pour distilled water until it is half filled, then finish filling the tube with simple syrup. The mixture at first will not be transparent, owing to the different refractive power of the mixture of liquids; after a time, however, the liquid appears homogeneous and transparent, and is apparently uniform, a diluted syrup. Place the tube near a warm stove, or hang it against a hot steam-pipe, and in a few moments the liquid will have divided into several sections by what appear to be sharp planes.† These planes of division resemble the plane which divides a layer of chloroform from a layer of water, and are fully as sharply defined, but the refraction of light from the surfaces of the upper and lower liquids is not as great. To observe the lines of division most readily place the eye on a level with the tube, and gradually raise or lower the head so as to bring the edges of the planes one after another before the eye, when sharp distinct lines will appear. If the eye be just above or just below the edge of the plane, a reflection from its surface will become apparent and which resembles the aforenamed reflection from the contact surfaces of chloroform and water. These divisions remain for some time, often for days, dependent upon the diameter and length of tube, difference in gravity and viscosity of the liquids and the heat to which the tube is subjected.*

Let us examine more closely the contents of the tube while heat is being applied, and during which the planes to which I have referred are distinct. If the solutions are transparent and the heat regular, the observer will not be able to detect a trace of motion. The lines which are the edges of the planes of demarcation will steadily hold their position as though fixed on the glass, and the liquid between the lines will appear to be at rest. These conclusions are erroneous, however, for the planes are gradually shifting their positions, and from time to time will severally disappear, to be succeeded by others, and the liquid within the tube is in rapid motion.

If the experimenter will scatter over the surface of the liquid a few particles of some finely divided powder, which is insoluble in the liquid, each particle will settle with a steady motion until it strikes the upper plane, where the downward motion will experience more or less of a check, as though it had struck some obstruction; then it will pass through the second section of liquid with decreased velocity. Upon reaching the second dividing plane another arrest in the velocity of the downward motion will be experienced, and the particles will afterwards settle more slowly. This experience will be repeated with each plane and each section of the solution until the fall of the powder ceases. Now it will be found that each plane or section of liquid will have arrested certain portions of the powder. This distribution is in accordance with the gravity of the different particles of which the powder is composed; those of less density being first arrested, and others in accordance with their weight, falling until they reach a section of solution, or a plane, of their own specific gravity, and such particles as have a greater gravity than the lower stratum of solution will have reached the bottom of the tube.

Let us now consider the composition of this solution, and the changes which give rise to the formation of these planes of division and intervening sections of liquid, each of different specific gravity.† When we poured the syrup into the water, by reason of its greater gravity a portion of it settled to the bottom and formed a layer of syrup. Other portions become more or less mixed with water, and, in accordance with the gravity of each mixture, arranged themselves over the syrup. This selection of position continued, the upper portion of the tube containing nearly pure water. In a short time the act of diffusion had blended the points of contact between the various solutions, giving to the contents of the tube the appearance of a homogeneous liquid. When heat was applied to one side of the tube, expansion of the liquid next to that side resulted. Each portion of the liquid next the heated side of the tube started upward, but, excepting more or less of the top of the liquid, each heavy layer quickly reached a lighter overlying stratum through which, by reason of its greater gravity, it could not ascend.

* Read at the meeting of the American Pharmaceutical Association held at Niagara Falls, 1882.

† It might naturally be supposed, that when the heat is applied to one side of the length of a tube under the conditions named, there would be one upward current of fluid would result along the entire side next to the heat. If this were the case, in a few moments the entire contents of the tube would be a uniform mixture. Such is not the result, however, and in consequence much time is necessary to effect this end. On a larger scale, but following the same principle, we have oceanic and atmospheric currents, giving us the Gulf Stream and the strata (clouds) of condensed or precipitated vapour between the moving currents of air.

* By viscosity of liquids I refer to those that have little diffusive power, and which are known to form ropy and sticky solutions. Thus, under the same conditions, a heavy solution of potassium bromide will disappear much sooner than a solution even of less gravity of gum or glucose.

† I have as yet simply made the statement, that these sections are composed of different solutions, and have brought no proof to demonstrate the fact. This is self-evident, however, although it is but just for me to say that these sections have been examined severally at different times, and invariably there is an increase of solid matter in solution as we progress from the surface downward. The following example illustrates this fact, a tube containing a dense solution of sodium chloride overlaid by distilled water having been submitted to a one-sided heat until it had formed five zones. Upon removing 1 c.c. from each zone, the proportion of sodium chloride was as follows:—

No. 1 (top), 0·24 gr.; No. 2, 0·73 gr.; No. 3, 2·37 grs.; No. 4, 3·97 grs.; No. 5, 4·44 grs.

Hence at intervals the top of each stratum of this current ceased to rise, but owing to the upward pressure of the current beneath it was crowded away from the side of the tube and into the cool solution beyond. The deficiency occasioned by this upward current was supplied from the lower part of each section of liquid, and quickly we had a circulation of liquid, Each of these eddies continued to increase in a horizontal direction, but remained bounded by nearly the same planes above and below. Finally the entire tube was filled with eddies each of less specific gravity than the one below.

When we dropped the powder on the surface of the liquid within the tube, each particle descended in the manner before explained, until it reached a section of solution nearly of its own specific gravity, where its fall was arrested. Not so the motion, however, for each particle of powder circulated with the liquid within which it was retained, thus showing us exactly the movement of each section of solution within the tube.* This movement will continue while heat is being applied, or until the entire liquid within the tube is of the same composition, and then the solution as one body will circulate from the bottom to the top of the tube.

The experiment which I have described, and which all can verify easily, is typical of the motion which always results when heat is applied to liquids of different specific gravities, and if they are capable of forming a solution one with another. A variety of movements may be obtained by varying the position of the body which imparts the heat, but such variations simply result from modification of manipulation. It matters little whether the heat be applied evenly to all parts of the vessel, to the bottom, or to other sections, circulation follows, and the result is finally a uniform mixture of the liquids.†

If a tincture or a fluid extract be made by percolation, and the percolate be received in the order obtained, there will be a decrease in gravity from the bottom of the container upward. This is in consequence of the well-known fact that the denser part of the percolate passes first, and that the percolate grows less dense with more or less regularity as percolation progresses. When such a percolate is permitted to stand it will resolve itself into strata, and the liquids will mix in a manner similar to those in the experiment we have cited. The phenomenon is not so readily observed in these instances, owing to the fact that most percolates are dark in colour and will not permit the passage of light, but the collection of strata of precipitates at one or more points throughout such liquids indicates where the lines of division are to be found; and it is for the purpose of introducing these precipitates understandingly that I have briefly directed attention to the experiment with the tube of liquid, and I will now return to a more minute analysis of the changes which occur.

Under the conditions we have named, it has been shown that each solution rested upon one more dense, and where the liquids are in contact we have motion in opposite directions. The surfaces of each of these liquids appear to be in direct contact, and to move as though pressing against a solid plane, which is the line of division between them. If we magnify this apparent line, it will be found of considerable thickness, and in reality to consist of a stratum of fluid almost at rest as compared with the rapid flow of the upper and lower strata. However, it is in a state of excitement occasioned by the friction of the two opposing solutions, and is eddying and struggling as it is tormented by these contrary agents. It will be further found that portions of the upper side of this thin stratum are being constantly torn off and carried mechanically into the upper liquid; and this is true also of the lower side and the lower liquid. As the stratum is made up of a mixture of these two revolving bodies, and its existence depends upon an admixture of these liquids, it follows that whenever a portion of the stratum is detached and carried into one liquid, the result is an admixture with it of a portion of the other liquid. Inasmuch as these admixtures are constantly taking place while the circulation of the liquid continues, it follows that there is a continual handing down of the upper revolving liquid, and a handing upward of the lower. When we consider that the foregoing example is a simile of changes that are taking place throughout the entire tube with each of the other sections, we must see that at some time the liquid at the bottom and the liquid at the top of the tube will have become identical in composition. We can also see that this interchange is independent of the act of diffusion, and can only be considered a result of mechanical action, the primary agent being heat. Now if we have a liquid at the top of the tube differing from that at the bottom to such an extent that when these liquids are mixed precipitation results, it follows that wherever the liquids are interchanging in the proper manner precipitation must follow at that point.* Hence it is that I have called attention to the foregoing argument and experiments as a means of illustrating a fact connected with precipitates in tinctures and fluid extracts, which perhaps has not presented itself to many of us, but which will be often noticed after attention has been called to the matter.

(*To be continued.*)

* I speak now of a rapidly circulating solution and a precipitate near its own gravity. If the section is moving slowly and the precipitate heavy, the particles of powder will either rest upon the plane of division, or, seeking the side of the vial next the heat, in obedience to the motion of the lower part of the stratum, will adhere to the glass.

† During the past six years I have carried on a series of experiments regarding this motion of fluids, but the example I have given is all that is necessary for the subject now under consideration.

* This may be nicely illustrated by introducing at the bottom of the tube a pellet containing a decided trace of potassium ferrocyanide, and dropping on the top of the liquid a little solution of a ferric salt. The formation of a blue precipitate in some intermediate stratum shows where the two come together.

THE LACQUER INDUSTRY OF JAPAN.

BY JOHN J. QUIN,

Her Majesty's Acting Consul at Hakodate.

(*Concluded from page* 309.)

Colouring Matters used.

Shu (vermilion).—For red lacquer, used also mixed with gold dust for shading.

Sei-shitsu (green lacquer).—A mixture of *Kiō* (chrome yellow) and *Bero-ai* (Prussian blue).

Muras-aki-ko (purple powder).—A mixture of white lead and *Tō-beni* (*Magenta roseine*).

Benigara (red oxide of iron).—Sometimes used instead of vermilion.

In the district of Aidzu the light colours are produced to the greatest perfection, viz., yellow, green, and intermediate shades. In Tôkiô, though the same materials are used, the resulting colours are inferior and darker. In Aidzu no after polishing takes place with coloured lacquers. The lacquer is applied like paint. Tôkiô is, however, best for black lacquer, as well as for such high-class red, etc., as are polished afterwards. These differences are attributed to some climatic influence.

The *Kioto*, so called "black lacquer," shows a reddish-brown tinge. With the exception of Tôkiô, Kioto, Osaka, Kaga, Tsugaru, Wakasa, Nagova, Suruga, and Shidzuoka, and one or two isolated places, the method of smoothing with charcoal and afterwards polishing is not pursued. In Tsugaru and Wakasa neither flat nor raised gold lacquer is manufactured.

It should be mentioned that the plain lacquered articles are almost exclusively manufactured by one set of workmen, who supply the workers in gold lacquer with the articles ready for the application of the gold powdering, various patterns, etc.

The wholesale lacquer trade is in the hands of a few large merchants. In Tôkiô there are two houses only. These receive the crude lacquer from the producers as it arrives from the various districts, either buying it outright or making advances to the contractors, who are bound by the rules of the guild to deliver only to them. They sell it in quantities as required to the lacquer manufacturers, who prepare and refine the sap for the market, and these again retail the material to the lacquer workers. The various processes that the lacquer undergoes in the hands of the manufacturers before retailing are kept secret, only the approximate mixtures being known.

That all lacquer, even that sold as pure lacquer, undergoes some adulteration, is rendered evident from the fact that, in accordance with a strange custom peculiar to the lacquer trade, the retail manufacturers sell even the smallest quantity at the same rate at which they buy it from the wholesale merchant.

Among the Tools and Materials used in the Manufacture of Gold Lacquer, are—

Neji-fude.—Brushes made of rats' hair, used for tracing out the patterns, and for drawing the very fine lines, etc. The best are made of the long hairs from the backs of "ship rats," whose fur is not so likely to get rubbed.

U-no-ke-usuji-fude (fine brushes made of hares' hair).—These are a little larger than rats' hair brushes, and are used for filling in the patterns of the best articles, also for drawing outlines on common articles and ground work. There are two sizes, *Dai* and *Sho*, used for drawing "large" and "small." There are besides five sizes of *Ji nuri fude* (grounding brushes).

U no-ke-hake (a flat brush made of hares' hair, used for spreading the lacquer on large pieces of work).—There are two sizes used.

Men-sō (a stiff brush made of deer's hair, used for applying the *Sabi*, etc., in making raised gold lacquer).—It is only used for stiff mixtures.

Haké (flat brushes of human hair, for smoothing the lacquer after application, as in ordinary plain lacquer).—There are two sizes used.

Bun-mawashi (compass with fine brush attached for describing circles).

Ké-bo (brushes made from the long body hairs of a horse, used for smoothing the fine gold powder and brushing off extra particles, used also for dusting).—There are four sizes.

Fude-arai (brush cleaner, made either of ivory or tortoise shell).—The brushes have to be very carefully cleaned, after using, with *Sesamum orientale* oil, to remove every trace of lacquer.

Tsutsu (a quill, from the wing of a swan or crane, over one end of which is stretched a piece of silk, used for scattering the gold dust).—There are two sizes used.

For applying *Nashiji* or *Hirame* bamboo tubes of three different sizes are used, with silk of more open texture.

Saji (spoon), for putting the gold dust into the quill or bamboo tube.

Hirame-fude.—A pointed piece of bamboo or other wood, used for picking up and applying *Hirame*, or the gold, or shell squares.

Kujira-bera (whalebone spatula).—Used for mixing the materials, and also when transferring the tracing on the paper to the article to be painted (process described farther on). The kind used is called island wholebone, and comes from China; that obtained from Japan is practically useless, being liable to split. Two sizes are used.

Hera. — Spatulas made of *Hinoki* (*Chamæcyparis obtusa*), smaller than those used by workers in plain lacquer. There are three sizes used for applying plain lacquer, and three sizes for applying *Sabi*.

The Tooth of a fish, ordinarily the *Tai* (*Cerranus marginalis*), fastened with lacquer on to a piece of bamboo, used for polishing such crevices as are too small to admit of charcoal, etc., being used.

A piece of polished shell, used for smoothing the paper on which the pattern is drawn before tracing with lacquer.

Tsume-ban.—A palette, made either of tortoise shell or buffalo horn, worn on the left thumb.

Take-ban.—A small bamboo board, used when cutting the gold and silver foils into squares.

Gold and Silver Dust used for Ornamentation.

Of these there are several kinds, viz:—*Yasuri-ko* or *fun* (file powder), made in *Yaki-kin*; (pure gold) *Koban-kin* (10 parts gold to 2$\frac{6}{10}$ silver); *Gin* (silver). There are twelve qualities of each differing, in fineness.

Besides these, there is an extra large kind, used for ground-work, called *Hira-me* (flat-eye). The coarsest filings, whether of pure gold, *Koban*, or silver, are taken and rolled out flat on an iron plate. Of *Hirame* there are eight kinds each.

Next comes the kind called *Nashiji*, from its resemblance, when applied to the article, to the rind of a pear. *Nashiji* is used for ground-work, in making which pure gold, also *Koban-kin* (10 parts gold, 2$\frac{6}{10}$ silver), *Jiki-ban* (10 parts gold, 3$\frac{1}{10}$ silver), *Nam-ban* (10 parts gold, 3$\frac{6}{10}$ silver), and silver, of seven qualities of fineness each, are used.

Aka-fun (red powder) is vermilion mixed with pure gold, *Koban-kin* and silver, for shading.

Kuro-fun (black powder) is camellia charcoal powder mixed with pure gold, *Koban*, and silver.

Giyōbu nashiji is the coarsest kind of *Nashiji* made; but it is little used, as it requires seven or eight coats of lacquer to be applied before it is covered sufficiently to stand polishing.

Keshi-fun.—This is the finest kind used; it is only made in pure gold and *Koban.* This is made by mixing gold-leaf in liquid glue till it is reduced to an impalpable powder; water is then added, and when the gold sinks the liquor is poured away. This is repeated till all the glue has been got rid of.

Shaku-dō-fun.—A mixture of seven parts pure gold and three parts of copper powder.

Kana-gai.—Foil made of pure gold, *Koban*, and silver. It is made of four thicknesses in each quality, viz:—*Hon-neji*, *Chiu-neji*, *Usushu*, *Kime-tsuke*, the last being the thinnest.

Besides the above, there are several mixtures as—

Kuri-iro-fun (chestnut-coloured powder).—A mixture of one-half gold dust with powdered camellia charcoal and vermilion.

Nedzumi-iro-fun (rat-colour grey).—A mixture of half silver and powdered camellia charcoal, and a little vermilion.

In each case it is evident that several distinct shades can be obtained according as more or less colour is added to the gold and silver dust. It is a remarkable fact that (as I am informed) no vegetable colours can be used with lacquer. They are all eaten up, as it were, by the lacquer and disappear, which accounts for the very few variations seen in the colours of lacquer. The workmen have never been able to produce white, purple, or any of the more delicate shades.

Of late years, since cheap work has been introduced, the custom of using tin dust has been adopted for making common *Nashiji*, It is manufactured of the same sizes as in gold and silver, and when plenty of gamboge is mixed with the lacquer to cover it an inexperienced person might easily mistake it for gold when the ware is new, but it soon deteriorates. Burnt tin dust is also sometimes used for under coats in making cheap raised lacquer.

Mode of making Gold Lacquer.

(*a.*) *Togi-dashi* (bringing out by polishing).—The article having been subjected to the first twenty-two processes, as described in making *Houji* (Class I.), is then treated as follows:—

The picture to be transferred to the article is drawn on thin paper, to which a coating of size made of glue and alum has been applied—that known as *Mino-gami* is best. The reverse is rubbed smooth with a polished shell or pebble, and the outline very lightly traced in lacquer, previously roasted over live charcoal to prevent its drying, with a fine brush made of rats' hair. The paper is then laid, with the lacquer side downwards on the article to be decorated, and is gently rubbed with a whalebone spatula wherever there is any tracing, and on removing the paper the impress may very faintly be perceived. To bring it out plainly, it is rubbed over very lightly with a piece of cotton wool, charged with powdered white whetstone or tin, which adheres to the lacquer. Japanese paper being peculiarly tough, upwards of twenty impressions can be taken off from one tracing, and when that is no longer possible, from the lacquer having become used up, it only requires a fresh tracing over the same paper to reproduce the design *ad infinitum.* This tracing does not dry owing to the lacquer used for the purpose having been partially roasted, as previously mentioned, and can be wiped off at any time.

The next process is to trace out the veining of the leaves, or such lines to which in the finished picture it is desired to give the most prominence, and these lines are powdered over with gold dust through a quill. The qualities called *Mijin*, *Koma-kame-mijin* and *Aragoku*, are generally used; either finer or coarser qualities cannot be used. The article is then set to dry for twenty-four hours in the damp press. The outline is now drawn carefully with a rats' hair brush over the original tracing line with a mixture of black and branch lacquer, called *Rō-sé.* The whole is then filled in with *Rō-sé* applied with a hare's hair grounding brush. Gold dust of a slightly coarser quality than *Mijin* is scattered over the lacquered portion, and the article is set to dry for twenty-four hours. Another thin coating of *Rō-sé* lacquer is again given to the gold-powdered portions, and the article set to dry for twelve hours. Next, a coat of *Rō* (black lacquer) is applied over the whole surface of the article, which is set to dry for at least three days. It is then roughly ground down with *Magnolia* charcoal, the surface dust being constantly wiped off with a damp cloth till the pattern begins to appear faintly. Another coating of *Rō* lacquer is then given and the article set to dry for thirty-six hours. It is again ground down with *Magnolia* charcoal as before, this time till the pattern comes well out. The ensuing processes are the same from 28 to 33 inclusive, as in black lacquer (*Honji* (*a*)).

In making *Togi-dashi* on hard woods, transparent lacquer is used instead of *Rō.*

(*b.*) *Hira-makiye* (flat gold lacquer).

The article having been thoroughly finished, either in black or red, etc., as already described under the head of *Honji*, Class I., and the following kinds, a tracing is applied to the surface as in *Togi-dashi*, the outline is carefully painted over with a fine brush of rat's hair, and then filled in with a hare's hair brush, using *Shitamaki* lacquer (branch laquer and red oxide of iron). Over this surface gold dust, of the quality called *Aragoku* being generally used, is scattered with a brush of horse's hair (*Kebo*) till the lacquer will not absorb any more. The article is then set to dry for twenty-four hours. A thin coating is next applied over the gold, of transparent lacquer or *Yoshino* lacquer, and set to dry for twenty-four hours at least. It is then most carefully smoothed with camellia charcoal, and finally polished off with *Tono-ko* and a little oil on the point of the finger, till the ornamented portion attains a fine polish. The veining of leaves and the painting of stamens, etc., of flowers, or such other fine work, is now done with a fine rat's hair brush charged with *Ke-uchi* lacquer over which fine gold dust (*Goku-mijin*) is scattered from a brush of horse's hair (*Kebo*) as before, and the article set to dry for twelve hours. Some *Yoshino* lacquer is then applied to a piece of cotton wool, and rubbed over the whole surface of the box or other article, and wiped off again with soft paper. It is set to dry for twelve hours, after which it is polished off with deer's-horn ashes and a trifle of oil. When very high-class work is desired, *Yoshino* lacquer, to which a little water has been added, is applied, and polished off a second time, and a very brilliant surface is attained.

More ordinary "flat gold lacquer" differs in the manufacture as follows:—The tracing is accomplished in the same manner, but *Shitamaki-nobe* lacquer (branch lacquer, red oxide of iron and camphor) is used for filling in the pattern with a hare's hair brush. The article is then set to dry in the press for ten to twenty minutes, during which time the lacquer has begun to harden, and less gold will adhere. Then gold dust (*Goku-mijin*) is applied with cotton wool thinly, and the article is set to dry for twenty-four hours. The whole surface is then smeared over with *Yoshino-nobe* lacquer (*Yoshino* lacquer and camphor) on a piece of cotton wool, and wiped off again with soft paper. The reason is that it is less trouble to smear over the whole surface thinly, and it is, moreover, not necessary to give a thick coat of lacquer to the decorated part, as the gold dust has been very thinly applied. It is set to dry for twelve hours and ground smooth with camellia charcoal and polished with powdered whetstone and oil on the point of the finger. The fine lines are then drawn with a rat's hair brush charged with *Shitamaki* lacquer, and sprinkled with gold dust (*Goku-mijin*) from a brush (*Kebo*), and the article set to dry for twelve hours. The whole is again smeared with *Yoshino-nobe* lacquer and carefully wiped off again with paper, and set to dry for twelve hours. The article is then polished with powdered whetstone and oil on the point of the finger, and a second application of *Yoshino-nobe* lacquer with a little water, wiped off with soft paper, set to dry for twelve hours, and finally polished off with deer's-horn ashes and oil on the finger, finishes the operation.

Should it be required to make any dark spots or lines, such as birds' eyes, or to draw human hair, etc., or other shading, this is done last of all with *Kuma*, "bear" lacquer, *Jō-hana*, and lampblack.

More Common Kind of Flat Gold Lacquer Painting.

Instead of tracing the design in roasted lacquer, it is done with a mixture of powdered *Tono-ko* and water, and the impression is transferred to the articles with the whalebone spatula as before. The reason for only using *Tono-ko* instead of lacquer is that the ground-work being inferior it cannot be ground or smoothed afterwards, and the edges of the pattern would not be clean, nor stand out clear, should any lacquer get smeared outside the tracing line. The outline is then filled in with *Shitamaki-nobe* lacquer with a coarse hare's hair brush, and the article is set to dry for twenty minutes, or till a thin skin has formed on the lacquer, and then the half-dry surface is wiped over with cotton wool charged with *Keshi-fun*, the finest gold powder, and set to dry for five or six hours. The whole surface is then smeared with *Yoshino-nobe* lacquer, which is carefully wiped off again with soft paper, and the article set to dry for half-a-day The surface is then rubbed over gently with deer's-horn ashes and soft paper to give it a polish, and to get rid of any of the last coat of *Yoshino-nobe* lacquer.

The fine lines are now drawn with a fine hare's hair brush charged with *Shitamaki-nobe* lacquer, and the article set to dry for twenty minutes or so; then *Keshi-fun* is applied with cotton wool, and again set to dry for five or six hours. No further process takes place.

(*c.*) *Taki-makiye* (raised gold lacquer).

The ground-work may be either black or coloured lacquer, *Nashiji* (pear basis of gold dust), or the plain wood.

The outlines of the pattern are transferred to the surface of the article in the same manner as in *Togi-dashi*, or "flat lacquer." The outline is then painted over with *Shitamaki* lacquer, and this is covered with powdered camellia charcoal. If the outside is to be higher than the inside, a broad margin is painted and covered with charcoal powder, leaving the centre untouched, and *vice versâ*; if the centre is to be higher a faint line only is painted outside, and the inside is given a thickish coating, which is sprinkled with the charcoal dust, and the article set to dry for twelve hours. When taken out of the press it is well dusted to get rid of any loose charcoal powder, and is also washed, using a brush made of human hair (*Hake*) to clean out all the crevices and bring out the lines, etc. Some *Yoshino-nobe*, or "branch lacquer," with camphor, is now rubbed on with a piece of cotton wool and carefully wiped off with soft paper, and the article set to dry for twelve hours. The raised parts are next carefully ground smooth with a piece of *Magnolia* charcoal, and a second coat of *Yoshino-nobe*, or of "branch lacquer," is applied as before and dried.

[If a well-raised pattern is required, one, two, or even three coats of *Sabi* ("branch lacquer" and *Tono-ko*) are applied, the outside edges being painted with a brush of deer's hair (*Menso*), and the inside lacquer applied with a small *Sabi* spatula, the article being set to dry between each application for twelve hours. For coarser work it is then ground smooth with a white whetstone, and for finer work with a yellow whetstone. Over this some "branch lacquer," mixed with camphor, is rubbed with cotton wool and wiped off with soft paper, and the article set to dry for twelve hours.]

If the pattern is not to be very high the operations described between the brackets are omitted. A coating of *Takamaki* lacquer is now given, the outside edges being carefully drawn with a rat's hair brush, and the inside of the pattern filled in with a hare's hair brush, and the article set to dry for thirty-six to forty-eight hours. When taken out of the press the surface is ground smooth with *Magnolia* charcoal, and then partly polished with camellia charcoal on a cotton cloth. A little oil is now rubbed on, and a further polishing takes place with powdered "whetstone" on a cloth. Next, "branch lacquer" is rubbed over the raised parts with cotton wool and wiped off with soft paper, and the article set to dry for twelve hours. It is next polished with deer's-horn ashes and a little "rape seed," or "sesamum" oil applied on the point of the finger. Up to this point the formation of the pattern, whether mountains, waves, trees, men, birds or animals, has been gradually completed.

If small squares of gold foil (known as *Kiri kane*), or of coloured shell, are used in producing the pattern, they are now applied one by one on the point of a bamboo stick (*Hirame fude*), the spot where they are to be affixed having been smeared with a little *Rō-sé* lacquer to make them adhere. When all that is required has been affixed, a piece of soft bibulous paper is spread over the freshly done parts and pressed very carefully with the finger. This is to get rid of as much of the *Rō-sé* lacquer as is not covered by the gold squares as possible; the article is set to dry for twelve hours, and then the portion where the gold has been applied is gently polished with a little camellia charcoal on the point of the finger, to get rid of the remainder of the *Rō-sé* lacquer. Shell patterns, and the coarser kinds of gold dust that may be required, are applied in the same manner. The finer kinds of gold dust are applied next, over a coat of *Shitamaki* lacquer, and the article set to dry for twelve hours. The remaining processes of polishing, drying, etc., are the same as in first-class "flat gold" lacquer.

For making raised lacquer patterns on plain wood the whole surface is covered with tin-foil, stuck on with rice paste, to keep the wood quite clean, and then the place only where the pattern is to come is cut out. In making all high-class lacquer the edges of every article are pasted over with tin-foil to prevent their being rubbed or injured by the workman, and the same is done over each portion as it is finished.

The above is the ordinary method of making best raised lacquer, but from a glance at the specimens which accompany this paper it will be seen immediately that there are such innumerable modifications of one process or another, according to the object to be produced, that it is manifestly impossible to do more than give the above cursory sketch. Nearly every piece of good lacquer made exhibits a specimen of each kind, viz, *Nashiji*, *Toga-dashi*, *Hira-makiye*, or *Taka-makiye*.

In making raised lacquer on inferior articles the methods do not vary much from the good kinds; the work is merely less carefully executed. The saving is in the quantity and quality of the gold dust used, and the absence of minute after-work, or in the use of silver and tin instead of gold dust. In the very cheapest kinds burnt tin dust is used instead of charcoal over the first coat of *Shitamaki*. This is burnished bright, and over it a thin coating of lacquer and gold dust is applied. At first it looks well, but loses its colour in a year or two. By using tin powder the same height is attained in one coat that would necessitate at least three coats of lacquer and charcoal dust. This kind of work is, however, only used for cheap articles for foreign export, and has been quite lately introduced.

(*d.*) *Lacquering on Metal.*

For lacquering on iron or copper, brass or silver, the metal is smoothed and polished, and then given a coating of "crude lacquer," or "black lacquer;" the article is put over a charcoal fire, and the lacquer is burnt on to the metal till all smoke ceases to escape. The fire must not be too fierce, and the metal must not be allowed to get red hot, or the lacquer turns to ashes. After the lacquer has burnt quite hard the surface is rubbed smooth with *Lagerstrœmia* charcoal; these operations are repeated three or four times, till a good foundation of lacquer has been obtained. Then the same operations exactly are repeated as in making best "black lacquer," *Togi-Dashi*, "flat gold lacquer," or "raised gold lacquer," only that the lacquer is burnt dry over the fire instead of being dried in the press. The lacquer is thus rendered quite hard and very durable. After the first two or three coats have been burnt on, the subsequent drying processes can be carried on in the damp press, should it be so desired.

In winter, or when any article is required in a hurry, the workmen sometimes put a charcoal fire in the press, over which a pan of hot water is placed. The steam which is thus generated helps to dry the lacquer in an hour or two, which would take twenty-four hours to harden ordinarily, but the lacquer thus dealt with loses its strength, and is never very hard. "Black lacquer" turns a rusty brown, the colouring virtue of the iron being apparently lost, and therefore this plan is never adopted for good work, and in second-rate work only for under coats.

Nashiji (pear basis).—This style of ornamentation, occupying an intermediate position between plain and ornamental lacquer, is therefore treated of last. Till the opening of Japan to foreign trade it was in the hands of workers in gold lacquer, but now for the most part all *Nashiji* on articles intended for exportation is applied by workers in plain lacquer. In making best *Nashiji*, as in *Togi-dashi*, the first twenty-two processes are identical with *Honji*, Class I. A coating of *Rō-sé* is applied, and the gold dust is sprinkled over the surface through one or other of the bamboo tubes, according to the fineness required. The article is set to dry in the press for forty-eight hours, and is then given a coating of pure transparent varnish. This is set to dry for three or four days, when it is roughly ground with *Magnolia* charcoal, and a second coat of transparent lacquer given. The article is set to dry for forty-eight hours, and then ground with *Magnolia* charcoal till a perfectly smooth surface is obtained. Transparent lacquer is then applied with a piece of cotton wool, and wiped off again with soft paper, and the article set to dry for twenty-four hours. It is then polished with a mixture of *Tono-ko* and camellia charcoal powder and a little oil. Next, a coating of *Yoshino* lacquer is given, and wiped off with paper; the article is set to dry for twelve hours, and then it is polished with deer's horn ashes and oil. This is repeated three times to finish the article.

The same processes are gone through when using silver instead of gold dust.

For cheap qualities tin dust is used, and the powder is scattered on glue immediately above a coating of *Kanoji* (whiting and glue). When the article is dry it is burnished with *To-kusa* (*Equisetum*), and as soon as it presents a bright surface a coating of pure transparent lacquer, with gamboge, is given to it. It is set to dry for a day in the press, and ground with *Magnolia* charcoal. Over this a coating of *Shu-urushi* (transparent varnish containing oil) is applied, and another drying for twenty-four hours completes the process.

SOLUBILITY OF COMMERCIAL SULPHATES OF MORPHINE.*

BY VIRGIL COBLENTZ, PH.G.

An article on this subject appeared in this Journal, March 25, p. 798, by Professor Power, giving the conflicting statements on the solubility of sulphate of morphine, and at the same time making an accurate determination of the solubility of the salt as made by Rosengarten and Son. The object of this article is the determination of the differences in the degree of solubility of this salt as produced by different manufacturers and found in our markets. The method employed to determine the solubilities is that recommended by Professor Power, viz., "An excess of sulphate of morphine was digested with distilled water at 15° C. for several days with frequent agitation, and the solution filtered from the excess of salt (proper temperature being observed), the amount of sulphate of morphine contained therein was determined by precipitation with chloride of barium, and from the ignited amount of barium sulphate the amount of crystallized sulphate of morphine, $(C_{17}H_{19}NO_3)_2.H_2SO_4+5H_2O$, was inversely calculated."

Example.—16·363 grams of cold saturated solution gave ·2650 gram of sulphate of barium, corresponding to ·8625 gram of crystallized sulphate of morphine.

$(BaSO_4)232{\cdot}8:(C_{17}H_{19}NO_3)_2HSO_4+5H_2O)758::{\cdot}2650:x.$

$x={\cdot}8625$ gram morphine sulphate crystallized.

(Solution) 16·336 : (Morph. Sulph.) ·8628 : : 100 : x.

$x=5{\cdot}272$ per cent., and $100:5{\cdot}272=18{\cdot}97$ parts of water.

Sample.	Weight of solution.	Weight of $BaSO_4$.	Weight of Morph. Sulph.	One part of the salt soluble at 15° C. in
I. . .	11·000 gm.	·1580 gm.	·5145 gm.	21·38 water.
II. . .	21·808 „	·2801 „	·912 „	23·90 „
III. . .	17·508 „	·232 „	·7554 „	23·18 „
IV. . .	13·020 „	·226 „	·7359 „	17·69 „
V. . .	16·363 „	·265 „	·8625 „	18·97 „
Average				21·00 „

In round numbers 1 part of this salt requires from 18 to 24 parts of water at 15° C. for solution.

SOLUBLE SACCHARATE OF IRON.†

BY DR. C. BRUNNENGRAEBER.

The author gives the following instructions for the preparation of "ferrum oxydatum saccharatum solubile," or "iron sugar" as the result of numerous experiments. The formula has been adopted for the new edition of the German Pharmacopœia.

Dissolve 9 parts of powdered sugar in 9 parts of water, and next 30 parts of solution of perchloride of iron (sp. gr. 1·280 to 1·282, containing 10 per cent. of iron); then add gradually, with stirring, a solution prepared with heat and allowed to cool of 24 parts of sodium carbonate in 48 parts of water. When the carbonic acid has been given off as completely as possible, add gradually 24 parts of soda ley (sp. gr. 1·159 to 1·163, containing 15 per cent. of NaHO), and allow the mixture to stand until it has become clear. After the addition of 9 parts of sodium bicarbonate, dilute it immediately with 600 parts of boiling water and put it aside to settle. Draw off the supernatant liquid by means of a siphon, and mix the precipitate with 400 parts of hot water. After clearing, remove the liquid and again heat the precipitate in a similar manner with another 400 parts of hot water. Then collect the precipitate upon a moistened cloth, wash it with hot water until the liquor running off, when diluted with five times its volume of water, is only rendered opalescent by silver nitrate, and press. Mix the precipitate so heated in a porcelain dish with 50 parts of powdered sugar, evaporate it to dryness in a steam-bath whilst stirring, rub it to a powder and add sufficient powdered sugar to bring the total weight of the mixture up to 100 parts.

The product should be a red-brown sweet powder, tasting of iron, containing 3 per cent. of iron, and giving with twenty times its weight of hot water a perfectly clear, red-brown, barely alkaline solution, which is not altered by potassium ferrocyanide, but upon the addition of hydrochloric acid becomes first a dirty green colour, and then a pure blue. An aqueous solution (1 in 20) first heated with excess of sulphuric acid and then cooled should only give an opalescent turbidity with silver nitrate.

* From the *American Journal of Pharmacy*, Sept., 1882.

THE "GLOBE" ON LICENSED POISONS.

The following editorial remarks upon the sale of patent medicines containing poisons appeared in the *Globe* of the 17th inst. The inquest referred to is reported on p. 339 :—

"The vices and virtues of soothing syrup as administered to infants were again discussed yesterday at an inquest held upon the body of a child which had been only too effectually soothed by a dose of it. This medicine, if it should so be called, is sold under a Government stamp, and is therefore naturally regarded by many persons who use it as having a sort of official certificate of harmlessness. The medical evidence produced yesterday is not at all calculated to support this view of its innocuous character, or to encourge ignorant people to put much faith in the supposed warranty which such a stamp carries with it. Dr. Diplock, who has had some experience before of the fatal results produced by these syrups, explained that some of them contained ingredients which may be harmless to one child, but 'most fatal' to another; and the medical man who had conducted the *post-mortem* examination averred that the bottle out of which the dose was taken contained enough poison to destroy half-a-dozen children. There are, no doubt, different kinds of soothing syrups, more or less poisonous in their character, and there may be some which are absolutely safe when taken in reasonable doses. But these later are most unfairly discredited through the ill-fame that now justly attaches to the others, while the credit of the Government itself is seriously impugned by its stamping with what is supposed to be a guarantee bottles containing such dangerous poisons as morphia and other strong narcotics. The revenue is, of course, benefited by allowing such mixtures to be stamped and sold, and would suffer considerably if the stamp were refused to all medicines containing any poison. But the public will very generally agree with the coroner's jury yesterday in thinking that 'some restriction should be placed on the sale of medicines which can be used as poisons.' It is often difficult to ascertain whether an overdose has been given or not; but in the case investigated yesterday it seems that even an ordinary dose may have caused death."

The Pharmaceutical Journal.

SATURDAY, OCTOBER 21, 1882.

MEETING OF THE AMERICAN PHARMACEUTICAL ASSOCIATION.

THE Thirtieth Annual Meeting of this Association was held on September 12 to 15, at Niagara Falls, New York, and commenced under the Presidency of Professor P. W. BEDFORD; in point of attendance it would appear to have been most successful, over three hundred members and fully as many ladies having been present. The meeting on the first day was, as usual, mainly devoted to the reading of the President's Address and to the routine work of organization. We hope on a future occasion to refer more fully to some of the topics discussed in this Address, and in the meantime refer our readers to some passages quoted om it on another page. The second session saw the election of the new officers, Mr. CHARLES HEINITSH, Lancaster, Pa, being the choice for President, w th Vice-Presidents from Maryland, Georgia and ιhode Island. Then there were the reports of the officers and committees; but further reference cannot be made to these here than to mention that the affairs of the Association appear to be in a most excellent and thriving condition, with a full supply in the treasury to meet all wants, and each department doing its share of the work well.

Several scientific papers were read at the second, third and fourth sessions, and were discussed at more or less length. The first paper was entitled, "Oil of Thyme of Commerce is said to be very often deprived of its Thymol. Is this Statement true?" The reply of Mr. J. L. LEMBERGER showed that from nine samples examined the yield of thymol varied widely, the lowest giving 0·42 per cent. and the highest 38·75 per cent. Only one other sample, however, contained as much as 16·67 per cent., the remainder yielding 6·67, 1·67, ·80, ·42, ·84, 7·92 per cent. respectively.

A paper by Mr. P. C. CANDIDUS gave the results of his experiments as to the solubility of officinal chemicals in dilute alcohol at 60° F., and at the boiling point. His paper can only be of service *in extenso,* as it deals entirely with figures.

Mr. G. W. KENNEDY read a paper on "The Quality of Mercurial Ointment in Commercial Use," the conclusion drawn from his investigation being that the bulk of that sold in the United States is probably bought for one-third mercury, instead of one-half, the strength ordered in the United States Pharmacopœia. Some of the samples examined had as low as 21 per cent. A few samples had nearly 50 per cent. This paper was succeeded by one on "The Manufacture of Mercurial Ointment," by Mr. EMLEN PAINTER.

Mr. J. H. FEEMSTER read a paper on "Guarana: the Percentage of Caffeine in Guarana and the Seed, the best Methods of Examination, and the best Menstruum for its Exhaustion." His experiments showed a percentage of 4·32 caffeine in guarana and 5·08 in the seed. The best method for its extraction was found to be that proposed by Professor E. S. WAYNE in 1877, the menstruum preferred being a mixture of 2 parts alcohol, and 1 part each glycerine and water (by measure).

Mr. R. H. COWDREY read a paper on "The Active Diastase in Extract of Malt." The author stated that when made and evaporated at a low temperature there was enough diastase in 1 fluid ounce of extract of malt to convert 1 ounce of starch into dextrine and sugar, but that most extracts of malt would not respond to such a test, because the diastase was injured in the evaporation by too great heat.

A paper on "Percolation, advancing some new Theories as to its *Modus operandi*" was partially read by Mr. N. ROSENWASSER, but owing to its length was referred to the Committee on Publication.

Professor P. W. BEDFORD, New York, read a paper on "The Quality of Commercial Salts of Bismuth." Six samples examined proved all to be well made, containing only traces of impurities, while as to the presence of arsenic, the quantity in 1000 grains varied from $\frac{4}{10}$ to 3 grains.

A paper on "Creasote of the Market," by the same writer, showed that the principal supply, and that which is sold chiefly in the United States, is the coal tar creasote or carbolic acid; but that the true wood creasote is to be had, and pure, without any difficulty.

Mr. WILLIAM SAUNDERS read a paper on "The Germination of Medicinal Seed." This was followed by a paper, sent by Mr. C. SPENCER, on "The Quality of Fluid Extract of Hydrastis Canadensis of the Market," showing, as judged by the analyses made, that there is considerable variation in the formulæ followed.

Professor W. T. WENTZELL furnished a paper on "Phosphoric Acid," the chief interest in which was a method for making the acid direct from phosphorus by the oxidizing influence of a moist atmosphere.

Mr. C. B. ALLAIRE read a paper on "Powdered Drugs and their Adulterations," in which he asserted that after an extensive examination he was of opinion that 40 per cent. of the drugs sold in the United States are impure.

In a paper on "Boracic Acid," Mr. E. DANA referred to its uses, and gave formulæ for various pharmaceutical preparations. Professor E. L. Patch presented a paper on "Gentio-Picrin," being a continuation of some investigations reported at the meeting last year; and Mr. A. Conrath presented a paper on the "Alcoholic Strength of various Fluid Extracts," by which it appears that in commercial extracts it varies considerably from the standard of the United States Pharmacopœia. The list of papers was completed by one by Professor J. U. Lloyd on "Precipitates in Fluid Extracts," which was a continuation of his paper of last year, and one of the best contributions to the meeting.

At the third session the following gentlemen were elected honorary members:—Thomas Greenish, Peter Squire, Joseph Ince, Michael Carteighe, and George W. Sandford, London; George F. Schacht, Clifton; Richard Reynolds, Leeds; Christian Brunnengräber, Rostock; Carl Schacht, Berlin; I. Martenson, St. Petersburg; and Nicholas Sinimberghi, Rome.

At the same session, Dr. W. B. Carpenter, of London, was introduced, and delivered an address.

The social features of the meeting were exceedingly pleasant, and were well carried out by the Committee of Entertainment. The next annual meeting will be held in Washington, D.C., on the second Tuesday of September, 1883.

SIEMENS'S ELECTRIC FURNACE.

Dr. C. W. Siemens and Professor A. K. Huntington read an interesting paper before Section B of the British Association, during the Southampton meeting, detailing a considerable number of experiments made with the "electric furnace." The general ideas and essentials of this apparatus have been previously described in this journal (*Pharm. Jour.*, [3], xii., p. 1030). In the present experiments a very powerful current, produced by five dynamo machines, driven by an engine of 12-horse power, was employed. The current in ampères varied from 250 to 300. The intensity of the heat was such that the most refractory clay crucibles supplied by the Patent Plumbago Crucible Company were invariably cut through in a few minutes, and except for experiments of short duration were useless. Plumbago crucibles stood extremely well. Obviously, however, they could not be employed for all purposes owing to their tendency to cause carbonization of the metal experimented with. In some experiments the fusion of the metal was effected in a bed of lime, sand or electric light carbon dust. The latter is a very bad conductor, and as in the case of lime and sand allows the arc when once formed to maintain a passage through it to the metal beneath. Experiments were made with wrought iron, steel, white iron, cast iron, spiegeleisen, silicious pig iron, nickel, copper, platinum and tungsten. Six pounds of wrought iron was fused in twenty minutes; on pouring into a mould the metal was found to be crystalline, and could not be forged. White iron fused in a clay crucible for thirty minutes when fractured did not appear to have undergone any change. As much as twenty pounds of steel files was melted in one hour; the metal was, however, invariably full of blowholes when working with such large quantities as this. Cast iron fused and kept under the action of the arc forty-five minutes in carbon dust was not materially changed as to greyness, and the general character of the metal as to the way in which it worked under the tool was not materially altered. The object of the experiment was to ascertain the maximum amount of carbon iron is capable of taking up under circumstances presumably the most favourable. The result is hardly that which would have been anticipated. When spiegeleisen was fused in a plumbago or a clay crucible graphite separated as the metal cooled. Silicious pig iron, containing about 10 per cent. of silicon, was fused by itself; it showed but little change, except that some graphite had separated. One pound of grain nickel was fused and poured in eight minutes. The fused metal had a brilliant granular fracture; it could not be cut properly in the shaping machine, shearing off under the tool. One pound of grain nickel fused in carbon dust for twenty-five minutes, yielded a dark grey carburized metal, which worked well under the tool. Three-quarters of a pound of copper was fused for about half an hour in carbon dust. On examining the result it was found that *all but three-quarters of an ounce had been vaporized.* Those who were present during the experiments suffered no ill effects from the atmosphere charged with copper, which they must have breathed. As much as eight pounds of platinum was rendered perfectly liquid in a quarter of an hour. The greatest difficulty was experienced in satisfactorily fusing tungsten; it was, however, accomplished for the first time on record, being previously known only as a grey powder. Tungsten when fused in the electric furnace is, when untarnished, pure white and brittle, the grain being very close. It was found to have its fusing point lowered by addition of carbon. The conclusion is drawn that the amount of any given metal which can be successfully fused in the electric furnace is dependent on (*a*) the relation between the volatilizing point and the fusing point, *i.e.*, the extent to which the volatilizing point is higher than the fusing point; (*b*) the conductivity of the metal for heat. It thus happens that platinum can be more readily melted than steel and in greater quantity for a given expenditure of energy.

CHEMISTS' ASSISTANTS' ASSOCIATION.

A meeting of the above Association will be held at 32a, George Street, Hanover Square, on Wednesday evening next, October 25, at 9 p.m. precisely, when a paper, "A Summary on Cinchona Barks of Commerce," will be read by Mr. William Elborne.

Pharmaceutical Society of Ireland.

MEETING OF THE COUNCIL.

The monthly meeting of the Council of this Society was held on Wednesday, the 4th inst., at the College of Physicians, Kildare Street, at three o'clock.

The President, Dr. Charles Tichborne, in the chair.

The other members present were:—Messrs. Allen, Bennett, Brunker, Doran, Grindley, Hayes, Hodgson, McIlwaine, Dr. Montgomery, Dr. Collins, Messrs. Payne, Pring, Simpson and Wells.

Mr. Hugh Fennell, the Registrar, read the minutes of the last meeting, which were confirmed.

A letter was read from Dr. Creed Meredith and Dr. Dunne, Secretaries of the Royal University, stating that certificates for practical pharmacy given by a pharmaceutical chemist were accepted by that University, the words of their regulation on the subject being "under an apothecary or a pharmaceutical chemist." If this did not meet the views of the Council the letter requested them to communicate.

The President: A paragraph on the subject should be inserted in the Calendar.

Mr. Fennell: The word "Irish" is not used.

Dr. Montgomery: They do not intend that there should be any objection to an English pharmaceutical chemist.

Mr. Hodgson: Would one of our pharmaceutical chemists be granted the same privilege in England?

The President: You cannot dictate to the Royal University what privileges they will give to anyone.

Mr. Hayes: It does not concern us whether they will admit Englishmen to the privilege in question or not. They say they will admit our pharmaceutical chemists, and that is all that we have to do with.

Mr. Brunker: The Royal University is an Irish body, and only contemplates the granting of degrees in this country.

Mr. Payne: The English Pharmaceutical Society would not recognize our certificates.

It was ordered that the Registrar should acknowledge the letter of the Secretaries of the Royal University, and state that the information conveyed therein was satisfactory.

A letter was received from Mr. David Baxter, M.P.S.I., asking for a duplicate of his licence, which, his letter stated, had been torn in transmission.

After some discussion,

On the motion of Dr. Montgomery, seconded by Mr. Hayes, it was ordered that Mr. Baxter should be informed that the Council could not grant him a fresh diploma, but would give him a certificate stating that he had passed the examination, on his paying a fee of 10*s.* 6*d.*

A report of the Law Committee was read stating that a case having been submitted to Mr. Purcell, Q.C., as to the legality of pharmaceutical establishments conducted by the representatives of deceased apothecaries who had not been registered as pharmaceutical chemists, Mr. Purcell had given the following opinion:—"I am clearly of opinion that neither of the cases comes within the provisions of the 32nd Section of the Pharmacy Act, Ireland, which applies only to the representative of a pharmaceutical chemist or druggist who was registered as such during his lifetime: and, therefore, that the parties are not entitled to carry on the business of a pharmaceutical chemist or druggist under that Act. Nor are they so entitled as representatives of a licentiate apothecary, as the Apothecaries Act contains no provision enabling them to do so. By doing so, therefore, they incur, in my opinion, the penalty imposed on them by Section 30 of the Pharmacy Act."

It was pointed out that apothecaries had the privilege of registering as pharmaceutical chemists and thus obtaining the privileges given under the Pharmacy Act, by the payment of a fee of three guineas.

On the motion of Mr. Hodgson, seconded by Mr. Grindley, the report of the Law Committee was adopted.

A report of the Certificate Committee dealt with the case of Mr. Walter Boyd, who sought to be admitted to the examination. He had made a declaration stating that he had been engaged for upwards of two years in the compounding of prescriptions and in practical pharmacy under the superintendence of the late Mr. John Goodwin, at No. 6, Merrion Row, but that the sudden and unexpected death of that gentleman prevented him from obtaining a certificate from him.

The Registrar, by direction of the Committee, wrote to Mr. Boyd asking if, during the time named in his declaration, he had been engaged in the *bonâ fide* practice of pharmacy at 6, Merrion Row, and not elsewhere; and he now replied, stating that he had been exclusively so engaged at that place during the time mentioned in his declaration.

After some discussion,

On the motion of Mr. Brunker, seconded by Mr. Hayes, it was resolved:—

"That Mr. Boyd's declaration be accepted in lieu of a certificate."

The Council then proceeded to consider the recommendations of the Pharmacy Act Amendment Committee. The first was:—

"That no pharmaceutical chemist or apothecary shall legally hold a branch establishment for the retail of poisons or compounding of prescriptions except under the responsible management of a duly qualified pharmacist."

Mr. Wells thought that the word "apothecary" ought to be inserted after the words "duly qualified pharmacist."

Mr. Hodgson: We have no power to deal with apothecaries.

Dr. Montgomery was of opinion that it would be best to legislate for themselves, and to leave the apothecaries out. Let the Apothecaries' Hall deal with them. It would lead to ill-feeling between the two bodies if they used the word "apothecary."

Mr. Hayes: Send a letter to them and ask them would they approve of the insertion of the word "apothecary." The object is that an apothecary shall not open half-a-dozen shops without having a qualified assistant in each.

Mr. Wells: I do not think they can do that now.

Dr. Montgomery: An apothecary may have either an apprentice, or an assistant who must be qualified under the Apothecaries' Act, under a penalty of £20.

Mr. Allen: A pharmaceutical chemist should be enabled to employ an apothecary if he chooses. If you don't add the word "apothecary," he must have a pharmacist.

Mr. Brunker expressed a similar opinion.

The President: My view is that we should assist the apothecaries in this matter. We asked the assistance of the Apothecaries' Hall in these amendments, and they said they were quite willing to act with us and to give us every assistance. Let us submit to them for their opinion a copy of the resolution with the word "apothecary" inserted. We may be doing them an injury by not inserting the word. It is used all through the Pharmacy Act.

Mr. Pring: An apothecary can register as a pharmaceutical chemist by paying three guineas. That gets over the difficulty at once.

The President said he thought that would meet the case.

The recommendation was unanimously adopted originally stood, but leaving out the word "apothecary.'

The next amendment proposed by the Committee was:—

"That all assistants engaged in dispensing must give sufficient proof of their competence by examination, or by having passed a sufficient time as apprentices."

Mr. Wells: Three years ago a resolution was passed that there should be an examination for assistants.

Mr. Pring said that it was very difficult to get assistants, and if an examination were made indispensable it would be a great deal more difficult. He believed that every man in his establishment was a qualified man, but they had not passed examinations for their places, although they might have passed them in England or elsewhere.

Mr. Brunker: The feeling of the Society is that there shall be an examination for the assistants.

Mr. Wells: But not a compulsory one.

The President: If you do not make it compulsory you need not have it at all.

Mr. Payne said he did not agree with the second recommendation. If adopted it would put a difficulty in the way of getting good assistants. They were hard enough to get at present. At present they got a very good class of assistants from Scotland and England, who possessed a great deal of practical knowledge because they had served apprenticeships.

Mr. Hayes: We shall not be prevented from having Englishman or Scotchmen if we wish it, but the adoption of this recommendation would prevent it.

Mr. Simpson considered that the recommendation, if passed, would interfere immensely with business.

Mr. Hodgson: What will you gain by passing this recommendation? Every respectable compounder feels that his position and his means depend upon the duties which he has undertaken being critically and properly performed, and, therefore, for his own safety he will be careful as to whom he engages as an assistant. It almost amounts to telling gentlemen that they require to be taught how to engage assistants.

Dr. Montgomery was in favour of having an examination for assistants. They had to look not to gentlemen occupying such positions as Mr. Pring or Mr. Payne; they had to take care of the interests of minor men.

Mr. Payne moved that the recommendation be rejected.

Mr. Wells seconded the motion, which was carried, Dr. Montgomery alone dissenting.

The third and last recommendation was as follows:—

"That all candidates for the licence shall be required to produce evidence of having passed three years in a *bonâ fide* apprenticeship to an apothecary or pharmaceutical chemist keeping open shop."

Mr. Hayes moved that the term be a minimum of five years.

Mr. Pring seconded the motion.

The President begged of the Council carefully to consider this proposal. It involved two points. First, were they likely to get Parliament to approve of such a clause. He was quite sure they would not as compulsory for a licence. Next, was the proposal a fair one. No doubt it would be the best thing that could happen to any youth to be in such an establishment as that of Mr. Pring for five years; but there was no earthly object in insisting upon an apprenticeship. That Council had nothing to do with the exigencies of trade. They were custodians of an Act of Parliament. The preamble of it declared that there was a scarcity of compounders in Ireland, and that it was desirable to create pharmaceutical chemists. The pharmaceutical chemist in that country owed his existence to the fact that there were not enough of men in country places to compound prescriptions. Therefore the Council should put aside every personal consideration in this matter and only have regard to whether or not they were properly carrying out the requirements of the Act of Parliament. That there were not enough of pharmacists in the country was plain from the fact that the Registrar of the Apothecaries' Hall had received five applications within the last six months, and two within the last week, for qualified men, either pharmaceutical chemists, or apothecaries, to take charge of establishments in the country, and he had been unable to get the men. Therefore would the Council be justified in putting restrictions upon candidates coming forward for the licence? If they thought three years a desirable minimum to teach a man his business, let them make that the term: it would not preclude the party from spending five years, or the principal from getting him as an apprentice for six; but that was a personal arrangement. There was no doubt that apprenticeships, particularly in country places, had been abused; and also that the system of apprenticeship was to a great extent exploded and gone out amongst medical licensing bodies. In a first-rate establishment the apprentice was in his right place, but he knew two or three very large establishments, in which six or seven men were employed at compounding, and in those establishments, nevertheless, they would not take apprentices. Had they any right to say to those assistants, that although they might have obtained the greatest skill and experience they should not come forward for the licence, simply because they had not submitted to a kind of black mail which was only imposed for the benefit of the employer? (No, no!) Well, that was his (the President's) opinion with respect to the apprenticeships. He also strongly objected to so long a period as five years being a minimum at present. On the other hand if they made it three years now they could, if necessary, lengthen the period by degrees afterwards. Besides there were other important educational branches as well as compounding. In England they were going to make theoretical and practical chemistry, botany and materia medica compulsory. His experience was that it was in these subjects that the dispenser failed. He therefore urged that the clause should provide that the person had passed three years as a *bonâ fide* "apprentice" or "assistant" to an apothecary or pharmaceutical chemist keeping open shop.

Mr. Wells: Have they it in England?

The President: They require a three years' apprenticeship, but I believe it is not strictly carried out. The want of it is winked at.

Mr. Brunker said he was not for adhering to the word "apprentice" in the clause, the words "or assistant" would answer the purpose. The President had spoken of large establishments that did not take apprentices, but if they went through those establishments they would find that every one of those assistants had served an apprenticeship elsewhere. He (Mr. Brunker) did not take apprentices, and yet every assistant in his establishment had served an apprenticeship elsewhere.

The President: I do not think that is always the case.

Mr. Brunker said it would be found that there were very few assistants that any of them would care to engage as compounders, who had not served an apprenticeship somewhere. Apprenticeship was not so inconsistent with the spirit of the times as the President appeared to suppose. It was very general in the business; and it was very important in the interests of pharmacy that some such regulation as that which was proposed should be laid down in a hard and fast way. They had seen how much difficulty arose from having matters left open. They had been fighting for month after month over the certificates of certain candidates for the licence, simply because the law was not laid down clearly as to what were the requirements in practical pharmacy from those candidates. Therefore, whether they made the term three or five years, let it be a hard and fast rule about which there could be no dispute. He believed himself that three years should be the minimum term for both apprentices and assistants, and he would not object to five years.

Mr. Wells was not sure that there was such a want of assistants. There were vacancies in one of the poor-law unions for which there were nearly twenty applicants. He knew of other situations for which first-class men were wanted, but only small salaries were offered.

Mr. Hodgson said they were now dealing with candidates for the licence and not assistants. He was completely opposed to the principle of apprenticeship. He considered that the adoption of it would be a move backward. Apprenticeship was completely ignored in the Pharmacy Act, and very properly. The principal was paid for the apprentice, who no doubt learned the general details of the business; but his relation of apprentice did not at all imply that he would be occupied in compounding during his term. The Pharmacy Act did not contemplate apprenticeship, but contemplated that the man should be occupied in compounding and practical pharmacy. It was for the purpose of opening the door to the Major licence for carefully trained compounders of medicine that apprenticeship was ignored in the English Pharmacy Act, and he now objected to any attempt to set up apprenticeship by a side wind.

The President: It is contrary to the spirit of the country.

Mr. Hodgson: It is contrary to the spirit of the Act of Parliament and I do not think it would work well. By adopting what is proposed you would shut out a great many competent and thoroughly qualified compounders.

Dr. Montgomery moved that the further discussion of the recommendation be adjourned to the next meeting. It was getting late and members of the Council were leaving.

Mr. Hayes seconded the motion.

The President: It should be understood that the first two recommendations have been disposed of.

Mr. Payne asked if a resolution were sent to the Privy Council and sanctioned by them, would it not have the same force as an Act of Parliament.

The President: Not if it were contrary to the Pharmacy Act.

Mr. Brunker gave notice that when the discussion of the question should be resumed he would move that all candidates for the licence should be required to produce evidence of having passed three years *bonâ fide* in the exclusive employment of an apothecary or pharmaceutical chemist keeping open shop.

The motion of Dr. Montgomery was then put and agreed to.

Mr. James Gray Fyvie, of Coleraine, was elected a member of the Society.

Some financial business having been disposed of, the Council adjourned.

Provincial Transactions.

EDINBURGH CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The opening meeting of the session was held on the evening of Wednesday, October 11, in the rooms of the North British Branch. Mr. Peter Boa, President, in the chair.

The minutes of the last meeting having been read and adopted—

Mr. Boa first made a few introductory remarks in which he pointed out the great value of such an Association, and the eminent desirability of every assistant and apprentice availing himself of its advantages. He also referred to the honour which had been conferred upon him by being elected their President, a position carrying with it a responsibility, which no feeling of inability on his part would prevent him from endeavouring to fulfil to the best of his power. Having urged the members to be regular in their attendance, so that the splendid audience which he was so gratified to see on the opening night might be continued during the session, he proceeded to deliver the inaugural address.

Mr. Boa said that the business of a chemist and druggist, as it is now conducted in these realms, was a very unsatisfactory one. Part of the work was worthy of being called professional, but another portion of the work could not by the greatest stretch of imagination be so denominated. It was this mixture of the professional and commercial types, which was the cause of all the ills to which the pharmaceutical body is heir, because the two were not compatible. Between the man of business and the professional man there was a well marked difference and it was useless to expect to have in one man, or business, a satisfactory combination of the two, unless on rare occasions. Until a condition was attained in which the two should be kept apart, pharmacy would not have attained its true position. The practice of pharmacy should be removed from the conditions and influences which make it necessary for its members to discuss the propriety of competing with co-operative stores, grocers, drapers, and such like, in the prices of patents and other commodities of a similar character. In dealing with stores the members of the public were not surprised if they found themselves occasionally "done," but they did not hesitate to run this risk for the sake of the average saving. With a pharmacist it was entirely different; to hm no suspicion of even a possibility of his supplying drugs of inferior quality should attach. To supply drugs of genuine quality and compound prescriptions in the most approved style was the proper province of the pharmacist, and in this he need never fear competition from stores. If he made himself a specialist in those things he need not fear any encroachment on his territories by unqualified persons. Specialists were the order of the times. The public demand them in every department of commercial or professional life. "Cutting" grocers and co-operative stores were specialists. In the departments in which they generally compete against pharmacists the latter are not specialists, hence the reason they found themselves defeated. In the case of drugs pharmacists argued that they were entitled to an extra profit on account of the guarantee of quality which the purchaser had in buying them from men who are specially trained to the recognition and testing of genuine specimens. The public was willing to admit this, but scarcely recognized the same argument in the case of retailing a tin of Swiss milk. When a man, through force of circumstances, engaged in work not in keeping with the business to which he had been specially trained, he did that work in an unsatisfactory manner. For instance, medical men who dispensed their own medicines invariably executed their compounding in as lovenly fashion, doing it under a state of chronic protest. So, in like manner, chemists, having to trade in articles belonging to the category of grocers or perfumery, conducted this portion of their business in a way which did not always give satisfaction to their patrons. There were at present few chemists' businesses that were not "mixed," the difference being only one of degree; but until this class of business disappeared there would always be anomalies which would prevent the public from according to the calling the respect and standing to which it was entitled on account of the knowledge and attainments of many of its members. This, however, would require many years for its attainment, but he did not despair of its being by-and-by brought about. There was great reason to be encouraged by the improvement in the status of pharmacists in recent years. It was only fourteen years since the compulsory examinations were established. Complaints were made that unqualified persons still conduct businesses and yet escape punishment. To the speaker fourteen years did not seem a very long time in which to effect a complete reorganization of a whole trade or profession throughout a country, and he was disposed to wonder rather that there were not more unqualified persons in practice than that there were any. The compulsory curriculum which it was proposed to establish for chemists and druggists was a subject now occupying some attention. At present there was an indefiniteness in the training of pharmacists which was highly to be deprecated in the case of a profession, the members of which were entrusted with such grave responsibilites, not only because it failed to satisfy the ideas of those who had to trust them, but on account of its leaving it possible for a chemist to go into business with an imperfect acquaintance with some parts of his duties which he might ever afterwards regret. In justice to himself and those who trusted him to compound their medicines, a definite course of scientific study ought to be established for a pharmacist. It would be the first step in establishing a status for him, which might have a reasonable claim to be designated professional. To make a student take certain classes at a university before he presented himself for examination would give some guarantee that he had been educated for the responsibilities he would be legally entitled to undertake should he satisfy the examiners. True he might pass the examination well without this course of training, but the mere fact of his doing so would never give him the standing that both taken together would confer. The percentage of failures in the examinations of the Pharmaceutical Society was larger than in those of any other examining body in the kingdom. He had not heard anyone say that the mental calibre of the men who became pharmacists was inferior to that of those who enter any other business or profession in which examinations are required. He might say that he was surprised rather that the percentage of passes was so high, and he considered it much to the credit of the candidates that they go up so well prepared as they do, when only a very small percentage of them had the advantage of a systematic preparation. If there were any means of obtaining a return of the failures of those who present themselves for examination after a course of training, say at Bloomsbury Square, he was confident that the percentage would be found very small indeed. This went to show that it was not the capacity of the candidates that was at fault, but rather the means at their command for acquiring the information required of them. In the event, too, of pharmaceutical students having to attend several of the classes at the Universities, they would have the opportunity of associating with the medical students who are to form their contemporary generation of physicians and surgeons, and in this way many friendships would be formed, and much done to promote reciprocity of confidence and respect. Another matter in which some changes on the present custom would have to be made, was the training of apprentices. At present the apprenticeship of a chemist and druggist was not an attractive period of his experience. In view of a compulsory curriculum and a professional status there must needs be some modifications of the present means of introducing him to his professional work. At present the initiatory stages of his career were largely taken up with dusting bottles, polishing drawer fronts, and, in some cases, washing measures and mortars—work which more appropriately belonged to some one whose educational advantages did not warrant his undertaking more responsible employment. The supporters of the present system said that at the outset the apprentice must learn habits of neatness, arrangement, etc., and that his period of bottle dusting was eminently calculated to enable him to acquire these; that by washing and drying the measures and mortars he acquired a familiarity with their handling, which world give him confidence in using them. The truth of these arguments he did not question, but those who advanced them seem to forget, however, that a lad who had been well brought up might have acquired neat and methodical habits before the time when he began his business career; and as for the confidence in the use of measures acquired by washing them it might as well be said that it is necessary for a man to go through a course of cleaning guns before he learns to shoot. Whilst, however, the present system of conducting the business continued it might be expected that more or less of the work now falling to the lot of the apprentice would still devolve upon him. The many and various ornamental accessories of the shop must be kept bright. Carboys, specie jars, show cases, fancy drawer fronts, elaborately labelled bottles, all these required constant attention to maintain the brilliant appearance which they were intended to give to the establishment. But good reason for maintainimg so scrupulously the present style of conducting business he failed to apprehend. The carboys of coloured water and specie jars with elaborately painted devices were relics of ancient times when the art of an apothecary was considered to be associated with the supernatural. The presence of these things did not lend any additional effect to the medicines. Their presence would not tempt people to buy more physic than they would do were they absent. The cost of their original purchase and of maintaining them was considerable, and the consequence was that the chemist had to resort to a trade in sundry commodities extraneous to his legitimate business in order to gain a living. For the purposes of a compounder of medicines all that the pharmacist required was a room or rooms, fitted with shelves, drawers, bottles, etc., for the storage of the drugs. His name and occupation could be advertised by a brass plate affixed to his door. It would be an advantage to the chemist not to have his laboratory open to the interruptions caused by any small boys who may find it convenient to run in for "coppers for a sixpence,"—as not unfrequently happened under the present arrangements. It was now considered unnecessary and in fact undignified to expose stock in the windows of a chemist's shop, and he hoped in a few years it would be unnecessary for a chemist to incur the expense of a shop at all.

Mr. C. F. Henry, in proposing a vote of thanks to Mr. Boa, said there could only be one opinion as to the instructive, and useful, and philosophical address to which they had all listened, he felt sure, with pleasure. He had come there expecting a good deal, but the result had exceeded even his highest anticipations. The address contained many very original ideas, some of which might prove matter for discussion during the present session. He did not think druggists ought to be frightened by the competition of stores, grocers, etc. It was well known that the drugs retailed in such places were, as a rule, of an inferior quality, and sooner or later the public would find out that if they wished to purchase drugs of reliable quality, they must do so from those who, from their special knowledge and training were competent to guarantee the purity of their wares. He had no doubt that the members of the Association would feel that they had been highly honoured by the attendance at their opening meeting of the President and other eminent members of Council of the North British Branch, and he had very great pleasure in inviting those gentlemen to address to them a few words of encouragement and advice.

Mr. J. R. Young said that he had great pleasure in seconding the vote of thanks to Mr. Boa. It was the first time he had been present at a meeting of this Association, and he was much gratified to see such a meeting. The address contained some very novel ideas, and some which had evidently been well weighed, and which had an important bearing upon the business of a chemist and druggist. He agreed with very much that had been said as to the training of apprentices, but believed that the introduction of the proposed compulsory curriculum would remove many objectionable features in the present state of things. An apprentice who had passed the Preliminary examination before entering the trade could hardly be expected to spend two or three years washing measures, dusting bottles, running messages, etc., and yet it was essential that he should have some training in the practical details of his calling. He thought they were still very far from the time when the chemist's shop would give place to a room in his private house, and the signboard to a brass plate on the door. On the Continent pharmacists were generally considered to be much in advance of them in professional status, and yet they still had shops, and he thought that no such serious change was likely to come about for many a long year to come. The cause of pharmacy had been greatly benefited by the efforts of the fourteen years which had elapsed since the institution of compulsory examinations. Looking back about twenty years he remembered that the assistants of that period had some meetings to get the hours of business shortened or something of that kind, but a meeting such as this and an opening address such as he had just listened to could not have been had at that time. He concluded by referring to the many advantages to be derived from such an Association, and expressed his earnest wish for its continued prosperity.

Mr. Alexander Napier, President of the North British Branch, had much pleasure in supporting the vote of thanks which had been proposed. By coming there that night his thoughts were thrown back to a time when an Association of a similar kind, though with comparatively very small numbers, existed in that city. They used to meet in a room in Princes Street, about the year 1862 or 1863, and he remembered that they had many enjoyable gatherings and many interesting papers. Some of those who were connected with that Association had now removed to other countries, but they still showed their appreciation of old acquaintances by occasional contributions to the North British Branch of the Pharmaceutical Society. He earnestly desired to see the Association prospering because he believed it to be a nucleus of very important and valuable influence.

Mr. J. B. Stephenson said he was very glad to be present that night, because he had known that for several years this Association had been doing good work. He had no intention to criticize the address, although it contained a good deal of explosive matter, especially toward the close. He would heartily congratulate Mr. Boa on his excellent address which contained many views which he had himself given expression to, on more than one occasion, from that chair. There was just one bit of advice which he would like to impress upon the members of this Association, and that was, that success did not depend upon numbers but upon individual effort. No matter how large the membership of such an Association as that might be, unless they had individual effort they could not succeed, and that was a principle which he would strongly advise every member to bear in mind and act upon. He had already congratulated Mr. Boa, and he would conclude by congratulating the Association on the truly academic address to which they had listened.

Mr. William Gilmour said he had been asked to say a single word, but he did not think it was necessary to add to what had already been said as to the excellent address to which they had listened. He believed that this Association was a great educational institution and that it gave a good tone to the whole profession. The department of their work to which he would more particularly refer was the prize competition for apprentices which they had just instituted. He would strongly advise all apprentices to avail themselves of that opportunity. Not that every one would get a prize, because that could only be the fortune of two; but, even if they should not be successful in gaining a prize, the experience of going in for the examination would help to give them confidence in the future. He observed that this confidence in going in for an examination had been emphasized by Mr. Ince, the other day, in his inaugural address to the students at Bloomsbury Square, and he believed it was of very great importance and that they were, as a rule, far too frightened for examinations. He thought there were many points in Mr. Boa's address which were worthy of the highest commendation and that it struck a keynote which he hoped would be maintained throughout the whole session.

The discussion was continued by Messrs. Crowden, Hill, Low, and McEwan, and the vote of thanks was briefly acknowledged by the President.

The Secretary then made a statement as to the apprentices' prize competition, and the President having intimated that the next meeting would be an open one, and would be held on Wednesday, November 1, the meeting was closed.

Proceedings of Scientific Societies.

AMERICAN PHARMACEUTICAL ASSOCIATION.

This Association commenced its Thirtieth Annual Meeting, on Tuesday, September 12, at Niagara Falls, N.Y. A lengthy and interesting address was delivered by the President, Professor P. W. Bedford, from which the following passages are taken:—

In many of the States where Pharmaceutical Associations have been formed there now exist Boards of Pharmacy, organized under State laws, which have been aided by the action of the State Association. Unfortunately, in a number of States the Associations have failed to secure the passage of pharmacy laws.

During the present and preceding years such failures have occurred in Massachusetts, New York, Pennsylvania, Louisiana, Virginia, and possibly other States. So far as I have been able to procure statistics, pharmacy laws exist in the following States:—Maine, New Hampshire, Connecticut, Rhode Island, New Jersey, West Virginia, North Carolina, South Carolina, Georgia, Alabama, Iowa, Illinois, Wisconsin, Missouri, and Kentucky; and in the cities of New York, Brooklyn, Philadelphia, Baltimore, Washington, Cincinnati, and San Francisco.

Pharmacy laws in the United States never can be made uniform. The feasibility of obtaining the favourable consideration of legislators to a fair, uniform pharmacy law is one of the possibilities of a later if not a "latter" day; but at present the literature of pharmacy laws is an entanglement of the mind in the mazes of legal enactments.

It seems that in the most of the Boards of Pharmacy there is a fair yet just and conservative rendering of the laws applicable to the subject.

From a correspondence with all the Boards of Pharmacy mentioned, I am led to believe that each board tries to faithfully execute the laws under which they are appointed. These laws vary, however, widely; in some cases permitting all in business to become registered, in others requiring an examination of all persons who have not been in business on their own account for a term of years.

Candidates are required to undergo an examination, usually before each member of the board to which he applies; and, on a comparison of replies to my inquiries I find that the lowest percentage at which any candidate can be passed successfully was 60 per cent., while in one or more boards they decline to pass any who fall below 80 per cent.

From the replies received by me from the Boards of Pharmacy, it would appear that on the first examination about 60 per cent. of the candidates are successful, the remaining coming up one or more times until successful or refused further examinations.

In some instances copies of questions used by the Boards of Pharmacy have been submitted to me for my own information on the subject, and it is fair to state that in every such case I have found them common-sense, practical questions, calculated to bring out knowledge rather than to surmise what the answer should be.

Under this incongruity of pharmaceutical legislation it seems almost impossible for Boards of Pharmacy to take any concerted action, save an agreement to increase the care exercised in questioning and valuing the replies of applicants examined.

To make the certificates of proficiency exchangeable in the several parts of the Union to which their possessors might direct their footsteps would seem to be not only impossible, but in some cases a positive error.

There should be a difference between the standing of one who has passed under a lax law and one who has been subjected to a critical examination, and both these should be of less value than the college diploma, which is a guarantee that its possessor has given the time to carefully pursue a pharmaceutical course of study and has gained his honour after an examination that is usually a very thorough one.

The college graduate necessarily has the advantage in education and thoroughness. I would not be considered as discouraging Boards of Pharmacy or unduly extolling the College of Pharmacy, but it seems a self-evident fact that the practical student with a college training is the man that will make the better mark in his life-work.

To-day I plead the cause of pharmaceutical education. I would call your attention to what the founders of this Association recorded at their meeting thirty years ago on this very subject:—

"The subject of pharmaceutical education being considered of paramount importance by this Convention, and having been deliberated upon by its committee, the following resolutions have been adopted expressive of the sense of the Convention in reference to this important subject: It is resolved—

"'1st. That this Convention earnestly recommends to the practising apothecaries in all sections of the United States, in places where they are sufficiently numerous, that they should organize themselves into societies for mutual improvement as pharmaceutists, for the encouragement of pharmaceutical literature by the formation of libraries, and for the adoption of rules of conduct calculated to elevate the character of the profession among them.

"'2nd. That as schools of pharmacy are the most effectual aids to the student, this Convention respectfully recommends to pharmaceutists in all cities where they are numerous, to take measures for the establishment of such institutions as powerful means of improving the education of their assistants and apprentices, and thus benefiting themselves and the public.

"'3rd. That this Convention also recommends that more attention should be given by proprietors to the claims of apprentices or assistants, who are in course of study, as regards the facilities for learning, and the tuition which of right should proceed from them (the proprietors) in the absence of schools of pharmacy, especially in the provision of the best books of reference on the several subjects that claim the attention of students of pharmacy.

"'4th. That in the opinion of this Convention it is desirable that apothecaries should be more generally careful, in taking pupils or apprentices, in reference to their fitness as regards natural endowments and preliminary education, believing that many persons who are now engaged in pharmacy and unfitted for its duties might thus have been prevented from misapplying their time and abilities in a profession for which they are not calculated.'"

Surely these resolutions of thirty years ago have the true spirit which should animate not only this Association collectively, but each member individually.

Boards of Pharmacy are, or should be, only a means to an end. They are intended as a safeguard for the present time, a method only to weed out the utterly incompetent, but they are not now, nor were they ever intended to be, educational.

The pharmacy law of England enforces an examination much more rigid than is carried out here, but it would seem that even there, to a large extent, the education given in most all the institutions have solely for their object the success of the candidate before the Board of Examiners, rather than a solid education.

Contrasting the educational establishment of the Pharmaceutical Society of Great Britain with the Colleges of Pharmacy of Philadelphia or New York, we would call the English organization a financial failure. Its students are comparatively few as contrasted with the two colleges named, certainly not more than one-fourth in number, yet there can be no doubt that its course of instruction is thoroughly practical and sound.

Throughout Great Britain there have been established rival schools, to "coach" or "cram" the applicants preparatory to the examinations.

Punch has aptly compared such teaching to the process by which water is charged with carbonic acid, and the examination to the removal of the cork which lets out all the knowledge attained, and they are never able afterward to come up for an examination without being crammed all over again.

There are some who are born pessimists, who see no bright future in pharmacy; who are for ever lamenting the days of the past, when the public were not so enlightened on facts relative to our business; when competition was not so sharp; when education and knowledge were not so necessary as now; who fear that business laws are tying them down as slaves to certain modes or business regulations, and they wish for the days of the past to be revived. No such lamentations are available. The present and the future have demands that must be met and conquered. The "sign of the times" is a sound and thorough education—one that will fully fit the young pharmacist to cope with the scientific problems of our business as well as the simple knowledge of cost and gain on his merchandize.

Those who have no soul above the merchandize side of our calling will ere long be left behind in the race, and it will be truly the "survival of the fittest."

Regarding the examinations of pharmaceutical students a few words may be added.

The records of the examinations in London show that fully one-half of the applicants fail on their first effort.

Doubtless the examinations are rigid, but from a careful examination of the papers with which I have been favoured in the past I should say that they were none too much so under the circumstances.

Of the large number of applicants but a small proportion fit themselves properly by education, but, seeking a shorter road, attend the establishments where they are forced into a superficial knowledge, and when the days of examination come, they risk their success, usually as risky as successful.

The colleges of pharmacy in our land are acknowledged to be excellent in their methods of teaching. Those who attend their instructions may be classed as the more intelligent and promising of those who are growing up in the ranks of pharmacy. Yet even with the large numbers of those availing themselves of such education, not one-tenth of the young men are attending our colleges of pharmacy. What is being done for the other nine-tenths? It is not my observation that employers, as a class, give themselves much trouble to advance the technical knowledge of their *employés*, being as a rule more anxious to have them know the money value than the properties of the commodities they handle.

The founders of this organization gave their views when they said:

"The subject of pharmaceutical education is considered of paramount importance."

The colleges of pharmacy were the originators of this Association; this in turn has been the originator of the State Associations, and we may note that some of the recently organized colleges of pharmacy are the outgrowth of the State Associations. There are none too many colleges; there is room for more; if they are only good ones and willing to maintain their standards of education and examination to equal in value those now adopted by the older colleges of pharmacy. If, however, such institutions are to be perverted to facilitate improper modes of procuring the insignia of competency without the substance, it should be our bounden duty to expose such schemes, and take active measures to prevent their practices.

Our colleges should be sustained and encouraged by the active co-operation of every pharmaceutist who has that respect for his business that leads him to see in it something more than mere merchandize. Our colleges are the educators, our pharmaceutical associations the promoters of pharmacy, yet not only the fifteen hundred members of this Association but the five thousand members of our State Associations should see to it that their valuable aid shall be given in the cause of pharmaceutical education; that they take active steps to send their young men to colleges of pharmacy that they may receive the solid foundation of a thorough education in their chosen profession.

Employers have also a duty to perform in another respect. It is the aid they can and should give their clerks in both theoretical and practical studies, and duty in their stores.

CHEMISTS' ASSISTANTS' ASSOCIATION.

The first meeting of the sixth session of the above Association was held at 32A, George Street, Hanover Square, on Wednesday evening, October 11, when the President, Mr. W. A. Wrenn, delivered the opening address. There was a large attendance of members. Mr. Wrenn commenced by stating what a privilege he felt it, to deliver the annual address at the commencement of the session, and to follow in the steps of the many worthy men who had preceded him. He then gave a review of the progress of the Association from its foundation, now six years ago, until the present time, and expressed his belief that those who had had the difficult task of organization must view with satisfaction and pleasure the benefits which it has continued to confer upon chemists' assistants. The first meeting was held in the rooms of the Pharmaceutical Society and from that time until this the primary objects of the Association, viz., the social and scientific improvement of its members, had been continually in view. This was the commencement of a new session, and on behalf of the Council he had very great pleasure in bidding the members welcome to the varied meetings which had been arranged for the first half of the session. Having alluded to the necessity of individual exertion as necessary to continued progress, Mr. Wrenn concluded with a few well-chosen words of advice to members.

A very hearty vote of thanks was given to Mr. Wrenn for his admirable address.

Parliamentary and Law Proceedings.

The Sale of Patent Medicines containing Poisons.

Dr. Diplock held an inquest on Monday, at Notting Hill, on the body of Edward Harris, aged ten months, the illegitimate son of Jessie Harris, a widow.

It appeared from the statement of the mother that on the morning of Sunday week last she gave the deceased twelve drops of "soothing syrup" to relieve a cough from which he was then suffering. On the following day the child was taken to St. George's Nursery, Peel Street, where it was seen by the matron, who noticed its drowsy condition. On the Tuesday following it was taken to Dr. Davis, who prescribed an emetic which took off the sickness. The child, however, became worse and died on Thursday.

Dr. Davis proved having made a *post-mortem* examination, and finding traces of morphia in the stomach. He said death was due to a narcotic.

A Juror observed that the sale of such a medicine should be at once prohibited.

The Coroner explained that the medicine was sold under a stamp duty. Juries had referred to the dangerous condition of the syrup in their verdicts on several occasions. To some children, the Coroner added, the syrup was a most fatal poison, but others could take it with impunity.

Dr. Davis informed the Court that the bottle which the mother bought contained sufficient syrup to poison half-a-dozen children.

The Jury returned a verdict that death was due to a narcotic, through misadventure, to which the following rider was attached:—"That some restriction should be made on the sale of patent medicines which could be used as poisons." The Jury also expressed their unanimous opinion that no blame whatever was attached to the matron of the Nursery.

The Coroner having promised to forward a copy of the verdict to the Home Secretary, the proceedings terminated.—*Standard.*

Poisoning by Vermin Killer.

At an inquest held at Bramley to inquire into the circumstances attending the death of Angelina Abbott, it appeared from the evidence that the deceased had taken some "vermin powder" in consequence of a dispute with a man with whom she had been keeping company. A verdict of "Poisoned by a dose of vermin powder, taken while in an unsound state of mind" was returned.—*Leeds Mercury.*

Obituary.

GEORGE HENRY KENDRICK THWAITES, F.R.S.

We regret to learn that intelligence has been received from Ceylon of the death, on the 11th ult., in his seventy-second year, of the celebrated botanist, Dr. Thwaites, formerly Director of the Royal Botanic Garden, Paradenia, in that island. Dr. Thwaites was an Honorary Member of the Pharmaceutical Society of Great Britain, having been elected in the year 1856.

Notice has also been received of the death of the following:—

On the 27th of August, Mr. William Potter, Chemist and Druggist, Fleckney, near Market Harborough. Aged 79 years.

On the 2nd of September, Mr. Gaudern Wilson, Chemist and Druggist, Crowland, Lincolnshire. Aged 68 years.

On the 13th of September. Mr. Clement Taylor, Chemist and Druggist, St. John's Road, Sevenoaks. Aged 62 years.

On the 17th of September, Mr. Edgar Humphries, Chemist and Druggist, Garston, Liverpool. Aged 34 years. Mr. Humphries had been an Associate of the Pharmaceutical Society since 1875.

On the 19th of September, Mr. Thomas Teasdale, Chemist and Druggist, Goulgreave, Derbyshire. Aged 53 years.

On the 23rd of September, Mr. Thomas William Drinkwater, Chemist and Druggist, Pollard Street, Manchester. Aged 50 years.

On the 23rd of September, Mr. James Michie, Chemist and Druggist, High Street, Forres. Aged 65 years.

On the 1st of October, Mr. Edmund Crossley, Chemist and Druggist, Princes Street, Bury. Aged 54 years.

On the 4th of October, Mr. Francis Johnson, Chemist and Druggist, Kentish Town, N.W. Aged 63 years.

On the 6th of October, Mr. James Dashwood, Chemist and Druggist, Fratton Street, Portsmouth. Aged 27 years. Mr. Dashwood had been an Associate of the Pharmaceutical Society since 1873.

On the 7th of October, Mr. John Facey, Chemist and Druggist, Woodwell Crescent, Bristol. Aged 42 years.

Correspondence.

Dr. Greenhow's Report and the Curriculum.

Sir,—I can well understand the consternation produced in the minds of Mr. Schacht, Dr. Symes, and the other supporters of the curriculum scheme, by the remarks that Dr. Greenhow thought fit to make in the concluding paragraph of his report. I can also appreciate the strong desire to explain away the obvious meaning of his words. And I would strongly recommend the advocates and opponents of the scheme to ponder them seriously.

Now Dr. Greenhow has not arrived at his conclusions hastily, but they are evidently the result of prolonged and careful observation and experience. In support of this statement I would refer your readers to his three previous reports (*vide Pharmaceutical Journal*, 1880-81, pp. 313 and 843). I will make one quotation, but I would advise all who are interested in the question to read the entire reports. In that dated March 8, 1881, writing of the Minor examination, he states:—"The propriety of compelling candidates for this examination to pass a certain time at a school of pharmacy has been a good deal discussed lately among persons who are interested in the subject of pharmaceutical education. I am, however, of opinion, that a curriculum or special course of study at a school of pharmacy is not required for persons who are preparing for the Minor qualification. The examination, when properly conducted, affords a sufficient guarantee of a candidate's fitness for registration under the Pharmacy Act."

Dr. Greenhow then proceeds to give his reasons, which I will refrain from quoting, being merely anxious to call attention to the reports themselves, and to show that the remarks in the last, viz., that under discussion at the recent Council meeting, were not made inadvertently or ignorantly.

I cannot quite understand Mr. Hampson's position in regard to the scheme, for he seems to me to halt between two opinions, and to be the connecting link between the two parties.

As chairman at the meeting of the Chemists and Druggists' Trade Association in May, he seemed disposed to throw in his lot with the advocates of the curriculum; but from the tone of his remarks in the discussion on the report on Wednesday, he seems to return to the views which first aroused my sympathy and active support. Truly the workings of Mr. Hampson's inner consciousness are mysterious. But I am not disposed to quarrel with Mr. Hampson, for, generally speaking, he evinces a highly practical turn of mind, and I suppose that sometimes what is termed the "Shadow of the Council" obscures his mental vision. Now again he and I are in complete accord. Again I ask with him, What is the prevailing state of affairs?

Are there any businesses which would utilize to the full the scientific knowledge which it is proposed to render imperative? I would not be misunderstood, it is compulsion I object to, for I would not discourage the acquisition of knowledge to any extent practicable by those who have the means and the inclination for it. But it does strike me as being not a little hard, that men should be compelled to acquire knowledge such as proposed, simply for its own sake. The compulsory examination should only require such an amount of knowledge and skill as is required for the protection of the public.

This view is neither mischievous nor misguided, but is, I contend, practical and what is more, fair. Why should men be driven out of the trade merely to satisfy the whims of those who, having by some means or other acquired a good financial position, now hanker for a professional status which they at present lack?

As to the class of men who enter the trade, the thing speaks for itself; they are for the most part suited to its requirements. For it must ever be borne in mind that our trade is of a most heterogeneous description. Why then should all be compelled to acquire such a highly trained condition? Let the Minor examination stand as it is. Institute a curriculum for the Major if you will; that is voluntary, and so no hardship would be inflicted. The two classes would be gradually differentiated and eventually perhaps, if pharmaceutical prospects improve, the Major men might bloom forth as a professional order.

But it is because the higher class fears that under the natural process it will itself disappear, or has not the patience to await its action, that it seeks to violently extinguish the lower, and having the ear of the authorities and command of the votes it may possibly achieve its purpose. Some may say that the admission contained in the latter statement cuts the ground from under my feet. I reply, Not at all, for it is, to a great extent, only the higher class that has votes. Take a plebiscite of the whole trade and then see which way the balance leans.

I, as a pharmaceutical chemist, most certainly desire to see our lot ameliorated, but not by unfair means. As soon as there is a real demand for a higher and better educated class of men, depend upon it there will be an ample supply, Openings in life are daily becoming more and more scarce for such, but they will not come forward in any numbers unless the prospect be considerably better than it is now. We cannot, under present circumstances, afford to cast aside that portion of our business which stamps us as traders, and, as Mr. Hampson says, in very many businesses pure pharmacy scarcely exists. Certainly many chemists would soon cease to exist if they relied solely upon it.

The great majority of practitioners in town and country do their own dispensing, and many of them dispense physicians' prescriptions whenever they get the chance. We, for the most part, act as jackals, picking up such scraps as may be left.

I therefore earnestly hope that whilst this state of things continues, the authorities will be cautious, and restrain somewhat their eager desire for a professional position, unless they can give us the means of supporting it.

Wantage. J. Gilbert Candy.

Rat Poison.—A correspondent has directed our attention to an article that has recently been introduced into this country as a rat poison, which he says consists of coloured arsenic. We should think no person would undertake the sale of such an article before he has satisfied himself as to its nature.

J. Ward.—We are unable to answer your question.

A Country Pharmaceutical Chemist is recommended to call the attention of the Inspector appointed under the Sale of Food and Drugs Act to the practice.

A. B. C.—See the case reported in the Journal for January 28 last, respecting the labelling of syrup of chloral hydrate for the only decision upon the subject with which we are acquainted.

Associate.—We are unable to furnish you with any information about the oil in question.

Antiseptic.—Neither an aqueous nor an alcoholic solution can be said to "keep indefinitely," and the permanence of either would probably depend upon the condition of the salt. Other things being equal the alcoholic solution would probably remain unaltered longest.

"*Nemo.*"—Tincture of hamamelis, made according to the published formula (1 to 10 of proof spirit) is dark brown. But as there is no authoritative formula the preparation as obtained from different sources may differ in appearance.

W. I. S.—The question is one that involves medical opinion. The dose of liquor strychniæ is below the maximum of the B.P.

R. Andrews.—The preparation of the article as directed in your formula would involve considerable risk.

"*Guerra el Cuetiello.*"—(1) The extract, being an alcoholic one, should be dissolved in spirit previously to mixing it with the water. (2) Insoluble carbolate of lead being formed the lotion will be unsightly. There is no remedy for it. (3) Crumb of bread. (4) Emulsify the ol. terebinth., *sec. artem,* with half its weight of pulv. acaciæ.

Communications, Letters, etc., have been received from Messrs. Bennett, Davis, Landerer, Dobson, Woodland, Brown, Morgan, Newsholme, Keyworth, Zinc, Pertinctus, Succus, Tegid, Junior, W. R. F.

"THE MONTH."

The recent gale and rain have produced quite a wintry effect on botanical gardens, denuding the trees of their foliage, and rotting the blossoms of the already limited number of autumnal flowers. The fruits of many medicinal plants may, however, still be observed in good condition. At the Botanical Gardens, at Regent's Park, the dulcamara grows side by side with a variety of *Solanum nigrum* (var. *miniatum*), with orange-red berries and another variety with yellow berries, the red ones look so like red currants that it is fortunate these varieties are not common, or cases of poisoning by *S. nigrum* would be more common than they are. Only last week another case of poisoning by the berries of *Solanum nigrum* occurred, this time in the north of London, but the child recovered after the administration of sulphate of zinc. As few as three or four berries have been known to produce sleep, and Dr. Taylor, in his work on Poisons (1875, p. 677), records the occurrence of a death from eating the black berries of this plant. The deaths which have resulted from eating these berries have been thought by some to have been caused by belladonna, which had been confounded with it. In the present case, however, there can be no doubt about the plant, the berries being stated to have been of the size of currants and to have grown in a London garden. The fruit of belladonna when black is as large as a black cherry. This plant (*S. nigrum*) certainly deserves chemical investigation to determine whether it contains solanine or some other alkaloid, and at the present time of year the berries could be procured in considerable quantity for the purpose.

About two years since, Dr. Harley, in an article that was reproduced in this Journal (vol. xi., p. 437), affirmed decidedly that there was no warrant for the generally accepted opinion that fool's parsley (*Æthusa Cynapium*) is poisonous. Some results of an investigation reported by M. Tanret to the Paris Pharmaceutical Society, at a recent meeting, fully bear out Dr. Harley's statement (*Journ. Pharm. et Chim.*, [5] vi., p. 325). M. Tanret says that he has failed to find in fool's parsley any alkaloid, glucoside, or other body, to which the reputed poisonous action of this plant could be attributed, and that physiological experiments gave equally negative results. He is, therefore, of opinion that fool's parsley is non-poisonous. M. Tanret has also observed that malic acid, which is rather abundant in the roots of fool's parsley, is replaced in the aerial parts of the plant by fumaric acid; vegetation would, therefore, in this case appear to produce upon malic acid the same effect as heat.

The carbohydrates contained in Ceylon moss (*Sphærococcus lichenoïdes*) form the subject of a communication by Mr. H. G. Greenish to the *Archiv der Pharmacie* (xvii., 241). Instead of confining his attention to one constituent, the author has endeavoured to ascertain what carbohydrates enter into the composition of the drug, to what extent they resemble or are identical with similar substances contained in phanerogams and to what extent they are present. He finds that the gelatinizing constituent (named by Payen "gelose") is a carbohydrate convertible by boiling with dilute acid into arabinose and probably identical with a similar constituent in the agar-agar of commerce; the latter differs from pararabin (its identity with which was asserted by Reichardt) in its insolubility in cold dilute hydrochloric acid. In addition to the gelatinizing constituent (36·7 per cent.) the drug appears to contain mucilage (2·7 per cent.), starch, metarabin (1·32 per cent.), wood-gum (3·17 per cent.), cellulose (identical with that of phanerogams, 10·17 per cent.); and further a carbohydrate, provisionally termed paramylan by the author, dissolved by dilute acid but differing from Reichardt's pararabin (which is extracted from phanerogamous plants in a similar manner) in being directly convertible into sugar and then yielding not arabinose but a fermentable sugar, probably grape-sugar. This substance is present to the amount of about 6·5 per cent. and appears, as the author remarks, to be deserving of closer investigation.

The observation that diastase is present in ungerminated corn was made by Dubrunfaut, and found confirmation in the discovery by Gorup-Besanez of a diastatic and peptone-forming ferment in vetch seed. Since then diastatic ferments have been reported to have been met with in various starchy and oleaginous seeds, potatoes, turnips, the buds of trees and other parts of plants. An investigation has now been undertaken by Dr. K. Nachbaur having for its chief object to determine what part of the corn grain is the seat of the diastase, the embryo being the part chosen for the first experiments and the grain used being Russian rye (*Monatshefte*, iii., 673). He has failed, however, to obtain from the finely powdered embryo any body capable of converting starch paste into sugar or coagulated albumen into peptone, and he draws the conclusion that the diastatic ferment observed in species of corn is not contained in the embryo. Qualitative and quantitative determinations of the embryo gave results corresponding perfectly with the statement of vegetable physiologists that it consists of protein substances, fat, cellulose, sugar, ash and water, but contains no starch.

It is, perhaps, not generally known that Dicotyledonous plants do not invariably consist of two entire cotyledons. Bentley and Hooker in the 'Genera Plantarum,' describe the genus *Bursera* as having cotyledons, "*interdum trifidæ, in una specie hippocrepiformæ.*" A specimen of the seeds of *Bursera microphylla*, collected at Arizona, near Maricopa, and cultivated at the Botanic Gardens of Harvard University, shows this species to possess cotyledons biternately dissected into linear lobes. The second pair of leaves are simpler than the cotyledons, the secondary lobes being fewer and short, while the next succeeding are pinnately divided into seven leaflets, thus approaching in character the adult form of leaf, which is pinnate with numerous very small leaflets, on an interruptedly margined leaf (Proc. American Academy of Arts and Sciences, xvii., 230).

Scientific botanical terms are often condemned as the dry bones of an otherwise interesting study; but even these may sometimes have points of interest. This is the case with the word *hilum*, of which, under the head of *Hilus renis*, Professor Hyrtl writes:—"The word *hilus* is, I must say, a barbarism, for it was only known to the Romans as *hilum*. They understood by the *hilum*, according to Festus, *id quod grano fabæ adherent*, that is, the *macula nigricans* on the concave border of beans. From the nature of this little spot, the Romans would talk of any trifling matter as not worth a hilum, *ne hilum*, contracted to *nihilum*, and through the latter term to *nihil*."

Cinchona cultivation appears to have a promising future in Jamaica. In the report on the public plantations and gardens in Jamaica for the year ending September 30, 1881, just issued, the energetic director, Mr. D. Morris, states that 330,000 seedlings and 49,000 plants had been distributed during the year, besides a considerable quantity of seed, whilst the number of plants remaining in the nurseries at the date of the report is estimated at 178,000. Of these about seven-eighths were *C. officinalis* plants; other kinds represented being the "*Uritusinga*" variety of the same species, *C. Calisaya*, *C. Ledgeriana*, *C. succirubra* and a "hybrid." One of the most important of these would appear to be the supposed "hybrid," which for some years received particular attention under the impression that it yielded yellow bark, the true *C. Calisaya* having been wrongly looked upon as a form of *C. officinalis*. The plant is said to be hardy and a remarkably free grower, and it is believed by Mr. J. E. Howard to closely resemble *C. officinalis*, var. *Uritusinga*, a point that Mr. Morris hopes to clear up shortly. Meanwhile it is interesting to learn that a sample of trunk bark from this "hybrid," analysed by Mr. Howard, yielded 6·0 per cent. of quinine alkaloid, 0·73 per cent. of cinchonidine, 0·10 per cent. of cinchonine and 0·03 per cent. of quinidine. The plant which, as mentioned before, was by mistake included under *C. officinalis* has been identified both by Mr. J. E. Howard and Mr. Morris as true *C. Calisaya*, and samples of trunk bark from it yielded upon analysis to the former gentleman 3·7 per cent. of quinine alkaloid, and to the latter 5·38 per cent., together with a little cinchonidine, cinchonine and quinidine.

In one of the papers read before the British Pharmaceutical Conference at York last year, Mr. Greenish gave the results of an examination of some samples of jalap tuber grown in Jamaica. In the report above mentioned, Mr. D. Morris gives some further details as to this interesting experiment in acclimatization. The land devoted to the growth of jalap in Jamaica during the period stated was five acres, and the crop of green tubers harvested weighed 3400 lbs., and yielded 1077 lbs. of cured jalap. The principal difficulty appears to have been met with in the drying. The smaller tubers were dried whole in the sun, and although a considerable proportion of them was lost through fermentation and mouldiness, the result was considered to be on the whole satisfactory. The larger tubers were sliced or gashed, and in the drying of some of these an American fruit dryer was successfully utilized, although the operation required to be carefully conducted to prevent alteration of the starch grains. According to information since received from Mexico, the jalap tubers after being uprooted are in that country soaked for four hours in water saturated with lime and then dried in the sun. Afterwards they are covered with blankets for three days and then again dried; this is said to prevent them from moulding. One consignment of the Jamaica grown tubers was sent to London, and two others were sent to New York. Some objection seems to have been raised in the former market to the slice form, although the slices really contained the largest proportion of resin, but not in the latter. The returns did not amount to enough to pay the cost of the experiment, but another attempt is to be made and it is to be hoped that Mr. Morris's perseverance will meet with the reward it deserves.

In Sicily the Cavalière d'Amico has succeeded in acclimatizing *Cinchona succirubra*, *Indigofera tinctoria* and *Myrica cerifera*, the latter being the plant yielding the bark known to herbalists in this country as bayberry bark (*Nature*, p. 186).

About eighteen months since (*Pharm. Jour.*, xi., 897) Herr Teegarten published some notes on a sample of Bulgarian opium that contained 8 per cent. of morphia. The same chemist has recently had some other samples of opium produced in the principality submitted to him, which appear to have shown a considerable improvement in morphia strength. One sample from the Küstendil district presented exceptional characters. It was in lumps weighing 120 to 300 grams, had an unusually strong smell of opium and tasted very bitter. It was well dried, yielding 92·37 per cent. of dried opium, and 19·15 per cent. of morphia, or calculated on the dried drug 80·73 per cent. A sample from the Lowtscha district gave 89·61 per cent. of dry opium, and 11·90 (or 13·28) per cent. of morphia. Another, from the Halitz district, gave 89·14 per cent. of dried opium, but this yielded only 7·25 (or 8·13) per cent. of morphia. The amount of ash was very low, ranging from 2·69 to 2·85 per cent. There appears to be some uncertainty as to the extent of opium production in Bulgaria whilst the principality was under Turkish dominion; but Herr Teegarten has been informed that nearly the whole of it was used by local pharmacists, any surplus being bought by Jews and Turks at low prices and carried to Constantinople, where it was sold as Turkish opium.

The occasional bad quality of drugs offered in the drug market is notorious among those who have to buy them wholesale, and at a recent drug sale called forth severe comment. This month, no less than 1½ ton of ipecacuanha was put up for sale, which was so covered with mildew that very little else was to be seen except the contour of the root. This reduced the price of the drug from 5*s.* to less than 2*s.* The question which naturally occurs to those concerned is, what will become of all this? Will it be washed and offered for sale again, or will it be exported to India, where the drug is used as a sheet anchor in dysentery, or will it find its way into the army and navy stores after it has been cleaned and "polished up equal to new?" Ipecacuanha root when examined under the microscope may often be found to contain fungoid threads, and this fact and the variable quality of the wine made from the drug indicates the probable correctness of the supposition that damaged drugs are not destroyed in this country, but actually enter into commerce. This is a matter into which Government should look. It would have nothing to lose and much to gain by the appointment of an inspector whose duty it would be to examine imported drugs and to condemn and see that those unfit for use are destroyed. It is a matter no less important than the inspection of food. At the present moment it is said that owing to the scarcity of hops, quassia, chiretta and calumba are going up in price, and that spent hops which have been used in brewing in this country are being dried and exported to the Continent. In the United States the appointment of a Government officer for the inspection of drugs has almost entirely stopped the previously large exportation of inferior drugs to that country.

In a letter to the *British Medical Journal* (p. 714), R. W. W. complains of being much annoyed by constantly meeting with worthless specimens of cannabis indica and hyoscyamus. He remarks that there are always worthless drugs in the market, and medical men would do well to test their action more frequently than they do. It may also be asked, what becomes of the poisonous Japanese star-anise that is so frequently offered in large quantities, of the false buchu, of the worthless yellow cinchona bark, and of numerous other spurious or very inferior drugs?

Dr. Squibb gives some valuable results obtained by himself in experiments with aconite (*Ephemeris*, i., 123). He considers it a good test of the quality of the root, if eight out of ten roots, broken across the middle, give a tingling taste when a minute fragment is bitten off and chewed for a moment between the front teeth. He remarks concerning the alkaloids that pseudaconitine has a less tingling taste and more of a peppery heat in it, and is about ten times stronger than aconitia. In one European specimen of aconitine, the taste was so bitter that Dr. Squibb believed it to consist chiefly of a decomposition product, picraconitine. The relative strengths of four samples of alkaloids compared by him with a standard solution were as follows:—Aconitia of unknown maker, 1; Merck's aconitine, 8; Merck's pseudaconitine, 83; Duquesnel's aconitine, 111. He further remarks that the last-mentioned produces a very different impression on the mouth from that of either of the other aconitias and from that of the root of *A. napellus*, causing in a greater degree the tingling element which commences almost immediately, while that of pseudaconitia is delayed from five to ten minutes. It also diminishes rapidly, which is not the case with pseudaconitia. The paper is full of valuable information and deserves a careful perusal.

In a communication to *Ephemeris* (i., 116) Dr. Reiter states that he has had personal experience of the value of the seeds of the common burdock (*Arctium Lappa*) in the relief of psoriasis inveterata. The preparations used were made by steeping the seeds in whisky, or dilute alcohol. Dr. Squibb recommends for the former to place one pound of well-crushed fresh burdock seeds in a bottle with one gallon of good old whisky, and keep in a warm place, occasionally shaking it, for a fortnight. The maximum dose of the clear tincture is 4 fluid drachms, well diluted, three times a day immediately after meals; when the dose is a large one whisky is recommended as a menstruum, but for smaller doses proof spirit is preferred. Dr. Reiter considers the therapeutic action of the tincture to be that of an alterative stomachic and says it appears to improve all the nutritive, secretive and assimilative functions. This use of burdock is by no means new, the root being used by herbalists in this country as a common remedy for skin diseases. Gerarde in his 'Herbal' quotes the statement of Columella that it is good for the king's evil. In Japan the plant is cultivated as a vegetable under the name of "gobo," and, according to information furnished by Professor Kinch, grows much larger and finer than in this country. The root and the petioles are used for this purpose. Several varieties of the plant are known, and are called by the names of the districts in which they are cultivated. From the occurrence of the seed among Japanese drugs it may be presumed that it is employed medicinally in that country. Gerarde in his 'Herbal' figures *Xanthium strumarium* under the name of "the lesse burre docke," and remarks, "It seemeth to be called Xanthium of the effect, for the burre or fruite before it be fully withered being stamped and put into an earthen vessel and afterwards when need requireth the weight of two ounces thereof and somewhat more being steeped in warm water and rubbed on maketh the hairs of the head red; yet the head is first to be dressed or rubbed with niter as Dioscorides writeth," a statement which suggests the idea that this plant might have been used by the ancient Greeks to dye the hair of the much prized colour, ξανθὴ κόμη, a term applied to the hair of Achilles and other heroes.

In the *British Medical Journal* (p. 719) Dr. E. Mackey calls attention to the value of salicylate of soda as a remedy for tonsillitis, and in cases of gout as a local application, the salt being, at the same time, also given internally in 10 grain doses every four hours. He sometimes orders the salicylate of soda to be dissolved in liquor ammoniæ citratis, with which, he states, it should form a clear colourless solution, which agrees well with patients; but he adds, "When dispensed by some chemists, I have known it turn brown and cause irritation and vomiting." This probably results from the natural acid being used in some cases and the artificial in others; at all events the point requires to be cleared up by experiment.

Professor Rapon has published (*Wien. med. Wochensch.*, No. 30 and 31, 1882) an account of further experiences of the value of naphthol. He states that when patients suffering from scabies are once rubbed with an ointment of naphthol, and then well powdered and covered with woollen clothing, the cure is often effected in a single day. His formula for the ointment is—lard, 100; soft soap, 50; naphthol, 15; creta alb. pulv., 10 parts. In prurigo also this remedy is highly recommended, a 5 per cent. ointment being used. In eczema a very weak ointment is applied, as the naphthol proves very irritating; and in prolonged cases simple ointment is substituted every fourth week to avoid any possible risk of absorption (*Brit. Med. J.*, p. 750).

The *Lancet* (p. 540) calls attention to the successful use of ergot in reducing enlargement of the spleen. In a severe case, in which the spleen nearly filled the abdominal cavity, the reduction was effected by this remedy in a fortnight. In this case, 3 drops of the fluid extract were given three times a day.

Dr. Froumuller, of Fürth, recommends tannate of cannabine as an excellent hypnotic, stating that its use is free from danger; that it does not disturb the secretions, and if the dose be suitable does not produce intoxication (*Med. Press and Circular*, p. 268). He administers it in doses commencing at $1\frac{1}{2}$ grain in powder, mixed with sugar, or dissolved in water by the aid of a small quantity of alkali.

Experiments made by Hillier (*Zeits. f. kl. Med.*, September; *Med. Press and Circular*, p. 268) show that hypodermic injections of colocynthin, citrullin and cathartic acid produce too much pain to be of any value in therapeutics, whilst aloin administered in the same way does not cause this inconvenience, but is very unreliable.

M. Melsens, having observed that persons suffering from pulmonary disease derive good effect from the emanations of carbonate of ammonia in the atmosphere of stables, conceived the idea that a moderate inhalation of the vapour of this salt might be useful in other affections of the respiratory tract, and tried it on himself, after a serious attack of bronchitis, by suspending from his neck a little bag containing small pieces of that salt. From the first day relief was felt, and the cough soon disappeared entirely. Further experiments showed that this remedy gave relief also in cases of chronic bronchitis (*Med. Press and Circular*, p. 337).

Dr. Brown-Séquard has recently (*Nature*, p. 557) made the interesting discovery that in certain animals complete local anæsthesia of the larynx, accompanied by incomplete general anæsthesia, may be obtained by directing on to the upper part of that organ a rapid current of carbonic acid during a period of fifteen seconds to two or three minutes. The anæsthesia lasts from two to eight minutes after stopping the current. Dr. Séquard proposes to experiment on the human subject by introducing carbonic acid through the mouth or nostrils. This singular action of the acid may perhaps throw some light on the sedative action of aerated waters in vomiting and nausea.

In a paper on the treatment of chronic ringworm (*Brit. Med. Journ.*, Oct. 7, p. 682) Mr. Alder Smith recommends a preparation made by dissolving 10 parts of oleate of mercury in 90 parts of heavy petroleum oil as the most efficacious parasiticide he knows for chronic ringworm. He states that he has found it less liable to decomposition than the ordinary preparation of oleate dissolved in oleic acid and less irritant to the scalp. For children under seven years of age, if the 10 per cent. solution be found too strong, it can be further diluted with ordinary petroleum.

Sulphur ointment is suggested as a simple remedy for *Bacterium decalvans*, to which Dr. Thin attributes alopecia areata. In a number of cases described by Dr. Thin in the *British Medical Journal* (p. 784) the application of this ointment was found to result in preventing the spread of the disease, which it cured, a growth of down taking place within a month after commencement of the treatment. This action of sulphur may possibly explain the apparently beneficial results obtained by the use of various hair lotions containing sulphur. Dr. Thin, however, considers that the fat mechanically prevents the growth of bacteria on the surface of the scalp, while the sulphur acts destructively upon them. If further confirmation of these results be obtained, it seems probable that sulphur pomade may in future become a regular article of stock for pharmacists.

Some interesting facts have recently been collected by M. D'Abaddee to show that sulphur emanations exert a marked influence on malaria (*Lancet*, p. 676). In Sicily the labourers in the sulphur works in plains where malaria is common enjoy an almost complete immunity from intermittent fever, only 8 or 9 per cent. of the villagers suffer from it, while of those in neighbouring villages not engaged in this occupation 90 per cent. are attacked. According to M. Fouqué, the city of Zephyria, situated in a marshy plain where it is impossible to pass the night without being attacked with ague, dates its decadence from the discontinuance of the sulphur workings formerly carried on in its vicinity. Three hundred years ago the city was said to have forty thousand inhabitants, but when the sulphur works were given up paludal fever gradually destroyed the population, so that twenty years ago only two hundred inhabitants remained. In the portion of the marshy plain of Catania where sulphur works exist the inhabitants suffer but little, while a village not far off is deserted. Elephant hunters in Ethiopia are said to enjoy an almost complete immunity from the disease through using a fumigation of sulphur daily. Dr. Thin's results, and the known value of sulphur in destroying the fungus which attacks the hop, seem to point to the need of ascertaining to what this anti-bacteric action is due, whether to sulphurous acid, sulphuretted hydrogen, the vapour of sulphur itself or of some peculiar oxide of sulphur.

In the *British Medical Journal* (pp. 736, 786) Dr. H. Gibbes gives some further hints on the best mode of staining the bacillus tuberculosis for the microscopical examination of sputum, and points out possible sources of error which may occur if the sputum be not obtained under suitable circumstances, *e.g.*, if it comes not from the lungs, but from the throat, or if the chemicals used be not of a definite character.

The researches of Messrs. Schloesing and Müntz on the Continent, and of Mr. Warington in this country, have established the fact that the phenomenon of nitrification in the soil and in organic liquids is due to the action of microscopic organisms. On the other hand a communication recently made by Messrs. Gayon and Dupetit to the Academy of Sciences (*Comptes Rendus*, xcv., 644) seems to show that the inverse reaction, the reduction of nitrates, is also a physiological phenomenon. They state that when decomposed urine is added to sewage liquid, or neutralized chicken broth, containing 0·020 gram of potassium nitrate per litre, the nitrate gradually disappears and the liquid becomes full of microscopic organisms. If the mixture is sterilized by heat, or if chloroform or sulphate of copper be added, the action does not take place. But, very curiously, carbolic and salicylic acids, even in proportions considerably beyond those used generally for antiseptic purposes, do not retard the reduction; on the contrary, they are themselves attacked by the microbes and disappear with the nitrate. Under favourable conditions, at a temperature between 35° and 40° C., the fermentation is so energetic and the multiplication of the microbes so great that a gram of nitrate per litre is reduced daily. The gas given off is pure nitrogen; the oxygen remains in the liquor as carbonate. As to the organisms, they belong to the class called anaërobes by Pasteur, and when cultivated at the surface of the liquid, in contact with air, become inactive or nearly so.

Dr. Brockhaus, of Godesburg, has recently been experimenting (*Medical Times and Gazette*, p. 505) *in propriâ personâ* on the alcohols and allied bodies likely to occur in alcohol made from grain, with a view to determine the properties of each. It has long been known that alcohol containing fusel oil causes delirium tremens, while pure grape spirit is said not to do so. Aldehyde has a very powerful effect, persons who have drunk brandy highly charged with it falling senseless within a few minutes. To the presence of this substance Dr. Brockhaus attributes the intense and early intoxication produced by some new wines, which when matured are harmless. Many cases in which the persons are supposed to have been drugged may be explainable in this way. Paraldehyde and acetal were found to resemble aldehyde, but the taste and effects are milder, though the latter last longer. Propyl and isobutyl alcohols seemed to exert less influence on the mental, but greater influence on the digestive functions than the foregoing; allyl alcohol, besides producing effects similar to amyl alcohol caused a weakness of the limbs approaching paralysis. This alcohol is said to be used in Germany to render spirit unfit for drinking, as the crude methylic is with us. Dr. Brockhaus says that as the ordinary modes of purification are inadequate to the entire removal of the liquids above mentioned the sale of potable spirits for other uses than in the arts should be forbidden.

Amylic alcohol is sometimes used as an alkaloidal solvent, but an observation made by Herr Haitinger (*Monatshefte*, iii., 687) seems to show that some circumspection is necessary in using it for this purpose in delicate investigations. Having occasion to examine an article of food for the presence of alkaloids he sought to separate any present by shaking it with amylic alcohol. From the alcohol, subsequently, a small quantity of substance was obtained as a deliquescent hydrochlorate, which gave the general alkaloid reactions with iodo-potassic iodide solution, but did not answer to any of the better-known poisonous alkaloids. This led to the closer examination of the amylic alcohol used, and upon shaking it with dilute sulphuric acid a small quantity of a basic substance was separated, and a similar result was obtained with eight out of nine samples of amylic alcohol from different sources. A larger quantity (2 kilograms) of "pure" amylic alcohol was then repeatedly shaken with dilute sulphuric acid, and the watery liquid concentrated and distilled with excess of caustic potash. The distillate was strongly basic, smelt strongly of pyridine, and eventually yielded crystals corresponding in appearance and composition with the platinum double salt of pyridine. From other samples different bases were obtained, one differing in odour from pyridine, boiling at a much higher temperature, and forming a platinum salt with a composition that seemed to indicate that the base was bivalent. Probably this difference in the alkaloids present in different samples finds its explanation in the varying materials from which amylic alcohol is derived. The proportions found ranged from 0 to 0·1 per cent., the average being 0·04 per cent.

Selmi, in prosecuting his researches on the alkaloids found in the human body, has come to the conclusion that in fatal cases from paralysis, tetanus, etc., death is due to poisons of an alkaloidal character, produced by the progress of the disease. He has found such bodies in the urine of patients suffering from these maladies (*Nature*, p. 568).

It has been pointed out by Mr. Pedler that some snake poisons are rendered inert by platinic chloride, possibly through the formation of an insoluble compound with the active principle of the poison, which has been said to be of an alkaloidal character. Confirmatory of this theory, Professor Henry Croft (*Chem. News*, Oct. 13, p. 165), writing from Texas where rattlesnakes are common, says that a favourite antidote to snake bites in that country is a strong solution of iodine in iodide of potassium, applied immediately to the wound, and a few drops taken inwardly. He states that he has had the opportunity of proving the efficacy of the solution in two cases of "cascabel" bites, one on a buck and the other on a dog, and he conjectures that the action might be due to the formation of an insoluble iodo-compound. Upon adding a drop of iodine solution to some of the white opaque poison taken from the fangs of a rattlesnake a dense light-brown non-crystalline precipitate was immediately formed, similar to that produced by the same reagent with several alkaloids.

M. Carles reports (*Répertoire*, x., 443) that in using Personne's test for the estimation of potassium iodide, which is based upon the amount of mercuric chloride that can be added to an aqueous solution before the formation of a permanent red precipitate, he has sometimes failed to obtain constant results with the same specimen of iodide. This he found to be due to the decomposition of the double iodide of mercury and potassium by water, which takes place in proportion to the extent of dilution of the solutions. He therefore proposes to substitute for water dilute spirit (containing 17·5 per cent. of alcohol), which he says he has found to give good results.

A new test for albumen in urine, which appears to be a convenient one, has been described by Dr. W. Roberts (*Lancet*, October 14, p. 613). It is based upon the fact that when albuminous urine is treated with a saturated solution of common salt, slightly acidulated, the albumen is thrown down as a dense white cloud. The test liquor is readily prepared by mixing a fluid ounce of dilute hydrochloric, sulphuric, acetic or phosphoric acid with a pint of water, saturating the mixture with common salt, and filtering. The precipitate is, in this case, not due to coagulation, it being redissolved by shaking, unless the brine be present in excess. The method of applying the test recommended is similar to that followed with the nitric acid test. A portion of the suspected urine is placed in a test tube, the tube is held aslant, and the salt solution is allowed to trickle along the side of the tube to the bottom, so that it may form a distinct layer; or the proceeding may be reversed and the urine added carefully to the salt solution. If albumen be present a white cloudy zone appears at the junction of the two layers, and the test carried out in this way is said to be as delicate as the nitric acid test. Unlike that test, however, it throws down peptones, if present, but not white clouds of urates. When there is resin in the urine, as in the case of patients taking copaiba resin, a cloudiness is produced, but this may be distinguished from albumen in not disappearing when shaken with excess of urine.

Attention has also been called, by Mr. G. N. Stephen (*Lancet*, October 14, p. 614) to an improvement on the nitric acid test, in the direction of the volumetric estimation of albumen in urine, due to M. Tanret. It consists in the precipitation of the albumen from the urine, previously acidulated with acetic acid, by means of a solution of double iodide of mercury and potassium. The formula for the solution, 0·05 gram of which is calculated to precipitate 0·005 gram of albumen, is—potassium iodide, 3·22 gram; mercuric chloride, 1·35 gram; water to 100 c.c. In applying the test 10 c.c. of urine is taken, into which 2 c.c. of acetic acid is stirred with a glass rod, and the test liquor is run in from a pipette discharging 0·05 c.c. at a time, until the precipitate formed is no longer redissolved by stirring; when this point is reached, a drop of urine is taken after each fresh addition and placed in a watch-glass with a minute quantity of a 1 per cent. solution of mercuric chloride. The precipitation is completed when a yellowish-red colour is observed in the watch-glass, due to the formation of red iodide of mercury. The number of 0·05 c.c. added, after deducting three as having been used in excess, if reckoned as half-grams, will represent the quantity of albumen in a litre of the urine. The test may be affected by the presence of alkaloids in the urine, but the precipitate formed in consequence will dissolve either on the application of heat or the addition of alcohol.

A case of poisoning is reported from France (*Journ. Pharm. et Chim.*, [5], vi., 271), due to the substitution of a packet of barium chloride, kept for use in the analysis of plastered wines, for a packet of magnesium sulphate. About six grams were taken by a woman of middle age, and the effects were probably intensified by the fact that it was previously mixed with some hot broth. The acridity almost immediately drew attention to the mistake, and first an emetic was administered, then a saturated solution of magnesium sulphate and albumen mixed with water, followed by stimulating drinks taken internally and external rubbing with a mixture of ammonia and oil. The symptoms were vomiting and diarrhœa, general coldness, cramps limited to the lower limbs, and loss of sensation in the feet, which diminished in intensity in a few hours and disappeared in the course of the next day. There was, however, subsequent constipation.

The *Times* has given an abstract of a recent paper read before the Belgian Academy by M. Spring, on "The Origin of Thunderstorms." The author relates that in a hut on the Urenal (at a height of 2198 metres) he one night experienced a violent thunderstorm. There was, for about half an hour, terrific hail, without a single drop of rain, and whenever the hail grew momentarily more intense a vivid lightning flash occurred, and at the same moment loud thunder like the report of a powerful cannon. Before long some raindrops began to fall, and as they increased the flashes and peals became less and less frequent. M. Spring thus theorizes:—Each hailstone, of whatever size, is the result of union by regelation of many crystals of sleet. In this process an enormous free surface disappears in a body that is a non-conductor of electricity, viz., ice, and in presence of another non-conducting substance, viz., dry air. Experiment leads us to expect in such a process a large development of electricity, and to this has to be added electricity arising from friction of the hailstones with the air. Thus there would be a large number of electrified spheres near each other, and separated by an insulating medium, and these forming in some sort the surface of the region, should, according to Faraday's researches, acquire an electric charge equal to the sum of the charges of the central spheres; hence enormous electric tension in that superficial part, relieved from time to time by discharge between the hailstones and the air or the ground. It is stated that M. Spring supports his view by a variety of facts, observed both in Alpine regions and in the laboratory.

Professor W. F. Barrett read a paper at the recent British Association Meeting at Southampton "On the Alteration in the Dimension of the Magnetic Metals Produced by the Act of Magnetization." The author found that iron elongated ·00000368 of its length and that cobalt elongated ·00000235 of its length, while nickel contracted ·00000835 of its length. The volume of the nickel bar used appeared to undergo very slight shrinkage on demagnetization amounting to less than one ten-millionth of the whole volume of the bar. The author states that the "magnetic tick" was heard well with nickel and cobalt, with the latter especially so, the sound on making and breaking contact having a sharp metallic ring. It is suggested that this fact indicates the desirability of trying cobalt and nickel for telephone receivers. Further experiments are in progress to determine the effect of longitudinal tension and of temperature on the change of dimensions of the nickel and cobalt.

The Gas Committee of the Birmingham Town Council has just published one of the most valuable and elaborate reports that has yet been drawn up by any municipal body on the burning question of gas *v.* electric lighting. The report commences with an expression of opinion that the experiment of supplying electricity from a common centre, if tried in Birmingham, should be conducted under the most favourable circumstances, and that every facility should be afforded for it, consistent with the public convenience, welfare and safety, and without being hampered by any question as to the possibility of other interests being affected by its success. But the Committee has arrived at the conclusion that at present the advantages to be gained by the experiment of distributing electricity will not compensate for the loss and inconvenience which must follow the breaking up of the streets for this purpose in the busiest part of the town. The report proceeds to discuss (*a*) monopolies; (*b*) control of the streets; (*c*) profits on undertaking. Under the last head is quoted Mr. Crompton's statement in his evidence before the Parliamentary Committee on the Electric Lighting Bill, that no remunerative return was to be expected during the first seven years at least of the experiment, as well as a statement made by Mr. Gainsford, in a recent debate in the Sheffield Town Council, based upon experience gained in collieries with which he is connected, that electricity cannot be produced at the cost of gas, even when the motive power is provided free. Estimates of Dr. Siemens for a quarter of a square mile area, and of Mr. Crompton, Dr. Hopkinson and Mr. Johnson for one square mile area are given. Dr. Siemens allows 24,000 to 30,000 incandescent lamps in his area and 70 arc lamps, and estimates the cost at £100,000; the other authorities allow 50,000 incandescent lamps and give the cost as £200,000. Nearly all the witnesses agreed that nothing but a large experiment from a common centre would properly determine the question of cost. In another part of the report, it is stated that the prime cost of the conductor from Messrs. Winfield's works to the Town Hall, about 500 yards in length, amounted to more than £800 or equal to £3000 a mile, without services. This sum appears tremendous, and until something is done to reduce the cost of this essential of electric lighting progress will be retarded very greatly. The Committee has framed estimates for the supply of gas and of electricity for the Market Hall Ward, covering an area of 1000 yards square and using at a moderate computation 120,000 lights.

The cost of gas works, mains and services for this consumption is stated as £170,000 as a maximum and £100,000 as a minimum. The cost of electric light plant for about 100,000 lights is given as £423,500. The cost of meters is left out in both statements, as it is not known that a practical electric meter has been devised. The report concludes with a number of practical suggestions, the main drift of which is that it is not advisable for the local authority to apply for powers of supply, but that the Committee be authorized to enter on negotiations with the companies applying for such powers.

PRECIPITATES IN FLUID EXTRACTS.*

BY J. U. LLOYD.

(*Concluded from page* 326.)

After a precipitate has formed in a tincture or a fluid extract it is generally accepted as permanent. All will admit that precipitates often continue to deposit for months and even years, but I cannot find it recorded that they disappear. It is true, however, that a line of precipitates may form and then decrease in size, only to form and waste away again. This growth and reduction is readily understood when we consider the cause of their production, and to do this I beg leave to refer to my last communication on this subject (Proceedings for 1881). I there called attention to the fact that a percolate was a mixture of solutions, and that continuous precipitation resulted after the percolate was mixed from inability of the mixture to dissolve substances which were perfectly soluble in the fractions of the percolate at various stages of its production. From this reason I argued that with ordinary hydro-alcoholic menstruums we could not expect a line of permanent fluid extracts. This explanation, however, is insufficient to carry the production of precipitates beyond certain moderate periods, and we know from experience that the act of precipitation may continue indefinitely, independent of evaporation of menstruum. It has never been stated, that I can find, in connection with this point, that at intervals the precipitate to a greater or less extent will dissolve, yet such is the case. Were it otherwise, a point would be reached when all of the dissolved matter would be thrown from solution, and consequently no further deposition could occur.

To illustrate how precipitates may increase and decrease, let us suppose that a fluid extract of senna has remained in an even temperature until an equilibrium has resulted and the menstruum is capable of holding in solution every particle of the dissolved matters which remain above the sediment; perfect rest will now result and precipitation cease. A change in solvent power of the solution must take place before further precipitation can follow, and a change of temperature will be followed by either decreased or increased solvent power, and consequently by more or less precipitation, or re-solution of the precipitate.

Let us accept the former, that there is a decrease of temperature after a precipitate has ceased to form under a constant temperature. Another precipitate will result which is entirely different from the former, and this precipitate can to the greater extent redissolve in the menstruum when the temperature increases. This precipitate during the low temperature settles to the bottom of the bottle, and upon an increase of temperature redissolves, giving us a dense layer of solution upon the bottom of the bottle. The solvent properties of this layer of solution differ from the liquid above, and as a consequence certain portions of the precipitate previously cast down will dissolve. This dense warm liquid acts upon other constituents of the precipitate, and as these dissolve the solvent power of the solution changes and other portions of the precipitate dissolve until finally a considerable amount of the precipitate has disappeared. During this time circulation of the liquid has formed, perhaps, more than one stratum at the bottom of the container, and then by the circulation I have exemplified in my previous experiments, there is a starting upward of this lower solution, and a downward motion of the upper. Finally, a condition will be reached in some portion of the liquid where, by the intermingling of the lower and the upper solutions, certain principles that were dissolved from the precipitate will become insoluble. This state is usually indicated by a cloudiness at the point of contact of two stratums, and the result is the formation of a precipitate. This precipitate will continue to form until the composition of the liquid within the container is again uniform and the strata have disappeared. Such a final state of affairs can only be reached under an unchanged temperature, and we know that under ordinary circumstances an even temperature for any length of time is impracticable. As a consequence we may expect to have more or less of strata in our containers, and repeated precipitation and re-solution. Our precipitates will come and go with the changes of temperature, and there can be no rest. Thus is explained, as I stated at the commencement of this article, how "continuous precipitation may be taking place without depleting the liquid of dissolved matters, and may continue for an indefinite period."

There is some difficulty in accurately studying the above-named phenomena, unless the experimenter will select some article that will yield much extractive and little colouring matter, but all who have observed the action of fluid extracts and examined their precipitates at different stages will recall many instances where the foregoing description of phenomena can be applied. In connection with this subject I shall now introduce the notes of an experiment which illustrates the formation of a precipitate by the gradual admixture of different portions of a transparent percolate, and which will show us the workings of the strata currents under ordinary conditions.

May 5, 1881. Eight troy ounces of powdered capsicum were properly moistened with dilute alcohol and packed in a cylindrical percolator. The receiving vessel was an ordinary 2-gallon bottle. Into the mouth of this the percolator was inserted, and to the exit of the percolator a rubber tube was attached. This tube extended to the bottom of the bottle, and the lower end of it was fixed to a cork, so that as percolation progressed the floating cork would hold the exit of the tube at the surface of the liquid. By this arrangement the percolate was collected in the order obtained and without mixing, the lightest liquid being on top.

Description of Percolate.—The percolate passed transparent from the beginning until the end of the act of percolation. The lower portion of the liquid was dark red in thin section, black as viewed in bulk. From the upper part of this dark layer the colour became gradually less and less in shade, until it passed to a light straw colour. This point was reached at a height of 4 inches above the dark layer; the remainder of the container (6 inches) was of a uniform light straw colour, and doubtless would have remained so had the act of percolation been continued for days. This percolate consisted then of three parts, a lower solution rich in dissolved matters, a central solution, where there was a marked and rapid decrease in colour from below upward, and an upper liquid of uniform colour; the proportion being as 3, 4 and 6. Undoubtedly the bottom of the lower section was most concentrated, although the colour of the first 3 inches of solution was so deep as to forbid a comparison by the colour test. However, the entire percolate had two points of distinct division, one where the colour rapidly decreased from dark red to light red, and the other where the change was rapid from light red to yellow.

Changes.—The container was retained in the laboratory

* Read at the meeting of the American Pharmaceutical Association held at Niagara Falls, 1882.

in the position where the act of percolation was accomplished. In two hours from the time of the cessation of percolation a muddy layer of liquid appeared between the dark red (lower) and light red (overlying) solutions. In four hours the entire light red percolate was muddy; in six hours it had resolved itself into three sections, each with distinct lines of demarcation. After twenty-four hours particles of yellow precipitate appeared abundantly in the upper of these sections and gradually settled to the surface of the second section; here there was a retardation of the motion of the particles and a diminution in the amount of precipitate, but finally it collected in large particles and fell through the second dividing plane. As the precipitate passed through this second section it decreased and finally entered the heavy dark lower liquid, *where it entirely dissolved.* After seven days the three central strata had resolved into two sections and had become transparent, throughout which were clots of precipitates. The upper portion of the liquid in the bottle was very muddy, and gave rise to a constant rain of precipitates that gradually settled through the lower strata, dissolving as they passed, until only a very small amount reached the bottom of the bottle. These appearances were maintained for ninety days, at which time the liquid in the bottle had become transparent and of one colour and composition, the strata and lines of demarcation had disappeared, a uniform yellow precipitate covered the bottom of the bottle, and a layer of oil globules overspread the surface of the liquid.

Analysis of Phenomena.—The examination we have given the changes which occurred in the tube makes this example simple and readily understood. The percolate from the capsicum formed a liquid in the bottle that was concentrated at the bottom, and which became dilute with more or less regularity as we passed towards the surface. This association of different liquids under the influence of change of temperature resulted in the formation of strata, and each stratum was circulating upon the principle of those of our tube, excepting that, as the temperature changed regularly over the surface of the entire cylinder, the circulation was from the outside of each section towards the centre of the bottle. This circulation even without the aid of diffusion gradually transferred the various portions of the liquid, effecting an even mixture.

Cause of Precipitation.—By referring to our article in the Proceedings of this Society for 1881, it will be found that when different portions of ordinary percolates are mixed precipitation is likely to result. Now, the precipitate under present consideration followed from the usual cause, a mixing of percolates. The concentrated solution at the bottom of the bottle was gradually transferred to the dilute solution above, and *vice versâ.* This caused a precipitation of substances insoluble in the new solvents, and as the greatest change or strain results from the rapid dilution of the heavy solution, precipitation was most rapid at intermediate parts or the upper portion of the liquid.

Re-solution of the Precipitate.—It will be noticed that after the precipitate was formed in the upper part of the liquid, it disappeared as it progressed towards the bottom of the bottle. This re-solution resulted from the fact that the lower strata were solvents for bodies that the upper could not hold in solution. Hence the gradual formation of the precipitate in the upper part of the bottle was followed by the re-solution of the larger part as it slowly settled towards the bottom. Indeed, after seven days had passed these aggregations of precipitate in the third stratum were in pieces as large as the first joint of the little finger, but these for a long time were almost entirely dissolved in their passage through the underlying strata, only reaching into the top of the lower liquid. It must be remembered that the lower solution gradually became more dilute, and that finally its solvent action was so decreased as to permit more or less of the precipitate to reach the bottom of the container.

The points I desire to present in this paper as a step further in our study of fluid extracts may be summed up as follows:—

We cannot hope to produce by percolation a line of permanent fluid extracts or tinctures, for most percolates will precipitate more or less owing to aforementioned causes, even without a change in temperature. Theoretically this precipitation, if we could maintain an unchangeable temperature, would continue until an equilibrium was established, and then the liquid could hold in solution all the dissolved principles. However, an unchangeable temperature is not practical under ordinary circumstances, hence it follows that occasionally the sediment is increased by a precipitation which results simply from low temperature. This precipitate will redissolve when the temperature increases, the solution formed may act upon and dissolve more or less of the precipitate already present, and this stratum of liquid by diffusion and circulation will reach the upper portions of the container, to be altered in composition and precipitate again. Thus we find that from natural causes precipitation in fluid extracts made by percolation may continue indefinitely, and that these precipitates may periodically continue to increase or decrease, and that there is little chance for absolute rest. It follows also that even though we may prepare a fluid extract with great care and shake the same until it is a uniform mixture, after a period it may be very different at the top and bottom of a container. This is explained by the fact that after a decrease of temperature a precipitate is formed, then an increase of temperature redissolves it, giving a lower stratum of liquid, perhaps *very* rich in some proximate principle.

There are other phases connected with this subject, and, from the manner in which my last article to the Society was received by pharmacists and manufacturers of pharmaceuticals, I am let to believe they would prove very interesting, but to consider them at this time would lengthen the paper and perhaps make it wearisome.

COMMERCIAL BISMUTH PREPARATIONS.*

BY PROFESSOR P. W. BEDFORD.

At the time this query was accepted (as even now) the United States Pharmacopœia of 1870 was the guide by which this query should be replied.

The writer has, however, made his experiments in the light of the more exact and definite tests of the Pharmacopœia of 1880.

The impurities sought for were lead, copper, silver, arsenic, alkaline earths, ammonia, chlorine, sulphuric acid.

Besides the salts, the writer examined specimens of metallic bismuth, one sample being from the new Australian source.

As the examination was so thoroughly satisfactory as to the medicinal quality, no enumeration will be made as the results of the examination of each individual maker, but the results may be embodied in a general statement. This may be stated as follows:—That each of the samples of subnitrate and subcarbonate of bismuth examined are fully equal to the requirements of the Pharmacopœia of 1880; that in none of the specimens examined is there any lead, copper, silver, chlorine, or sulphuric acid. By a more rigid test than the United States Pharmacopœia exacts, there were traces of ammonia in two samples, in all there were traces of alkaline earths or salts, both due, undoubtedly, to imperfect washing of the precipitates in process of manufacture, yet in both the quantities were so minute, that they were practically not noticeable in an analysis beyond "a trace."

The same may be said about arsenic, though in this a quantitative determination was made. The amounts present of arsenic varied from less than $\frac{1}{10}$ grain to 3 grains in 1000 grains.

The specimen of Australian bismuth gave evidences of a trace of copper and arsenic, but neither were estimated.

The Pharmaceutical Journal.

SATURDAY, OCTOBER 28, 1882.

Communications for the Editorial department of the Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

DR. GREENHOW'S REPORT ON THE EXAMINATIONS.

THE reports presented annually to the Privy Council by the visitors appointed under the provisions of the Pharmacy Act, 1868, to attend the examinations conducted in London and Edinburgh, always command respectful attention, not only because they are the embodiment of official opinion as to the manner in which the Pharmaceutical Society performs the important duty confided to it in the interest of the public, but also because the reporters are gentlemen of mature experience, intimately acquainted with the nature of the work to be done by the examining boards, and at the same time viewing it from a position outside purely pharmaceutical influences. It was, therefore, natural that when the latest report of Dr. GREENHOW, through the courtesy of the Lords of the Council, came under the notice of the Pharmaceutical Council at its recent meeting, it should give rise to considerable discussion, though possibly some of the speculations as to what Dr. GREENHOW might or might not mean to imply in the last sentence, concerning a subject upon which he just previously declares his intention to defer offering an opinion, may turn out to have been superfluous. There is, however, plenty that is definite and unmistakable in the report which is worthy of the most careful consideration.

As in previous years, Dr. GREENHOW gives to statistics a prominent place in his report, and these are the more acceptable because they furnish some details, respecting the subjects in which failures occurred, not published elsewhere. Referring first to the Preliminary examination, he points out that the percentage of failures in 1881 was unusually large, amounting to 56·8 per cent. of the 1187 candidates examined. This unfavourable result he does not attribute to an excessive stringency of the examination, but to the very inadequate early education of the candidates, an opinion which certainly finds corroboration in the fact that by far the largest proportion of failures was in arithmetic. Moreover, large as was the percentage of unsuccessful candidates, it may be said to find a parallel in the case of the Oxford and Cambridge Local Examinations. According to the joint annual report on this subject, recently issued by the Universities, the number of candidates who presented themselves at the different centres in the past year was 734, and of these 350, or nearly 48 per cent., failed to obtain a certificate. But it appears that one out of every three of the successful candidates had already passed the examination on a previous occasion, and if this be taken in consideration in connection with the fact that the candidates as a rule are scholars selected from various schools on account of their presumed fitness, it will be seen that the indication furnished by the Universities Local Examinations as to the quality of the middle class education throughout the country is hardly more favourable than that given by the Preliminary examination conducted under the provisions of the Pharmacy Act.

The fact that there were more than 50 per cent. of failures in the Minor examination, Dr. GREENHOW attributes, as in former years, to the very defective training the men had received during the three years they had passed in a chemist's shop prior to presenting themselves. Unfortunately it is too true that many of the candidates have had but "scanty opportunities for practically learning to read prescriptions written in Latin or to dispense and compound medicines;" but this is mainly attributable to a condition of affairs over which pharmacists have little control, namely, the relative absence in many cases of that portion of their work which they are supposed to have been specially trained to perform. The report gives the number of failures in the different subjects of the Minor, from which it appears that chemistry was by far the weakest subject, whilst the failures in prescription and practical dispensing, notwithstanding the defective training commented upon, were comparatively few. However, it must be remembered that the figures quoted only partially reveal the facts, since a candidate who fails to a certain extent is not carried further, and therefore they must necessarily be affected by the order in which the subjects are taken. In respect of the Major examination also, the figures quoted show that the largest proportion of failures was in chemistry.

Dr. GREENHOW abstains from offering any comment at present on the proceedings of the Council in respect to the report of the Special Committee appointed to consider the relation to each other of pharmaceutical education and the pharmaceutical examinations, and contents himself with alluding to the recommendations and pointing out that the first two adopted, providing for a three years' apprenticeship or pupilage, and the previous passing of the Preliminary examination, are in accord with views expressed by him in previous reports. With respect to the fourth recommendation, as to the division of the Minor examination into two parts, it may be remarked that although Dr. GREENHOW is quite correct in saying that it was not adopted, the opposition to it was not based upon disapproval of the principle that there should be such a division, but was directed chiefly against some alterations that had been introduced as to the manner in which it should be carried out.

EXTRA-JUDICIAL UTTERANCES OF CORONERS.

A case reported on another page well illustrates the capricious manner in which every now and then a coroner oversteps his proper functions and inflicts such a penalty as is involved in censure by a prominent public officer upon no other basis than his own notion of what the law is or ought to be. In this case, in the course of an inquiry as to the cause of death of a man, who it was at first erroneously supposed had died from the effects of poison, it came out that he had been supplied by a chemist and druggist in Belfast with an ounce and a half of laudanum. The seller had not only complied with the requirements of the law as to labelling, but had exceeded them by making inquiry as to the purpose for which the poison was required and had received a reasonably satisfactory answer. This, however, did not satisfy the coroner, and having first alleged that the law provides that the name and address of the buyer shall be taken in the case of a sale of laudanum, and been corrected, he then affirmed that it ought to be done. If Dr. Dill thinks that laudanum should be included in the first part of the poison schedule he has a right to say so, and he belongs to a class of functionaries whose opinions upon such a subject are entitled to respect, but his expression of opinion involved an act of injustice, inasmuch as it took the form of an unwarranted censure of a person who had even exceeded the precautions with which Parliament has surrounded the sale of laudanum, when sold as such and not as a patent medicine. The suggestion that a chemist and druggist should sell a diluted article while taking the price of one of full strength, if made by Dr. Dill, as reported, is beneath criticism, even if such a practice has the sanction of custom in surgeries. But it would seem to show that he must be ignorant of the existence of another public functionary, whose opinion in respect to such a practice would be of greater importance than even that of a coroner.

THE INSTITUTE OF CHEMISTRY.

Last week a meeting of members of the Institute of Chemistry was held in Birmingham. The proceedings commenced on Friday morning with a visit to the alkali works of Messrs. Chance and Co., where the new process of sulphur recovery invented by Messrs. Schaffner and Helbig (see *Pharm. Jour.*, xii., 969) is in operation, and another to the Earl of Dudley's Round Oak iron works.

In the evening the members dined together at the Great Western Hotel, under the presidency of Professor Abel. In responding to the toast of the evening, Professor Abel traced the history of the Institute, which he said had had its origin seven years ago in the want that was recognized by a considerable section of the Chemical Society of an organization through which the status of the profession of chemistry could be definitely established, and he expressed an opinion that although the present was only the sixth year of the existence of the Institute, the Fellows might venture to believe that its future prosperity and utility to the profession were fully secured.

On Saturday, the meeting was brought to a close by visits to Messrs. Chance's Glass Works, the Corporation Gas Works, the Birmingham Mint, and Messrs. Elkington's electro-plating works.

THE NEXT EVENING MEETING.

An Evening Meeting of the Pharmaceutical Society will be held on Wednesday next, November 1, when a paper will be read on "The Orchard Alum Spring," by Dr. Thresh. The chair will be taken at half-past eight o'clock.

CHEMICAL SOCIETY.

The first meeting of this Society for the new session will be held on Thursday next, November 2, when the following papers are to be read:—"On some Halogen Compounds of Acetylene," by Dr. R. T. Plimpton; "On Dihydroxybenzoic Acids and Iodosalicylic Acids," by Dr. A. K. Miller; "Crystalline Molecular Compounds of Naphthalene and Benzene with Antimony Chloride," by Watson Smith and G. W. Davis; "Additional Evidence that Quinoline belongs to the Aromatic Series of Organic Substances," by Watson Smith and G. W. Davis; "On Orcin and some of the other Dioxytoluols," by R. H. P. Nevile and Dr. A. Winter.

THE SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

It affords us pleasure to call the attention of past and present students in the School at Bloomsbury Square to the announcement that the first meeting of the School of Pharmacy Students' Association in the new session will be held on Thursday evening, November 16, when an address will be delivered by the President, Professor Attfield. The Associasion is one that is entitled to the best wishes of pharmacists, since it has for its object the encouragement of study and original work in the sciences upon which pharmacy is based, and there has also been founded in connection with it a "research fund" for rendering aid to students in the investigation of subjects of direct pharmaceutical interest. At a time when there is a marked dearth of first-class pharmaceutical research, as evidenced in the paucity of communications to the Evening Meetings of the Pharmaceutical Society and other bodies, both in town and country, associations which, like this one, foster a taste for original investigation among the rising generation of pharmacists, are doing most useful service.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

October, 1882.

Present on each day—Mr. Carteighe, President; Mr. Atkins, Vice-President; Messrs. Barnes, Benger, Brady, Corder, Ekin, Gale, Greenish, Linford, Martindale, Plowman, Southall, Taylor and Thresh.

Dr. Greenhow attended on the 19th and 26th, on behalf of the Privy Council.

October 18.

MAJOR EXAMINATION.

Eight candidates were examined. *Six* failed. The undermentioned *two* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Fletcher, James Edward.........Saltley.
Foden, Edwin ....Eccles.

MINOR EXAMINATION.

Seventeen candidates were examined. *Twelve* failed. The undermentioned *five* passed, and were declared qualified to be registered as Chemists and Druggists:—

Betts, Charles Ernest Oscar ...Woodbridge.
Bray, William ....Redruth.
Brough, Frank Thompson ......Northampton.
Cardwell, Augustus ....Derby.
Cooper, Harry Stanley ....London.

MODIFIED EXAMINATION.

Three candidates were examined. *Two* failed. The undermentioned passed, and was declared qualified to be registered as a Chemist and Druggist:—

Colvin, John Thomson ....Bodmin.

October 19.

MAJOR EXAMINATION.

Six candidates were examined. *Four* failed. The undermentioned *two* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

MacDermott, Robert John......London.
Parker, William Henry ....Hitchin.

MINOR EXAMINATION.

Twenty candidates were examined. *Twelve* failed. The undermentioned *eight* passed, and were declared qualified to be registered as Chemists and Druggists:—

Dadson, Horace Charles ....King's Lynn.
Deacon, Frederick George ......Frome.
Dodsworth, Martin ....Harrogate.
Dunn, George Stewart ....Landport.
Dye, Charles Page ....Bury St. Edmund's.
East, William Alfred ....Princes Risboro'.
Fawssett, Theodore ....London.
Gummow, James Freeman......London.

October 25.

MAJOR EXAMINATION.

Seven candidates were examined. *Two* failed. The undermentioned *five* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Roper, Robert Francis............East Stonehouse.
Rouw, Theodore John.............Ruthin.
Steel, Alexander ....Torquay.
Thornley, Frederick...............Devizes.
Wakefield, John ....Birmingham.

MINOR EXAMINATION.

Twenty-one candidates were examined. *Sixteen* failed. The undermentioned *five* passed, and were declared qualified to be registered as Chemists and Druggists:—

Heynes, Thomas Edward ......Maidenhead.
Maddox, Frank Walter ....Ealing.
Millward, Rowland Donne......Ashbourne.
Norman, William Francis ......Towcester.
Rees, David ....Haverfordwest.

October 26.

MINOR EXAMINATION.

Twenty-four candidates were examined. *Thirteen* failed. The undermentioned *eleven* passed, and were declared qualified to be registered as Chemists and Druggists:—

Hudson, Tom ....Wells.
Pell, Alfred ....Wisbeach.
Pinchen, William John ....Norwich.
Prothero, George Rees ....Pontypridd.
Rees, Rice William ....Swansea.
Robertson, John ....Aberdeen.
Salmon, Ernest Frederick ......London.
Surman, Thomas William ......Bristol.
Tottle, Henry John ....Bath.
Treharne, Frederick Gwilym...Weston-super-Mare.
Yates, George Albert ....Manchester.

PRELIMINARY EXAMINATION.

The undermentioned certificates were received in lieu of the Society's examination:—

Certificates of the College of Preceptors.

Hathaway, Fredk. Hy. Wm. ...Lydney.
Hemens, Frank......................Hutton,
Wookey, Lionel ....Bath.

Certificate of the Incorporated Law Society.

Lewis, Rees Martin ....Cheltenham.

Certificates of the University of Cambridge.

Chater, Arthur Brand............Elmdon.
Corder, Edward ....Norwich.
Harrison, Rd. Caswell Clark...Birmingham,
March, Thomas Frederick ......New Brompton.
Midgley, Walter ....Keighley.
Shenton, Arthur Holland ......Birkenhead.

Certificates of the University of Oxford.

Minchin, William..................Bedford.
Oldershaw, John ....Nottingham.
Wyatt, Harold ....Bootle.

EXAMINATIONS IN EDINBURGH.

October, 1882.

Present on each day—Messrs. Ainslie, Baildon, Clark, Gibson, Gilmour, Kininmont, Nesbit and Stephenson.

Professor Maclagan was present on the 19th, on behalf of the Privy Council.

October 18.

MAJOR EXAMINATION.

One candidates was examined, and was declared qualified to be registered as a Pharmaceutical Chemist:—

Wright, Robert.....................Buxton.

MINOR EXAMINATION.

Twelve candidates were examined. *Seven* failed. The undermentioned *five* passed, and were declared qualified to be registered as Chemists and Druggists:—

Brown, Alexander..................Dumbarton.
Cobden, Alfred George ....London.
Cunningham, John James ......Cambuslang.
Law, Thomas Wm. Thorburn...Falkirk.
McNeilage, Alexander............Greenock.

October 19.

MINOR EXAMINATION.

Thirteen candidates were examined. *Eight* failed. The undermentioned *five* passed, and were declared qualified to be registered as Chemists and Druggists:—

Moore, Frank Philip ....Aberdeen.
Ombler, William Henry ....Windsor.
Rowand, Robert ....Glasgow.
Watson, Robert William.........Maryport.
Young, William Ferguson ....Elgin.

PRELIMINARY EXAMINATION.

The undermentioned certificate was received in lieu of the Society's Examination:—

Certificate of the University of Edinburgh.

Pirie, John ....Edinburgh.

PRELIMINARY EXAMINATION.

At a meeting of the Board of Examiners for England and Wales, held on Wednesday, October 25, 1882, the report of the College of Preceptors on the examination held on October 3rd was received.

Two hundred and forty-eight candidates had presented themselves for examination, of whom *one hundred and seventeen* had failed. The following *one hundred and thirty-one* passed, and the Registrar was authorized to place their names upon the Register of Apprentices or Students:—

(Arranged alphabetically.)

Abbott, Herbert E. Tripp ......Lowestoft.
Allan, Hy. Wemyss F............Glasgow.
Arthur, Arthur......................Carmarthen.
Baker, Wm. Weaver ....London.
Barnes, Fredk. Walter............London.
Barstow, William ....Marple.
Beale, Charles Henry ....Chard.
Bennet, Andrew R. ....Uphall.
Bennett, Albert Edward ....Leigh.
Bertram, David Paul J. ....London.
Birrell, Robert ....Forfar.
Bones, Arthur Anderson ....Manchester.
Booth, George Hy. W.............Alfreton.
Bransby, Chas. Kirby ....Manchester.
Brook, Thomas Turner ....Elland.
Bugden, William Beale ....Blandford.
Burton, Robert Charles ....Kendal.
Bygott, John William............Huddersfield.
Caldwell, John......................Edinburgh.
Campbell, Peter, jun. ....Leven.
Carrie, Robert Smith ....Kirkcaldy.
Cartwright, William Henry ...Whitchurch, Salop.
Chatterton, Benjamin ....Sheffield.
Clarkson, Thos. Edward ....Wibsey.
Clatworthy, Wm. Jno. Hicks ...Saltash.
Cobb, Herbert Ernest ....Bury St. Edmunds.
Cornell, Henry Currie............King's Lynn.
Crockett, Henry ....East Grinstead.
Cullwick, John Henry............Birmingham.
Cupit, Alfred Henry ....Loughborough.
Curtis, Joseph Levi ....Huntly.
Dalton, Edwin T....................Hull.
Darnbrough, Arthur...............Southport.
Dean, John Thomas...............Haslingden.
Denny, John Harvey ....Woodbridge.
Donald, John Martin ....Perth.
Duncan, William ....Elgin.
Edmondson, Thomas ....Cockermouth.
Eyval, Thomas Brown............Edinburgh.
Felton, William ....Maidstone.
Forsyth, Ebenezer ....Edinburgh.
Fowler, Geoge Ross................Edinburgh.
Freeman, Thomas ....Beverley.
Funnell, Richard ....Whitlesea.
Gaddes, Andrew ....Penrith.
Graham, Joseph ....South Shields.
Gregson, Joseph ....Manchester.
Griffiths, Charles John ....Shanklin.
Griffiths, John Egbert............London.
Grime, James ....Darwen.
Hall, Alfred Eves...................Sevenoaks.
Hanson, Arthur William.........Devonport.
Hendry, Fred. Harry ....Hull.
Hendry, Robert Love ....Edinburgh.
Heyhoe, Horace James ....Swaffham.
Holt, James Hartley ....Ormskirk.
Hornby, Louis Francis ....Great Harwood.
Hucklebridge, Wilfred ....London.
Hudson, George Charlton ......London.
Hudson, James......................Dumbarton.
Hughes, John ....Carnarvon.
Hull, Robert S. ....Sunderland.
Hurst, Herbert Frederic R. ...Colchester.
Jones, David Lloyd ....Eglwyswrw.
Jones, Richard Alan ....Holyhead.
Jones, Thomas ....Swansea.
Jones, Thomas ....London.
Jones, Thomas John ....Holyhead.
Lewis, John Lloyd ....Llandyssul.
Lloyd, Walter George ....Cardiff.
Lobbett, James Godfrey.........Hingham.
Lomax, William Henry ....Darwen.
Lowe, Albert John ....Guernsey.
McDonald, James ....Lochee.
McKilligin, Hay Grant ....Portsoy.
McMurtrie, John ....Glasgow.
Mahood, Trevor Corry ....London.
Marsh, Charles David ....Devizes.
Mason, John Henry...............Wirksworth.
Massey, Samuel Jeffrey ....Purston.
Miller, Alex. Sunderland ......Edinburgh.
Mills, William Henry ....Walsall.
Milton, William, jun. ....Edinburgh.
Moir, William Sinclair ....Aberdeen.
Morley, William Henry ....London.
Morrison, Andrew ....Glasgow.
Morrow, George ....Hornsea.
Mossop, Henry......................Whitehaven.
Nicholson, John...................Broughton-in-Furness
Noyes, Edward T. ....Wokingham.
Owen, Henry ....Carnarvon.
Owen, John Lewis .... Holyhead.
Palmer, Frank Hermann ......Hull.
Park, John ....Aberdeen.
Payne, Charles Frederick ......Ramsgate.
Peck, Henry Fredrick............London.
Peebles, Thomas Smith ....Dundee.
Pennington, John Noble.........Ulverston.
Perrett, George Stanley ....Bath.
Porter, Caleb Thomas Geo.......London.
Potter, Herbert Mills ....Walsall.
Prosser, Evan Charles ....Colchester.
Raine, James Arthur ....Over Darwen.
Reid, Neil ....London.
Reith, Alexander ....Aberdeen.
Ridley, Albert Paul................Ipswich.
Roberts, Alfred Dean ....Lincoln.
Rudd, Henry Bulmer ....Bradford.
Rutter, William ....Masham.
Seccombe, Maurice Otto ....Tavistock.
Smith, John Henry ....Coventry.
Spry, Richard ....London.
Thirsk, Arthur Thomas ....Hull.
Thomas, James......................Newcastle Emlyn.
Thomas, Joseph ....Garstang.
Thompson, Henry Clarence ...Belford.
Underwood, George...............Whitby.
Veitch, Alexander ....Edinburgh.
Vivian, Richard ....Penzance.
Walton, James Thomas ....West Hartlepool.
Weir, Robert.........................Campbeltown.
Wells, Thomas Peter ....Blackburn.
Whitmore, William Fryer ......Hoddesdon.
Whitworth, James William ...Oldham.
Wilkes, Thomas ....Shrewsbury.
Williams, David ....Cardigan.

Williams, William Pierce ......Llanberis.
Wilson, James B. ....Nottingham.
Wilson, Joseph Harwood ......Wigan.
Wright, Charles Rowland ......Portsmouth.
Yuill, Stephen ....Belfast.

The following is a list of the centres at which the examination was held, showing the number of candidates at each centre and the result:—

	Candidates. Examined.	Passed.	Failed.		Candidates. Examined.	Passed.	Failed.
Aberdeen	9	5	4	Inverness	2	1	1
Birmingham......	9	4	5	Lancaster	6	4	2
Brighton	1	1	0	Leeds	14	5	9
Bristol	6	2	4	Lincoln............	6	1	5
Cambridge	4	0	4	Liverpool	9	4	5
Canterbury	4	2	2	London..............	39	19	20
Cardiff	9	2	7	Manchester	20	12	8
Carlisle............	3	3	0	Newcastle-on-T.	3	2	1
Carmarthen	7	5	2	Norwich	7	6	1
Carnarvon	7	6	1	Nottingham	9	4	5
Darlington	2	2	0	Peterborough ...	2	1	1
Dundee...........	7	4	3	Sheffield	4	1	3
Edinburgh	16	10	6	Shrewsbury	3	1	2
Exeter	7	4	3	Southampton ..	4	3	1
Glasgow	9	7	2	Truro	4	1	3
Guernsey	1	1	0	Worcester	3	0	3
Hull	6	6	0	York...............	6	2	4

The questions for examination were as follows:—

Time allowed: Three Hours for the three subjects.

I. LATIN.

1. Translate into English:—

(i.) Trium mensium molita cibaria sibi quemque domo efferre jubet. (ii.) Hoc toto prœlio aversum hostem videre nemo potuit. (iii.) Eos ita dicere: Non esse fas Germanos superare, si ante novam lunam prœlio contendissent. (iv.) Hoc prœlio trans Rhenum nuntiato, Suevi, qui ad ripas Rheni venerant, domum reverti cœperunt. (v.) Hoc prœlio facto, reliquas copias Helvetiorum ut consequi posset, pontem in Arare faciendum curat atque ita exercitum transducit. Helvetii, repentino ejus adventu commoti, quum id, quod ipsi diebus viginti ægerrime confecerant, ut flumen transirent, illum uno die fecisse intelligerent, legatos ad eum mittunt; cujus legationis Divico princeps fuit, qui bello Cassiano dux Helvetiorum fuerat.

2. To what classes of verbs do *potuit, consequi, transducit, fuit,* respectively, belong? Write in full the indicative perfect and subjunctive present of these verbs.

3. Give some rule for the use of the subjunctive mood.

4. Translate into Latin:—(i.) They had done Cæsar great injury. (ii.) Cæsar set out for Italy and came to Rome. (iii.) A river separated the two armies. (iv.) Who does not love peace more than war? (v.) Having pitched his camp, he waited till the enemy should attack.

II. ARITHMETIC.

[The working of these examples, as well as the answers, must be written out in full.]

1. How many yards of carpet, 25 inches wide, will it take to cover a floor that is 19 feet 7 inches long by 18 feet 9 inches wide?

2. Multiply the sum of 1, $\frac{1}{2}$, $\frac{2}{3}$, and $\frac{3}{4}$ by the difference of $\frac{4}{15}$ and $\frac{3}{20}$, and divide that product by the double of $21\frac{7}{9}$.

3. Multiply ·285 by 4·02; divide 2·961 by ·007; and find the value of 2·778125 of 6*s.* 8*d.*

4. If, after selling $\frac{3}{4}$ of an estate, I sell $\frac{2}{3}$ of $\frac{7}{9}$ of the remainder for $\frac{3}{5}$ of $\frac{7}{8}$ of £$200\frac{5}{8}$, what is the value of $\frac{2}{3}$ of the estate.

5. If a sack of corn, containing 1 hectol. 20 lit., cost 18 francs; what ought to be paid for a sack of corn of the same quality containing 1 hectol. 60 lit.?

III. ENGLISH.

1. Define *case.* What indications of it are there in English?

2. Give the perfect tense and past participle of the verbs *sew, read, throw, rise, lie, strive.*

3. Correct the following sentences, giving your reasons in each case:—

(i.) Neither of them had a sixpence of their own.
(ii.) Avoid those kind of things.
(iii.) Who did you give that book to?
(iv.) That was the man whom I saw was to blame.

4. Parse the words in italics in the following passage:—

"You take *my* house *when* you *do take* the prop
That doth sustain my house; you take my life
When you do take the *means whereby* I live."

5. Write a short composition on one of the following subjects:—"Waste of Time," "The Study of the Laws of Health," "Patience"; or give an account of some remarkable place or of some distinguished writer.

Provincial Transactions.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL SOCIETY.

A general meeting was held in the Society's Rooms, on Wednesday evening, October 11. Mr. Preston, President, in the chair. There was a moderate attendance.

The minutes of the previous meeting were confirmed.

The President, after alluding to his pleasant visit to the Pharmaceutical Conference at Southampton, called upon Mr. Furness to read his paper on "Our Trade and Professional Interests."

Mr. Furness commenced his remarks by referring to the composite nature of the business of a chemist and druggist, and defined it as a mixture of the professional and trade elements, in which the latter greatly predominated. The trade element had been and was being assailed on all sides, and the dealing in a number of articles which used to lie almost exclusively in the chemist's hands had now been diverted into other and possibly more legitimate channels. But chemists could not be so indifferent now that the trade in drugs, patent medicines, specialties, sundries, dietetic articles, etc., was so seriously threatened. Simple articles, such as salts and senna, had long been supplied by small shopkeepers in villages and other places; but these persons had generally maintained the prices, and moreover the public had been able to recognize the superior quality of the articles sold by chemists. But now the trade was grievously assailed by large grocers, drapers, and "stores," who supplied patent medicines, and specialties, and nine-tenths of the Pharmacopœia, and even in some cases made arrangements to dispense prescriptions and deal in poisons at reduced prices. With respect to patent medicines and similar articles the public could not be expected to pay 25 or 30 per cent. more at one shop than they would at another a few yards off, but it was not to the interest of chemists to sell these articles at cost price. It was, however, useless to look to the Government, the Pharmaceutical Society or the Trade Association for the remedy of this vexed state of things. Chemists must rely upon their individual tact and learning to supply the income lost in this direction, and must rely upon their collective strength and exertions to destroy the trust the public had acquired for patent medicines. Chemists had made this trade assume the dimensions it had. They had recommended these "patents," kept them in stock, distributed hand bills, exhibited show cards, lent their windows for gratuitous advertisements, and now, having established them thus firmly, were entirely ignored, saving when some new enterprise was endeavouring to secure public favour. But the same means that had been instrumental in building up this trade could be used in combating the evil, and if the proprietors would not help to maintain the interests of chemists they must combine to help themselves. As to the sale of drugs, there were many of the articles and preparations in the British Pharmacopœia which were not absolutely poisonous, but the supply of which still required supervision by a responsible person. This was illustrated by a case which had come under the speaker's notice, where a solid had been supplied for "sal volatile" and the buyer told to take two teaspoonfuls, resulting in the inconvenience attending the swallowing of about two drachms of carbonate of ammonia; and by another case where nitrate of potash had been supplied for Epsom salts. He was of opinion that the supply to the public of all the chemical and Galenical preparations, the mineral and animal substances and the majority of the vegetable products in the British Pharmacopœia, as well as the dispensing of prescriptions, ought to be exclusively in the hands of chemists and druggists, and he wished to see an amendment of the Pharmacy Act in this sense. It could easily be demonstrated that such an alteration would be for the public benefit, and it would be simple justice to a respectable and deserving body. This end could be best attained by joining the local associations, supporting the Trade Association, and influencing the constitution of the Council of the Pharmaceutical Society, both of these last-mentioned bodies possessing great influence if they could only be got to work in the proper direction. The speaker then briefly referred to the subject of pharmaceutical education. Although he considered the examinations were sufficiently comprehensive and stringent as compared with the position of the pharmacist, he was of opinion that if it were understood that all persons presenting themselves for instruction had previously attended a suitable course of instruction, it would strengthen the hands of the examiners, and they would be better able to make allowances and draw inferences with respect to the individuals coming before them. It was necessary there should be some suitable provincial education established, easily and cheaply procurable at recognized centres. If this could not be done to be self-supporting, some other scheme must be adopted. Arrangements might be made with the Science and Art Department, which had organizations in many provincial towns, or terms might be arrived at with such educational bodies as Frith College, Yorkshire College of Science, and Owens College, etc., to establish a course of lectures similar to those delivered at Bloomsbury Square. The reading of the paper was brought to a close by a reference to the relation of chemists and druggists to the public and the medical profession.

The President remarked that there was a large field for discussion, and proposed a vote of thanks to Mr. Furness for his valuable paper.

A discussion then followed on the various topics of the paper, in which Messrs. Ellinor, Newsholme, Lowe, Fox and Mould took part.

LIVERPOOL CHEMISTS' ASSOCIATION.

The first general meeting of the above Association was held at the Royal Institution on Thursday, October 12, 1882, the President, Mr. Joseph Woodcock, in the chair.

The minutes of the last meeting were read and confirmed, and the following donations announced:—The *Pharmaceutical Journal*, from the Society; List of Foreign Correspondents of the Smithsonian Institution, from the Institution.

Mr. J. E. Saul was elected an associate.

Mr. Shaw showed an "Electric Gas Lighter." This instrument, which is said to be capable of lighting a gas jet thirty thousand times before it requires recharging, costs primarily 30*s*. If this statement is correct it will, therefore, be seen that, independently of the small cost of recharging, which is a few shillings, it is, for this purpose, very little more expensive than wax matches.

The President then delivered his inaugural address. After welcoming the members at the commencement of the thirty-fourth session, he referred to various causes that had tended to deprive the Association of some of the classes formerly represented in it and had somewhat altered its character. He then continued:—

"This probably places us in our true position as chemists and pharmacists, and we shall not fail to remain efficient, successful and self-existing, provided we supply papers, discussions and miscellaneous contributions calculated to advance our calling from a professional aspect. In the first place we must never lose sight of the fact that we are a recognized educational body, and that we should provide lectures in our School of Pharmacy for the education of our apprentices. We have hitherto done so, but it is requisite an adequate number of students should present themselves to defray the necessary cost, and in this we have not always been successful, more especially since the introduction of the much-to-be-lamented system of 'cram.' But let us hope its last days are numbered.

"The subject that has perhaps above all others occupied the attention of British pharmacists during the last twelve months has been the question of establishing a more satisfactory relationship between the education of embryo-pharmacists and their examination, and when the time arrives that a compulsory curriculum is enforced no doubt our school provision will be in demand. At the some time we may congratulate ourselves that we are not the only body that suffers from the same cause. The recent report of the Liverpool School of Medicine states that the members of the medical profession did not increase in equal ratio with the population; not only was there no increase, but a slight diminution in the numbers of students throughout the country, and the same statement applies to the numbers of those examined at Bloomsbury Square. No doubt this is caused by the increased stringency of examinations. But this should not deter us; we must rather advocate, and advocate strongly, a sufficiently compulsory curriculum as the test for education, rather than recognize the supply of a cursory, transient and superficial knowledge merely intended for the purpose of enabling the student to surmount an examination which otherwise would not be overcome.

"And here let us give a word of praise to Professor Attfield for his long-continued and successful endeavours to attain the desirable result that is now likely to be accomplished and crown his wishes. From the time he inaugurated the advocacy of a recognized compulsory curriculum at the Pharmaceutical Conference at Brighton, ten years ago, to the present, his exertions have been unceasing. His able, instructive and comprehensive speech at Manchester; his pamphlet, which he distributed amongst our own body broad-cast over the country, and which contained a very large number of arguments for the proposed change, that were practically unanswerable, all entitle him to our highest appreciation, warmest gratitude and sincerest thanks.

"I have read with much interest the long and able discussion of the Council of the Pharmaceutical Society upon the various recommendations their Committee had advanced with reference to the "Relation to each other of Education and Examination," and it is noteworthy that the subject was considered of such importance by the leaders of our profession that every member of the Council contributed thoughtful and powerful expressions of opinion on that occasion. But holding to a great extent the views of the majority of that Committee, I must confess myself disappointed at the rejection by the Council of the *fourth* recommendation. I have been very much pleased by the recent decision to refer the whole subject back to a committee for reconsideration, and personally I trust the fourth recommendation, or one similar to it in purport, will be finally adopted by the Council. There can be no doubt that the student by concentrating his attention on a lesser number of subjects would be likely to attain a more thorough knowledge of all and acquire a more perfect acquaintance with their details.

"I am quite of opinion that the first portion need not necessarily be passed in London. At present few students think of systematically commencing their studies till they have completed their apprenticeship and attained their majority; they then rush off to the metropolis to avail themselves of those so-called educational systems and learn merely for the sake of passing their examination, without reference to that higher end to which examination should always be subservient, namely, the acquiring a thorough knowledge of their future calling with its allied sciences, and, the qualifying Minor surmounted, cast their studies on one side for ever. This first portion of the examination should, I consider, also be passed previously to leaving the master with whom the candidate has been articled, and before accepting a situation in London or elsewhere; a dominant idea being to attain London and gravitate towards the schools; this system already exists on the Continent, the employer being compelled to complete the education of his apprentice if he should fail in fulfilling the requirements of the examiners. It would not only stimulate young men to study hard during their apprenticeship, but would also compel their masters to take more interest in their pharmaceutical education. Numbers of employers only think of the work they can obtain from their apprentices, without fulfilling their covenants and teaching them the art and mystery of their profession. Many influential persons imagine that immediately an apprentice has passed his Preliminary he will devote himself during the whole period of his apprenticeship to qualify for the distant Minor; this unfortunately is not the case. Few lads at that age will, without great external pressure, begin a series of studies at such a long period anterior to the time when they will be eligible to present themselves for examination. When first apprenticed they are only too glad at having escaped the irksome trammels of school and are most unwilling to recommence a system of study, in addition to performing the practical work of their business.

"In speaking of the deficiency displayed by Minor candidates in their knowledge of dispensing, some have considered that the fault lay altogether in the very small number of prescriptions many of the students have been called upon to dispense during their apprenticeship. There is, no doubt, a considerable amount of truth in this belief, but I think the matter has been overrated. It is notorious that the majority of prescriptions given to candates to dispense at Bloomsbury Square are such as would never, or very rarely, occur in actual practice. If students were to devote more attention to what I may call the *theory* of dispensing there would be a great diminution in the number of failures on that particular subject. For the study of this 'theoretical dispensing,' I can recommend nothing superior to an examination and judicious tabulation of the various queries and replies that have appeared during the last four or five years in the *Pharmaceutical Journal* under the head of Dispensing Memoranda, I would recommend that especial attention be devoted to the able summary written by an accomplished pharmacist which appears in the Journal every month.

"It is to be regretted that proceedings in Parliament have rendered the passage or even the introduction of a revised Pharmacy Bill a matter of impossibility. But it is to be hoped future legislation will result in having the Pharmacy Act more fully extended and more strictly fulfilled, for if pharmacists are willing to obtain a suitable and costly education, and are required to possess exceptional and superior attainments for the benefit and advantage of the State and the public they are at least entitled to receive equivalents and sureties that their labour has not been in vain. It is abundantly obvious that medicines should only be handed to the public by persons who, from education are well acquainted with their properties, and that the mere restricting of the sale to qualified persons of a very limited number of poisons, which in most cases are rarely if ever demanded, is no suitable recompense for his labour and expense, and cannot be called just to the pharmacist. If the public interests require, which they certainly do, that he should undergo an expensive system of education, and obtain a high degree of qualification, legislation should not be for the public to the detriment of the pharmacist, and hence the necessity has arisen that the latter should enlist public sympathy and rouse public feeling against his province being invaded and trespassed upon by unprincipled traders and that, a technical examination being compulsory, adequate legal protection should be granted.

"The subject of the sale of poisons has been attracting considerable attention during the year, not only in the pharmaceutical world but amongst the public generally. A writer entirely outside our own circle has recently said:—'By the Pharmacy Act very stringent restrictions are placed on the sale of poisons. No one, unless he be a medical man, can obtain any of the more potent poisons without very considerable difficulty, such as giving name and address, stating purposes for which they are required, signing his name before witnesses, etc. The less virulent poisons are also put under restrictions, such as labelling distinctly the name of the substance, with the name of the seller and also the word "poison." The seller in both cases requiring to be on the Register of Chemists and Druggists. All patent medicine vendors are, however, exempt from these restrictions. It is open to any one, even the most ignorant, to put up and sell those powerful medicines (poisons they may be) in any quantity and of any strength, without control by Government or guarantee of any kind as to the ingredients. It will, we think, strike most minds that the proverbial coach-and-six may be driven under such circumstances with some facility through this Act of Parliament.' The warning thus given as to a certain class of patent medicines does not come too soon. They have been increasing to a very great extent in recent years, in fact supplanting very much the old well-known family medicines; and owing to the success of one or two comparatively innocent and even efficacious preparations, others of a baleful tendency have unfortunately become popular.

"Proprietary medicines are not only put up in this country, but as vendors we have actually to supply to the public what other countries choose to advertise. As an instance of this, I may mention an article now being freely advertised under the catching title "Rough on Rats." It cannot be supposed that vendors are to open and examine the innumerable proprietary articles that come from America. In this instance nothing but an examination by a qualified chemist would lead the public to suppose they were simply purchasing 'coloured arsenic.' How are we as vendors to know that we are liable to impeachment if we do not register the sale in the usual way?

"The desirability of including stamped proprietary medicines under the same liability as other drugs with reference to the poison regulations is now practically admitted by the medical and pharmaceutical professions and by the public generally, and let us hope will be easy of attainment. It will behove the Pharmaceutical Society to be watchful that the Government or some private legislator does not introduce a Bill having clauses inimical to the interests of pharmacy when dealing with this all-important question.

"The attention of pharmacists has recently been drawn to the refusal of the Privy Council to support the Pharmaceutical Society in its endeavour to place some restriction on the sale of several powerful chemicals which have been the cause of many an unfortunate and painful death. That refusal, I think, can be justified, however, by the explanation of their lordships that as Parliamentary legislation was impending, it would be advisable to refrain from taking action just at present. The recent statement of a correspondent of the *Chemist and Druggist* that this refusal to sanction the resolution was a snub to the Council of the Society is sufficiently disposed of on this ground. And when due consideration is given to the fact that the resolution has excited the violent opposition of numerous interested and powerful trades, it will be immediately apparent that there was very little possibility of a body like the Privy Council, not possessing legislative functions, interferin in the matter.

"The Pharmaceutical Council have, in my opinion, scarcely acted wisely on the principle they have adopted, when drawing up the schedule of articles which they consider are entitled to rank as poisons within the meaning of the Pharmacy Act. It has evidently been considered that they would be serving the interests of the public best by including in the list only such virulent and destructive substances as are in common demand, omitting not only all that are not exceptionally poisonous but also many powerful bodies, which, although recognized by the Pharmacopœia, are not frequently made use of by would-be murderers and suicides. I may mention as an instance of this latter objection the case of calabar bean and its preparations, which are certainly as poisonous as most of the scheduled articles, and I cannot but think that if when first drawing up their list they had included all the corrosive acids, together with any pharmacopœial or other substances possessing poisonous or even moderately poisonous properties, they would not have found the Privy Council Committee of that date unwilling to ratify their action.

"But, as Professor Attfield has said, 'All drugs are more or less poisons,' and instead of scheduling a few powerful poisons it would be much wiser to draw up a list of such drugs as are quite innocuous, or that it would be an inconvenience to the public if the sale were restricted.

"Turning now more directly to what may be called the internal politics of our body, there is unfortunately little cause for congratulation, or even moderate satisfaction. Chemists have been proverbially disunited, jealous and suspicious of each other. To this very day they have never been able materially to shorten the hours of labour, which had they been more cosmopolitan and less selfish would almost as a matter of course have followed the foundation of the Pharmaceutical Society. As several eminent pharmacists have frequently said the great want of the day in our body is to awaken individual interest and arouse individual action. A stride, and a long one, in the right direction might be made if pharmacists by passing their examination became not only qualified in the eye of the law, but also necessarily members of a United Association. It has been long on the *tapis*, and has even been advocated by Dr. Greenhow, the representative of the Privy Council, that the term *Fellow* should be used instead of Member of the Society as heretofore. There is not much doubt that if this very desirable change were effected students would be far more inclined to press on for the higher qualification than they now are and the public would appreciate the difference between Fellow and Associate far more than they at present do between Member and Associate, which by many fairly informed persons are considered as synonymous terms. If by passing the Major examination this degree of Fellow of the Pharmaceutical Society were obtained, it would undoubtedly induce a larger number of candidates to come forward, and by that means the examination fee for the higher qualification might in course of time be done away with and a small annual subscription rendered compulsory in its stead.

"The recent meeting of the British Pharmaceutical Conference, at Southampton, was signalled and honoured by the presence in the presidential chair of one whose labours have been as unremitting as they were valuable in the cause of pharmaceutical progress, and there are few who, after reading the masterly address delivered by Professor Attfield, will not unhesitatingly assert that as an elaborate treatise upon the present position and future prospects of pharmacy in our country, it was emphatically a masterpiece; there can be little doubt that, whilst being the first, it was also the most important of all the literary contributions presented on that more than usually interesting occasion. Agreeing almost entirely with the Professor's ably advocated conclusions, it may not be altogether inappropriate that this evening I should make a few remarks suggested by special points occurring in the course of his address.

"One suggestion is the establishment throughout the country of drug farms on a larger scale than is the case at present. This is an excellent idea, but, as it would not directly affect the general body of pharmacists, perhaps is of minor moment. I think that if country druggists, instead of devoting their gardens entirely to flowers, fruit and vegetables, were to separate a space for the cultivation of small quantities of aconite, belladonna, henbane and other indigenous and easily grown medicinal plants, they would be able not merely to make many of their own preparations with a considerable saving in cost, but it would be of unusual advantage as an educational medium, not only to the pharmacist himself, but to his assistants and apprentices, who would only be too glad to spend a little time daily in cultivating the plants. With the exception of the more expensive and intricate processes, chemists should be encouraged to prepare their own medicines and be thus able to offer a personal guarantee of their strength and integrity. It would not only keep themselves in practice, but would also be a capital school for their *employés* and would undoubtedly be a powerful means of raising pharmacy in Great Britain to a level with that of other countries. They should also devote more attention to ascertaining the quality of important drugs than I fear they at present do. They should not allow such an article as opium or cinchona bark to pass their inspection without submitting it to a quantitative assay. The great disparity that exists in the amount of quinine present in the official yellow cinchona bark, for example, should place every pharmacist on his guard, as it is well known that those barks which are discarded by quinine manufacturers as being deficient in alkaloidal strength are the kinds frequently supplied to retail pharmacists for distribution to their customers; and until wholesale druggists adopt the practice of affixing a guaranteed table of assay to all packages of important drugs supplied, as is already done by a few of their number, the utmost care and supervision should be exerised.

"Reference to cinchona calls to mind the appearance in commerce of a new bark, differing from all known cinchonas in its aspect, density, texture and colour, etc., but which contains alkaloids characteristic of the true cinchonas (called cinchona cuprea). Mr. D. Howard announced to the Chemical Society in December last that, in conjunction with Mr. Hodgkin, he had extracted from the bark of cinchona cuprea an alkaloid closely resembling quinine in its general properties. It differs in the solubility of its salts and the readiness with which the alkaloid crystallizes from ether. This newly discovered alkaloid of the cinchonæ, or most probably of the *Remijiæ* (an allied genus), they named homo-quinine; it is found as yet only in this cuprea bark, and, except for a somewhat shorter crystal, exactly resembles quinine in appearance. It is also a remarkable fact that Mr. Whiffen, Dr. Paul, and Mr. Cownley, in this country, and Dr. Hesse, in Germany, isolated this alkaloid almost at the same time and quite independently of each other. From a commercial aspect this article has turned the bark market upside down.

"The suggestion that in sparsely populated districts which could not possibly support a qualified pharmacist, it should be allowable for agents to retail in unbroken packages, guaranteed and, of course, innocuous drugs, is a good one; but it should, I think, be stipulated that they might only be supplied to the agent by a duly qualified man resident in the district, who would thus be almost personally responsible. In the case of the more powerful medicines this course should not be adopted, as I think it would be no hardship for a person to undertake a journey to the nearest qualified pharmacist when it would be necessary to procure them.

"In passing, I may just refer to a statement made by Professor Redwood at the Pharmaceutical Conference, with reference to an early re-issue of the British Pharmacopœia. From the tone of the Professor's speech, I should imagine that there can be little doubt that the boon—in fact, right—so long desired by pharmacists, will at length be conceded, and the Pharmaceutical Society will be invited to delegate some of the leaders of our profession as members of the Committee appointed by the General Medical Council for that purpose. I think that British pharmacists have reason to congratulate themselves on the progress they have made in this matter, and let us trust that this step upwards will never be retraced.

"The next Pharmaceutical Conference will be held at Southport, and I hope our members will give their encouragement and support, not only by their presence but with their contributions.

"The associated soirée will also be held, as is now usual, at St. George's Hall, and we must hope to maintain the prestige our own Association has hitherto held, by contributing exhibits of a suitable character, and helping in other ways that may be deemed desirable.

"The coming session promises well for success; papers have already been promised by Messrs. A. C. Abraham, T. F. Abraham, Conroy, Davies, Haddock, Mason, Sumner and Symes, and I hope everyone will endeavour to aid. All communications and inquiries stimulate interest, and we are here, as a body, to give you any information we can afford. If you have any doubt, try us."

The President then made some remarks upon the subject of the proposed compulsory notification of disease in Liverpool and concluded a lengthy address by expressing a hope that the officers might be cheered during the coming session by liberal offers of papers and interesting objects for exhibition.

Mr. Conroy moved a vote of thanks to the President for his most interesting address, and confirmed the President's remarks respecting "Rough on Rats," which he had found to be simply arsenic slightly coloured.

This motion was seconded by Mr. Shaw, who referred to the difficulty young men engaged in pharmacy experienced, owing to the fact that the first-rate houses did not receive apprentices.

The motion was supported by Mr. R. M. Sumner, who thought that apprentices would receive more personal instruction in the smaller houses than in the large ones, where the business was carried on by assistants. As "Rough on Rats" had been mentioned, he might say that he thought that the President had been "rough on wholesale druggists," who he believed were anxious to supply the best articles to anyone who would pay the necessary price.

Mr. A. H. Samuel referred to the prospect before a well-educated chemist, and thought that it was not to the credit of the English that so many of their manufactories should be presided over by German chemists.

Mr. A. H. Mason (Vice-President), in conveying the vote of thanks to the President, added additional testimony to the pleasure with which he had listened to the address. He was not disposed to criticize it, but desired to remind the members that in pressing for action to be taken with respect to those illegal traders who trespassed upon the dearly attained privileges of the pharmacist, it was absolutely necessary to educate the public to agitate for their defence. If the Pharmaceutical Society went to Government for protection they would be looked upon simply as a trade body, and legislation was always in favour of the public benefit and not to protect any class of traders. He hardly agreed with the President that drug farms would not affect the body of pharmacists, but was of opinion that if sufficient capital were obtained and a company formed for the protection and cultivation of indigenous medicinal plants, with appliances for the careful collection, drying, distillation, etc., it would eventually be a lucrative concern; besides, British pharmacy would be raised and the quality of English medicines in their efficacy would be maintained; they could be produced in such quantities as would enable them to meet foreign competition. If such an organization had existed at the present time, would English oil of lavender be at the present enormous price, besides running the risk of being an article of the past? He quite agreed that it was desirable that pharmacists should make their own pharmaceutical preparations, but there were many instances in which the quantities required were so small that it was not profitable for them to do so, and although they purchased these articles it did not follow that they were incompetent to manufacture them. It seemed to be overlooked by those who were rather inclined to condemn the wholesale manufacture of these articles, that most of the wholesale manufacturers were themselves pharmaceutical chemists and many of them prize medalists, and that they also gave employment to hundreds of pharmaceutical chemists, and further the mild insinuation of deception on the part of wholesale manufacturers was unjust, for it must not be overlooked that in maintaining their reputation they had by far a larger pecuniary interest at stake than any retailer. The President rather advocated the purchase of assayed drugs. To his mind, those who quoted such articles in their price lists rather cast a reflection upon the purchasers, and in carrying out this principle it was not likely the purchaser would further assay for himself, therefore the object of Professor Attfield's suggestions would be destroyed. Respecting the notification of infectious diseases, he was of opinion that it was not fair to throw the whole onus of notification upon the medical man.

The President, in reply, said he had occupied so much time that evening in reading his address that he would not on that occasion enter into further discussion. It was sufficient recompense to him that it had evoked so much favourable approval, and such only fair criticism. The opinions expressed were individual and it was only by the clashings of opinion that right judgment was arrived at. At some future time some of the subjects mentioned might fairly occupy the attention of the Association.

ABERDEEN CHEMISTS' ASSISTANTS' MUTUAL IMPROVEMENT ASSOCIATION.

On Friday, October 20, a meeting of Aberdeen chemists' assistants and apprentices was held in the Café Buildings, Shiprow, for the purpose of forming a Mutual Improvement Association. Mr. Kidd occupied the chair, and there was a large attendance. A very satisfactory report was submitted by a committee that had been appointed to arrange as to preliminaries. This report was approved of, and the formation of a Mutual Improvement Association followed, after which a considerable number of members were enrolled.

The following were elected a Committee of Management:—Messrs. Peter Smith, Angus, Kidd, Wilson, Anderson, Mackenzie, Davidson, Watson, and Moir. Mr. G. Bowie was elected secretary, and Mr. Mathieson, treasurer. A number of the employers have consented to become honorary members.

The members will meet weekly for the discussion of matters relating to their business, and several gentlemen from the south are expected to give lectures at intervals during the winter.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

A meeting of the Executive Committee was held at 17, Bloomsbury Square, on Wednesday, October 18, 1882, at 4 p.m. Present—Professor Attfield, F.R.S., President, in the chair; Messrs. Bentley, Brady, Carteighe, Ekin, Groves, Naylor, Southall, Squire, Taylor, Dr. Thresh, and Messrs. Benger and Plowman (Hon. Secs.).

The minutes of the previous meeting were read and confirmed.

Letters of apology for non-attendance were read from Messrs. Kinninmont and Young.

The question of the cost of entertainment of visitors incurred by the towns in which the meetings of the Conference are held was considered. It was deemed advisable that the practice of the British Association should be followed as nearly as possible. It was therefore resolved:—

"That it be a general instruction to the local committees of towns in which the Annual Conference is to be held, that their arrangements, both in respect to the business of the Conference and the entertainment of its members be approved by the Executive before publication, and that the attention of local committees should be called to the report of the Executive after the Sheffield meeting, in so far as it relates to questions of entertainment."

Respecting the place of meeting for 1883, the President reported that he had received a letter from Oxford, which he had been directed by a previous Committee to acknowledge. It was from Mr. Geo. T. Prior, who wrote to the effect that in the case of Oxford being selected as the town in which the British Pharmaceutical Conference would meet in 1883, the chemists of that city had deputed him to say that they would be glad to receive the Conference, and would do their best to help the Executive Committee in organizing the meeting. They were too few in number to offer the hospitality that the members had received in other towns, but they would engage a meeting room, arrange for hotel accommodation, and would endeavour to promote the objects and welfare of the Conference and the comfort and convenience of visiting members.

The following is the President's reply:—

"To Mr. G. T. Prior, Oxford.

"My dear Sir,—I am directed by the Executive Committee of the British Pharmaceutical Conference, to thank the chemists of Oxford for their kind offer to give their best assistance in organizing any meeting of the Conference that may be held in Oxford, in 1883. I am also desired to acknowledge the kindness of Mr. Thomas Houghton in allowing himself to be put in nomination as a Vice-President of the Conference, Mr. Charles Gerrard Hitchcock for consenting to be a member of the Executive Committee, yourself for agreeing to act as a Local Secretary, and Mr. H. Thurland for being willing to perform the duties of an Auditor. I am further to add that the Executive Committee was quite gratified to find that the pharmacists of Oxford purposed receiving the members of the Conference in a manner strictly in accord with the objects of the Conference, and with the already published wishes of the Committee. I, in common with the other members of the Committee regret that the unforeseen circumstances which render Oxford unable to carry out the arranged meeting of the British Association in 1883 have obliged the Conference to postpone any decision respecting our own place of meeting for that year, for as a rule the Conference and the Association meet in the same town. For the same reason also we must postpone the acceptance of the services of yourself and colleagues. I shall doubtless again have the pleasure of corresponding with you after the Executive Committee has held a meeting.

"Yours faithfully, JOHN ATTFIELD."

A letter from the chemists of Southport was read, inviting the Conference to meet in their town in 1883. It was unanimously agreed to accept this invitation.

Respecting the invitation to meet in Aberdeen, as it was offered for 1884 as well as 1883, its consideration was postponed.

The following four officers, which the General Meeting had given power to this Committee to appoint, were then elected:—Vice-President, Mr. W. V. Radley, Southport; Member of Executive Committee, Mr. James Kershaw; Local Secretary, Mr. William Ashton; Auditor, Mr. Thomas H. Sykes.

Fifteen gentlemen were elected to membership.

CHEMISTS' ASSISTANTS' ASSOCIATION.

At a meeting held on Wednesday evening last, October 25, at 32A, George Street, Mr. W. A. Wrenn in the chair, a paper on "Cinchona Barks of Commerce" was read by Mr. W. Elborne, who gave a very interesting account of the various kinds of barks of commerce.

There was a good discussion, in which Messrs. R. W. Giles, R. H. Parker, W. A. Wrenn, J. O. Braithwaite, and others took part; after which a hearty vote of thanks was proposed by Mr. Hartridge and seconded by Mr. Parker, to which Mr. Elborne made a suitable reply.

Parliamentary and Law Proceedings.

A CORONER ON THE SALE OF LAUDANUM.

On Friday, October 20, an inquest was held in the Royal Hospital, Belfast, by the borough coroner, Dr. Dill, concerning the death of Thomas Thompson, a publican, who had been admitted to the hospital on the previous Tuesday, suffering from the effects of an overdose of laudanum, and who died on Friday morniug.

After other evidence had been given, John Patrick Henry, chemist, 97, Donegall Street, Belfast, stated that on Tuesday, about three o'clock, a man whom he believed to be the deceased came into his business establishment, and asked for sixpennyworth of laudanum. Witness inquired what it was for, and he said for a horse that was ailing. The deceased then got a bottle with an 1½ ounce of laudanum, and witness labelled it "Laudanum—poison," with his name and address. Witness thought from the appearance of the deceased that he had something to do with the management of horses. The deceased had not the slightest appearance of having taken drink. Witness did not consider it necessary to inquire the name and address.

A Juror thought that when such a dangerous thing as laudanum was asked for there should be more inquiries made than had been done by the witness.

Witness: I did more in the matter than the law directs, for I not only labelled the article, but inquired the purpose for which it was intended.

The Coroner: But the law provides that you should take the name and address of the purchaser.

Witness: Excuse me; it does not in the case of laudanum.

The Coroner: I know that, but it is a great mistake not to do it.

Witness: But the taking of his name and addr would not have prevented this man from committing act that he did. There are plenty of druggists in Belfa and he had only to got a pennyworth of a number them and he would have had as much as he wanted.

The Coroner: I am sure that intending suicides abroad in the neighbourhood of Belfast will be thankful to you for the information you have given.

The Coroner said when Mr. Henry went the length of asking the man's name he might have gone further, as the asking for such a quantity of laudanum looked very suspicious.

Mr. Henry: I thought I did all that was necessary; I had no idea that the laudanum was intended for any other purpose than that told to me.

The Coroner: Would you do the same thing again?

Witness: I would rather not sell laudanum at all.

The Coroner: I wish you never had sold it. If you had not done so you would not have got into trouble.

Witness: The man was as sober-looking as any of the jury are at this minute.

The Coroner: The only point in the matter is the selling of such a quantity to a stranger without making yourself thoroughly acquainted with the purpose for which it was intended. My impression is that the law should be a little more stringent than it is with regard to a drug like laudanum. I have heard of people going into surgeries and not being given more than a pennyworth, and that not full strength.

Witness: If I mixed it I could be prosecuted.

The Coroner: As you say yourself, you would rather not sell laudanum, and I wish you did give it up, for there are too many in Belfast dealing in this poison.

In reply to a juror, the wife of the deceased stated that her husband was in the habit of taking laudanum in pennyworths to produce sleep, as when he was drinking he never got any rest at night.

Robert Campbell, druggist, 15, Bridge Street, stated that a person named Thompson received an ounce and three-quarters of laudanum in his shop between three and half-past three o'clock on Tuesday. Witness took his name and address, which he gave correctly. He said he wanted the laudanum for a horse. There was nothing in his appearance that could lead one to believe that he was under the influence of drink.

The Coroner: What made you ask him for his name and address?

Witness: I always make it a point to take the names and addresses of persons receiving half an ounce of laudanum or anything beyond that.

The Coroner; Did you ever sell anything like this for a horse before?

Witness: Yes; I have often, and have known a horse to get 2 ounces.

In reply to a juror, Mrs. Thompson stated that she never heard her husband threatening to commit suicide. He was a little annoyed about the sale of a house that he had lost some money over, and was occasionally depressed in spirits.

Head-Constable Furey said that when the deceased was brought to the police office and searched, four bottles which had contained laudanum were found in his pocket. As soon as this was discovered witness feared that he had poisoned himself, and had him removed at once to the Royal Hospital. Two of the bottles were labelled Haslett and Co., North Street. Witness inquired there about the matter, but they were unable to say whether any laudanum had been sold to the deceased.

Dr. James Barron, House Surgeon, deposed that death resulted from congestion of the lungs. The deceased was insensible when admitted, but after the effects of the morphia had disappeared he regained his senses, which he preserved up to within a short time before his death. He told witness that he had only taken a pennyworth of laudanum to cause him to sleep. Witness believed that at the time when the deceased took the narcotic poison the deceased was not aware of what he was doing.

The Coroner said he was not at all satisfied that the deceased took the laudanum with any suicidal intention. He was in an unfit state to take care of himself, and appeared to have fallen back on the old idea of the pennyworth of laudanum to produce sleep. To his (the Coroner's) mind, the man did not know what he was doing.

Dr. Barron said that was his impression also.

The Coroner having summed up the evidence, the Jury returned a verdict to the effect that death resulted from congestion of the lungs, accelerated by heavy drinking and the excessive use of laudanum.—*Belfast Evening News.*

Poisoning by Vermin Killer.

An inquest has been held by the Middlesbrough Coroner, Mr. Belk, touching the death of Mr. A. Woodford, late cashier to the firm of Swan Brothers, Middlesbrough.

Mr. H. H. Taylor proved selling deceased sixpennyworth of "Battle's Vermin Killer," which deceased said he wanted "to destroy some nocturnal friends." He had purchased what contained 6 to 8 grains of strychnia, or enough to kill a dozen men.

Dr. Walker testified to being sent for on Wednesday night, when deceased owned to having taken vermin killer, and though every effort was made to save his life, he died in a quarter of an hour after he was called.

The Coroner having summed up, the Jury returned a verdict "that deceased had taken 'Battle's Vermin Killer,' containing strychnia, while in an unsound state of mind."—*Leeds Mercury.*

Review.

Adolph Strecker's Short Text-Book of Organic Chemistry. By Dr. Johannes Wislicenus, Professor of Chemistry in the University of Würzburg. Translated and Edited, with Extensive Additions, by W. R. Hodgkinson, Ph.D., and A. J. Greenaway, F.C.S. London: Kegan Paul, French and Co. 1881.

At the beginning of this century, chemists could almost count upon their fingers the organic substances with the properties of which they were acquainted, and even within recent years it was not so difficult to include, within one moderate volume, a full account of all that was known about organic chemistry. Now it is different, and the author of a text-book has to undertake the arduous task of picking and sifting what he thinks will be useful to his readers from what he thinks they do not want. He cannot expect to satisfy all, but must be content to cater to the wants of a particular class of readers. In this way text-books of organic chemistry come to be separable into distinct species. There is the *elementary* book, the object of which is to explain the leading principles of the science, the general group characteristics, and so forth, the properties of individual substances being only so far discussed as they exemplify general laws. Of this class one of the best representatives is Armstrong's volume in the science series published by Longman. Then there is the *cram* book, which gives the student, in concise form, all the facts he need burden his memory with prior to examination; an example of which is Piner's Repetitorium. A third species may be called the *dictionary* text-book, whose chief requisites are that it shall be well up to date, omit nothing, and give full references to original papers, and which is the invaluable companion of the more advanced chemist. We do not here include the various forms of pharmaceutical text-books, nor those known as technical text-books, for they in reality can hardly be classed under the head of organic chemistry as understood by scientific chemists. Now the book before us does not belong to the elementary, the cram-book or the dictionary species, but must be placed in a separate group. Professor Wislicenus himself says, "it is neither a primer nor a dictionary," and he certainly would not allow that it was written purely for examination purposes. So the question arises, what is the class of men for whom such a book is written? and we cannot but come to the conclusion that there is really no class likely to profit greatly by its publication. No teacher would prescribe such a book to a student new to organic chemistry, or, if he did, the student would fail to understand it; while anyone sufficiently far advanced to use the book would certainly find it insufficient for his purpose. We think that the same criticism is applicable to other and similar text-books, which are too full to be read by the student, yet not full enough to be consulted by the chemist. As an example of how useless it may be for consultation, let us imagine a chemist looking up this book for a method of making dichloracetic acid. He turns to p. 455, and finds that it is "prepared by the action of equal molecules of chloral hydrate and potassic cyanide." The extraordinary construction which assumes that molecules of these two bodies can, under any circumstances whatever, be equal, is probably due to careless translation, *molecule for molecule* being, of course, what is meant. But what we chiefly object to here is that the above sentence is merely a verbal interpretation of the equation which follows it. No one could learn from it how to make dichloracetic acid, nor is there any reference to original papers which might enlighten him. Similarly on p. 366 we read that "ethylic acetate" (acetic ether) "is *best prepared* by distilling 10 parts of sodic acetate with a mixture of 15 parts of sulphuric acid and 6 parts of alcohol," no reference being made to the advantage derived from first dehydrating and fusing the sodic acetate. While dealing with practical details, we notice that under the head of chloroform, its ready decomposition in some circumstances is attributed, at least in part, to the *presence* of alcohol. One characteristic of the book is its large dealing with graphic formulæ. These are, no doubt, of great assistance, being, in fact, at present, the organic chemist's special language. But, as has been so often pointed out, there is considerable danger attending the use of them by the student, who is apt to forget that they are, after all, but an imperfect representation on paper of some of tho properties of substances; to forget, for instance, that alcohol is a liquid boiling at 79° C., and to think of it as a combination of letters and strokes. In one or two cases this book errs in this direction, as when (p. 36) it says "of the many instances of isomerism of the second kind . . . there may be mentioned

$$CH_3-CH_2-CH_2-CH_2-OH \text{ and}$$

$$\begin{matrix} CH_3 \searrow \\ CH_3 \nearrow \end{matrix} CH-CH_2-OH\text{"}$$

No names are given—nothing more is said. Surely one may fairly say that this is not mentioning instances but drawing diagrams. This kind of error, however, is far less common throughout the book than the author's extensive use of graphic formulæ might lead one to expect. Indeed one of the best chapters in it, and one which will be found really useful, is that which treats of isomerism among the aromatic compounds, for here the student will find well described the practical distinctions between ortho, meta and para compounds, as well as the causes which theory assigns to these differences. It is not uncommon to find a student well up in the latter, but totally ignorant of the former. Some parts of the introduction, also, are worth reading; but it is by no means free from errors. Thus it is asserted (p. 41) that the atomic volume of oxygen, when combined as in alcohol, is 6·4. This might have been put down as a misprint for 7·8, but, unfortunately, two of the calculations on the next page are based upon the assumption of this erroneous value. So also the atomic volume of nitrogen when combined as in cyanogen is given as 28·0, whereas it is only 17, that of cyanogen itself being 28·0. The three pages dealing with this subject of specific volumes might, with advantage, be entirely rewritten.

We have mentioned some of the bad points of this book. That it has many good ones, the names on the title page are a sufficient guarantee; but we fear it will be found, as we say, too difficult for the student, too meagre for the chemist. If, indeed, there does exist an intermediate class of readers, we may recommend it to them as neither much better nor much worse than others of its kind. The translation is good, except in a few cases where German idiom has been allowed to creep in and spoil the English.

Percentage of Morphia in Liquid Extract of Opium, and Commercial Silver Nitrate.

Sir,—Not being present at the British Pharmaceutical Conference when my papers were read, will you allow me to state the method by which I calculated the percentage of morphia in liquid extract of opium, data of which were required by Mr. Plowman.

On reference to the figures obtained I find that ·58 was the percentage of morphia that should have been stated and not ·38 as appeared in the paper. About 21·5 grs. of solid extract are contained in each fluid ounce of the liquid form, the average specific gravity of which I found to be ·972, and the average yield of opium (of 8 per cent. of morphia quality) in extract to be 66 per cent. Therefore in 66 grains of this solid extract there would be 8 grs. of morphia. One fluid ounce of the liquid extract, specific gravity ·972 will weigh 450 grs. and in this 450 grs. are dissolved 21·5 grs. of solid extract (66 grs. of which contain 8 of morphia), and if 66 grs.contain 8 then 21·5 grs. will contain 2·6, so that if 450 grs. of the liquid extract contain 2·6 of morphia the percentage will be ·58; on looking at the residues of the ten samples which I examined I find deposits in eight of them; whether these deposits contain morphia or not I have not yet determined.

I had hoped to have been present at the Conference to to ask if any maker of liquid extract of opium could explain why the percentage of morphia was so much under the average in this preparation, but could not reach Southampton from the Shetland Islands in time.

In answer to Mr. Mason respecting the source of the samples of nitrate of silver, the two found pure were obtained from Messrs. Herring and Co., and Messrs. Rouse and Co., Wigmore Street respectively; one I received for analysis from a former pupil of mine, and three I purchased from itinerant photographers. Seeing Mr. Williams's remarks relative to his experience of these crystals I have forwarded to him through the courtesy of the editor of the *British Journal of Photography*, two samples containing as an impurity nitrate of potassium, which were also purchased from itinerant photographers.

Grosvenor Villa, Devonport Road, Uxbridge Road, W. JOHN WOODLAND.

Junior.—In one case the word is placed in the accusative as the direct object of the verb; in the other it is in the genitive, some such phrase as "a sufficiency of" being understood.

"*Succus.*"—The percentage of citric acid in raw lime juice is variable. As to the average strength, see two papers by Mr. Warington, in the present series of this Journal, vol. vi., pp. 385 and 768.

"*Pertinctus.*"—"38° B." would stand for the density represented by 38 degrees of Beaumé's hydrometer. The equivalent specific gravities may be found in Squire's 'Companion' and many other works; that of 38° B. is specific gravity 1·333.

"*Dispenser.*—The ointment should be quite a creamy white when made, but changes to a yellow colour when kept.

Junior.—The formula is not suitable for pills. The aniline liquifies the camphor and the result is a soft paste.

Student.—Nitric acid, "azote" being used to designate nitrogen.

W. R. F.—(1) Pharmaceutical chemists have no special exemption from special constable service. (2) Such a practice would involve an illegality.

Communications, Letters, etc., have been received from Messrs. Tichborne, Keyworth, Gravill, Surfleet, Jones, C. J. S. T.

THE ORCHARD ALUM SPRING.*

BY DR. THRESH.

The examination of all substances used in curing or alleviating disease, whether they be of mineral or vegetable origin, falls within the province of the pharmacist, and where the remedy consists of a number of proximate constituents it is his duty to isolate these, and if possible to ascertain to which of them its efficacy is due. As the water of the spring giving the title to this paper has long had a local reputation, I have made a somewhat careful examination of it, and as it is being constantly employed as a curative agent, it has been deemed a suitable subject for a contribution to this Society.

The spring, which appears to be a "descending" one, originates in a disused coal mine, near the summit of Axe Edge, the highest point in the Peak country. To get rid of this water a narrow tunnel has been bored through the side of the hill, just over the Staffordshire border, and about five miles from Buxton, and the water flows from the open end of this conduit into a tributary of the Dane. As the farm on the hillside is known as the Orchard (a most singular name for such a bleak and desolate spot), and the water has a strongly astringent taste, the spring is usually called the Orchard Alum Spring.

The country people round have great faith in the virtues of the water, and not only make use of it themselves but frequently bottle it to send long distances to their friends or others who arrange with them so to do. It is chiefly valued as a vermifuge, and no matter what may be the description of the parasite, nor whether it infest young or old, human beings or cattle, one or more doses of this remedy is said to bring about the desired result. It is for this purpose usually taken fasting. Cattle, after being kept without food and water for some time, are allowed to drink as much of the fluid as they will, and the effect produced is frequently described as astonishing. As a tonic its reputation is waning, continued use of it even in small quantities producing obstinate constipation, and generally doing much more harm than good. I am informed that years ago many members of the medical profession in the neighbouring towns and villages prescribed it frequently, but I do not think such is the case at the present time.

Applied externally it is said to cure ringworm, and it is largely used by the farmers as an outward application for various skin diseases on cattle.

The water has a very decided red tint, varying in depth according to the character of the season. The sample analysed was collected after a period of continuous rain, and was not near so dark as it is usually seen, yet when placed in a wine glass it looked like a pale sherry. Seen in larger volumes, in the deeper portions of the stream, it has the colour of blood. It reddens litmus paper, but contains no free acid. When heated to about 150° F., it becomes quite opaque from the separation of a basic ferric sulphate, but if allowed to evaporate on the water-bath nearly to dryness, the basic salt redissolves and a yellow vitreous residue remains. When heated so as to cause the above salt to deposit, the supernatant fluid is quite colourless.

The mean of two concordant determinations of the specific gravity gave 1·00351 as compared with pure water at the same temperature, and each gallon was found to contain—

$Fe_2 3SO_4$	174·426	grains.
Fe_2O_3	6·275	"
$Al_2 3SO_4$	72·908	"
$MgSO_4$	21·055	"
$CaSO_4$	14·381	"
$FeSO_4$	1·596	"
Na_2SO_4	·537	"
K_2SO_4	·822	"
$AlPO_4$	·456	"
KCl	·282	"
NH_4Cl	·125	"
KNO_3	·170	"
SiO_2	5·776	"
	298·809	"

The results from which these quantities are calculated are tabulated at the end of the paper, and with regard thereto it may be remarked that in the first estimation of the phosphoric acid, the dried and weighed mixture of ferric and aluminic oxides and phosphates was fused with six times its weight of a mixture of 4 parts of sodium carbonate and 1 of silicic acid. The mass was exhausted with water containing a little ammonia carbonate, traces of silica removed by evaporation with acid, and the phosphoric acid precipitated with magnesia mixture. In the second determination the mixed oxides, etc., were dissolved in nitric acid, and the phosphoric acid removed by aid of ammonium molybdate.

Reference to the composition of the water, as given above, shows that the medicinal properties of the spring are due to the ferric and aluminic sulphates of which it contains so large a quantity. Undoubtedly it is of too powerful a character for internal use unless very considerably diluted, but even then as a tonic its value is impaired by the presence of the sulphate of aluminium. Its acid reaction, of course, is due to the presence of these salts, and the excess of ferric oxide explains the decomposition which takes place when the water is heated. It is somewhat singular, however, that when carefully evaporated, the basic salt first deposited redissolves, yielding a residue which can be diluted, forming a very nearly colourless solution. The acidulous and basylous radicals in this latter case can scarcely be in the same state of combination as in the original water.

We have not far to look for the source of the more abundant constituents. The spring rises or rather issues from the hillside immediately above the upper surface of the millstone grit formation, which is here exposed and forms the bed of the rivulet into which the water flows. Overlying the sandstone is a layer of aluminous shale of a blue-grey colour, and doubtless by the action of the air and water this suffers such decomposition as to produce the soluble salts found in the spring. The exposed edges of this shale are encrusted with ferric oxide, and here and there after rain the water dripping off is seen to be distinctly coloured. Usually water passing through such a stratum contains a considerable amount of ferrous sulphate, together with aluminic sulphate and a smaller or larger proportion of ferric salts, the formation of the first named being represented by the equation—

$$2FeS_2 + 7O_2 + 2H_2O = 2FeSO_4 + 2H_2SO_4.$$

The sulphuric acid then reacting upon the clay will form the aluminic sulphate. On the opposite side of the hill, the water flowing from a similar

* Read at an Evening Meeting of the Pharmaceutical Society, November 1, 1882.

mine contains ferrous salt equivalent to 50 grains of crystallized ferrous sulphate to the gallon, with only a trace of ferric salt, and doubtless this is derived, by some such decomposition as the above equation represents, from the pyrites in the surrounding strata. To account for the formation of the ferric salt the oxidation must be carried further, the reaction being represented as follows:—

$$4FeS_2 + 15O_2 + 2H_2O = 2Fe_2\,3SO_4 + 2H_2SO_4.$$

Further, by action of the ferric sulphate on the magnesium and calcium carbonates, with which doubtless the water comes in contact in some part of its course, the sulphates of magnesium and calcium would be formed together with ferric oxide and the basic ferric salt. An illustration of this decomposition is furnished by the stream into which the alum water flows. A few yards beyond the point where the iron water enters it, it receives another little tributary. The water in the latter appears to be rich in calcium carbonate, for where it falls into the larger stream the whole of the mixed water becomes perfectly muddy and for a considerable distance below the bed of the stream is thickly coated with an ochry deposit.

The only water of a similar character of which I can find an analysis occurs in a mine belonging to the Luzerne Company (*Dingl. polyt. J.*, ccxviii., 267), but this only contains 122 grains of solids per gallon, whilst as much as 23 grains of free sulphuric acid occur therein.

By way of conclusion it may be remarked that a water of this kind proves in a marked degree the futility of attempting to check the analytical results by comparison with the amount of solid residue left upon evaporation of a given quantity, whatever may be the temperature at which the residue is finally dried. The whole of the water could only be driven off in this case by heating to such a degree that the ferric sulphate began to decompose, and the residue then was so hygroscopic that an accurate weighing was impossible.

Table of amounts of products obtained during the analyses calculated as from 10,000 parts of water.*

	Portion of residue soluble in water.	Portion insoluble in water.	Total.	Total Estimation.	Mean.

NOTE UPON THE USE OF OXALIC ACID AS A TEST FOR ARSENIATES IN ALKALINE SALTS.*

BY C. PATROUILLARD, GISORS.

In an interesting memoir presented recently at the meeting of the British Pharmaceutical Conference, and published in the *Pharmaceutical Journal* of the 16th of September last, Messrs. Naylor and Braithwaite give an account of several experiments made by them with considerable care, and affirm that they have recognized afresh that oxalic acid does not exercise any reducing action upon arsenic acid, and, after having quoted a few lines from the memoir in which I published the result of my researches, they express the opinion that, under the conditions described by me, nothing of that which I have announced takes place.

Nevertheless, I maintain that which I wrote in 1874, and which I have repeated many times since in the testing of salts employed in my pharmacy; it may be summarized as follows:—When a *salt* contains at least 1 to 2 per cent. of an *arseniate*, if it be boiled with oxalic acid or oxalate of ammonia for a few minutes, sulphydrate of ammonia or sulphuretted hydrogen, after the addition of a few drops of pure sulphuric acid, will produce in it, at the end of an interval more or less long, a yellow precipitate of trisulphide of arsenic. This precipitate may be accompanied by a varying quantity of sulphur. If the proportion of arseniate contained in the salt amount to 5 or 10 per cent., and especially if the mixture be still sufficiently hot, the precipitate is produced *immediately*.

In my previous experiments I have always employed salts such as nitrate of potash, the sulphates of soda and magnesia, the bicarbonates of potash and soda, etc., to which had been added either biarseniate of potash or arseniate of soda. I have noted in my laboratory register a large number of testings, as varied as possible, and checked in such a manner as not to allow of error. The precipitating agent has been sometimes sulphydric acid, and more frequently sulphydrate of ammonia, which is more easily kept ready in a good state of preservation, provided that it be dissolved in glycerine. In any case, in order not to be led into error by a precipitate of sulphur, which might mask a small quantity of trisulphide of arsenic, it is always advisable to make at the same time a comparative test with a specimen of a salt which is known to be pure.

The following are some new experiments that I have made since reading the memoir of Messrs. Naylor and Braithwaite.

Five grams of arsenic acid were dissolved in 100 grams of distilled water, and the solution was divided into two equal parts. The first part was heated to boiling during five minutes with 0·50 gram of oxalic acid; the second part, after having been exactly neutralized with caustic soda, was treated in the same manner. To the two liquids were afterwards added a few drops of sulphuric acid and then sulphydrate of ammonia. In both cases a precipitate was produced *immediately*: in the acid liquid a greyish-yellow one of sulphur; in the neutral liquid a distinctly yellow one of trisulphide of arsenic.

I have also repeated an experiment that I had already made previously. One gram of neutral

* Read at an Evening Meeting of the Pharmaceutical Society, November 1, 1882.

arseniate of soda, dissolved in 50 grams of distilled water, was boiled during ten minutes with 1 gram of oxalate of lime; the hot liquid, filtered and acidulated, yielded *at once* a precipitate of trisulphide of arsenic of a fine yellow colour.

A mixture of solutions of neutral arseniate of soda and oxalate of ammonia, boiled during two or three minutes only, then acidulated, gives with sulphydrate of ammonia a yellow precipitate. The same mixture, not boiled, but acidulated, gives with sulphydrate of ammonia a milky turbidity of sulphur, which by boiling is contracted into greyish-yellow flocks. The reactions have appeared to me so distinct that I have not thought it necessary to study them more minutely.

From the experiments of Messrs. Naylor and Braithwaite, and my own, I conclude that oxalic acid does not exercise a reducing action upon free arsenic acid; but that when that acid is combined with an alkali it is reduced by oxalic acid to arsenious acid, and the reduction is more complete in proportion to the perfectness of the neutrality of the medium in which it is effected. So that the gentlemen who have contradicted me, notwithstanding their good intention, have failed to place themselves within the conditions described by me.

The idea never occurred to me to examine the action of oxalic acid upon uncombined arsenic acid: *à priori*, I should have thought, I must say, that it was the same as upon arseniates. My original memoir, published in the *Bulletin No.* 1 *de la Société des Pharmaciens de l'Eure*, which is in the library of the Pharmaceutical Society, is entitled, "Recherche des Arséniates dans les Sels alcalins." The extract which was published in the *Répertoire de Pharmacie*, in 1875, is entitled, "Recherche des Composés arsénicaux dans les Sels alcalins." Lastly, in the book to which Messrs. Naylor and Braithwaite have made allusion, in every place where arsenic acid is in question, it is always understood that it is the acid combined with alkalies that is referred to; it could hardly be found mixed with other salts except in that state.

[*The discussion on this paper is printed at p.* 377.]

NOTE ON TINCTURA CAMPHORÆ COMPOSITA.*

BY J. BLAND.

For some years past I have had a difficulty in preparing this tincture, which has, I daresay, occurred to others.

By a little care in the manipulation, the whole of the oil of anise should be soluble in the proof spirit directed by the Pharmacopœia, as was shown by Mr. Ince in an early volume of the *Pharmaceutical Journal*, and until about the time of the issue of the first British Pharmacopœia I had no trouble in getting a satisfactory solution. Since then I have found that a great part of the oil of anise separated, and although the deposit could by the aid of the powdered opium be readily filtered out, it was yet evident that a part only of the oil of anise was contained in the finished tincture.

After many failures to account for this result, it struck me that the oils of *Pimpinella anisum* and *Illicium anisatum*, though similar, might not be identical; and this proved to be the case.

In the London Pharmacopœia, the oil of *Pimpinella anisum* alone is official, and is stated by Phillips to be sometimes "adulterated" with oil of star-anise; the B.P. recognizes both oils as official, and, from the difficulty I had in procuring an authentic sample of the former oil, I infer that practically the whole of the oil of aniseed of commerce is derived from star-anise.

Whether the chemical and therapeutical properties of the two oils are identical, perhaps requires further investigation, but considering the statements that have been made as to the poisonous properties of the oil of the *Illicium religiosum*, and the comparative insolubility of the oil of star-anise in proof spirit, I would suggest that the oil of *Pimpinella anisum* should be preferred for medicinal use.

[*The discussion on this paper is printed at p.* 378.]

* Read at an Evening Meeting of the Pharmaceutical Society, November 1, 1882.

THE AVERAGE AMOUNT OF CAFFEINE IN THE GUARANA OF COMMERCE AS COMPARED WITH THAT IN THE SEEDS, ETC.*

BY J. H. FEEMSTER, CINCINNATI.

In reply to this query I shall take up three questions in the order presented:

1. What is the average amount of caffeine in the guarana of commerce as compared with that of the seeds?

From a select sample of seeds procured from Messrs. Lehn and Fink, of New York, I obtained five and eight-hundredths (5·08) per cent. of caffeine. Taking this as a basis of comparison five samples of guarana of the usual cylindrical form were purchased from as many dealers, and with these analyses were conducted with the appended results. Five hundred grains guarana used in each case.

No. 1	yielded 21 grs. caffeine, or	. .	4·2	per cent.
No. 2	„ 25 „ „	. .	5·0	„
No. 3	„ 21 „ „	. .	4·2	„
No. 4	„ 19·5 „ „	. .	3·9	„
No. 5	„ 21·5 „ „	. .	4·3	„

The aggregate yield of caffeine from the five samples was one hundred and eight (108) grains, making the average per cent. of the five determinations four and thirty-two (4·32) hundredths.

2. Determine a rapid and pharmaceutically correct method of getting at the percentage of caffeine from guarana.

The process employed in securing the above result was that recommended by Professor E. S. Wayne, for the extraction of caffeine from tea (*American Journal of Pharmacy*, 1875, p. 135), and afterwards used so successfully upon guarana by Francis V. Greene, U. S. Navy (*American Journ. Pharm.*, 1877, p. 337; *Pharm. Journ.*, [3], viii., 87).

The directions for conducting the analysis are so full and explicit in the article of Mr. Greene, that it would seem unnecessary to repeat them, but I will mention that the addition of a few drops of liquor plumbi subacet. to the boiling mixture of guarana, litharge and water, when the colour begins to disappear from the solution, seems to facilitate the deposition of the insoluble portion, and to leave the liquid more free from colouring matter.

The crystals of caffeine from the solution thus treated are so white that recrystallizing from diluted alcohol is done away with.

The guarana and litharge require to be boiled about three hours before the solution upon the subsidence of the solid matter remains clear, and I was surprised to find when operating with the seeds that the change takes place in less than one hour.

The cause of this I leave open for future investigation

* Read at the meeting of the American Pharmaceutical Association held at Niagara Falls, 1882.

A plan for the extraction of caffeine from guarana tea or coffee, more free from objection than the one proposed by Professor Wayne, would be found with difficulty.

It is so free from complications, and can be conducted with such rapidity and accuracy, that it is without hesitation I recommend it as the one best answering the second portion of this query.

3. Give the most desirable alcoholic menstruum that is adapted to the extraction of caffeine and the preparation of fluid extract of guarana.

Sixteen troy ounces of guarana in moderately fine powder was moistened with two (2) ounces of menstruum composed of alcohol, three (3) fluid ounces, glycerine, four (4) fluid ounces, and water five (5) fluid ounces.

The drug was packed in a conical glass percolator, the remainder of the 12 fluid ounces of menstruum poured on, and after the liquid had disappeared from the surface it was followed with a mixture of alcohol, 4 fluid ounces, and water 12 fluid ounces.

When the liquid began to drop from the lower orifice a cork was inserted, and maceration continued for two days. The percolation was then proceeded with, the first 12 fluid ounces reserved, and 2 pints more of percolate collected, the last portion of which was void of colour and taste. This was evaporated to 3 fluid ounces added to 1 ounce of alcohol and mixed with the 12 fluid ounces reserved, to make 1 pint of finished fluid extract.

The finished fluid extract kept bright and free from deposit for several months, but after that time a heavy chocolate-coloured precipitate formed, and upon examination was found to contain groups of crystals of caffeine. (Sample submitted.)

The exhausted guarana was removed from the percolator, and after drying thoroughly, tested for caffeine yielding about 1 per cent.

Four additional experiments were made with the following menstrua:—No. 2 contained five (5) fluid ounces of alcohol; No. 3, six (6) ounces; No. 4, seven (7) ounces, and No. 5, eight (8) ounces; the proportion of glycerine corresponding in each case to that used in experiment No. 1.

What I have said concerning experiment No. 1, can be repeated as to Nos. 2, 3, and 4, except that the deposit was diminished as the quantity of alcohol was increased, No. 4 being very slight.

No. 5 containing fifty (50) per cent. of alcohol and four (4) fluid ounces of glycerine to the pint makes a fluid extract which I regard as a true representative of the drug, and the menstruum as containing the least quantity of alcohol in association with glycerine that can be credited with giving good results. Dilute alcohol without glycerine is not free from the objection mentioned in connection with menstrua Nos. 1, 2, 3 and 4, viz., its liability to deposit.

In proof of this I submit a sample from a lot made in November, 1880, containing 50 per cent. alcohol, but without glycerine.

THE HISTORY OF CITRINE OINTMENT.*

BY R. A. CRIPPS,

Bell Scholar in the School of Pharmacy of the Pharmaceutical Society.

A short time ago I was asked by Professor Attfield to reply to some queries which had been put to him by Mr. Adolf G. Vogeler, of Chicago, respecting citrine ointment. I gladly undertook the work, and the outcome is the present paper. Mr. Vogeler concurs in my wish to read it before this Association.

The preparation known as citrine ointment has from time to time been prepared from numerous and widely-differing formulæ.

The first notice of it is found in the 'London Pharmacopœia of 1650, a most complicated formula being given to it; among the ingredients may be mentioned white coral, limpet shells, tragacanth, quartz, white marble and white lead, made upon a basis of hog's lard, suet and hen's grease. How such substances could be made into a presentable ointment is difficult to imagine, when we remember how little apparatus was at the command of the pharmacist of that day. It is said to have been used in many skin diseases and for freckles.

In the London Pharmacopœia of 1668 the formula remains the same, while in those of 1678 and 1682 several of the ingredients are omitted, sugar of lead replaces carbonate, and rose water, frankincense, and citron bark are added. The Edinburgh Pharmacopœia of 1722 orders under the same name an ointment of an entirely different nature, the formula being:—

℞ Hydrargyri . . . . . . unciam unam.
Spiritus nitri . . . . . . q.s.
Ut fiat solutionem, cui adde paulatim
Axungiæ porcinæ liquefactæ. libram unam.
Misce. Fiat unguentum.

It was not till long after this that a citrine ointment containing mercury was admitted to the London Pharmacopœia, perhaps from the fact that with a formula such as the above very varying results were naturally obtained; indeed we find no mention whatever of it in the London Pharmacopœia of 1724, while in that of 1746 it is similar to resin ointment with the addition of 1 oz. of yellow wax to each 8 ozs.

Quincy, in the 'London Dispensatory' of 1730, gives a similar formula, viz.:—

Yellow resin . . . . $\frac{1}{2}$ lb.
Sheep's suet . . . . 4 ozs.
Turpentine . . . . 2 ozs.

To be melted together and strained. No doubt the pharmacist thought this a vast improvement on the former ointment so difficult to prepare; but he was not long to remain in this state of ease as regards citrine ointment, for in the London Pharmacopœia of 1787 a new formula was given to it which bade fair to cause him more trouble than the last.

Some say it was introduced in imitation of the well-known "golden eye salve," but others state that it was of French origin, having been used in Paris for the cure of the itch. If the former were the case, it was not satisfactory, "golden eye salve" being an ointment of yellow oxide of mercury.

The formula was:—

℞ Hydrargyri pur. . . . . . unciam unam.
Acidi nitrosi . . . . . . uncias duas.
Axungiæ præp. . . . . . . libram unam.

Dissolve the mercury in the acid, and then mix the boiling liquid with the lard previously melted, remove from the dish and allow to cool. The same formula was used in the Edinburgh Pharmacopœia of 1792, but it was ordered to be stirred diligently during the cooling; a milder ointment was also official, containing half the quantity of lard. In 1803 the Edinburgh Pharmacopœia ordered 12 ozs. of lard instead of 16, the milder ointment containing three times that amount. Notwithstanding these continued alterations the ointment was still very unsatisfactory, it varied greatly with the temperature employed in preparing it, and after keeping usually became grey with greenish patches, and so hard that it could sometimes be powdered. This was stated to be due to the oxidation of the lard by the nitric acid, and many other substances were tried as a basis, among which the most important were butter, olive oil, and neat's foot oil. Accordingly we find in the Edinburgh Pharmacopœias of 1807, 1809, 1813 and 1817 a formula having as a basis 1 part lard to 3 parts of olive oil; in that of Dublin, 1807, 1 of lard to 4 of oil; and London, 1809, 2 parts oil to 3 of lard: still the results were quite unsatisfactory, and many were the theories propounded to account for the changes to which it was liable, excess of nitric acid, deficiency of nitric acid, too high or too low

* Paper read before the School of Pharmacy Students' Association, June 22, 1882.

a temperature, the presence of salt in the lard, impure mercury, and a fatty basis of unsuitable nature, all received their supporters. Acting upon the first of these theories the authorities of the London Pharmacopœias of 1817, 1824, 1836, and 1851 ordered 11 drachms of acid in place of 2 ounces, the formula of the last being:—

℞ Hydrarg. pur.	℥j,
Acid. nitric.	ʒxj.
Ol. olivæ	℥iv.
Adipis præp.	ʒviij.

Ft. unguent.

They also ordered a milder ointment, containing 1 part of strong ointment to 7 of lard. The Dublin Pharmacopœia of 1850 also orders less acid, while those of Edinburgh, 1839 and 1841, direct a larger quantity.

The British Pharmacopœia of 1864 gives the following formula:—

Take of—

Mercury	4 ounces.
Nitric acid, sp. gr. 1·5 . . .	8 „
Lard	15 „
Olive oil	32 „

Dissolve the mercury in the acid with the aid of a gentle heat, melt the lard in the oil, by a steam or water-bath in a porcelain vessel capable of holding six times the quantity, and while the mixture is hot, add the solution of mercury, also hot, mixing them thoroughly; if the mixture does not froth up, heat till this occurs.

The B.P. of 1867 orders 12 ounces of nitric acid, sp. gr. 1·42.

This formula will give an excellent ointment, and when complaints are made of the result it will be found that the fault is in the operator not in the formula. The instructions must be strictly adhered to, or a failure will probably result, and especial regard must be paid to the temperature at which the mixture is made, which should range from 180°–200° F., and should not be too long continued, but only until the ointment froths up well; if large quantities be made the temperature may be a little lower. As thus prepared it is of a fine lemon-yellow colour, and keeps for a fair length of time, perfectly good.

Such are the varied formulæ which have from time to time been given to this interesting ointment; but before leaving the subject I should like to devote a short notice to the chemistry of the preparation.

The views of chemists regarding the chemical composition of the ointment vary considerably. Evidently the original idea was to obtain an ointment of mercuric nitrate; hence the name given to it in the Pharmacopœias. But this was entirely a failure, for on adding the acid solution of nitrate to the melted lard chemical decomposition occurs, as indicated by the frothing. Still, this was considered as simply the result of the oxidation of the fat by the excess of acid; but Mr. Schacht, who made a number of experiments in the laboratories of the School of Pharmacy, showed that the ointment, when carefully prepared, is soluble in ether, thus indicating that the mercury exists as some compound with a fatty acid, the nitric acid in combination with the mercury being in some way retained while the excess is evolved during effervescence. In Mr. Schacht's valuable paper (which will be found in the *Pharmaceutical Journal*, [1], vol. iv., p. 450), he also states that the failure in obtaining a good ointment is not due to the presence of salt in the lard, or of lead in the mercury, and that ointment spoiled by keeping may be restored by warming with nitric acid, thus indicating that nitric acid is essential to its preservation, and that by keeping some of the acid is lost.

But in the *Pharmaceutical Journal*, [3], vol. vi., p. 708, in a paper by Mr. Fredigke, of Chicago, it is stated that a superior ointment both in appearance and in durability may be prepared by oxidizing the fat by nitric acid, previous to adding the mercurial solution. This would seem to show that the oxidized fat forms a compound with the mercuric nitrate, the colour being due to the elaidin formed by reaction of fat and acid.

Such then are the results of their experiments; but as they are to a great extent conflicting, it is impossible to arrive at any definite conclusions without experimental research, and pressure of time debarred me from such a course, so that I have been obliged to leave the subject with this historical sketch.

THE POISONOUS CONSTITUENT OF ANDROMEDA JAPONICA, THUNBERG.*

BY PROFESSOR J. F. EYKMAN.

Among the many plants belonging to the natural family Ericaceæ and the genus Andromeda, indigenous to Japan and China, is *Andromeda japonica*, Thunberg, an arboraceous shrub, commonly regarded as poisonous by the Japanese, and mentioned as such even in the oldest Japanese works on natural history. The investigation of this plant appeared to be very interesting, from a toxicological point of view, since the natural family of Ericaceæ furnishes only a limited number of poisons, and those but little known.

What is recorded in the Japanese or Chinese literature regarding this plant may be comprised in the following:—

The oblong, bitter, and astringent leaves are poisonous and have a stupefying or deadly effect upon horses and cows which eat them. Hence the plant is named *basuiboku*, *makuwasu*, also *shikaku kuwasu*, and *sishi kuwasu*.†

A decoction of the leaves kills insects and worms, also the pediculus capitis.‡ It is used as a wash in ulcerations and in scabies, and as an antidote against *fugu*.§ The finely-powdered leaves are used as a remedy in snake-bite; and the odour of a decoction of the leaves causes headache to human beings.||

The plant grows everywhere upon the mountains, is evergreen, and is, for this reason, used as an ornamental plant. It reaches a height not exceeding seven, and usually only two metres. A whole series of names is used for it in the different provinces; they are chiefly recorded in the 'Honzokomoku keimo of Ono.'¶

Of these, *asebu* and *basuiboku* are the Chinese names most in use; *shin-boku* and *tin-shu-kwa* are names given from the globular form of the flower;** and *bei-han-kwa*,†† from the resemblance of the flower to boiled rice.

E. Kaempfer, in his 'Amœnitates Exoticæ,'‡‡ describes this plant already in a somewhat detailed manner, under the names *asjebo* and *asjemi*; but Thunberg was the first who gave a complete description, besides a good illustration of the flowering plant.§§

* Translated from the author's manuscript. Reprinted from *New Remedies*, October, 1882.

† *Ba*, horse; *sui*, stunning; *boku*, tree.—'*ma*' horse; *kuwasu*, not eat.—*shikaku*, deer;—*sishi* is a collective name for wild animals, also wild hogs and for lion. Thunberg, in his 'Flora Japonica,' mentions also the name *sishi-gakure*; *gakure*=to conceal, to hide one's self, on account of the dense foliage of the shrub.

‡ According to the 'Honzokomoku keimo' (the commentary of the 'Honzokomoku' by Li-shi-shin).

§ From this it is also called *fugu shiba*; *fugu*, poison-fish; *shiba*, plant.

|| According to the 'Yudoku somoku susetsu' (Explanation and Illustration of Poisonous Plants). It is also stated in this work, that deer, after eating the leaves suddenly lose their antlers. In Li-shi-shin's 'Honzokomoku' is also found the statement that a decoction of the leaves drives off the impure blood, in women, after childbed.

¶ On all these works, and some others of similar nature, see the article on Japanese Medicine and Pharmacy, *Pharm. Journ.* [3], vii., 674.

** *Tin*, peculiar; *shu*, ball; *kwa*, flower.

†† *Bei*, rice; *han*, food; *kwa*, flower.

‡‡ 'Fascic.,' v., p. 896, Pl. 1712.

§§ 'Flora Japonica,' p. 181, Pl. 1784.

The poisonous principle is extracted from the fresh leaves in the following manner:—

The leaves are infused with water, and the strained liquid evaporated on a steam-bath to a thin syrup. The latter, which has a brownish-red colour, is filtered and then shaken, several times in succession, with chloroform. The chloroformic solution, which has a faint greenish-yellow colour, is reduced, by distillation, to a small volume, and petroleum spirit added to the residue, until nothing further is thrown down by it. The separated amorphous substance is dried, and then dissolved in ether containing alcohol; this solution is shaken with water, the watery liquid, which is almost entirely colourless, separated from the yellow ethereal layer, and evaporated at a moderate heat. There is left, as residue, a soft, light yellow, amorphous mass, which, by a gentle heat, dries up to a transparent substance, colourless in thin layers. I have tried in various ways and by using different solvents, to cause this substance to crystallize, but at no time could there be observed even a trace of crystals. The substance is always obtained in the same condition, so that I considered myself justified in assuming to have under my hand a pure, homogeneous substance. In addition to the above treatment, the powdered substance was thoroughly extracted with petroleum spirit, and afterwards with benzol, the residuary powder again dissolved in ether mixed with some alcohol, and the colourless solution once more shaken with water. Upon evaporation of the aqueous liquid, at a moderate temperature, there was again obtained an amorphous substance of precisely the same properties as before. After having been partially dried on the water-bath, it was reduced to powder, and the latter subjected to ultimate analysis (I. and II.). Another portion was partially extracted with absolute ether (free from alcohol) in which it is only slightly soluble, and thus divided into two fractions. Analyses were also made both of the fraction left undissolved by the ether (III.), and of that which the latter had dissolved and left behind on evaporation (IV.).

I obtained the following results:—

I. 0·2732 gram, dried at 110° to 115° C., yielded 0·2631 gram of dry substance, and after combustion, 0·5815 gram of CO_2 and 0·1983 gram of H_2O.

II. 0·3288 gram, dried at 110° to 115° C., yielded 0·3181 gram, and after combustion, 0·7073 gram of CO_2 and 0·2087 gram of H_2O.

III. 0·3575 gram of the fraction left undissolved by ether after being dried at 110° to 115° C., yielded 0·7929 gram CO_2 and 0·2368 gram H_2O.

IV. 0·3898 gram of the fraction dissolved by ether, after being dried at 110° to 115° C., yielded 0·8651 gram of CO_2 and 0·2610 gram H_2O.

These results, expressed in percentage, calculated upon the *dry* substance, represent:—

	I.	II.	III.	IV.	MEAN.
Carbon (C=12)	60·28	60·64	60·49	60·52	60·48
Hydrogen (H=1)	7·53	7·29	7·36	7·44	7·405
Oxygen (O=16).	32·19	32·17	32·15	32·04	32·115
	100·00	100·10	100 00	100·00	100·000

The agreement of the figures under III. and IV. among themselves and also with those under I. and II. confirm the belief that we have here a homogeneous definite principle, and not a mere mixture.

I have chosen the name *asebotoxin* for the substance.

Properties of Asebotoxin.—It is a colourless substance, soft while moist, but brittle and transparent when dried at a gentle heat. When covered with water, it cakes together, becomes soft below 100° C., but does not melt until the temperature 120° C. is reached, and then forms a transparent light-brown mass. It is only slightly soluble in cold, more readily in hot water, and very easily in alcohol, amylic alcohol, glacial acetic acid, and chloroform. These solutions have a neutral reaction. Ether, free from alcohol or water, dissolves it but sparingly; but it is readily soluble in ether mixed with alcohol. Petroleum spirit, benzol, and disulphide of carbon do not dissolve it at all, or only in very small quantity.

Water of ammonia dissolves it tolerably well, solution of soda less easily. The watery solution is neither precipitated nor altered by ferric chloride, sulphate of copper, mercuric chloride, chloride of gold, nitrate of silver, or even solution of acetate of lead. But basic acetate of lead causes a white flocculent precipitate.

When heated with alkaline copper solution, and still more, after being first heated with diluted sulphuric acid (the resinous precipitate being removed by filtration), it causes a separation of red cuprous oxide (Cu_2O). Asebotoxin, therefore, belongs to the glucosides; it contains no nitrogen. On combustion it produces vapours which excite coughing, then chars, and is consumed without leaving a residue. The aqueous solution has a bitter taste, and produces a strong tingling upon the tongue.

I found the fatal dose for rabbits to be 3 milligrams (about $\frac{1}{20}$th grain) for each kilogram of the animal, by hypodermic injection.

Weight of rabbit in kilos.	Asebotoxin injected in aqueous solution.	Dose calculated for each kilo of the animal.	Result.
3·24	9·5 milligr.	2·9 milligr.	Death in 1¾ hour.
2·80	5·5 „	2·0 „	Recovery after several hours.
1·35	4·5 „	3·3 „	Death in 1 hour.
1·28	3·6 „	2·8 „	Death in 3 hours.
1·25	2·5 „	2·0 „	Recovery after several hours.

The observed external symptoms are chiefly the following:—After administering a dose, of about the fatal limit, the rabbit is seized, in about fifteen to twenty minutes, by a strong trembling, and begins, while producing snarling or groaning sounds, to make slight retractive motions with the head. These become gradually more intense; the forward movement of the head being made with wide-open mouth, and accompanied by a smacking, sucking sound; the nostrils being widely opened. Sometimes diuresis or defecation are observed. Now and then the animal suddenly springs up and runs around anxious and groaning. The temperature of the body diminishes sensibly; by degrees, the animal loses its power of motion, and lies on one side. Next, there appear symptoms of paralysis in the extremities, the mucous membranes of mouth and nostrils appear very anæmic, and exude mucus, and, after some convulsions, the mouth and nostrils being wide open, death supervenes, under symptoms of cyanosis, apparently by suffocation.

In the rabbit which weighed 3·24 kilos, I observed, shortly before death, a strong exudation of a milky turbid liquid in the eye.

Dogs begin to vomit soon after the poison is injected.

The differences are entirely analogous to those which are observed after injecting a watery infusion of the fresh leaves. One cubic centimetre of this infusion, corresponding to about 200 milligrams of fresh leaves, kills rabbits of about 1·25 kilo within a few hours, and, therefore, agrees in effect with 3 to 4 milligrams of asebotoxin.

Asebotoxin exhibits some fine colour-reactions, which are of importance toxicologically. If an alcoholic solution of the substance be poured into a watch-glass and strong hydrochloric acid be added, a *magnificent blue* *colour* is gradually developed, and, at the same time, a peculiar odour resembling that of *Spiræa ulmaria*. On evaporating the blue solution on a water-bath, a fine violet-red tint developes itself at the edge of the liquid. If the blue solution be left to itself, it turns after some time to reddish-grey, and the liquid becomes turbid from the separation of a bluish-grey substance. Concentrated sulphuric acid dissolves asebotoxin with a red colour, which becomes, after some time, fine rose-red, while the liquid is rendered turbid from the separation of a bluish-grey substance. If asebotoxin be boiled with diluted hydrochloric acid, the liquid assumes a fine rose-red colour, and a brown resinous substance separates. The same effect is produced by diluted sulphuric acid. The above mentioned peculiar odour is also noticeable during the last named reactions.

CITRATE OF IRON AND QUINIA.*

Complaint is very often made of the difficult solubility of the officinal citrate of iron and quinia. of the United States Pharmacopœia, and it is very often erroneously said to be insoluble. Such complaints and statements are simply due to the faulty teachings in materia medica and pharmacy and faulty practice in therapeutics.

As long ago as the revision of the Pharmacopœia of 1860 it was recognized that the bitterness of quinia preparations, both to the palate and in the stomach, was in many cases destructive of appetite in sensitive patients, and, therefore, when given as a tonic this bitterness in a measure defeated the quinia. Hence a preparation of iron and quinia was adopted, containing a large and effective proportion of quinia, which, when well dried, was so slowly soluble that it could be easily given, either in form of pill or powder or suspended in syrup, to women and children, or in the most delicate conditions of palate or stomach, with but slight bitterness. Such a preparation passed over the palate easily, and when in the stomach dissolved and was assimilated slowly and easily with the least possible shock—for intense bitterness is as shocking and as disturbing to many stomachs as intense acidity or alkalinity is. This preparation, when taken between the teeth, feels almost like so much sand, and its solubility and bitterness are developed so slowly that although containing about 11 per cent. of quinia, it is often condemned as containing no quinia at all. And when stirred up with water it at once settles out, leaving the water colourless and tasteless, or nearly so, in proportion to the time allowed, and it is often at once discarded as useless, and letters written about it which have some of the bitterness in which it is supposed to be deficient, the fact being all the while that it is entirely soluble even in its own weight of water, but only very slowly soluble, as it should be and was intended to be. For a long time after its introduction to the Pharmacopœia it was used as was intended in powder, pill or syrup, and attained the high character which it has always so well deserved, but gradually, through defective teaching or through want of thought, physicians began to make the mistake of prescribing it in solution. Then those physicians and pharmacists who had skill enough and patience enough to get it into solution by tying it up in a cloth and suspending it in the water and setting it in a warm place for some hours, found they had a dreadfully bitter solution, and one which in a short time became mouldy, as all salts with organic acids will. To avoid this slow and troublesome solubility and some of the intensity of bitterness, the manufacturers soon supplied a preparation by exactly the same name, wherein, by the addition of citrate of ammonia, a readily soluble salt of similar appearance with less bitterness was supplied at a lower price. Of course this contained a smaller proportion of both iron and quinia and a larger proportion of citric acid and water; but this escaped attention so long as the preparation had the desired solubility, the diminished bitterness in solution, and was sold at a lower price. This new preparation, unofficinal, though called by the officinal name, was for a time designated as soluble citrate of iron and quinia —not so much for the purpose of indicating any difference of composition as for the purpose of distinguishing it in order so as to avoid the objectionable insoluble salt of the Pharmacopœia. But after a while it almost entirely usurped the place as well as the name of the better preparation, and it holds these at this time so firmly that perhaps a hundred ounces of it are sold to one of the original officinal preparation, while the latter is really much more valuable, and as valuable, therapeutically, to-day as it was in 1860, when adopted by the Pharmacopœia; and the reasons for its adoption are as good and as sound to-day as they were then, only the pecuniary profits upon it are less than on the more dilute and soluble preparation. So little is the better agent used now in proportion to the weaker one that in the present revision of the Pharmacopœia there was but a feeble opposition to the adoption of a formula for the weaker preparation, while some effort was needed to prevent the dismissal of the older and better salt.

The ground that the Pharmacopœia must follow the usage and requirements of physicians in general, even when the latter do fall into errors, may be the only safe general rule; but unless there be a multitude of exceptions it is not a good rule for the highest and best interests of the art of medicine. It has always been the rule of the manufacturer and is well illustrated in the history of citrate of iron and quinia, but this history also illustrates that what is a good rule for the manufacturer may even satisfy a large majority of physicians, without being a good rule for their patients.

Beside all this, there is one point in the history of this preparation that is difficult to comprehend. The officinal salt is tasteless when given in a well-made uncoated pill, and is very nearly tasteless when in powder or suspended extemporaneously in any thick liquid as mucilage or syrup, and the constant demand of late has been for tasteless medicines, or, at least, those which are not nauseous. So prominent is this demand that physicians are often heard to complain that they lose their practice to homœopathy, etc., because their medicines are not made less disagreeable. Yet here in the case of this valuable agent, within twenty years a large majority of the whole profession has abandoned the tasteless form of it, and gone over to an inferior preparation, so as to give it in a solution which is very bitter, and which would be very justly objectionable to their patients if these knew they could take a better preparation in a nearly tasteless condition.

INFLUENCE OF PEPTONES AND CERTAIN INORGANIC SALTS ON THE DIASTATIC ACTION OF SALIVA.*

BY R. H. CHITTENDEN AND J. S. ELY.

Recent experiments† on the diastatic action of saliva under various conditions have revealed the fact that human mixed saliva in the presence of an equal volume of artificial gastric juice containing 0·05 per cent. of hydrochloric acid, is capable of forming, from a given quantity of starch, a much larger amount of sugar than the same quantity of saliva alone can do under a like degree of dilution; this being the more remarkable when it is remembered that the same percentage of acid by itself greatly retards the diastatic action. This somewhat curious fact has led us to study the individual

* From the *American Chemical Journal*.

† Chittenden and Griswold, *American Chemical Journal*, iii., 305.

influence of several bodies of physiological importance on salivary fermentation. It is our conviction that many of the digestive processes of the body are more dependent for their fullest action on the stimulating or other influence caused by the mere presence of many of the digestive products than has hitherto been supposed. Experiment, to be sure, has revealed the fact that several of the products of digestion when present in the digestive mixture in excess, notably sugar in the case of salivary digestion and peptones in gastric digestion, retard the digestive process. Under ordinary circumstances, however, all conditions are favourable, in the normal body, for a rapid absorption of the digestive products, and thus any excessive accumulation is prevented. Schmidt-Mülheim* found in his recent study of proteid digestion, that in the case of dogs, the quantity of peptones present in the stomach was practically the same at all times during the digestion; thus, one, four, and six hours after feeding a dog, 61 grams of albumin, the stomach contained 3·08 grams, 3·31 grams, and 2·91 grams of peptones respectively, which would seem to indicate that after the formation of a definite quantity of the digestive products the transportation of these bodies keeps pace with the digestion. Again, there are no facts to warrant the belief that the products of one digestive process necessarily hinder the action of some other allied ferment; indeed, it is ordinarily understood that any accumulation of the digestive products simply hinders the action of that particular ferment by clogging the digestive fluid.

There is nothing inconsistent then in the statement that the products of one digestion may act as a stimulant to some other digestive process. The results of the experiments about to be described show plainly that *peptones, a product of gastric digestion, exercise a decided influence on salivary digestion, stimulating the ferment to increased action, particularly in the presence of acid which by itself completely prevents the conversion of starch into sugar.* If now we are led, in virtue of this fact, to infer that there may be a possible continuation of salivary digestion in the stomach, it follows that the ferment must act at the first period of digestion, when the acid fluids are exceedingly weak. The fact that the quantity of peptones present in the stomach at this stage of digestion may be quite small offers no objection whatever to a possible action of the peptones, since the experiments already quoted, and those about to be described, well illustrate how extremely sensitive the saliva is to a change of conditions, however slight; thus even minute quantities of inorganic salts, even to the extent of only 0·015 per cent., exercise a decided influence on ferment action.

We may also reasonably infer that the saliva is, to a certain extent, a type of the other diastatic fluids of the body, and that the ferment itself is doubtless similar in its action to other like ferments, notably the ferment or ferments of the liver, which presumably convert the glycogen of the hepatic cells into sugar. Thus conditions which modify the diastatic action of saliva may not be wholly without similar influence on other like ferments. It has, therefore, seemed to us that the results of our work may have some bearing upon the recently published experiments of Seegen,† of Vienna, who found that when an aqueous solution of peptones was poured over a small piece of fresh liver, the quantity of sugar formed in a specified time was greater than in a piece of the same liver treated in a like manner but without peptones; at the same time, however, the total amount of carbohydrate matter appeared to be increased in the presence of the peptones. Finding that the peptones themselves had no diastatic action on glycogen, Seegen then concluded that the liver possesses the power of transforming peptones into sugar and carbohydrates which are capable of being converted into sugar. While our results may in nowise affect Seegen's conclusions, they certainly suggest the possibility that the increase of sugar noticed in the presence of the peptones may be due, in part at least, to some cause other than that attributed by Seegen.

We have attempted at first in our experiments to ascertain whether by themselves or under such conditions as may presumably exist in the body, peptones have any influence on the conversion of amylaceous matter into sugar by the saliva. The amylaceous material employed was starch and glycogen, while the diastatic agent was human mixed saliva, which was usually collected in quantities of 150–250 c.c. by the chewing of some tasteless substance, then filtered and thoroughly mixed before using. The saliva was ordinarily used an hour or two after collecting, and being as a rule always furnished by the same person, possessed approximately the same strength, although control experiments with starch and saliva alone under a like degree of dilution were made in each case. The method employed consisted in dissolving a weighed amount of starch or glycogen in 25 c.c. of water, then adding 50 c.c. of water or other fluid in which a weighed quantity of peptone or other substance was dissolved, and lastly, 25 c.c. of filtered saliva. The mixture, consisting of 100 c.c. of fluid, was then warmed for a definite time, usually forty-five minutes, at 40° C., when further action was prevented by boiling the mixture. The fluid was then diluted with water to 500 c.c., and when thoroughly mixed, 50 c.c., or one-tenth of the filtered fluid, was precipitated by cupro-potassium tartrate according to the method of Maercker, described in another place.* The copper was weighed as metallic copper, from which the percentage of reducing substance calculated as dextrose was determined by the use of Maercker's tables.

Influence of Peptones in Aqueous Solution.

The peptones employed were prepared especially for the purpose and were made as pure as possible. Three samples were prepared from thoroughly washed blood-fibrin by the action of an active gastric juice made from a glycerine extract of pepsin and 0·2 per cent. hydrochloric acid, while the fourth was made from coagulated egg-albumin by the use of a similar gastric juice. All four preparations were the products of an active digestion, and were therefore free from syntonin or other preliminary products. The peptones were purified by repeated precipitation and standing under alcohol and ether, while the fourth was especially purified from soluble salts by dialysis. The following results show plainly the action of the peptones. In each experiment 1 gram of the dried peptones dissolved in 50 c.c. of water was added to 1 gram of starch previously boiled with 25 c.c. of water, the 25 c.c. of saliva making a digestive mixture of 100 c.c., in which the peptones were present to the extent of 1 per cent. In the control experiment the mixture was made up to the same volume with water. Different saliva was used in each experiment.

SATURDAY, NOVEMBER 4, 1882.

SPURIOUS AND WORTHLESS DRUGS.

We are glad to learn, from the report of the proceedings at the meeting of the Council on Wednesday last, that a subject to which attention has been called repeatedly in the pages of this Journal, namely, the frequent appearance of parcels of inferior or misnamed drugs in the market, is provoking consideration with a view to the practice being energetically dealt with. It was brought under the notice of the Council by Mr. Williams, who quoted as instances the mouldy ipecacuanha to which reference was made in this Journal last week, some jalap tubers that had been exhausted of resin, and balsam of tolu containing 40 per cent. of common rosin. These three examples fairly represent three varieties of objectionable drugs that are met with,—those that have become deteriorated from more or less natural causes, those that have been deprived of their active principles, and those that have been sophisticated by the addition of some extraneous substances. To these may be added parcels of drugs of vegetable origin which consist either partly or wholly of something which is not represented by the name given to them, such as the spurious senna, concerning which a warning was first given in this Journal some time since, the substitution of Japanese for star-anise, and the adulterations of senega and other drugs that have been since referred to. Mr. Williams further stated that several gentlemen connected with the wholesale trade wished the Society to take the matter up and use its influence in securing such measures as would put some check upon the questionable practice.

The question seems to have given rise to considerable discussion, which was terminated by the Council appointing a Committee to consider the subject of the sale by auction of spurious and worthless drugs and to report on a future occasion as to the steps it would recommend to be taken with a view of checking the practice. It will be obvious that this was a discreet course; for the subject will require to be carefully considered from every point of view, and before arriving at any conclusion the Committee will have to estimate not only its bearing on the object professedly in view, but also its influence in many other ways. Many of these points could not be well discussed in a formal public debate, and will stand a much better chance of having due weight given to them in the more informal proceedings of a committee. For instance, the proposition to appoint an inspector of drugs, with power to condemn and destroy what he might deem to be worthless or hurtful, is one that may well be looked upon with anxiety in respect to the powers that would have to be entrusted to such an officer in order to enable him to perform such a duty effectually. Then there is the difficulty of defining what should be deemed worthless or deleterious, a point that evidently would often depend upon the use to which the substance is put after its sale has been effected. For it must be admitted that whilst the appearance of a quantity of damaged drugs in the market might justly arouse suspicion, and their use for some purposes would deserve condemnation, nevertheless for other purposes they might be justifiably used, and, therefore, it would be hard to deprive their owners of their market value. Beyond this, there is a decided indisposition in the present day to interfere between sellers and buyers in restraint of trade in any way.

There is another consideration, too, that must not be lost sight of, and that is, the manner in which the demand for an inspector of drugs would affect public opinion as to the position and qualification of pharmacists. It is admitted that the members of the wholesale trade are not likely to be betrayed into purchasing as of good quality such articles as those to which reference has been made, and it is implied, perhaps, rather than stated distinctly, that the suggested appointment would be for the protection of the chemist and druggist who is unable or too busy to protect himself. But the question arises: How far will it be wise on the part of the chemist and druggist to accept such a position, especially at the present moment? It is true that after the crude drug is ground or otherwise disguised it may be more difficult to distinguish sophistications or substitutions. But will it be wise for the pharmacist, whilst on the one hand he claims to be entitled to take a higher status than the ordinary tradesman on account of the superior education and training that he has undergone with a view to specially qualifying him to deal in powerful drugs, on the other to declare that without extraneous assistance from the State he is as helpless, or nearly so, as the grocer or the manager of a co-operative store? The subject is a difficult one, but we do not think that it could be more fitly taken in hand by any body than the Committee to which it has been referred.

THE LOCAL GOVERNMENT BOARD ON THE SALE OF FOOD AND DRUGS ACT.

The Eleventh Annual Report of the Local Government Board, which was issued last week, includes the usual reference to proceedings taken under the Sale of Food and Drugs Act. In the first place it appears that there has been during the year a considerable increase in the number of municipal corporations which have complied with the provisions of the statute as regards the appointment of public analysts. In previous reports the Board had been able to say that all the county authorities and the several vestries and district boards of works in the metropolis had made such appointments, but up to the end of the year 1880 only 156 municipal corporations had done so; now we learn that, as the result of steps taken by the Board, additional appointments have been made, and at the end of last year the total number of districts in which public analysts were acting was 260. In connection with this subject a question has arisen as to the duty of a town council that has entered into an agreement with the county authority for the "watching" of the town, concerning which the Board has been advised that in such a case it devolves upon the town council either to appoint an analyst or make an arrangement for the performance of analyses by an analyst holding an appointment in a neighbouring borough or for the county.

It would appear that the provisions of the Act as to the analysis of articles bought by private individuals are still almost ignored by the public, and the operation of the Act depends principally upon the extent to which the local authorities choose to exercise their power of procuring samples for analysis, only 358 having been purchased by private individuals during the year. The result is said to be that while in some districts the Act is well enforced, in others it is almost a dead letter, and it is remarked that the town councils, of the smaller boroughs especially, appear generally very unwilling to entertain a suspicion that the articles sold in their districts may possibly be adulterated.

The total number of analyses reported upon during the year 1881 by public analysts in their official capacity was 17,283, and of these 5039, or two-sevenths, were made in the metropolis. Outside the metropolitan district the standard suggested by the Board, of the analysis of at least one sample for every thousand inhabitants of a district, was attained only in three counties and twenty-nine boroughs. On the other hand, the analyses reported from twelve counties only numbered fifty altogether, whilst from sixty-six boroughs the returns were absolutely *nil*. Of the 17,283 samples analysed, 2613, or 14·7 per cent. were reported as adulterated, being the lowest average percentage in any year since the Act has been in force, and 1 per cent. less than in 1880. The highest percentage of ascertained adulteration (28·4) is reported in "spirits other than gin" and next follows gin (25·9). Then at some distance (19·5 per cent.) comes milk, of which nearly seven thousand samples were reported upon, and next coffee (18·3 per cent.).

With respect to the foregoing classes, there is some precision as to the individuality of the articles examined and of their probable source, as well as of the nature of the adulterants, but there is no indication of one or the other under the heading "drugs." It is simply stated that the number of samples reported upon (398) is still much smaller than is, in the opinion of the Board, desirable, and that the percentage of adulteration (15·0) continues very large. That these points, however, might have an important bearing upon the results is at least suggested by some figures that appear in the tabular abstract of reports found in the appendix. For instance, it appears that of 107 samples of "drugs" analysed in the metropolitan district, only 8 were reported to be adulterated. In the county of Lincoln 37 samples of drugs were examined and all reported genuine; and in Lancaster, too, of 47 samples none were reported adulterated; but in the neighbouring county of Durham, out of 51 samples 22 were reported adulterated, or more than one-third of the total number of samples of drugs reported upon adversely throughout England and Wales. Can it be pretended, therefore, that these figures represent even approximately the relative degrees of purity in drugs which obtain in the districts mentioned? Indeed, the Board itself admits a doubt whether the relative prevalence of adulteration is accurately represented by the figures given, the doubt being induced by the fact that in the case of milk the limit of an area in which an adulterated article is supplied appears frequently to be coincident with the boundary of the sanitary district.

With respect to the samples purchased privately and submitted to the public analyst, it is stated that a much larger proportion of them were reported to be adulterated than of those obtained by officers of local authorities. This is what might be expected, as a private individual would not be likely to incur the cost and trouble involved if he were not fairly confident that the article sold to him is not genuine. In order to encourage a greater development of the Act in this direction the authorities in Bristol, Salford and some other boroughs have made arrangements with the analyst to analyse samples for the public at 2*s*. 6*d*. each, instead of the half-guinea fee mentioned in the Act. It will be evident, however, that any movement in this direction will require to be made with discretion.

THE NORTH BRITISH BRANCH.

On Wednesday evening next, November 8, the North British Branch of the Pharmaceutical Society will commence a new session. The President of the Branch, Mr. Alexander Napier, will open the proceedings with an Address, and this will be followed by the reading of a "Note on the Solubility of Morphia Salts," by Mr. D. B. Dott.

THE CHEMISTS' BALL.

On Monday evening next, November 6, at 9 o'clock, a meeting will be held at 17, Bloomsbury Square, for the purpose of making the preliminary arrangements for the usual Chemists' Ball. Gentlemen who are desirous of becoming Stewards, but who will be unable to attend the meeting, are requested to communicate with the Honorary Secretary, Mr. J. F. Savory, 143, New Bond Street, W.

CHEMISTS' ASSISTANTS' ASSOCIATION.

A meeting of the above Association will be held at 32a, George Street, Hanover Square, on Wednesday evening next, November 8, when a paper on "Subnitrate of Bismuth" will be read by Mr. F. H. Alcock.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, November 1, 1882.

MR. MICHAEL CARTEIGHE, PRESIDENT.

MR. SAMUEL RALPH ATKINS, VICE-PRESIDENT.

Present—Messrs. Andrews, Borland, Bottle, Butt, Churchill, Gostling, Greenish, Hampson, W. Hills, Radley, Richardson, Robbins, Savage, Schacht, P. W. Squire, Symes, Williams, Woolley and Young.

The minutes of the last meeting were read and confirmed.

The following, being duly registered as Pharmaceutical Chemists, were respectively granted a diploma stamped with the seal of the Society:—

Fletcher, James Edward.
Foden, Edwin.
MacDermott, Robert John.
Parker, William Henry.
Roper, Robert Francis.
Rouw, Theodore John.
Steel, Alexander.
Thornley, Frederiek.
Wakefield, John.
Wright, Robert.

Elections.

MEMBERS.

Pharmaceutical Chemists.

The following, having passed the Major examination and tendered their subscriptions for the current year, were elected "Members" of the Society:—

Roper, Robert Francis............London.
Steel, Alexander ....London.
Wakefield, John ....Birmingham.

ASSOCIATES.

The following, having passed the Minor examination, and tendered (or paid as Apprentices or Students) their subscriptions for the current year, were elected "Associates" of the Society:—

Dye, Charles Page ....Bury St. Edmunds.
Fawssett, Theodore ....London.
Heynes, Thomas Edward ......Maidenhead.
Hudson, Tom ....Wells.
Prothero, George Rees ....Pontypridd.
Rees, Rice William ....Swansea.
Robertson, John ....Aberdeen.
Salmon, Ernest Frederick ......London.
Surman, Thomas William ......Bristol.
Treharne, Frederick Gwilym...Weston-super-Mare.
Yates, George Albert ....Manchester.

APPRENTICES OR STUDENTS.

The following, having passed the Preliminary examination and tendered their subscriptions for the current year, were elected "Apprentices or Students" of the Society:—

Axford, Sidney Bertram.........London.
Hatfield, George William ......London.
Richards, John William ....Pontypridd.
Thiele, Johann F....................London.
Wright, Charles Rowland ......Portsmouth.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a fine.

Mr. William Broom was appointed Local Secretary and Superintendent of Written Examinations for Exeter, in the room of Mr. George Delves, who has resigned.

Addition to the Register.

The Registrar reported that—

John Mitchell Humble, Marsh House, Rothwell, near Leeds,

having made the statutory declaration that he was in business before the passing of the Pharmacy Act, 1868, and this declaration having been supported by a duly qualified practitioner, his name had been placed on the Register.

Reports of Committees.

FINANCE.

The report and recommendations of this Committee were received and adopted, and several accounts were ordered to be paid.

LIBRARY, MUSEUM, LABORATORY AND HOUSE.

Librarian's Report.

The report of the Librarian had been received, and included the following particulars:—

	Attendance.	Total.	Highest.	Lowest.	Average.
July	Day	429	24	6	16
	Evening	108	10	1	5
August	Day	113	9	0	4

Circulation of books.	No. of Entries. Town.	Country.	Total.
July	155	98	253
August	51	54	105

Carriage paid	£	s.	d.
July	2	5	4
August	1	5	11
September	0	10	0

The Librarian had also reported that in making the annual inspection of the Library, he had found that the undermentioned book was missing:—

Glasgow University Calendar, 1881.

The number of volumes and pamphlets in the Library on September 30, was 8513.

The undermentioned donations to the Library had been received, and the Committee recommended that the usual letter of thanks be sent to the respective donors:—

Liverpool Chemists' Association, Reports, 1852-81. From the Association.

Flückiger (F. A.), Pharmakognosie des Pflanzenreiches, 2e Aufl., 2e Lief., 1882. From the Author.

Dragendorff (G.), Beiträge zur gerichtlichen Chemie, 1882.

Sitzungsberichte der Dorpater-Naturforscher Gesellschaft, 1882. Separat-Abzug. From Professor Dragendorff.

Thompson (E. S.), Oration delivered before the Medical Society of London, 1882. From the Author.

Kinch (E.), The soy bean. From the Author.

Guermonprez (Fr.), Doigtier metallique pour le traitement des plaies des doigts.

— Notes cliniques sur quelques plaies des doigts, 1881.

— Simulation des douleurs d'origine traumatique, 1881.

— Revue de zoologie médicale, 1881.

— Étude sur les indications thérapeutiques dans le traitement des ascarides lombricoïdes, 1882. From the Author.

Smithsonian Institution, List of foreign correspondents, 1882. From the Institution.

Tommasi (D.) & G. Pellizzari, Action du temps sur l'hydrate ferrique. From Dr. Tommasi.

Tommasi (D.), Réduction du bromure d'argent par la lumière.

— Action de l'aluminium sur le chlorure cuivrique.

— Sur un nouvel appareil destiné à montrer la dissociation des sels ammoniacaux.

Tommasi (D.), Electrolyse de l'eau, 1881.
— Appareil différentiel pour le dosage de l'ozone dans l'air.
— Sur l'électrolyse de l'eau distillée.
— Sur l'électrolyse.
— Sur le travail chimique produit par la pile. Two pamphlets.
— De l'influence de l'électrode positive de la pile sur son travail chimique.
— Réponse à M. Berthelot sur la force électromotrice d'un couple zinc-charbon.
— Relations numériques entre les données thermiques.
— Sur la loi des constantes thermiques de substitution. From the AUTHOR.
Hamberg (N. P.), Aix les Bains och några andra kurorter i Savojen, 1882. From the AUTHOR.
Gille (N.), Onguent égyptiac, 1882. From the AUTHOR.

The Committee recommended the purchase of the undermentioned books:—

Pharmacopœa Germanica, editio altera, 1882. 2 *copies.*
Christy (T.), New Commercial Plants and Drugs, parts 1–6. To be continued.
Smith (J.), Dictionary of Popular Names of Economic Plants, 1882.
Taylor (E. B.), Anthropology, 1881.

The Librarian had presented his report on the fifth annual meeting of the Library Association of the United Kingdom, held in Cambridge, September 5 to 8.

Curator's Report.

The Curator had reported the average attendance in the Museum to have been—

Attendance.		Total.	Highest.	Lowest.	Average.
July	Morning	276	27	0	10
	Evening	57	6	0	3

August—Total attendance during the first four days, 14 in the morning and 2 in the evening.

The following donations to the Museum had been received and the Committee recommended that the usual letter of thanks be sent to the respective donors:—

Specimens of the flowers of *Inula britannica* and *Artemisia judaica*; the root of *Camphorosma monspeliaca*; a fragrant oil from Colombo (*Lavandula sp?*); new Copal from Calcutta; bark of *Cinchona pubescens*; an original bundle of white Ipecacuanha; crystals of Tincal; Vegetable Tallow Seeds and the fat obtained from them, from Singapore; and Mauritius Anime. From Mons. C. CHANTRE.
Herbarium specimen of the Japanese Peppermint Plant. From Messrs. T. CHRISTY and Co.
Herbarium specimens of the Damiana plants, *Turnera aphrodisiaca* and *T. diffusa*; specimens of Juglandin (*Juglans cinerea*); Euonymin from the root and stem bark respectively; Irisin (*Iris versicolor*); Baptisin; Leptandrin; Barosmin (from root bark of *B. crenulata*); Pepsin in scales; Desiccated Oxgall. From Messrs. PARKE, DAVIS and Co.
Specimen of the volatile oil of *Eucalyptus dumosa*. From Messrs. HEARON, SQUIRE and FRANCIS.
Specimens of the Dyak Arrow Poison of Borneo. From Mr. R. JAMIE, of Singapore.
Specimen of the root of *Camphorosma monspeliaca*. From Mr. H. COCKSEDGE.
Specimen of the original deposit of crystals of Terpin Hydrate and selected crystals of the same. From Mr. W. ADAMS, Shrewsbury.
Specimens of Terpin Hydrate, with crystals and wooden models illustrating their crystallography. From Mr. R. H. PARKER.
Fine specimen of Cuprea bark. From Messrs. BURGOYNE, BURBIDGES, CYRIAX and FARRIES.

That the following specimens for distribution to provincial associations, etc., had been purchased:—Adulterated Saffron, Japanese Star-anise, Bengal Cardamoms.

Professors Bentley and Attfield had attended the Committee and reported satisfactorily as to their respective classes.

The report and recommendations of the Committee were received and adopted.

BENEVOLENT FUND.

The report of this Committee included a recommendation of the following grant:—

£10 to the widow of a registered chemist and druggist.

One application had been deferred until the next meeting, and another case the Committee had declined to entertain.

It was also recommended that the list of contributors to the Benevolent Fund be published in the *Pharmaceutical Journal* in January, and that a copy of that number be sent to each chemist and druggist on the Register.

The Council went into committee to discuss some of the details of the above report.

On resuming, the report and recommendations, with the exception of the case which the Committee had declined to entertain, were adopted. The case alluded to was referred back for further inquiries.

Mr. ROBBINS suggested that the Committee should be instructed to take into consideration the appropriation of the interest on certain gas shares which he had given in January last, on condition that the proceeds be given to such annuitant as had in former years contributed most to the Fund. He said he had intended to provide for a yearly sum of £5, but in the present year he found the interest amounted to £6 15*s.* 2*d.*, leaving a reserve of £1 15*s.* 2*d.* for any future deficiency.

Mr. RICHARDSON accordingly moved a resolution that the Committee take this matter into consideration, which was carried unanimously.

GENERAL PURPOSES.

The report of this Committee included the usual report from the Solicitor as to cases which had been placed in his hands. It stated that Mr. J. F. Craig, of Blackfriars Street, Manchester, who had been proceeded against for a breach of the Pharmacy Act, had paid the penalty and costs without action.

Several other cases of alleged infringement of the Act had been considered by the Committee, and in the majority of them it was recommended that proceedings be commenced.

The Council, as usual, went into committee to consider the above report.

On resuming, the report and recommendations were received and adopted.

REPORT OF EXAMINATIONS.

October, 1882.

ENGLAND AND WALES.

	Candidates. Examined.	Passed.	Failed.
Major (18th)	8	2	6

SPURIOUS AND WORTHLESS DRUGS.

Mr. WILLIAMS said there was a matter which he wished to bring before the Council with reference to the public sale in London of spurious and worthless drugs. Not long ago it was brought to his attention that upwards of a ton and a half of ipecacuanha was offered for sale, which, on examination was obviously worthless and rotten, but which still found a purchaser at a comparatively high price. This was not by any means the only case. He would pass round a sample of jalap, which no doubt was genuine jalap at one time, and he had endeavoured to ascertain its history. It appeared that this had been imported from Paris, where the jalapin had all been extracted from it; it had then been dried and sent to this market again, where it found purchasers as jalap. Several wholesale druggists had drawn attention not only to these cases but others; in one case there was some balsam of tolu, which contained 40 per cent. of resin, and such things he had been informed occurred at nearly every drug sale. In America, the government appointed inspectors of drugs, and prohibited the importation of any drugs unless they came up to certain standards. Now such a measure as that would, he feared, be very injurious to a market like the London market; nearly all the drugs in the world came either to England or to Hamburg, and he feared if anything like the American system were established, a great many drugs which were useful would leave this market and go to another. At the same time it was considered by many in the wholesale trade that there ought to be a power to destroy absolutely spurious and injurious drugs, in the same way as spurious tea or unwholesome fish or meat were destroyed. Some of the wholesale druggists thought the Society might assist very materially by going to the Government on public grounds, and asking for the establishment of a system under which inspection should be enforced under certain conditions, and that there should be a power to prohibit the sale of or to destroy these spurious things. What he would like to know was whether if he brought forward a series of cases of the kind he had described, properly authenticated, the Council would be inclined to join with the wholesale trade in making a representation to the Government on the subject, and so proving that it took interest in the welfare of the general public. There might be a good deal to be said on the other side of the question with regard to the restrictions on trade, and so on, but he hoped the Society would encourage the wholesale druggists by promising to support and assist them in obtaining a healthier state of things.

Mr. HAMPSON said the Council was indebted to Mr. Williams for bringing the question forward, but he thought it would be well if a committee were appointed to consider it before any steps were taken. It was a delicate question and would require very careful management or they might find more Government interference than they liked. The aim should be to remedy the grievance without establishing another.

Mr. SYMES suggested that one of the existing committees might deal with the question.

The PRESIDENT thought perhaps the best plan would be to let the Library, Museum and Laboratory Committee appoint a sub-committee at its next meeting. He thought it would have a good moral effect if a paper dealing with several of these cases, properly authenticated, were read at an Evening Meeting to call attention to the subject.

Mr. WILLIAMS said there was an Adulteration Act which affected the retail trade, but it would not in any way affect these wholesale dealings, so the most worthless articles could be sold openly and publicly without any possibility of touching the sellers under the Adulteration Act. At the same time it would be very unfortunate for any interference to take place with the legitimate wholesale trade; what was wanted was to find some happy medium by which the public could be protected from the fraud which now occurred without restricting the liberty of trade. He thought that any committee which was appointed would be glad of the advice and opinion of the Council.

Mr. WOOLLEY suggested that some good might be done by the publication of Mr. Williams's remarks.

Mr. SAVAGE said this was an interesting subject to the whole of the chemists in England, and it was very important that they should be made acquainted with the facts. If it were generally known it would show the public the importance of going to respectable shops for their drugs.

Mr. WILLIAMS said he would move that the question be referred to the Law and Parliamentary Committee with power to confer with certain members of the wholesale trade as to what steps should be taken, if any, with regard to the sale of spurious drugs.

Mr. RICHARDSON thought it would be better to have a special committee. He was not on the Parliamentary Committee and should be very glad to take part in this inquiry.

Mr. SYMES said the Law and Parliamentary Committee would have power to call in the aid of the wholesale trade.

Mr. WILLIAMS said it would be easy to add Mr. Richardson's name to the Law and Parliamentary Committee.

Mr. GREENISH remarked that scarcely an Evening Meeting took place at that house, at which instances of adulterated drugs were not brought forward. He did not think Mr. Holmes ever explained the specimens he had on the table without one or two being shown as adulterated specimens. The subject was not new, but it might perhaps be brought forward with more force than had hitherto been the case.

The VICE-PRESIDENT said it would have more effect if a paper were prepared on the subject. He should be very glad if Mr. Williams would prepare one. He thought it would be well to appoint a special committee with power to add to its number so that it might bring in two or three wholesale druggists from outside.

Mr. RICHARDSON agreed with Mr. Greenish that these matters were not new; they had been spoken of over and over again for years, but he was afraid that the sinners in the city took not the slightest notice of these exposures. The better plan would be to have a committee from the Council to co-operate with some of the wholesale people, and see if anything could be done. It was known to all wholesale dealers that this had been going on for years, and it was impossible to stop it unless Government aid were invoked. As a wholesale druggist he was rejoiced to think something was going to be done to put a stop to this pernicious practice, for it was very hard on those who wished to be honest that so many facilities were given to malpractice.

Mr. Robbins said, some years ago it was the practice of the Editor of the Journal to bring before the notice of his readers any adulterated article which came on the market, but he did not think those in the trade had any idea of what was going on until their attention was directed to it in this way. It was only necessary for the chemist to know that adulteration was being practised on any article and then he would take proper precautions, and that article would soon be expelled from the market. He recollected several instances of that kind. On one occasion a quantity of spurious senna leaves were offered for sale, but the fact was noticed, the mode of detection pointed out and the thing soon came to an end. Thus the evil cured itself when it was properly brought before the members, and he believed if the same thing were done now, a full description being given of the adulteration and mode of detection, it would put a stop to it.

Mr. Schacht said he was not certain that he saw the practical outcome of this proposed action. It occurred to him that as a body of pharmacists it was undoubtedly within their province to ascertain the facts connected with the adulteration of drugs, and to make those facts as widely known as possible, but he was not quite sure that in the action which seemed to be proposed the Council would not be going a little outside its legitimate work. Supposing this evil to exist to a very large extent, what was to be the process by which it was to be eradicated? How could the root of the evil be reached. First of all by a process which would go to the examination of all drugs, certifying what was good and what was imperfect, and, secondly, by punishing those offenders who were detected; but the task in each case would be an exceedingly difficult one. Supposing either of these things were accomplished, there would be the risk of absolving the wholesale dealers who purchased and distributed the drugs from their legitimate duty, viz., of satisfying themselves that the materials they had bought and sold were good. With regard to these articles he found by experience that he could place more trust in some men than he could in others; he knew that he had a personal duty to perform after them, but he felt it more incumbent on him when materials came from certain sources to perform that duty, than when they came from other sources. He was rather disposed to think that in order to remedy this evil, the Council must be content with exposing it, and he should be rather sorry if it were understood that the committee to be appointed should co-operate with gentlemen outside the body for a purpose which lay, in his opinion, a little beyond the proper province of the Society. He was very much inclined to think that the sole duty of the Council consisted in teaching the processes by which good things could be recognized from bad, and in exposing as much as possible attempts to palm off fraudulent articles. Those powers it already possessed, and he should be disposed to endorse all the recommendations of Mr. Williams. He hoped he would put his knowledge in the form of a communication to the Society, and let it be made public.

Mr. Williams said it was not a question of adulteration altogether. Every druggist in the market could tell that the specimen before the Council was bad jalap; it was an evident case of fraud.

Mr. Symes thoroughly approved of the suggestion that a committee should be appointed, because it would be only carrying out one of the very objects for which the Society was instituted, viz., the protection of those carrying on the business of chemists and druggists. Wherever the Society found a useful purpose could be served by exercising that power it should do so; complaints were often heard that it did not exercise that power and look after the interests of chemists and druggists, and this was one particular in which it might very well do so. A good deal had been said about discriminating between drugs, and there was no difficulty whatever in discriminating between this exhausted jalap and the rotten ipecacuanha as they were now shown, but when they came to be ground up and mixed with a little of the good article a great deal more difficulty would arise. These things were not like chemicals, which could be tested and determined at once whether they were good or bad, or merely of second quality. Mr. Schacht's argument would scarcely go the length of rejecting the motion, because the committee would not take any responsibility of action without reporting to the Council, even if it recommended any action at all. He took it, too, that there would still be a good deal of discretion left with the wholesale houses in declaring the various qualities of drugs; it was only suggested that, if the committee thought it desirable, someone should be appointed to destroy the really worthless articles, and that, it appeared to him, would be a step in the right direction. It would convince the Government and the public generally that the Society was exercising the powers it possessed for the public good.

Mr. Greenish agreed in the main with the observations of Mr. Schacht. He thought the publication of the facts at an Evening Meeting and in the Journal would be amply sufficient, and did not see what benefit could result from a committee. He might mention a case which occurred about twelve months ago, when a large quantity of rose leaves artificially coloured was put upon the market. Some came under his notice and he requested his son to examine them, which he did, and read a paper before one of the Evening Meetings, in which he showed that these leaves were coloured with magenta. The bubble burst at once, and he was told by the principal of one wholesale house that he had disposed of a large quantity of these leaves for sachets or something of that sort—they were taken out of the domain of medicine.

Mr. Andrews supported the proposal for a committee, because, notwithstanding there had been these exposures at Evening Meetings and in the Journal, the evil still went on, showing that the reading of papers alone was not sufficient. He thought with the careful limitations, which no doubt would be introduced, there would be no danger to the trade to be feared.

Mr. Savage said one thing occurred to him which he thought would meet the difficulty without going into that minute detail which would require the objectionable practice of having an inspector visiting chemists' shops and examining the drugs, which was once the case, and led to a great deal of abuse,—there might be an inspector to examine the imports and exports so as to avoid adulterated goods coming in. There was already an Act condemning those adulterated drugs found on the premises of any chemist, and if drugs which were manifestly impure could be kept out of the market it would meet the case.

Mr. Bottle agreed with the remarks of Mr. Savage. If there could be an inspector who should inspect and destroy all those drugs which were absolutely useless, in the same way as the inspector of meat or fish at Smithfield or Billingsgate, it would meet the case. Those inspectors did not destroy that which was of inferior quality, but only that which was absolutely deleterious. But he rather viewed this specimen of jalap from a different point of view, for it seemed to him that the Sale of Food and Drugs Act was quite sufficient to meet such a case. He believed that those individuals who sold such an article would be liable to the penalties of the Act.

Mr. Gostling said it was most important that chemists should be able to procure good drugs in a powdered state; at the same time he was very much afraid of Government interference. Not that he should object to an inspector coming to look at his stock, or that of any gentleman round the table; but it appeared to him that the remark of Mr. Greenish met the case entirely, especially if a person like the Curator were appointed to go into the drug market and ascertain the condition of things, which was presented and periodically reported to the Council.

The PRESIDENT said that was done at the present time.

Mr. GOSTLING said the result was not made public. If printed reports were presented from time to time people's eyes would be opened.

Mr. WOOLLEY said that through this subject coming forward so suddenly he had hardly made up his mind what was best to be done; but he understood from Mr. Williams that certain gentlemen connected with the wholesale drug trade wished the Society to take the matter up.

Mr. WILLIAMS said that was so.

Mr. WOOLLEY said with that view he should strongly support the appointment of a committee, if it were only to meet those gentlemen and show them that the Council was willing to see what grievance there was and help to remedy it if possible.

Mr. RICHARDSON said it was the duty of the Council to protect the chemist as far as it could, even against the malpractices of wholesale druggists.

The VICE-PRESIDENT said Mr. Richardson had expressed what he was about to say. He was as jealous as any man well could be of Government interference, but it struck him that the appointment of an inspector would only refer to the importation, not to go into provincial pharmacies. His duty would be to do as was done in the case of tea, to condemn on the spot that which was adulterated or exhausted. He did not know whether all wholesale houses kept their own analysts, but it would be an immense advantage to have the thing stopped before the article came into their possession.

Mr. SQUIRE thought that everyone who had passed the Minor examination could detect the absolutely worthless character of the two specimens of ipecacuanha and jalap which had been referred to.

Mr. GREENISH (handing up the sample of jalap) said it was absurd to suppose that any wholesale dealer required anything to protect him from the purchase of such an article as that.

Mr. HILLS thought very likely the committee would be able to collect useful information, but he was not satisfied at present that it would be able to do anything further. He did not think the cases of the fish and meat inspectors were altogether parallel, because in the case of drugs he presumed there were instances in which a sample would be quite useless for one purpose and yet might be useful for another. There might be certain drugs which were not entirely deprived of their active ingredients and yet not suitable to sell in the condition in which they were, but which might be useful for manufacturing purposes, and there would probably be a large number with regard to which it would be difficult to decide whether they had any value or not. After all it was a matter of price, and as a rule if the chemist would pay a fair price he would get very good powdered jalap or ipecacuanha, but if he chose the lowest priced articles he must expect to get something inferior.

Mr. CHURCHILL said that both from the wholesale and retail point of view it was a great hardship that the honest man should be undersold by one who was content to buy such stuff as that produced. He should not like to give an opinion offhand whether an inspector should be appointed or not, but he thought no harm could be done by appointing a committee which in the first place would endeavour to ascertain how much of this sort of thing actually took place.

Mr. SCHACHT said if the committee came to the conclusion that it was desirable to appoint an inspector, the question should also be considered whether the inspector's duties should take him into the wholesale druggist's warehouse as well as the open market.

Mr. WILLIAMS then moved formally:—

"That a committee be appointed to consider the question of the sale by auction of spurious and worthless drugs and to report to the Council what steps, if any, should be taken to check this practice. That the Committee consist of the President, Vice-President, Messrs. Greenish, Hampson, Richardson, Symes, Williams, Woolley and Young, with power to add to their number."

In reply to some of the remarks which had been made he should like to say that he trusted the committee would not go to work with any foregone conclusion that no action was to be taken. It would hardly be fair to call on their wholesale brethren to come and give time and attention to the Committee if such were the case. He had approached this question with great caution and did not wish to commit the Council in any way. He saw the difficulties, as clearly as Mr. Schacht did, of anything like legislative action or grandmotherly care; all he wished to urge was that when a case of exhausted or spurious or spoilt drugs or something not fit for human consumption was pointed out there should be power somewhere to prevent that thing being sold. Several gentlemen had observed that druggists both in town and country were generally quite able to distinguish a good article from a bad; but this ipecacuanha when scrubbed up, washed, dried and powdered would go out as *pulvis ipecac.*, and it would be more difficult for many persons to distinguish it. It was very well known who purchased these things; the buyers were as well known as the sellers, and it had lately led to a scandal in the market. Those who did not buy such things challenged those who did and asked, "How can you buy such rubbish?" But the answer had always been that they sent it abroad and that they did not sell it in England. There seemed to be a sale somewhere for all the rubbish that could be collected in the London market. Mr. Greenish seemed to think that exposure was sufficient and gave the illustration of rose-leaves coloured with magenta. He would be somewhat surprised to hear, perhaps, that these leaves were still in the market and were purchased in large quantities, so that exposure had done no good whatever in destroying these improper practices. Under these circumstances he thought he might fairly ask the Council to appoint a committee with the serious intention of supporting the action of the wholesale drug trade in applying to the Government to do something to check the importation and sale of absolutely spurious or rotten drugs; not in any way to prevent the importation of any quality of drugs if genuine, because the lower qualities were often very useful for manufacturing purposes.

Mr. SYMES seconded the motion.

The PRESIDENT said the gist of the whole matter was that the attention of the Council had been called, not for the first time, to the sale of those things by auction; and it was notorious that any person, whether a druggist or not, could go and see the attempt made to sell by public auction materials absolutely worthless. It was a cruel form of deception, and as that was the only Society representing the intelligence of the drug trade, it was only fair that it should be asked to consider if anything could be done to check such practices. The best pharmacists in the world, those in the United States, had come to the conclusion that it was necessary to have an inspector, though no one would suppose that the average pharmacist in the United States was not an educated man, and, as far as the analytical processes would allow, able to protect himself. The Committee would consider the matter with the greatest care before making its report to the Council.

The motion was then put and carried unanimously.

THE LATE MR. ALLCHIN.

The VICE-PRESIDENT said a telegram had been received that morning stating that Mr. Allchin had died at half-past nine o'clock, and he felt that no time ought to be lost in referring to this painful event. He could not claim such a long and intimate knowledge of Mr. Allchin as some of the members of the Council, but he had known him some years and very highly esteemed him. It was needless to dwell on his genial qualities as a man, but he had also occupied a prominent position in connection with the Society, sufficient to justify the Council in taking marked notice of his decease. He was one of the earlier Major certificated men, he believed he was once demonstrator in the school and certainly had been for some years one of the examiners. Since he had had the honour of being Vice-President he had been brought into close contact with him and had learned to esteem him very highly. He therefore begged leave to move—

"That this Council learns, with much regret, the death of Mr. Allchin, and that the President be requested to write a letter of condolence to Mrs. Allchin expressing the sympathy of the Council with her and the members of her family."

Mr. BOTTLE seconded the motion. He said the Vice-President had left nothing to add other than this, that it was his privilege to have known Mr. Allchin for a great many years, he could scarcely say how long, but from a very early date in the formation of the Society he had know him as an active worker. Mr. Allchin was at all times a genial and pleasant companion, and he deplored his loss very much.

Mr. SAVAGE could not allow the opportunity to pass without expressing his deep sympathy with the family of Mr. Allchin. He had probably known him longer than any member of the Council, for he knew him when he was an apprentice at Brighton. He, therefore, did sincerely sympathize with the widow and family of Mr. Allchin, and regretted deeply the loss the Society had sustained.

Mr. WILLIAMS said Mr. Allchin was an old friend of his, he having known him when he was a student in the school. He saw him last at the Conference, at Southampton, when he felt doubtful whether he should see him again. He was deeply grieved to hear of the death of his old friend, who was one of the most able pharmacists he had known.

Mr. ANDREWS said it was hardly necessary to multiply testimonies of respect to Mr. Allchin, but he had known him a very long time and was very intimately acquainted with him. After the meeting at Southampton he had spent a few days with him in the neighbourhood of the New Forest, and was then painfully convinced that he was not long for this world. He could only say he had never known a more amiable or more lovable man.

Mr. GREENISH wished also to express his regret at the death of Mr. Allchin, and his sympathy with his family. He had known Mr. Allchin for very many years, he could scarcely say how long. He esteemed him as a friend, and had a high opinion of his abilities as a chemist and pharmacist. His death would be a great loss to the Board of Examiners.

The PRESIDENT, in putting the motion, said he fully endorsed every word which had been said of Mr. Allchin. He had known him for many years, and, having worked side by side with him as an examiner, could testify to the extreme value of his services on that Board.

The motion was carried unanimously.

EVENING MEETING.

Wednesday, November 1, 1882.

MR. MICHAEL CARTEIGHE, PRESIDENT, IN THE CHAIR.

An Evening Meeting of the Pharmaceutical Society was held on Wednesday evening last. The chair was taken at half-past eight by the President.

The minutes of the previous meeting were read and confirmed.

The PRESIDENT commenced the proceedings by reading a paper on—

THE ORCHARD ALUM SPRING.

BY DR. THRESH.

The paper is printed on p. 361, and gave rise to the following discussion:—

Mr. POSTANS said the meeting was greatly indebted to Dr. Thresh for presenting such an interesting and able paper, in which he had given a most excellent analysis of the water from this spring. He said he was informed, though he did not give any medical testimony, that it was an excellent vermifuge, and he need not say that anyone who would bring to light a British spring which possessed all the properties which Dr. Thresh ascribed to this had really conferred a great boon on the medical profession. All that was necessary to bring it into use was that medical testimony to its efficacy should be forthcoming. Germany had long maintained a high reputation for its waters; it might be that there were plenty of most useful springs in our own country if they were only known.

Mr. EKIN said that springs having a blood-red appearance were not uncommon in coal districts. He had himself examined an iron spring of some considerable volume, issuing from a coal mine, which contained about 60 grains per gallon of iron as ferrous sulphate. He was considerably startled at what seemed to him the enormous quantity, but on referring to one of the reports of the Rivers Pollution Commissioners he found that they had examined several springs of the same kind. One feature of this spring was the large amount of sulphate of alumina. No doubt there were many springs in England containing large amounts of iron and alumina. Bunsen's method of analysis, by which the table at the end of the paper was arrived at, had an immense superiority over the older methods, as the change of condition brought about by evaporation was avoided. At the same time he was a little struck at the boldness of Dr. Thresh in the matrimonial way; he thought a more timid man would have hesitated a little before he brought out his figures as he had done. For instance, to say that in the case of the chloride of ammonium, which was present in the water to the extent only of ·125 grain per gallon, to say that the ammonium was necessarily combined with the chlorine was taking a good deal for granted. And again, in the case of the ·170 grain of nitrate of potassium, it was of course just as likely that the nitric acid was in combination with the calcium as with the potassium. He must confess to having a preference for giving the bases and acids separately; all this fitting in was very nice, but anyone who had any experience of analysis of this sort must know that there must be a certain amount of straining to make things fit so completely. He thought that the plan of giving the bases and acids separately was the more scientific and proper way.

Mr. WILLIAMS said he noticed in the table at the end $BaSO_4$ were said to be found in enormous quantities, but he apprehended this must be a printer's error, as there was nothing in the former table to show this quantity of barium.

The PRESIDENT said Dr. Thresh gave this table to show the correctness of his original analysis, and in it he gave, according to Bunsen's method, the results of the various constituents he got in the portion of the residue soluble in water, the portion insoluble in water, and the total. So in determining the sulphuric acid, he had so much barium sulphate, etc. In a footnote Dr. Thresh referred to the *Journal of the Chemical Society*, which contained a paper he had read, probably the best paper published for many years on the analysis of mineral waters. He believed it was due to Dr. Thresh's modesty that he had not lengthened this paper and given fuller details. In that paper he showed conclusively the advantages of Bunsen's method, which consisted in determining the constituents of the soluble portion, the insoluble, and the total, giving the results, and leaving those who had to judge to draw their own conclusions. There was in the present paper a supplemental table to enable those interested in the subject to check his results. He had had some opportunities of seeing springs in the Lancashire and Yorkshire coal districts, and had there seen water which would probably give something like these results. He had seen some of a deep blue-red colour indicating a large quantity of ferric sulphate, but these waters had not been analysed in any large number, except those referred to by Mr. Ekin, which had been dealt with by the Rivers Pollution Commission. It was well known that these iron springs had some effect on organic matter, and if anyone present had any experience in rural districts and could speak as to the effects which salts of iron were supposed to have in purifying water from organic matter he should be glad to hear the result. Very extraordinary results were said to have been obtained not only by adding ferrous sulphate to water, but also by passing water through a spongy iron filter, and so on.

Mr. SCHACHT said if Dr. Thresh had been present he should have liked to have asked him if he had any further grounds for the assumption contained in one paragraph, where he said it was singular that when carefully evaporating, the basic salt redissolved, yielding a residue which could be diluted, and formed a nearly colourless solution. He should like to know if that was the only justification for the statement that the acidulous and basylous radicals in the latter case would scarcely be in the same state of combination as in the original water. If so, there might be some reason in his mind that did not appear for his exact distribution of the elements in their combinations to which Mr. Ekin had taken some exception.

Mr. EKIN said that in a case, not long ago, in which he was consulted, an action was brought against a local board in Staffordshire, which poured the whole of its sewage into a river, and it was proved that the water from a disused coal mine containing a large amount of iron as ferrous sulphate had mixed with this river, and in the course of a very short run the sewage was destroyed. The case for the prosecution, which was conducted by the riparian owners, was based largely on the fact that the stones and banks for some mile or two down the river were coloured with a nasty yellow deposit; but that was proved to be simply ochre, and the local board won their case completely. He believed that within the last two or three months Dr. Thresh had discovered another spring in the neighbourhood of Buxton, which he was utilizing for this purpose, having been consulted by the local board there in their sewage difficulty. He was still experimenting in that direction, and he believed the local board of Buxton would probably be indebted to him for getting them out of the difficulty with the least possible cost and trouble.

Mr. ALLEN said it might not be generally known, but travellers on the Great Western Railway into the Cornish district were not unfrequently astonished to see large streams of blood-red water running down through the valleys, and of course full of impurity. This blood-red colour was no doubt due to a considerable quantity of iron impurities washed out from the tin stones, and he had also noticed the yellow deposit which Mr. Ekin had spoken of on the border of the streams, which he had always thought to be an oxide of iron. If any gentleman in the Society wished to analyse any of this water he would undertake to procure a quantity of it, but whether it represented thousands of gallons of disinfectant running into the sea, he was not prepared to say.

The PRESIDENT said with regard to the first criticism, as to the bold way in which Dr. Thresh had tabulated his results, he was quite sure if he had been present he would have been only too happy to have given the results on the basis of the investigation which he published in April last in the *Journal of the Chemical Society*; but practically that would not have given to a large number of members the kind of information which they wished. He had given the results in the old-fashioned and popular way. Everyone knew that pairing was a difficult process in all affairs of life, and not the least so in analysis. It was very difficult indeed to give a table of this sort and put the acidulous and basylous radicals in a satisfactory way. His own impression was that Dr. Thresh had given the very best practical result he could on the total results as mentioned in the last table. He concluded by proposing a vote of thanks to Dr. Thresh, which was carried unanimously.

The PRESIDENT then read a—

NOTE UPON THE USE OF OXALIC ACID AS A TEST FOR ARSENIATES IN ALKALINE SALTS.

BY C. PATROUILLARD.

The paper is printed on p. 362, and gave rise to the following discussion:—

The PRESIDENT said this paper, by a distinguished pharmacien and chemist, was a rejoinder to the excellent paper read by Messrs. Naylor and Braithwaite at the Conference, in which they had repeated the experiments of M. Patrouillard, using arsenic oxide and water instead of alkaline arseniates, and had not obtained the results by him described. If either of those gentlemen had any remarks to make he was sure the meeting would be pleased to hear them.

Mr. NAYLOR said no one present could possibly feel greater satisfaction at receiving this paper from M. Patrouillard than Mr. Braithwaite and himself. He thought they might at least be congratulated on one important admission. He referred to the fact that oxalic acid did not act as a reducing agent on arsenic acid. But on referring to the original paper of M. Patrouillard it was perfectly evident that at the time the author wrote it he was of opinion that oxalic acid did exert a reducing action on arsenic acid, for he there stated, "Oxalic acid appears then to act on arsenic acid as well when it is combined as when it is in a free condition." He must say that it was quite unintentional on the part of himself and Mr. Braithwaite selecting arsenic acid mainly for experiments; although they had M. Patrouillard's instructions before them they certainly had no intention of deviating from them, and when they employed the acid instead of the salt they did it inadvertently. For his own part he was a little disappointed with this communication in one particular. It was a little unfortunate that M. Patrouillard should have confined himself to the use of a single reagent. When he had employed the oxalic acid or oxalate of ammonia he had not tested that solution to see if reduction had taken place or not, but had immediately employed a reagent which itself had a reducing action upon arsenical salts. With this sentence he could quite agree:—"When a *salt* contains at least 1 to 2 per cent. of an *arseniate*, if it be boiled with oxalic acid or oxalate of ammonia for a few minutes, sulphydrate of ammonia or sulphuretted hydrogen, after the addition of a few drops of pure sulphuric acid, will produce in it, at the end of an interval more or less long, a yellow precipitate of trisulphide of arsenic. This precipitate may be accompanied by a varying quantity of sulphur. If the proportion of arseniate contained in the salt amount to 5 or 10 per cent., and especially if the mixture be still sufficiently hot, the precipitate is produced *immediately*." He should not be at all surprised at this; in fact, if he were to take an alkaline arseniate and dissolve it in hot water and then acidify it with strong sulphuric acid and add a few drops of sulphydrate of ammonia he should expect to get down, not pure sulphur, but a precipitate consisting of tersulphide of arsenicum with a varying proportion of sulphur; how much he was not at present prepared to say, because the quantity would depend on certain conditions, notably temperature. M. Patrouillard said that he had noted in his laboratory register a large number of testings, and it was rather unfortunate he had not given in this paper the manner in which he obtained them. Although in the main he and Mr. Braithwaite had used arsenic acid in their experiments, they did not confine themselves entirely to it, and he found on looking back over his notes that in two or three cases disodic arseniate was employed. They did not, however, exactly follow Patrouillard's directions, for having dissolved the arseniate and boiled from a quarter to half an hour with oxalic acid, they did not then pass sulphuretted hydrogen through it, but tested the solution as it was, expecting if a reduction had taken place to find it. There was a question in his mind as to the part which the sulphuretted hydrogen played in this reaction, and, as text-books varied very much in their statements with reference to the action of sulphuretted hydrogen on arsenic compounds, they had paid some attention to it, and they thought it would be only paying due respect to M. Patrouillard if they were to repeat his experiments and present the results at the next Evening Meeting. Meanwhile he wished it to be understood they still considered that oxalic acid not only had no reducing action on arsenic acid, but that *per se* it had no reducing action on alkaline arseniates.

The PRESIDENT asked if Mr. Naylor wished it to be understood that his last statement was the result of experiment.

Mr. NAYLOR said it was not the result of recorded experiments, but only of note-book experiments.

The PRESIDENT said it was very important to study carefully the action of reducing agents on these oxidized compounds of arsenicum, and anyone who had experience in the matter would confer a benefit on all engaged in analytical work if they would state them. He thought now it might be assumed that with regard to arsenic acid, Mr. Naylor and his colleague had made good their case, but with regard to the unrecorded experiments, they must wait until they had further information before giving any opinion. They were indebted to M. Patrouillard for his courtesy in sending this paper in answer to that of two Englishmen, and he was sure the meeting would accord him a hearty vote of thanks.

Professor REDWOOD thought it was due to Mr. Naylor to state that he, from h s own experience, agreed with him as to the effect of using sulphuretted hydrogen or sulphydrate of ammonia as a precipitant where arsenic acid was concerned. All chemists were aware that sulphuretted hydrogen was not an accepted precipitant for arsenic acid, inasmuch as it did not in the first instance throw down arsenical sulphide, and an operator could not depend on the arsenic being precipitated from the solution by the mere use of sulphuretted hydrogen; but at the same time it was familiar to all who had any experience of the matter that if sulphuretted hydrogen were passed through solution of arsenic acid continuously for some time there would be ultimately a very appreciable precipitation. That appeared to be very much the view which Mr. Naylor was depending upon being able to justify by further experiments.

The PRESIDENT said the experience of Professor Redwood was no doubt that of those who had anything to do with this subject. Some years ago, when he had more to do with analytical chemistry than he had at present, he had many opportunities of proving the correctness of what had now been stated with reference to this reaction.

A vote of thanks to M. Patrouillard was passed unanimously.

The last paper read was a—

NOTE ON TINCTURA CAMPHORÆ COMPOSITA.

BY J. BLAND.

The paper is printed on p. 363, and gave rise to the following discussion:—

Mr. HOLMES said it gave him great pleasure to hear, at last, a paper on a pharmaceutical subject. With regard to star-anise, Mr. Bland had brought forward a very practical point in the fact that it is less soluble than ordinary oil of anise in proof spirit. In order to test this statement he had made two solutions, one of the oil *Pimpinella anisum*, and the other of the oil of *Illicium anisatum*, both of the strength of the tinct. camph. co. of the British Pharmacopœia, and it would be seen on comparing them that one was less soluble than the other, though the difference was not very great. In a former number of the Journal other features were pointed out by which the two oils could be distinguished; one was the congealing point, another the molecular rotation, another the fact that alcoholic hydrochloric acid would give with the true oil a reddish colour after a time, whereas the star-anise oil remained colourless. He should like to know if it were the fact that the oil of anise of commerce was almost entirely obtained from star-anise, as Mr. Bland supposed. The oil of anise became solid at a little above 50° F., whereas star-anise oil remained fluid down to nearly 35° F.; this difference could be easily observed in winter. With regard to the poisonous property of Japanese star-anise, a writer in the Journal had stated that the poisonous principle was soluble in water. He did not know whether it would in any way contaminate the oil, but if not, of course the oil would not be dangerous, even if Japanese star-anise fruits were mixed with ordinary star-anise. The Japanese star-anise fruit had lately come in large quantities into the market, but he had not been able to trace what became of it. He was somewhat surprised to find how rarely members of the Society made notes on points of interest which must inevitably crop up during their daily avocations. He thought, as a rule, such notes were of general interest, and would add much to the success of the Evening Meetings if brought forward more frequently.

Mr. GERRARD said he could corroborate what Mr. Bland had stated, but not as a rule; it had been rather an exception with him to find a separation of the oil of anise from tinct. camph. comp.

Professor REDWOOD congratulated the meeting upon having a truly pharmaceutical subject brought before it, and hoped they would more frequently have papers of this description. With reference to the subject itself, he should like to know a little more specifically than had been indicated the exact difference in solubility of the two oils, and whether the difference, looking at the quantity used in making the compound tincture of camphor, would be sufficient to account for the separation referred to by Mr. Bland. He believed it was generally admitted that a great part, if not the greater part, of the oil of aniseed which was commercial in this country was the oil of star-anise. Moreover, he had been for years accustomed to consider, having taken his opinion from such works as Dr. Pereira's, that the oil of star-anise was preferable to the other variety. Considering that those who had had experience in the use of these oils had given the preference to the oil of star-anise, and that on that account it was recognized in the B.P., considering that they had no evidence at the time, and he did not know what the evidence was now, of its having any poisonous effect, he should be rather disposed to think if any such effects had been observed they might be due to the fact of the oil being imported in copper vessels. At any rate he should like to know somewhat more definitely the grounds upon which such an accusation had been made against it. Considering, again, the preference given by high authorities to the oil of star-anise, and that it had a higher congealing point than the other oil, it was quite possible that a practice which had been detected in some instances was more common than they were aware of, namely, that of giving to the ordinary oil of anise a resemblance to the oil of star-anise by dissolving in it a small quantity of spermaceti. This substance had been detected in some specimens of oil of anise which had been sold as oil of star-anise; and seeing that spermaceti was not soluble in proof spirit, seeing, moreover, that some of those largely engaged in making this tincture had not experienced the difficulty Mr. Bland referred to, he thought it might be accounted for by a small amount of impurity in the oil employed.

Mr. ALLEN said there was one point to which Mr. Bland had not referred, viz., that a decrease of temperature, after the first solution had been made, would have the effect of throwing the anise out of solution. He had never found any difficulty in making the tinct. camph. comp., nor had he found the oil insoluble which he happened to use; but he did prepare an essence of aniseed containing more oil of anise than the tinct. camph. comp., with a much smaller amount of spirit, and with that his experience was that during the summer months it was perfectly soluble, and could be filtered bright into the stock bottles; but when the winter came there was not exactly a deposit, but an appearance through the liquid of a most remarkable series of apparently irridescent crystals. It was perfectly evident in a case of that proportion, that the fall of temperature threw the oil of anise out of solution, though in the first place it was thoroughly dissolved and passed through a filter.

Mr. HOLMES remarked that the vessels in which oil of anise was generally imported were, he believed, made of lead, and, therefore, it was not likely that the oil would be contaminated with copper. He was referring to that imported from China, and he was not sure whether the Japanese tree grew in that part of China where the *Illicium anisatum* grew; and, therefore, it was not at all likely that the imported oil would be poisonous, except that it had been shown by Mr. Eykman that the same poisonous principle was present in very small quantity in star anise itself. The fruit of the Japanese star-anise had been shown to contain a poisonous principle which was soluble in water, but he was not sure that there was any evidence of its being found in the oil. In the samples on the table there were 3 drops of oil to 2 ounces of proof spirit; he also made a third solution with 6 drops of *Pimpinella Anisum* to 2 ounces of proof spirit, and found that it left just as much insoluble matter, judging by the eye, as the 3 drops of oil of *Illicium anisatum* did, which would seem to indicate that the former was about twice as soluble.

Mr. BLAND, in reply, said he had recently obtained some oil of *Pimpinella Anisum* which he had reason to believe was genuine, and which was quite soluble. The oil used in his former experiments, in which he failed to get a bright solution, was obtained from five or six different sources; and until he got this last specimen, which he was informed was distilled from Russian fruit, he had not for some years seen a specimen which was entirely soluble in the proportion of ½ drachm to a pint of proof spirit. Even then success depended on a slight variation in the manipulation. It did not do, as was pointed out by Mr. Ince, to put the oil of anise directly into the proof spirit and shake them up. If he wished to prepare a pint of tinct. camph. co. according to the directions of the *London* Pharmacopœia he should proceed thus. The directions were to take 25 grains of camphor, 36 grains each of benzoic acid and powdered opium, ½ drachm of oil of anise, and 1 pint of proof spirit. He should take 7½ ounces of distilled water, and 12½ ounces of rectified spirit; in 4 oz. of the rectified spirit he should dissolve the oil of anise, the camphor and the benzoic acid; he should then mix the remainder of the spirit and the water together, shake them up briskly to facilitate the escape of air from the mixture, and allow it to cool down to the ordinary temperature; then pouring that gradually into the solution of oil and camphor, and shaking them up together, a bright solution was produced. Then to that solution he should, under the London Pharmacopœia, have added 1 oz. of tinct. opii, because in that formulary the quantity of opium in the tinct. opii bore a simple relation to that in the tinct. camph. co., being exactly twenty times as much; and besides that the 1 ounce of tinct. opii, added to the previous mixture, almost exactly compensated for the condensation which took place on the mixture of the water and the rectified spirit. In that way he got a tincture which scarcely required filtering at all, and then only from some slight mechanical impurities in the benzoic acid. With regard to the temperature at which these two oils solidified, he found so much divergence amongst the authorities he had consulted that he feared little dependence could be placed upon them. With the oil of *Pimpinella Anisum* one could get a perfect solution of ½ drachm in a pint of proof spirit, but he had not succeeded in so doing with the oil he had been getting for some years past, even varying the manipulation in every possible way. Another thing he had observed with regard to the star-anise was that it was not so attractive to rats and mice as the oil of *Pimpinella Anisum.* Another preparation was spirit of aniseed, which was a very weak spirit, sweetened with sugar; its only use, he believed, being as a cordial for infants. He had never found spermaceti as an adulterant in any specimen of the oil he had examined. There were two very simple tests for this oil, viz., if it were entirely volatilized by heat, and if it were perfectly soluble in rectified spirit; if it answered these two tests there was not much to find fault with. There had been a material alteration in the formula for the tinct. camph. co. in the British Pharmacopœia. The tinct. opii in the British Pharmacopœia was about 9 per cent. weaker, and the tinct. camph. co. about 11 per cent. stronger in opium than those of the London Pharmacopœia, and therefore his practice of using an ounce of tinct. opii to make the tinct. camph. co. of the London Pharmacopœia would not answer for the British Pharmacopœia. It required a rather more complicated calculation to arrive at the exact proportion.

The PRESIDENT proposed a vote of thanks to Mr. Bland for his paper, which was carried unanimously, and the meeting adjourned to December 6.

Parliamentary and Law Proceedings.

PROSECUTION UNDER THE 17TH SECTION OF THE PHARMACY ACT.

On Wednesday last, at the Lambeth Police Court, Sidney Joshua Marsh, oilman, of Lambeth Walk, was summoned by Mr. Templeman, acting on behalf of the Chemists and Druggists' Trade Association, for unlawfully selling oxalic acid, the same not being labelled with the name of the article or the word "poison," together with the name and address of the seller.

Mr. Glaisyer prosecuted for the Association, and Mr. Mayo defended.

Evidence was given to the effect that Mr. Templeman went into the shop and asked for some oxalic acid, and was served with some in a bottle on which there was no label.

In cross-examination by Mr. Mayo, the complainant said he was asked by the defendant what he wanted the oxalic acid for, and he told him to clean some brass-work. He (complainant) was obliged to tell an untruth in order to detect the defendant. The defendant at first declined to serve him at all.

Mr. Mayo, in defence, said there was a deal of epsom salts in the stuff sold by the defendant, and what he had done was in ignorance of the law. He urged also that if there were to be a conviction his worship should make the penalty as low as possible.

Mr. Saunders said it was a clear case, and if ignorance of the law was put forward, he had only to say that parties in whatever business they entered upon were bound to know what was the law appertaining to such business.

Mr. Glaisyer referred his worship to the section of the Act of Parliament showing that the defendant really had no right to sell the poison at all.

Mr. Saunders ordered the defendant to pay a fine of 40*s*., together with 23*s*. costs.—*Standard.*

POISONING BY LAUDANUM.

An inquest was held on Monday, October 30, at Mexborough, on an infant named Henry Harrys, son of a miner. The mother of the deceased left the child in charge of her daughter, aged eleven, and, as it was cross, professedly to quiet it a neighbour gave it five drops of laudanum in some sugar and water. The child lingered in an unconscious state until the next morning, when it died. The medical evidence went to prove that deceased died from the effects of narcotic poisoning.

Mrs. Tomlinson admitted giving the laudanum to the child, but protested that she had no evil intention.

Evidence was also given to the effect that the prisoner was under the influence of drink when she administered the laudanum.

The Jury, after a brief consultation, returned a verdict of manslaughter against the prisoner, who was committed to take her trial at the assizes.—*Leeds Express.*

Obituary.

ALFRED ALLCHIN.

It is with very great regret that we record the death, on Wednesday morning last, of Mr. Alfred Allchin, of England House, Primrose Hill Road, since British pharmacy loses in him one who has served it well and faithfully during a long series of years, and many pharmacists lose a kind-hearted and genial friend. Mr. Allchin was born at East Malling, Kent, on February 28, 1824, and was the youngest son of Mr. W. H. Allchin, surgeon, of that place. He was apprenticed to Mr. Stedman, of West Malling, and subsequently lived with Mr. Poole, of Queen Square, Brighton, and Messrs. Keating, of St. Paul's Churchyard. In the session for 1845–6 he entered the School of Pharmacy, in Bloomsbury Square, where he took the first certificate in pharmacy, and in the ensuing session received the appointment of demonstrator in practical chemistry. In 1848 Mr. Allchin went into business on his own account in the Richmond Road, Barnsbury, where he remained until 1872, when he removed to Primrose Hill Road.

In June, 1870, Mr. Allchin was appointed a member of the Board of Examiners, and he fulfilled the duties of the office up to within a short interval of his death. In the earlier part of his career he occasionally read a paper at an Evening Meeting of the Society, and some of these papers,—as, for instance, one on "Aquaria for the Preservation of Leeches," and another on the "Preparation of Smelling Salts,"—were of considerable practical value. He also communicated a paper on "Infusions" to the present series of this Journal.

Mr. Allchin had been suffering more or less for some time past from the disease to which eventually he succumbed. At the time of the recent meeting of the British Pharmaceutical Conference he was staying for his health in the neighbourhood of the New Forest, and he availed himself of the opportunity to be present. But many of his old friends who saw him there were grieved to mark the change that had already become evident in him, and which was so soon to result in death.

Notice has also been received of the death of the following:—

On the 23rd of September, Mr. Thomas Gardner, Chemist and Druggist, Queen Street, Morecambe. Aged 37 years. Mr. Gardner had been a Member of the Pharmaceutical Society since 1876.

On the 10th of October, Mr. Herbert Inglis, Chemist and Druggist, Every Street, Manchester. Aged 42 years.

On the 20th of October, Mr. John Sweet Cape, Chemist and Druggist, High Street, Exeter. Aged 41 years. Mr. Cape had been an Associate in Business of the Pharmaceutical Society since 1869.

On the 20th of October, Mr. Robert Richmond, Pharmaceutical Chemist, Leighton Buzzard. Aged 67 years. Mr. Richmond had been a Member of the Pharmaceutical Society since 1842.

On the 23rd of October, Mr. Morgan Thomas, Chemist and Druggist, Taff's Well, near Cardiff. Aged 42 years.

Correspondence.

Commercial Nitrate of Silver.

Sir,—With reference to Mr. Woodland's note on nitrate of silver, published in the last number of the *Pharmaceutical Journal*, I may say that I received a small sample of nitrate of silver from my friend Mr. Greenwood of Liverpool, but understanding it had been purchased from an itinerant photographer—whatever that may mean—I took no further notice of the matter.

Had Mr. Woodland stated in his paper, read at the meeting of the British Pharmaceutical Conference at Southampton, that he had purchased pure samples of nitrate of silver from respectable houses (both wholesale and retail), but samples he had purchased from "itinerant photographers" were impure and adulterated with nitrate of potash, I do not think any of the members present would have expressed much surprise; but the tenor of the paper was rather to throw discredit upon a large and respectable body of men who make it their business to supply photographic and other chemicals. This led me and others to protest against such an inference.

I must say I was not previously aware that nitrate of silver was sold by itinerant photographers, and think the propriety of purchasing the article from such a source, even if obtained in a pure and unadulterated state, very questionable.

London. John Williams.

A Correction.

Sir,—I am much obliged to Mr. Woodland for his courtesy in furnishing his data and elucidating his method of calculation in taking the percentage of morphia in extractum opii liquidum, B.P. I am, however, compelled to take exception to one of his fundamental statements. He says that "one fluid ounce of the liquid extract, specific gravity ·972, will weigh 450 grains." According to this statement it would appear that the weight of a fluid ounce of distilled water is 462·96 grains, but I regret to be under the necessity of informing Mr. Woodland that it is 437·5 grains. I had really hoped that in these days this elementary fact was known to every tyro in pharmacy.

With regard to nitrate of silver, I leave your readers to judge of the wisdom of making general assertions as to its purity or otherwise, from analyses of samples obtained from peripatetic photographers.

St. Thomas's Hospital. Sidney Plowman.

Sir,—Mr. Woodland will, I trust, forgive me if I point out a slight inaccuracy which has crept into his calculations published in the Journal last week.

One fluid ounce of liquid extract of opium having the sp. gr. ·972, would weight $437·5 \times ·972 = 425·25$ grains, not 450 as stated. From this it follows that the standard morphia percentage, calculated from the data given, is ·61 (instead of ·58) by weight.

W. Pickard.

⁂ [A communication to the same effect has also been received, bearing the signature "Specific Gravity."]

J. G. K.—(1) Taylor in his work 'On Poisons' quotes a case, reported by Löbel, of Jena, of a lunatic who died from a dose of one-eighth of a grain of phosphorus. (2) The amount of resin present in a sample would be a good indication of its quality.

Inquirer.—Dr. Symes has pointed out that lemon juice may be preserved unaltered for a long time by heating it to a temperature of 150° F., and excluding it from air at that temperature, provided that the operation be performed in the winter.

J. H.—Apply to the Secretaries of the Societies.

"*Vivisection.*"—(1) The certificate would have to be laid before the Board and accepted, and your name placed upon the Register of Apprentices, before you could enter for the Minor examination. (2) We do not know the address.

C. Jones.—Your letter could not be published without casting an unjust reflection upon those pharmacists in the district who have complied with the law.

Communications, Letters, etc., have been received from Messrs. Keyworth, Knight, Crook, Rimmington, Williams, Pickard, Henry, Maitland, Drew, Hollingworth, White, Parrott, Medicus, J. H.

THE JAPANESE PEPPERMINT PLANT.

BY E. M. HOLMES, F.L.S.,

Curator of the Museum of the Pharmaceutical Society of Great Britain.

When examining some leaves of this plant, presented, together with a series of Japanese drugs, to the Museum of the Pharmaceutical Society, by Messrs. Christy and Co., in 1879, I thought it desirable to compare them with those of the plant which is stated to yield the Chinese oil of peppermint. Through the courtesy of the keeper of the Kew Herbarium, I was permitted to taste a fragment of a leaf of the Chinese plant and of one of Blume's specimen of *M. arvensis*, L., var. *Javanica*, the plant to which this peppermint is referred in 'Pharmacographia.' To my surprise I found that neither Blume's specimen nor any others of the same plant from various localities had the taste of peppermint, but possessed a flavour similar to that of the garden mint (*M. viridis*). Judging that the Japanese plant could not belong to *M. arvensis*, var. *Javanica*, I referred to the Japanese work 'Zo Mokou Zoussetz,' in which the Japanese peppermint plant is stated to be *Mentha arvensis*, var. *vulgaris*, Benth. On tasting the type specimen of this plant at Kew, I found that this also did not possess the taste of peppermint, but only that peculiar to European specimens of *M. arvensis.* I therefore wrote to China and Japan for specimens of the peppermint plants of those countries. After the lapse of more than a year, Mr. C. Ford, the director of the Botanical Gardens at Hong Kong, was able to procure a flowering specimen of the Chinese plant for me, but no specimens of the Japanese plant could be procured by my correspondents. Mr. T. Christy, however, after having first obtained seeds of the plant, attempted to grow them, without success, but was ultimately, and after considerable difficulty, able to procure from Japan living plants which flowered this year in his garden at Sydenham, and a specimen of the plant was exhibited for the first time, I believe, in this country, at the meeting of the Pharmaceutical Conference, at Southampton. On careful examination, both the Chinese and Japanese plants thus obtained were found to possess the botanical characters of *Mentha arvensis*, as defined in De Candolle's 'Prodromus;' the leaves being stalked, ovate lanceolate, and the hairs on the stems and pedicels reflexed, those of the calyx being erecto-patent, and those of the upper surface of the leaf appressed, the calyx being bell-shaped with acute lanceolate or narrowly-triangular teeth. The Chinese plant differs from the Japanese one in the leaves being narrower in proportion to their length and in the calyx teeth being shorter and more broadly triangular. In outline, the leaves of both plants taper more to the base and have a longer petiole than the English forms of *M. arvensis*, coming very near to *M. canadensis* in this feature. The latter plant, however, has spreading hairs on the stem. The Chinese plant appeared to so nearly resemble *M. canadensis*, var. *glabrata*, that I applied to Professor Asa Gray for specimens of that species for comparison. The specimens of *M. canadensis* which he kindly forwarded to me were derived from different localities in the United States, and varied considerably in taste and appearance, some having the flavour of pennyroyal, others that of *M. viridis*, and others again that of peppermint, in a feeble degree. The specimen having a peppermint flavour is labelled *M. canadensis*, var. *glabrata*; it has reflexed hairs on the stem and differs from the typical plant in having more triangular and shorter calyx teeth, which, as well as the petioles, have erect hairs; in fact, it appears in every respect to be the same plant as that grown at Canton. It is not surprising, however, to find Japanese or Chinese plants extending to North America.

It appears, then, that there are two plants possessing a widely different taste and both referred to *M. arvensis*, var. *Javanica*, by botanists. This might lead to confusion if the Chinese or Japanese peppermint plants ever came into demand for purposes of cultivation, unless a special name be given to the form which possesses the peppermint flavour, even although it does not possess characters sufficiently definite to separate it from *M. arvensis*. The mints are well known to form an uninterrupted series of plants which it is difficult to separate into species. Deeming it advisable, therefore, before giving it a name, to consult those botanists who have critically studied the mints, specimens of the Japanese peppermint plant were forwarded to several authorities on the genus, and the following opinions have been expressed:—Mr. J. G. Baker, of the Kew Herbarium, considers it to be a form of *Mentha sativa*, Sm. (It may be here remarked that this form, as recognized by Hooker and Babington in their 'British Floras,' is a species differing from *M. arvensis* in the smaller upper leaves and longer calyx teeth, while De Candolle includes it under *M. arvensis.*) Professor Baillon, of Paris, expresses the opinion that it must be referred to *M. arvensis*, var. *Javanica*, unless it be a hybrid between *M. arvensis* and *M. piperita*. Dr. Garcke, of Berlin, finds the plant to be nearly allied to *Mentha canadensis*, D.C., and also to *M. aquatica*, var. *subspicata*, D.C. Dr. Franchet, one of the authors of the most recent 'Flora' of Japan, believes the Japanese plant to be "a form of *M. arvensis*, characterized by the acuminate calycine segments, a feature which constantly occurs in specimens from Eastern Asia." He adds, "After carefully comparing your specimen and having vainly sought an analogous taste in the different forms of the *M. arvensis* of Europe, I have found in them only an insipid and herbaceous flavour; I can say the same of *M. arvensis* from the neighbourhoods of Pekin and Chefu, in the province of Shantung, and from the neighbourhood of the lake Sitau, in the province of Sche-kiuny; but I find the taste of peppermint developed in a very high degree in a specimen gathered at Voosung, near Shanghai. From Japan I possess specimens of *M. arvensis* gathered in very many localities and I have found the taste of peppermint in all my specimens, without exception. This taste is absolutely the same as that furnished by your plant. I remark, however, that the taste is more pronounced in proportion as the plants are more robust; puny specimens with small leaves from Kanasawa (in Nipphon) possess it only in a feeble degree." He thinks that the peppermint flavour is not the result of hybridity, since no other species has hitherto been observed in Japan, either in a cultivated or wild state, except *M. crispa* ('So Mokou Zoussetz,' xi., pl. 29) (which no botanist, that he is aware of, has ever brought back from that country), and *M. gentilis*, which is well delineated under the name of *M. arvensis* on the same page as *M. piperita*, after information probably furnished by the Dutch. M. Malinvaud remarks that the name *piperita* cannot be appropriated to the Japanese plant, as it is already applied to a form of *M. arvensis* with flower spikes. He therefore suggests the name *Mentha arvensis*, var. *piperascens*.

The weight of opinion is therefore on the side of considering the Japanese plant as a form of *Mentha arvensis*, D.C. If *M. sativa*, Lin., and *M. arvensis*, as defined by Babington, as well as *M. Javanica*, D.C., are to be considered as forms of one species, then the Japanese plant might, I think, also rank as a form under the name of *M. arvensis f. piperascens*, differing from *M. arvensis* as described by Babington in having the calyx teeth longer than broad, and in the upper leaves being gradually smaller; from *M. sativa*, in the leaves having longer stalks and tapering below; from *M. Javanica*, in the uppermost leaves being more than twice (usually six or eight times) as long as the verticillasters, and in the veins being hairy on the under surface of the leaf whilst those on the calyx are erecto-patent; and from *M. canadensis*, in the reflexed pubescence of the stems.

With respect to the Chinese peppermint plant, it so exactly agrees with the specimen of *Mentha canadensis*, var. *glabrata*, furnished to me by Dr. A. Gray, that if the latter be a typical specimen* I can only consider that it should be referred to *M. arvensis*, under the name of *M. arvensis*, var. *glabrata*.

Dr. Gray's specimen has the calyx teeth much shorter than those of the typical *M. canadensis* sent at the same time, and the hairs on the stem and pedicels are reflexed, while those of the calyx tube are erecto-patent.

There are some other points in connection with peppermint which are extremely suggestive, and to which I desire to call the attention of those who have greater ability and more time for investigation than myself.

A number of varieties and forms of so-called species possess the same odour and flavour, as shown in the following list:—

Mentha piperita, *Mentha arvensis*, var. *piperascens*, *M. canadensis*, var. *glabrata* (!), and *M. incana* (!), cultivated near Bombay for producing peppermint oil (Dymock).

Spearmint, *Mentha viridis*, L., *Mentha sylvestris* (!), *rotundifolia* (!), *sylvestris* (!), *canadensis* (!),† *M. arvensis*, var.

The questions then arise:—

1st. Do the oils of these species differ among themselves, as has been shown to be the case with those of *M. piperita* and *M. arvensis*, var. *piperascens*?‡

2nd. If so, is this difference dependent on degree of development, on climate, soil§ or sex?

3rd. Is the oil in each case a mixture, in which one ingredient is present in variable quantity in the different plants?

4th. Do the oils of spearmint and peppermint bear any chemical relation to each other?

5th. Which species, containing an oil of peppermint, yields the largest quantity and which the most valuable one for medicinal purposes?

To recapitulate: The writer would recommend that for convenience the name of *Mentha arvensis f. piperascens* should be retained for the Japanese peppermint plant and that of *Mentha arvensis f. glabrata* for the Chinese one.

* Dr. Franchet notes, in his 'Flore du Japon,' the reflexed leaves in some specimens of *M. canadensis*.

† Those marked (!) have been tasted by myself.—E. M. Holmes.

‡ *Pharm. Journ* (3), ii., p. 321.

§ Mr. J. Lloyd found a variety of *M. aquatica* possessing a lemon odour on *calcareous* soil near the sea, and M. Malinvaud a specimen of *M. arvensis* with a lemon odour in a ditch near Ivry, where other plants of the same species possessed only the usual odour of the plant.—*Bull. Soc. Bot.*, 1881, p. 370,

RESEARCHES UPON THE JALAPS.*

BY A. BOURIEZ.

In commercial specimens of any kind of true jalap (tuberous, fusiform, or Tampico) several varieties of tubercules can be distinguished by their external characters. Those which constitute the greater part of the jalap, and which I designate under the name of "typical tubercules," always present at one of their extremities (the upper) the remains of aerial organs. Sometimes they terminate in a point at both their extremities; sometimes one of the extremities only becomes slender, whilst the other presents a large surface of insertion. There are met with, besides, tubercules inserted on other tubercules, and very small fragments [*grabeaux*] showing tubercules inserted upon an organ which is most frequently slender and cylindrical, but sometimes fusiform and more or less swollen. The question presented itself to me, whether these tubercules of the different varieties answered to variations in appearance of one and the same organ, or whether they represented organs of a different morphological nature.

An examination with the naked eye, and aided by a glass, of transverse sections made at different points of these tubercules, yielded me some useful information, but not sufficient to answer the question with certainty. I then submitted the same sections to a microscopical examination.

As a basis for this micrographic study I selected a typical tubercule of the tuberous or official jalap.

A transverse section made at the lower extremity of the tubercule enabled me to conclude that the organ there presents the structure of a root. Towards the centre of the section there were observed four primary woody layers, symmetrical around the centre, and convergent in pairs. Each of these layers is formed of some spiral vessels, the most slender of which are nearest the exterior, the largest being nearest the centre. The differentiation has therefore proceeded in each of these primary ligneous layers from the centre of development (indicated by the most slender spiral vessels) towards the centre of the organ. It may thence be concluded that the centre of the organ is occupied by a single tetracentral primary bundle, the centre of which coincides with the centre of the organ, and it may be inferred from this conclusion that the organ, at this stage, is a root.

Among the histological details presented by this root, I will refer here only to the formation of the elements of the liber. Among the young cells with tangential divisions belonging to the cambial zone, the most external present very early longitudinal septa, which subdivide them into a number of narrow elongated cells, such as are seen in the Asclepiadaceæ, Apocynaceæ, Solanaceæ and Acanthaceæ. The transverse septum which separates two superposed cells is reabsorbed, following the meshes of the tissue, and in this way are originated the per-

* From the *Journal de Pharmacie*, [5], vi., 329.

-forated plates of cells characteristic of the liber. The elements of the cambial zone which do not present these septa make up the liber parenchyma, in the midst of which occur numerous resiniferous cells and glands containing crystals.

The resin-cells would appear to be parenchymatous elements, hypertrophied and gorged with resin. Generally they are superposed end to end, so as to form rather long vertical rows; but in no case have I observed the reabsorption of the wall common to two successive cells. There is therefore no formation of a canal, and I look upon these resin cells as unicellular glands distributed in the mass of the liber.

The crystal-bearing glands consist of parenchymatous cells, subdivided into as many compartments as they contain groups of crystals. These groups are sphæraphides of oxalate of lime. A radial section, treated with a mineral acid which dissolves the oxalate of lime, shows readily the subdivision of these glands.

I will now briefly sketch the structure of the part of the tubercule comprised between the lower extremity and the point which corresponds to the maximum volume of the organ, setting forth the mechanism of the formation of the tuber.

In sections which follow those which presented the structure of a well-characterized root, there is observed, in proportion as they rise towards the central part of the tuber, the interposition, among the hardened and characteristic elements of the root, of a parenchymatous tissue, supplied at first solely by the cambial zone. The interposition of this tissue, which I will call the "muriform parenchyma," results in separating the woody layers from each other, and quickly interfering with the primitive symmetry of the organ. The spiral layers, carried away and twisted in every direction by the secondary ligneous lobes, quickly disappears, so that at a very short distance from the lower extremity of the tubercule it is already impossible to recognize them.

Higher up the muriform parenchyma which surrounds the indurated ligneous masses splits up parallel to the surface of these masses, and thus originate true secondary generating zones, which produce, on the side of the wood, some rows of muriform parenchyma, and, on the other side, secondary liber, with numerous glands containing resinous and crystalline matter.

In the most swollen parts are seen important layers of muriform parenchyma, divided tangentially in every direction, and furnishing, at the same time, liber products on the one side and parenchymatous elements on the other. All the parenchymatous cells are gorged with starch, and the tubercule constitutes an important alimentary reserve for the plant.

In studying the upper portion of the tubercule I have followed the reverse order, and starting from the upper extremity descended towards the centre.

The transverse section made at the top extremity of the tubercule shows that the organ, at this point, has the structure of a stem. The primary ligneous mass forms, in fact, an annular zone around the centre of the organ, but at a certain distance from the centre. It is formed of radiating layers grouped in badly defined bundles. Each layer of primary wood comprises three or four contiguous spiral vessels disposed radially, the most slender being inside. The differentiation of the primary ligneous elements, therefore, has proceeded from the centre of the development (indicated by the most slender spiral vessel) in a direction which passes by the centre of the organ, but which leaves the centre of development between the centre of the organ and the ligneous layer. The centre of the organ presents, therefore, a central crown of bundles with centrifugal differentiation. From this it may be concluded that the organ at this level is a stem.

Moreover, at the top of the cicatrices, to which I have referred before, is observed the issue of four bundles, in two opposite appendages on each side. At the axil of each of these appendages a bud that is frequently developed is placed between the two bundles in relation with the bundles of the stem. In the interval comprised between the point of issue of the appendages and the swollen middle portion of the tubercule occurs the extinction of the primary ligneous layers of the stem. The organ becomes tuberized in this region by the same process as in the inferior portion.

The extinction of the primary ligneous layers of the stem shows that there is here a lower termination of the principal stem. Therefore, the stem which forms the upper portion of the typical tubercules of jalap is a principal stem, its inferior appendages are cotyledons, and their axillary buds correspond to creeping branches.

The secondary elements of the stem are in direct continuation with the secondary elements of the root; from this it follows that the root which forms the lower end of the tubercule below is the principal root. The part comprised between the points where the cotyledons issue and the point of insertion of the principal root corresponds therefore to the hypocotyledonous axis.

This investigation allows of the conclusion that the typical tubercules of jalap represent the stock of the convolvulaceous plants which produce them, and that the tuberized portion corresponds to hypertrophy: (*a*) of the base of the principal stem; (*b*) of the hypocotyledonous base; (*c*) of the region of insertion of the principal root upon the hypocotyledonous axis; and (*d*) of the upper part of the principal root.

I have studied in the same manner the various tubercules of jalap that never present the remains of aerial organs at one of their extremities, and I have in this way recognized that—

(1) Most of the varieties of tubercules represent tuberized roots of different orders;

(2) Some tubercules represent subterranean stems, which, having to play the same physiological *rôle* as the radical tubercules, are tuberized by the same process and present a nearly identical structure.

Finally, comparison of the three commercial kinds has shown me, that in respect of structure there is no difference, however slight, between the different kinds of true jalap.

From the materia medica point of view, the jalaps are therefore principally formed of tubercules which correspond to the stocks of the convolvulaceous plants that produce them; they include, besides, a certain number of tubercules which represent tuberized roots of different orders; lastly, tubercules are met with derived from tuberized subterraneous stems.

I will now add some pharmaceutical observations upon jalap and the resin extracted from it.

In none of the published analyses of jalap is mention made of oxalate of lime, but a microscopic examination and microchemic tests detect it in considerable proportion in the tubercules.

I am unable to accept the opinion of M. Andouard, according to which the small roots of jalap would be generally more rich in resin than the large tubercules from the same plant. This does not agree with what is revealed by the microscopic investigation, and, moreover, is not in accord with the amounts found by M. Guibourt. Would not M. Andouard consider as "small roots" the slightly tuberized fragments which are met with in the *débris*, which are derived from subterranean stems and which in fact contain much resin?

With the object of adding something new to the results already known, I have extracted the resin, by the Codex process, from nine specimens of jalap. In order to utilize the products of the aqueous macerations involved in this process, I prepared extracts evaporated in a water-bath to a pilular consistence, of which I have given the yield.

	Resin dried at 100°. Per cent.	Aqueous Extract. Per cent.
I. TYPE SPECIMENS OF JALAP. Supplied by the *Pharmacie Centrale.*		
Tuberous or Official Jalap	12·5	38
Light Jalap (small specimens)	2·0	35
Digitate Major Jalap	7·0	12
Digitate Minor Jalap	9·0	11·5
II. PICKED COMMERCIAL JALAP.		
No. 1	12·5	35

III. DÉBRIS	8·5	27

It follows from the investigations of different authors that jalap owes its purgative properties to two homologous resinous glucosides, convolvulin and jalapin. I have, however, nowhere met with mention of clinical experiments made with the pure glucosides. Might there not be, if not an alkaloid, as alleged by Hume, at least a principle other than the resinous glucosides, and which has hitherto escaped analysis? If the opinion of Le Maout and Decaisne is to be accepted (*Traité général de Botanique*) the resin of the Convolvulaceæ owes its purgative properties only to the aroma which accompanies it, for the rhizomes lose them when powdered and exposed for a long time to the air, although they preserve the purely resinous principle. The odorous oleaginous substance which floats at the top towards the end of the distillation, when nearly all the alcohol is removed from the tincture of jalap from which it is desired to extract the resin, would deserve attention from this point of view.

When jalap resin is prepared by the Codex process, and, in following the mode of operation prescribed, the residue from the distillation of the alcoholic liquor is poured into boiling water, the resin precipitated agglomerates under the form of a thick turpentine, which adheres strongly to the sides of the vessel and can only be collected completely with great difficulty. I have found that if, on the contrary, the residue from the distillation be poured into well-cooled water, the precipitated resin will remain on the sides of the vessel in a very divided form; the resinous particles are separated one from another by drops of water, and it is very easy to collect the product with the aid of a flexible spatula. Upon placing all the resin together in a small capsule the water gradually floats to the top whilst the resinous particles agglutinate.

Finally, I have compared, in respect to yield, the Codex process, which gives an odorous greenish-brown resin, and M. Nativelle's process, which gives an inodorous resin, as white as starch. The following are the results I have obtained:—

	Codex process. Resin.	Codex process. Extract.	Nativelle's process. Resin.	Nativelle's process. Extract.
No. 1	7	11·5	3·0	9·0
No. 2	12·5	33·0	6·0	27·0
No. 3	7·5	23·0	3·3	17·0

This enormous difference in the yield of resin is due to the use of 65° alcohol, as recommended by M. Nativelle, which does not dissolve all the resin removed by 90° alcohol, as ordered in the Codex.

It is worthy of notice that more aqueous extract was obtained in evaporating the products of the macerations yielded by the Codex process than in evaporating the products of the decoctions necessitated in following the process of M. Nativelle.

REPORT UPON THE CREASOTE IMPURITIES OCCURRING IN THE AMERICAN MARKET.*

BY PROFESSOR P. W. BEDFORD.

The object of this query can be but one, namely: to inquire whether the wood creasote offered for sale is a pure article, or not; and if not, what is the impurity present?

The relative commercial value of the articles sold as coal tar creasote and wood creasote disposes of the question as to the latter being present in the former article, and we are quite certain that the cheap variety is nothing more or less than a phenol or carbolic acid. Wood creasote, it has been frequently stated, is adulterated with coal tar creasote, or phenol. The object of my experiments has been to prove the identity of wood creasote, and its freedom from phenol. The following tests are laid down in various works as conclusive evidence of its purity, and each has been fully tried with the several samples of wood creasote to prove their identity and purity, and also with phenol, sold as commercial creasote or coal tar creasote, and for comparison with mixtures of the two, that even small percentages of admixture might be identified should such exist in the wood creasote of the market.

The following tests were used:—

1. Equal volumes of anhydrous glycerine and wood creasote make a turbid mixture, separating on standing. *Phenol dissolves.* If three volumes of water be added, the separation of the wood creasote is immediate. *Phenol remains in permanent solution.*

2. One volume of wood creasote added to 2 volumes of glycerine: the former is not dissolved, but separates on standing. *Phenol dissolves.*

3. Three parts of a mixture containing 75 per cent. of glycerine and 25 of water to 1 part of wood creasote shows no increase of volume of glycerine, and wood creasote separates. *Phenol dissolves and forms a clear mixture.* Were any phenol present in the wood creasote, the increase in the volume of the glycerine solution, if in a graduated tube, would distinctly indicate the percentage of phenol present.

4. Solubility in benzine. Wood creasote entirely soluble. *Phenol is insoluble.*

5. A 1 per cent. solution of wood creasote. Take of this 10 cubic centimetres, add 1 drop of a test solution of ferric chloride; an evanescent blue colour is formed passing quickly into a red colour. *Phenol gives a permanent blue colour.*

6. Collodion or albumen with an equal bulk of wood

* Read at the meeting of the American Pharmaceutical Association held at Niagara Falls, 1882.

creasote makes a perfect mixture without coagulation. *Phenol at once coagulates into a more or less firm mass or clot.*

7. Bromine solution with wood creasote gives a reddish brown precipitate. *Phenol gives a white precipitate.*

All tests enumerated above were repeatedly tried with four samples of wood creasote sold as such; one a sample of Morson's, one of Merck's, one evidently of German origin, but bearing the label and capsule of an American manufacturer, and one of unknown origin, but sold as beechwood creasote, German, and each proved to be *pure wood creasote.*

Two samples of commercial creasote which, from the low cost were known to be of coal tar origin, gave the negative tests, showing that they were phenol.

Corroborative experiments were made by mixing 10 to 20 per cent. of phenol with samples of the beechwood creasote, but in every case, each of the tests named showed the presence of the phenol.

The writer on other occasions applied single tests (the collodion test) to samples of beechwood creasote that he had an opportunity of procuring small specimens of, and satisfied himself that they were pure. The conclusion is that the wood creasote of the market of the present time is in abundant supply, is of unexceptionable quality, and reasonable in price, so that there is no excuse for the substitution of the phenol commonly sold for it. When it is directed for use for internal administration (the medicinal effect being entirely dissimilar) wood creasote only should be dispensed.

The general sales of creasote by the pharmacist are in small quantities as a toothache remedy, and phenol has the power of coagulating albumen which effectually relieves the suffering. Wood creasote does not coagulate albumen, and is, therefore, not as serviceable. This is, perhaps, the reason that it has become, in a great measure, supplanted in general sale by the coal tar creasote, to say nothing of the argument of a lower cost.

FERRATED ALBUMEN.*

BY GEORGE BUCHNER, OF MUNICH.

From the author's investigations and observations on compounds of ferric chloride with albumen we make the following abstracts:—

The amount of chloride in egg albumen was determined by ignition with sodium carbonate and titration with nitrate of silver; 1·6 per cent. Cl was found. The chlorine of the compound was determined in the same manner, deducting the chlorine of the albumen. The iron was estimated by ignition, dissolving in hydrochloric acid, reduction to ferrous salt by zinc, and titration by potassium permanganate.

1. Solution of ferric chloride (1 : 20) was added to a filtered solution of albumen (1 : 10) until the voluminous yellowish-brown precipitate was just dissolved. In the clear red-brown liquid albumen as well as ferric chloride responded to the usual reagents. On evaporating this liquid at a temperature not exceeding 50° C. and drying the gelatinous mass at the same temperature, a dark-brown powder or transparent brown-red scales were obtained, only partly soluble in water, the insoluble portion becoming transparent and gelatinous. Analysis: Fe 2·193, Cl 7·980, albumen 89·827 = Fe_2Cl_6 6·354, excess of Cl 3·819.

2. The preceding product was thoroughly washed with water and the residue dried at 50° C. Analysis: Fe 1·488, Cl 2·700, albumen 95·812 = 4·119 Fe_2Cl_6, excess of iron as $Fe_2(OH)_6$ 0·131.

3. On slowly evaporating the original ferrated albumen solution the liquid becomes turbid, separating a thick jelly, which is soluble in warm water, yielding a clear solution which is not precipitated by boiling. The jelly well drained, pressed and thoroughly dried over sulphuric acid, yielded Fe 0·998, Cl 4·531, albumen 94·471 = Fe_2Cl_6 2·895, excess of Cl 2·634. The powder was completely soluble in water and the solution was not disturbed by boiling or by alkalies; acids caused a precipitate of albumen, while sodium chloride and potassium sulphocyanide precipitated ferrated albumen.

4. The original ferrated albumen solution was completely precipitated by a saturated solution of table salt; the precipitate was collected upon a filter, drained, pressed, the press cake rapidly washed by agitation with water and decantation, again pressed between bibulous paper and dried over sulphuric acid. The powder swells with water, and dissolves after some time to a solution which is not disturbed by silver nitrate, but is precipitated by potassium sulphocyanide; its composition is Fe 1·703, Cl 1·680, albumen 96·617 = Fe_2Cl_6 2·563, excess of iron as $Fe_2(OH)_6$ 1·566.

5. The original solution of ferrated albumen was mixed with excess of ferric chloride and precipitated by table salt; treated as before, the powder contained Fe 1·15, Cl 1·78, albumen 97·07 = Fe_2Cl_6 2·175, excess of iron as $Fe_2(OH)_6$ 0·41. It behaved to reagents like the preceding. Both, if left in prolonged contact with water while being washed, become transparent, gelatinous and then dissolve.

6. The original solution yields with excess of ferric chloride, on standing, a precipitate which, treated as before, gave a powder containing Fe 1·25, Cl 4·48, albumen 94·27 = Fe_2Cl_6 3·627, excess of Cl 2·103.

7. The original ferrated albumen solution was dialysed, the water being renewed until silver nitrate ceased to give a reaction. The contents of the dialyser had a neutral reaction and could be readily filtered. The liquid was not disturbed by boiling, by alcohol, caustic alkalies, carbonic acid gas, or silver nitrate. It was coloured violet-blue by tannin, and green, without precipitate, by ammonium sulphydrate. Nitric and hydrochloric acid caused a precipitate of albumen, the solution being yellow; lime-water a brownish-yellow precipitate; potassium ferrocyanide a bluish-green precipitate, turning dark-blue on the addition of hydrochloric acid; potassium ferridcyanide a green precipitate not altered by hydrochloric acid; potassium sulphocyanide a yellowish-brown precipitate, the solution becoming deep red on the addition of hydrochloric acid; sodium chloride a light yellowish-brown precipitate.

The liquid, evaporated at a moderate heat, yielded brown-red, nearly tasteless scales, which retained their solubility in water, the solution on being kept for a year becoming slightly mouldy, but not putrid. The scales contained Fe 1·1715, Cl 0·510, albumen 97·775 = Fe_2Cl_6 0·778, excess of iron as $Fe_2(OH)_6$ 2·765.

It is obvious from the foregoing that these products are readily altered and cannot be of uniform composition unless obtained under precisely identical conditions of temperature, dilution, action of water, etc. It is remarkable that with the entrance of $Fe_2(OH)_6$ into the compound these products become soluble in water and non-coagulable by heat, properties which, together with the peculiar behaviour to reagents, are best observed in the dialysed product, and result from a relatively small amount of iron. The difficulties of studying the nature of such products are increased by the uncertainty of determining the water without altering the composition, and of ascertaining whether definite compounds or mixtures of such are under investigation.

The formation of iron-albuminates may be used for proving the presence of albumen. A very diluted solution of albumen, which is scarcely rendered opalescent by boiling, if mixed with a saturated solution of table salt, yields on the addition of a little ferric chloride, near the point of contact a yellowish-white zone, and on agitation, at first a dense turbidity, changing after a while to a rather voluminous precipitate.

* From the *Archiv d. Pharmacie*, June, 1882, pp. 417—425. Reprinted from the *American Journal of Pharmacy*, October, 1882.

On digesting iron in solution of albumen for a few days a yellowish-brown liquid is obtained, which on evaporation at a moderate heat yields light brownish-red scales, similar in behaviour to the dialysed ferrated albumen; in two cases 1·2 and 2 per cent. of iron was obtained. Freshly precipitated ferric hydroxide dissolves in albumen; the dry product contained 0·65 $Fe = 1·24\ Fe_2(OH)_6$. Ferrous hydroxide is very slightly soluble in albumen.

INFLUENCE OF PEPTONES AND CERTAIN INORGANIC SALTS ON THE DIASTATIC ACTION OF SALIVA.*

BY R. H. CHITTENDEN AND J. S. ELY.

(*Continued from page* 368.)

The increased diastatic action of the saliva in the presence of the peptones is made more plainly apparent by the following table, in which are given the percentage amounts of starch converted into sugar; calling the sugar $C_6H_{12}O_6$ and the starch $C_6H_{10}O_5$.

	Without peptones.	With peptones.
1.	41·01 per cent.	44·03 per cent.
2.	41·69 "	44·58 "
3.	41·88 "	47·83 "
4.	41·38 "	44·72 "
5.	39·13 "	42·89 "
6.	38·22 "	43·43 "

It is thus seen that the presence of 1 per cent. of peptones causes an increased conversion of starch into sugar, amounting on an average to 4 per cent.

Similar experiments made with glycogen yielded like results. Two grams of pure dried glycogen, prepared from *Pecten Irradians*,† were employed in each experiment, and the digestions continued for thirty minutes. One gram of peptones was used as before.

	Without peptones.		With peptones.	
	Wt. Cu in one-tenth. Gram.	Total amount of sugar. Gram.	Wt. Cu in one-tenth. Gram.	Total amount of sugar. Gram.
1.	0·1405	0·7297	0·1477	0·7671
2.	0·1286	0·6581	0·1386	0·7144
3.	0·1300	0·6653	0·1328	0·6771
4.	0·1281	0·6556	0·1306	0·6684

A few experiments were then tried, both with glycogen and starch, using 2 grams of peptones. Following are the results:—

	Without peptones. Wt. Cu in one-tenth.	With 1 grm. peptones. Wt. Cu in one-tenth.	With 2 grms. peptones. Wt. Cu in one-tenth.
Starch .	0·0835 gm.	0·0949 gm.	0·0960 gm.
Glycogen	0·1405 "	0·1477 "	0·1472 "
"	0·1286 "	0·1386 "	0·1429 "
"	0·1300 "	0·1328 "	0·1362 "

Here it is to be noticed that the presence of 2 per cent. of peptones has but little additional influence on the diastatic action. That peptones themselves were entirely free from carbohydrate matter and that the saliva is wholly without action on the peptones was clearly shown by digesting 2 grams of peptones with 25 c.c. of saliva. This experiment was repeated twice, but in neither case was any reduction obtained on boiling the diluted fluid with Fehling's solution. Again, the possibility suggested itself that the peptones might exercise some influence on the precipitation of the copper, and that the increase of copper obtained when peptones were present was due not to any stimulating action they might exert on the ferment, but to a precipitation or reduction of the copper. In order to settle this point three digestions were made in the usual manner with 2 grams of glycogen. No. 1 contained, in addition, 2 grams of peptones. No. 2 had added to it after the destruction of the ferment by boiling, 2 grams of peptones, while No. 3 served as a control.

* From the *American Chemical Journal.*

† Chittenden, *American Journal of Science and Arts*, x., 26.

A determination of the amount of sugar in the aliquoted fluids gave the following results, clearly showing that the mere presence of the peptones has no influence on the precipitation of the copper:—

No. 1.	No. 2.	No. 3.
Wt. Cu in one-tenth.	Wt. Cu in one-tenth.	Wt. Cu in one-tenth.
0·1472 gram.	0·1403 gram.	0·1405 gram.

There still remained two possible chances of error, viz., the possibility of the peptones containing a trace of a diastatic ferment, or of their possessing a diastatic action, and secondly, that the slightly acid reaction of the peptone solution might exert some modifying influence. The former supposition was easily disproved by making a digestion of starch and peptones alone. This led, as would naturally be expected, to a negative result; the solution showing no reducing action whatever. An endeavour was then made to obtain the same result in a somewhat different manner: a series of digestions was made, in which one of the peptone solutions was vigorously boiled before being added to the starch solution, the digestions then being made in the usual manner.

	Without peptones.	With 1 grm. peptones.	Peptone sol. boiled.	Peptone sol. boiled and water replaced.
	Wt. Cu in one-tenth. Gram.	Wt. Cu in one tenth. Gram.	Wt. Cu in one-tenth. Gram.	Wt. Cu in one-tenth. Gram.
No. 1.	0·0856	0·0937	0·0950	0·0952
No. 2.	0·0904	0·0977	0·1035	—

That the peptones contain no ferment is plainly apparent, but the slight increase of sugar when the peptone solution is boiled is certainly somewhat singular. Three of the peptones employed in these experiments gave, when dissolved in water, very faintly acid solutions. The acidity of 1 gram of peptones, however, was never sufficient to neutralize the alkali of 25 c.c. of saliva.* The fourth sample, which was purified by dialysis, gave a neutral solution, and this sample did not differ in its action in the least from the other three. An attempt was made, however, to neutralize one of the peptone solutions, previous to the digestion, by the use of an exceedingly dilute alkali. The following results were obtained:—

Without peptones.	With 1 grm. peptones.	With 1 grm. neutralized peptones.
Wt. Cu in one-tenth.	Wt. Cu in one-tenth.	Wt. Cu in one-tenth.
0·0915 grm.	0·1045 grm.	0·0991 grm.

The slight decrease of copper in the neutralized peptone, as later experiments would seem to indicate, is due probably to the retarding influence of the alkali salt formed by neutralization, although it seems hardly possible that such a minute trace could exert any influence whatever on the action of the saliva.

O. Nasse,† in his work on unformed ferments, found that in 4 per cent. solutions of certain inorganic salts there was an increased ferment action. It therefore seemed desirable to ascertain in the present case whether the inorganic salts contained in the peptones could exert any influence on the salivary ferment. The four samples of peptones contained the following percentages of ash:—

No. 1.	No. 2.	No. 3.	No. 4.
1·71 per cent.	0·89 per cent.	1·25 per cent.	1·58 per cent.

With the exception of No. 4 the ash was composed of sodium chloride, sodium phosphate, and calcium phosphate.

No. 4, which was prepared from coagulated albumin and purified by dialysis, left an ash composed wholly of calcium phosphate. The following results show the individual influence of the three inorganic salts on the dias-

* Neutral saliva appears to have as great a diastatic action as saliva of normal alkalinity. Thus while a digestion made with freshly collected alkaline saliva gave 0·0905 gram Cu, a portion of the same saliva neutralized gave 0·0943 gram Cu under the same conditions.

† *Untersuchungen über die ungeformten Fermenten*, Pflüger's *Archiv*, xi., 138.

tatic action of saliva when present in the digestive fluid in approximately such percentages as the peptones give when added to the starch and saliva mixture:—

First Experiment.

	Wt. Cu in one-tenth. Gram.
Saliva and starch alone	0·0872
" " + 0·012 grm. NaCl = 0·012 p. c.	0·0862
" " + 0·024 " " = 0·024 "	0·0925
" " + 0·012 " Na_2HPO_4 = 0·012 "	0·0886
" " + 0·024 " " = 0·024 "	0·0834

Second Experiment.

	Wt. Cu in one-tenth. Gram.
Saliva and starch alone	0·0844
" " + 0·015 grm. $CaHPO_4$ = 0·015 p. c.	0·0839
" " + 0·030 " " = 0·030 "	0·0870

From these results it is apparent that no one of the inorganic salts in the peptones is present in sufficient quantity to have any stimulating action whatever in aqueous solution, for increased diastatic action is noticed only in the presence of 24 milligrams of sodium chloride, an amount much larger than the total ash of 1 gram of peptones. Again, peptone No. 4, which was freed from all trace of chloride by dialysis, had exactly the same stimulating effect as the other samples.

In order to ascertain exactly what the influence of the *mixture* of inorganic salts, as present in the peptones, would be, a series of digestions was made, in two of which the ash of 1 gram and of 2 grams of peptones respectively was employed; the ash, as in the experiments with the peptones themselves, being dissolved in 50 c.c. of water, and in this manner added to the starch solution previous to the addition of the 25 c.c. of saliva. The peptones employed were the ones which contained 1·71 per cent. of ash; thus the digestive mixtures contained respectively 0·017 and 0·034 per cent. of inorganic matter. The following results were obtained:—

Saliva and starch alone. Wt. Cu in one-tenth.	With ash from 1 gram peptones. Wt. Cu in one-tenth.	With ash from 2 grams peptones. Wt. Cu in one-tenth.
0·0862 gram.	0·0851 gram.	0·0715 gram.

It is thus very apparent that the stimulating action of the peptones is not due to the inorganic salts contained in them, for these latter, as the foregoing experiment shows, have, by themselves, in aqueous solution, a retarding influence. We therefore deem it proven that peptones under such conditions as have already been described have in aqueous solution a stimulating influence on salivary digestion. In other words, peptones when present to the extent of 1·2 per cent. cause, under the same conditions as saliva alone, an increased conversion of starch into sugar, amounting on a average to 4 per cent.

Influence of Peptones in Acid Solution.

Previous experiments* have plainly demonstrated the extreme sensitiveness of the saliva to the action of dilute acids. Thus the addition of 50 c.c. of 0·05 per cent. hydrochloric acid to a digestive mixture, thereby making the fluid contain but 0·025 per cent. of acid, very greatly diminishes the diastatic action. This result has been recently verified by J. N. Langley,† as also the results of Chittenden and Griswold in regard to the destruction of the salivary ferment by gastric juice and by 0·2 per cent. hydrochloric acid at 40° C.

An attempt was now made to ascertain the influence of peptones in an acid solution of the above strength, viz., 0·025 per cent. The experiments were conducted in the same manner as the preceding, with this exception: the peptones, instead of being dissolved in water, were in each case dissolved in 50 c.c. of 0·05 per cent. hydrochloric acid. One gram of peptones was used in each experiment, starch being the amylaceous material employed.

	Saliva alone.		Saliva and acid.		Saliva, acid, and peptones.	
	Wt. Cu in one-tenth. Gram	Total amount of sugar. Gram	Wt. Cu in one-tenth. Gram	Total amount of sugar. Gram	Wt. Cu in one-tenth. Gram	Total amount of sugar. Gram
1.	0·0896	0·4557	0·0076	0·0389	0·1068	0·5428
2.	0·0911	0·4633	0·0079	0·0405	0·1070	0·5439
3.	0·0915	0·4654	0·0098	0·0502	0·1060	0·5388
4.	0·0835	0·4247	—	—	0·0985	0·5010

The percentage amounts of starch converted into sugar under the three conditions are as follows:—

	Saliva alone	Saliva and acid.	Saliva, acid, and peptones.
1.	41·01 per cent.	3·50 per cent.	48·85 per cent.
2.	41·69 "	3·64 "	48·95 "
3.	41·88 "	4·51 "	48·48 "
4.	38·22 "	—	45·09 "

Similar experiments were tried with glycogen, 2 grams of this substance being dissolved in 25 c.c. of water and employed in the same manner as the starch; 1 gram of peptones was used as before. The following results were obtained.—

	Saliva alone. Wt. Cu in one-tenth.	Saliva and acid Wt. Cu in one-tenth.	Saliva, acid, and peptones. Wt. Cu in one-tenth.
1.	0·1300 gram	0·0049 gram	0·1408 gram
2.	0·1281 "	trace	0·1424 "

It is thus seen that the presence of 1 gram of peptones exercises a very remarkable influence on the diastatic action of saliva in an acid solution of the above strength. The peptones are present in the digestive mixture to the extent of only 1 per cent., while the acid is but 0·025 per cent., yet this quantity of peptones is sufficient not only to counteract the retarding influence of the acid, but increases the conversion of the starch to the extent of 7 per cent. above the action of the saliva alone. Increasing the amount of peptones to 2 per cent. does not appear to have any effect whatever, as the following results show:—

	1 gram peptones and 0·025 per cent. acid Wt. Cu in one-tenth.	2 grams peptones and 0·025 per cent. acid. Wt. Cu in one-tenth.
1.	0·1060 gram.	0·1084 gram.
2.	0·0985 "	0·0974 "

In acid solutions of increased strength the peptones appear to exercise but slight if any influence; thus when the solution contained 0·1 per cent. hydrochloric acid, no diastatic action at all was observed, even in the presence of the peptones. In 0·05 per cent. acid solution, however, one-tenth of the diluted and mixed digestive fluid yielded 0·013 gram Cu, showing a slightly increased action over and above what the acid fluid alone would give.

Control experiments with saliva, peptones, and acid without starch yielded negative results, thus showing that the saliva is entirely without action on the peptones in an acid solution of the above strength. Again, digestions of starch, peptones, and acid without saliva also gave negative results, proving that the peptones are wholly without diastatic action in the acid fluid. We deemed it advisable next to examine how far inorganic salts could influence the action of the ferment in an acid solution of the strength used. In aqueous solution it will be remembered the inorganic salts experimented with had but little or no action. In the acid solution the salts used were the same as before, viz., those present in the ash of the peptones. The experiments were conducted in the same manner as the preceding; 100 c.c. being the volume of the mixed fluid, of which 25 c.c. were filtered saliva, 25 c.c. water containing 1 gram of starch, and 50 c.c. 0·05 per cent. hydrochloric acid containing the salt.

(*To be continued.*)

PHARMACY ACT, 1868.

RECTIFICATION OF THE REGISTERS OF PHARMACEUTICAL CHEMISTS AND CHEMISTS AND DRUGGISTS.

We are requested by the Registrar to publish the following list of persons whose names will be erased from the Registers unless they communicate with him on or before 30th December next.

Those marked (*) are Pharmaceutical Chemists.

Abbott, Joseph	1, Bellevue, Clevedon.
Abraham, William	16, Lawford Road, Rugby, Warwickshire.
Adams, Henry Gardiner	35, Burgate Street, Canterbury.
Alexander, William	Strichen, Aberdeenshire.
*Andrews, William Leatham	19, The Terrace, Peckham Road, London, S.E.
Armstrong, Brooksbank	71, King's Road, Chelsea, London, S.W.
Arnold, George James	17, Hardwick Place, Commercial Road, London, E.
Ashmore, George Johnson	Lindsworth, King's Heath, Birmingham.
Atkinson, Edward Fenton	42, Kirkstall Road, Leeds.
Attwater, Thomas Chipping	47, Kerr Street, Devonport.
Atwell, Benjamin Arthur	Wincanton.
*Bachelot, Pierre Eloy	Paris.
Baker, Arthur George	98, Hampstead Rd., London, N.W.
Ballinger, Arthur John	21, St. Alban's Street, Kennington Road, London, S.E.
Barnes, Benjamin	7, Cross Street, Hatton Garden, London, E.C.
Barry, Henry	79, High Street East, Sunderland.
Beesley, Thomas	10, High Street, Salisbury.
Bell, George	65, Hopwood Street, Spring Bank, Hull.
Bendelack, Charles	112, High Street, Southampton.
Berry, Robert Innes	65, St. Nicolas Street, Aberdeen.
Best, Robert	33, Strickland Street, Hessle Road, Hull.
Betts, John Howe	7, Bedford Row, Limerick.
Billsborough, Thomas	23, London Road, Preston, Lancs.
Bingham, Samuel	Eton.
Birchall, Samuel	39, Tennyson Place, Otley Road, Bradford.
Birrell, George	Post Office, Highgate, London, N.
Black, William Jones	21, High Street, Bangor.
Bluett, Reginald	Tetbury, Gloucestershire.
Boe, James	43, Blackett Street, Newcastle-on-Tyne.
Bond, Alfred	13, Pelham Road, High Road, Tottenham, London, N.
Boor, Jonathan	38, East Street, Brighton.
Booth, Jonathan	6, Cavendish Terrace, West Hill Park, Halifax, Yorks.
Boulton, Joseph Oakwell	Albert House, Claremont Street, Bristol.
Branch, George	26, St. Peter's Street, Mile End, London, E.
Branson, Alice	7, Back Lane, Bradford, Yorks.
Breton, Harvey Wolstenholme	29, Loseby Lane, Leicester.
Brierley, John	Barrow-in-Furness.
Bristow, Robert Anthony	47, Eastlake Road, Brixton, London, S.W.
Britten, John	272, Albany Road, Camberwell, London, S.E.
Brown, Benjamin	6, Russell Street, Hull.
*Brown, William Braithwaite	Kibworth-Beauchamp, Leicestershire.

Griffiths Joseph	8, Church Street, Wrexham.
Hambridge, Thomas	West Street, Reading.
Hancorne, Edward	9, East India Dock Road, Limehouse, London, E.
Hanson, Philip Freeman	Chagford, near Exeter, Devon.
Harding, George	High Street, Farningham, Kent.
Harries, Thomas	22, Page Street, Swansea.
Harris, Waddelow Chambers	170, Westgate, Bradford, Yorks.
Hawthorne, Charles Oliver	109, Chobham Road, Stratford, London, E.
Hayward, Charles William	54, Gartside Street, Manchester.
Healy, Patrick J.	25, Felstead Street, Victoria Park, London, E.
Heaps, William	16, Lime Street, Preston, Lancs.
Heaton, George	198, Manchester Road East, Little Hulton, near Bolton, Lancs.
Henderson, John	125, Gairbraid Street, Maryhill, Glasgow.
Heslop, John	South Shields.
Higgins, Joseph Slatterie	Clarence Cottage, St. John's, Fulham, London, S.W.
Hodsall, James	8, Lowfield Street, Dartford, Kent.
Hogg, Walter	3, Nesham Street, Westmoreland Road, Newcastle-on-Tyne.
Holland, Henry	97, Higate Lane, Sparkbrook, Birmingham.
Horner, James William	5A, Banyard Terrace, Banyard Road, Bermondsey, London, S.E.
Horsfall, Henry	31, Vicar Lane, Leeds.
Horsfall, Thomas	Burley Road, Leeds.
Howard, George	72, Rochdale Road, Manchester.
Howard, James Walker	39, Green Road, Leeds.
House, Henry William	28, Red Lion Square, London, W.C.
Huff, Evan	330, Ashton Old Road, Openshaw, Manchester.
Hunneman, Charles Julius	Hanover.
Hunter, William Bildad	42, Lansdowne Street, Hull.
Huntley, Henry Edwin	36, Heygate Street, Walworth, London, S.E.
Huskinson, John Lovett	Frodsham, Cheshire.
Huxtable, James	1 Wine Office Court, Fleet Street, London, E.C.
Ives, Robert Hanworth	Chapeltown Road, Leeds.
Jack, George	100, King Street, Dundee.
Jackson, Nathaniel	192, Rochdale Road, Manchester.
Jackson, Richard	High Street, Teddington.
Jackson, William Kilvington	Horton, near Belford, Northumberland.
James, Abel	69, Oxford Street, Mountain Ash, Glamorganshire.
James, John	Pontypridd, Glamorganshire.
Jenkins, John	Church Street, Tredegar, Mon.
Jessop, John Arthur	Market Place, Willenhall, Staffs.
Jessop, Josiah Benjamin	12, Darlington Street, Wolverhampton.
Johnson, Edward	22, Pimblett Street, Cheetham, Manchester.
Johnson, Edward	48, Stamford Street, Stalybridge.
Johnston, Robert	212, New City Road, Glasgow.
Jones, Henry William Burnell	64, High Street, Newport, Mon.
Joy, Josiah Rudduck	1, St. Joseph Street, Hunslet Road, Leeds.
Judd, Richard	110, Suffolk Street, Birmingham.
Keith, Alexander Reid	15, Princes Square, Kennington, London, S.E.
Kirby, John Henry	124, Wheeler Street, Birmingham.
Kirkman, Thomas Charles	20, Ellerby Lane, Bank, Leeds.
Knight, John	5, Chapel Street, Somers Town, London, N.W.
Lanchenick, Emma	High Street, Marlborough, Wilts.
Langford, William	119, London Road, Lynn, Norfolk.
Langridge, Thomas Benjamin	Maud Villa, Colworth Road, Leytonstone, Essex.
Lavender, Joseph	Frog Island, Leicester.
Lemmon, Charles	12, South Street, Worthing.
Leppard, James	Guildford Street, Chertsey, Surrey.
Levie, Alexander Mair	73, Wales Street, Aberdeen, N.B.
Lewis, Rebecca	Ebbw Vale, Mon.
Lickiss, Charles	55, Liddell Street, Hull.
Little, Henry	107, Broad Street, Reading.
Lodge, Arthur William	London Hospital, Whitechapel, London, E.
Lomas, Charles Benjamin	25, King Street, Leicester.
Longfield, Joshua	17, Whitehouse Road, Sunderland.
Lyddon, Richard	138, Mile End Road, London, E.
Lynch, Edwin Bould	25, Cheetham Street, Rochdale.
Lynch, Thomas Bold	9, London Road, Preston, Lancs.
McCheyne, James	45, High Street, Dumfries, N.B.
McConachy, John	Hagley Street, Halesowen, Birmingham.
McCulloch, Charles	6, Cross Lane, St. Mary-at-Hill, London, E.C.
MacFarlane, Peter	191, Fulham Road, London, S.W.
McGown, John Porter	11, Caledonia Street, Paisley, N.B.
McGruer, John	47, South Kinning Place, Paisley Road, Glasgow.
McKenzie, Hector	116, Castle Street, Montrose, N.B.
McKinnell, Thomas Maxwell	16, Brougham Place, Edinburgh.
Macneill, Archibald	324, Caledonian Road, London, N.
McOwan, John Townsend	1, Powlett Place, Harmood Street, Camden Town, London, N.W.
Mann, John	68, St. Ann's Road, Nottingham.
Marlow, Frederick William	11, High Street, Battersea Square, Battersea, London, S.W.
Marrion, William	Oxford Street, Oaken Gates, Salop.
Marsden, John	17, Barony Street, Edinburgh.
Marsh, Thomas	Elm Cottage, Slindon, near Arundel, Sussex.
Martin, Michael	142, Mill Street, Liverpool.
Melton, Frederick	22, Worship Street, London, E.C.
Merrett, Joseph Hughes	48, East Street, Brighton.
Miller, William Henry	62, Bean Street, Hull.
Millington, Edward	162, Bermondsey Street, London, S.E.
Mills, John Perry	The Cross, Exmouth, Devon.
Mills, Thomas William	8, Lowfield Street, Dartford, Kent.
Milne, James	Forrest Road, Edinburgh.
Morgan, John	13, Methley Street, Kennington, London, S.E.
Morgan, Richard Thomas	Brook House Dispensary, Cricklade, Wilts.

Owen, Richard Lewis	Turf Square, Carnarvon.
Padley, William	5, Norfolk Street, Lynn.
Parker, Frederick Carr	Lady Bank Works, Dundee.
Parr, Frederick Richard	Silverdale, Staffs.
Patman, George	White Lion Street, Norwich.
Pattison, Frederick	38, St. Paul's Road, South Tranmere, Cheshire.
Peat, William Henry	The Crescent, Birmingham.
Pemberton, William	51, Tithebarn Street, Preston, Lancs.
Penketh, John	197, Westminster Road, Kirkdale, Liverpool.
Phillips, Charles	34, Montgomery Street, Sparkbrook, Birmingham.
Pickering, Samuel Whaley	The Lache, near Chester.
Pidgeon, Joshua David	Hatherleigh, Devon.
*Pisani, Orestes Victoriano	23, Ravensdon Street, Kennington, London, S.E.
*Place, William Thomas	17, Brunswick Terrace, Aire Street, Leeds.
Poate, Stephen	1, Charles Street, Landport, Hants.
Pollard, Jeremiah	43, Winchester Street, London, S.W.
Pollard, John Frederick	North Street, Milverton, Somerset.
Poole, John	20, Garratt Street, Manchester.
Powell, Thomas Quarton	32, Cordingley Street, Otley Road, Bradford, Yorks.
Pye, John	Duke Street, Dartmouth, Devon.
Raynes, Sydney Herbert	10, Woodsome Road, Highgate, London, N.
Reed, Johnson	47, Diana Street, Newcastle-on-Tyne.
Reed, Willliam	47, Diana Street, Newcastle-on-Tyne.
Reekie, Arthur	Loanhead, Midlothian.
Reeve, James	Bell Hotel, Ely, Cambs.
Rennison, James	119, High Street, Sunderland.
Revell, John	11, Clifton Road, Maida Vale, London, W.
Richards, Frederick Johnson	60, Albion Road, Dalston, London, E.
Richards, Thomas	18, Saville Place, Lambeth Road, London, S.E.
Richardson, Joseph Hancock	3, Arundel Terrace, Cork.
Ring, Edward James	324, Caledonian Road, London, N
Roberts, Thomas	29, Rectory Road, Stoke Newington, London, N.
Roberts, Thomas Edwards	69, Beacon's Hill, Denbigh.
Robinson, George	27, Arlington Street, Salford, Manchester.
Robinson, Herbert	52, Royal York Crescent, Clifton, Bristol.
Robinson, John	15, Wellington Terrace, Norwood, Beverley.
Robinson, Thomas	Easington, Yorks.
Roper, George Arthur	4, Summerfield Terrace, Newnham, Cambs.
Routlidge, George	362, Rochdale Road, Manchester.
Salter, Sophia	Eltham, Kent.
Sargeant, Samuel	61, Roden Street, Holloway, London, N.
Shannon, John	168, Gallowgate, Glasgow.
Shearer, David Brown	156, New City Road, Glasgow.
Sheriff, Thomas Jackson	149, Chapel Street, Salford, Manchester.
Sibbering, George	Middlesex Hospital, Charles Street, London, W.
Sim, Robert	58, Aughton Street, Everton, Liverpool.
Simnett, Thomas	52, Royal York Crescent, Clifton, Bristol.
Simpson, Alexander	31, Ronald Street, Glasgow.
Simpson, John	80, Patrick Street, Cork.
Simpson, William	Market Place, Bedale, Yorks.
Slater, Samuel	Headingley, Yorks.
Smith, Anthony	11, Upper Well Street, Hill Cross, Coventry.
Smith, Charles Albert	42, Canal Street, Derby.
Smith, Charles Henry	4, Newby Terrace, Bootham Stray, York.
Smith, Percival Henry	80, Argyle Street, Birkenhead, Cheshire.
Smith, William Lyall	Great Hautbois, Coltishall, Norfolk.
Snape, John	Swinton, Lancs.
Soppet, Robert	5, Allerton Terrace, East Cotham, near Redcar, Yorks.
Sotaan, Paul Hellesen	2, Garford Street, Limehouse, London, E.
Spalding, William Richard	Lea Bridge Road, Leyton, Essex.
Spicer, Charles	Ferndale Lodge, Ennersdale Road, Lewisham, Kent.
Spicer, Thomas	Finedon, Northamptonshire.
Spreekley, George	58, Long Row, Nottingham.
Spurgin, Frederick William	Hounslow, Middlesex.
Stanley, Henry	Fore St., Edmonton, Middlesex.
Stead, Samuel	Hanover Place, Leeds.
Stenhouse, Robert	1, Malta Terrace, Edinburgh.
Stevens, Stephen Nobbs	Bridge Street, Downham Market.
Stevenson, Robert Albert William	44, Taylor Street, Liverpool.
Stewart, William Henry	11, Appleford Road, Upper Westbourne Park, London, W.
Stocks, Alfred	Halifax, Yorks.
Stonehouse, William	2, Bridge Street, South Stockton.
Story, William	Worksop, Notts.
Sutcliffe, Radcliffe	113, Crown Buildings, Boothtown, Halifax, Yorks.
Swallow, James Edward	Albert Cottage, Kensal New Town, London, W.
Tamplin, George William Dunlop Haddington	University College, Gower Street, London, W.C.
Tanner, Benjamin	2, Hargreave Buildings, Chapel Street, Liverpool.
*Tanner, Herbert	133, Oxford Street, London, W.
*Taplin, Frederick	Bristol.
Taylor, Hannah	17, Saville Street, Manchester.
Taylor, Sydney	Old Charlton, Kent.
Templar, Alfred	3, Denmark Street, Bristol.
Thomas, Richard	Crosswall, Dover.
Thomson, Frederick Charles	Victoria Place, Eastbourne.
Thorp, John	790, Rochdale Road, Harpurhey, Manchester.
Tomlinson, William Frederick	8, Blenheim Square, Leeds.
Toy, George Bentley	153, Summer Lane, Birmingham.
Traverse, Thomas	53, St. Peter's Street, Islington, N.
Turner, Robert John	185, Church Road, Essex Road, London, N.
Twizell, Robert	South Hylton, Durham.
Vincer, Frank	71, East Street, Brighton.
Vine, Richard	112, Westbourne Park Road, London, W.
Ward, Thomas Rowland	3, Ashley Lane, Long Milgate, Manchester.
Warner, Richard	20, Charterhouse Square, London, E.C.
Warren, Frederick	52, Preston Street, Brighton.
Waterfield, David	132, Ladbroke Grove Road, Notting Hill, London, W.
Waterworth, William	77, Cambridge Street, Sheffield.
Watson, Thomas Harrison	30, Osborne Road, Tue Brook, Liverpool.
Watts, John Taylor	69, Hall St., Stockport, Cheshire.
Watts, Walter	15, High Street, Kington, Herefordshire.
Wedge, Theophilus Aston	80, Victoria St., Wolverhampton.
Weller, James William	Nice.
Wells, Joshua Holroyd	6, Church Row, Kirkgate, Leeds.
Wheeler, Frederick Ebenezer	8, Victoria Street, Ryde, Isle of Wight.

The Pharmaceutical Journal.

SATURDAY, NOVEMBER 11, 1882.

Communications for the Editorial department of the Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

INSPECTION OF DRUGS IN THE UNITED STATES.

THE reference made last week, in the course of the discussion on Mr. WILLIAMS'S motion, to the existence in the United States of a system of inspection of imported drugs, will perhaps have raised some curiosity as to the nature of the regulations under which it is carried on and whether they would be at all applicable to the conditions obtaining in this country. We therefore avail ourselves of the opportunity afforded by the appearance in a United States contemporary of an article on this particular subject to quote some details as to the legislation under the authority of which the inspection is made, as well as the extent to which the provisions of the law have been carried out.

The United States statute law upon the subject is in substance as follows. It provides that all drugs, medicines, and medicinal preparations (including medicinal essential oils) and chemical preparations, used wholly or in part as medicine, imported from abroad, shall, before passing the custom house, be examined as well in reference to their quality, purity, and fitness for medical purposes, as to their identity as specified in the invoice, and if on such examination any of them are found, in the opinion of the examiner, to be so far adulterated, or in any manner deteriorated, as to render them inferior in strength or purity to the standard established by the United States, Edinburgh, London, French and German Pharmacopœias, and thereby improper, unsafe or dangerous to be used for medical purposes, they are not to be allowed to pass. When a consignment of drugs is condemned the consignee is allowed to re-export it at any period within six months from the date of the condemnation, upon executing a bond to land them outside the United States. If not so re-exported before the expiration of six months the drugs are then destroyed by the custom house officers. At the port of New York, one of the assistant appraisers is appointed with special reference to his qualifications for carrying out such inspection. In the event of an inspector's decision being challenged, an appeal is allowed, and the goods are referred for examination to an analytical chemist of good repute with the medical colleges in the State in which the custom house is situated; but in the event of the referee giving an adverse decision the consignee has to pay all the costs incurred before he is allowed to re-export the goods.

According to an official list furnished by the Deputy-Collector of the New York Custom House, one hundred and seventy-eight bales or packages of drugs were condemned at that port in the course of the twelve months ending June 1 of the present year; no definition is, however, given as to the weight of a "bale" or "package." Of these fourteen were destroyed by fire, one hundred and two were re-exported under bonds, and the remainder were at the close of the year in store, the six months' limit which was to determine their treatment not having yet expired. Among the articles rejected were valerian root (36 bales), sarsaparilla (24 bales), gentian (19 bales), belladonna root and leaves, colchicum corms and seeds, aconite root and leaves, senna, wormwood, comfrey root, horehound, hellebore, Persian opium, rhubarb (30 lbs.), balsam of copaiba and orange peel. No chemicals, medicinal preparations or essential oils were condemned during the same period.

It will be obvious that the introduction of such a law into this country would, as pointed out by Mr. WILLIAMS, probably act injuriously upon the London market. If carried out in its integrity it would prevent the importation of many articles for which manufacturers and others find a legitimate use, although they may not come up to a pharmacopœia standard. For instance, the Persian opium condemned would probably have had its value in the market for alkaloid manufacture, although the sophistication in which the Persians are proving themselves such adepts may have brought its morphia strength down to a low standard. On the other hand, a drug naturally of low quality, which is neither deteriorated nor adulterated, would not appear to be covered by the language of the statute. But it might almost be assumed from the fact that no chemicals or essential oils had been condemned that the statute is only partially carried out, and this view is confirmed by the sensational statements made every now and then as to the quality of specimens of drugs,—imported as well as native,—that are to be met with in the United States markets.

THE INTERFERENCE OF PUBLIC SERVANTS IN TRADING OPERATIONS.

WE notice that among the questions set down on the House of Commons paper are three that bear upon a subject in which many of our readers are much interested, namely, the extent to which public servants should be allowed to take part in the management of trading corporations carrying on business in competition with tax-paying tradesmen. Mr. HUBBARD proposes to ask the First Lord of the Treasury whether officials in the public service are at liberty to engage as promoters, trustees or directors in financial, commercial or industrial adventures, failure in which might involve them in pecuniary embarrassment or personal discredit, and bring reproach upon the public service; also whether the public servants of the country are adequately remunerated for the services to which the State has an exclusive claim, or whether there exists any excuse or sanction for persons in the service of the State supplementing their official salaries by the proceeds of private engagements; and, lastly, whether in the event of there being no excuse or sanction for the practice he will take effectual means to announce and enforce his disapproval.

At the time of our going to press, these questions have not yet been put, but we shall look with some curiosity for the answer, since it will probably indicate the course the present Government is prepared to take in respect to a grievance from which, more or less, chemists and druggists, in common with all tradesmen are suffering.

THE RECTIFICATION OF THE REGISTER.

On pp. 388—90 will be found a list of persons whose names have become liable to be struck off the Register of Chemists and Druggists through their failure to communicate their whereabouts to the Registrar. It will be remembered that under the provision in the tenth section of the Pharmacy Act, 1868, to enable the Registrar to fulfil the duty imposed upon him of keeping the Register correct, he is empowered to send a registered letter to any registered person, addressed to him according to his address on the Register, to inquire whether he has ceased to carry on business or changed his residence. If no answer be returned to such letter within six months, a second of similar purport is to be sent, and if no answer be given to this within three months it becomes lawful to erase the name of that person from the Register. This is the course, so far as the sending of the letters is concerned, that has been taken with respect to each person whose name is in the list printed this week, and the Registrar now gives formal notice of his intention to proceed to the erasure of these names, unless the persons whom they represent communicate with him on or before the 30th of December next.

It will be observed with regret that the list, which includes about four hundred and twenty names, is an unusually long one, as compared with those that have been published previously at biennial intervals. This difference is hardly likely to be explainable by so large an increase in the number of unreported deaths. The fair inference is that it is mainly due to the failure on the part of a large number of registered persons to take sufficient trouble to inform the Registrar as to their changes of residence. It is a pity, however, that so much labour and expense should be put upon others before such defaulters can be stimulated into the performance of an act which is solely for their own benefit.

EXTRACT OF MEAT, AND THE LAW RELATING TO TRADE NAMES.

In July last, Mr. Justice Field, sitting in Chancery, was occupied for little short of a week in the trial of cases in which Liebig's Extract of Meat Company, Limited, pressed allegations that it was entitled to restrain the use by Mr. R. W. Anderson and others of the title "Baron Liebig's Extract of Meat," and of any portrait of the late Baron Justus Von Liebig. This position was assumed notwithstanding the result of the action against Messrs. Allen and Hanburys, in 1867, in which that firm sustained the public right to call "Liebig's Extract of Meat" by that its proper name, and notwithstanding that the Company had never called the article "Baron Liebig's Extract of Meat," or used any portrait in connection with sales of it. It was felt by us at the time that the case was of especial interest to our readers, but as at the close of the trial judgment was reserved, it did not appear to us desirable to trouble our readers then with the lengthy arguments of counsel or details of the evidence.

On Wednesday, judgment was delivered in favour of the defendants. It contains a *résumé* of the evidence and arguments, and as we intend to present it to our readers *in extenso* next week, we defer for the present any detailed comment upon it. We think that as a judgment carefully prepared after argument by very eminent members of the Bar, and as an embodiment in a concise readable form of the facts of the case and of the law applicable to cases of the kind, it will be found to amply repay attentive perusal.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

At the first meeting of the present Session, to be held on Thursday, November 16, at 8.30 p.m., an address on "The British Pharmacopœia as a Students' Manual" will be delivered by the President, Professor Attfield, F.R.S. The address will be followed by a discussion. At this meeting also the election of officers for the present session will take place.

CHEMISTS' ASSISTANTS' ASSOCIATION.

A meeting of the above Association will be held at 32a, George Street, Hanover Square, on Wednesday evening next, 9 p.m., November 15, when a paper on "Wild Flowers and their Relation to Insects," will be read by Mr. Cracknell.

THE AUSTRIAN PHARMACEUTICAL ASSOCIATION.

According to a statement made in a report presented at the recent meeting of the Austrian Pharmaceutical Association, in Agram, that Society now consists of 508 ordinary members, 50 corresponding members and 70 honorary members.

Pharmaceutical Society of Ireland.

MEETING OF THE COUNCIL.

The monthly meeting of the Council of this Society was held on Wednesday, the 1st of November, at the College of Physicians, Kildare Street, Dublin, at three o'clock.

The chair was taken by Mr. Pring and subsequently by the President, Dr. Tichborne.

The other members of the Council present, were Messrs. Allen, Bennett, Brunker, Dr. Collins, Mr. Grindley, Dr. Montgomery, Messrs. McIlwaine, Minchin, Payne and Wells.

The minutes of the annual meeting of the Society and of the last meeting of the Council were read and confirmed.

On the motion of Mr. Allen, seconded by Mr. Grindley, the four examiners of the Society were re-elected.

The next business was the consideration of recommendation No. 3, from the Pharmacy Act Amendment Committee, as follows :—

"That all candidates for the licence shall be required to produce evidence of having passed three years in a *bonâ fide* apprenticeship to an apothecary or pharmaceutical chemist keeping open shop."

Mr. J. C. C. Payne moved, by way of amendment, that the following be substituted for recommendation No. 3:—

"Candidates, before presenting themselves for their final examination, are required to produce indentures of apprenticeship, duly signed by a pharmaceutical chemist or apothecary keeping open shop, stating that the candidate has served a *bonâ fide* engagement of four years in his establishment."

He had carefully thought over the matter and discussed it with members of the Council who were actively engaged in pharmacy, and they agreed with him that a two years' certificate of practical pharmacy was not sufficient, and that the only satisfactory way of preparing young men for functions which were very important for the public was by apprenticeship. Two years was a very short period to give a young man for acquiring all the knowledge of pharmaceutical work that was required from him. He maintained that even four years was a short period for the purpose. It had been said that apprenticeship had to a great extent ceased to exist, but he did not think that those who were practically engaged in pharmacy would agree with that. Young men could only be made practical pharmacists in a medical hall or pharmacy where they got constant practical everyday work. He did not say that it was necessary that they should be employed for the whole four years in compounding prescriptions. The making of tinctures, and the mixing of powders and pill masses were matters to be learned ; and during the first twelve months of his apprenticeship, a young man would have very little chance of being allowed to compound prescriptions. He should learn how to make the preparations first, and there were a number of other matters, apparently trifling in themselves, which it was also necessary for him to learn, so that he would have to spend the first two years in preparing himself for the task of learning how to compound the prescriptions. It had been urged that there were other subjects which he had to learn, such as materia medica and botany; but the fact was that he learnt these daily in his practice of pharmacy. Every time he made a tincture he came across something connected with them. Chemistry also he learned daily in the same way. Analytical chemistry no doubt, he would not get ; but provision had been made for that. Schools for the purpose of teaching it had been recognized by the Council, some of which, if not all, had evening classes. In Belfast they had a chemical school which had been recognized by the Council, and at the evening classes of which young men, who were engaged during the day with pharmacists, learned practical chemistry. From all these reasons he thought a four years' service was necessary, in order to produce pharmacists in whom the physicians and the public would have confidence. He did not propose that his resolution should apply to those who were at present taking out a two years' course ; it should not come into force until after it had received the sanction of the Privy Council.

Mr. Pring: Make it law from the 1st of January, 1884.

Mr. Payne: I consent to make that alteration.

Mr. McIlwaine seconded the amendment.

Mr. Brunker said that while he agreed with almost everything that Mr. Payne had said, he did not approve of requiring from every candidate an indentured apprenticeship. No doubt the four years' service was desirable; but they might extend it to assistants who had been employed during that period with pharmaceutical chemists keeping open shop. He would suggest that the regulation should be:—"Candidates are required to produce a certificate signed by a pharmaceutical chemist or apothecary keeping open shop, stating that they had served a *bonâ fide* engagement either as apprentice or assistant with the person giving the certificate for a term of four years." But if they had a hard and fast rule requiring apprenticeship, they would shut out a great many men who might be ornaments to the Society. Besides some of the best houses did not take apprentices, and such a hard and fast rule would prevent the rising generation from learning their business in those places.

Dr. Collins said he was an old member of the Apothecaries' Hall and had had a good deal of experience in the compounding of medicines for more than fifty years. Several years ago this question was considered at a general meeting of the apothecaries' profession, at which there was a large attendance, and it was then unanimously decided that an apprenticeship or pupilage of three years was long enough to fit a young man entering their branch of the profession for the important function of compounding medicines and for taking charge of an establishment during his employer or master's absence. His own opinion was that unless a young man was extremely dull three years was sufficient for the purpose. Of course that had no reference to the teaching of the other parts of the business. A great many pharmaceutical chemists might think it necessary to have other employments for their apprentices and pupils besides compounding medicines; but in that Society they had simply to consider what time it would take a man to become a good safe compounder of medicine. For his own part he thought three years abundantly sufficient for that. Apprenticeship had now been largely done away with and pupilage was generally taking its place.

Mr. Simpson observed that in country establishments where other business besides compounding had to be done it took the student a longer time than elsewhere to learn compounding. During the first two years the apprentice had to do a great many things besides compounding. Therefore he was not in favour of a shorter period than four years.

Mr. Pring said he had had a great deal of practical experience and would consequently be in favour of a period of five years, but as he could not get it he would accept four. Young men should be at the business for one or two years before they could commence compounding; in many establishments it was three years before they got into the compounding department. They had first to become acquainted with the poisonous and the non-poisonous medicines and to learn to make preparations.

Dr. Montgomery considered that the observations of Dr. Collins applied to apothecaries, who looked forward to practice rather than to the compounding of prescriptions. But those who sought the licence of that Society should have every iota connected with the compounding of prescriptions at their fingers' ends. He was a strong advocate for apprenticeship, otherwise there would be so many doors left open for imposition that they would have endless difficulties in investigating whether a man had put in his time or not. His opinion was that without apprenticeship they would not be able to get a young man to learn his business, or have any test by which they could ascertain whether he was applying himself to it or not. On the other hand apprenticeship gave the employer a legal authority over the young man. He (Dr. Montgomery) would have a period of three years at least. No employer in his senses, or who had any regard for the safety of his clients, would think of putting a young man of perhaps seventeen years of age, and only in his first year, to the work of compounding prescriptions. He served five years himself, and he spent the first in learning mere matters of routine. He thought they might go on from three to a period of five years.

The President said the proposal which was before them involved two matters. One was the length of the apprenticeship or pupilage. In the abstract he had not the slightest objection to a period of five years if it was found to be necessary; but on the other hand they should not throw an impediment in the way of men presenting themselves for the licence. He did not even think that they would be justified all at once in running the period up to four years. He would prefer three years. During the last twelve months only seventeen candidates had passed, and that did not show such a rush to the profession as required a drag to be put on the wheel. Only one passed at the last examination. They knew that a man would be all the better compounder for having served six or eight years; but the Council should have due regard to the practical bearings of any regulations that they made and to how they could be carried out. He was strongly of opinion—and there were a great many members of the Society who agreed with him—that their licentiates came short in general knowledge of the sciences outside compounding. Although they were supposed to have passed an examination in those subjects, their instruction in them was generally of the most superficial kind. There was one of those branches in which instruction was compulsory, and three more in which it was not. He did not agree with Mr. Payne that apprentices learned those things. On the contrary they knew perfectly well that they did not learn either botany or materia medica thoroughly. A great many of them would not know rhubarb or "hippo" in the lump states, because they generally saw them in the powdered form. He was alluding to those who depended for such knowledge solely on what they could acquire during their apprenticeship. However, it was a matter of opinion. Coming to the question of apprenticeship, previous speakers had lost sight of the fact that there was a very large contingent of men who might present themselves for the licence and had had large experience—much larger than those who had served apprenticeships of three or four years could get—although they had never served apprenticeships. Four of the principal establishments in that city would not take apprentices. They said that they preferred to be independent of them, and to engage assistants who were certified having undergone an examination. Of them there were a great number. Perhaps some members of the Council might not be aware of the fact that hardly a week elapsed in which some young man was not examined to see if he were qualified to be an assistant. The anxiety of some gentlemen to create apprentices was hardly consistent with the fact that they refused to allow a recommendation to go forward that the Council should have the power of examining assistants; in fact the course they took really looked as if they wanted to drive young men into becoming apprentices rather than take care that they learned their business. Mr. Payne was one of the gentlemen who objected to the recommendation going forward that there should be an examination for assistants. He thought that was hardly consistent with the position taken by him on the present occasion. He agreed that the Council should, if possible, do away with any certificate that should be a sham. It should be a proof that the four years had been *bonâ fide* spent in compounding; and if that were so the student would have got his knowledge, whether he were an indentured apprentice or not. As to the length of time, he thought it might be three years, and subsequently it could be increased to four.

Mr. Wells said he knew of a house which took a large number of apprentices. They were not bound at first, but indentures were given to them when they were leaving after having served for five years.

Dr. Collins: That was not apprenticeship at all.

The President said he alluded to large establishments in which there were from four to six assistants employed in compounding.

Mr. Payne, in the course of his reply, said he was thoroughly in favour of indentured apprenticeship. He was sure that anyone who had been such an apprentice for four years in a pharmacy where practical work was carried on would recognize rhubarb root or any other root in the Pharmacopœia. It was to be presumed that he would even have to powder the root himself.

The President: I do not think there is one pharmacist in twenty who even makes his own tinctures.

Mr. Pring: We make our own tinctures.

Mr. Allen: So do I.

Mr. Payne: I do not think there is a tincture that we sell that we do not make in our place and I presume it is the same with everyone round the table. All this has been brought about by sham certificates. Mr. Payne said in conclusion that in order to meet the views of the general body of the Council he would alter his amendment to the following:—

"That all candidates for the licence shall be required to produce a certificate, signed by a pharmaceutical chemist or apothecary keeping open shop, stating that he has served a *bonâ fide* engagement with him, either as apprentice or assistant, in his sole employment, for a term of four years; this resolution to come into force on January 1, 1884."

The President: That entirely meets my views in every respect, only that I wish you would make the period three years at first.

The President having to withdraw his objection to the time,

The amendment was then put and unanimously agreed to, and was subsequently adopted as a bye-law in place of No. 3 recommendation of the Pharmacy Act Amendment Committee.

Mr. Payne then moved the adoption of the following regulation:—

"To entitle a candidate to pass his final examination he must have a majority of the votes of the examiners, of which that of the examiner in pharmacy must be one."

At the final examination there were three examiners—one in chemistry, one in materia medica and botany, and one in pharmacy. As these regulations at present stood, provided the candidate could satisfy the examiners in materia medica, botany, and chemistry, he could pass his final examination, although he knew little or nothing of practical pharmacy. Now this was not in accordance with the requirements of the Pharmacy Act. It might be urged that it did not occur; but he had been told by an examiner that on one occasion a candidate who was very good in two or three subjects, but could not satisfy the examiner in pharmacy, obtained a certificate. He (Mr. Payne) maintained that in order to obtain a certificate a man should be a good practical pharmacist.

Mr. Wells seconded the motion.

Mr. Allen said he agreed in the main with Mr. Payne's resolution, but he objected *in toto* to the practice of the matter being decided by the examiners giving votes. It should be decided by a maximum or minimum number of marks. The latter had been the practice for years in the English Society. Mr. Bremridge, the Secretary of that Society, had written to him stating that many years ago they followed the practice of passing the candidates by a majority of votes of the examiners, but that it had been found inconvenient and had been abandoned. He (Mr. Allen) would move the following amendment:—

"To entitle a candidate to pass he must make with the examiner in pharmacy a minimum of 300 out of a maximum of 600; with the examiner in chemistry a minimum of 140 out of a maximum of 300; with the examiner in materia medica and botany a minimum of 140 out of a maximum of 300; and he must not have less than a total minimum of 650 out of a total maximum of 1200."

According to this regulation if the candidate had only a minimum in every subject he would not pass because he would only have a total minimum of 580, consequently he would have to pull up in all or some of the subjects in order to qualify. This was the plan adopted in the Pharmaceutical Society on the other side. He (Mr. Allen) knew that the present examiners were in favour of this mode of proceeding—at least Dr. Duffey and Dr. Davy were.

The President said he agreed in the main with what Mr. Allen proposed. When he was an examiner in the University the practice followed there was somewhat similar. A minimum of 40 per cent. passed the candidate in each subject. He (the President) was opposed to any candidate being allowed to pass who was deficient in any one subject, but he also objected strongly to the result of the examination being placed in the hands of any one examiner. So that he was in favour of Mr. Allen's system; at the same time he would suggest that before deciding on the subject they should get a report from their examiners as to their views on the matter.

Mr. Brunker seconded the amendment of Mr. Allen. His scheme had the merit of giving half the total of marks to the most important subject, namely, pharmacy, and of dividing the remainder of the marks judiciously between the other subjects.

Dr. Montgomery said it would be well to defer their decision on the matter until they should have referred it to their examiners and obtained a report from them.

Mr. Payne withdrew his motion, and moved in place of it that the amendment of Mr. Allen be referred to a committee, consisting of the President, Mr. Brunker, Mr. Allen and Dr. Montgomery, with a request that they would confer with the examiners on the subject.

This proposal was unanimously agreed to.

The Registrar read a letter from Mr. Daniel Joseph McGrath, of No. 2, Dublin Street, Carlow, asking whether hardware merchants, oilmen, etc., were at liberty to keep in stock and vend corrosive sublimate and arsenic, and, if not, what protection was afforded in the matter to pharmaceutical chemists?

The President: He should be referred to the clauses of the Act, and informed that we are not in a position to give a legal opinion on the matter.

Mr. Brunker: The police have power to act if there be any breach of the law.

The President: He should also be informed that if any infringement of the law occurs the police should be informed of the matter.

A letter was read from Mr. John Patrick Henry, of 97, Donegall Street, Belfast, in reference to certain observations lately made by the Coroner of Belfast, on the occasion of an inquest there.

The President said the letter, which had only arrived that day, was too important to be discussed then, and had better be postponed to the next meeting.

Agreed to.

In pursuance of a resolution passed at the Annual Meeting of the Society, the following committee was, on the motion of Mr. Brunker, seconded by Mr. Wells, appointed to confer with four members of the Society, not on the Council, as to the best means of making the Society more attractive to its members:—Dr. Collins, Dr. Montgomery, Mr. Hayes and Mr. Grindley.

Mr. John Evans, of Dawson Street, Dublin, apothecary and pharmaceutical chemist, was elected a member of the Society.

A report of the pharmaceutical examination, held on October 4, stated that one candidate had passed, and one had been rejected.

The Council then adjourned.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The second general meeting of the above Association was held at the Royal Institution, on Thursday, October 26, 1882.

The Secretary announced that he had received a letter from the President, in which that gentleman explained that he should not be able to attend. He, therefore, in the absence of the Vice-President, who was out of the town, proposed that Mr. Conroy should occupy that position. This motion was seconded by Dr. Symes and carried by acclamation.

The minutes of the last meeting were read and confirmed and the following donations announced:—The *Pharmaceutical Journal*, from the Society, and the *Canadian Pharmaceutical Journal*, from the Editor.

Mr. A. G. Haddock then read the following paper upon—

Fertilizers.

BY ARTHUR G. HADDOCK, A.I.C.

In a former paper (*Pharmaceutical Journal*, April 22, 1882) I dealt generally with the constitution of plants, and of the manner by which they obtained their nutrition and sustenance. I pointed out that they obtain all their mineral constituents and also their nitrogen from the soil in which they grow, and that in land which has been cropped for a length of time, it is necessary to replace those elements which have been abstracted by the removal of the produce.

We saw that the ash of plants varied very considerably in amount and character, and that different vegetables exhausted the soil of different ingredients, or at all events of the same ingredients in different proportions, and hence the wisdom of adopting a system of rotation of crops. But if this system could be carried to its most successful issue it is perfectly clear that it could not go on *ad infinitum*. There must come a time when this robbery would be impracticable, since every useful article had been abstracted and there was nothing left to afford the slightest nutriment to the plants, which we might vainly endeavour to cultivate.

Coming to the question of the repair of the deficiencies by means of fertilizing materials, I may say that there is no such thing as a specific manure, that is to say, one which would be suitable for any kind of crop, and might be applied to any soil under any circumstances. The nature of the requirements must be studied, and the plant must have food, the constituents of which are the same, and as nearly as possible in the same proportion, as its own. Plants meet with a difficulty which does not obtain with animals, since the appetites and natural instincts of the latter lead them in search of the particular kind of food they require, a convenience denied to vegetables, as they are endowed with a very limited power of locomotion. They have, however, considerable gastronomic taste (if I may be allowed to use the expression) and much prefer a substance which is easy of assimilation to one which they have a great deal of difficulty in digesting. For instance, if you placed in the proximity of a plant which required nitrogen, a little nitrate of soda, a little blood, and some torrefied leather, it would commence its attack on the nitrate of soda, to the neglect of the other two, but if its hunger were not satisfied when this was consumed, it would turn its attention to the blood, leaving the more difficult task of dissolving and absorbing the leather to the less fortunate plant which might succeed it.

It will, then, be seen, in a district which has been heavily cropped, that even if the whole of the nutritive matters have not been removed, those most assimilable must have been abstracted. When this is the case the land must either be allowed to lie fallow for some time, or fertilizers must be added. Except the plant can get at its food in a state of solution during the time of its growth, it is of no earthly use to it. By allowing the land to lie fallow, weathering influence and that of carbonic acid and of water are brought to bear upon the insoluble substances in the soil, so that in time these are rendered soluble and in a condition to be absorbed by the plant. But this would take some time, and the poor British farmer, paying say £4 per acre rent for his land, would likely, before nature had completed this operation, be compelled to "seek fresh woods and pastures new."

The second remedy is the application of fertilizing materials. To be able to say what kind of fertilizer the farmer should use, one ought to analyse the soil to which it is to be applied, and also to know what kind of crop is desired of it. But I am afraid it is expecting too much of the British farmer to think he will pay the necessary fee for obtaining an analysis which he does not appreciate, and which, I sadly fear, he does not believe in.

But although different crops exhaust the land of different substances, we may take it pretty generally that all of these, with the exception of calcium phosphate, alkaline salts, and nitrogen, have been present in such very considerable quantity originally that they will not want renewing, or only at considerable intervals. This statement must be taken in a general sense, and as only involving chemical restitution. Most of the artificial manures in the market are compounded with a view to providing for deficiency in the above-mentioned substances.

Guano is the name given to a large number of artificial and natural fertilizers. Originally this term signified the excreta of sea fowls, and I suppose, properly speaking, does so still, but in ordinary parlance it means pretty nearly anything. The Simon Pure (*i.e.*, Peruvian) guano was found to give such excellent results that it became a very popular article, and was imported in large quantities to this country. The demand for it was so great, and the price so high, that the usual result under such circumstances, adulteration and sophistication, followed, till now the meaning of the word guano has entirely changed, and in fact by itself has practically no signification whatever. We hear, for instance, of Megillones *guano*, which is a *mineral* phosphate of lime, and I have even come across the Alta Vela phosphate designated as guano. The phosphoric acid in the latter phosphate is entirely combined with the oxide of iron and alumina, and is almost worthless.

Then, again, the genuine Peruvian guano is only the ghost of its former self. It retains its distinctive odour, but the amount of nitrogen contained in it has wofully decreased. I do not exactly know what is the reason of this deterioration, but I have noticed that most samples contain a much larger proportion of stones than formerly, which may be attributable to a lower excavation of the deposit. However, it is still a very valuable manure, as it contains both soluble and insoluble phosphate, nitrogen and alkaline salts. The soluble phosphoric acid is combined with soda, potash and ammonia, and the insoluble with lime and magnesia. (The soluble phosphate cannot very well be determined by extracting it with water, as the samples frequently contain oxalate of ammonia, which dissolves some of the insoluble portion. The total P_2O_5 has therefore to be determined, and also the lime and magnesia. These latter are calculated into phosphate, and any P_2O_5 remaining is considered as soluble, and united with the alkalies. But this, by the way.)

The greater portion of Peruvian guano is soluble or readily susceptible to solution in the soil, and is highly stimulative, and must on this account be used sparingly. Another reason why it should be applied in small quantities at a time is that if dealt out with too liberal a hand a portion would get washed away into the drains, or soak into the subsoil, in either of which cases it would be lost. Peruvian guano is very effective on land which is very much exhausted, and should be applied, together with mineral phosphate, rather as a stimulant than a food, and to get the land into good heart, when further applications will be unnecessary. In leaving this, our old friend, I may say that for a soil suffering from ordinary famine, I consider it the premier of fertilizers, and affords us a capital model to imitate.

But as the deposits of natural guano could not yield a sufficient quantity it was necessary to turn attention to other substances which might supply its place, and it is generally considered that, as a rule, artificial fertilizers should contain phosphoric acid, lime, magnesia, alkaline salts and nitrogen. Some chemists, indeed, do not attribute much importance to magnesium salts, as, for instance, M. Ville, in his work on 'Agricultural Chemistry,' recently translated into English by Mr. Crookes, thinks the soil always contains a sufficient quantity, and he has a great opinion of the efficacy of lime, applied as such, or as gypsum. He is also of opinion that the nitrogen of the plant is derived to a large extent from the atmosphere, and that, therefore, the addition of nitrogenous substances to the soil is superfluous.

I was surprised to see this statement, as I thought that question had been quite threshed out, and if the results of the elaborate and careful experiments of Sir J. B. Lawes, Drs. Gilbert and Voelcker, Mr. T Jamieson, and others, in this direction, are not controverted, I think it has been pretty plainly shown that the addition of nitrogen to the soil is a very important factor in the success of the operation.

But all authorities are agreed that phosphoric acid in some form or other must be contained in a fertilizer, and the question then comes as to the mode of combination in which it is to be administered. Almost all natural phosphates yet found are insoluble in water, or very nearly so, and until they can be brought to dissolve in the saline solution and juices found in the soil they are useless, as the plant is unable to absorb them.

Insoluble phosphates of lime, both of mineral and of animal origin, are generally rendered soluble by treating them with sulphuric acid. A quantity of acid is used insufficient to convert the whole of the lime into sulphate, but only two-thirds of it, leaving one-third of it combined with the phosphoric acid, forming a salt freely soluble in water. This compound is called soluble phosphate, or sometimes monophosphate, or again, biphosphate of lime. Why the latter name, which is frequently employed, should be given to it, I am at a loss to see. Insoluble phosphates are thus rendered soluble on a very large scale in this country, and the mixture with the sulphate of lime formed in the reaction is sold under the name of superphosphate. The superphosphate made from bones has been generally regarded as being superior to that made from a mineral phosphate of lime, but unless the mineral contains a large quantity of oxide of iron and alumina, one would think that soluble phosphate was equally valuable, whether it had an organic or a mineral origin. The presence of oxide of iron and alumina in a phosphate is an objection, as the soluble phosphate made from it has a great tendency to revert, or go back into an insoluble form.

There is by no means unanimity of opinion as to whether this reverted or reduced phosphate is as valuable as the soluble variety, but at all events it will not fetch nearly the same price in the market. The processes which have been devised for estimating the amount of the retrograde phosphate are not, to my mind, altogether satisfactory. The method generally adopted is that of first removing the soluble phosphate by lixiviation with cold water, and then treating the insoluble portion with an alkaline solution of ammonium citrate, and reckoning the amount of phosphate dissolved by this reagent as reverted. I have found that a portion of the phosphoric acid of natural tribasic phosphates, such as coprolite, is removed by this process. The ground urged for placing reduced phosphate on the same scale as soluble, is that the latter is converted into an insoluble modification when applied to the soil. This, one would naturally say, is so, since any oxide or carbonate will reprecipitate soluble phosphate; and these are found in every soil.

This theory of reprecipitation before absorption by the plant must, I think, be freely admitted. The idea has of late years been carried further. Admitting the theory, it follows that the insoluble phosphate must meet with certain influences in the soil, which bring it into a state of solution, since it has to be absorbed in this condition by the plant. What causes this solution? In speaking of tribasic phosphate of lime as being insoluble in water, we are not making a statement which is absolutely correct. Certainly, if we placed a lump of mineral phosphate in pure water the amount dissolved, even after digestion for a very considerable period of time, would be quite inappreciable, and the experiment made in this way would appear to justify the usual definition. Again, glass in sheet, if treated with pure water, would remain practically intact, but if we ground the glass to an exceedingly fine powder, we should find that it yielded a weighable quantity to solution. So with phosphates. If they are ground sufficiently fine, it is found that they are to a certain extent soluble. In *pure* water they will dissolve, but the solvent action is much increased if the water contains salts of various kinds and carbonic acid. Such salts are contained in the soil, and so the tribasic phosphate is, to a certain extent, rendered soluble. It would seem, then, that fineness of division is all that is wanted, and all that is gained by making superphosphate. Of course when a soluble phosphate reverts the particles are in an infinitely finer state of division than could possibly be obtained by the most perfect mechanical means. The phosphate would be precipitated in molecules. It would consequently offer an enormously greater surface to the solvent action, and therefore, one would think, should be of greater efficacy.

If fineness of division is all that affects the value of phosphate of lime, one would expect that precipitated phosphate would be as valuable as soluble phosphate. By precipitated phosphate, I mean the article which is sold under that name or under the title of bone extract, and which is made by dissolving tribasic phosphate in acid, and adding lime until all the phosphoric acid is precipitated. In this country it is generally made from bone ash, but I should think that mineral phosphate would do equally well, and that the reason it is not used is on account of the popular prejudice against phosphates of a mineral origin. Sufficient lime is not added in the precipitation to convert it into tribasic phosphate, but generally only enough to form bibasic, and occasionally only a mixture of the latter and monobasic phosphate, so that it frequently happens that if the phosphoric acid found on analysis is calculated into tribasic phosphate (the usual way of stating it) the result shows more than 100 per cent. It is, therefore, necessary to give the amount of lime and of phosphoric acid separately.

As this form of manufactured phosphate is coming more into favour, I thought I would look up the different experiments which have been carried on with it comparatively with soluble phosphate, and I was surprised to find that there is a wonderful consensus of opinion with respect to its value. The reason of my surprise was that there is usually a very perplexing conflict of statements with regard to the relative efficacy of any particular kind of manure. Anyone need only refer to recent literature on agriculture to satisfy himself as to the truth of this statement. However, authorities seem generally agreed in giving high rank to precipitated phosphate, some chemists attaching a higher value to it than to soluble phosphate. Mr. T. Jamieson, of Aberdeen, gives a relative value to soluble phosphate of 12, and to precipitated phosphate of 13, bone ash being 10. This was after six years' careful experimenting. At the International Congress of the Directors of Agricultural Experimental Stations, held in Paris a short time ago, M. Maercker, a director, stated:—"In general, precipitated phosphate of lime employed in the same quantity as soluble phosphate in average soils in good condition has shown itself equal to the soluble phosphate." M. L. Grandeau, the Commissary-General of the Congress, rejoices to hear this expression of opinion from so eminent an authority, as he himself holds the same opinion. He says:—"The experiments of M. Petermann, at the station of Gembloux, and quite recently those also at Halle, published by M. Maercker, clearly confirm the results of my eight years' experience, viz.:—That the crops yielded by equal quantities of phosphoric acid given to plants in the form of superphosphate and in the form of precipitated phosphates are obviously equal." M. Grandeau has experimented on yellow turnips, swedes, oats, grass, potatoes, beet, rape, rye, wheat, barley, maize and oats.

I think that the manufacture of precipitated phosphate will greatly extend, and if so, we shall not be so much troubled with the question of reverted phosphate.

Mr. Thomas Jamieson, F.I.C., to whose researches I have once or twice referred, is the chemist to the Aberdeenshire Agricultural Association, under whose auspices he has conducted a series of experiments with fertilizers, extending over a period of six years, and the results are embodied in the sixth annual report of the Association, a copy of which I am indebted to his courtesy for. These experiments have apparently been very carefully conducted, and that he has not twisted the facts to suit any pet theory he might have formed is proved by his having arrived, at the end of each year, at certain conclusions which he regarded in a tentative manner, and some of which he has much modified. Mr. Jamieson now, however, considers that he has got sufficient weight of evidence to justify him in giving a definite relative value to the different forms of phosphate and nitrogen. As I could not in this paper touch the question of nitrogenous fertilizers, I will content myself with giving his table of the relative value of nitrogen in them, and notice more particularly only the experiments with phosphates.

They have been made by using the system of rotation —the particular one being turnips, oats, grass,—and also, as it was found that the application of phosphates to turnips produced the most marked effect, by cultivating turnips for six consecutive years on the same soil.

I have not space to enter into the minutiæ of the details, which I consider well worth disseminating in agricultural circles, but must confine myself to the general conclusions to which Mr. Jamieson has arrived. These are some of them:—

"1. Non-crystalline phosphate of lime, ground to a floury state, applied to soil deficient in phosphate, greatly increases the turnip crop, and also, though to a less extent, the cereal and grass crops, but always with equal effect, whether it be derived from animal or mineral matter.

"2. Soluble phosphate is not superior in effect to insoluble phosphate, if the latter be in finely disaggregated form, *e.g.*, disaggregation effected by precipitation from solution, or by grinding bones after being steamed at high pressure. In such finely divided conditions the difference is in favour of the insoluble form, in the proportion of about 12 for the soluble to 13 and 14 for the above insoluble forms respectively. In less finely divided form (such as mineral phosphate impalpable powder) insoluble phosphate is inferior to soluble phosphate in the relation of about 10 to 12.

"3. This conclusion has reference to nitrogenous materials.

"4. Fine division (or perfect disaggregation) of phosphates assists the braird nearly as much, and with more healthy results, than application of nitrogenous manure.

"The most economical manure is probably non-crystalline, floury, insoluble phosphate of lime; the cheapest form being mixed with an equal quantity of the form in which the highest degree of disaggregation is reached."

Experiments which have been carried on in Sussex, Kent, and Huntingdon confirm these conclusions very remarkably, so that it would appear that superphosphate is, as a rule, a very expensive form of fertilizer. Mr. Jamieson brings to light another great objection to it as regards root crops, or more particularly the turnip crop.

Turnips are frequently affected with a disease of a fungoid character known as club-root disease, a most distressing affliction to the farmer, as it is liable to spread very rapidly, and renders useless and kills a large portion of his crop. Now Mr. Jamieson has found as an invariable rule that the growth of this fungus is stimulated by the use of manures containing sulphuric acid, and thinks, therefore, on that account alone, they should be tabooed. This indeed seems a fatal objection to the use of vitriolized manures for turnips.

Phosphates maintain their relative values when applied to rotations in these experiments, though in these cases the effect of them is not so clearly seen as with the turnips, as their effect is obscured by the influence of nitrogenous materials which must be employed. The concordance of the figures leads Mr. Jamieson to the conclusion—"That the superiority of soluble phosphate over precipitated phosphate is practically *nil.* In a final summary of the results of the six years' experimenting he enunciates the follow opinions:—

"Dissolved phosphate is ready but rapid, and tends to unhealthy growth.

"Raw bone powder is steady, but slow and costly. Steamed bone flour is ready, steady, but more costly than insoluble mineral phosphate, which is slow but steady, and least expensive."

He recommends for general use a mixture of two extremes—the largest producer, such as steamed bone flour, or precipitated phosphate, together with the cheapest producer, finely ground mineral phosphates.

As a guide to farmers he gives the following relative values for different kinds of phosphates:—

"Phosphate of iron	0
Phosphate of alumina (Redonda)	3
Tribasic phosphate of lime in bone	10
Tribasic phosphate of lime in mineral	10
Monobasic phosphate of lime in soluble phosphate	12
Bibasic or tribasic phosphate of lime in precipitated form	13
Tribasic phosphate of lime in steamed bone flour	14"

Although I have not been able to go into the question of nitrogenous fertilizers, I think Mr. Jamieson's standards of value for some of them deserve quoting here.

"Nitrate of soda	10
Sulphate of ammonia	10
Guano	10
Nitrogen (only) in bones	8
Dried blood	8"

The latest report of the Aberdeenshire Agricultural Association is pregnant with information, and will well repay careful perusal.

The Chairman having made a few remarks upon the value and interest of the paper,

Mr. A. Smetham discussed the subject, pointing out the difficulties experienced owing to the variations of soil and climate, and concluded by moving a vote of thanks to Mr. Haddock.

This was seconded by Dr. Symes, and after a few remarks by the Secretary and Mr. A. H. Samuel, the proceedings terminated.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

On Tuesday evening, October 31, a lecture was delivered in connection with the above Association by Mr. W. B. Clark, on the "Halogens." The subject was handled in a very able manner, each element being brought before the audience in a very instructive light, much to the credit of the lecturer.

A vote of thanks was accorded to the lecturer at the close, on the proposition of the Chairman, Mr. Edwards, after having been seconded by Mr. Garrett.

EDINBURGH CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

An open meeting of this Association was held in the Pharmaceutical Society's rooms, Edinburgh, on Wednesday evening, November 1, Mr. Peter Boa, President, in the chair.

The minutes of the previous meeting were read and confirmed.

The report of the Apprentices' Prize Examination Committee was then submitted. It showed that the competition had been eminently successful; eight candidates had competed, with the following result:—First prize (three months' practical chemistry, under Dr. Macadam), awarded to Mr. George Coull; second prize (value half a guinea), awarded to Mr. G. A. Grierson; special prize (Griffith's 'Materia Medica,' presented by Mr. William Aitken), awarded to Mr. Thomas Stephenson.

On the motion of Mr. J. D. Robertson, the report was unanimously adopted, and a vote of thanks was awarded to the Committee for their services, and to Mr. Aitken, for his donation of the special prize.

Mr. Boa, in presenting the prizes, congratulated the winners on the excellence of their papers. He regretted that the Committee had not power to award more prizes, as several of the competitors well deserved recognition.

An interval of fifteen minutes was then allowed for the inspection of an exhibition of microscopic objects and rare pharmaceutical specimens. Afterwards two lectures were delivered, on "How to Prepare for the Minor," by Mr. J. R. Hill, and on "Practical Pharmaceutical Chemistry," by Mr. Peter MacEwan.

After the members had expressed opinions on these subjects, votes of thanks were awarded to all who had contributed to the success of the meeting, special mention being made of the interesting contributions of Messrs. Hume, Maben and Purves.

The President having intimated that the next meeting would be on November 22, when a paper on "Alkali Manufacture: Old and New Processes" will be read, the meeting was closed.

ABERDEEN CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The first meeting of the Chemists' Assistants and Apprentices' Association was held in the Café Buildings, Ship Row, on Friday, November 3, the President in the chair, when Mr. Ritchie, Market Street, delivered the inaugural address, in the course of which he pointed out the advantages derived from and the best modes of conducting such associations.

The address was highly appreciated by all present.

Dr. Moir, Union Place, made some suitable remarks.

A large and successful meeting was brought to a close by hearty votes of thanks to the speakers.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

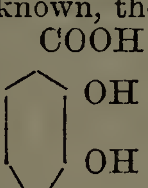
A meeting of this Society was held on Thursday, November 2, F. A. Abel, F.R.S., Vice-President, in the chair.

It was announced that a ballot for the election of Fellows would take place at the next meeting (November 16).

The following certificates were read for the first time:—F. W. Branson, J. S. Bishop, E. E. Berry, R. Blair, R. Coulthard, W. J. Chrystal, T. R. Cowie, R. Carruthers, E. G. Clayton, J. T. Dunn, H. L. Dampier, A. G. Earl, G. Gray, J. L. Howe, A. G. Howard, W. A. L. Hammersley, H. Hotblack, E. Jackson, A. E. Johnson, A. Keen, F. J. Kilner, J. D. McCarthy, H. E. Newton, R. H. Parker, T. E. Peppé, S. E. Phillips, S. Rideal, G. M. Taylor, T. E. Vasey.

Dr. A. K. Miller, then read a paper—

On Dihydroxybenzoic Acids and Iodosalicylic Acids.—Of the six possible dihydroxybenzoic acids five are already known, the sixth acid being represented by the formula



. Two methods were tried for preparing this body:—1. Catechol was heated with concentrated solution of ammonium carbonate in sealed tubes for several hours. The product of the reaction consisted of a mixture of two acids, one of which was protocatechuic acid, the other must be the acid sought for, as this and protocatechuic acid are the only two dihydroxybenzoic acids derivable from catechol. The above reaction gave a very poor yield, and a second method for preparing this catecholorthocarboxylic acid was tried. 2. Salicylic acid and iodine were heated together in alcoholic solution and the resulting iodosalicylic acids purified by crystallization from water. The results obtained differ from those published by Lautermann, Liechti, Demole, etc. It was found that two iodosalicylic acids had been formed, paraiodosalicylic acid melting at 197° and a new isomer melting at 198°. The two differed in crystalline appearance, solubility, etc., but most markedly in yielding two distinct dihydroxybenzoic acids when heated with potash. From the former quinolcarboxylic acid was obtained; from the latter an acid which split up on heating into carbonic anhydride and catechol. The fact of a dihydroxybenzoic acid, derived from salicylic acid, splitting up on heating into carbonic anhydride and catechol is of itself proof that it must have the constitution indicated above. This constitution is however the only one possible for the acid produced together with protocatechuic acid by introducing a carboxyl group into catechol, and since a comparison of the products of both reactions has shown the two to be identical, there can be no doubt that the constitution given is the correct one.

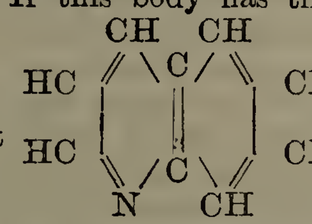
The Secretary then read a paper—

On Crystalline Molecular Compounds of Naphthalene and Benzene with Antimony Trichloride. By WATSON SMITH and G. W. DAVIS.—On melting 3 parts by weight of antimony trichloride, and 2 of naphthalene, minute but perfectly symmetrical clinorhombic tables formed in the liquid, after the source of heat had been removed; these crystals were separated with a warmed platinum spatula. They were very deliquescent and had the composition $3SbCl_3, 2C_{10}H_8$.

A similar compound is formed with benzene, having the composition $3SbCl_3, 2C_6H_6$.

A second communication was also read by the Secretary entitled—

Additional Evidence, by an Analysis of the Quinoline Molecule, that this Base belongs to the Aromatic Series of Organic Substances.—By WATSON SMITH and G. W. DAVIS. The authors have investigated the effect of an exhaustive perclorination, according to the method of V. Merz, on quinoline. If this body has the constitution usually assigned to it



the portion of the compound nucleus containing nitrogen might be expected to be least stable and to yield, when chlorinated, perchlorethane, perchlormethane and nitrogen, whilst the other portion would yield perchlorbenzene

$$C_9Cl_7N + 7\,Cl = C_6Cl_6 + C_3Cl_8 + N$$
$$C_3Cl_8 + Cl_2 = C_2Cl_6 + CCl_4.$$

Pure quinoline was therefore heated in a strong tube of hard glass with ten times its weight of antimony pentachloride to 170°, then to 280°, to 320°, and finally to 400°, each for a space of five hours. After each heating the hydrochloric acid gas and nitrogen were allowed to escape, an operation attended with some danger; a crystalline black mass was the result, which was washed out with hydrochloric acid, and the antimony separated. The residue was dried and sublimed; by resublimation, etc., perchlorethane melting at 182° and perchlorbenzene melting at 223° were separated. No perchlormethane could be detected, but owing to its volatility it was probably carried off in the violent rushes of gas which took place on opening the tube.

The Secretary then communicated a paper on—

Orcin and some of the other Dioxytoluols. By R. H. C. NEVILE and Dr. A. WINTHER.—Various considerations led the authors to the conclusion that orcin was a dioxytoluol of the constitution 1.3.5, a supposition which has since been shown to be true by Tiemann and Streng. The present research was undertaken to discover, if possible, some practicable method for the artificial production of orcin. The starting point was dinitrotoluol, 1.3.5, prepared from dinitroparatoluidine, the yield being 60 to 65 per cent. The dinitrotoluol was dissolved in an alcoholic solution of ammonium sulphide and water added, when an orange-red substance is precipitated. This was dissolved in dilute hydrochloric acid and reprecipitated by ammonia. The nitrotoluidine was purified, converted into nitrokresol, which was reduced with tin and hydrochloric acid. The chloride was dissolved in a hot mixture of equal parts of sulphuric acid and water, the solution diluted with water and a dilute solution of potassium nitrite added. The liquid was then warmed, filtered and extracted with ether. The red-brown oil so obtained was purified by distillation, and the product by crystallization furnished the dioxytoluol, identical in all respects with orcin. The authors have also prepared orcin from metabromotoluol metasulphonic acid and from metadibromotoluol. The authors have also prepared the dioxytoluol 1.2.4 and 1.2.5, and have investigated the preparation of the body 1.3.4. They have tabulated the reactions of the various dioxytoluols with ammonia, chloride of lime, ferric chloride, etc.

On the Varying Quantities of Malt Albumenoids extracted by Waters of different Types. By E. R. MORITZ and A. HARTLEY.—The authors give tables showing the specific gravity of the worts and the percentage of nitrogen extracted by distilled water and waters containing NaCl, $MgSO_4$, Na_2CO_3, Burton crystals, $Ca(NO_3)_2$, etc. The experiments show that distilled water extracts the smallest amount of albumenoids; salt does not much increase the extractive power, but calcium salts, especially the nitrate, have a strong extractive power. The authors, however, conclude that the influence of the extracted albumenoids has been very much overrated, as the differences in results are comparatively insignificant; they attribute the characteristics of the finished produce to the direct influence of the mineral matters on fermention, a subject which they are at present investigating.

Mr. Warington suggested that the authors might have carried their investigations further, and estimated the non-albumenoid as well as the albumenoid nitrogen, the extract might have been precipitated by phosphotungstic acid and the nitrogen determined in the filtrate.

On the Derivatives of Ethylene Chlorobromide. By J. W. James.—The author summarizes his principal results as follows:—When preparing ethylene chlorobromide by passing the gas into a solution of chloride of bromine (ClBr), it is necessary, to obtain a pure product and a good percentage, that the chlorine be passed into the bromide at 0° C., otherwise a substance is formed boiling 3° or 4° higher than pure C_2H_4ClBr, which is useless for the advantageous preparation of ethylene chlorothiocyanate. If an aqueous solution of neutral sodium sulphite and ethylene chlorothiocyanate be brought together in direct sunlight the sodium salt of a new acid, ethylene thiocyanosulphonic acid $C_2H_4{}^{SO_3H}_{SCN}$ is produced. By passing ammonia gas into an ethereal solution of chlorethylsulphonic chloride no amide is formed; with ethylsulphonic chloride, however, the corresponding amide is easily obtained. By the action of neutral sodium sulphite in aqueous solution upon ethylene dibromide or chlorobromide isethionate of sodium is produced with evolution of sulphurous anhydride, in addition to the well-known ethylene disulphonate of sodium obtained by Strecker.

After the thanks of the meeting had been given to the authors for their respective papers, the Society adjourned to November 16, when a ballot for the election of Fellows will be held, and the following papers are to be read:—"Contributions to the Chemistry of Tartaric and Citric Acids," by the late B. J. Grosjean; Contributions from the Jodrell Laboratory, Kew: (i.) "Constitution of Lignin and Bastose," by C. F. Cross and E. J. Bevan; (ii.) "Contributions to the Chemistry of Plant Fibre," by C. F. Cross, E. J. Bevan and S. S. Webster; (iii.) "Action of Nitric Acid on Cellulose," by C. F. Cross and E. J. Bevan; "On the Constitution of some Bromine Derivatives of Naphthalene," by R. Meldola.

CHEMISTS' ASSISTANTS' ASSOCIATION.

On Wednesday, a meeting was held at the rooms, 32a, George Street, Hanover Square, W. Mr. Wrenn, President, in the chair. There was a large attendance.

A paper by Mr. F. H. Alcock on "Subnitrate of Bismuth" was read, which will be published in a future number.

A good discussion followed, in which the President, Messrs. Thompson, Winfrey, Braithwaite, Woods, Millhouse and Palmer took part.

A vote of thanks, proposed by Mr. Phillips and seconded by Mr. Woods, was accorded to the author.

Parliamentary and Law Proceedings.

Pharmaceutical Society *v.* Bradford.

The case of the Pharmaceutical Society of Great Britain *versus* Bradford, instituted in the County Court of Yorkshire, holden at Bridlington, in which the plaintiffs sued the defendant for a penalty of £5, incurred by his having used the title of chemist, has been terminated by the defendant paying into court the amount of such penalty and costs.

Pharmaceutical Society *v.* Rickman.

The case of the Pharmaceutical Society of Great Britain *versus* Rickman, instituted in the County Court of Yorkshire, holden at Malton, in which the plaintiffs sued the defendant for a penalty of £5 incurred by him in having kept open shop for the retailing, dispensing or compounding of poison, has been terminated by the defendant paying into court the amount of such penalty and costs.

Pharmaceutical Society *v.* Fletcher.

The case of the Pharmaceutical Society of Great Britain *versus* Fletcher, instituted in the County Court of Lancashire, holden at Southport, in which the plaintiffs sued the defendant for a penalty of £5, incurred by his having used the title of chemist and druggist, has been terminated by the defendant paying into court the amount of such penalty and costs.

Correspondence.

Citrine Ointment.

Sir,—In the course of an interesting paper upon the "History of Citrine Ointment," published by Mr. Cripps in last Saturday's Journal, the author refers incidentally to the "well-known golden eye ointment" which, he intimates, is a preparation of precipitated mercuric oxide. This fact, if it be such, is quite new to me, my impression being that one of the sulphides of arsenic was the active constituent, and that the only doubt which was entertained upon the subject was the question whether orpiment (As_2S_3) or realgar (As_2S_2) was the specific ingredient, no salt of mercury being indicated. I am quite aware that ointments prepared with the yellow and red oxides are used, like the diluted citrine, as substitutes for the original preparation, but, of course, that does not affect the question of its composition.

Possibly Mr. Cripps may have some further information bearing upon the subject to communicate.

Eldon Grove, Rockferry. J. E. Saul.

Inferior Drugs.

Sir,—In corroboration of Mr. Williams's remarks at the last Council meeting and to give further weight to his views, allow me to state that some weeks ago I was offered a parcel of belladonna root a little below the market value. Upon examination it turned out to be the root of *Scopolia Japonica*, a plant closely allied, it is true, to *Atropa Belladonna*, but the substitution of which for belladonna could be no more justified than the use of hyoscyamus or stramonium.

I think it may be assumed this root was purchased at a cheaper rate than belladonna and if distributed might be used in making official preparations; the evil consequence of such a result needs no further comment.

University College Hospital. A. W. Gerrard.

Percentage of Morphia in Ext. Opii Liquid.

Sir,—Will you allow me to thank Mr. Pickard for kindly pointing out an error in my calculations, which is so obvious that I can only account for it by its being one of those slips to which we are liable when over worked?

Shepherd's Bush. John Woodland.

An Old Subscriber.—You do not say what colour you wish to use, but recipes for making suitable coloured liquids of all colours may be found by referring to the indexes.

W. S. Parrott.—We are unable to give you the formula with certainty. The correspondence respecting "Pil. Philip." will be found in vol. iv., pp. 419 and 440.

F. W. Hollingsworth.—(1) No. (2) The Secretaries are Messrs. Stewart and Chrisp; the Assistant Secretary is Mr. W. W. Reeves.

C. W. Price.—We have failed to obtain any information respecting the preparation, but are not quite certain that we have made out the name correctly.

Communications, Letters, etc., have been received from Messrs. Savage, Bedford, Haydon, Shenstone, Lee, A. T., Euretes, Pulvis.

THE SOLUBILITY OF MORPHIA SALTS.*

BY D. B. DOTT, F.R.S.E.

Before describing my experiments on the solubility of morphia salts, it seems desirable to say something on the general subject of solubility, having especially in view the remarks which were made after the reading of my note at the recent meeting of the British Pharmaceutical Conference.

At the outset we ought to have a distinct idea of what is implied by the expression *solubility*. It is too true, as Professor Attfield has said,† that there is a great deal of "haziness and indefiniteness" about this subject, and the sooner the matter is made clear the better. Of the real nature of solution and of what determines and limits solubility, we know very little. When we say that solution results from the attraction exerted between the molecules of different substances, by which a homogeneous liquid is produced, and that the solubility varies with the temperature and pressure, we are stating very nearly all that is known definitely in this department. However that may be, we are at present only concerned with the methods of ascertaining solubilities, the manner of stating the same, and the sources of error appertaining thereto. Generally speaking, such a determination consists of two stages:—

First. The preparation of the solution.

Second. The estimation of the amount of substance dissolved.

Before going further I should like to quote some sentences from Storer, which occur in the introduction to his 'Dictionary of Solubilities.'

"It may be well to remark here that the text-books do not generally lay sufficient stress upon *the preparation of the solution* of the substance under examination, and yet this is the single fundamental point of a correct determination, the other steps of the process being altogether subsidiary, and in general easy of execution as well as comparatively free from sources of error. It is commonly stated that an exactly saturated solution of a salt may be prepared either by exposing a large excess of the salt to the action of the solvent during several hours at the desired temperature (*method by digestion*), or by heating a mixture of the salt and solvent until a strong solution has been obtained at a temperature higher than that at which the determination is to be made, and then cooling the solution to the desired degree, and maintaining it at this point for some time in contact with crystals of the salt, the whole being frequently agitated (*method by cooling*). Now the latter method, though theoretically correct, is in practice peculiarly liable to error, and great care should consequently be exercised in employing it. It is no doubt true, that as regards most substances, the saturated solutions prepared by either method would finally coincide in composition, provided the cooled solution be allow to stand under proper conditions, for a sufficient length of time. Yet it is often exceedingly difficult thus to obtain normally saturated solutions, even of our most common and easily crystallized salts, within the limits of time which can conveniently be allotted to a single experiment. This depends upon the tendency of the solutions of many, if not of most, substances to an indeterminate supersaturation when cooled from a higher to a lower temperation. This supersaturation is not always to be easily detected unless comparative solutions are prepared by the method of digestion, and the length of time required by any given solution to assume the normal condition is a point not readily ascertained. . . . . Indeed it is my opinion, that next to the impurity of the material operated upon, by which many published statements have unqestionably been vitiated, there is no source of error so grave, none which has so seldom been fully guarded against, or so often altogether overlooked, as this tendency to supersaturation.

"On the other hand, in the preparation of solutions by the method of digestion, a difficulty is encountered in the tendency of many substances, like arsenious oxide for instance, to dissolve with extreme slowness; this can, however, be overcome by the exercise of patience, and in any event admits of being detected and controlled. It would, therefore, appear that when practicable the method by digestion should generally be preferred, at least for temperatures low enough to ensure the experiment against the influence of evaporation. The completion of the solution can always be ascertained by determining from time to time the amount of substance dissolved; the operation being considered finished when the results of two of these tests accord with each other."

My own experience thoroughly confirms the general truth of these remarks, although to one expression I must take exception. I do not think that the *method by cooling* is "theoretically correct" any more than it is practically so. It must be remembered that the solubility of a substance in a given liquid at a given temperature means primarily the proportion of the substance which is taken into solution by the solvent at that temperature; and *not* what proportion is retained at the same temperature after the solution has cooled from a higher temperature. If substances in solution did not undergo any chemical decomposition or physical alteration by heating, or even if they immediately returned to their normal condition on the solution cooling, the two methods would yield identical results. When, however, it is observed that many compounds undergo decomposition or suffer some permanent change when their solutions are heated, it is manifest that in their case the method by cooling is quite inadmissible. Solutions of sugar and of aloïn, for example, are so altered by boiling that however long they may be allowed to stand after cooling they will retain a greater amount of matter than if the solution had been prepared by digesting the substance with the solvent at the lower temperature. No doubt some salts undergo decomposition by contact with water at the ordinary temperature. This is the case with some of the alkaloidal salts and to a certain extent with some of the ammonium salts, as was recently well demonstrated by W. W. J. Nicol in a paper read before our Royal Society. The condition of salts in solution is a very interesting subject, but has only an indirect bearing on the question with which we are now engaged, except indeed in those cases where a precipitate is produced when the salt is dissolved. If citrate of caffeine, for instance, dissolves in water to a certain extent, I think it is quite right to take this as the measure of its solubility, whether or not it exists in solution as citrate of caffeine. As a matter of fact our knowledge of the condition of salts in solution is very limited. There is no proof, for instance, that the hydrates in all cases dissolve as such and do not part with their water; and, as was lately ably shown by spectroscopic observation,* changes take place which were formerly not suspected, on mixing solutions of different compounds. In any case, it is obvious that no more accurate method of preparing the solution is known, than causing the solvent to take up the

* Read at an Evening Meeting of the North British Branch of the Pharmaceutical Society, November 8, 1882.

† *Pharmaceutical Journal*, xiii., 253.

* *Journ. Chem. Soc.*, xlii., 1018.

maximum amount it is capable of dissolving at the temperature at which it is desired to make the determination. When, however, the "method by cooling" is adopted, the case is very different. As formerly observed, there are instances in which well-marked chemical decomposition takes place upon boiling a solution, and as the substance does not return to its original condition when the solution cools, any results obtained by this process are entirely vitiated. Besides the very common occurrence of the dissociation of hydrates by heating their solutions, physical changes may result, by which the determination is rendered fallacious. In some cases the cooled solution never attains the same composition as a cold saturated solution of the same temperature, and in other instances this result is reached only after a long time. In fine, we can never be sure that a determination made by the "method by cooling" is trustworthy, unless a check experiment is performed by the "method by digestion;" whence it is manifest that the latter method ought always to be employed.

Having prepared the solution, we have next to determine the proportion of substance dissolved. In most cases this can be easily done by evaporating a weighed portion to dryness and weighing the residue. All that is essential is that there should be no loss by volatilization, and that the residue has a known composition. The difficulty involved in a substance being volatile may in many instances be overcome by conducting the evaporation at a low temperature, or in other cases by adding a known weight of some body capable of forming a non-volatile compound. When a substance has to be dealt with, which is not amenable to these methods, perhaps the best plan is to add to a weighed portion of the same, little by little of the solvent from a burette, agitating after each addition, until complete solution is effected. It would be superfluous to discuss all the precautions which experience might suggest to meet special emergencies.

In regard to the sources of error in such determinations, it is important to consider the causes of the great discrepancies which occur in the published statements of solubilities. I have not the least hesitation in giving the first place to carelessness. After making all allowances, it must be admitted that some of the information supplied to us in this department is mere guess-work, or at the best the result of experiments so carelessly conducted as to make them of less than no value. When we see a solubility given as anything between "1 in 4," and "1 in 15," we cannot help feeling that "some one has blundered." Another fertile source of error is the presence of impurities in the materials employed, although I must say that I do not attach the importance to this matter which it has received from others. Generally speaking the amount of impurity at all likely to be present in a substance whose solubility was being ascertained would not seriously affect the accuracy of the result. It is, of course, well known that the solubility of a body is often greatly increased by the presence in solution of a second compound, but as a rule this result is only obtained when the impurity is present in considerable quantity, so that no experiment conducted with reasonable care would be falsified in this manner. I am quite aware that the existence in solution of certain foreign matters greatly influences the crystallization of organic compounds; but this fountain of error would only come into play when the determination is made by the "method by cooling," which we have already condemned. Supposing, then, that every ordinary precaution has been observed in making the experiment, through what sources are errors likely to creep in? I think they are principally two. In the first place there is the variation in physical condition. That is to say, that compounds having the same chemical composition may exhibit divergence in their solubilities on account of some difference in structure. I do not here refer to isomers, which one would expect to show such divergence. We have elsewhere discussed the influence of the amorphous state on solubility. It may be laid down as a general rule that a body is much more soluble in the non-crystalline condition than in the crystalline form, so that if a compound is capable of existing in both forms, it will dissolve far more readily when in the former condition than when in the latter, unless it very rapidly assumes the crystalline state. Thus, salts which have been partially fused are sometimes rendered more soluble than normally. In the next place we have to consider that the degree of solubility is very much affected by variations of temperature. Although this fact is well known, and therefore every care ought to be taken to maintain the solution at a constant temperature up to the time of the determination, in practice it is extremely difficult to do so. No doubt, many of the minor discrepancies in accounts of solubilities are due to the temperature having varied in the different determinations.

As regards the manner of stating the ratio of solubility, it is evident that there are two sides to the question. We may either take as our standard the solvent or the substance dissolved. In some cases the former method, in others, the latter, is the more convenient. We may give the number of parts of the substance dissolved by 100 parts of the solvent, or we may give the number of parts of the solvent required to dissolve unity of the substance. Contrary to the opinion of some authorities, I think the latter method is certainly the simpler and better adapted for the purposes of pharmacy, and it is the one I have adopted. It is true that a solubility is sometimes stated—say, as 1 in 10, the meaning being that 10 parts of the solution contain 1 part of the salt. Unless this method of expressing the facts is explained in each instance, it is only likely to lead to confusion. A much more objectionable—indeed, quite inaccurate system, consists in referring parts by weight to volumes of the same denomination, without stating what is intended. For instance, we may see it stated, that 1 part of salicin is soluble in 60 parts of alcohol; the meaning being, that 1 ounce of salicin is soluble in 60 *fluid ounces* of alcohol. The word "part" always refers to weight, unless it is otherwise stated. Perhaps the pharmacopœial dictum of "solids by weight, liquids by measure," has something to do with this form of erroneous expression.

It now only remains for me to give the results of the experiments which I have recently made on the solubility in water of the better-known morphia salts. The determinations were in all cases made by the "method by digestion," and the values given are believed to be nearly correct. The temperature in each experiment was 60° F., and it is, therefore, not mentioned in the following notes. M signifies $C_{17}H_{19}NO_3$:—

Morphia Hydrochloride.

(1). Solution = 92·06 grs. Residue = 3·18 grs.
3·18 grs. $MHCl$ = 3·71 grs. $MHCl.3H_2O$.

$$\frac{92{\cdot}06 - 3{\cdot}71}{3{\cdot}71} = 23{\cdot}81$$

(2). Solution = 78·94 grs. Residue = 2·71 grs.
2·71 grs. $MHCl$ = 3·16 grs. $MHCl.3H_2O$.

$$\frac{78{\cdot}94 - 3{\cdot}16}{3{\cdot}16} = 23{\cdot}98$$

(3). Solution = 128·54 grs. Residue = 4·44 grs.
4·44 grs. $MHCl$ = 5·18 grs. $MHCl.3H_2O$.

$$\frac{128{\cdot}54 - 5{\cdot}18}{5{\cdot}18} = 23{\cdot}81$$

(4). Solution = 164·92 grs. Residue = 5·65 grs.
5·65 grs. $MHCl$ = 6·59 grs. $MHCl.3H_2O$.

$$\frac{164{\cdot}92 - 6{\cdot}59}{6{\cdot}59} = 24{\cdot}02$$

Note.—These determinations were made with different samples. The mean result is:—1 part of the salt soluble in 23·9 parts water.

Morphia Sulphate.

(1). Solution = 118·44 grs. Residue = 4·62 grs.
4·62 grs. $M_2H_2SO_4.2H_2O$ = 4·95 grs. $M_2H_2SO_4.5H_2O$

$$\frac{118{\cdot}44 - 4{\cdot}95}{4{\cdot}95} = 22{\cdot}92$$

(2). Solution = 127·31 grs. Residue = 4·91 grs.
4·91 grs. $M_2H_2SO_4.2H_2O$ = 5·28 grs. $M_2H_2SO_4.5H_2O$

$$\frac{127{\cdot}31 - 5{\cdot}28}{5{\cdot}28} = 23{\cdot}11$$

(3). Solution = 119·98 grs. Residue = 4·64 grs.
4·64 grs. $M_2H_2SO_4.2H_2O$ = 4·99 grs. $M_2H_2SO_4.5H_2O$

$$\frac{119{\cdot}98 - 4{\cdot}99}{4{\cdot}99} = 23{\cdot}04$$

(4). Solution = 100·21 grs. Residue = 3·89 grs.
3·89 grs. $M_2H_2SO_4.2H_2O$ = 4·18 $M_2H_2SO_4.5H_2O$

$$\frac{100{\cdot}21 - 4{\cdot}18}{4{\cdot}18} = 22{\cdot}97$$

Note.—As with the muriate, these results were obtained from different samples. The mean of the four determinations is:—1 in 23·01.

Morphia Acetate.

(1). Solution = 70·01 grs. Residue = 15·20 grs.
15·20 grs. M. = 21·28 $M.C_2H_4O_2.3H_2O$

$$\frac{70{\cdot}01 - 21{\cdot}28}{21{\cdot}28} = 2{\cdot}28$$

(2). Solution = 55·50 grs. Residue = 12·085 grs.
12·085 grs. M = 16·91 grs. $M.C_2H_4O_2.3H_2O$

$$\frac{55{\cdot}50 - 16{\cdot}91}{16{\cdot}91} = 2{\cdot}28$$

(3). Solution = 94·26 grs. Residue = 18·59 grs.
18·59 grs. M = 26·02 grs. $M.C_2H_4O_2.3H_2O$

$$\frac{94{\cdot}26 - 26{\cdot}02}{26{\cdot}02} = 2{\cdot}62$$

(4). Solution = 86·07 grs. Residue = 16·88 grs.
16·88 grs. M = 23·63 grs. $M.C_2H_4O_2.3H_2O$

$$\frac{86{\cdot}07 - 23{\cdot}63}{23{\cdot}63} = 2{\cdot}64$$

(5). Solution = 106·67 grs. Residue = 22·03 grs.
22·03 grs. M = 30·84 grs. $M.C_2H_4O_2.3H_2O$

$$\frac{106{\cdot}67 - 30{\cdot}84}{30{\cdot}84} = 2{\cdot}45$$

(6). Solution = 86·13 grs. Residue = 17·86 grs.
17·86 grs. M = 25·00 grs. $M.C_2H_4O_2.3H_2O$

$$\frac{86{\cdot}13 - 25{\cdot}00}{25{\cdot}00} = 2{\cdot}44$$

Note.—The acetate is the most unsatisfactory salt to work with, on account of the difficulty in having it perfectly neutral. The determinations (1) and (2) were made with the ordinary salt, which contains an excess of morphia. (3) and (4) were performed with a specially prepared salt, which was as nearly neutral as possible. These results ought therefore to be the best. (5) and (6) are determinations made with solutions containing considerable excess of acid. The mean of the six experiment gives the solubility:—1 of acetate in 2·44 of water.

Morphia Tartrate.

(1). Solution = 105·04 grs. Residue = 9·15 grs.
9·15 grs. $M_2C_4H_6O_6$ = 9·83 grs. $M_2C_4H_6O_6.3H_2O$

$$\frac{105{\cdot}04 - 9{\cdot}83}{9{\cdot}83} = 9{\cdot}68$$

(2). Solution = 130·185 grs. Residue = 11·325 grs.
11·325 grs. $M_2C_4H_6O_6$ = 12·17 grs. $M_2C_4H_6O_6.3H_2O$

$$\frac{130{\cdot}185 - 12{\cdot}17}{12{\cdot}17} = 9{\cdot}69$$

Note.—The solubility may therefore be taken as 1 part of neutral tartrate in 9·7 parts of water.

Morphia Meconate.

(1). Solution = 189·36 grs. Residue = 4·86 grs.
4·86 grs. $M_2C_7H_4O_7$ = 5·42 grs. $M_2C_7H_4O_7.5H_2O$

$$\frac{189{\cdot}36 - 5{\cdot}42}{5{\cdot}42} = 33{\cdot}93$$

(2). Solution = 158·63 grs. Residue = 4·07 grs.
4·07 grs. $M_2C_7H_4O_7$ = 4·54 $M_2C_7H_4O_7.5H_2O$

$$\frac{158{\cdot}63 - 4{\cdot}54}{4{\cdot}54} = 33{\cdot}94$$

Note.—These determinations were made with the same sample. They are the only values which differ considerably from those I formerly gave. This result I attribute to the fact that the crystals used in these last experiments were dried by exposure to the air for a short time, while the salt employed in the older experiments was probably over-dried with the aid of heat. The mean of the determinations makes the solubility of the meconate 1 in 33·9 of water.

Since writing the foregoing I have noticed a paper,* by V. Coblentz, on the "Solubilty of Commercial Sulphates of Morphine," which calls for some attention. This pharmacist follows the process of Professor Power, which consists in estimating the sulphuric acid in the solution, and then calculating the equivalent amount of morphia sulphate. It is hardly necessary to say, that we have here a method which is only admissible when the sulphate is pure. If the salt were to contain free sulphuric acid, or a sulphate having a different proportion of acid from sulphate of morphia, the results would be to a greater or less extent erroneous. Mr. Coblentz falls into the same mistake as Professor Power, in so far as he finds the solubility of the sulphate in water by dividing the weight of the solution by the weight of the salt dissolved. This gives the ratio of salt to solution, not of salt to solvent. According to the results given, samples of sulphate from different makers require for solution from 18 to 24 parts of water. No doubt by the presence of certain impurities in small quantity, or from the salt having been over-dried, the solubility of the sulphate will be appreciably increased; but I can scarcely credit that any sample in the market would dissolve in 18 parts of water at 15° C. Regarding what has been remarked of the "variable nature of solubility," I just wish to say that I do not believe that in any true sense of the words there is the least variation about it. If I or others should use impure materials, or make bad observations, the results will doubtless vary; but, given a pure compound and properly performed experiments, the results will always be the same.

* *Pharm. Journ.*, [3], xiii., 330.

I conclude by giving a table showing the solubility of the morphia salts as above described.

The Solubility of Morphia Salts at 60° F.

Acetate . .	1 part is soluble in	$2\frac{1}{2}$	parts water.
Tartrate . .	" "	$9\frac{3}{4}$	"
Sulphate . .	" "	23	"
Hydrochloride	" "	24	"
Meconate .	" "	34	"

THE BEST FORM OF ADMINISTERING PUMPKIN SEED.*

BY L. WOLFF, M.D.

What is the best form of administering the seed of the pumpkin (*Cucurbita Pepo*)?

For the object of this query, to obtain in a pharmaceutical preparation of the seed of *Cucurbita pepo* the best possible results in the most palatable and effective manner for the expulsion of tape-worm, it is absolutely necessary that we should be well acquainted with the drug itself and its proximate constituents, in order to ascertain to which of these it owes its peculiar tænifuge power.

This property seems to be inherent not alone to the common pumpkin (*Cucurbita Pepo*), indigenous to our country, but also to other species of the cucurbitaceæ, such as *Cucurbita occidentalis* of the West Indies, and *Cucurbita maxima*, Duch., and others.

Pepo, though well known for ages as a domestic anthelmintic and tænifuge, was brought to the notice of the profession in 1845, by Brunet, who reported twenty-five or thirty successful cases of tænia treated with it.

Others have since then used this article largely for the same purpose, but only with varying success, as the action of any drug cannot be determined without a thorough knowledge of the principle or principles to which it owes its peculiar efficacy. These must be closely studied before a rule can be laid down for its use, with a view to its uniform action.

Pepo has been repeatedly examined and investigated by many able authorities, but the results have at all times been conflicting as to the nature of its active ingredients. Its general constituents have been uniformly established as fixed oil, starch, cellulose, pectin, and protein compounds. Free fatty acids, sugar, resin, and even a glucoside, have also been claimed to exist therein. To test this latter, I have made an extensive series of experiments, in order to be able to either verify or disprove them. As none of the former ingredients can be viewed as tænifuge in its nature, and this drug itself is such in a marked degree, the inference is that a peculiar principle exists in it to which it owes its remedial property.

Dorner and Wolkowtch (1870) claimed to have discovered in pumpkin seed an alkaloid, which they propose to call cucurbitin (cucurbita?) but which both as an alkaloid, as well as a glucoside, Kapylow (1876) has failed to establish. Slop attributes its action to the oil, of which he gives a description in the *Pharmaceutische Centralhalle*, but advises the use of an electuary of the seed as a tape-worm remedy.

Herard thinks its active principle resides in the kernel, and Lelievre in the gemmule.

Heikel maintains that it is contained in the menisperm, and, to prove it, has given this exclusively, with good effect. Of the resin extracted from it, he gave 75 centigrams in six pills, expelling the tape-worm. This amount would represent 17 grams of the green membrane or 250 grams of peeled seed. In further experiments, about 6 ounces of the perisperm, tegumentum, and testæ were given without result, while 1 ounce of the membrane surrounding the embryo expelled the parasite.

This membrane was found to consist of two layers, the outer of which contained a quantity of resin (one in seventeen).

As opinions of investigators on this subject are so much divided and with a view of presenting a definite answer to this query, I was led to experiment personally, going over the entire field in numerous experiments and observations.

While I found my results to correspond with the nature and quality of the general constituents, I am slightly at variance with Slop and Kapylow in regard to the oil. While I found it to be a glyceride of oleic, palmitic, and myristic acids, I could not detect at any time any free fatty acids in the recently dried seed; nor could I confirm the fractional solubility of the oil in alcohol, and must attribute their results to the spontaneous decomposition of the oil in old seed into fatty acids and glycerine.

While they assert that the expressed oil possessed tænifuge properties, I have not been able to verify this; nor have I observed it in the oil of pepo, which was extracted with petroleum benzine, but found it markedly so in oil extracted with ether or chloroform.

My experiments for the separation of an alkaloid or glucoside have also been unsuccessful, and I must side with Kapylow in claiming an absence of either of these. I arrived, therefore, by exclusion to entertain the views of Heikel as to a resin forming the active principle of the seed, and extended my experiments in that direction. I exhausted a quantity of recently dried and well-comminuted seed with petroleum benzine, previously proven not to extract the active ingredient, and the residue was repeatedly treated with ether, chloroform, and alcohol. The product on evaporation of the menstruum was a soft resin of a greenish brown colour and acrid bitter taste, reminding of the oleoresin of male fern in that respect. Oil which had been extracted with ether or chloroform yielded, on shaking with stronger alcohol, a similar substance. This resin administered in 15 grain doses, certainly possessed tænifuge properties, and I was thus led to regard it as the active principle of pepo. It would seem from this that stronger alcohol is the proper menstruum for preparations of this drug. As the resin, however, as well as the fluid extract, did not prove laxative in my observations, and the alcoholic strength of the latter besides would contra-indicate, in the doses required, its use for children, I examined the emulsion of the seed to determine if, and in what quantities, it contained the resin. I evaporated to this end an emulsion of the seed to dryness and treated it with stronger alcohol, which, after filtration, left on evaporation, a corresponding quantity of the resin, which had evidently been emulsified in the process.

I would, therefore, in answer to the above query, recommend as the most desirable and effective preparation for administering the seed of "*Cucurbita Pepo*" for adults:

First. Fifteen grains of the above-mentioned resin in pill form.

Secondly. One to 2 fluid ounces of the alcoholic fluid extract in broken doses and largely diluted; both of these taken fasting in the morning and to be followed two or three hours afterwards by a dose of castor oil; or better than either of these for children, an emulsion of 1 ounce of the recently dried and finely comminuted seed, and $\frac{1}{2}$ ounce of granular sugar, with 4 ounces of water, in which preparation the natural oil acts as a mild laxative; this to be also taken in broken doses, following closely on each other after a fast of six to eight hours.

The electuary, formed by pounding the decorticated seed into a pulp with sugar, has proved with me not alone unreliable, but presented in many cases serious obstacles to deglutition.

THE BOARD OF TRADE ON THE WEIGHTS AND MEASURES ACT.

AMONG the Parliamentary papers issued during the past week is a Report recently made to Parliament by the Board of Trade as to its proceedings and business under the Weights and Measures Act, 1878. It is satisfactory to learn from this Report that since the date of the previous one no question of importance has arisen with reference to the verification and stamping of the weights and measures used by chemists and druggists, and that in this respect the Act appears to be working satisfactorily. But the Report mentions that a "pharmaceutical chemist" in Edinburgh has been "fined for having unstamped weights used in dispensing poisons," and it further quotes a statement of the St. Pancras inspector that he recently visited thirty-six chemists' shops and in nearly every instance found weights that were unjust or incorrect. It does not, however, appear from the Report whether in these last-mentioned cases the weights alleged to be incorrect were also unstamped, although it must be obvious that the culpability or non-culpability of the persons in whose possession incorrect weights or measures may be found must depend very much upon whether they have complied with the law as far as can be reasonably expected, and secured the verification of an official inspector as to their correctness. This proper and safe course is, we regret to say, not so universally followed as might be expected, and only recently we received a semi-official notification, through a gentlemen who is himself a chemist and druggist, that a large number of chemists and druggists in a certain metropolitan district had up to that time failed to have their weights and measures stamped in accordance with the provisions of the Act passed four years ago, and seemed bent upon compelling the local authority to undertake the unpleasant task of commencing legal proceedings against them for their default. If this be a fact, and the result of sheer neglect, persons thus omitting to bring themselves within the conditions prescribed by law will have only themselves to blame for possible annoyance and ignominy such as are sure to be associated with any charge of being in possession of false weights or measures, since it cannot be said that, as a rule, undue harshness or haste has been shown in the enforcement of this Act. But it may be that some of the weights referred to are used solely in dispensing, and that the persons using them are of the same opinion as a correspondent, whose letter appears this week on another page, that the dispensing counter ought to be exempt from the inspector's visits. This contention will, no doubt, have the sympathy of many of our readers, and the question whether an attempt should be made to secure such an exemption authoritatively is one well worthy of consideration. Meanwhile the prudence of acting as if this exemption already existed appears to us to be very doubtful, for even if it were held that the dispensing and supply of medicines is not of the nature of a trading transaction, it would be difficult for a chemist and druggist to prove on every occasion that weights and measures, kept as a rule in the same shop where trade is carried on, are never used for any other purpose than dispensing.

Other points in this Report are also worthy of notice. It appears that serious complaints have been made to the Board by persons who have been required to have weights and measures, of which the accuracy was not questioned, restamped by the inspectors of the districts in which they were used. It seems strange that the plain provision of section 45 of the Act,—that a weight or measure "shall not be liable to be restamped because used in any place other than that in which it was originally stamped,"—should be thus ignored; but instances of this propensity of inspectors are known to be numerous, and it may be hoped that the official opinion now expressed may help to keep it in check. Questions have arisen as to the mode of stamping iron weights, which usually bear the verification stamp on the plug of lead or other metal by which they are adjusted, but which are sometimes meet with having more than one adjusting plug, each of which is stamped. This latter practice, it is pointed out, is bad, and hardly in accord with the words of the Act, which refer to "a plug." Inquiries have also been made as to the marking and stamping of earthenware measures, which is sometimes carried out by submitting them to the inspector while in the green state and again after firing, and the Board expresses approval of this practice, provided all that prove to be incorrect after firing are either destroyed entirely, or have the verification marks completely effaced. In addition, the subject of false statements of weight or measure placed on made-up parcels of goods exposed for sale has been under the consideration of the Board, and an opinion has been expressed that, except in respect to certain articles and localities which are the subject of special legislation, the proper remedy would lie at common law and that the Weights and Measures Act does not deal with offences of this kind.

As science advances and commerce extends fresh demands are made upon the Department for the creation of new standards, and its attention has been called during the past year to the expediency of adopting, among other things, photometric standards for gas and also to possible means of measuring electricity. It is not quite clear, however, under what section of the Weights and Measures Act authority will be found for undertaking work of this kind, or at any rate for enforcing generally the use of such standards if created, although similar power is to some extent vested in the Board of Trade in connection with various Gas Acts. But probably an extension of this power would be readily conferred by Parliament, as in the case of the petroleum-testing apparatus, under the Petroleum Act, and indeed a hope is expressed that an opportunity will shortly be afforded of laying before Parliament a Bill for consolidating and amending the enactments for regulating measures used in the sale of gas and of dealing with the mode of testing the illuminating power of gas. In connection with the Petroleum Act it is mentioned that an omission has been pointed out by Dr. Foerster, the Director of the Imperial Standards Commission of Germany, in the rules for testing petroleum, where no allowance is made for variations of atmospheric pressure at the time of determining the "flashing point" of an oil. The necessity for such an allowance is shown by the fact that some oils recently tested in London, when the barometric pressure was equal to 29·80 ins., showed flashing points of 89° and 74° F. respectively; but when tested at Buxton, with the barometer at 28·35 ins., the same oils flashed at 86° and 72° F., so that the oil that would have passed in London, as flashing at 74°, would have been condemned at Buxton, as flashing at 72° F., or one degree below the legal standard.

A brief but not very encouraging reference is made in the Report to the metric system. Beyond the verification of metric standards for scientific purposes and the issue of new cards of equivalents of imperial and metric weights and measures there have been no important proceedings or inquiries with reference to it. On the other hand, in Turkey the metric system of weights and measures came into operation, under a decree of the Sultan, on the 1st of March last.

In the appendix are given lists of the counties, boroughs, etc., that have adopted the uniform stamp of verification suggested by the Board of Trade, with the distinguishing number of each, as well as *fac-similes* of the special designs adopted by other local authorities.

THE EXTRACT OF MEAT CASE.

The full report of Mr. Justice Field's judgment in this suit proved to be so very lengthy that we have felt constrained to omit a few passages; but everything material has been preserved, and for all practical purposes the judgment may be considered to be given *in extenso*. It will be seen that the result of the judgment is in favour of the public, and opposed to the virtual monopoly which must have resulted from any decision which protected, in favour of a prosperous and wealthy company, exclusive use of the name of a commercial article.

In reading the judgment it is somewhat startling to find that the invention is attributed, by the Company, not to the late Baron Justus von Liebig, but to the French chemist, Proust, and dated as far back as the commencement of the century. The judgment does not disclose the authority for so attributing the invention, but the statement was made by Dr. Max von Pettenkofer, who gave evidence in the case, in the course of which he said that prepared extract of meat was first invented by Proust, an eminent French chemist, in the year 1801, and that, therefore, Liebig was not the real inventor of extract of meat. Dr. Pettenkofer added further, that the process of making what is now in England called Liebig's Extract, was, on the whole, the same as that known to Proust.

The curiosities of litigation are various, but it certainly is surprising to find that the eminent chemist, Baron Justus von Liebig, who undoubtedly did take credit for presenting to the world a very important discovery and desired that the extract of meat should be called by his name, should appear to have stipulated with the Fray Bentos Company for 2 per cent. of its profits during a period, and it is not less surprising that long after his decease his colleague and bosom friend should come to this country and in a witness box divert from him to a French chemist whatever honour may attach to the discovery.

MUNICIPAL HONOURS.

We notice that among the gentlemen who have recently been chosen to fill the office of Mayor there are several who are connected more or less with pharmacy. At Bolton, Mr. E. G. Harwood, who is still a member of the Pharmaceutical Society, although now out of business, has been chosen; at Brighton, Mr. A. H. Cox has been elected; at Denbigh, Mr. J. H. Jones; at Dorchester, Mr. H. Durden; at Hartlepool, Mr. John Horsley (re-elected); at Leominster, Mr. Michael J. Ellwood (re-elected); at Lymington, Mr. Henry Badcock; and at Peterborough, Mr. J. Whitwell. In addition, Mr. T. W. Atkinson has been appointed Sheriff of the Town and County of Poole, and in Scotland Mr. J. Harvie has been elected Senior Magistrate of Airdrie.

CHEMISTS' ASSISTANTS' ASSOCIATION.

We learn that on Wednesday evening next, the 22nd inst., the above Association will hold a Conversazione in the Banqueting Room, St. James's Hall, in connection with which there will be an exhibition of electrical apparatus, microscopes, etc., and rare chemicals.

Transactions of the Pharmaceutical Society.

NORTH BRITISH BRANCH.

The first meeting of the twenty-ninth session was held in the Society's Rooms, 119A, George Street, Edinburgh, on Wednesday, November 8, at 8.30 p.m.

Mr. Alexander Napier, President of the Branch, in the chair.

The minutes of the last meeting of the previous session having been read and confirmed, Mr. Napier read the following—

Presidential Address.

Gentlemen,—I have, in the first place, to thank my brethren in Council for the honour they have done me in electing me their chairman for the present year. In taking the chair I must rely on your kindness and assistance as I humbly endeavour to discharge its duties, and I am encouraged by the assurance of support from Mr. Nesbit, who has kindly given his services for another year as Vice-President, and I rely on the help of the other members of Council. You know, gentlemen, it is no easy task to come after Mr. Stephenson, who has discharged the duties of this chair so admirably for these five years past. I cannot lay claim to either his qualifications or experience; but such abilities as I have are freely at your service. It shall be my endeavour to keep before me the interests of the North British Branch of the Society and to discharge the duties of this chair so that at the close of the year we may all have the satisfaction of finding that it has been a successful one.

In accordance with time-honoured custom I venture to offer a few opening remarks.

Perhaps the most noteworthy incident in the course of the year, in the world of pharmacy, outside the operations of our Society, was the meeting of the Pharmaceutical Conference, at Southampton, in August, under the able Presidency of Professor Attfield. His opening address was a masterly presentation of various aspects of pharmacy in this country, which were happily grouped under the departments of collection, preparation, and distribution. This address alone will stamp the recent Conference as probably the most memorable which has yet taken place. The scientific papers read and discussed are all valuable contributions to our scientific knowledge. The Conference gave another opportunity for the expression of mutual friendship and goodwill among the members of our common calling. Pharmaceutical gatherings have also been announced in Germany, Austria, and America; and invitations issued to members of other pharmaceutical associations to take part in them. The importance of these gatherings cannot well be over-estimated, whether we consider them in their scientific or social aspects.

I may refer to another set of scientific meetings, less pretentious, but well worthy of our regard—the Edinburgh Chemists' Assistants' Association, inaugurated for the fifth session in this place a month ago. The opening address delivered by their President and the programme of papers promised augur well for the success of the Association during the session. This Association has done good work in the past, and should be taken advantage of by all young men who are able to attend the meetings. In this and similar associations young men are not only educated, but are gradually drawn on to take part in the discussions of the subjects, and the habit is acquired of submitting to paper thoughts upon matters requiring investigation or upon which there are differences of opinion, and courage is gained to express these thoughts in public. These associations of junior pharmacists are nurseries from which the Pharmaceutical Society may confidently hope to draw valuable workers. They give substantial evidence that so far as the scientific meetings of the Society are concerned all the material required for their maintenance may be found within our borders. Among the members of this Association I see the names of some gentlemen whose qualifications are well known to all of us. I am sure I am right in saying it will gratify the Council to find these gentlemen taking part in the Evening Meetings of this Society as well. This remark need not be restricted to those who reside in Edinburgh, but should extend to all who have been associated with us, whether in Edinburgh or not. From time to time members are passing away from us. It is only by the younger men being alive to their duty and coming forward to take the vacant places that the prosperity of pharmacy and of this Society can be ensured.

As pharmaceutical education and examination are destined by a recent decision of the Council in London to receive greater prominence and to be more closely allied to each other than they have ever been in Great Britain, this subject may be said justly to occupy the foremost place in interest with the Society at this time. I am, therefore, induced to give it a place in my remarks this evening.

Pharmacy, to be seen aright, must be looked at as one of the departments of progressive medical science. It is only there the extent of its educational requirements can be estimated. Medical science now demands of those who pursue it enlightened and exact knowledge of the nature and causes of disease and of the methods of treatment. It is important for us to notice how the work of acquiring this knowledge is gone about. It is systematic, comprehensive, and thorough. It is carried on under the best training that can be procured and is tested periodically as it proceeds.

When medicine came to be prosecuted on thorough scientific principles it was found to be expedient to relieve students and practitioners of medicine from the more mechanical and routine duties of collecting, compounding, and dispensing drugs. The expediency and utility of this separation is witnessed to by the special position of pharmacy being now almost universally recognized. The ever-increasing demands upon practitioners of medicine for exact knowledge of the causes and nature of disease and for intelligent action in counteracting it, appeal for increased scientific knowledge in pharmacists.

Medical science, not satisfied with present attainments, is ransacking every repository of knowledge in quest of agents to combat the diseases common to men and animals. This science holds in Britain a distinguished place because of the thoroughness of instruction in our medical schools, the ability of its teachers, and the number of students who willingly devote their energies of mind and body to the mastery of the studies assigned to them.

Aware of the importance of thorough instruction, the State has declared for curriculum in elementary and general knowledge, by giving its awards according to results ascertained by attendances and examination.

The recent resolutions of our Council prescribing a compulsory curriculum to be imposed on all persons who are to have any legal standing in pharmacy is designed to ensure in the pharmacists of the future in this country such an amount of familiarity with the principles and facts relating to pharmacy as shall make them theoretically as well as practically masters of their art. The standard of knowledge for students of pharmacy in this country ought not to be behind the average standard in other countries. It should not be set at the point where acquaintance with the routine of pharmaceutical details and mechanical compliance with defined instructions is guaranteed. This is the more necessary from the growing objection to large doses of crude forms of medicines, and the corresponding tendency to eliminate all inert matter and administer medicines in the highest possible state of concentration. Errors in dispensing increase in proportion to the concentration of the drugs, and call for intelligent knowledge of their nature and properties in those who compound and dispense them.

There is also a wide field of labour, not more than fairly opened up, lying before the rising generation of pharmacists. There is a vast amount of work valuable to medical science and to pharmacy which can only be carried on to purpose by men who prepare themselves for it by liberal scientific instruction. This the compulsory examination under the Act of 1868 has hitherto failed to accomplish. The Council of the Society, after much observation and experience, came to the conclusion that the proposed curriculum is not only desirable but necessary. The Examiners found in very many cases that the general mode of preparation for examination in the special subjects of scientific study was imperfect and not founded upon any systematic or comprehensive plan.

Examination of itself revealed the fact that the knowledge hitherto acquired by many candidates was too superficial and too hastily imbibed to exercise a permanent influence on the reflecting powers; that it had been taken in in too crude a form for assimilation. The remedy which the Council have sought out and adopted for the purpose of rectifying this state of things begins with a compulsory examination in elementary knowledge before entering on apprenticeship. By adopting this measure the greatest hindrance to pharmaceutical study and progress will be taken out of the way.

Next to a compulsory Preliminary examination before apprenticeship, the Council has decided for compulsory and systematic instruction in theoretical chemistry, botany and materia medica, with practical instruction in chemistry. No one can doubt that this is the best means of insuring thoroughly intelligent agents for the general work of our profession, or that the highest interests of pharmacy and medicine can well be secured without it. Pharmacy in Britain, as shown by Mr. H. J. Möller, in his "Remarks on Modern Pharmaceutical Study," in the *Pharmaceutical Journal*, pp. 160, 258, and 379, vol. xii. (1881–82), and by Professor Attfield, in his able pamphlet on 'Education and Examination,' stands alone, in respect that it has as yet made no compulsory demand upon its students for systematic public instruction.

The average time devoted to general pharmaceutical education on the Continent may be said to be about three years, subsequent to three years of practical work in a pharmacy. The time must come when pharmaceutical students in Great Britain also will have to devote a certain time exclusively to scientific education. The present system, or no-system, of having an engagement in a pharmacy and attending lectures and studying privately in by-hours is unsatisfactory to the students and to their employers. It involves loss to both. The progress made in recent years in many branches of art is largely due to the application of chemistry and physics. Those who are to direct these require to take public instruction in chemistry and physics. Chemists and druggists may then fairly be expected to know something about chemistry, and may also be supposed to be able to turn such knowledge to practical account—be able to make it commercially valuable. It is only reasonable, too, that those who are to prepare and distribute poisonous drugs should understand materia medica, and botany so far as it relates to materia medica. In a word, what the rest of Europe and America has not only decided should be done, but is doing, Britain cannot but comply with; especially when the thing about which there is unity of action is education. In the words of Matthew Arnold, "Europe is to be regarded as now being, for intellectual and spiritual purposes, one great confederation bound to a joint action, and working to a common result.'

Only to those who have received years of public instruction is the work of pharmacy entrusted on the Continent; and to persons possessed of such qualification only is it intended to delegate the distribution of poisonous drugs in Britain. The course of public instruction required by the Council is stated to qualify for the "Minor," and differs little from that for "Graduates in Pharmacy" in Europe and America. In the meantime, no more extended and comprehensive course is announced as a "Major" standard for "Masters in Pharmacy" or "Pharmaceutical Chemists."

Pharmaceutical students have to remember, in view of the demands made upon them, that all other professions affecting culture can only be entered by the portal of a special training. Those who enter the drug business in future without complying with the compulsory requirements of the curriculum must be prepared to remain permanently in a subordinate position without the power of becoming principals.

It has been said that expediency dictates that curriculum should be introduced gradually, rather than all at once. The proposal of Professor Attfield was that a public system of pharmaceutical education should be arranged to meet the practical needs and requirements of a not too remunerative calling: a public system tentatively and gradually applied at first it may be to the Major only. Past experience points the other way. The Medical Act of 1858, the Education Act, the Act affecting Law Agents, the Dentists Act, and others, were introduced at once, with due regard to existing interests. The changes proposed by our Council may have to be introduced in the same way.

Experience fortunately proves that increased stringency of admission to the before-named professions has in no way diminished, but, on the contrary, has augmented the number of candidates, and the quality of brain-power offered. The necessity for advance in education is admitted on all hands. Its importance to pharmacy cannot be over-estimated.

This being a uniform experience, pharmacy should form no exception. By making the whole course of instruction at once compulsory, better provision may be made for imparting it; and students would have at once to devote a year or more to public training. If the course of instruction may be taken at intervals, to allow of students engaging in practical pharmacy, then it will be desirable to divide the examinations for the "Minor" into two sections, giving two chances to pass in all subjects, and in the case of failure, to impose a fresh course of study in the subjects in which they are deficient.

It is doubted by some whether a sudden withdrawal of entrants who aim at taking a first place in pharmacy may not result in the need for the introduction of unskilled labour in greater amount than heretofore into practical work. While they see the necessity for an advance in the amount of scientific knowledge which pharmacists should possess, up to, and even beyond what is to be required by the curriculum, they have a fear that while the qualification is being elevated at the one end it may be lowered at the other. It is to be hoped that the labour necessary for the work of pharmacy may suffer no depreciation in intelligence by a sudden introduction of curriculum.

The aim of all legislation relating to pharmacy, whether by the State or the Executive of the Pharmaceutical Society, is to render it more than ever a potent and reliable factor in public-health.

But, now that compulsory curriculum is to be a fact, the consideration is not so much as to the drawbacks attendant on its introduction, for in time these will adjust themselves. It is more important to consider by what agency the work of public instruction is to conducted. Where? By whom, and at what cost? and to be assured that when the results of the new system become visible it will be found that pharmacy is a better aid to medicine; that pharmacists better perform their duties to the public; that they are more respected and better remunerated for their services. There is no doubt the Committee entrusted with the maturing of the details of the compulsory measure will devise means to meet the occasion; as they may be presumed to be fully alive to the situation, and to the necessity for increased facilities for obtaining sound education. This work may have to be commenced at first in some of the leading centres. In Germany pharmaceutical education is conducted in twenty different Universities, viz., at every University in the State. Our model school in Bloomsbury Square is invaluable; but to very many young men engaged in pharmacies, even in London, it is inaccessible under present circumstances. When, however, practical work has to be abandoned for a season, for the right fulfilment of the course of public instruction, students will most consult their own good and that of pharmacy by repairing to the most thoroughly equipped school. Apart from the superior advantages of the school, there will be an opportunity, perhaps with many the only opportunity, of studying men and things in the greatest centre of human influence at the present day; an experience which would be of life-long value.

The wants of the provinces may be met by arranging for the necessary instruction being given in some of the principal centres of population: in Edinburgh, Glasgow and Aberdeen, for example, so far as Scotland is concerned. And the teachers, for the most part, will have to be the teachers in existing schools of medicine, or persons who have been trained in pharmacy schools at home or abroad.

The questions are put, "Will the Society institute such instruction?" and, "Can the funds of the Society subsidize public education in pharmacy?" In other professions students have to bear the cost of their public instruction, except in the cases of those who obtain bursaries. The Pharmaceutical Society may have to consider how far it can in this way aid higher education.

In the general absence of pharmacy schools in the past throughout the country, it is not to be wondered at that outsiders should, from a commercial point of view, have set themselves to meet the demands for preparation for examination; neither need it be wondered if only as much meat is put into the pie as will stave off present requirements and yield a good return for the undertaking.

It need not be surprising, either, that pharmaceutical students whose time is taken up with practical business, and who cannot well afford to throw themselves out of employment, should run to the shop where the ready-made article can be obtained, even if it is known to be unsatisfactory and ill adapted to the purpose of an education, which after-experience demonstrates to be a misfit. Pharmaceutical students have hitherto been placed in an unfair position in this respect, and are entitled to sympathy more than censure in seeking out the short cut to a pass in examination, injurious as it is in every respect.

Had time and circumstances permitted, I might have considered this subject as bearing on the questions of apprenticeship, remuneration, and the supply of drugs in thinly populated districts, when the people's medicine man,—the old chemist and druggist,—imperfect as he is, may give place to a yet more imperfect packet system of supply—imperfect because of the perishable nature of drugs. I might also have spoken of the pharmacist as the custodier of poisonous drugs, and of the right of the people to demand the intelligence of the seller in purchasing them. But I am satisfied that the most experienced and judicial minds have been, and still are, engaged in the consideration of these matters. I should not have thought of enlarging on the subject of curriculum, after the very full consideration it received when brought before you by my predecessor in his opening address last session, were it not to keep it before the minds of our younger brethren, whom it will certainly most affect. Last year it was a thing of contemplation; this year it has matured into fact in all but its details. The resolutions of the Council vitally concern the whole constituency. It is, therefore, desirable that they be kept before the notice of the Society and the public; and that they be heartily endorsed by us all. I, for one, will rejoice to know that those who comprise our apprentices and assistants throughout the trade at the present time approve, as Professor Attfield found most of the pharmaceutical students in the south with whom he conversed approved, of a compulsory course of scientific instruction such as the Council have adopted as the only way of entrance to pharmacy. With the hearty co-operation of the younger portion of the body, the educational difficulties which appear to beset pharmacy would be greatly modified, if not altogether removed.

Before closing, let me make a remark or two about the Evening Meetings. Happily under their influence the petty jealousies which prevailed before their institution are year by year disappearing, and a growing disposition is manifested by members for interchange of thoughts on pharmaceutical subjects. Of this we have had notable evidence in the papers read before this Branch of the Society in past years. One pleasing feature in connection with the discussions which have followed the reading of papers is, that they have often resulted in further investigations and more papers. The days have passed when men can live in a state of isolation in the prosecution of a common calling. There must be intercourse of men, and interchange of thought, and a spirit of common brotherhood—a desire to help one another. It is in this spirit that pharmacy can alone advance and keep pace with the other departments of medicine. It is this spirit that will furnish for our Evening Meetings profitable subjects for discussion, and temper criticism with a kindly moderation.

It has been grateful to observe the presence of this spirit in a marked degree in the remarks made by members upon the papers read at our Evening Meetings. If I would offer any observation now on this point, it would be that not unfrequently out of a modesty that is not wise, many who had opinions on the subjects under discussion have held back and refrained from speaking. This has arisen to some extent from the presence of those who from long usage had, from the foundation of the Branch, taken a conspicuous part in all its business being counted on to conduct the discussions. This—if not wise—was at least a high tribute to the worth of those to whom this duty and many more were intrusted. But the time has come when younger men must put their shoulder to the wheel, if the chariot of pharmacy is to make real progress and be in its place in the line of march with other branches of the arts and sciences which are to ameliorate the condition of mankind; especially if we desire to be helpful to that section which has set itself the task of preventing or mitigating human suffering.

Your Council desire that these Evening Meetings may prove highly instructive and agreeable to all, more especially to the younger members, so that if at a future time they come to be far removed from these rooms and this city, they may have cause to think gratefully of the evenings spent in this place. And, if they have begun to contribute pabulum for these meetings when on the spot, they may be encouraged to continue the good habit, and come up with, or send occasionally, notes on matters in pharmacy to be read and discussed. Such notes from brethren at a distance will, I am sure, be listened to with interest, and, in the discussions and results which follow, labourers will have their reward. They will thus feel that though separated from the centre they are yet present and potential.

In this I presume to express the mind of the Council; but, for the remarks I have made on the subject of education, I must be personally responsible.

Gentleman, suffer me to say a word for the Benevolent Fund, and then I have done. During the last year, as you are aware, a special effort has been made on behalf of our Benevolent Fund, which has been so successful that the Council were able at last meeting to make arrangements for electing six additional annuitants, bringing up the number of them to forty-two, each of whom receives, as you know, £30 or £35. I am glad to say that Edinburgh was not behind in this matter. My predecessor, as you will recollect, made an eloquent appeal in its behalf in his opening remarks last year; and this was followed up by energetic action on the part of himself and Mr. Young, and the result was even beyond expectation. My principal object in referring to the subject is to impress on you that the interest then awakened to be of any practical avail must continue from year to year. No one should withhold from subscribing because of the smallness of the amount it is convenient to give. A shilling or half-crown, from one, may be more than a guinea from another, when measured by the means of the givers. It is often the smallest things that accomplish most; the smallest things often repeated. And those who give a shilling when they can may be trusted to give more when convenient for them. Whether it be owing to Scotch thrift and independence, or to ignorance of the benefits at command, very few Scotch members have ever availed themselves of the Benevolent Fund. But, when a call has been made, it has always been freely responded to. Here as elsewhere "it is more blessed to give than to receive."

Mr. Young, in proposing a vote of thanks to the President for his address, remarked, that he was sure that the meeting had listened to it with much pleasure. Referring to the remarks on the Evening Meetings, he urged that the young men when qualified should identify themselves with the Branch, and give their fellow pharmacists the benefit of the experience which they had acquired in the course of their studies. He felt it unnecessary to comment in detail on the topics which the President had considered, but he might remark that a very able Committee was considering the whole question of compulsory pharmaceutical education, and this Committee, he had no doubt, would consider the opinions expressed in the provinces. In concluding, he emphasized the appeal for contributions to the Benevolent Fund, and hoped that all persons interested in pharmacy would contribute to it.

Mr. Stephenson supported the vote of thanks.

Mr. Dott then read a paper on "The Solubility of Morphia."

Dr. Inglis Clark said that the remarks which Mr. Dott had made on the solubility of morphia salts were very valuable. The whole question of solubility was wrapt in mystery, yet such observations as Mr. Dott's greatly favoured elucidation. He had drawn attention last session to the mechanical action of carbonic acid gas on the separation of caramel from a saccharine liquid; since that time he had observed that the pungent principle of ginger is thrown out of solution, or rather that it is brought to the surface of a tumbler of ginger ale, in the same circumstances. He remarked that Mr. Dott's experiments on the morphia salts were very valuable, and were a worthy contribution to the literature on the subject. The author deserved their thanks, and he had pleasure in moving that this should be accorded to him.

Messrs. Boa and McEwan supported the motion, and commented upon the introductory portion of the paper.

The Secretary to the Branch then announced the following donations:—

To the Library.

Year-Books of Pharmacy, for 1876 and 1879.
From the British Pharmaceutical Conference.

Six parts, *Journal of the Chemical Society*.
One part, *Journal of the Royal Society*, and
One part, *American Pharmaceutical Journal*, to complete volumes.
From the Pharmaceutical Society.

Twelve parts, *Journal of the Chemical Society*.
From Mr. G. D. Mackay, Edinburgh.

Eberle's 'Materia Medica,' vol. 2.
From Mr. Edwin Jones, London.

American Pharmaceutical Association, Proceedings, 1881. From the Association.

Smithsonian Institution, Report for 1880.
Smithsonian List of Foreign Correspondents.
From the Institution.

Massachusetts College of Pharmacy, Catalogue.
Philadelphia Alumni Association, Report.
Toronto School of Medicine, Report.
Victoria Pharmaceutical Society, Register for 1881.
Victoria Pharmaceutical Society, Pharmacy Act.
From the respective Publishing Committees.

Canadian Pharmaceutical Journal, January to October. From the Toronto College of Pharmacy.

To the Museum:—

Gadus morrhua, liver oil, specimens of British, Norwegian and Newfoundland products.
Gadus aeglefinus, liver oil, first and second extractions.
From Messrs. Carr and Sons, Berwick-on-Tweed.

Aspidium Filix-mas, large rhizome.
From Messrs. T. & H. Smith and Co., Edinburgh.

Thirty specimens of Indian Medicinal Plants from the collection of Dr. Trimen, Ceylon.
From the Pharmaceutical Society.

Herbarium Specimens of Indigenous Plants.
From Mr. Thomas Stephenson, Edinburgh.

Iodide of Bismuth, three samples.
From Mr. J. R. Hill, Edinburgh.

Sulphate of Magnesia.
From Mr. J. P. Coats, Leith.

Mr. MacEwan remarked that the herbarium specimens of Indian plants sent by Mr. Holmes were a valuable contribution to the Museum, and perhaps they were of more than usual interest from the fact that they were from the collection of Dr. Trimen, who was associated with Professor Bentley in the editing of 'Medicinal Plants.' The specimens with the fruit attached were very good, particularly *Canarium commune*, *Coffea Arabica*, *Coffea liberica* and *Toluifera Pereira*. Of the other specimens, six plants belonging to Zingiberaceæ were very interesting, and the specimens of *Cinchona succirubra*, *Croton Tiglium*, *Maranta arundinacea*, and a few others would prove very acceptable to many students. He hoped that more students would follow Mr. T. Stephenson's example in contributing their duplicate specimens of indigenous plants. The specimen of male fern rhizome was an exceptionally large one,—nearly 10 inches long and 8 inches in diameter. Attention was also drawn to the specimens of fish oils and the other contributions on the table.

Mr. Stephenson moved that the thanks of the Branch be accorded to the donors. This was agreed to with acclamation.

The meeting then adjourned.

Parliamentary and Law Proceedings.

Pharmaceutical Society of Great Britain *v.* James Kelsall.

This case was tried at the County Court at Stockport, on the 10th inst., before T. Hughes, Esq., Q.C., Judge.

Mr. Yates, instructed by Messrs. Flux, Son and Co., appeared for the plaintiffs, and Mr. Brown (Brown and Ainsworth) appeared for the defendant.

Mr. Yates said: May it please your honour, this is an action brought by the Pharmaceutical Society of Great Britain to recover from the defendant, James Kelsall, a penalty of £5 for an infringement of the Pharmacy Act passed in 1868. By a section of that Act it is enacted that from and after the 31st of December, 1868, any person who shall take, use or exhibit the name or title of "chemist and druggist," or "chemist" or "druggist," not being a duly registered "pharmaceutical chemist" or "chemist and druggist," shall, for every such offence, be liable to a penalty of £5 to be recovered in the way prescribed by the Pharmacy Act. The circumstances of the case are these:—The defendant had a shop in Sandy Lane, Stockport, and over the door he had a notice "Kelsall, Analytical Chemist." He also had numerous handbills published, in which there was the heading "James Kelsall, Analytical Chemist." Of course it is of the highest importance that people who are not duly qualified should not be allowed to act as chemists, and exhibit over their door the title of chemist. A chemist, duly registered, is allowed to sell poisons and other dangerous drugs, and, therefore, it is of the very greatest importance that people in this line, especially those who deal largely with the working classes, shall be duly qualified to dispense these dangerous drugs. This gentleman, having the words I have given you over his shop, is written to by the Society, and his answer is certainly a somewhat curious one. The answer is filed as part of his defence to-day. He said that when he used and exhibited the title of "analytical chemist," he was not infringing the Act of Parliament.

Mr. Brown: No.

Mr. Yates: I say that the defendant said "that when he used the words 'analytical chemist' that it was not his intention to act contrary to the provisions of the Pharmacy Act." The question is, did he use or exhibit the name? The Act says nothing at all about the intention—not a single word. In his letter which he writes in reply to the one received from the Registrar of the Pharmaceutical Society, the defendant sets up another extraordinary contention. He says, practically:—I know the Act well. I have not used any of the terms which are forbidden by the Act, because I have put before the word "chemist" the word "analytical." That is an extraordinary defence indeed.

Mr. Brown: I dispute your rendering of the defence to be set up.

Mr. Yates: It is plain from his letter, which distinctly implies this:—The title I do assume and use is that of "analytical chemist." And this he contends is not within the meaning of the Act. The whole question for your honour is, did he use the word "chemist." If the defendant had called himself an "analytical person" we should have said nothing at all to him, but having used the words "analytical chemist," he therefore infringed the Act, he made use of a title he was forbidden to use, and therefore incurred the penalty. The facts of the case are very short and simple.

Mr. Brown: I will admit the facts.

Subsequently it was decided to hear the evidence.

Thomas William Stroud, managing clerk to Messrs. Flux, Son and Co, 3, East India Avenue, London, E.C., was examined by Mr. Yates.

On the 14th of October last did you go to the shop of the defendant in Stockport?—Yes, I did.

Did you see exhibited over the doorway his name and title of business?—Yes.

Where was it particularly?—On the fanlight, a glass fanlight.

What was it?—"Kelsall, Analytical Chemist."

You say it was on the fanlight?—Yes.

Did you go into the shop?—Yes, I went into the shop and bought some glycerine.

Did you see anything on the counter, any bills, handbills of any sort?—Yes, I saw some bills, one of which I have got (handed to the Bench).

Do you know the person who sold you the glycerine,—did you speak to him?—Yes.

Did you ask him if he was Mr. Kelsall?—Yes.

And what did he say?—He said he was Mr. Kelsall, and in the course of our conversation he told me that he was an analytical chemist.

And you took the bill, which has been produced, from the counter?—Yes.

I believe there is the same notice to-day of the name and business on the fanlight?—Yes.

In fact, I believe you have been this morning?—Yes.

I believe that the Secretary of the Pharmaceutical Society is Mr. Elias Bremridge. I mean the Registrar to the Society?—Yes.

In August last he wrote to the defendant.

Mr. Brown: I object to the answer.

Mr. Yates: Do you produce as per notice?

Mr. Brown: I produce nothing.

His Honour: Then you can prove in the ordinary way.

Mr. Yates: The defendant was written to in August last by Mr. Bremridge, and in reply, on the 15th of August, the defendant wrote back:—"I have the honour to acknowledge the receipt of your communication of the 12th inst., wherein you state that representations have been made to you, as the Registrar of the Pharmaceutical Society of Great Britain. that I am acting in contravention of the provisions of the Pharmacy Act of 1868, by the use of the title 'chemist,' and calling on me to offer an explanation as to the representations which have been made to you. In reply I have to state that you have been wrongly informed. I have not assumed or used the title 'chemist,' or 'chemist and druggist,' or 'druggist or 'pharmacist,' or 'dispensing chemist or druggist,' or 'pharmaceutical chemist' within the meaning of the said Act. The title I do assume and use is that of 'analytical chemist,' a profession I have practised for sixteen years, and which I am advised is without the jurisdiction of the Pharmaceutical Society." In reply to that, Mr. Bremridge wrote:—"Referring to your communication, I have to inform you that the use of the title 'chemist' in any form whatever by you is illegal, and I must request that the infringement be at once discontinued." By this letter of the defendant's he forced an issue, and when he asked if the explanation was satisfactory, he was told that it was not. (To witness.) Do you know Mr. Bremridge?—Yes.

He is acting every day as the Registrar of this Society?—Yes.

Was he present at his office yesterday?—I saw him yesterday at the office of the Society.

Do you produce the Register of Pharmaceutical Chemists?—Yes.

Just look and see if the name of the defendant appears?—It does not.

And that Register by the provisions of the Act is evidence?—Yes, it is.

Mr. Yates: I have no other questions to ask.

By Mr. Brown: You say that you noticed the words "analytical chemist?"—Yes.

Did you see the word "laboratory?"—No.

I mean when you went the first time?—No. Nor did I see it this morning.

Mr. Brown: I understand it is there.

The Defendant: It is.

Witness: I did not see it.

And you have come down from London to prove what you saw at his shop?—Yes, and what I got by the handbill.

Exactly. In the Register now produced there is no register of analytical chemists?—No, not as such.

Just look if you can find the name of Mr. Oswald Wilkinson, analytical chemist—analyst for the borough of Stockport?—There is no such thing.

I want you to look though. Is there a person of the name of Oswald Wilkinson. Is he registered?—Not as a chemist and druggist.

In any way whatever?—No, sir.

Next, look if you can find the name of Mr. Carter Bell, the analyst for the County of Chester.—I cannot.

You cannot. Then look if you can find the name of Dr. Bourgart, analytical chemist, Manchester.

Mr. Yates: You are assuming that he is an analytical chemist.

Witness: I dare say that he will be on the Medical Register.

Mr. Brown: Never mind. Is he there, I ask you?

Witness: I do not think that he is.

Is there the name of Mr. Estcourt, or Estcourt and Co., Analysts for the City of Manchester?

Witness: No.

His Honour: Is it worth while going further into this point, Mr. Brown? You have got several examples.

Mr. Brown: Yes, it is. Here is 'Slater's Directory.' I will just ask the witness to look at this work. (Book handed to witness.)

Is there a heading, "Analytical Chemists?"—Yes, there is.

Under that heading is there Estcourt and Co.?—Yes.

Under that heading is there Oswald Wilkinson?—Yes.

Is there Carter Bell?—Yes.

And in point of fact all these gentlemen are under the heading of "Analytical Chemists?"—Yes.

And yet they are not registered?—Yes, but is that Directory their own act?

Mr. Yates: That is just the point.

His Honour: What is that?

Mr. Yates: The witness say, Is what is in that Directory "their own act?" It is Mr. Slater who calls them analytical chemists, and we have nothing whatever to do with what Mr. Salter calls them.

Mr. Brown having addressed the court for the defendant—

His Honour said: This, I must say, is a very unfortunate case for the defendant, and to the public it is a very important case. The defendant appears to be a person who has served his country in foreign parts and to have been wounded there, and everyone must feel the greatest sympathy for him. From his experience in South Africa it is said that he is considerably skilled in the healing of wounds, and it is also said that he is a competent analyst. Of course I am not prepared to say that he is not thoroughly competent, from his experience in South Africa, both to deal with wounds, etc., such as those he states in his prospectus, and also to sell drugs.

Mr. Brown: He does not sell drugs.

His Honour: You see that I have this bill before me. One of the contentions is that he is not a pharmaceutical chemist. I have here before me his own bill, which says that "James Kelsall, Analytical Chemist, late Surgeon's Assistant, Government Hospital, South Africa, cures burns, scalds, ulcers, bruises, etc., etc., at the little hospital in Sandy Lane." In fact he names nearly all the ills to which flesh is subject, and, therefore, there must be dressings and medicines.

Mr. Brown: He uses patent medicines, for which he has a licence.

His Honour: Now the case on behalf of the defendant has been opened as a very hard one for him, and certainly in one sense it was very hard that everyone should not be able to exercise every faculty they may possess for their own good; but for the protection of society the British Legislature has enacted that which has for its object the protection of the British public from those practitioners in the country who are not fully competent. Now, if the defendant is fully competent he has only to go through the ordinary course of obtaining power to deal as he wishes to deal with these drugs and other medicines. But now comes the question which really has to be settled, and which I must decide. The merits of the case I have thoroughly followed. I wish to state that I have respect for a man who has personally suffered in the service of his country, but then comes the legal question to be decided. This person puts himself forward as an "analytical chemist." He knows thoroughly well what he is about, for as early as August he was reminded by the Pharmaceutical Society that he had no right to the employment of the term "chemist." And what did he say in reply? He said that he did not use it in any sense which would bring him within the meaning of the Legislature in passing the Pharmacy Acts, and his argument has been an argument which has been well put before the court by Mr. Brown. He does not say that he is a chemist at all, because he says he is an "analytical chemist." It seems to me that, having regard to the meaning of the word "chemist," one might as well contend with regard to a man that he was not a man because he is a warm-blooded man. I think that is a contention which cannot be sustained at all. And what is the consequence? Mr. Brown, in his speech, has called attention to the fact that the Act should be strictly construed. I think that in the case of any such person as this, who uses or exhibits the name or title of chemist and druggist, or chemist or druggist, not being a duly registered pharmaceutical chemist or chemist and druggist,—it seems to me that it is impossible on the strictest construction of the terms of the section,—it is impossible to say that a person who publishes himself as an analytical chemist does not come within the meaning of the Act. I think that in this case the defendant has distinctly and clearly infringed the terms of the Act. The case seems precisely to be one of those which the Act is intended to meet, and to be applied to. Defendant has incurred the penalty, and judgment must be for the plaintiffs.

Judgment for the plaintiffs for £5 penalty, and £5 12s. costs.

Liebig's Extract of Meat Company, Limited, *v.* Anderson.

Judgment.

Mr. Justice Field: The action is brought to restrain the advertisement and sale by the defendant of an article known as "Liebig's Extract of Meat" under the designation and in a manner which the plaintiffs allege to be an invasion of their exclusive rights. The facts, not substantially in dispute, are these:—The plaintiff company was established in 1865 for carrying on, and have since carried on the business of manufacturing and selling Liebig's Extract of Meat, an article of medicine and food which has been extensively made and sold under that designation ever since the year 1856. Originally discovered by Proust, the French chemist, and published by him in 1801, the method of preparing it suggested by him was rendered practicable by the late Baron Justus von Liebig, and fully explained by him in 'The Annals of Chemistry and Pharmacy, 1847,' and again in 1851 in his well-known 'Familiar Letters on Chemistry,' published in London. Up to this time used principally as a medicine, the extract soon became an article of food in general demand; and at this period, at all events, Baron Liebig's express wish with regard to the discovery was that the benefit of it should be in no way reserved or made the source of pecuniary advantage to himself, but should be placed at the command of as large a number of persons as possible by the extension of the manufacture, and consequently, a reduction in the cost. The views which he expressed at this time are best to be found in an article published by him in 'The Annals of Chemistry' in 1865, in which he details the steps taken by him to effect these objects, and his intention that a connection which he had, in 1863, formed with a commercial adventure, undertaken by a company known as the Société de Fray Bentos, should not interfere with them. The material parts of this article (it is not necessary that I should read the whole of it) are these:—"Since my examination of the nature of meat, made in the year 1847 ('Annals of Chemistry and Pharmacy,' vol. lxii.), I have constantly endeavoured to promote, in countries where beef is much cheaper than with us, the manufacture of extract of meat according to the method then described." Then he compares the extract with soup tablets and other extracts, and then he says:—"To give an idea of the extensive use of the extract as a medicine, it will, perhaps, suffice to state that in the Royal Pharmacy of Munich nearly 5000 lbs. of beef are employed yearly for its preparation." Then he goes on to show how extensively it is used. Then he says:—"The introduction of extract of meat at half or a third of the price now paid in Europe, from countries where meat has but a nominal value, would be regarded as a real blessing to the people of this quarter of the globe. In Podolia, Buenos Ayres and Australia, I earnestly drew attention to the manufacture of extract of meat, and was always ready to explain the method of preparation to such persons as were desirous of being acquainted with it, and assist them with my advice. I introduced Mr. Giebert to my friend, Dr. Pettenkofer, who willingly admitted him to the Royal Pharmacy, and made him acquainted with the minutest details of the process of preparation." And then he goes on to say that he received samples from Mr. Giebert of his first results of his manufacture of extract of meat. Now comes a very important part of the circular, because it is one of the things on which the plaintiff company rely for a portion of the reputation which they say their extract of meat has obtained amongst the public. He says, "Mr. Giebert expressed a desire that the extract should be designated by my name, *Extractum carnis Liebig*, as it was prepared according to the method prescribed by myself. I agreed to his request." Then he says, "on the other hand, we promised him (Dr. Pettenkofer and myself) that if he would send the entire produce of his extract to Munich we should be willing, without any compensation whatever, to submit each of his consignments to an analysis, and, in the event of its possessing the qualities required by science, to guarantee its genuineness on the condition that the retail price of the extract of meat per pound should not exceed one-third of the present price in Europe. We would not lend our names to support a pecuniary speculation. This arrangement was of course to continue only during the first period of the introduction of the extract into Europe, as it is assumed that when the public is once acquainted with the trade mark of the genuine extract of meat they will no longer need the chemist's guarantee to form their own judgment of its excellence." Now there can be no doubt upon that, that the Baron there does expressly state his view and desire to be that this extract should become an article of common use, and to take away from it all species of monopoly, because he wishes to have it reduced to at least one-third of its then price; and at the same time in the interest of science he says, "I have come to an arrangement with the company by which I will guarantee a quality such as they produce and thereby be assured that the product which they send into the market is one which has been properly prepared according to my method." But the account which he gives of his arrangement with Mr. Giebert is not quite so full as it might have been, for he did not disclose that by the arrangement of 1863 made with the Fray Bentos Company, he and Dr. Pettenkofer were to receive for a period of five years, the pecuniary compensation of 2 per cent. on the annual profits of the manufacture and, which is the important part, that Dr. Pettenkofer and the Baron in return for that 2 per cent. engaged to analyse and certify their approval of the extract produced by the company. Now up to this year of 1865 the bulk, if not the whole of the extract sold in the London market, was the produce of the Fray Bentos Company. There had been, I think, certain persons who, in certain parts of England had manufactured this extract, but it had reached to no great extent up to this year, 1865. Between 1861 and 1865 the value of the extract, as an article of commerce, had become by that time generally known and in that year, or the following year, 1866, various manufacturing chemists in England and elsewhere had commenced or were intending to commence to manufacture, and some of them, including Mr. Giebert, were desirous of securing the advantage of putting their products into the market with a guarantee of quality by Baron Liebig, the inventor of the discovery. The extract thus manufactured was sold in England by some of the manufacturers as "Liebig's Extract," and by other manufacturers as "Baron Liebig's Extract of Meat." Amongst others, a Mr. Robert Tooth, of Sydney, proposed to make use of the waste meat of Australia in the same way as the Fray Bentos Company did of that of Uruguay, and he entered into negotiations with the Baron for the purpose of obtaining his co-operation by his analysis and guarantee in return for a pecuniary compensation to the Baron; and thereupon a correspondence ensued, which was very much relied upon at the trial, and very properly so, and therefore I shall refer to the material parts of that correspondence. On the 16th of September, 1865, there is a letter from Justus von Liebig to Mr. Robert Tooth. Just before that time Mr. Tooth had sent to him his proposal for an arrangement with the Baron for the purpose of securing an analysis, and this is the answer of the Baron to that application:—"Dear Sir, —In acknowledging the receipt of your letter of this day's date, I wish to express my concurrence in the points of the agreement proposed therein, which, however, on my part can only be executed after having arrived at a satisfactory arrangement with Messrs. Giebert and Co. at Antwerp. The process is, however, no secret, and so simple, and you seem to understand it so well, that for the present a more detailed instruction is hardly necessary." On the 23rd of September comes another letter in which he repeats an objection to evaporation, which is not material for the present purpose to discuss. Then he says this:—"I should always prefer your mode of evaporating. The Government in consequence of my recommendation uses already the extract of meat in several hospitals, but you do not want Government, there is no fear of selling every quantity brought to market. I transmit a copy of your letter of the 16th, and in a few days I shall communicate to you some additional articles to be inserted into the document of agreement for your consideration and approval?" It therefore seems that at that time, although the Baron was under the arrangement come to in 1863 with the Fray Bentos Company, he still entertained the proposal of Mr. Tooth for the purpose of seeing whether he could come to some agreement with him, but, as the next letter will show, he did not carry that out by reason of what was occurring at that time. What was happening at that time was this, that the Société de Fray Bentos were utterly unable, with the capital at their command, to meet the demand for extract of meat, which had become so great and universal, and they were at that time preparing to enlarge their operations, as they ultimately did, and form what was called the Anglo-Belgian Company, consisting of Mr. Giebert, who was an Antwerp engineer, and certain English gentlemen, the seat of which was to be in London, for the purpose of extending and promoting the manufacture. During this time, while the correspondence was going on between the Baron and Mr. Tooth, the Baron was already receiving proposals from them by which his name was to appear as the Scientific Director, and it did so appear in the preliminary prospectus of the New Anglo-Belgian Company. This is a letter dated 6th October, from Munich:—"Soon after your departure I have taken all possible steps to free myself from the obligations under which I am towards Messrs. Giebert and Co., but there is no chance to arrive at a satisfactory result with respect to this previous to the 16th of this month. For this reason a personal interview could not possibly lead to any result. I am still most willing to help and assist you in your undertaking, because it would not only be a benefit for the colony but also for the world." Nothing can be more clear or conclusive to show that the Baron wished to extend the advantage of his preparation all over the world and to get it made at as low a cost as possible. "Allow me to tell you that you need not trouble yourself with finding out a new method or a simpler one for the preparation of the Extract of Meat, all this has been done a hundred times; there is only one method for manufactory and this is to mix the chopped flesh with its volume of soft water (without gypsum) and to raise the temperature of that mixture at the temperature of 180° F. To extract the essence with cold water is not applicable for manufacturing." Then he describes what it is. Then he says, "I am told that one of the best houses in London for the sale of the Extract is Allen and Hanbury, another is William Hooper, of Pall Mall. I request you to have the kindness to name me an agent, with full power to act, residing at London, with whom I may further confer on this matter." He, therefore, still continued to hold out, as I said before, a sort of prospect to Mr. Tooth, that he would soon be able to give him the benefit of his analysis. In November appeared the preliminary prospectus of the Anglo-Belgian Company, and, of course, as soon as it appeared that Baron Liebig was the Scientific Director of the Company, his negotiations with Mr. Tooth came to an end. At the same time he also corresponded with Mr. Hooper, a chemist of distinction. I think that only one letter of that correspondence is important, and that is, I think, the letter of October 6. He says:—"Your manufacture is perfect; there is nothing equal in Germany. I have written Messrs. Giebert and Company about the extract of meat, but the demand is so great and the supply so small in proportion that they seem to be unable to send you more, as they did. They are increasing their manufacture and in a few months there will no lack of *ex. carnis.* Mr. Steven Squire has sent me his letter, printed in the *Lancet,* about my food for infants in its improved form. Messrs. Savory and Moore and Hassall have "caught it," and I think that the *extractum carnis* and my food for infants are now better known in England, I should even say, than in Germany." Then another letter comes, which is very important indeed, in which he says this:—"It is very unfortunate that the supply of *extractum carnis* is so small in proportion to the demand, being only 3000 to 4000 pounds per month, presently not sufficient for the town of Berlin alone, but no person in the world could foresee that the article would so soon be appreciated by the public. This great success has led to the transformation of the Fray Bentos Company into a new Anglo-Belgian Company, Limited, with an enlarged capital, and in six or eight months two new establishments will be formed, which, joined to the manufacture at Fray Bentos, are able to produce 30,000 to 40,000 pounds per day. I am not a rich man but I have taken myself one hundred shares. I have undertaken the direction of the scientific part and shall give to the public, by severe chemical control, a guarantee of the genuineness of the article. If you establish a similar manufactory you may be certain to succeed. The produce of the new company, with all its enlargements, will prove insufficient for the wants of the world." Then there is another letter of the same gentleman, later on, in which he says that everything concerning it is in the thirty-second of the 'Letters on Chemistry,' which is one of the letters published in the 'Familiar Letters,' and that the Anglo-Belgian Company has patent rights in Uruguay, Buenos Ayres and the United States, but not in England. That is the correspondence, as far as material, with Mr. Hooper. That as I have said before speaks for itself, showing that the Baron had not the remotest idea that anything he had done, or was about to do, would interfere with the sale, or create a monopoly in England, at all events, whatever may be the state of things elsewhere. Now, at that time, as I said before, he had consented to become a director of the New Anglo-Belgian Company. It was established in 1865. What is now the 137th, but what was formerly the 141st Article of Association, is very important indeed, because it forms the starting point of the plaintiff Company's argument upon which their case rests, and a very strong starting point it is, there is no doubt about that. Now, the article is in these terms:—

"Baron Liebig shall be the first and present Director of the Scientific Department, and for Control of Analysis.' It will be observed that he is here spoken of by his title. He was a Professor at Giessen at that time, and a man of great eminence, and was induced to remove to the Capital of Munich when the King of Bavaria made him a Baron. In this article he is described by his title "Baron Liebig." It says "Baron Liebig shall be the first and present director of the Scientific Department, and for Control of Analysis. The analysis of all extract of meat arriving at the Company's general dépôt at Antwerp shall be under the immediate control of Baron Liebig, and such chemist as may be appointed by him as his delegate." Then the directors are to pay him 2 per cent. on the net annual profits of the Company. That was the arrangement which was come to under that Article. But again, in that Article of Association there is no monopoly of any sort or kind, and no attempt at creating it. It is simply this, you, the inventor, may be of service in analysing the article, and telling the public that the article is a good one, and in return for that we will give you 2 per cent. upon our profits. Services are rendered and there is a reward for those services. Now in the latter end of 1865 or the first six months of 1866, Tooth had brought or was bringing practically into operation his arrangement for manufacturing in Australia, and bringing the extract to the London market. He had in 1865 entered into an agreement with Messrs. Allen and Hanbury, gentlemen who are referred to by the Baron in his letter as being the first chemists in England, for a consignment to them of the article manufactured by Tooth in Australia. It is important to observe that at the time of that agreement in November, 1865, Messrs. Allen and Hanbury, who had dealt considerably before that time in Extract of Meat with the Fray Bentos Company by taking it from Antwerp and consigning to them there, entertained the hope that they would be able to secure the Baron's analysis for themselves, because in the agreement between Tooth and Allen and Hanbury they inserted this proviso that they should not be compellable to sell any extract in Australia unless with the approval, or under the analysis of Justus von Liebig, or, if he declined, some other chemist who might be agreed upon between the parties. In this state of things it appears on the whole to have been thought advisable by those who were interested in the success of the new company, called Liebig's Extract of Meat Company, to tighten the bonds of connection between it and the Baron, and to create if possible an exclusive right to his name and manufacture in them. That was very natural, because there was a competition springing up all round. There was the competition of Harvey and Reynolds, Savory and Moore, Allen and Hanbury and Tooth. This was too valuable an article for anybody who chose to be allowed to deal in, and evidently the Company began to feel the competition and wished to secure the Baron from lending his aid to anybody else, and to secure if possible a monoply for themselves Accordingly, in the month of April, 1866, two documents were signed which are of the greatest possible importance in the present case, and which are greatly relied upon by the plaintiff Company. One is a power of attorney by which the Baron professes to grant "the sole and exclusive right, power and privilege to use the name '*Extractum carnis Liebig,*' or to use my name in any other manner which the said company may from time to time see fit, in naming or indicating the *Extractum carnis*, manufactured according to my method or with any improvements therein." Then it gave them power to take out patents for various other manufactures of the same kind. But a more important instrument was the agreement, signed on the same day, between the Baron and the Company. The agreement of 1863 was for the limited period of five years, and that was one between Dr. Pettenkofer on the one hand, and the Company on the other. Dr. Pettenkofer is not made a party to this second agreement at all. He is an eminent chemist, but I do not know that he succeeded in reaching the reputation that Baron Liebig did. Baron Liebig's name, as we are aware, was a household word; Dr. Pettenkofer was a chemist of great repute in Munich, but still not having that reputation which Baron Liebig had, and therefore, Dr. Pettenkofer, although he was made to play a subsidiary part under this agreement, was not made a direct party to it, nor was the agreement made directly with him as it was in 1863. This is the agreement: It recites the Articles of Association, and then it comes to this, that Baron Liebig grants the full use and benefit of the invention in South America and in any other part of the world. It confirms the power of attorney, and says that for ten years from 1866 "the analysis of all extracts of meat arriving at the Company's general depôt shall be under the immediate control of him, the said Baron Justus von Liebig and his delegate, Dr. Max Pettenkofer." Then it provides that he will keep secret or not disclose the invention. Then there is a clause for the exclusive use of the name of the manufacture so far as the Baron could grant it at that time. I think there is not the smallest doubt that he did grant it. It is to be observed that Dr. Pettenkofer becomes what is called the delegate, which really amounts to this, that when a sample of extract of meat came from America, as Baron Liebig could not analyse it personally he, therefore, appointed Dr. Pettenkofer to do so. If samples go to London they are to be examined by one or the other, as the case may be, and they both certify their approval in the manner which appears on the plaintiffs' labels. Then the course was that of every parcel of extract consigned to the depôt at Antwerp a sample was sent direct from South America to Munich where it was analysed by either Baron Liebig or Dr. Pettenkofer. After they had analysed it they certified to the effect that it contained so much ash, so much water, and so on. Now the Company of course carried on a wholesale business. They dealt with Allen and Hanbury, and Savory and Moore, and everybody who liked to deal with them. They also had an agency in London for the purpose of the sale of their article. They were in the habit of supplying large customers like Allen and Hanbury, in bulk to be sub-divided by them, and again grocers and other people they supplied with small pots for the purpose of selling them retail. Messrs. Allen and Hanbury in 1865 began receiving extract from Mr. Tooth and the description of what they did then is to be found in paragraph 20 of the Bill:—"The plaintiff Company a short time since for the first time ascertained that the defendants have recently commenced selling under the name of "Liebig's Extract of Meat," and in pots closely resembling in size and material and general appearance those used by the plaintiff Company as aforesaid, an extract of meat prepared by a person named Robert Tooth, of Sydney, in Australia. Such pots have burnt in on one side the following words and figures:—"Liebig's Extract of Meat. Allen and Hanburys. Trade (an ox and a plough) Mark, A.D., 1715, London." And on the opposite side is pasted a printed paper describing the mode of manufacture, preparation, and so on. I need not go through all this. There was a paper label which was headed "Liebig's Extract of Meat," and an advertisement also to the same effect. Now the plaintiff Company complained of that; they said as soon as they saw these advertisements (I have got them all here, but it is not worth while going through them) the vice in them, for there was a vice in them, as far as the Company's view of the case was concerned, was that they were calling this thing "Liebig's Extract of Meat." Accordingly in 1866 they filed a Bill against Messrs. Allen and Hanbury for the purpose of restraining the use by them of the words "Liebig's Extract of Meat," or any other title of which the word "Liebig" forms a part. The case came on for hearing before the late Lord Hatherley, then Vice-Chancellor Wood, and his judgment was a direct decision, I will not say conclusive. The evidence before him was very much the same as the evidence before me. The Vice-Chancellor did not call upon the counsel of the defendants, but gave judgment in this way. He says, "I think it is impossible in this case to grant to the plaintiffs an injunction to restrain the sale of the article upon the ground of the use of the term Liebig's Extract of Meat. Then he says, "As to the use of the name,"—which is the great point—"it all turns upon the proposition (which is a simple proposition of fact) whether or not this article which the defendants sell had acquired the name of Liebig's Extract of Meat at the time they adopted the name for the purpose of using it, and irrespective of its being also a common name which was used by the plaintiffs. In other words, whether the only thing then existing in commerce was some article manufactured by the plaintiffs, or by those through whom they claimed a title." Then he says: "The plaintiffs claimed a right to use the name, so that the extract made by them could be thereby distinguished from anything made by the rest of the world." That to my mind is almost the governing proposition in the present case. The claim is the same here. The plaintiffs claimed a right to use the name so that the extract made by them could be "thereby distinguished from anything else made by all the rest of the world, and so as to exclude the rest of the world from taking a title exclusively adopted by the plaintiffs. It appears to me, that the case wholly fails on that ground. It seems to me upon the evidence that the title of the Liebig's Extract of Meat was a title acquired before the firm of Fray Bentos had distinctly acquired any interest whatever, that being in the year 1862." Then he says:—"Looking at the whole of this evidence it amounts to nothing more than this, that having a great reputation he did not wish to see his name bandied about and applied to other articles in the same manner as Dr. Clark's and Dr. Locock's well-known names have been attached to pills and wafers, the composition of other persons. His name was used from 1860 to the end of 1864, according to the statement of Dr. Pettenkofer. The extract being largely used at Munich was quite sufficient to give it a name. The name was not used in any way as a sort of right of property, which the Baron wished to reserve. Nothing of that kind appears, but simply that he did not wish his name to be attached to an improper article. In that way the name became generally known; it was known all over Germany; it was known to some people in this country; but it might not have been known to all, and that might account for the discrepancy (if it may be so called, for there really is none) between the two classes of witnesses." The Vice-Chancellor says that it is a question of fact. His finding on a question of fact does not bind me, nor am I am bound to follow him, but I am bound to say on the evidence before me, which is exactly the same as the evidence before him, that I come to the same conclusion on the question of fact that he did, namely, that up to 1866, when the Baron and the present plaintiff Company entered into that arrangement that the power of the Baron to create what he then did, was gone; it had become before that time in the words of the Vice-Chancellor "common property." Liebig's Extract of Meat had become a commercial article, known under that name, and that ceased to be the distinctive mark, if ever it was, of the manufacture of Liebig. Then he goes on to comment upon the evidence, and says, "I cannot be asked to interfere unless these gentlemen make out that from the character of their business this article would be supposed to be made and sold by them as being exclusively their article:—'The object of this Company is to manufacture on a large scale, not an article of commerce to be called Liebig's Extract, but to manufacture on a large scale the pure and genuine *Extractum carnis Liebig.*'" That is to say, "There is the article, but like everything else it is adulterated. There is a well-known article in commerce known as *Extractum carnis Liebig,* and we are going to give you the genuine article." What follows is relied upon as of great importance by the plaintiffs, and so it is; it is this, with the assistance and under the immediate control of Baron Liebig, and this is the real advantage the plaintiffs possess. They have the Baron's assistance, and they have his fiat to what they issue forth to the world, and no doubt it is a considerable advantage as far as they are concerned. This authority was not at all disputed. Although they gave notice of appeal to the House of Lords, they did not follow that up. That case had been acted upon and is distinctly approved of if, it were necessary, by the present Master of the Rolls in the case of Thorley *v.* Massam. But since that the Company made various alterations, and they altered the designation of their article. Up to that time they called it "Liebig's Extract of Meat." This decision had established that that was common property. A man has a right, as far as I can understand, to carry on his business, so long as he does not interfere with the rights of anybody else. That case established that "Liebig" was common property. There is no suggestion that the article manufactured by Anderson is an inferior article which would not pass in the market on its own merits, but only on the back of the Company's reputation through an imitation of their mark. Therefore, they altered their title. It is very important to see what they did not do and what they did do. They, therefore, first of all made a trade mark. It is very important to see what their trade mark was. It was this "Extractum Carnis Liebig;" they altered that title to "Liebig Company's Extract of Meat;" they did not take the word "Baron" although the word "Baron" was a word known in the market before. This alteration continued until the death of Justus von Liebig in 1873. Dr. Pettenkofer took the Baron's place, and Hermann von Liebig, who is one of the plaintiffs in the present action, took Dr. Pettenkofer's place, and from that time down to the present time the process of analysing has been gone through in the same way, except that the analysis is signed by Dr. Pettenkofer and Hermann von Liebig instead of being signed by Justus von Liebig and Dr. Pettenkofer. The *facsimile* autograph of the Baron was still continued, and has been continued up to the present time upon the labels of the company. In 1881 a company known as the Australian Meat Company, otherwise called the Ramornie Company, who manufactured in Australia in competition with Mr. Tooth, and everybody else, were what is called wound up. Mr. Anderson, the present defendant, had been their secretary. Of course it is obvious that as their secretary, if he attended to his duties properly, which I dare say he did, he would become acquainted with their trade and would know what the character of the article was, and of course a great many of the business connections with it. Under those circumstances he appeared to have made up his mind, which he had a right to do, to undertake the business of selling Liebig's Extract of Meat. The course he adopted was this: there are numerous manufacturers, indeed every place in South America makes extract of meat, and he imported it to London in bulk, and then subdivided that into pots, and sold it in retail either by himself or by means of other houses. By that means Anderson was getting his business in order and disposing of his extract of meat. Now the plaintiff Company complained again of that. They said, "This will not do, you cannot go on doing this." It is perfectly true, they said, "You have a right to call your article Liebig's Extract of Meat if you will; you have a perfect right to use the word 'Liebig,' but you have no right to use the words 'Baron Liebig;' that is wrong. "You may call it 'Liebig," but you must not call it 'Baron Liebig.' Moreover it appears that Mr. Anderson got hold in some way or other of a photograph of the Baron, but I am bound to say that I do not think there is any ground for suggesting that he got hold of it dishonestly. We are perfectly well aware of the effect of pictures, we know how much everything is sold by pictorial illustrations and photographs. Although I must not bring my own evidence into the case, I am perfectly well aware that when I walk along the street, I see everybody photographed. It occurred to Mr. Anderson that if he could put a photo of Baron Liebig on his pots, that that would be an attractive mode of selling the articles, and he was right in his conjecture, for it turned out very attractive indeed. But that is the head and front of his offending. The plaintiff Company complained of the use of the word "Baron" and of the use of this picture, and wrote letters, and the present Bill was filed. Now, having reached this stage it is necessary to describe what it was the defendant did. I have said before he did not call his extract merely as he might have done "Liebig's Extract," but he used the word "Baron," and that word was a word that had been used before in 1865 and 1866, and certainly I rather think at an earlier period by Savory and Moore, and I rather think by Harvey and Reynolds, but it does not matter who used it, because the fact was it had been known before as "Baron Liebig's Extract." The plaintiff Company, it will be observed, had never used the word "Baron," and they had never used a picture of any sort or kind, therefore it cannot be said that this had been any imitation of their use of the word "Baron." Then it was said, although there was no imitation of that kind, yet the word "Baron" and the picture were calculated to mislead. "The object and intention of the defendant in calling his extract by the names and designations aforesaid, and in using the pots aforesaid, and in affixing thereto a likeness whether photographic, lithographic, or otherwise, purporting to be a likeness of Baron Liebig, and the words 'Brand Baron Liebig,' was and is to get (as the defendant has in fact thereby got) the benefit of the reputation in which the plaintiff Company's extract is held, and to mislead (as the defendant has in fact thereby misled) purchasers into the belief that in buying the defendant's extract of meat they were in fact buying the extract of meat manufactured by the plaintiff Company." That being the state of matters the charge against the defendant is twofold. First, it is alleged that the defendant had in fact got the benefit of the reputation to which the plaintiffs' extract is alleged to be entitled, and has in fact misled the public into the belief that in buying that extract they are buying the article which is the plaintiffs' well-known manufacture. Then it is also alleged that in doing that he did it intentionally, with the object of getting that benefit and so misleading the public. Now if the plaintiffs were to be confined to the exact terms of their allegation, the question would have been more limited than it really now is, and that would have been whether the extract sold by the defendant was sold under such a title, because there was but little evidence of any misleading in point of fact. The real question argued before me, which I propose to decide, is whether the extract sold by the defendant is sold under such titles, designations and brands as to be reasonably calculated to deceive and mislead, not the trade, because the trade would not be misled at all, but the ultimate purchasers, the public, into the belief that they were buying the extract of Baron Liebig. As I said before, of actual misleading in point of fact there is very little evidence. That evidence, I think, fails, even if it is to be believed. The question is not what a fraudulent retailer may, by successful manœuvres in his shop, succeed in inducing people to take, but whether, under ordinary circumstances, reasonable people who have got eyes in their heads and who really use them and make use of them fairly and reasonably would be misled. If what the defendant does is so calculated to mislead, of course the plaintiffs would be entitled, at all events, to an injunction, because if it was done originally fraudulently and with an intention to deceive, there is no doubt that action for deceit would lie. Whether or not it is necessary in an action for deceit that fraud should exist, and whether or not it is necessary that there should be held to be a right of property in a mark other than a trade mark, about which the Court has expressed some considerable doubt in the recent case of the Singer Manufacturing Company *v.* Wilson, it is not necessary here to say, because there is no doubt whatever that if a man honestly believes that he is only exercising his *bonâ fide* rights and makes use of any portion of the mark of another, or in any way suggests by reason of any brand or designation of his own that his article is the article of another, there is no doubt whatever, and everybody agrees in this, that as soon as he ascertains and knows that what he has done, innocently perhaps, or ignorantly, possibly, is in violation of the rights of another that imposes a liability upon him of discontinuing the wrong. If in the present case it can be established that the defendant's marks and brand are calculated to deceive the public the plaintiffs would be entitled to the injunction which they ask. I think it is hardly necessary to quote authorities for that, but I will name the two cases which I have taken for that proposition, namely, Wotherspoon *v.* Currie, and the Singer Manufacturing Company *v.* Wilson. That being the law which I want to apply I have to consider whether the facts bring this case within the principle so laid down. In support of their case the plaintiffs called a large number of respectable and very well qualified witnesses in the trade who established to my satisfaction that the plaintiff Company's extract has had and still has a considerable reputation in the market, and that that reputation is due, not only to the fact that Liebig's name is connected with it,—although that, according to the decision in Liebig's Extract of Meat Company, Limited, against Hanbury, ceased to be a distinctive mark,—but it is due, among other things, to that which is pointed out by Vice-Chanceller Page Wood in his judgment, the personal connection of the Baron with the plaintiff Company formed as it was in 1863, and which continued down to his death. It was also continued by the analysis all this time by him and Dr. Pettenkofer, and since then by Dr. Pettenkofer and Dr. Hermann von Liebig. Nobody else has a right to assert, that they have distinctly a right to the reputation of having from the time of the Baron's first connection with the Fray Bentos Company down to the present time had the advantage of having been able to put their goods in the market with the certificate and analysis of the Baron and Dr. Pettenkofer, and after that of Dr. Pettenkofer and Hermann v. Liebig. Now, therefore, that being so, the question is whether or not the defendant suggested, it was not asserted that he had alleged it, that that personal connection exists between his extract and the Baron, and that he has the advantage of any such supervision or control of the Baron. It was said that the word "Baron" and the picture itself did suggest that there was a personal connection between the defendant and the Baron, so as to induce people who bought to believe that goods sold by the defendant had received that analysis and was the product of that personal connection existing between them, so that, in point of fact, if that were true the defendant was able to pass off his goods as the goods of the plaintiffs. Now the reputation of the plaintiffs and their mode of selling was this: they sold in pots, like the pots I have in my hand. (The learned Judge then contrasted the articles as made up for sale by the plaintiffs and the defendant, saying) It seems to me, and the conclusion I have come to is, that the distinctive marks by which the plaintiffs' goods are to be distinguished from anybody else's are to be found in these wrappers and envelopes, and also in their advertisements. I suppose I must not allude to my own personal knowledge, but I may say that I never heard of Dr. Pettenkofer before this case, but I have heard of the name of "Liebig." Whether you call him "The Baron" or "The Professor," or whether, as I think I put it in the argument, you allude to him as a man who wore a blue coat with yellow buttons, does not matter. The thing which is wanted is the thing which Baron Liebig invented and discovered, and brought into practical use, and that is the thing which has become public. The plaintiffs' witnesses stated that they always understood that purchasers asked for "Baron Liebig's Extract of Meat" when they wanted the plaintiffs', but they also stated that the mere use of the term "Liebig's Extract of Meat" would have the same misleading effect. On the other hand, the defendant called witnesses. They said that they did not understand that "The Baron" was anything more than "Liebig." I really think if I had to decide the case upon the weight of evidence that I could not say which side weighed the most. Of course, the great question for me now is to use my own eyes. I am a juryman on this occasion as well as a judge. I have got to determine whether or not I can come to the conclusion that there has been here such a user of marks and brands by the defendant as is reasonably calculated to deceive people into the belief that they have got the plaintiffs' goods. These are the two pots. They are similar in two respects, that is to say, they are both of stoneware, and they are both round; but they are different in size, for, although they hold the same quantity, one is short and the other is tall. I suppose I am now to convert myself into an unwary buyer; I must make myself unreasonable and ask myself a number of questions. Being an unwary buyer, and a supposed ignorant man, and wanting to purchase Liebig's Extract of Meat, I am to suppose that I went into a shop wanting a very good article, and this pot is put into my hands, and I, finding it very good, go to that shop again and ask for some more of that extract, and they give me *this*; then I should say, "Why, goodness, gracious! that is not like the other; there is a capsule instead of there being a trade mark; there is no caution that none is genuine unless the label round the pot is intact." I find here it says, "Baron Liebig's Extract of Meat, guaranteed by R. W. Anderson." If I were relying on the reputation of Liebig, Pettenkofer, and Hermann Liebig, I should say, "Where are the signatures of Hermann Liebig and Pettenkofer? Let me look at their signatures. I do not see their signatures. Where is the blue ink signature of Justus von Liebig?" No, there is nothing of the kind, but it is "guaranteed by Anderson." Then round the capsule there is this: "All Baron Liebig's Extract of Meat guaranteed by me bears my signature thus: Guaranteed by R. W. Anderson." It is said that the use of the word "Baron" indicates a personal connection with Baron Liebig different from that which would be indicated by the use of the word "Liebig." On the other side comes a picture of the Baron, a very intelligent face, and underneath is written "Baron Liebig." It is said also that that has the same effect. But then, I must take all the points of difference as well as all the points of resemblance and I must confess I am inclined to believe those gentlemen who gave evidence for the defence. I am not satisfied with the plaintiffs' case that unwary purchasers might be deceived. Purchasers must use their eyes. Of course I know there are persons who will run against posts at railway stations; so there are people who do not use their eyes, and who buy things which they are said to be deceived by. In this case, like all others, if the plaintiffs say that the defendants have been guilty of culpable conduct, they must make out that conduct by reasonable evidence. It is said that vague conjectures are sufficient. I think it must be more than that. I think that the liberty which there is for every man to sell his goods by the title which he thinks most attractive should not be restrained unless it is proved that what he is doing is reasonably calculated to deceive. Something turned on the question whether there had been any intention to deceive.

If a person were endeavouring to sail as near as he could to the wind, and therefore has done just enough, as he thinks, to sell his goods, one would look on his marks with a very different eye, and would look very carefully at his mark to see whether or not he had infringed. If I found it to be the case, as Mr. Anderson stated, that he had undertaken this as a commercial speculation in the belief that he had not infringed anybody's mark, I must have very strong evidence to prove the contrary. What he said was, "I know all the marks in the trade. I considered this to be a distinctive mark. I did not know that anyone used the word 'Baron,' and I never knew that anybody had used the picture." There really was no evidence of anything else, unless there was evidence from the similarity of the things. Of course one implies to everybody the reasonable consequences of his own acts; therefore, if a man does put into the market a thing which is a copy of a portion, at all events, or the whole of a man's mark or reputation, and then he puts in some slight distinctions which nobody would observe, you imply to him the reasonable consequences of his own acts, and you would say "You are a fraudulent man;" and I should not listen to his oath when he says, "I am not a fraudulent man, and did not intend to do it fraudulently." That was the principle which Mr. Higgins relied upon so strenuously, and that was the principle which was laid down in the case of Seizo *v.* Provezendo. That was a case where Baron Seizo sold sherry with a crown, calling it the "Seizo Crown Sherry." Another man, who happened also to have been a baron, put his coronet upon a cask of sherry, calling it "Seizo," with the addition of something else and he said none would mistake the two. But the Court said:—Here is a crown, and your coronet is very much like it, and then there is the word 'Seizo,' which is common to both." Then there was the Two Elephant trade mark case of Orr-Ewing *v.* Johnstone. In that case the plaintiff's cotton or twist was known by the mark of two elephants. The other man took two elephants, but he put their heads in a different way, or something of that sort, to the two elephants of the plaintiff, and then he put in his marks, which, if read carefully through would be found not to be exactly the same; but as there were two elephants, the Court came to the conclusion that he had done that which was in effect sailing as near to the wind as he possibly could. It was the same in the White Selvage case. In that case also they had taken a distinctive mark; but in the original when the mark was put on the stuff it did not show until it was dyed, which made the differences disappear and then it resembled in all respects the plaintiff's. Then there was another case, in which the same principle was laid down, which is known as the "Dog Head Beer" case. It was the case of Reid *v.* Richardson. One man put the head of a Mount St. Bernard dog and the other man put the head of a terrier dog. The plaintiff's beer had become known as the "Dog Head Beer." In the present case I must say that it is for the plaintiffs to make out their case. Taking the evidence and using my own eyesight I have come to the conclusion that the plaintiffs have not made out that case which I think they ought to make out to establish a case, not merely of fraud, but of unconscientious and continued fraud. Therefore my judgment will be for the defendant.

Defective Lime Water.

At Longton, on Wednesday, November 8, before J. H. Goddard and J. F. Wileman, Esqs., Mr. John Lichfield, chemist, High Street, was charged with selling lime water, which was not of the strength required according to the provisions of the statute.

Major Knight produced the analyst's certificate, which showed that instead of the lime water containing 0·56 grain of lime per ounce, it only contained 0·1 grain per ounce.

Defendant explained that the cost of the lime required was so very small as to preclude the idea of any motive in the amount therein being too little, but that this had come about in consequence of an accidental exposure to the atmosphere. He had always made lime water of the proper strength.

The Magistrates said they quite thought it had been done by an act of carelessness, and not with any intent on defendant's part, and inflicted a fine of 5*s.* and costs.—*Staffordshire Sentinel.*

Obituary.

GEORGE BLANSHARD.

The news of the death of Mr. George Blanshard, late of the firm of Raimes, Blanshard and Co., Wholesale Druggists, Edinburgh and York, will be received with very general feelings of regret and surprise, for until quite recently he was amongst us, hale and hearty as ever.

Mr. Blanshard was born at Angleton, Yorkshire, in 1814. At an early age he was apprenticed to Messrs. J. and R. Raimes, Leith Walk, Edinburgh, in which firm he subsequently became a partner. Eleven weeks ago, while visiting his native place on account of the state of his health, he was prostrated by a paralytic stroke, from which he never rallied. He died on the morning of the 14th inst.

Mr. Blanshard became a member of the Society in 1852. He has been a member of the Council of the North British Branch during most of the time since then, and was elected President for the year 1863–4. Few members took a more lively interest in the affairs of the Branch than he, or have been more regular in attendance at all its meetings, whether business or scientific, although he seldom took a prominent part in the proceedings.

For many years he was a member of the Leith Town Council, and during some of that time occupied a seat on the magisterial bench. It was proposed to raise him to the Provostship, the highest position in that body, but his business engagements led him to decline the honour. He was also for some time President of the Royal Scottish Society of Arts.

Mr. Blanshard was a man of excellent business habits, and a universal favourite amongst a very wide connection of friends. He possessed all the heartiness and geniality characteristic of the Yorkshire gentleman, and these qualities never failed him, notwithstanding the unexpected change of circumstances that somewhat overshadowed his later years.

He is survived by his widow and a family of two daughters and four sons, the eldest of whom is engaged in the establishment of Messrs. Raimes at York.

Notice has also been received of the death of the following:—

On the 26th of September, Mr. John Francis Garland, Chemist and Druggist, Marshfield, Gloucestershire. Aged 52 years.

On the 26th of October, Mr. John Stovin Woodruffe, Chemist and Druggist, Queen Street, Hull. Aged 59 years.

On the 28th of October, Mr. Charles Philip Heyland, Chemist and Druggist, High Street, Redcar. Aged 39 years.

On the 2nd of November, Mr. Robert Fincham, Pharmaceutical Chemist, Baker Street, W. Aged 72 years. Mr. Fincham had been a Member of the Pharmaceutical Society since 1842.

On the 4th of November, Mr. William Walter B. Stoddart, Chemist and Druggist, Grafton Lodge, Sneyd Park, Bristol. Aged 28 years. Mr. Stoddart had been an Associate of the Pharmaceutical Society since 1869.

On the 6th of November, Mr. John Stafford, Chemist and Druggist, High Street, Ross. Aged 42 years. Mr. Stafford had been an Assoeiate of the Pharmaceutieal Society since 1869.

On the 13th of November, Mr. Edward Henry Webb Roswell, Chemist and Druggist, Market Street, Lewes. Aged 62 years.

BOOKS, PAMPHLETS, ETC., RECEIVED.

PRACTICAL CHEMISTRY; Analytieal Tables and Exercises for Students. By J. CAMPBELL BROWN, D.Sc. (Lond). Second Edition. London: J. and A. Churehill. 1882. From the Publishers.

A CONCISE HAND-BOOK OF THE LAWS RELATING TO MEDICAL MEN. By JAMES GREENWOOD, Barrister. Together with a Preface and Chapter on the Law relating to Lunacy Practice. By L. S. FORBES-WINSLOW, M.R.C.P., ete. London: Baillière, Tindall and Cox. 1882. From the Publishers.

THE CONTAGIOUSNESS OF CONSUMPTION and its ANTISEPTIC TREATMENT. By J. BURNEY YEO, F.R.C.P., etc. London: J. and A. Churchill. 1882. From the Publishers.

DIET FOR THE SICK, being Nutritious Combinations suitable for Severe Cases of Illness. By JAMES RIDGE, M.D., etc. Second Edition. London: J. and A. Churchill. 1882. From the Publishers.

DIE PARFUMERIE-FABRIKATION. Auf Grundlage eigener Ehrfahrungen veröffentlicht von Dr. chem. George William Askinson, Parfumerie-Fabrikant. [Chemiseh-teehnische Bibliothek.] Vienna: A. Hartleben. From the Publisher.

A DICTIONARY of MEDICINE, including General Pathology, General Therapeutics, Hygiene, and the Diseases peculiar to Women and Children. By Various Writers. Edited by RICHARD QUAIN, M.D., F.R.S., etc. London: Longmans, Green and Co. 1882. From the Publishers.

DIE CHINARINDEN in pharmakognostischer Hinsicht dargestellt. VON F. A. FLUCKIGER. Berlin: R. Gaertner. 1882. From the Publisher.

Notes and Queries.

[739]. OIL OF PEPPERMINT.—On mixing Hotchkiss's oil of peppermint with rectified spirits of wine a bright green colour was produced.

Similar spirit and oil have been repeatedly mixed before without any like result.

Could anyone kindly explain the reason?

ASSOCIATE.

[740]. BLUE COLOUR FOR PIPE CLAY.—Can any of your readers furnish me with a good reeeipt for colouring pipe clay a deep blue, as used for pipe-claying doorsteps, etc.?

FORTH.

[741]. SMELLING SALTS.—"Agricola" will be glad of a good formula for a pungent smelling salt, that will not require the addition of any liquor ammoniæ.

[742]. POLYGRAPHIC INK.—Would some reader kindly give me, through the Journal, a formula for a good black polygraphic ink?

EURETES.

[743]. PRESERVATION OF ESSENCE OF LEMON.—Could any of your readers inform me the best means of preserving essenee of lemon? I have a considerable quantity of 1881 essenee, and wish to prevent it beeoming terebinthinous. I have been advised to mix it with equal parts of alcohol, the same as is frequently done with oil of lavender. But before doing this I thought I would ask the question through the medium of the Journal.

W. L.

[744]. POTASH POWDERS.—Will someone kindly inform me how to send out potash powders for a 3-pint gasogene, stating strength, etc.?

PULVIS.

Correspondence.

THE CURRICULUM.

Sir,—In perusing Mr. Candy's letter in a reeent issue, on Dr. Greenhow's report and the currieulum, I regret to see the one-sided view he takes of this important question. The prevailing ideas seem, to postpone the matter to some other time, and will it improve our position when in operation?

There can be no doubt that the present system of "cramming" in many of the sehools will tell, in years to come, and those who have gone into a thorough course of training are the men who will rise in their profession.

Until the curriculum becomes eompulsory, the large majority of the candidates for our examinations will be prepared in this way.

Your correspondent asks, "Are there any businesses which would utilize to the full the scientifie knowledge whieh it is proposed to render imperative?" I affirm that in every pharmaey this seientific knowledge is neeessary and requisite, and till the proper means of acquiring it is made eompulsory, the majority will not seek them of their own aecord. We must move with the times and not rest satisfied on what was done ten years ago.

It would be a poor reward for the man who has expended both time and means in taking the Major qualifieation to be elassed on a level with the ordinary tradesman.

There is no doubt when the eurrieulum is established we shall get a better class of candidates for examination; men who, I hope, will have some ambition to elevate the profession to whieh they belong, and who will not be diseouraged by hard work from attempting to attain the highest point.

I believe when medieal men in the eountry, and those places where they now compound their own medicines, find they can rely upon men who have had a thorough scientifie training, and possess an intimate knowledge of their business, they will see it is to the advantage of both that their medicines should be prepared by the pharmacist.

This, I ean testify from my own experience, is working well in many towns.

Liverpool. C. J. S. T.

THE POWERS NOW POSSESSED BY INSPECTORS OF WEIGHTS AND MEASURES.

Sir,—Permit me to draw attention to the power now possessed in eertain districts by inspeetors of weights and measures of entering the shops of dispensing ehemists and examining the weights and measures used therein.

This appears to me and others to be an odious, degrading and needless interferenee with a delieate and responsible occupation, already overburdened with peculiar distractions and anxieties. The increasing competition arising from co-operative stores eauses a growing reluctanee to pay the ehemist for his skill, that one possession on which he must rely. It fell to my lot to prepare a memorial for presentation to the Hastings Town Council, setting forth the objcetions felt by ehemists to this procedure. This memorial was signed by twenty-one chemists of the Borough of Hastings and St. Leonards, and received the hearty assent of an influential portion of the medical profession there. It was stated that this inquisitorial power was regarded with deep regret and annoyance. That "our weights and measures are those of the British Pharmacopœia, a standard work containing minute directions for the preparation of medicines, with delicate physical and chemical tests and all necessary details. To us the law assigns the responsible and arduous task of preparing, compounding and dispensing medicines at all hours. We are necessarily trusted with this, the greater matter; the greater includes the less; why deem us unworthy of trust in this lesser matter, the use of our own true medicinal weights and measures in dispensing, and why this needless and vexatious interference with our duties? This opens the door to petty tyranny and the odious calling of the informer, from which we have hitherto been free."

Dispensaries of various kinds and surgeries are exempt from the visits of the inspector; it is exceedingly desirable to obtain the same privilege for dispensing chemists who are undoubtedly fully deserving of it. It will be remembered that measures stamped with the legal mark of one district are legal in all others, hence it is usual to purchase measures from the manufacturer which have been duly tested and stamped. This should suffice, as it affords every security.

It will, probably, be necessary to place before Parliament a short Bill exempting dispensing chemists from the operation of that part of the Apothecaries' Weights and Measures Act which empowers inspectors to visit the shops of chemists. This can be easily accomplished. It will then rest with the dispensing chemists of Great Britain to give a hearty and earnest support to this measure by numerous petitions and by letters to as many members of Parliament as possible. The removal of an odious, humiliating and ridiculous espionage is well worthy of some continuous effort.

I shall be glad to receive any suggestions or assistance.

Hastings. G. A. Keyworth, F.C.S.

Citrine Ointment.

Sir,—Your correspondent, Mr. J. E. Saul, writing in last week's Journal on this subject, appears to be unaware of the fact that the question of the composition of "golden ointment" was set at rest some ten years (it may be more) since, when it was shown to be a well-prepared ointment of red oxide of mercury. I am unable, at the present moment to lay my hand upon the paper in which this result was given, but it was published (if not in our Journal) in one of the journals devoted to pharmacy. Be this as it may, he may easily and quickly solve the question for himself thus, as I have just done:—Take about ·5 gm. of the ointment and place it in a test tube with about 4 c.c. of water to which a few drops of nitric acid have been added; boil the mixture gently for a short time, when the red colour will be seen to fade and finally disappear; pour the whole on a filter and place a drop of the filtrate on a gold coin; on placing an iron key in contact with both the coin and the drop of liquid, the mercury will be deposited on the coin and the stain so produced will disappear on heating. Further tests may be applied to the filtrate, but no evidence of an arsenical compound was to be found in the sample of "golden ointment" I thus examined. Incidentally I would mention that I am unable to agree with the statement made in Mr. R. A. Cripps's paper on "The History of Citrine Ointment," that "golden eye salve" is an ointment of yellow oxide of mercury; if by this designation he means the well-known proprietary article—for the colour alone would seem to negative this assumption, it being a bright red and not yellow colour; the colour, in fact, that very finely levigated red oxide of mercury would have. Query, how has Mr. Cripps satisfied himself that it is an ointment of yellow oxide of mercury?

It is somewhat curious that the colleges should have introduced citrine ointment (ung. hydrag. nitratis) as a substitute for "golden ointment," which it could not in any way have resembled; but that they did so we have it on the authority both of Christison and Squire. Quite as curious also is the oft-repeated statement in text books, both English and foreign, that it is an ointment of sulphuret of arsenic, some giving it as orpiment (Dorvault, Beasley, etc.), others as realgar (Paris, Gray, etc.), though in point of fact it resembles neither. The facility with which errors are perpetuated must have struck most of us, and I entirely agree with the expression made use of by a late President of our Society, that there was quite as much good work to be done in verifying or otherwise the results of others, as in striking out new branches of research. There is one explanation, however, which may account for these discrepancies; it is well known that many of these proprietary preparations have varied considerably from what they were originally, and it may, after all, be quite true that "golden ointment" of past time was prepared with a sulphuret of arsenic.

I trust that Mr. Cripps will pursue his researches into the composition of citrine ointment, as there is still much to be worked out.

Tottenham High Cross. Alfred E. Tanner.

Sir,—It is very easy for any person to criticize a paper which must have cost Mr. Cripps hours of study and patient research, but I think Mr. J. E. Saul is justified in calling attention to an error, viz., that "golden eye salve" was "an ointment of yellow oxide of mercury."

Mr. Cripps says Singleton's eye salve was "an ointment of yellow oxide of mercury." How this mistake was made I know not.

Paris most distinctly says:—"Under this name is sold a preparation, which consists of sulphuret of arsenic (orpiment) with lard, or spermaceti ointment." But he adds:—"The unguentum hydrargyri nitrico-oxidi of the London College is also sold under the same title."

Mr. Cripps might have said whether we are really entitled to call the ancient "unguentum basilicum flavum" the "unguentum balsilicum," and the linimentum arcæi of last century by the name "citrine." It is not my object to go further to prove Mr. Cripps's exertions to be at fault than in this respect, that if he is right, any yellow ointment may be called "citrine;" but I hold the "yellow ointment," or "unguentum citrinum" of the Edinburgh Pharmacopœia, 1722, is the real citrine ointment, from which all other colleges have copied, and that was a mercurial ointment—an ointment of "nitrate of mercury."

It will thus be seen that although an ointment of red oxide of mercury was sold as Singleton's, it did not possess the colour of golden eye salve. It was a substitute.

Christison says:—"The object of the officinal processes for this important ointment (unguentum citrinum) has been to imitate, as exactly as possible, a nostrum, well known by the name of the golden eye ointment."

Mr. Cripps does not mention the fact that "sandarach" or "sandaracha" was used long before the Christian era as an application in ophthalmic affections. In Pliny's time it was the red variety, or realgar, that was most esteemed. Whole pages might be written upon this subject, but of one thing I am convinced that Singleton's eye ointment was not an ointment of yellow oxide of mercury, but of yellow sulphuret of arsenic (As_2S_3)—orpiment.

Northallerton. Henry Brown.

Apprentice.—We thank you for the communication; similar absurdities are continually met with, but are hardly worth repeating in print.

Querist (who should have sent his name and address).—Such a preparation would be subject to duty, the only evidence of the payment of which, that we are acquainted with, is the presence of the Government stamp.

S. P. Q. R.—Brush the coins carefully with very dilute acid, then wash them thoroughly in water.

T. W. L.—The definite oleate of mercury is used and the "heavy petroleum oil" is the portion of petroleum having a high boiling point.

J. D. Morgan.—The chloride of calcium will absorb moisture from the atmosphere. Mix the ingredients each in as dry a condition as possible, and send out the divided powders in a closed bottle.

Fritz.—Use 1 grain of very dry soap to each pill, and the pil. galb. co. in powder.

A. T.—Cacao butter.

J. White.—As a rule crystalline substances, when dispensed, should be in powder, but this is not necessary with quinine.

Zinc.—Acid. hydrocyan. dil., B.P.

Medicus.—Seven parts of syr. simp., B.P., contain six parts by weight of sugar; the calculation is easy.

Communications, Letters, etc., have been received from Messrs. Baynes, Brown, Bumpstead, Orton, Abraham, Benger, Illingworth, Allen, Martin, Davies, An Old Subscriber, Chemicus, W.L.P.

THE PHARMACOPŒIA AS A STUDENT'S MANUAL.*

BY PROFESSOR ATTFIELD, F.R.S.

A pharmacopœia, the great medicine book of a country, is not primarily written for pupils. And yet it is the volume which, perhaps before all others, should be placed in the hands of the medical or pharmaceutical student. For it contains a description of the armoury with which as physician or pharmacist he will presently have to carry on, very literally, the battle of life; the fight against ill-health, disease, and decay. A glance through it in his earliest days of pupilage will reveal, even to his still untrained eye, what are unmistakably weapons of offence and of defence; and his general education and his common sense will rightly suggest that with the use of every kind of instrument there mentioned he will some day have to be familiar. Nay, he will rightly conclude that not only with the use, but with the construction, of each weapon he must sooner or later become acquainted. He will, moreover, reflect that before he can be a skilled warrior, or even a trusted armour-bearer, he must largely increase his more fundamental knowledge, both of matter and of force, and must more highly cultivate his powers of thought and of reason. Afterwards, during the period that he is extending that knowledge and maturing those powers, he will now and again glance into the collection, until, having acquired a mastery over underlying principles, he regularly frequents the armoury, and, intelligently, enjoyably and with ease, learns everything connected with the fabrication and properties and uses of the instruments there brought together.

Leaving metaphor, a pharmacopœia, British or foreign, is an index of work, a book which points out or makes manifest the pharmaceutical work which it is our duty and our pleasure to perform. To the student it is an index of educational scientific work, to the principal an index of practical art work, in pharmacy. For pharmacy includes both science and art, and may be regarded not as a distinct and separate art or science, so much as a mosaic of arts and sciences, of the chief details of which the Pharmacopœia is an index or catalogue. Thus, the book embraces physics and mechanics without being a physical or mechanical treatise; it includes chemistry and botany without being a handbook of either; it contains a list of materials for medical prescriptions without being a volume on that combination of subjects known as materia medica; and if, outside physics, mechanics, chemistry, botany and materia medica, there remain anything that can be termed pharmacy, the Pharmacopœia embodies it, yet the book is not a manual of pharmacy. That is to say, it is not a student's manual of pharmacy, whatever it may be for the medical or pharmaceutical practitioner. For either of these latter workers a pharmacopœia is perhaps such a text-book. At all events it is primarily written for them, not for students as students. Indeed, the preface of the British Pharmacopœia — the Pharmacopœia with which we are just now more immediately concerned —states that it is "a book containing a list of medicines and compounds, and the manner of preparing them, together with the true weights and measures by which they are to be prepared and mixed. . . . It is intended to afford to the members of the medical profession and those engaged in the preparation of medicines throughout the British Empire one uniform standard and guide, whereby the nature and composition of substances to be used in medicine may be ascertained and determined." One of its objects is "the definition of substances which the physician prescribes, and which are required to be kept at one uniform standard of strength and composition." Again, "pains have been taken to make the descriptions of all the substances referred to in the work sufficiently comprehensive and minute to afford a clear indication of what the medicines of the Pharmacopœia are intended to be, and to enable those who are engaged in their administration to determine the identity and test the purity of such as are met with in commerce." Here is no direct word for the pupil as a pupil.

But the student of pharmacy, medical or pharmaceutical, hopes and intends, at some future time, himself to administer or to manufacture medicines and to maintain them of standard strength; hence, before he has finished reading even the preface of the work, he will appreciate the thoughtfulness of those who placed the Pharmacopœia in his 'prentice hands and will lose no opportunity of studying a book which promises to give him such an insight into and such a grasp of his future career.

Here a question will arise in some minds as to whether or not a pharmacopœia could perhaps be made, what admittedly it is not now, namely, a systematic educational work for students. Such a course is probably quite impracticable. For to carry it out thoroughly would involve the conversion of a single handy book into a work of many volumes, amongst whose multitudinous pages all that relates to the practical manufacture or administration of medicines would be dwarfed if not hidden altogether. To adopt the plan partially and pithily would involve the giving of high official sanction to that too rapid and superficial acquirement of information still, alas, too common, though now everywhere deprecated; that is, would encourage, not the digestion, assimilation and retention of knowledge by the student himself, but, his mere temporary possession and employment of knowledge which, falsely labelled as his own, has, in reality, been collected and elaborated by others. Some pharmacopœias are more, some less, educationally valuable than the British; but, speaking generally, we may say that a pharmacopœia is not, and probably never will be, what is ordinarily understood by an educational work. Some of its peculiarities may perhaps be retained because their educational value adds weight to other reasons for their retention, but a systematic student's manual it can never become.

How, then, should a medical, and more especially a pharmaceutical, pupil deal with this book, one clearly not designed as a student's book, yet one with which a student must very early make close acquaintance and sooner or later become thoroughly familiar? How should he study the book, not the arts and sciences to which it is the index or guide, but the book as a book? For in the case of a pharmacopœia the student might, I think, with much advantage, at all events in the present stage of progress in British pharmaceutical education, adopt this mode of dealing with a volume. It is an unusual mode, no doubt. Commonly an educa-

* Presidential Address delivered at the opening meeting of the School of Pharmacy Students' Association, 1882-3.

tional work is read for the knowledge it will afford. A man pores over a manual of physics not to consider its construction but to study physics. He brings brain power to bear on a botanical book for the sake of its botany. He cares little for the plan or construction of a chemical treatise, but a great deal for the construction of its formulæ, theories and processes. Occasionally, however, a book is studied from the point of view of construction or method of arrangement. Thus, to write a critique a man must study a work from that point of view. And perhaps a young man intent on mastering his Pharmacopœia might well adopt the attitude or standpoint of the critic, not with the object of the critic, that of criticising, nor with the hope of studying with the ability possessed by a practised critic, but with the endeavour to employ the mode or manner of studying followed by a critic. For the time being his question regarding the Pharmacopœia will then be, not what is contained therein, but how is it contained. Into what classes or categories may its rich stores of facts be divided.

From this aspect, then, the young pupil or apprentice first examines the Pharmacopœia. He has scarcely finished reading the prefatory pages, has not glanced over more than half a dozen leaves, before he finds that the articles or sections have to do with vegetable substances, with mineral substances and with less definite mixtures or compounds. One of several courses he might then follow would be to purchase three small note-books and set to work to produce, as far as his own unaided ability might carry him, a manuscript catalogue of each of the three classes just mentioned; in fact, compile a kind of *catalogue raisonné* or subject-catalogue from one which is arranged alphabetically. Let him but do this earnestly and with reasonable intelligence and he may rest assured he will have laid a trustworthy foundation, at all events, of a knowledge of chemistry, botany and pharmacy.

What the pupil may next do, as regards the Pharmacopœia, will depend on his tastes, on his general mental character as formed by nature, on home-training and school associations, and on the variety of good advice with which he may have been favoured. Perhaps his inclinations will lead him further to divide and subdivide. Perhaps he will still more wisely prefer to spend occasional hours for a month or two with more truly educational books on chemistry, botany, etc., and then again proceed with his analysis of the Pharmacopœia. Sooner or later, however, the pharmaceutical apprentice who means to be something more than a mere mechanical mixer of drugs, and not a mere hand-to-mouth vendor of drugs and sundries, will have himself prepared the following manuscripts:—First, a well arranged list of the chemical substances mentioned in the Pharmacopœia, an improved form of his first rough catalogue of mineral preparations. Secondly, a similarly well arranged list of the vegetable products, with, perhaps, added columns showing the botanical name of the plant, its common name, the part employed, the country whence obtained, etc. Thirdly, a complete list of the compounded drugs or mixtures, with added columns showing the names of their chief or more powerful components, and the proportions in which the active agents occur in the respective preparations, etc. The compounds might be subdivided into powders, pills, ointments, etc.

A philological examination, by the student, of the chemical, botanical and other terms in the Pharmacopœia will be found to be both instructive and entertaining. And if he extends his labours, as he probably will, to the generic and specific names of wayside flowers, he will go far towards fitting himself to be a charming companion for a summer ramble, a strong link in the conversational chain encircling the dinner table, and a valued contributor to the tales and tit-bits of a winter's fireside. He will find poetry associated with a daphne, mythology with an atropa, music murmuring in the Latin name of the elder, history with gentian, lobelia and valerian, and geography with carum and colchicum. He will learn how graphic are the names humulus lupulus, crocus, helleborus, oxalis, digitalis, fœniculum, hyoscyamus. And should he not already be strong in classics he will be instructed by such adjectival terms as æstivus, agrarius, aquilina, arvensis, borealis, campestris, ciliaris, collinus, fluviatilis, gracilis, graveolens, hypnoides, lacustris, littoralis, muralis; nemoralis, petræa, pulchella, riparia, sativus, sylvestris, usitatissimum, vernalis, virosus. A search for the derivations of the chemical names of the Pharmacopœia is also an extremely interesting and instructive task.

An examination of the Pharmacopœia from the geographical standpoint will enlarge a pupil's mind as well as give him knowledge valuable in pharmacy. A few pen-and-ink skeleton maps are easily and quickly drawn, on which may be written, by the student himself, in different coloured inks, the habitats of the minerals and plants yielding officially recognized drugs. These habitats he should himself search out from works on materia medica.

There are formulæ and formulæ in a pharmacopœia. Thus in literary construction the following formulæ are alike:—

Take of—

Fine iron wire	$1\frac{1}{2}$ ounces.
Iodine	3 ounces.
Distilled water	15 fluid ounces.

Take of—

Mercury	2 ounces.
Confection of roses	3 ounces.
Liquorice root	1 ounce.

But in the latter, the proportions of ingredients are fixed by the authorities who issue the Pharmacopœia; in the former, nature, to whom all such authorities must bow, fixes absolute limits to the proportions of constituents in the product. The one product is a mechanical mixture, the other a chemical mixture; and although a student would scarcely be wise in drawing up lists of the whole of the formulæ for the mechanical mixtures of the Pharmacopœia as compared with those for chemical compounds, he may well select a score or so of each, for in so doing he will be planting seeds of information in his mind which, well nurtured, will mature into knowledge of some of the grandest forces of nature.

A medical pupil might, in addition, convert the alphabetical list of official remedial substances into a therapeutical list;—antacids, cathartics, diuretics, narcotics, stimulants, tonics, etc.

The Latin of the Pharmacopœia and even the arithmetic, including all weights and measures, might claim attention in the cases, of course very few, in which pupils feel they are not quite so strong in those subjects as they could desire.

And now, having broken up the great alphabetically arranged catalogue of matters called a pharmacopœia into lists chemical, botanical and pharmaceutical, and, perhaps, lists philological and geographical, the whole forming a manuscript pharmacopœial *catalogue raisonné*, the student will probably find himself nearing the end of his pupilage or apprenticeship. If his career is to be the medical profession, he will soon proceed to a medical school, fortunate if he has had any time to go through such preparatory work. If he is following the calling of a chemist and druggist, he will have completed his reading, so far, and his more or less practical acquaintance with the preparation of confections, decoctions, enemas, extracts, glycerines, infusions, inhalations, juices, liniments, lozenges, mixtures, ointments, pills, plasters, poultices, powders, spirits, suppositories, syrups, tinctures and wines; and will probably soon make such arrangements as will enable him to give some months to the systematic study of chemistry, including much practical chemistry, botany, materia medica and some physics.

This academic course completed, or being within measurable distance of completion, he will doubtless once more return to his Pharmacopœia. In a period of time the shortness of which will astonish him he will have gone through it with ease and with pleasure, adding to his memoranda those explanations of processes and of tests which his chemistry has revealed and those botanical facts which his study of the natural orders of plants has unveiled. Then according to the extent of his knowledge of principles and his personal ability, he will find himself more or less its master. In studying the book as a book, and in regarding it as an index of educational and practical work, he will have acquired a sound knowledge of those branches of art and science which together form pharmacy, and will have gone through an invaluable course of mental discipline.

A word of caution. No student will truly help his friend by lending him his manuscript notes *to copy*. What I have many times said privately, I now say publicly, namely that the value of such a summary lies in its being the result of a student's own reading, own learning, own work, own training. A summary, good enough in itself, but made by somebody else may, no doubt, be committed to memory, but the knowledge it affords will be superficial and ephemeral; it will not train the powers of thought and reason, and will do harm to the mind and the morals.

A word of encouragement. If this short address should meet the eye of any pupil in pharmacy who thinks that the calling will not pay for such effort as is here shadowed forth, let him be confirmed in his idea. The effort would never repay *him*. Let him quit the calling. He has already lost enough time and money in following it; he will lose more if he remain. To the pupil whose heart is in his work, and who believes that such endeavours will bring a commensurate reward, to him due reward will come. Future success in pharmacy will lie with those best educated.

In conclusion, I will only add that the most accomplished pharmacist owes most to the Pharmacopœia, and considers himself bound according to his opportunities to do his best to maintain its value. A true student of the Pharmacopœia, he never ceases to be its student. But his attitude towards it of unquestioning loyalty ever merges into one of good and intelligent scepticism, an attitude which provokes sound experimental research and results in improved processes and products.

CONVALLAMARIN,*

THE ACTIVE PRINCIPLE OF THE LILY OF THE VALLEY.

BY C. TANRET.

At a time when the attention of the medical public has just been called to the lily of the valley (*Convallaria majalis*), I have thought it would not be without interest, to complete, from a pharmacological point of view, the communications of Messrs. Sée and Langlebert.†

Those authors have attempted to ascertain which is the most active part of the plant, but without, in my opinion, arriving at any very clear conclusion. In fact, the roots did not give the results sought for; on the other hand the extract of the flowers exercised a very energetic action upon animals, but produced much less intense effects upon man, while an infusion of five or six grams of flowers remained without effect. The leaves showed so little activity that an extract from them required to be given in a dose three times larger than that of the extracts from other parts of the plant. In short, the best results were obtained with aqueous extracts prepared from the flowers and stems, with an addition of one-third of their weight of roots and leaves.

It will be remarked, first, that the time of flowering is not generally that which is recommended as the best for the collection of leaves and roots, the too aqueous juices of which have not yet been sufficiently elaborated. It follows, therefore, that the results obtained with the lily of the valley might vary when a plant collected in a more advanced stage is employed, a serious consideration in dealing with a rather energetic medicine. When it is added that the extracts alter, more or less profoundly, during their evaporation, it will be seen that in order to reckon upon the action of the lily of the valley, it will be necessary to look, not to the extract, but to the active principle.

This active principle has been known for many years. Walz, in 1858, announced that the lily of the valley contained two glucosides, which he named "convallarin" and "convallamarin." In 1867, Marmé made some physiological experiments with these two bodies, and published his researches under the title, "Ueber Convallamarin, ein neues Herzgift."‡ With convallarin, in doses of 3 to 4 grains, he obtained only a purgative effect; but he found that convallamarin acted principally upon the heart, and in a very small dose when injected into the circulatory system: 7 to 10 milligrams for dogs weighing 7 to 14 kilograms; 3 to 8 milligrams for cats of 2 to 3 kilograms; 2 to 3 milligrams for rabbits of 1 to 1·2 kilograms, etc. He also determined the toxic doses to be a crural injection of 15 to 30 milligrams for dogs, 5 to 8 milligrams for rabbits, etc. Death followed usually a few minutes after the administration of these doses; happening by stoppage of the heart and nearly always accompanied by very intense clonic convulsions. He adds that there is no doubt

* *Journal de Pharmacie*, [6], iii., 355; from the *Bull. Gén. de Thérapeutique*.

† See before, pp. 143, 144.

‡ *Nachrichten von der k. Gesellschaft der Wissens.*, Göttingen, 1867, p. 160.

that convallamarin is a heart poison, and that its physiological action approaches qualitatively and quantitatively that of digitalin, helleborin, the upas principles, etc.

Whilst convallarin is soluble in alcohol, but insoluble in water, convallamarin dissolves in water in all proportions, and is very soluble in ordinary alcohol and methylic alcohol. Convallamarin is insoluble in ether, chloroform and amylic alcohol, and is uncrystallizable. I have observed that it rotates the plane of polarization of light strongly to the left, and I have found its rotatory power in alcoholic solution to be $\alpha_D = -55°$. Pure convallamarin does not reduce Fehling's liquor until it has been boiled with dilute acid, when, according to Walz, it splits up into glucose and convallamaretin. Sulphuric acid dissolves it with a brown colour; but if it be treated with this reagent after having been moistened [? with water], a beautiful violet colour is developed which disappears upon the addition of water. Its taste is bitter, followed by a peculiar after-taste.

As the solvents of this glucoside are the same as those of the accompanying reduced sugar, it did not appear to me possible to obtain pure convallamarin,—not reducing cupric solution,—by the action alone of neutral liquids employed successively upon the plant or its extract. The process of Walz gives a satisfactory product, but as it is long and specially inconvenient, I have modified it in the following manner.

An alcoholic tincture made from the whole plant is precipitated with subacetate of lead and filtered, excess of lead is removed with dilute sulphuric acid, avoiding the use of more than is necessary, and after neutralizing, the tincture is distilled, the last portion of alcohol being driven off in the open air; then the cooled and filtered liquor is treated with tannin, care being taken to keep the liquid neutral by sparing additions of a dilute solution of carbonate of soda. A compound of tannin and convallamarin is precipitated, which, after washing, is dissolved in 60° alcohol, the solution decolorized with charcoal, decomposed with zinc oxide, filtered and evaporated to dryness. In this way convallamarin is obtained nearly white and having the appearance of ordinary digitalin. To free it from the salts that are sometimes carried down by the tannin precipitate it is a good plan to redissolve it in 90° alcohol, filter and then evaporate.

This treatment, applied to the lily of the valley collected in the first days of August in the present year, produced a yield of two grams of convallamarin per kilogram of the fresh plant.

With this process, the preparation of convallamarin will not present any serious difficulties; and if the lily of the valley should remain in the medical armamentarium, its active principle should be substituted for the plant by those who wish to protect themselves from the inconveniences presented by so unequal a distribution of convallamarin in the various parts, its variability according to the time of collection and its alteration in the extracts.

In order to verify this latter point I made the following experiment, based upon the loss of rotatory power which solutions of convallamarin undergo when the glucoside decomposes.

A pound of lily of the valley being taken, of which the strength in convallamarin was known, I commenced by estimating its acidity, which I represented in oxalic acid; then I dissolved in 100 grams of water corresponding quantities of convallamarin and acid. This solution was evaporated in a water-bath to the consistence of an extract, then redissolved in water and examined polarimetrically. The rotatory power had diminished one-half;* one-half, therefore, of the active principle had been decomposed and was no longer present as such in the extract, which, however, had been prepared under the most favourable conditions, the quantity of liquid to evaporate having been very small.

It remains only to refer to an alkaloid which M. Stanislas Martin has stated that he found in the fresh flowers of the lily of the valley and which he named "maialine."† In any case this body would have nothing to do with the activity of the rest of the plant, for I have not been able to find it in the leaves, stems or roots.

ELECTRIC LIGHTING AND THE TRANSMISSION OF FORCE BY ELECTRICITY.‡

Amongst the practical questions that now chiefly occupy public attention are those of electric lighting, and of the transmission of force by electricity. These together form a subject which has occupied my attention and that of my brothers for a great number of years, and upon which I may consequently be expected to dwell on the present occasion, considering that at Southampton I could deal only with some purely scientific considerations involved in this important subject. I need hardly remind you that electric lighting, viewed as a physical experiment, has been known to us since the early part of the present century, and that many attempts have, from time to time, been made to promote its application. Two principal difficulties have stood in the way of its practical introduction, viz., the great cost of producing an electric current so long as chemical means had to be resorted to, and the mechanical difficulty of constructing electric lamps capable of sustaining, with steadiness, prolonged effects. The dynamo-machine, which enables us to convert mechanical into electrical force, purely and simply, has very effectually disposed of the former difficulty, inasmuch as a properly conceived and well-constructed machine of this character converts more than 90 per cent. of the mechanical force imparted to it into electricity, 90 per cent. again of which may be re-converted into mechanical force at a moderate distance. The margin of loss, therefore, does not exceed 20 per cent., excluding purely mechanical losses, and this is quite capable of being further reduced to some extent by improved modes of construction; but it results from these figures that no great step in advance can be looked for in this direction. The dynamo-machine presents the great advantage of simplicity over steam or other power-transmitting engines; it has but one working part, namely, a shaft which, revolving in a pair of bearings, carries a coil or coils of wire admitting of perfect balancing. Frictional resistance is thus reduced to an absolute minimum, and no allowance has to be made for loss by condensation, or badly fitting pistons, stuffing boxes, or valves, or for the jerking action due to oscillating weights. The materials composing the machine, namely, soft iron and copper wire, undergo no deterioration or change by continuous working, and the depreciation of value is therefore a minimum, except where currents of exceptionally high potential are used, which appear to render the copper wire brittle.

* I have ascertained that the glucoside derived from the breaking up of convallamarin is without action upon polarized light.

† *Union Pharmaceutique*, 1865.

‡ From a Presidential Address delivered by Dr. C. W. Siemens, F.R.S., before the Society of Arts, November 15.

The essential points to be attended to in the construction of the dynamo-machine, are the prevention of induced currents in the iron, and the placing of the wire in such position as to make the whole of it effective for the production of outward current. These principles, which have been clearly established by the labours of comparatively few workers in applied science, admit of being carried out in an almost infinite variety of constructive forms, for each of which may be claimed some real or imaginary merits regarding questions of convenience or cost of production.

For many years after the principles involved in the construction of dynamo-machines had been made known, little general interest was manifested in their favour, and few were the forms of construction offered for public use. The essential features involved in the dynamo-machine, the Siemens' armature (1856), the Pacinotti ring (1861), and the self-exciting principle (1867), were published by their authors for the pure scientific interest attached to them, without being made subject matter of letters patent, which circumstance appears to have had the contrary effect of what might have been expected, in that it has retarded the introduction of this class of electrical machine, because no person or firm had a sufficient commercial interest to undertake the large expenditure which must necessarily be incurred in reducing a first conception into a practical shape. Great credit is due to Monsieur Gramme for taking the initiative in the practical introduction of dynamo-machines embodying those principles, but when five years ago I ventured to predict for the dynamo-electric current a great practical future, as a means of transmitting power to a distance, those views were still looked upon as more or less chimerical. A few striking examples of what could be practically effected by the dynamo-electric current, such as the illumination of the Place de l'Opéra, Paris, the occasional exhibition of powerful arc lights, and their adoption for military and lighthouse purposes, but especially the gradual accomplishment of the much desired lamp by incandescence in vacuum, gave rise to a somewhat sudden reversion of public feeling; and you may remember the scare at the Stock Exchange affecting the value of gas shares, which ensued in 1878, when the accomplishment of the sub-division of the electric light by incandescent wire was first announced, somewhat prematurely, through the Atlantic cable.

From this time forward electric lighting has been attracting more and more public attention, until the brilliant displays at the exhibition of Paris, and at the Crystal Palace last year, served to excite public interest to an extraordinary degree. New companies for the purpose of introducing electric light and power have been announced almost daily, whose claims to public attention as investments were based in some cases upon only very slight modifications of well-known forms of dynamo-machines, of arc regulators, or of incandescent carbon lights, the merits of which rested rather upon anticipations than upon any scientific or practical proof. These arrangements were supposed to be of such superlative merit that gas and other illuminants must soon be matters simply of history, and hence arose great speculative excitement. It should be born in mind, however, that any great technical advance is necessarily the work of time and serious labour, and that, when accomplished, it is generally found that so far from injuring existing industries, it calls additional ones into existence, to supply new demands, and thus gives rise to an increase in the sum total of our resources. It is, therefore, reasonable to expect that, side by side with the introduction of the new illuminant, gas lighting will go on improving and extending, although the advantage of electric light for many applications, such as the lighting of public halls and warehouses, of our drawing-rooms and dining-rooms, our passenger steamers, our docks and harbours, are so evident, that its advent may be looked upon as a matter of certainty.

Our Legislature has not been slow in recognizing the importance of the new illuminant. In 1879, a Select Committee in the House of Commons instituted a careful inquiry into its nature and probable cost, with a view to legislation, and the conclusions at which they arrived were, I consider, the best that could have been laid down. They advised that applications should be encouraged tentatively by the granting of permissive Bills, and this policy has given rise to the Electric Lighting Bill, 1882, promoted by Mr. Chamberlain, the President of the Board of Trade, regarding which much controversy has arisen. It could, indeed, hardly be expected that any act of legislation upon this subject could give universal satisfaction, because while there are many believers in gas who would gladly oppose any measure likely to favour the progress of the rival illuminant, and others who wish to see it monopolized, either by local authorities, or by large financial corporations, there are others again who would throw the doors open so wide as to enable almost all comers to interfere with the public thoroughfares, for the establishment of conducting wires, without let or hindrance.

The law as now established takes, I consider, a medium course between these diverging opinions, and, if properly interpreted, will protect, I believe, all legitimate interests, without impeding the healthy growth of establishments for the distribution of electric energy for lighting and for the transmission of power. Any firm or lighting company may, by application to the local authorities, obtain leave to place electric conductors below public thoroughfares, subject to such conditions as may be mutually agreed upon, the terms of such licence being limited to seven years; or an application may be made to the Board of Trade for a provisional order to the same effect, which, when sanctioned by Parliament, secures a right of occupation for twenty-one years. The licence offers the advantage of cheapness, and may be regarded as a purely tentative measure, to enable the firm or company to prove the value of their plant. If this is fairly established, the licence would in all probability be affirmed, either by an engagement for its prolongation from time to time, or by a provisional order which would, in that case, be obtained by joint application of the contractor and the local authority. At the time of expiration of the provisional order, a pre-emption of purchase is accorded to the local authority, against which it has been objected with much force by so competent an authority as Sir Frederick Bramwell, that the conditions of purchase laid down are not such as fairly to remunerate the contracting companies for their expenditure and risk, and that the power of purchase would inevitably induce the parochial bodies to become mere trading associations. But while admitting the undesirability of such a consummation, I cannot help thinking that it was necessary to put some term to contracts entered into with speculative bodies at a time when the true value of electric energy, and the best conditions under which it should be applied, are still very imperfectly understood. The supply of electric energy, particularly in its application to transmission of power, is a matter simply of commercial demand and supply, which need not partake of the character of a large monopoly similar to gas and water supply, and which may therefore be safely left in the hand of individuals, or of local associations, subject to a certain control for the protection of public interests. At the termination of the period of the provisional order, the contract may be renewed upon such terms and conditions as may at that time appear just and reasonable to Parliament, under whose authority the Board of Trade will be empowered to effect such renewal.

Complaints appear almost daily in the public papers to the effect that townships refuse their assent to applications by electric light companies for provisional orders; but it may be surmised that many of these applications are of a more or less speculative character, the object being to secure monopolies for eventual use or sale, under which circumstances the authorities are clearly justified in withholding their assent; and no licences or provisional orders should, indeed, be granted, I consider, unless the applicants can give assurance of being able and willing to carry out the work within a reasonable time. But there are technical questions involved which are not yet sufficiently well understood to admit of immediate operations upon a large scale.

Attention has been very properly called to the great divergence in the opinions expressed by scientific men regarding the area that each lighting district should comprise, the capital required to light such an area, and the amount of electric tension that should be allowed in the conductors. In the case of gas supply, the works are necessarily situated in the outskirts of the town, on account of the nuisance this manufacture occasions to the immediate neighbourhood; and, therefore, gas supply must range over a large area. It would be possible, no doubt, to deal with electricity on a similar basis, to establish electrical mains in the shape of copper rods of great thickness, with branches diverging from them in all directions; but the question to be considered is, whether such an imitative course is desirable on account either of relative expense or of facility of working. My own opinion, based upon considerable practical experience and thought devoted to the subject, is decidedly adverse to such a plan. In my evidence before the Parliamentary Committee, I limited the desirable area of an electric district in densely populated towns to a quarter of a square mile, and estimated the cost of the necessary establishment of engines, dynamo-machines, and conductors, at £100,000, while other witnesses held that areas from one to four square miles could be worked advantageously from one centre, and at a cost not exceeding materially the figure I had given. These discrepancies do not necessarily imply wide differences in the estimated cost of each machine or electric light, inasmuch as such estimates are necessarily based upon various assumptions regarding the number of houses and of public buildings comprised in such a district, and the amount of light to be apportioned to each, but I still maintain my preference for small districts.

By way of illustration, let us take the parish of St James's, near at hand, a district not more densely populated that other equal areas within the metropolis, although comprising, perhaps, a greater number of public buildings. Its population, according to the preliminary report of the census taken on the 4th of April, 1881, was 29,865, it contains 3018 inhabited houses, and its area is 784,000 square yards, or slightly above a quarter of a square mile.

To light a comfortable house of moderate dimensions in all its parts, to the exclusion of gas, oil, or candles, would require about 100 incandescent lights of from 15- to 18-candle power each, that being, for instance, the number of Swan lights employed by Sir William Thomson in lighting his house at Glasgow University. Eleven-horse power would be required to excite this number of incandescent lights, and at this rate the parish of St. James's would require $3018 \times 11 = 33{,}200$ horse-power to work it. It may be fairly objected, however, that there are many houses in the parish much below the standard here referred to, but on the other hand, there are six hundred of them with shops on the ground floor, involving larger requirements. Nor does this estimate provide for the large consumption of electric energy that would take place in lighting the eleven churches, eighteen club-houses, nine concert halls, three theatres, besides numerous hotels, restaurants and lecture halls. A theatre of moderate dimensions, such as the Savoy Theatre, has been proved by experience to require 1200 incandescent lights, representing an expenditure of 133 horse-power; and about one-half that power would have to be set aside for each of the other public buildings here mentioned, constituting an aggregate of 2926 horse-power; nor does this general estimate comprise street lighting, and to light the six and a half miles of principal streets of the parish with electric light would require, per mile, thirty-five arc lights of 350 candle-power each or a total of 227 lights. This, taken at the rate of 0·8 horse-power per light, represents a further requirement of 182 horse-power, making a total of 3108 horse-power, for purposes independent of house lighting, being equivalent to 1 horse-power per inhabited house, and bringing the total requirements up to 109 lights = 12 horse-power per house.

I do not, however, agree with those who expect that gas lighting will be entirely superseded, but have, on the contrary, always maintained that the electric light, while possessing great and peculiar advantages for lighting our principal rooms, halls, warehouses, etc., owing to its brilliancy, and more particularly to its non-interference with the healthful condition of the atmosphere, will leave ample room for the developement of the former, which is susceptible of great improvement, and is likely to hold its own for the ordinary lighting up of our streets and dwellings.

Assuming, therefore, that the bulk of domestic lighting remains to the gas companies, and that the electric light is introduced into private houses, only, at the rate of, say 12 incandescent lights per house, the parish of St. James's would have to be provided with electric energy sufficient to work $(9+12)\ 3018 = 63{,}378$ lights $= 7042$ horse-power effective; this is equal to about one-fourth the total lighting power required, taking into account that the total number of lights that have to be provided for a house are not all used at one and the same time. No allowance is made in this estimate for the transmission of power, which, in course of time, will form a very large application of electric energy; but considering that power will be required mostly in the day time, when light is not needed, a material increase in plant will not be necessary for that purpose.

In order to minimize the length and thickness of the electric conductor, it would be important to establish the source of power, as nearly as may be, in the centre of the parish, and the position that suggests itself to my mind is that of Golden Square. If the unoccupied area of this square, representing 2500 square yards, were excavated to a depth of 25 feet, and then arched over so as to re-establish the present ground level, a suitable covered space would be provided for the boilers, engines, and dynamo-machines, without causing obstruction or public annoyance; the only erection above the surface would be the chimney, which, if made monumental in form, might be placed in the centre of the square, and be combined with shafts for ventilating the subterranean chamber, care being taken of course to avoid smoke by insuring perfect combustion of the fuel used. The cost of such a chamber, of engine-power, and of dynamo-machines, capable of converting that power into electric energy, I estimate at £140,000. To this expense would have to be added that of providing and laying the conductors, together with the switches, current regulators, and arrangements for testing the insulation of the wire.

The cost and dimensions of the conductors would depend upon their length, and the electromotive force to to be allowed. The latter would no doubt be limited, by the authorities, to the point at which contact of the two conductors with the human frame would not produce injurious effects, or say to 200 volts, except for street lighting, for which purpose a higher tension is admissible. In considering the proper size of conductor to be used in any given installation, two principal factors have to be taken into account; first, the charge for interest and depreciation on the original cost of a unit length of the conductor; and, secondly, the cost of the electrical energy lost through the resistance of a unit of length. The sum of these two, which may be regarded as the cost of conveyance of electricity, is clearly least, as Sir William Thomson pointed out some time ago, when the two components are equal. This, then, is the principle on which the size of a conductor should be determined.

From the experience of large installations, I consider that electricity can, roughly speaking, be produced in London at a cost of about one shilling per 10,000 ampère-volts or watts (746 watts being equal to 1 horse-power) for an hour. Hence, assuming that each set of four incandescent lamps in series (such as Swan's, but for which may be substituted a smaller number of higher resistance and higher luminosity) requires 200 volts electromotive force, and 60 watts for their efficient working, the total current required for 64,000 such lights is 19,200 ampères, and the cost of the electric energy lost by this current in passing through 1-100th of an ohm resistance, is £16 per hour.

The resistance of a copper bar one quarter of a mile in length, and 1 square inch in section, is very nearly 1-100th of an ohm, and the weight is about $2\frac{1}{4}$ tons. Assuming, then, the price of insulated copper conductor at £90 per ton, and the rate of interest and depreciation at $7\frac{1}{2}$ per cent., the charge per hour of the above conductor, when used eight hours per day, is $1\frac{1}{2}d.$ Hence, following the principle I have stated above, the proper size of conductor to use for an installation of the magnitude I have supposed would be one of 48·29 inches section, or a round rod 8 inches diameter.

If the mean distance of the lamps from the station be assumed at 350 yards, the weight of copper used in the complete system of conductors would be nearly 168 tons, and its cost £15,120. To this must be added the cost of iron pipes, for carrying the conductors underground, and of testing boxes, and labour in placing them. Four pipes of 10 inch diameter each, would have to proceed in different directions from the central station, each containing sixteen separate conductors of 1 inch diameter, and separately insulated, each of them supplying a sub-district of 1000 lights. The total cost of establishing these conductors may be taken at £37,000, which brings the total expenditure for central station and leads to £177,000. I assume the conductors to be placed underground, as I consider it quite inadmissible, both as regards permanency and public safety and convenience, to place them above ground, within the precincts of towns. With this expenditure, the parish of St. James's would be supplied with the electric light to the extent of about 25 per cent. of the total illuminating power required. To provide a larger percentage of electric energy would increase the cost of establishment proportionately; and that of conductors, nearly in the square ratio of the increase of the district, unless the loss of energy by resistance is allowed to augment instead.

It may surprise uninitiated persons to be told that to supply a single parish with electric energy necessitates copper conductors of a collective area equal to a rod of 8 inches in diameter; and how, it may be asked, will it be possible under such conditions to transmit the energy of waterfalls to a distance of twenty or thirty miles, as has been suggested? It must indeed be admitted that the transmission of electric energy of such potential (200 volts) as is admissible in private dwellings would involve conductors of impracticable dimensions, and in order to transmit electrical energy to such distances, it is necessary to resort in the first place to an electric current of high tension. By increasing the tension from 200 to 1200 volts the conductors may be reduced to one-sixth their area, and if we are content to lose a larger proportion of the energy obtained cheaply from a waterfall, we may effect a still greater reduction. A current of such high potential could not be introduced into houses for lighting purposes, but it could be passed through the coils of a secondary dynamo-machine, to give motion to another primary machine, producing currents of low potential to be distributed for general consumption. Or secondary batteries may be used to effect the conversion of currents of high into those of low potential, whichever means may be found the cheaper in first cost, in maintenance, and most economical of energy. It may be advisable to have several such relays of energy for great distances, the result of which would be a reduction of the size and cost of conductor at the expense of final effect, and the policy of the electrical engineer will, in such cases, have to be governed by the relative cost of the conductor, and of the power at its original source. If secondary batteries should become more permanent in their action than they are at the present time, they may be largely resorted to by consumers, to receive a charge of electrical energy during the day time, or the small hours of the night, when the central engine would otherwise be unemployed, and the advantage of resorting to these means will depend upon the relative first cost, and cost of working the secondary battery and the engine respectively. These questions are, however, outside the range of our present consideration.

The large aggregate of dwellings comprising the metropolis of London covers about seventy square miles, thirty of which may be taken to consist of parks, squares, and sparely inhabited areas, which are not to be considered for our present purpose. The remaining forty square miles could be divided into say one hundred and forty districts, slightly exceeding a quarter of a square mile on the average, but containing each fully three thousand houses, and a population similar to that of St. James's.

Assuming twenty of these districts to rank with the parish of St. James's (after deducting the six hundred shops which I did not include in my estimate) as central districts, sixty to be residential districts, and sixty to be comparatively poor neighbourhoods, and estimating the illuminating power required for these three classes in the proportion of 1 to $\frac{2}{3}$ to $\frac{1}{3}$, we should find that the total capital expenditure for supplying the metropolis with electric energy to the extent of 25 per cent. of the total lighting requirements would be—

$$\begin{aligned} 20 \times \phantom{\tfrac{2}{3}\times}\ 177{,}000 &= £3{,}540{,}000 \\ 60 \times \tfrac{2}{3} \times 177{,}000 &= £7{,}080{,}000 \\ 60 \times \tfrac{1}{3} \times 177{,}000 &= £3{,}540{,}000 \\ \hline & \ £14{,}160{,}000 \end{aligned}$$

or say £14,000,000, without including lamps and internal fittings, and making an average capital expenditure of £100,000 per district.

To extend the same system over the towns of Great Britain, and Ireland would absorb a capital exceeding certainly £64,000,000, to which must be added £16,000,000 for lamps and internal fittings, making a total capital expenditure of £80,000,000. Some of us may live to see this capital realized, but to find such an amount of capital, and, what is more important, to find the manufacturing appliances to produce work representing this value of machinery and wire, must necessarily be the result of many years of technical development. If, therefore, we see that electric companies apply for provisional orders to supply electric energy, not only for every town throughout the country, but also for the colonies, and for foreign parts, we are forced to the conclusion that their ambition is somewhat in excess of their power of performance; and that no provisional order should be granted except conditionally on the work being executed within a reasonable time, as without such a provision the powers granted may have the effect of retarding instead of advancing electric lighting, and of providing an undue encouragement to purely speculative operations.

The extension of a district beyond the quarter of a square mile limit would necessitate an establishment of unwieldy dimensions, and the total cost of electric conductors per unit area would be materially increased; but independently of the consideration of cost, great public inconvenience would arise in consequence of the number and dimensions of the electric conductors, which could no longer be accommodated in narrow channels placed below the kerb stones, but would necessitate the construction of costly subways—veritable *cava electrica*.

The amount of the working charges of an establishment comprising the parish of St. James's would depend on the number of working hours in the day, and on the price of fuel per ton. Assuming the 64,000 lights to incandesce for six hours a day, the price of coal to be 20*s.* a ton, and the consumption 2 lbs. per effective horse-power per hour, the annual charge under this head, taking eight hours' firing, would amount to about £18,300, to which would have to be added for wages, repairs, and sundries, about £6000, for interest with depreciation at 7½ per cent., £13,300, and for general management say £3400, making a total annual charge of £41,000, or at the rate of 12*s.* 9½*d.* per incandescent lamp per annum. To this has to be added the cost of renewal of lamps, which may be taken at 5*s.* per lamp of sixteen candles, lasting 1200 hours, or to 9*s.* per annum, making a total of 21*s.* 9½*d.* per lamp for a year.

In comparing these results with the cost of gas lighting, we shall find that it takes 5 cubic feet of gas, in a good argand burner, to produce the same luminous effect as 1 incandescent light of 16-candle power. In lighting such a burner every day for six hours on the average, we obtain an annual gas consumption of 10,950 cubic feet, the value of which, taken at the rate of 2*s.* 8*d.* per thousand, represents an annual charge of 29*s.*, showing that electric light by incandescence, when carried out on a large scale, is decidedly cheaper than gas lighting at present prices, and with the ordinary gas-burners.

On the other hand, the cost of establishing gas-works and mains of a capacity equal to 64,000 argand burners would involve an expenditure not exceeding £80,000 as compared with £177,000 in the case of electricity; and it is thus shown that although it is more costly to establish a given supply of illuminating power by electricity than gas, the former has the advantage as regards current cost of production.

It would not be safe, however, for the advocates of electric lighting to rely upon these figures as representing a permanent state of things. In calculating the cost of electric light, I have only allowed for depreciation and 5 per cent. interest upon capital expenditure, whereas gas companies are in the habit of dividing large dividends, and can afford to supply gas at a cheaper rate, by taking advantage of recent improvements in manufacturing operations, and of the ever-increasing value of their by-products, including tar, coke, and ammoniacal liquor. Burners have, moreover, been recently devised by which the luminous effect for a given expenditure of gas can be nearly doubled by purely mechanical arrangements, and the brilliancy of the light can be greatly improved.

On the other hand, electric lighting also may certainly be cheapened by resorting, to a greater extent than has been assumed, to arc lighting, which though less agreeable than the incandescent light for domestic purposes, can be produced at less than half the cost, and deserves on that account the preference for street lighting, and for large halls, in combination with incandescent lights. Lamps by incandescence may be produced hereafter at a lower cost, and of a more enduring character.

Considering the increasing public demand for improved illumination, it is not unreasonable to expect that the introduction of the electric light to the full extent here contemplated would go hand in hand with an increasing consumption of gas for illuminating and for heating purposes, and the neck-to-neck competition between the representatives of the two systems of illumination, which is likely to ensue, cannot fail to improve the quality, and to cheapen the supply of both, a competition which the consuming public can afford to watch with complacent self-satisfaction. Electricity must win the day, as the light of luxury; but gas will, at the same time, find an ever-increasing application for the more humble purposes of diffusing light.

In my address to the British Association I dwelt upon the capabilities and prospects of gas, both as an illuminant and as a heating agent, and I do not think that I was over-sanguine in predicting for this combustible a future exceeding all present anticipations.

I also called attention to the advantages of gas as a heating agent, showing that if supplied specially for the purpose, it would become not only the most convenient, but by far the cheapest form of fuel that can be supplied to our towns. Such a general supply of heating separately from illuminating gas, by collecting the two gases into separate holders during the process of distillation, would have the beneficial effects—

1. Of giving to lighting gas a higher illuminating power.
2. Of relieving our towns of their most objectionable traffic—that in coal and ashes.
3. Of effecting the perfect cure of that bugbear of our winter existence—the smoke nuisance.
4. Of largely increasing the production of these valuable by-products, tar, coke, and ammonia, the annual value of which already exceeds by nearly £3,000,000 that of the coal consumed in the gas-works.

The late exhibitions have been beneficial in arousing public interest in favour of smoke abatement, and it is satisfactory to find that many persons, without being compelled to do so, are now introducing perfectly smokeless arrangements for their domestic and kitchen fires.

The Society of Arts, which for more than a hundred years has given its attention to important questions regarding public health, comfort, and instruction, would, in my opinion, be the proper body to examine thoroughly into the question of the supply and economical application of gas and electricity for the purposes of lighting, of power production, and of heating. They would thus pave the way to such legislative reform as may be necessary to facilitate the introduction of a national system.

If I can be instrumental in engaging the interest of the Society in these important questions, especially that of smoke prevention, I shall vacate this chair next year with the pleasing consciousness that my term of office has not been devoid of a practical result.

INFLUENCE OF PEPTONES AND CERTAIN INORGANIC SALTS ON THE DIASTATIC ACTION OF SALIVA.*

BY R. H. CHITTENDEN AND J. S. ELY.

(*Concluded from page 387.*)

First Experiment.

	Wt. Cu in one-tenth. Gram.
Saliva and starch alone	0·0872
Saliva and starch + 0·05 per cent. HCl = 0·025 per cent.	0·0088
Saliva and starch + 0·05 per cent. HCl + 0·012 gram NaCl	0·0132
Saliva and starch + 0·05 per cent. + 0·012 gram Na_2HPO_4	0·0120

Second Experiment.

	Wt. Cu in one-tenth. Gram.
Saliva and starch alone	0·0835
Saliva and starch + 0·05 per cent. HCl = 0·025 per cent.	0·0050
Saliva and starch + 0·05 per cent. HCl + 0·012 gram $CaHPO_4$	0·0079
Saliva and starch + 0·05 per cent. HCl + 0·015 gram $CaHPO_4$	0·0490
Saliva and starch + 0·05 per cent. HCl + 0·024 gram $CaHPO_4$	0·0600

It is thus evident that sodium chloride and phosphate when present to the extent of 0·012 per cent. exercise but a very slight influence on the action of the saliva. Calcium phosphate, however, is seen to decidedly increase the diastatic action, though the amount contained in the

* From the *American Chemical Journal.*

peptones can have but little influence on the formation of sugar. Very striking is the great increase of sugar formed in the presence of 24 milligrams of calcium phosphate. This result is certainly suggestive of a possible utility of the calcium phosphate invariably present in wheat, oats, and carbohydrate matter in general. What may be the exact explanation of the action of the phosphate in such a weak acid solution is of course hypothetical. The salt dissolves, in part at least, in the acid, and is thus probably modified with formation of bodies more favourable to the action of the ferment; it certainly cannot diminish to any extent the strength of the acid.

The influence of the combined inorganic matter of the peptones was now determined by experiment with the ash of No. 1, which contained 1·71 per cent.

	Saliva and starch. Wt. Cu in one-tenth.	+0·05 per cent. HCl. Wt. Cu in one-tenth.	+1 gram peptone. Wt. Cu in one-tenth.	+Ash 1 gram peptone. Wt. Cu in one-tenth.
1.	0·0866 gram	0·0053 gram	0·1058 gram	0·0370 gram
2.	0·0862 „	—	—	0·0123 „

Thus, in the sample containing the largest percentage of ash, and presumably therefore of calcium phosphate, and under the same conditions as this salt appears to work to the best advantage, only a slight increase is noticed in the diastatic action of the saliva. It is therefore evident that while the addition of 50 c.c. 0·05 per cent. hydrochloric acid to an equal volume of saliva and water brings the diastatic action down almost to zero, the addition of 1 gram of peptones to this acid fluid increases the diastatic action of the saliva to above its normal amount. In other words the presence of 1 per cent. of gastric peptones in a salivary mixture containing 0·025 per cent. of acid acts as a stimulant to the diastatic ferment, causing it to act with greatly increased vigour. This fact appears to us to be of prime importance in solving the question as to the possibility of a continued action of the salivary ferment in the stomach. In 1881 one* of us, experimenting with human saliva, found that its diastatic action was increased by the presence of very minute quantities of hydrochloric acid; thus while the quantity of sugar formed by freshly collected saliva was regarded as 100, the quantity formed by saliva of the same collecting in a mixture containing 0·005 per cent. of hydrochloric acid was 110. Increasing the percentage of acid diminishes the diastatic action, until at last, when the fluid contains 0·025 per cent. of hydrochloric acid, the formation of sugar is almost entirely stopped. Again, it was found† on digesting 25 c.c. of human saliva with 50 c.c. of gastric juice containing 0·2 per cent. of hydrochloric acid, at 40° C. for two hours, that the diastatic ferment was entirely destroyed; likewise that simple warming of the saliva with 0·2 per cent. acid at 40° C. for two hours was sufficient to destroy the greater part of the ferment, as was evinced by the low diastatic power of the neutralized fluid. Both of these results have received recent confirmation from the experiments of J. N. Langley‡ on the diastatic ferments of the parotid of rabbits. From his experiments he concludes that the ptyalin is destroyed by 0·2—0·04 per cent. hydrochloric acid in from seven to twenty-four hours at 40° C., and that the presence of 0·014 per cent. of acid is sufficient to destroy all but the merest trace of ferment for five minutes at 39° C. It appears to us, however, that in the case of human saliva at least there may be in the presence of a very dilute acid a simple stopping of the diastatic action without destruction of the ferment; thus, in the presence of 0·025 per cent. of acid there is but little diastatic action, but if that percentage of acid is sufficient to destroy the ferment in such a short time, in what manner does the 1 per cent. of peptones in an acid solution of the same strength cause such an increased formation of sugar? Again, the experiments of Chittenden and Griswold showed that by warming a mixture of starch, saliva, and artificial gastric juice of weak acidity at 40° C. for forty-five minutes, the diastatic action of the saliva was greatly increased; thus, in the digestion of 1 gram of starch + 25 c.c. of water + 50 c.c. of gastric juice, containing 0·5 per cent. hydrochloric acid + 25 c.c. saliva, the amount of sugar formed as compared with the amount formed by the saliva alone was 133 : 100; while, as the present experiments show, the presence of 0·025 per cent. hydrochloric acid alone stops the action almost completely. It therefore seems probable that in the presence of such dilute acids as the above the ferment is simply hindered in its action, the presence of the peptones being sufficient to counteract the retarding influence of the acid. That this view, as to the non-destruction of the ferment is correct, as regards human saliva at least, we think is plainly demonstrated by the following experiment. 75 c.c. of filtered saliva were divided into three equal parts, which were treated as follows:—

1st. 25 c.c. saliva + 25 c.c. 0·05 per cent. HCl warmed at 40° C. for forty-five minutes. Solution then neutralized with Na_2CO_3. One gram of starch made into a paste with 50 c.c. H_2O was then added and the mixture warmed at 40° C. for forty-five minutes. Solution boiled and diluted to 500 c.c. 50 c.c. of this solution reduced 0·0862 gram Cu.

2nd. 25 c.c. saliva + 25 c.c. H_2O + 50 c.c. 0·05 per cent. HCl warmed at 40° C. for forty-five minutes. Solution then neutralized with Na_2CO_3. 1 gram of starch made into a paste with 25 c.c. H_2O was then added and the mixture warmed at 40° C. for forty-five minutes. Solution boiled and diluted to 500 c.c. 50 c.c. of this solution reduced 0·0805 gram Cu.

3rd. 25 c.c. saliva + 75 c.c. H_2O warmed at 40° C. for forty-five minutes. 1 gram of starch made into a paste with 25 c.c. H_2O was then added and the mixture warmed at 40° C. for forty-five minutes. Solution boiled and diluted to 500 c.c. 50 c.c. of this solution reduced 0·0824 gram Cu.

Here it is plainly seen that the ferment has not been in the least affected by the action of 0·025 per cent.* hydrochloric acid at this temperature. In the case of 0·1 or 0·2 per cent. acid the peptones are wholly without influence, since these strengths of acid are capable of destroying the ferment. It is evident that the salivary ferment is ultimately destroyed in the stomach by the gastric juice, but this fact does not necessarily preclude the possibility of a continued action of the saliva in the stomach. There is a growing impression that in the first stage of stomach digestion there is but little or no free acid present; thus Reinhard v. d. Velden† claims, as a result of observation, that for the first three-fourths of

* Chittenden and Griswold, *American Chemical Journal*, iii., 305.

† Chittenden and Griswold, *loc. cit.*

‡ Foster's *Journal of Physiology*, iii., 246.

* It should be mentioned here that the real percentage of acid is somewhat less than 0·025, owing to the slight alkalinity of the saliva. Ordinarily, however, the alkalinity is not so great in a sample of several hundred cubic centimetres as in a small quantity of freshly secreted saliva. That there might be no possible chance of error, 25 c.c. of mixed saliva were carefully neutralized with diluted hydrochloric acid. Then 25 c.c. of 0·05 per cent. HCl were added, making an exactly 0·025 per cent. HCl solution. This mixture was then warmed at 40° C. for forty-five minutes, after which it was exactly neutralized with Na_2CO_3 solution. 1 gram of starch in 50 c.c. H_2O was then added and the whole warmed at 40° C. for forty-five minutes; 50 c.c. or one-tenth of the diluted fluid yielded 0·0882 gram Cu. Thus here, as in the above experiments, it is plainly evident, from the diastatic action of the neutralized saliva, that the ptyalin is not destroyed or even affected by 0·025 per cent. of actual HCl under the above conditions.

† *Zeitschrift f. physiolog. Chem.*, iii., 205.

an hour after eating a hearty meal, human gastric juice fails to contain much if any free acid.

It now seemed desirable to ascertain the rapidity with which starch is converted into sugar by the saliva. 125 c.c. of filtered saliva were thoroughly mixed, and 12 c.c. of this fluid were used in each experiment. The starchy solution was made by boiling 0·5 gram of starch with 40 c.c. of water, and to this solution the 12 c.c. of saliva were added, making approximately 52 c.c. of fluid. The mixtures were kept at a temperature of 40° C. for the specified time, then boiled to destroy the ferment. Each fluid was then diluted to 200 c.c. and the sugar determined as before in 50 c.c. of the mixed and filtered solution. Following are the results:—

Period of digestion.	Wt. Cu in one-fourth.	Total amount of sugar.	Percentage of starch converted into sugar.
1 minute	0·0870 gram	0·4425 gram	39·82 per cent.
5 minutes	0·0963 "	0·4898 "	44·09 "
10 "	0·0991 "	0·5040 "	45·36 "
15 "	0·1005 "	0·5111 "	45·99 "
30 "	0·1040 "	0·5286 "	47·57 "
45 "	0·1087 "	0·5525 "	49·72 "
1 hour	0·1109 "	0·5637 "	50·73 "
2 hours	0·1147 "	0·5842 "	52·57 "

This experiment makes it very apparent that by far the greater part of the starch is almost immediately converted into sugar. It seems, therefore, quite possible, especially in view of the action of peptones in a weak acid solution, that in the case of human beings there may be a continuation of salivary digestion in the stomach, provided the contents of the stomach during the first stage of digestion do not contain more than 0·025 per cent. of free acid.

Influence of Peptones in Alkaline Solution.

Previous experiments have demonstrated that the addition of sodium carbonate to saliva has a retarding influence on salivary digestion. It now seemed advisable to study the influence of peptones in the presence of dilute solutions of sodium carbonate, with especial reference to the pancreatic ptyalin, for presumably in the intestinal canal the diastatic ferment there present acts on starch in an alkaline medium. 0·6 per cent., 0·3 per cent., and 0·1 per cent. solutions of sodium carbonate were employed, experiments being tried with both starch and glycogen. One gram of peptones was used in each case, and as this amount was dissolved in 50 c.c. of the dilute alkali, the digestive mixture of 100 c.c. contained approximately one-half the percentage of alkali employed. The following results were obtained:—

1.—With 0·6 per cent. Na_2CO_3 and 1 gram peptones.

	Saliva alone. Wt. Cu in one-tenth.	Saliva + 50 c.c. alkali. Wt. Cu in one-tenth.	Saliva, alkali, and peptones. Wt. Cu in one-tenth.
Starch .	0·0905 gm.	0·0239 gm.	0·0456 gm.
" .	0·0904 "	0·0222 "	0·0486 "
" .	0·0835 "	0·0214 "	0·0515 "
Glycogen	0·1300 "	0·0312 "	0·0683 "

2.—With 0·3 per cent. Na_2CO_3 and 1 gram peptones.

	Saliva alone. Wt. Cu in one-tenth.	Saliva + 50 c.c. alkali. Wt. Cu in one-tenth.	Saliva, alkali, and peptones. Wt. Cu in one-tenth.
Starch .	0·0904 gm.	0·0393 gm.	0·0685 gm.
" .	0·0835 "	0·0331 "	0·0710 "
Glycogen	0·1281 "	0·0423 "	0·1050 "

3.—With 0·1 per cent. Na_2CO_3 and 1 gram peptones.

	Saliva alone. Wt. Cu in one-tenth.	Saliva + 50 c.c. alkali. Wt. Cu in one-tenth.	Saliva, alkali, and peptones, Wt. Cu in one-tenth.
Glycogen	0·1281 gm.	0·0908 gm.	0·1197 gm.

It becomes evident then from these experiments that in a solution containing either 0·3 per cent. or 0·15 per cent. of sodium carbonate, the presence of the peptones nearly doubles (quite and even more in the case of glycogen) the diastatic action, bringing it up almost to the action of the unaltered saliva. It may be questionable whether these experiments afford proof positive that the peptones stimulate the pancreatic ferment in the conversion of starch into sugar in the intestinal canal, but it is certainly proven that under such conditions as have been described here, the presence of 1 per cent. of peptones in a 0·3 per cent. sodium carbonate solution causes a greatly increased formation of sugar. Thus it seems probable that in the proteid and diastatic pancreatic digestion the formation of peptones, which must go on side by side with the formation of sugar, affords a decided aid to the latter process.

We next endeavoured to ascertain whether the salts already experimented with have any influence on diastatic action in alkaline solutions of the strength specified. The following experiments were tried:—

First Experiment.

	Wt. Cu in one-tenth. Gram.
Saliva and starch alone	0·0872
Saliva and starch + 50 c.c. 0·6 per cent. Na_2CO_3 = 3 per cent. alkali	0·0220
Saliva and starch + 50 c.c. 0·6 per cent, Na_2CO_3 + 0·012 gram NaCl	0·0287
Saliva and starch + 50 c.c. 0·6 per cent. Na_2CO_3 + 0·012 gram Na_2HPO_4	0·0275

Second Experiment.

	Wt. Cu in one-tenth. Gram.
Saliva and starch alone	0·0844
Saliva and starch + 50 c.c. 0·6 per cent. Na_2CO_3 = 0·3 per cent. alkali	0·0225
Saliva and starch + 50 c.c. 0·6 per cent. Na_2CO_3 + 0·015 gram $CaHPO_4$	0·0211
Saliva and starch + 50 c.c. 0·3 per cent. Na_2CO_3 = 0·15 per cent. alkali . . . . . . , . . .	0·0348
Saliva and starch + 50 c.c. 0·3 per cent. Na_2CO_3 + 0·015 gram $CaHPO_4$	0·0395

It is thus very evident that these salts have little or no influence on diastatic action, in alkaline solutions of the strength used. It next remained to try the influence of the ash of the peptones in alkaline solution. The ash of 1 gram of peptones was employed, the experiment being conducted in the same manner as the preceding. The peptones used were those with 1·71 per cent. of ash. Following are the results:—

	Wt. Cu in one-tenth. Gram.
Saliva and starch alone	0·0892
Saliva and starch + 50 c.c. 0·6 per cent. Na_2CO_3 = 0·3 per cent. alkali	0·0216
Saliva and starch + 50 c.c. 0·6 per cent. Na_2CO_3 + ash 1 gram peptone	0·0313
Saliva and starch + 50 c.c. 0·6 per cent. Na_2CO_3 + 1 gram peptone	0·0520
Saliva and starch + 50 c.c. 0·3 per cent. Na_2CO_3 = 0·15 per cent. alkali	0·0305
Saliva and starch + 50 c.c. 0·3 per cent. Na_2CO_3 + ash 1 gram peptones	0·0400
Saliva and starch + 50 c.c. 0·3 per cent. Na_2CO_3 + 1 gram peptone	0·0740

We therefore deem it safe to conclude that the inorganic salts contained in the peptones play but an unimportant part in the stimulating action noticed in an alkaline solution of the strength specified.

The Pharmaceutical Journal.

SATURDAY, NOVEMBER 25, 1882.

Communications for the Editorial department of the Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

NEW PHARMACOPŒIAS FOR GERMANY AND THE UNITED STATES.

THE arrival within the last few days of a complete copy of the new edition of the United States Pharmacopœia, preceded as it was a few weeks since by copies of the new edition of the German Pharmacopœia, marks a stage in the history of pharmaceutical literature sufficiently important in these days of running to and fro over the earth to warrant more than a passing notice. Constituting as these works do two out of the four most important Pharmacopœias in the world, they must of necessity occasionally become the text-book of some pharmacists at least in many of the cities and towns of this country of cosmopolitan resort. Moreover, the report that at this moment steps are being taken towards the preparation of a new edition of the British Pharmacopœia will be sure to invest these two important books, issued almost simultaneously, with additional interest, and speculation as to how far our own national Pharmacopœia may be influenced by one or the other, or both, may well be excused, since there can be no doubt as to the qualifications of the members of the two committees to which the revision of these works was entrusted, or the ability they have manifested in accomplishing their respective tasks. It is proposed, therefore, to discuss both these Pharmacopœias in some detail in a series of articles that will shortly be commenced in this Journal, but meanwhile there are a few features that can be referred to briefly now.

It may fairly be said of the two new Pharmacopœias, without disparagement to either, that in many respects they are as unlike one another as can well be imagined, and represent what may be looked upon as two distinct types. On the one hand, there is the German Pharmacopœia, orignated by Imperial decree, having the force of law, written in Latin, and showing a distinct tendency to decrease the number of articles in the list of materia medica and preparations and to confine what is said about those that remain within the narrowest limits, not even chemical formulæ or molecular weights being given. On the other hand, the United States Pharmacopœia is a volunteer work, which is not backed by any authority beyond what it acquires through its acceptance by medical men and pharmacists and a kind of adventitious recognition which it obtains in the legislation in some of the States respecting adulteration; which is written in the vulgar tongue, and which shows a distinct tendency to include within its limits any and every substance or preparation that is ordered with moderate frequency by physicians and to describe them with considerable fulness. Perhaps of all these differences the most noteworthy appears in the fact that whilst from the German Pharmacopœia 360 articles have been struck out and only 48 added, showing a decrease of 312, in the case of the United States Pharmacopœia although 229 articles have been dismissed, there have been 256 added, resulting in an increase of 27. The net result is that whilst the former now contains only 600 articles, the latter includes just under 1000. It would appear, indeed, that whilst in Germany a conservative policy has been followed, similar to that which Professor REDWOOD described at the last meeting of the British Pharmaceutical Conference as ruling the editors of the Pharmacopœia with respect to the introduction of drugs and preparations, the policy followed in the United States has been similar to that advocated by Professor OLDBERG in a paper read before the last International Pharmaceutical Congress, on the disadvantages of therapeutical conservatism in reference to the pharmacopœial materia medica. In that paper Professor OLDBERG argued that instead of a Pharmacopœia being edited in such an exclusive spirit that the fact of a certain substance having been accorded a place in it becomes looked upon as evidence of positive therapeutic value, it should, on the contrary, include descriptions of all new remedies which, in the opinion of the revisers, might present a probability of usefulness, in order that members of the medical profession who might desire to investigate more closely the properties of such remedies might be able to identify them, and ensure the genuineness of the substances they use. It must be admitted that such an argument would in no country have greater force than in the United States, where the competition in searching out new remedies and bringing them before the medical public as specialties is keener than, perhaps, in any other part of the world. Moreover, a United States Pharmacopœia must needs be a somewhat inclusive one, not only in consequence of the vast extent of country over which it is intended to do service, covering many districts capable of contributing to it from their local materia medica, but because of the continual immigration of people of every nationality, each with its peculiarities, prejudices and wants in respect to medicine as well as other things. But in view of the present state of things it is interesting to note that in the preface to the first edition of the United States Pharmacopœia, published in 1820, the fault, *par excellence*, then specified as existing in the lists of materia medica that had been adopted in other countries was their redundancy. In fact, the "secondary list," which has hitherto been a feature of the United States Pharmacopœia, but has now disappeared, appears to have been the result of a compromise between a disinclination to admit articles other than those that had already an established reputation and the impossibility of ignoring altogether many indigenous aspirants to that position.

There are, however, also some important points of resemblance between the two Pharmacopœias. The adoption in the United States Pharmacopœia of the method of expressing formulæ, as a rule, in parts by weight, instead of the actual weights and measures, as in the last edition, and the favour shown towards the metric system where opportunity offered, manifest an important approximation towards the methods followed in its German contemporary. Another point of resemblance, and not the least satisfactory, is that each of these books is the product of the labours of a committee in which pharmacists took part upon an equal footing with the medical profession, and in each case with a result that quite justifies their having been accorded such a position and that reflects honour upon their calling.

THE INTERFERENCE OF PUBLIC SERVANTS IN TRADING OPERATIONS.

A fortnight since, reference was made in these columns to a question that had been set down on the notice paper of the House of Commons, but had not yet been asked, as to the extent to which officials in the public service are permitted to engage in financial, commercial or industrial adventures. In the course of his reply to this question, Mr. Gladstone said that, speaking in general terms, there was no doubt that the claim of the State to the service of those in its employ is an exclusive claim, and he added that there was a rule of the Treasury, which was construed as an absolute rule as regarded that department, that no person employed in it should take any office or employment whatever outside the range of his official duties. But the power of the Treasury appears to be strictly limited to certain special departments, and this particular rule has, therefore, no force in respect to other departments of the public service. Mr. Gladstone, however, promised to lay upon the table some papers bearing on the subject and to consult Sir R. Lingen upon his return to town.

These papers have since been issued as a parliamentary paper and consist of copies of an extract from a Treasury minute, dated March, 1849, and some correspondence upon the subject between the Home Office and the Treasury in 1877. The Treasury minute is definite enough as far as it goes, and states that their Lordships consider that the public is entitled to the whole time of its servants, and that "officers holding situations which require daily attend-"ance should not be allowed to accept employment "as directors of companies of various descriptions "requiring their personal attendance elsewhere dur-"ing office hours." The correspondence between the two departments goes more directly to the root of the question. It originated in a request from the Home Office to be informed as to any regulations issued by the Treasury bearing upon the question of allowing officers to accept nominations to local offices, such as way wardens, members of school boards, etc., and for an opinion as to whether the practice, if thought not consistent with the interests of the public service, should be discouraged or altogether forbidden. The reply from the Treasury recapitulated the points of the minute above referred to, limited as it is to employment within office hours, as representing the rule of action in the department. But their Lordships added their "strong opinion" that such extra employment is generally prejudicial to the public service, because no one can serve two masters, and in private service it was believed to be universally forbidden. Their Lordships further stated that in departments under their control they would be disposed to forbid it, or to regard it as *primâ facie* disqualifying for promotion.

It does not appear from the papers what course the Home Office decided to take in respect to the question raised; but it is a decided gain to have placed on record so clear a condemnation, by an important public department like the Treasury, of the objectionable and now widely spread practice of public servants competing with ratepayers in trading operations. For if a sound objection lies to the acceptance of an honorary office like membership of a school board, it would apply *à fortiori* against engagements entered into for the sake of pecuniary profit.

MEDICAL LEGISLATION.

On Wednesday a deputation from the British Medical Association had an interview with the Lord President and the Vice-President of the Council to urge upon the Government the immediate necessity for legislation upon the basis of the Report of the Royal Commission upon the Medical Acts, in order to remedy the deplorable state of medical education. Lord Carlingford, whilst expressing his inability to make any announcement on the part of the Government, expressed his concurrence as to the necessity for legislation and a hope that it might be effected in the course of next session.

ABERDEEN AND NORTH OF SCOTLAND SOCIETY OF CHEMISTS AND DRUGGISTS.

In June last, at a meeting of the chemists and druggists of Aberdeen and the North-East of Scotland, it was resolved to found a Society to include the district between Forfar and Aberdeen. This has since been done by extending the operations of the existing Aberdeen Society of Chemists and Druggists, and adopting for it the above title. A circular has now been issued, signed by Mr. Alexander Strachan, of Richmond Street, Aberdeen, inviting persons to become members, the annual subscription, dating from March, 1883, being 10*s*. 6*d*.

BRIGHTON ASSOCIATION OF PHARMACY.

A meeting of the Association will be held in the ante-room of the Brighton Town Hall, on Friday next, December 1, when W. D. Savage, Esq., J.P., will read a paper entitled "Some Thoughts suggested by Professor Attfield's Presidential Address to the Pharmaceutical Conference at Southampton." The Chair to be taken at 8.30 p.m. by the President.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The third general meeting of the above Association was held at the Royal Institution, November 9, 1882. The President, Mr. Councillor Woodcock, in the chair.

The minutes of the last meeting were read and confirmed.

The following donations were announced:—The *Pharmaceutical Journal*, from the Society, and the *Canadian Pharmaceutical Journal*, from the Editor.

Dr. Symes then referred to the opinions expressed by the President (in his absence), respecting the examinations of the Pharmaceutical Society, and their proposed partial conduct in the provinces. He was pleased to read the President's opinion on this question, with which he entirely concurred.

The following paper was then read—

Lime Water: its Preparation, Preservation and Estimation.

BY A. C. ABRAHAM.

So simple and common an article as lime water may be thought to be quite unworthy of attention, but it should be remembered that the more simple and easily prepared an article may be, the more blame to us if we do not make it as perfect as possible. Lime water should be a simple saturated solution of hydrate of calcium, but owing to the fact that pure hydrate of calcium is not practically obtainable, the formula of the British Pharmacopœia produces an article more or less contaminated with chlorides, sulphates, and other soluble salts. To eliminate these, it is, I believe, the general practice to use a larger proportion of slaked lime than the British Pharmacopœia orders and to reject the first washings. This practice, which is, I consider, undoubtedly the correct one, may, however lead to error if the matter is not carefully watched.

Having on more than one occasion found the lime water made in the ordinary course not satisfactory, I determined in future to have it made under my own eye and always tested. To enable me to do this, it was necessary to have it made in larger quantities and in such a manner that it could be efficiently kept and conveniently drawn off. For this purpose I devised a little apparatus which I have found to answer all its requirements admirably.

To a wide-mouthed glass bottle of the capacity of 4 or 5 gallons, and having a hole bored near the bottom, is fitted a cork, previously well soaked in melted paraffin, and having two holes, the larger to admit a funnel, and the smaller a vent peg. A large and slightly tapering wooden plug and an ordinary vent peg should be fitted to these holes while the paraffin is still soft. A paraffined cork is also inserted into the tap hole. Passing through this cork is a tube bent upwards inside and projecting slightly outside. Instead of an ordinary stopcock, all kinds of which have objections, an india-rubber tube with a pinch-cock and a bent glass tube is adapted for drawing off the liquid.

Several pounds of lime should now be slaked: a large quantity of distilled water poured on, and, after subsidence, the clear liquid thrown away. This should be repeated until the lime water, when rendered slightly acid with nitric acid, is no longer precipitated by nitrate of silver. When this is the case, it should be stirred up and the lighter portions poured off from any stony matter which may be present, into the bottle before described, which is then filled up with distilled water, well stirred, and allowed to subside.

The advantage of having the tap hole near the bottom of the bottle is that by simply turning the tube, its upper end may be lowered so that nearly all the supernatant liquid can be drawn off from the deposit without drawing with it any of the particles which adhere to the sides of the bottle.

To enable the lime water to be tested without inconvenience each time it is made, I have been in the habit of running off into each of a number of suitable bottles quantities of 40 fl. gr. of volumetric solution of oxalic acid made half the strength of that ordered by the British Pharmacopœia.

I may say that I always use the latter, in consequence of the fact that if made of the full strength it crystallizes out if subjected to a temperature much, if any, below 60° F., and is very troublesome to redissolve without applying a heat which may cause a loss of water.

Each 40 fl. gr. of this solution should, according to the Pharmacopœia, be rendered alkaline by 1 fl. oz. of lime water. For some time after taking these precautions every sample answered perfectly to the required test. At last, however, to my surprise the lime water failed to do what was expected of it. I first blamed the man who had been charged to stir it, but I found that no amount of stirring would make any difference.

It then occurred to me that the chlorides or sulphates might exercise some influence on the solubility. I tried sulphate and chloride of sodium, but although the former, on the first experiment, did raise the standard above that of the Pharmacopœia,* I soon found that it was not to be relied upon.

It had not previously occurred to me that the Pharmacopœia sailed so close to the wind that a few degrees of temperature could make the difference. Such, however, I found to be the case; the weather had become warmer, and, as everyone knows, lime is less soluble in hot than cold water, consequently lime water could not be made at that time of the year of the recognized strength.

Watts, in his 'Dictionary,' quoting Dalton as his authority, gives the solubility at 60° F. as 1 in 778, almost exactly the *minimum* of the Pharmacopœia, which is equivalent to 1 in 781. My experiments very closely tally with these figures as far as 60° F. is concerned. As, however, even our British summers will not always permit this temperature to be maintained, I think that 70° should at least be calculated upon and at this temperature, according to my experiments, the solubility is reduced not very far from 10 per cent.

I would, therefore, suggest the reduction of the quantity of volumetric solution given as the minimum required from 200 to 180 fl. gr.

I regret that I am unable to give the exact solubilities at all temperatures between 60°, and, say, 75° or 80°, but the difficulties are greater than might be supposed, owing to the rapidity with which the lime is dssolved if the liquid is allowed to cool even, for instance, from the exposure during filtration. The only estimations, indeed, upon which I can rely, except those in which an even temperature was maintained for some time, were made by using a filter under the surface of the liquid from which samples were drawn by means of a syphon.

I should say that before adopting the plan described I had been in the habit of using a syphon, passing through a cork and started by means of a blow-tube. This arrangement had, however, several disadvantages.

Mr. Conroy, in proposing a vote of thanks, said that he also had found it impossible sometimes in preparing lime water to attain the Pharmacopœia strength, but had not recognized the cause, not indeed being aware of the great effect of temperature. He asked Mr. Abraham whether he had found it necessary to re-stir the lime water from time to time, to make good the loss due to surface carbonation. He also expressed his decided preference for the method recommended for drawing off, compared to that previously adopted by Mr. Abraham, viz., by a syphon and a blow-tube, by which means carbonic acid was introduced from the lungs.

Dr. C. Symes thought that no apology was necessary

* No doubt by slightly lowering the temperature.

for bringing this subject forward, especially seeing that there had been prosecutions, and indeed one was then pending, for selling lime water which was not of the proper strength. It was therefore of importance to have placed before them any means by which the preparation could be made, so as to insure chemists from the danger of being prosecuted for an unintentional fault. The apparatus described seemed to fulfil the required conditions. He had at one time himself been in the habit of using, for the purpose of drawing off the supernatant liquid from deposits, a glass tube passing upwards from the bottom of the vessel and sliding through a short piece of india-rubber tube. This arrangement he thought had one advantage, viz., that by moving the tube above the surface of the liquid, the settlement therein of lime, after stirring, which he thought might involve the running off of a gallon or say half a gallon of liquid, was avoided. He concluded by supporting the vote of thanks.

This having been given, Mr. Abraham replied. He explained that he had not found it necessary to re-stir the lime, and that indeed the diffusion more than neutralized the effect of carbonation, which was extremely slight. As air only contained a very minute quantity of carbonic acid, and as his plan had been adopted so that only sufficient air should be admitted to allow the liquid to run out, this difficulty was avoided. Mr. Conroy's objection to the method of using a blow-tube, was no doubt correct, although practically, very little air was required from the lungs to start a small syphon. The plan sketched by Dr. Symes was, no doubt, a good one, but for this purpose, he preferred his own. With regard to the quantity of liquid requiring to be drawn off to remove any sediment from the exit pipe, he had not found nearly so much as a gallon necessary; on the contrary, one or two ounces, he believed, was sufficient.

There was one matter which he had not mentioned. the Pharmacopœia ordered the use of lime water for the preparation of oxide of silver, but did not recommend any means for the removal of chlorides. If chlorides were not well removed before using for this purpose, there would probably be more chloride than oxide of silver present in the product.

The proceedings then terminated.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION AND SCHOOL OF PHARMACY.

The fourteenth annual meeting was held in the Memorial Hall, on Wednesday evening, November 8, Mr. W. Wilkinson, Vice-President, in the chair.

The annual report of the Council was read by Mr. Benger, Honorary Secretary. Since the last annual meeting, the members had not been called together monthly as in former years, the attendance at meetings of a scientific character having become too small to encourage authors of papers to expend time and trouble in preparing for them. The Council had, however, met frequently, a fourth edition of the 'Manchester Price List' had been published and they had endeavoured, as far as their influence went, to encourage a spirit of loyalty to each other amongst members of the trade in the district. Late in the autumn a letter had been received from Mr. Siebold, who had for so many years conducted the classes in connection with the Association, stating that his numerous engagements compelled him to relinquish the post he had held with so much pleasure. In accepting Mr. Siebold's resignation, the Council had expressed their regret at losing his valuable services. It was then too late to reorganize classes for the present session, but some important propositions had been received from the leading educational institutions of the city, and the Council hoped shortly to have a programme ready to lay before the members. In the meantime classes were being held in Manchester by private teachers which would meet the immediate requirements of pharmaceutical students.

The following report on the classes had been received from Mr. Siebold:—

"Gentlemen,—The lecture courses of the past session of the Manchester School of Pharmacy commenced on October 11, 1881, and terminated on May 19, 1882. In accordance with the circular issued by the Honorary Secretary in September, 1881, the following courses were delivered by me during the session:—Pharmaceutical Chemistry, including the Elements of Physics: thirty-five lectures, on Tuesday evenings, from 7.30 to 8.45. Fee 35*s*. Materia Medica and Pharmacy: twenty-five lectures, on Tuesday evenings, from 8.45 to 9.45. Fee 25*s*. Structural Botany: fifteen lectures, on Friday evenings, from 7.30 to 8.30. Fee 15*s*. Composition fee, admitting the student to all three courses, £3 10*s*. Fourteen students entered for the chemistry course, twelve for the course of materia medica and pharmacy, and eight for the botany course, making a total of thirty-four entries. The fees received amounted in all to £42. Throughout the session the regularity of attendances and the attention paid by the students to the lectures were very satisfactory; and it gives me the greatest pleasure to remember that I was able to report in equally favourable terms at the close of every one of the twelve sessions during which I have filled the post of lecturer to our Society's school.

"In now resigning my appointment into your hands I have great pleasure in thanking you most sincerely for the confidence and kind appreciation of my services with which you have always favoured me, and in thanking the students of all the past sessions for their kind and sympathetic attention."

Mr. G. S. Woolley, Treasurer, presented his statement of account, showing a balance in hand of £7 1*s*. 8*d*. on the general account, and £11 1*s*. on the Library Fund.

The Chairman, in moving the adoption of the report and Treasurer's statement, said he regretted very much, as he was sure they all would, that the state of the President's health did not allow him to come amongst them, for they all knew how much they had been indebted to Mr. Brown, who was always ready to further the interests of the Society by every means in his power. The report was not so satisfactory as could be wished, but the truth was that the efforts of the Council were not supported by the members of the trade, and it was useless attempting to hold meetings for scientific discussion or other purposes if the members would not attend. With regard to the lectures and classes of study, they had not been able to arrange them, in consequence of Mr. Siebold's resignation, but it was hoped that before another session some satisfactory arrangements would be made if only a sufficient number of students presented themselves. Speaking of the price list, it was satisfactory to find that it was in pretty general request in various parts of the country; indeed, the chief reason for the issue of the new edition was that Mr. Silverlock was continually applied to for copies which he could not supply; the last edition, published in 1880, being out of print. There were no burning questions in matters affecting pharmacists at present, but should any such arise he had no doubt that the Association would be found at the front and do good service, as it had done on former occasions.

Mr. Woolley regretted that so few of the chemists of Manchester and Salford took an interest in the affairs of the Association. This was the more deplorable and incomprehensible when the advisability of united action was becoming every day more and more obvious. He had hoped that a sufficient number of members would have been present to have had a discussion on the educational question, of which a good deal had been heard lately. Surely it was worth while to devote an evening occasionally to the discussion of topics of such vital importance to the trade, and which were continually cropping up. He quoted an instance, showing that the actual meaning of the words "compulsory curriculum" was not understood in all quarters; they had a somewhat harsh sound, and the idea of being compelled to do a thing was distasteful. Still, if they would consider the proposal fairly, they would see that there was nothing but good in it, the object aimed at being the welfare of the young men engaged in, and who may enter the trade in the future.

After some further remarks on the subject of the curriculum, Mr. Woolley pointed out the importance of those young men, who wished to join classes, sending in their names so as to enable the Council to make suitable arrangements. He also alluded to the new edition of the 'Manchester List of Retail Prices,' upon which the committee had expended a considerable amount of labour. Former editions had been favourably received, and largely appreciated throughout the country.

Mr. Benjamin Robinson, in supporting the motion, begged to observe, in answer to a question just asked, that the Council, in making arrangements for the various classes each session, had always been mindful that the lectures and instruction given at those classes should be specially adapted to meet the requirements of the students. The great obstacle that the Council had to contend with was not the organization of classes, but the difficulty of getting a sufficient number of young men to attend them. The Council at the present moment was in this dilemma. Two educational institutions in the city were quite willing to enter into arrangements for a series of lectures to be delivered solely for the instruction of pharmaceutical students, but the Council was deterred from entering into any engagement with them, in consequence of the great indifference shown by the majority of the young men for whom these lectures were intended.

Mr. J. L. Slack said, although there were some depressing circumstances connected with the meeting, arising from the apathy of those for whose benefit the Association was formed, he could not allow that in any sense the Association was a failure. The Council was able and willing to carry on lectures and classes if the fees were forthcoming, but not to incur pecuniary loss. The Association had done great good by bringing the trade together, affording the only means for the druggists to become personally known to each other; thus increasing the mutual confidence and respect that ought to exist, and also affording the readiest means of acting in case any emergency should arise threatening the trade interests.

Mr. A. H. Jackson, B.Sc., Mr. Holt, Mr. Benger, Mr. Cooper, Mr. Stokoe, Mr. Boden and others took part in the discussion.

The following gentlemen were elected officers of the Council for the ensuing year:—

President, Mr. W. Scott Brown; Vice-President, Mr. W. Wilkinson; Treasurer, Mr. G. S. Woolley; Honorary Secretary, Mr. F. B. Benger, F.C.S. Other members of Council:—Messrs. Blain, Boor, Botham, Bowden, Drinkwater, A. H. Jackson, B.Sc., S. Kay, Robinson, Slack, Stones, Westmacott and Hermann Woolley.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES ASSOCIATION.

A lecture was delivered at the rooms of the above Association, on Wednesday evening, November 15, by Mr. H. Pickering, on "Galvanic Electricity." The chair was taken by Mr. J. J. Edwards, President, and there was a large attendance.

The lecturer had explained in a previous lecture the theory of the subject, and the different kinds of batteries, their structures and powers. He now explained the electro-magnet and its use in the electric telegraph, which he illustrated by experiment. A model electric railway was also shown in working order, also a small electric engine suitable for working a powder mixer or pill coater. Edison and Swan's lamps for the electric light were shown and their adaptability for general use explained. The lecturer also performed a number of experiments, showing the different uses to which this important science was applied, which brought a very instructive and interesting lecture to a close.

Mr. Edwards proposed a hearty vote of thanks to the lecturer which was ably seconded by Mr. Thully, and carried unanimously.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on Thursday, November 16, Professor J. Dewar, F.R.S., Vice-President, in the chair.

It was announced that a ballot for the election of Fellows would take place at the next meeting (December 7).

The following certificates were read for the first time:—J. Brock, A. M. Chance, H. C. Foote, W. Fox, J. A. M. Fallon, F. Gothard, Joowansinghji, R. B. Lee, T. Turner, J. E. Tuit.

During the evening a ballot was held and the Scrutineers, Dr. Japp and Mr. J. M. Thomson, declared the following to be duly elected Fellows:—J. Ferrier, T. Hughes, J. Hodgkin, F. Jordan, G. Jarmay, W. C. Nicholson, H. H. Robinson, L. Reid, J. E. Stead, G. H. Sharpe, P. G. Sanford, E. S. Spalding, C. J. Waterfall.

Mr. Warington then read a paper entitled—

Contributions to the Chemistry of Tartaric and Citric Acids. By the late BEAUMONT J. GROSJEAN.—Mr. Warington said that for five years, 1870–1875, he had worked in the laboratory at Millwall with the author of this paper, who had since then been the sole chemist till his death in June, 1882. Mr. Warington had, with the consent of Sir J. B. Lawes, compiled from the laboratory note books of the late author an abstract of his numerous unpublished investigations. 1. On the different rates of loss of different specimens of citric acid in dry air. Three specimens of different samples of citric acid were powdered and placed in two desiccators over fresh oil of vitriol on April 21, 1880; on May 6 one specimen had lost 0·68 per cent., the second 6·25 per cent., the third 8·55 per cent. On May 15 the first had lost 1·75 per cent., the second 8·55 per cent. On June 21 the first specimen had lost 8·47 per cent. The theoretical amount of moisture present was 8·57 per cent. 2. Determination of citric acid in lemon and other juices. The method used by precipitation with $CaCl_2$, etc., has already been described (*Chem. Soc. Jour.*, 1875, 931). It appears that the precipitable acid in commercial concentrated lemon juice is, on the average, very nearly equal in quantity to the free acid present. Thus, in 65 analyses, representing 895 pipes, the precipitated acid averaged 99·2 per cent. of the free acid. Some exceptional samples gave numbers from 85·8 per cent. to 103·6 per cent. In bergamot juice the average number from 90 pipes was 98·4 per cent.; in lime juice 91 to 92 per cent. In orange juice about 68·5 per cent. of the free acid was found to be precipitable. Thus, while the determination of the free acid gives trustworthy results with lemon juice, it furnishes with lime and orange juice a very unsafe guide to the quantity of citric acid present. 3. Influence of heat on solutions of tartaric acid. Forty grams of tartaric acid were dissolved in water and concentrated till a crust formed. The acidity was now reduced to 97·9 per cent. of the original acid, while the orthotartaric acid, precipitated by potassium citrate, was only 74·6 per cent. On diluting and boiling for two hours the solution gave 99·0 per cent. free acidity and 99·9 per cent. orthotartaric acid. The metatartaric acid, formed as above, is also slowly reconverted into orthotartaric acid by standing in dilute solution at the ordinary temperature. Thus, the percentage of orthotartaric acid in the above solution increased after standing two months from 74·6 to 90·0. 4. Influence of sulphuric acid on the crystallization of tartaric acid. Sulphuric acid considerably diminishes the solubility of tartaric acid. Much more tartaric acid crystallizes out from a saturated solution in dilute sulphuric acid than from a hot saturated aqueous solution; the latter deposits only 50 per cent. of its tartaric acid on cooling, whilst a hot solution in 1 volume of water and 1½ volume of oil of vitriol deposits 70 per cent. of its tartaric acid. 5. Actions of solutions of potassium and sodium sulphates on calcium tartrate. In the ordinary manufacture of tartaric acid, moist gypsum is added to decompose neutral tartrate of potash and precipitate calcium tartrate; under certain conditions this reaction is reversed, and if the solutions of potassium or sodium sulphate be sufficiently strong, practically the whole of the tartaric acid in calcium tartrate may be brought into solution as potassium or sodium tartrate. 6. Destruction of citrates and tartrates by peroxide of hydrogen. 7. Destruction of neutral tartrates when their solutions are heated with iron salts. 8. Determination of free sulphuric acid in tartaric acid liquors. To ascertain when enough sulphuric acid has been added to decompose the calcium tartrate, the workman usually adds a few drops of calcium chloride solution; if a precipitate appears in a few minutes, free sulphuric acid is present. It is proved in the present paper that this test, with certain precautions as to time and dilution, may be used quantitatively. 9. Determination of tartaric acid by precipitation as acid potassium tartrate. The ordinary method consists in the precipitation of tartaric acid with an excess of potassium citrate, washing the precipitated bitartrate with a 5 per cent. solution of potassium chloride, saturated with bitartrate, and determining by titration the acidity of the precipitate. This method is subject to two errors, one of excess due to the precipitation of an acid citrate, and one of deficiency due to the solubility of bitartrate in solutions of citric acid and potassium citrate. The author concludes that in all accurate determinations it is necessary to make preliminary experiments with graduated quantities of potassium citrate to discover the proportion which gives a precipitate of maximum acidity. This being ascertained a final determination is made with this quantity, the precipitate thoroughly washed and its acidity determined. If much sulphuric acid is present the result is usually about 1 per cent. in excess of the truth. 10. Detection of tartaric acid in the presence of citric acid, Cailletet's bichromate test (*Chem. Soc. Jour. Abstracts*, 1879, 674) gives satisfactory results. 11. Determination of organic acids from the neutralizing capacity of the ash of the salts. With potassium or sodium salts the ignition must be effected by a spirit lamp, *i.e.*, at a low temperature to avoid loss. 12. Standardizing of alkali used in titration. The best material for this purpose is acid potassium tartrate; it is easily prepared pure, can be dried at 100, is not hygroscopic, and being of low acidity a large weight can be taken.

Mr. C. F. Cross then communicated briefly the three following papers:—

Contributions to the Chemistry of Bast Fibre. By C. F. Cross and E. J. Bevan.—The authors detail further experiments showing that lignified fibres are to be regarded as a chemical whole, rather than the mixture which is involved in the incrustation theory. Fractional solution in the Schweitzer-Pelouse reagent and precipitation by acid give amorphous modifications of the fibre substance exhibiting uniformity in characteristic properties. With respect, moreover, to the property of giving a yellow colour with anilin sulphate, a diminution was observed, and after a second precipitation it had disappeared. That this reaction was not due to the lignose itself, but to some product of its decomposition, was confirmed by other experiments. The authors find that the mairogallol of Stenhouse and Groves gives with sodium sulphite the brilliant colour reaction characteristic of chlorinated derivatives of lignose; this, together with similarity of formula points to a probable connection between the aromatic derivatives of fibres and the trihydric phenols. The authors describe a higher chlorinated derivative of jute, $C_{33}H_{44}Cl_{11}O_{16}$, a body of identical formula being obtained from *Musa paradisiaca.*

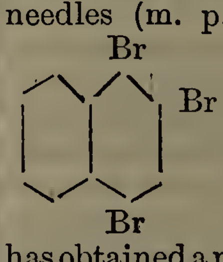
On the Oxidation of Cellulose. By C. F. Cross and E. S. Bevan.—By the action of boiling 60 per cent. nitric acid, cellulose is converted into an amorphous substance, which swells up on washing to a gummy mass. On analysis it gave constant numbers, although obtained from various sources, indicating the formula $C_{18}H_{26}O_{16}$. The authors propose the name oxycellulose. This substance yields a trinitric ether. In this and other properties it exhibits undoubted cellulosic characteristics.

On the Analysis of certain Vegetable Fibres. By C. S. Webster.—The author has investigated the following fibres:—*Ananassa S.*, *Musa P.*, *Agave*, *Phormium T.*, *Bœhmeria P.*, *Crotalaria J.*, *Linum U.*, *Urtica H.* His results comprise ultimate elementary analysis, determinations of cellulose by chlorination, and a statement of general properties and reactions. None of these fibres appear to preserve the definiteness and uniformity of the jute fibre.

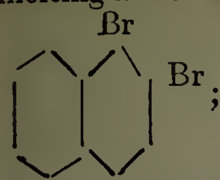
Mr. Warington asked whether the jute fibre was entirely soluble by repeated treatment with bromine and ammonia.

Professor Thiselton Dyer said that he was much indebted to the authors for the explanations which they had given him, from time to time, of their work in the Jodrell Laboratory, at Kew. There was no doubt that the field which lay in the borderland between vegetable physiology and organic chemistry, and in which these chemists had worked, was regarded by many scientific men with the greatest curiosity. The botanists arrived at various results empirically and were obliged to make up a sort of spurious chemistry to explain them. Thus in some way cellulose is converted into lignin; the chemist infers that cellulose is related to starch and some believe that starch is the starting point of plant life. This position is challenged by Strasburger, who thinks that cellulose and starch are formed by the breaking up of proteids. It seemed admitted by the chemist that the subject was one of the greatest importance, and yet upon turning to chemical books the crust of the subject was found to be scarcely broken; the voice of the chemist was silent where the botanist ardently desired information. He was, therefore, only too glad when two chemists expressed their intention of, at any rate, driving a furrow into this unknown tract. The botanist met constantly with such common substances as starch, cellulose, lignin, mucilage, etc., and yet the present state of knowledge about these substances was such that he was almost ashamed to ask a question about them at an examination.

On the Constitution of some Bromine Derivatives of Naphthalene. (*Third Notice*). By R. Meldola.—A careful comparison has been made by the author between Glaser's α-dibromnaphthalene produced by the direct action of bromine on $C_{10}H_8$, and the author's metadibromnaphthalene (m. p. 64°), and he concludes that these two modifications are isomeric and not identical. β-dibromnaphthalene (m. p. 81°) has been obtained by the diazo-reaction from Rother's bromnaphthylamin, thus confirming the view that this modification is a para-compound. By means of the diazo-reaction a new tribromnaphthalene has been obtained from the author's dibromnaphthylamin. This substance forms white needles (m. p. 113°–114°), and has the constitution—



By means of the diazo-reaction, the author has obtained a new dibromnaphthalene from Cosiner's brom-β-naphthylamin; it crystallizes in oblique rhombic prisms melting at 63° and is an orthocompound of the formula—



; by the further action of bromine on orthobrom-β-acetnaphthalide the author has prepared a tetrabrom derivative of m. p. 138°. By brominating paranitracetnaphthalide a monobrom derivative has been obtained, isomeric with that of Liebermann and Scheiding; it forms pale yellow needles, m. p. 224°–225°. The author proposes that naphthalene derivatives in which the substituents are in the same benzene nucleus should be called *homonucleal*, and those in which they are in different nuclei, *heteronucleal*. It seems to be a general rule that the homonucleal diderivatives melt at lower temperatures than their heteronucleal isomerides. Thirty specimens of naphthalene derivatives obtained in the course of this and former investigations were exhibited by the author.

On the Constitution of Lophin. By F. R. Japp.—Radziszewski has communicated (*Chem. Soc. Journ. Abstracts*, 1882, 1063) a new synthesis of this substance by the interaction of benzil, benzaldehyde and ammonia and he comes to the conclusion that lophin has the constitution

$$\begin{array}{l} C_6H_5—C=N\diagdown \\ \quad\quad\;\; | \qquad\qquad CH—C_6H_5 \\ C_6H_5—C=N\diagup \end{array}$$

and rejects the formula proposed by the author, which represents this substance as belonging to the class of anhydrobases described by Hübner. This latter formula was based by the author chiefly on certain analogies drawn from the reactions of phenanthraquinone with aldehydes and ammonia, and in the present paper it is shown that these analogies are well founded, and that the formula explains the known reactions of lophin more consistently than that of Radziszewski. In conclusion, the author describes an experiment which, though not absolutely conclusive, affords a strong presumption in favour of the anhydrobase formula. If it were possible by heating lophin with hydriodic acid and amorphous phosphorus to split up this body, Radziszewski's formula should yield benzaldehyde, which should be reduced to toluene; the anhydrobase formula should yield benzoic acid. Lophin, when thus heated to about 300°, does yield benzoic acid. This temperature, though high, is 100° below the temperature at which lophin boils without decomposition.

The Society then adjourned to December 7, when a ballot for the election of Fellows will be held, and the following papers will be read:—1 "On the Condensation Product of Phenanthraquinone with Ethylic Aceto-acetate," by F. R. Japp and F. W. Streatfield; 2 "On the Condensation Products of Oenanthol, Part I.," by W. H. Perkin, jun.; 3 "On the Formula of Lophin," by H. E. Armstrong; 4 "On the Molecular Weight of Basic Ferric Sulphate," by S. U. Pickering; 5 "On Certain Brominated Compounds obtained in the Manufacture of Bromine," by S. Dyson.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

The first meeting of the present session was held on Thursday, November 16, 1882. Professor Attfield, F.R.S., President, in the chair.

After the confirmation of the minutes, Messrs. F. Ransom and W. H. Ince were appointed Scrutineers to examine the voting papers by means of which the election of officers is carried on.

The following gentlemen were elected officers for the ensuing session:—Vice-Presidents, Mr. H. G. Greenish and Mr. R. H. Parker; Members of the Executive Committee, Messrs. A. T. Job, W. E. Crow, W. F. Gulliver, J. B. Barnes; Honorary Secretary and Treasurer, Mr. Wyndham R. Dunstan, 17, Bloomsbury Square, W.C.

Mr. Hamilton then proposed, and Mr. Ince seconded, a vote of thanks to the outgoing officers, which was replied to by Mr. F. W. Short.

The President then delivered an address upon "The Pharmacopœia as a Students' Manual," which will be found on p. 421.

A discussion followed, in which Messrs. Braithwaite, Elborne, Giles, Parker, Taylor and the Secretary took part.

On the motion of the Secretary, seconded by Mr Elworthy, a vote of thanks to the President for his address was carried unanimously.

CHEMISTS' ASSISTANTS' ASSOCIATION.

A meeting of the above Association was held at 32A, George Street, Hanover Square, on Wednesday, November 14, 1882, the President, Mr. Wrenn, in the chair, when a paper on "The Relation between Insects and Flowers" was read by Mr. H. Cracknell.

Mr. Cracknell alluded to Sprengel as being the first who noticed that a relation existed between insects and flowers, but he pointed out that it was not until the late Charles Darwin studied the subject that we had any positive proofs of the existence of that relation. He then gave a general description of the relation existing between insects and flowers and the advantages obtained thereby, also showing how, that although plants presented at first sight every arrangement for self-fertilization, nature had really provided means in most flowers for the prevention of self-fertilization, the principal arrangements for this purpose being:—1st, the stamens and pistil are in different flowers; 2nd, the stamens and pistil are not mature at the same time; and 3rd, there exists a difference between the relative length and position of stamens and pistil. He then proceeded to give a descriptive account of how plants are fertilized by means of insects, showing also how they are adapted to the visits of insects. The first plant mentioned was the *Arum maculatum*. He showed how insects visited this plant, and when they reached the bottom of the spathe they are prevented, by means of a row of hairs pointing downwards, from leaving the flower until the stigmas have ripened, when the hairs shrivel up,—but in the meantime the anthers having ripened, the insects as they left the flower were dusted with pollen, which, if they then visited a younger flower, they deposited on to the stigmas of this flower, and thus cross-fertilization was effected. He then gave an account of the fertilization of the *Geranium pratense*, pointing out the remarkable movement of the stamens. The next flower alluded to was the *Lamium album*. This flower, he said, showed the adaptation of flowers to insects very clearly. There were also other flowers in the *Labiatæ* which were just as markedly adapted to the visits of insects, the *Salvia* being one of the most remarkable, especially as regards the arrangements of its anthers. He then mentioned the *Primula*, drawing attention to the difference in the relative length of stamens and pistil, also pointing out the difference in the size of the pollen of the two forms of *Primula*, and at the same time stating the advantages gained by these differences. He described the *Lythrum Salicaria* as being a trimorphous plant, showing the number of modes of union possible between this plant. He then proceeded to give an interesting account of the fertilization of the *Orchis mascula*. In conclusion, he drew a graphic account of insectivorous plants, *Drosera rotundifolia* being quoted as an example.

The paper was profusely illustrated by diagrams, which were very accurately drawn.

A lively discussion took place, in which Messrs. Wrenn, Alcock, Winfrey, Parkinson, Perkins and others took part.

A hearty vote of thanks to Mr. Cracknell for his valuable paper terminated a very successful meeting.

Parliamentary and Law Proceedings.

CONVICTION UNDER THE WEIGHTS AND MEASURES ACT.

On Thursday, November 2, at the Clerkenwell Police Court, Mr. John Knowles, chemist, 40, Seymour Street, was summoned for having two measures that were false and unjust.

The inspector said he had cautioned defendant in April last. He found he had still some weights and measures unstamped on his second visit. One of the measures mentioned in the summons was a 60 minims measure; it held 70 instead of 60 minims. As this measure was used for poisons and other potent drugs it was most important that it should hold the proper quantity and be stamped.

Mr. Barstow said it was a serious matter, and fined the defendant 20*s*. and costs.

IMPORTANT PROSECUTION UNDER THE SPIRITS ACT.

On Tuesday, November 21, at the Lambeth Police Court, Mr. W. J. Bush, wholesale chemist and distiller of essential oils, essences, etc., having works and premises in Artillery Lane, Bishopsgate Street, and Ash Grove, Hackney, appeared to answer several summonses under the Excise laws which had been first before the Court in August last.

The several summonses set forth the following alleged offences:—First, for using a still on July 27 last without a licence; second, for carrying on the trade of a compounder of spirits and for compounding spirits without a licence; third, for retailing spirits on July 27 without a licence; fourth, a similar offence on July 24; fifth, a similar offence on July 24; sixth, for separating gum resin from methylated spirit mixed with gum resin on July 27.

Mr. N. J. Highmore, barrister, and Mr. Squires, one of the solicitors to the Inland Revenue Department, prosecuted; and Mr. E. Pollock defended.

The case was reported upon the first hearing, when it was shown that Mr. R. W. Parry and Mr. Harper, supervisors of Excise, visited the premises of the defendant at Hackney, and found various stills at work, varying from 30 to 1000 gallons contents. Methylated spirit was found running from the worm end of the still. In answer to questions put a man there said they were distilling "a varnish or finish." Close to the still the officers found several drums containing 110 gallons of methylated spirit from which the gum had been extracted. The defendant, when spoken to, said it was the practice of the trade, and that he was ignorant of the law on the subject. An ordinary still licence was produced at the time. A visit was paid to the premises in Artillery Lane, City, where purchase was made by one of the officers of some "essences of brandy, gin, port wine, and curaçoa."

Upon the first hearing Mr. Pollock cross-examined the several witnesses and put forward his contention with regard to the meaning of the word "spirits." He also pointed out that the defendant had carried on the business for many years, and produced circulars of many others who, he said, had carried on a similar trade, and likewise pointed out with regard to the "essences," that as long back as the Exhibition of 1851, medals had been awarded for such "essences," and yet no proceedings had been taken.

After a long argument, Mr. Chance decided to adjourn his decision to give him an opportunity of looking fully into the question.

Upon the matter being again brought before the Court yesterday, Mr. Chance gave judgment. After referring to some of the facts of the case, he said that the question remaining was what penalties he ought to impose. He would take the last-named offence first, "for separating gum resin from methylated spirit mixed with gum resin," and with regard to that, he did not think there was the slightest excuse for a violation of the section of the Act, which to his mind was as clear as possible on the subject. He then proceeded to read the 131st section of the 43 and 44 Vict., bearing on the matter, and added that anyone reading that could scarcely make a mistake. With regard to that offence, he find the defendant £200. Then for using a still the same remarks would apply, and for that he imposed a penalty of £500. His only doubt at first was with regard to the offence of "compounding," but in carefully considering the various points those doubts were removed, and he did not feel justified in mitigating the penalty for that, which would be £500. With regard to the three remaining offences of retailing without a licence, he imposed three fines of £25, instead of £50 each.

Mr. Pollock said there were various points of law which he would should like to carry still further.

Mr. Chance replied that he would be glad to hear an application on a future day, and to grant a case for a superior court.

Mr. Pollock, after some further argument, asked that payment of the penalties should be suspended until he had decided what course to take.

Mr. Highmore said he had no objection so long as security was given for the payment.

Mr. Pollock said there was not the slightest objection to that.—*Standard.*

Reviews.

DIET FOR THE SICK, being Nutritious Combinations suitable for Severe Cases of Illness. By J. JAMES RIDGE, M.D., B.S., B.A., B.Sc., Lond., etc. London: J. and A. Churchill.

This is altogether an admirable little book. It is small in size, excellent in arrangement, clear in direction, scientific in principle, and is destitute of padding.

It commences with directions for making beef-tea. We all know what horribly flavourless messes sometimes go by the name. The beef is conscientiously boiled to rags, the whole is then strained, and the result is that the so-called beef-tea contains little more than gelatin.

Dr. Ridge's directions are entirely free from any scientific terms, and are capable of being understood by anyone. For making beef-tea they are so good that we reproduce them *in toto*.

"BEEF-TEA.

"1. Take 1 pound of lean gravy beef and cut it into pieces as small as possible. A sausage-machine will accomplish this most thoroughly, and thus save half the time of step No. 5, while it will enable you to extract all the goodness of the meat more thoroughly.

"2. Place the meat in a preserve jar with one saltspoonful of salt, and put the jar in a saucepan sufficiently large to allow the lid to be placed on when the jar is in it.

"3. Mix in a large jug equal quantities (carefully measured) of boiling water and cold water.

"4. Put half a pint of this mixed water into the jar which contains the meat, and pour sufficient of the remainder into the saucepan outside the jar to reach as high as the water inside the jar, then put the lid on the saucepan and place it on the hearth, *not* on the fire or on the hob. It will do no harm to cover the saucepan with a cloth or anything which will keep in the heat.

"5. The meat must remain in the jar from three-quarters of an hour to two hours, according to the fineness to which it has been chopped, being stirred every quarter of an hour. If cut into pieces a little smaller than dice, one hour and a half will be sufficient. At the end of this time take out of the jar and strain through a hair sieve, or through muslin, with gentle pressure.

"6. Place the red meat juice thus obtained in a small saucepan, and heat it to boiling while you stir. It will turn brown and curdle. Strain off the solid flakes and rub these thoroughly with a small teaspoonful of arrowroot or cornflour, then boil these again five minutes with the liquor which was strained off, and set it on one side for the present.

"7. Now take the meat which was left in the sieve at the end of step No. 5, and put it into a saucepan with a quart of boiling water, cover, and let it simmer over a slow fire for three hours; then allow it to boil and strain immediately.

"8. Now boil this strained liquor down to half a pint.

"9. Then mix this half pint with the half pint left at the end of step No. 6, and you will have 1 pint of strong beef-tea containing all the soluble portion of the meat."

Reasons for this process are then clearly and simply given, and then follow directions for making beef-teas modified to meet varying circumstances.

The uselessness of Liebig's extract given solely as a food to the exclusion of other things is pointed out, but its value as a stimulant is fully recognized.

The book contains directions for making all kinds of broths, meat biscuits, milk and farinaceous preparations, wheys, teas and various refreshing drinks, and concludes with processes for preparing digested and partially digested foods and enemata. Dr. Ridge's methods are throughout uniformly simple and sound. We smack our lips over some of them, and though we hope we are in the most robust health, we could heartily relish some of the varieties of spoon-food, if our anything-but-neat-handed Phyllis below stairs would condescend to follow Dr. Ridge's directions.

Chemisch-Technisches Repertorium. Uebersichtlich geordnete Mittheilungen der neuesten Erfindungen, Fortschritte und Verbesserungen auf dem Gebiete der technischen und industriellen Chemie mit Hinweis auf Maschinen, Apparate und Literatur. Herausgeben von Dr. Emil Jacobsen. 1881. Berlin: R. Gaertner. 1882.*

This 'Repertorium,' as stated in its title, consists of short abstracts of communications upon the latest discoveries, progress and improvements in the domain of technical and industrial chemistry, systematically arranged under suitable headings. It is now issued quarterly, the four parts of one year containing the history of the previous twelve months. Although the majority of the subjects lie outside pharmacy, few of them are so far removed as to be devoid of interest to the student of chemistry in this direction, and to any person able to read German the work presents an epitome of the technical literature scattered over a wide field, no less than one hundred and twenty-two journals being represented in the references, each by a particular number. The abstracts appear to be made with judgment; brief, but not too curt to be of use. As an example one may be quoted, not as being the best suited for the purpose, but simply because it refers to a subject upon which information has been asked for by correspondents:—

"Starch Glaze Preparations.— . . . Several specimens of the so-called 'starch glaze,' which at present is sent into commerce in considerable quantity, were examined. Only three samples, in powder, were analysed quantitatively. Their composition was as follows:—

	Water per cent.	Mineral Substace (Borax) per cent.	Starch calculated from difference. per cent.
No. 1 . . .	29·80	32·27	37·83
No. 2 . . .	29·94	41·04	29·22
No. 3 . . .	22·95	21·00	56·04

"The complete solubility of Nos. 1 and 2 in hot water, as well as their appearance under the microscope, showed that the starch used in their preparation had previously been rendered soluble. Probably this was done by strongly heating it under pressure and only then mixing it with the borax finely powdered. But a similar preparation may also be obtained by boiling the starch for a long time in a concentrated solution of borax, evaporating the starch solution obtained to dryness, and reducing the dried mass to a fine powder. By both methods a fine powder, consisting of borax and starch, is obtained, that with hot water forms a solution from which no starch separates upon cooling. Sample No. 3, which dissolved only after considerable boiling, was evidently only a mechanical mixture of finely powdered borax with ordinary rice starch, not rendered soluble. The addition of borax has probably for its chief object to bring the starch into solution so that it may penetrate into the tissue and thus render the pieces stiffer upon drying. But a too great addition of borax may act injuriously on the articles washed by rendering them brittle."

* Large 8vo., Part I., pp. 1-112; Part II., pp. 113-216.

A Compendium of Modern Pharmacy and Druggists' Formulary. Fourth Edition, with Supplement. By Walter B. Kilner, Pharmaceutist. London: Henry Kimpton. 1882.

A few months since a notice of Mr. Kilner's useful book in this Journal (vol xi., p. 756) drew forth a number of inquiries as to whether copies might be obtained in this country. We are therefore glad to have the opportunity of saying that a fourth edition has now been issued, and that it is published by Mr. Kimpton, of High Holborn.

Notes and Queries.

[739]. Oil of Peppermint.—I have noticed the same green colour; it is no doubt due to the ol. menthæ pip., as on opening a fresh bottle I found it mix with the same bulk of same sample s. v. r., quite a pale straw colour.—Inceptor.

[741]. Smelling Salts.—Equal parts of pulv. potassæ carb. (dry) and pulv. ammon. mur., rubbed together thoroughly and a few minims of ol. lavand. and ol. geranii will make a very pungent salt.—Inceptor.

[743]. Preservation of Essence of Lemon.—I have kept ess. limonis for years without any deterioration, by adding ½ pint distilled water to ½ gallon of essence. After a time the water at the bottom of the bottle appears loaded with resin, etc. I then decant the essence carefully and put it into another bottle and add more water, and repeat this when required. By this plan I have kept essence of lemon unaltered for eight years.—Percy Wells.

[743]. Preservation of Essence of Lemon.—W. L. would find 10 per cent. of alcohol quite sufficient.—374.

[743]. With reference to the query concerning the preservation of ess. lemon. I would state that having heard some years ago that ess. lemon might be preserved in its purity of odour by keeping it with its bulk of water in small bottles, I placed some in a small vial; after the lapse of at least a twelvemonth, it was apparently unaltered.—H. J. B.

[743]. I have found the best way to keep essence of lemon, is to mix it with equal parts of absolute alcohol, or to put it into ℥j. or ℥ij. bottles, and hermetically seal it, only using from one bottle at a time.—Fossil.

[744]. Potash Powders.—I should think potash powders could be made as ordinary gasogene charges, only substituting pot. bicarb. for sodæ bicarb.—374.

[745]. Boracic Acid Lint.—Will any reader kindly inform me how to make "Lister's boracic acid lint?"—W. L. P.

[746]. Cleaning of Fossils.—I have a number of fossils, etc., which have become discoloured. Could anyone kindly inform me the best way to clean them? Also to clean white coral?—Fossil.

[747]. Pulv. Alk. Co.—The formula for "pulv. alk. co." as prescribed by Dr. Bell, of Glasgow, would greatly oblige.—23.

Correspondence.

Golden Ointment.

Sir,—While thanking Mr. Alfred E. Tanner for his courtesy in publishing the result of his examination of Singleton's golden eye ointment, an analysis that undoubtedly establishes the composition of the article as at present manufactured, I must, in the absence of the paper to which he refers, and which a search I have made with some diligence has altogether failed to discover, ask his pardon for disagreeing with one of the opening sentences of his contribution, in which he states that the matter has some time since been set at rest and can no longer be considered a debatable question.

Coinciding, to a certain extent, with his opinion that the work of former investigators would be much the better for verification or otherwise by persons who could bring to their aid the discoveries which a long lapse of years has produced, I do not think that modern experimentalists should, without the deepest consideration and almost incontrovertible proofs, cast doubts upon the deliberate assertions of authorities who, like Dr. Paris, stand, preeminent amongst the pharmacologists of our country.

Mr. Tanner, I think, will readily acknowledge that no one with the attainments of the author of such a work as 'Pharmacologia' would be unable to tell the difference between an ointment prepared with red oxide of mercury and another containing such a totally dissimilar ingredient as orpiment, nor would he, after stating that the ung. hydrarg. nit. oxid. of the London Pharmacopœia was sold as a substitute for the original preparation, affirm that the genuine "golden eye-salve," which, according to Mr. Tanner, would be almost identical in appearance, owed its properties and colour, not even to the red sulphide, realgar, but to a yellow pigment like orpiment; and when the citrine or yellow ointment of Edinburgh was introduced into the London Pharmacopœia for the purpose, as Dr. Christison wrote in 1842 ('Dispensatory,' 1st edition, p. 531) of "imitating as exactly as possible a nostrum well-known by the name of golden eye-ointment," a view in which he is supported by Nevins, Royle, Squire and others, can any one consider that the compilers were attempting to produce a preparation which would be recognized by the general public as identical in composition with the so-called "golden ointment" they had been accustomed to?

Since Mr. Tanner's letter has appeared I have been at some pains, by an examination of contemporary authors, to gain a little light upon the subject. I find Cooley in 1855, more than thirty years after the statement of Dr. Paris had appeared, after quoting the remarks in 'Pharmacologia,' writing:—"There appears to be some mistake in this, as that sold us under the name had nearly the same composition as the ung. hydrarg. nit. oxid. of the Pharmacopœia. It did not contain of arsenic or sulphur. The action of the nostrum and the reputation it has acquired fully justify our conclusions."

This effectually proves that the ointment as sold at that time was composed of the red oxide of mercury, but does not by any means assert that the preparation was the same at the time to which Mr. Cripps referred in his paper; and I may add here that the last sentence of the paragraph I have quoted from Cooley cannot be advanced in evidence to the contrary, as there is no doubt but that orpiment is not only a good, but a valuable remedy for certain eye diseases, and especially for those in which the "golden ointment" was recommended. This fact may possibly not be so apparent to many of your readers, therefore I may just mention that the following prescription, published in the *Dublin Quarterly Journal of Medical Science* (September, 1870), was put forward as a valuable specific for granular lids and in all cases of chronic ophthalmia:—

℞ Arsenici Sulphureti . .	gr. ij.
Unguenti Citrini .	ʒij.
Axungiæ Præparatæ	ʒvj.

Misce bene.

My researches have led me to the conclusion that the original "golden ointment" which was the indirect means of securing a place for ung. hydrarg. nitratis in the London Pharmacopœia was of a yellow and not of a red colour, in fact the hue was so pronounced that Christison, Duncan, and others undoubtedly considered it to consist only of well prepared citrine ointment, and hence their endeavours to improve their own formulæ; in support of this statement I may mention that Barker and Montgomery ('Transl. Dub. Pharm.'), writing in 1830, say that they think the difference in the two preparations was due to the fact that unsalted butter was used as the basis of the secret nostrum. Duncan, also ('New Dispensatory,' 12th edition, p. 1050), about the same date expressly mentions that both the "empirical remedy" and the citrine ointment, as prepared by his namesake's process, had a "fine golden colour," a description which could not justly be applied to a preparation of the red oxide.

On these grounds I think that the question is narrowed to one of the following substances:—the yellow oxide of Mr. Cripps, citrine ointment or arsenious sulphide. There are several reasons why the yellow oxide of mercury may not be considered the specific ingredient; in the first place the substance itself is only of recent introduction and cannot be said to possess in any special degree the particular remedial qualities "golden ointment" was famous for. Again I am unable to see what authority Mr. Cripps has for noticing it, unless a statement by the compiler of the 'Chemists and Druggists' Diary (1881) will account for the circumstance; the writer, after quoting Dr. Paris, asserts that a very general impression is current that Singleton's "golden ointment" is prepared with precipitated mercuric oxide, and this is the only case in which I find the yellow oxide even mentioned. With regard to citrine ointment I do not think it in any degree probable that Dr. Paris, well acquainted with the ordinarily accepted opinion, would have gone out of his way to state definitely that orpiment was the active constituent without having first satisfied himself by careful analysis that the announcement would be correct.

The only way in which I can account for the statement in Gray and Redwood's 'Supplement,' etc., that the ointment was prepared with realgar is by supposing that having seen the sulphuret of arsenic mentioned by Paris, they, from a superficial examination of the proprietary article, considered that he had intended the red variety, realgar, and not orpiment as stated.

Elden Grove, Rockferry, Cheshire. J. E. Saul.

M. Leigh.—A *résumé* of one of the most interesting cases of the occurrence of disease germs in milk will be found in vol. i. of the present series of this Journal, p. 616.

Chemicus and *An Apprentice.*.—We cannot supply technical information to anonymous correspondents who do not comply with the rule printed weekly at the commencement of the "Correspondence."

Inquirer.—The book is a good one as far as it goes, but you are advised not to limit your chemical studies to the pages of a single work.

Inquirer.—The General Medical Council does not conduct a preliminary examination.

X.—See a note on green extracts in suppositories in vol. ix., p. 949.

G. L. Lloyd.—See the last paragraph in a note by Dr. Vulpius, printed in the *Pharm. Journ.* for April 8 last, p. 825.

R. G. Bumpstead.—The names of the writers were appended to all the letters that appeared on the subject.

W. Miller.—(1) Yes. (2) Too fragmentary to determine. (3) *Cornus sanguinea.* (4) Yes. (5) *Clematis vita-alba.* (6) *Euphorbia amygdaloides.*

Chemicus.—The subject has already been frequently discussed in this Journal. See several papers in vol. xi. of the second series, and especially one on p. 542.

An Old Subscriber.—We should think that dilute glycerine would answer the purpose.

Communications, Letters, etc., have been received from Messrs. Shenstone, Pollard, Tichborne, Napier, Hogg, H. J. B.

"THE MONTH."

The weather, with the exception of a few frosty nights, has been so favourable to vegetation during the past month, at all events in the south of England, that many of our spring flowers may be found in blossom. Kentish primroses are being sold in the London streets, whilst an Isle of Wight correspondent forwards the red poppy, the winter heliotrope (*Petasites fragrans*), and the *Lamium album* in flower, and states that the primroses are in blossom, the hazel catkins are budding, and the *Daphne Laureola* is almost in flower.

On the rockwork at Kew, *Gentiana Kurroo* is now in flower and also *Erigeron philadelphicum*. In the Economic House, *Monodora myristica*, or Calabash nutmeg, is in full bloom.

In the Economic House at Kew may also be seen a specimen of the "tonga" plant. According to Mr. N. E. Brown, who has just described the "tonga" plant in detail (*Journ. Bot.*, Nov., p. 332) it must now pass under the name of *Epipremnum mirabile*, Schott, instead of *Rhaphidophora vitiensis*, the supposed two plants having proved to be identical and the former name having been given to the plant fifteen years before the latter. It would appear that it is by no means confined to Fiji, but has been found in Java, Baly, Amboina, Timor, and Tropical Australia. It has been some time in cultivation in this country, having been grown by Mr. W. Bull. The youngest leaves are entire, but the subsequent leaves are divided on the left and right hand side alternately, both sides finally becoming divided and forming a pinnatifid leaf.

In the same Journal, it is stated that a very rare British plant, *Eriophorum gracile*, has been found by Mr. Bolton King, in three bogs in the New Forest within a range of about two miles. A yellow-fruited variety of *Rubus discolor*, which does not appear to have been recorded as British since the time of Bobart, in 1696, has been detected by Mr. J. W. White, near the Mendip Hills.

The *Gardeners' Chronicle* (p. 566) records two curious facts which, although they have no apparent bearing on pharmacy, yet may lead to valuable results. One is the successful attempt to graft potato tubers and so form hybrids. As the potato is an underground stem, this is something like the grafting of cinchonas, which also promises good results. The other fact is the development of a variety of the apple, without any core. How this was produced is not stated, but it is known that pears having a similar character are sometimes produced by a plentiful supply of moisture being suddenly given to the tree after a long drought and while the pears are in course of formation.

An interesting account of the effects of the stinging tree, *Laportea gigas*, is given in the same journal (p. 567), by Mr. N. E. Brown. The pain produced by the sting of a single hair on the right hand gave rise to remarkable symptoms, the pain being confined to the right side of the body and being succeeded by a numbness and slight paralysis. Besides the pain, a sensation of losing the senses, or rather, of becoming insane, was experienced. The severe symptoms lasted two hours; the spot pricked remaining constantly painful for nearly a month after being stung. Mr. Brown expresses surprise at the fact that the pain extended to the right side of the brain instead of the left, it being generally received that the right side of the brain governs the left half of the body. Dr. Ferrier, in *Brain* for October, mentions a singular condition in which impressions on one half of the body are referred to the corresponding point on the opposite side, a phenomenon termed "allochiria" by Obeisteiner; and considering the effect of *Laportea* on the brain, as described by Mr. Brown, this may be a further illustration of the same phenomenon (*Lancet*, p. 709). As the liquor injected could not have been more than the dot over an *i*, such a virulent poison could not possibly be used in medicine except in a homœopathic dose; but the chemical nature of the substance is deserving of investigation, if only to discover an antidote for its effects. Mr. A. W. Bennett has recently, in this Journal, called in question the common statement concerning the nettle owing its stinging property to formic acid, and suggested that the irritant is more probably of an alkaline nature.

According to M. Maumené (*Comptes Rendus*, xcv., 924), the colouring matter of black grapes and of red wines, to which he has given the name of "œnocyanine" is colourless during eight to twelve days before its complete formation. He finds that if a green grape be taken from a bunch in which some are already turning red, and dried over strong sulphuric acid, the seeds when quite dry become yellowish, but that in a few minutes after their removal from the bell-glass they rapidly absorb oxygen and atmospheric moisture and can be seen to darken in a few minutes to the natural colour that they would have in the ripe grape. He therefore concludes that iron has nothing to do with the coloration.

The purple-red colouring matter of the fungus, *Agaricus ruber* (*A. sanguineus*) has been examined by Dr. T. L. Phipson, who proposes to name it "ruberine" (*Chem. News*, Nov. 3, p. 199). It is described as soluble in water and in alcohol, the solution being of a beautiful rose-red colour when seen by transmitted light, but presenting a very vivid blue fluorescence, and giving in its spectrum two dark absorption bands in the green. In these latter characters it differs from "palmelline," the colouring matter obtained by Dr. Phipson from *Palmella cruenta*, a solution of which is also rose-red by transmitted light, but presents an intense yellow fluorescence and shows dark absorption bands in the yellow part of the spectrum. Dr. Phipson has also separated from the peeled fungus a substance, which he considers to be an alkaloid, and which he proposes to name "agarythrine." From a solution in ether it was deposited upon evaporation as a white or yellowish-white amorphous substance, soluble in alcohol, ether, and dilute hydrochloric acid, and having a distinctly bitter taste, followed by a burning sensation on the tongue. When treated with nitric acid, or oxidized by contact with air, the solution acquired a rose-red colour, and for this and other reasons Dr. Phipson thinks that the colouring matter, "ruberine," is derived from the alkaloidal substance, "agarythrine," under the influence of the air and solar rays. It may be presumed that the fungus referred to is the *Russula rubra*, Fr. (Cooke's 'Handbook'), that species being bitter, whereas *R. sanguinea* is not. Red colouring matter occurs also in several other species.

A contribution to the settlement of the question as to how far the vital processes of plants are influenced by various mineral compounds presented by the soil to their roots has been made by Mr. F. C. Phillips (*Chem. News*, Nov. 17, p. 224), who has carried out a number of experiments with geraniums, coleuses, ageratums, achyranthes and pansies, planted in soils containing one-half per cent. of carbonate of zinc, copper or lead, or arsenate of lime. The most strongly marked effect was observed to be produced by the arsenate of lime, and from the general results Mr. Phillips concludes (1) that healthy plants grown under favourable conditions may absorb through their roots small quantities of lead, zinc, copper and arsenic; (2) that lead and zinc may enter the tissues in this way without causing any disturbance in the growth, nutrition and functions of the plant; and (3) that compounds of copper and arsenic exert a distinctly poisonous influence, tending, when present in larger quantity, to check the formation of roots, and either killing the plant or so far reducing its vitality as to interfere with nutrition and growth. It will be obvious that these conclusions have an important practical bearing upon the extensive use of Paris green (arsenite of copper) as an agricultural insecticide in the United States.

A further contribution to the knowledge of the conditions attending the reduction of nitrates in soils under the influence of a ferment has been made by Messrs. Dehérain and Maquenne (*Comptes Rendus*, xcv., 854). When the fermentation was provoked artificially by adding solution of sugar and potassium nitrate to garden soil, multitudes of vibrios could be seen, with the aid of a microscope, presenting all the characters of *Bacillus amylobacter*, the "butyric ferment" of Pasteur. The composition of the gas evolved differed with the rate of fermentation. When this was slack it was found to consist of CO_2, 80·5; NO, 8·2; N, 11·3; and when more energetic of CO_2, 67·3; H, 31·5; N, 1·2. The butyric ferment obtained from other sources was found to act similarly; but when the lactic fermentation was set up alone no reduction of nitrates was effected. The authors think that the hydrogen produced by the butyric fermentation has the same action upon nitric acid as nascent hydrogen is known to have.

M. Marcano, who recently pointed out the intervention of microbes in the fermentation of an Indian beverage prepared from ungerminated maize (see before, p. 184) has been extending his observations in other directions. His results appear to confirm the opinion previously expressed that under the influence of a micro-organism, which occurs under the three forms of vibrios, spores and mycelial tubes, and is easily detected on the pellicle of maize and other grains, starch is converted into dextrin, sugar, and afterwards alcohol, apart from the action of any diastatic ferment emanating from the vegetable cells. There appears, however, to be a considerable quantity of diastase formed as "a product of the vital activity of the vibrios," for when the microbes were cultivated for a time under favourable conditions in a mixture of ungelatinized starch and water, containing some albumen, and then rendered inert by the action of chloroform, it was found that the liquid in which the action had been going on possessed, after filtration, a diastatic action equal to good extract of malt. The same microbe is said to be the cause of the fermentation of cane juice during the manufacture of sugar, and to be easily detected in the cells of the stalks. It is also capable of fermenting lactose, and this property may be utilized in the preparation of koumiss, by sowing the microbes in lukewarm milk, to which lactose has been added in proportion to the alcoholic strength desired. The fermentation goes on very actively, and even tumultuously, at the ordinary temperature, for eight or ten hours, or until all the sugar is transformed, and the sourish tasted alcoholic liquor produced contains a large proportion of diastase.

Some comparative experiments, made by Dr. W. Detmer, of the University of Jena (*Zeits. f. phys. Chem.*, vii., 1), appear to show that the action of the diastatic ferment upon starch is considerably accelerated when it takes place in an atmosphere of carbonic acid. A similar result has been found to follow the addition of minute quantities of citric, phosphoric and nitric acids to the liquid containing the starch and ferment, the activity increasing with the proportion of acid added up to a certain point, which being exceeded the action was again proportionally retarded. On the other hand, when the liquid was made extremely faintly alkaline the breaking up of the starch went on very slowly, and when made more alkaline it completely stopped. The formation of sugar was not much interfered with by the presence of even relatively large quantities of carbolic acid.

Fehleison has found that in erysipelas micrococci are constantly present in the lymphatic vessels of the skin (*Lancet*, Nov. 4, p. 771). When cultivated in gelatine prepared by Koch's method they were found to grow rapidly, and the fourth generation of these organisms was capable of producing the disease when inoculated into the skin of human beings.

In the *British Medical Journal* (Nov. 25, p. 1051), attention has been directed to the use of naphthalin. It appears that in Strassburg it has been used for dressing wounds as an antiseptic, all animal or vegetable micro-organisms being destroyed by it, whilst neither wounded surfaces nor the healthy structures around them are in the least irritated. It has also been used for the disinfection of sick rooms and closets, as a parasiticide in certain skin diseases, and as an inhalation in infectious diseases involving the respiratory organs, such as diphtheria. The crystals have the disadvantage of cutting the flesh by their sharp edges, when applied to wounds. Naphthalin is soluble in various fixed oils, in cold ether and in warm alcohol, but not in dilute acids or alkalies.

At a recent meeting of the Medical Society of London, Dr. Richardson read a paper on the properties of ammonia, chloroform, and ammoniated chloroform, as antiseptics (*Lancet*, Nov. 25, p. 892). He also exhibited two small specimens of lung, which had been preserved in chloroform vapour and had remained untouched in their respective bottles for thirty-five years, and were still well preserved. As an illustration of the antiseptic power of ammonia vapour, he showed a specimen of blood which had been drawn from a sheep's neck in April, 1862, and kept in a well-corked bottle ever since; it was still perfectly fresh and fluid. He found that structures containing much fat became saponified unless chloroform were mixed with the ammonia, and that when it was desirable to retain the colour of the blood, the addition to the chloroform of coal gas which contained sufficient carbonic oxide for the purpose was entirely successful. The knowledge that it is possible to retain specimens of viscera in a perfectly sound state, during a long investigation, in ammonia or chloroform vapour, will be welcome to analysts and toxicologists. Dr. Richardson remarked that he feared the process could not be carried out on the large scale. He added that he had found that chloride of zinc and spirit embalmed a body perfectly but made it too hard for dissection.

Dr. Von Mering has recently been investigating the physiological properties of acetal (*Med. Times and Gaz.*, Nov. 11, p. 585, from *Berliner klin. Woch.*). He finds that it causes gradual loss of consciousness and then stops the respiration before arresting the action of the heart. In experiments upon frogs, rabbits, dogs and cats, it was found that when death occurred from its use it resulted from apnœa caused by paralysis of the respiratory muscles. Eight experiments have been made with men, in six of these there was a notable effect both in the relief of pain and in the procuring of sleep. The author points out the remarkable fact that such bodies as alcohol, ether, paraldehyde, acetal and several other bodies not containing chlorine, act primarily and more powerfully on the respiratory centre, whilst chloral, chloroform, and bichloride of methylene affect the circulation and respiration in almost an equal degree.

In the *British Medical Journal* (Nov. 11, p. 934), an account is published of Dr. W. Squire's further inquiries into the action of bromide of ethyl. He remarks that the safety of anæsthetics depends in some measure upon the readiness with which they are cleared from the lungs by ordinary diffusion, the rate of diffusion depending upon the vapour density. Thus nitrous oxide of density, 1·5, and ether, 2·56, allow of more rapid return to consciousness than bromic ether, the vapour density of which is 3·75 or chloroform, which has that of 4·2. Bromic ether, however, possesses the valuable property of acting as an anodyne without causing complete unconsciousness and hence can be used to allay labour pains, the vapour being diffused from the lungs during the intervals of pain. For the relief of spasmodic affections, such as whooping cough and angina pectoris, a solution of 1 part of bromic ether in 200 parts of water could be given. Dr. Squire considers that far too large a proportion of anæsthetics is generally used, a less amount, more largely diluted, being quite as successful and much safer. In the discussion on the paper, Dr. Spanton remarked, concerning the use of bromide of ethyl as a local anæsthetic, that when used in the form of spray insensibility of the skin can be produced by it without causing actual freezing, as is necessary when ether vapour is applied, and hence the tissues can be cut while still soft and the subsequent pain of thawing is entirely avoided. He also remarked that he had found the inhalation of small quantities of great service in some cases of asthma supervening on old standing bronchitis.

Another new test for albumen, which promises to prove a very convenient one, has been described by Dr. George Johnson (*Lancet*, Nov. 4, p. 737). It depends upon the application of an observation published by his son in 1874 (*Jour. Chem. Soc.*, Aug.) that albumen is coagulated by picric acid. It has been found that when albuminous urine is treated with an equal volume of saturated solution of picric acid it immediately becomes turbid with coagulated albumen. This test is said to be even more delicate than the nitric acid test, while the coagulum produced is about equally insoluble in water; but the coagulum is readily soluble in caustic potash and ammonia, so that an alkaline urine should be neutralized before applying the test. A small crystal or powder of picric acid quickly dissolves and produces the same effect in the urine, and Dr. Johnson suggests that a few crystals in a bottle, or, better still, solid pellets made of the powder, would be much preferable to nitric acid as a portable test.

Subsequent to the above communication, Dr. Johnson announced (*Lancet*, Nov. 18 and 25, pp. 869 and 898) that picric acid also furnishes a very valuable test for grape sugar, by increasing to an extraordinary degree the delicacy of Moore's test for sugar in urine, *i.e.*, boiling it with an equal volume of liquor potassæ. In order to prevent the obscuration of the test by the intensity of colour produced, a weak solution of potash, not exceeding 2 per cent., must be used, and only enough picric acid that the picrate of potash formed shall tinge the liquid yellow. Upon boiling this alkaline solution of picrate of potash with a liquid containing grape sugar, an intense deepening of colour takes place immediately, and so delicate is the reaction that it is reported to indicate that a trace of grape sugar is present in all normal urine. The reaction does not occur when only cane sugar is present.

Very contradictory statements have been made as to the behaviour of hydrated calcium chloride when submitted to a temperature of from 180° to 200° C. According to Mitscherlich the compound containing 6 molecules of water ($CaCl_2 + 6H_2O$) loses 4 molecules only at 200° C., whilst according to Legrand calcium chloride in aqueous solution, boiling at 179·4° C., already contains less than 2 molecules. To clear up this point Herr Weber has heated pure hydrated calcium chloride ($CaCl_2 + 6H_2O$) to 200° C., and he reports (*Berichte*, xiv., 2316) that at that temperature it becomes practically anhydrous, losing not more than another ¼ per cent. in weight when fused. The product forms a porous mass, very suitable for drying purposes; it has an alkaline reaction, probably through loss of hydrochloric acid and formation of oxychloride, but the alkalinity is greatly increased by fusing.

About eighteen months since Dr. Hofmann communicated the results of some experiments (*Berichte*, xiv., 705) from which it appeared that the true formula for coniine was $C_8H_{17}N$, instead of $C_8H_{15}N$, by which its composition had hitherto been expressed. Assuming this to be correct it became evident that a revision was necessary of the published statements with respect to conydrine, the other base discovered in conium by Wertheim, which had been represented to be a hydrate of coniine ($C_8H_{17}NO$) from which a molecule of water was removable by treatment with phosphoric anhydride, leaving a base that was identical with coniine; for either the formula for this base also would have to be increased by H_2, or the decomposition could not be so simple as had been stated. Dr. Hofmann therefore made some analyses (*Berichte*, xiv., 2313) of purified conydrine, which agreed in indicating that Wertheim's formula, $C_8H_{17}NO$, represents the proper proportion of hydrogen present in the base. Further, upon treatment of the same substance with phosphori-anhydride a strongly basic volatile oil was obtained, which though it had the smell of coniine, proved on nearer examination to be a mixture of various bodies, requiring further investigation to clear up their composition.

"Kairine" and "kairoline" are the names of two synthetically prepared bases which form the latest additions to the already large number of substances put forward as possible substitutes of quinine. They are said (*Pharm. Zeitung*, No. 89) to be two out of many similar bodies, prepared by Dr. O. Fischer and Dr. W. Königs, whose investigations in connection with the alkaloids are well known. In the belief that the characteristic properties of quinine are not referable to a chinoline nucleus, as has been assumed, but to a hydrogenized chinoline nucleus, and keeping in view the presence of oxygen in quinine, Dr. Fischer worked in the direction of preparing compounds in which hydrogen was introduced into chinoline in the form of hydroxyl or other oxygen-containing groups, whilst Dr. Königs prepared compounds by the introduction of molecules free from oxygen. After a large number of different compounds had been prepared they were entrusted for therapeutical experiment to Dr. W. Filehne, of Erlangen, who found that the power of reducing the temperature in fevers is possessed by those compounds in which the nitrogen atom, besides its combination with two atoms of carbon in the chinoline ring, is joined to the carbon of a methyl or other alcohol group. This condition is present in three known compounds, Dr. Fischer's oxychinolinmethylhydride, which has received the more convenient name of "kairine," Dr. König's "chinolinmethylhydride," similarly named "kairoline," and Wischnegradzky's analogous "chinolinethylhydride." The last two appear to be at present put out of court by difficulties attending their preparation and their disagreeable taste. Kairine, represented by the formula $C_{10}H_{13}NO$ (that of chinoline being C_9H_7N), is represented as forming a hydrochlorate which is a crystalline powder, not quite white (greyish-yellow), easily soluble in water, and having a mixed saline bitter and aromatic taste, the latter similar to guaiacol, but not burning. Upon healthy powerful full-grown persons doses of 1 to 1·5 gram are said to be without physiological action and produce no disagreeable effects; but upon full-grown invalids, or weakly persons, a dose of 1 gram every two hours must not be exceeded, or cyanotic symptoms may result. The dose recommended in cases of fever in adults is 0·3 to 0·5 gram at intervals of not more than an hour or an hour and a half.

The attention of several pharmacists in Germany and Austria has been directed recently to working out a satisfactory method of preparing quinine tannate, one of the slowly soluble, and therefore nearly tasteless, compounds of that alkaloid. Herr Dukla (*Pharm. Zeitung*, No. 92) recommends to suspend 20 parts of quinine sulphate in 80 parts of distilled water, add about 20 parts of dilute sulphuric acid so as to completely dissolve the quinine, then dilute with sufficient distilled water to bring the entire quantity up to 1000 parts and add to the filtered solution, under diligent stirring, a solution of 40 parts of sodium carbonate in 160 parts of water. The resulting precipitate of quinine hydrate is to be collected on a filter, washed well in cold distilled water, allowed to drain, and then dissolved whilst moist in 200 parts of 96 per cent. alcohol. The alcoholic solution is filtered, and allowed ot trickle, under constant stirring, into a clear solution of 60 parts of tannic acid in 1000 of water, prepared in the cold, the mixture being occasionally stirred during some hours after and then allowed to settle. The abundant nearly white precipitate should be collected on a moistened paper filter, washed with distilled water at 30° C. until the water running off no longer has an astringent taste, dried on blotting paper at a temperature not exceeding 30° C., and rubbed to a powder. The neutral tannate of quinine thus obtained is described as nearly white, and entirely without odour or taste.

Dr. T. Browne, of Yarmouth, has published, in the *Brit. Med. Journ.* (Nov. 25, p. 1030), the results of his experiments upon the therapeutic value of hyoscyamine. He used in his experiments Merck's crystalline hyoscyamine, and arrived at the following conclusions concerning its use: That the action of hyoscyamine when given by the mouth is very uncertain and dangerous; that no curative action could be claimed for it, although it proved capable of moderating, in maniacs, violence of action and of soothing without causing sleep; that hypodermic injection was the only safe method of using the drug. The following formula was the one which was employed, but while satisfactory as regards strength, it was found to lack stability.

Hyoscyamine (Merck's crystallized) .	4 grains.
Glycerine and distilled water, of each	½ ounce.
Carbolic acid	2 minims.

Dissolve without heat.

Of this solution 4 to 8 minims are injected hypodermically. Dr. Browne states that it is very important to make the solution without heat, as heat renders the alkaloid nearly inert. He finds that the strength of any solution yet devised cannot be depended on for more than a month.

Dr. Chahbazian, of Paris, has recently been experimenting with Tanret's ergotinine (*Med. Times and Gazette*, Nov. 18, p. 624). He finds it to act more quickly than the so-called ergotine (watery extract) and that it does not cause local abscesses or indurations. The strength used for hypodermic injection was 5 to 10 minims of a solution of $\frac{1}{30}$th of a grain in 20 minims. Ergotinine is soluble in alcohol or chloroform, and insoluble in water; but the solvent used in the experiments is not stated. The activity of this alkaloid should be very great, seeing that only 3 grains are obtained from 1 lb. of ergot.

A case of strychnia poisoning is reported (*Lancet*, Oct. 28, p. 724), in which the symptoms were delayed by the action of laudanum taken at the same time. The doctor who attended it hints that opium might be used when chloral is not at hand. Except in the eastern counties (the case happened in Lincolnshire) laudanum is not more likely to be at hand than chloral, whereas tobacco, mentioned by Dr. Neligan as an antidote to strychnia, is almost always to be obtained easily and quickly.

Mr. J. D. Forbes has recently examined the potato beetle, *Doryphora decemlineata*, and finds that it contains a vesicating principle, which he has extracted in the form of a dark oily fluid; but no evidence of the presence of cantharidin has been detected (*Amer. Journ. Pharm.*, [4], xii., 550).

The *Lancet* (Oct. 28, p. 716) directs attention to a new styptic, which was discovered during the French expedition to Mexico. This remedy is a plant named *Tradescantia erecta*, which in a crushed or chewed state is said to possess the property of stopping any hæmorrhage, its action exceeding that of all styptics as yet known, as for example, perchloride of iron. A specimen was planted by the discoverer at Versailles, in 1867, and is said to retain its properties unimpaired by the difference of climate. This plant belongs to a natural order *Commelynaceæ*, remarkable rather for the mucilaginous than for the medicinal character of its members.

In the *Practitioner* (November, p. 327), Dr. Murrell gives an account of the action of white agaric (*Polyporus officinalis*) in the sweating of phthisis. After numerous experiments he has arrived at the conclusion that it is a good remedy, and that there are times when it may be used with advantage; but he much doubts if it is equal to atropia, picrotoxin, pilocarpine or Dover's powder. In small doses it is uncertain in its action, whilst in large doses it purges violently. The agaric was given in doses of 3 grains up to 30. The drug in 3 grain doses acted slowly, and not with certainty, 3 grains of extract, equal to 9 grains of the powder, acting better; whilst 30 grains purged violently. A tincture 1 in 6 and a fluid extract 1 in 3 have also been prepared. The active principle, agaricine, has been given in the dose of $\frac{1}{12}$ of a grain and was found to check cough and to promote sleep as well as to restrain sweating.

An "emplastrum impermeabile russicum" is being introduced upon the continent which is said to be likely to throw English plaster into the shade. It is described (*Pharm. Zeitung*, No. 89) as a white enamel-like ribbed membrane, made adhesive on one side by a coat of isinglass. A sample examined by Herr Dietrich was found, after removal of the isinglass, to dissolve in ether-alcohol to collodion, with a separation of a white powder which was recognized as zinc oxide. The collodion shaken with chloroform yielded a thick oily residue which proved to be castor oil. Herr Dietrich therefore thinks the probable method of making the plaster is to use a flexible collodion containing sufficient castor oil to bind some zinc oxide, afterwards to add collodion, and then to dip glass plates into this mixture two or three times, or until a sufficiently thick membrane has been deposited upon them; to this a coat of strong solution of isinglass is given, and the plaster, when dry, can be removed from the glass.

Some further information concerning the production of opium in the Zambesi district (see *Pharm. Journ.*, [3], viii., 1007; ix., 63) has been given by M. Guyot (*Comptes Rendus*, xcv., 798), who recently visited the locality. The cultivation, which is carried on at Chaïma, lying between the Muto and Quaqua rivers, was commenced in 1879, and now occupies about three hundred labourers. The collection of opium is effected about seventy-five days after the sowing of the poppy seed, and the yield appears to compare favourably with that usual in India. The product, in its viscous condition, is said to exhale an odour *sui generis*, but no particulars are given as to its average morphia strength; indeed the whole of it is stated to be sophisticated on the spot by the addition of 80 to 100 per cent. of a special matter the composition of which is known only to the European cultivators. The mixture is made up into balls weighing about 500 grams, which are packed in boxes at the bottom of which is a bed of powdered empty capsules and poppy leaves covered over with a layer of indigenous cotton. After the collection of the opium the capsules are allowed to completely ripen and then gathered for the sake of the seed.

According to a 'Commercial Report,' issued by Messrs. Sachsse and Co., several of the largest producers of citronelle oil have given up its production in favour of coffee cultivation, and the price is consequently expected to be higher. Lavender is said to have yielded a larger harvest than last year, and this has brought about a decline in price. The peppermint crop is reported to be an almost total failure, both in England and the United States.

At the drug sales this month, three bales of false buchu leaves, *Empleurum serrulatum*, and five bags of a new buchu with linear obtuse leaves, and also the leaves of *Barosma vulgaris*, were offered. A bag of a bitter bark, apparently that of a species of *Esenbeckia*, and some of which has on previous occasions been sold as Cusparia bark, was again placed on the market. Seventy-five bags of the stems of *Coscinium fenestratum* were offered as Colombo root, and some of the mouldy ipecacuanha, mentioned last month, after having been washed and dried, was again put up for auction. Adulterated matico was also offered for sale. Among the rarer drugs there were observed the following:—Korarina cardamoms, Ceylon cardamoms, condurango barks, salep, castoreum, and Yunnan musk.

Mr. N. Stevenson has recently utilized the electric light in a novel direction, by using a small incandescent lamp, fitted into a vulcanite cup, for illuminating the cavity of the mouth during dental operations. The vulcanite cup serves to keep the mouth open (*Lancet*, Nov. 25, p. 928).

In a paper presented to the Academy of Sciences (*Comptes Rendus*, xcv., 841), M. Delacharlonny describes a new ferric sulphate and its application to the making of blood manure. When blood is treated for this purpose with solution of ordinary ferric sulphate it is coagulated and forms a pasty mass that requires considerable evaporation before it is dry. A better effect is said to be produced by using an acid ferric sulphate, corresponding in composition to the formula $Fe_2O_34SO_3$, which is prepared by oxidizing ferrous sulphate with nitric acid, adding to the solution a sufficient quantity of sulphuric acid to make up the relative proportions, and concentrating, when it forms a crystalline mass. A solution of this salt, sp. gr. 1·4, added to fresh blood is said to convert it almost instantaneously into a stiff clay-like but elastic paste, from which most of the water drains away, leaving only a small quantity to be removed by expression or heat. The new salt forms a hydrate which crystallizes readily with twelve molecules of water.

Mr. E. H. Cook has contributed a thoughtful and interesting paper to the *Philosophical Magazine* ([5], vol. xiv., p. 387) on "Carbon Dioxide as a Constituent of the Atmosphere." The sources whence the air derives its carbon dioxide are taken as four, namely, (1) combustion of carbonaceous bodies; (2) respiration of animals; (3) decomposition of vegetable and animal substances; (4) volcanoes and other subterranean supplies. The author deduces from calculation and statistics that these four sources yield at least 50,000,000,000 kilogrammes of carbon dioxide daily. Further, he states that the amount of carbon dioxide in the atmosphere would be double what it is at present in about one hundred years if there were no means of compensation. The compensating influences are taken as three: (1) fixation of carbon by growing plants; (2) removal of dioxide by zoophytes; (3) absorption of dioxide by inorganic chemical actions. After making all allowances the author considers that terrestrial vegetation absorbs as much as 900,000,000,000 of kilogrammes of dioxide per day, an amount which is much greater than that produced from all sources taken together. Mr. Cook believes that the second compensating cause, although very powerful, seems rather to be one whose influence is only felt after the lapse of many years, and for activity cannot be equal to the first one. The third cause is apparently almost as great as the first, inasmuch as Dr. Sterry Hunt has shown "that a weight of carbonic dioxide equal to more than twenty-one times that of our present atmosphere would be absorbed in the production from orthoclase of a layer of kaolin extending over the earth's surface with a thickness of 500 metres, an amount which evidently represents but a small proportion of the results of felspathic decay in the sedimentary strata of the globe." Reliable data are not available for definitely answering the question as to the maintenance of a constant proportion of carbon dioxide in the atmosphere. The author, however, inclines to the belief that the causes at work removing atmospheric dioxide are more powerful than those producing it, and that the greater part of this so removed is becoming fixed in the earth's crust. The question as to the source of the immense quantities already fixed in this way is still left an open one. Brongniart has suggested that it all at one time formed part of the atmosphere of the globe. Dr. Sterry Hunt considers that a universal atmosphere of the same quality as that of the earth's exists, from which the carbon dioxide now fixed in the earth's crust has been derived. It is pointed out that if Dr. Hunt's hypothesis be a correct one it is interesting to remember that the carbon contained in our bodies may have existed at one time as a portion of the body of an inhabitant of the most distant member of the universe.

In the course of the past month the Council of the Royal Society has made known its decision as to the award of medals for the current year. The Copley medal goes to Professor Cayley, for his researches in pure mathematics, and the Rumford medal to Captain Abney, for his investigations in connection with photography. One Royal medal is awarded to Professor W. H. Flower for zoological work and another to Lord Rayleigh for his papers on mathematical and experimental physics. Lastly, the Davy medal is to be presented in duplicate, the recipients being Professors D. Mendelejeef and Lothar Meyer, in recognition of their discovery of the periodic relations of the atomic weights.

A NEW FORM OF APPARATUS FOR ESTIMATING AMMONIA IN POTABLE WATERS.*

BY C. R. TICHBORNE, LL.D., F.C.S., ETC.

According to the generally accepted method of examining potable waters, the estimation of minute traces of ammonia existing as such, and the ammonia which results from the oxidation of nitrogenous organic matter, are looked upon as being of the greatest importance in arriving at a conclusion as regards the quality of the water. The process may be concisely described as distilling off a third of the water, and estimating the ammonia in the distillate by Nessler's delicate process, which leaves nothing to be desired as regards its accuracy.

As the amount to be determined does not much exceed 1 part in 10,000,000 parts, it is evident that is it necessary to avoid any accidental contamination from atmospheric ammonia. This is particularly the case in chemical laboratories, where ammoniacal solutions are constantly undergoing evaporation, and the air is contaminated with that volatile base.

The fact is, of course, well recognized by all expert analysts, and is generally guarded against by the use of a special cupboard or chamber, in which the whole operation can be performed. Such a method is more or less imperfect, because the gas-burner used will itself, under certain conditions, become a source of ammonia. Also, it is evident that a general ammoniacal atmosphere in the adjacent laboratory will find its way into the chamber by the ordinary laws of diffusion.

The capacity of the vapour of water (when in the act of condensing) of absorbing traces of ammonia is something extraordinary, and can only be appreciated by the practical worker.

In distilling potable waters, I was accustomed to work with an ordinary retort and receiver—the latter being provided with a specially-contrived mercurial valve. Now, although this was satisfactory in closing the interior of the retort and receiver from general contact with atmospheric impurities, occasionally a regurgitation would take place, and admitted a little of the laboratory air.

The following arrangement has been lately adopted by myself, and, both as regards simplicity and efficacy, leaves nothing to be desired. It is, in fact, so simple that, to a superficial observer, my communication might at first sight appear superfluous, but the importance of the question involved renders any apology unnecessary.*

At ordinary temperatures very weak solutions of ammoniacal gas (such as we have to deal with in the analysis of potable waters) are fairly permanent; but, in the gaseous conditions, owing to the different tensions of the vapour of water and ammonia, this stability no longer exists. Again, small traces of ammonia in the gaseous condition are instantly absorbed by water in the non-gaseous condition. These are the two equal sources of error to be guarded against in the distillation of ammonia from potable waters, and, bearing these two points in view, I adopted the arrangement figured on the next page.

It consists of a retort fitting into a fairly long-necked receiver, with an india-rubber stopper. The arrangement must be air-tight. The receiver is connected with a bent tube proceeding from its stopper, and connecting it with two bulb tubes of a special form, and marked respectively "A" and "Z." This marking is to prevent any confusion in the hurry of manipulation, as they are exactly the same shape. The bulb tubes are somewhat, similar to a flat Liebig's potash bulb, but with two pear-shaped bulbs on each side, to prevent regurgitation of the fluid, and three absorption bulbs at the bottom. The centre bulb of these three is provided with a glass tap for filling and emptying the apparatus.†

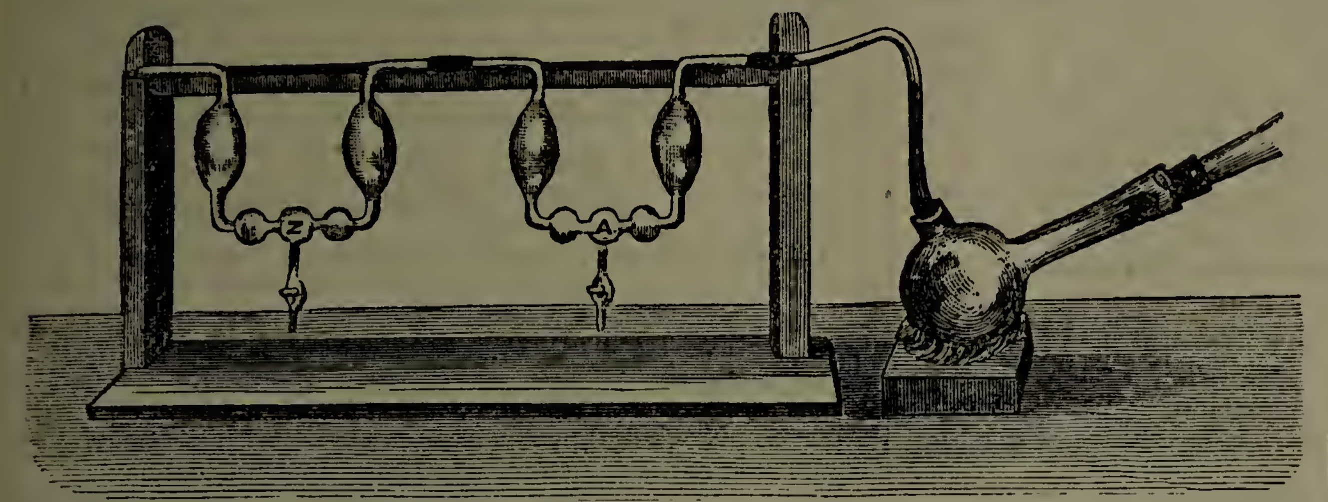
The water to be examined is poured into the retort and one-third distilled over gently, but at a fairly good rate. If operating upon half a pint, the operation should take about one hour. The whole apparatus is previously connected together, and the two bulbs are filled with

* Paper read before the Royal Dublin Society, February 20, 1882. From the *Scientific Proceedings* vol. iii., part v.

* One of the recent important works upon chemistry, is Roscoe and Schorlemmer's 'Treatise on Chemistry.' In that book there is a description of the determination of ammonia in potable waters, but there is no provision against this fruitful source of error. If the determination were carried on as it is figured at page 252, vol. i., of that work, the results would be utterly unreliable in any laboratory where other analyses were being performed.

† Bulbs of my pattern are made by Messrs. Cette and Co., of London.

water free from ammonia (*i.e.*, water which has been boiled rapidly in a flask, until it gives no reaction with



the Nessler reagent). The bulbs are easily filled by opening the tap, inserting the point of the tap tube into a beaker of the water, and sucking with the breath gently—at the same time, stopping the other end of the bulb tube by the finger.

After the operation is completed, the most of the ammonia, if not all, is present in the receiver, whilst any vapour which might have escaped therefrom is caught in the tube "A;" at the same time, any atmospheric ammonia which enters by regurgitation is caught in the bulb tube "Z." "A" is run into the distillate in the receiver, whilst "Z" is rejected. In practice, it is not necessary that the water in "Z" should be changed for twenty or thirty operations, providing that an increased amount of ammonia is not about in the laboratory atmosphere; but if so, it is desirable to change with each experiment.

If we consider the points that I have dwelt upon as being sources of error, we shall see that this simple apparatus fulfils absolutely the necessary conditions, and that the tube connecting the bulbs "A" and "Z," *contains an atmosphere perfectly neutral as regards ammonia*, because it is the space between two liquids which do not give off ammoniacal gas, and which give off vapour of an equal tension.

I may mention that, on submitting it to experimental proof, the use of an acid in either of the bulb tubes proved a mistake.

It is not necessary to give further details, but I may as well state that in many crucial experiments, I have been in the habit of estimating the amount of ammonia in the receiver, and both bulbs "A" and "Z." The following, as regards Vartry water, will serve as an illustration:—

Distillate in receiver	0·003 per 100,000.
Bulb "A" (nearly)	0·001 "

Bulb "Z" gave an indication which affected the Nessler, but which was not sufficient to estimate.

A SUMMARY OF THE CINCHONA BARKS OF COMMERCE.*

BY WILLIAM ELBORNE,

Assistant Curator of the Museum of the Pharmaceutical Society of Great Britain.

The important genus Cinchona gives its name to the order of which it is a member, namely, *Cinchonaceæ*. Botanically the genus includes trees of various sizes, some reaching an altitude of 80 feet and upwards, with evergreen leaves and deciduous stipules. The flowers are of a white or pinkish colour, very fragrant and arranged in panicles. The corolla is salver shaped, and nearly, if not quite, conceals the five stamens. The ovary is crowned with a fleshy disc; the style simple; the stigma two-cleft. The fruit is an ovate capsule, grooved on both sides, crowned by the limb of the calyx, and dehiscing from below upwards, in order to allow of the escape of the numerous winged seeds, which latter peculiarity is especially characteristic of the order. According to the enumeration of Bentham and Hooker, thirty-six species have been distinguished; but of these not more than about a dozen have been economically utilized as furnishing the commercial cinchona, or Peruvian bark. The plants are natives of the western mountainous regions of South America, their geographical range extending from 10° N. to 22° S. lat.; and they flourish generally at an elevation of from 5000 to 8000 feet above the level of the sea, although some have been noted as growing as high as 11,000 feet, and others have been found down to 2600 feet. Of the commercial barks there are several varieties They are as follows:—

I.	*C. officinalis*, var. *a*, *Condaminea* " " *b*, *Bonplandiana* " " *c*, *crispa*	yielding crown bark.
II.	*C. succirubra* (Pavon)	yielding red bark.
III.	*C. lancifolia* *C. cordifolia*	yielding Colombian bark.
IV.	*C. Pitayensis*,	yielding Pitayo bark.
V.	*C. nitida* *C. micrantha* *C. Peruviana*	" grey bark.
VI.	*C. Calisaya*	" yellow bark.
VII.	*Remijia Purdieana* " *pedunculata*	yielding Cuprea bark.

The official barks of the British Pharmacopœia are four in number:—(1) The pale Loxa or crown bark (*cortex cinchonæ pallidæ*), yielded by *Cinchona officinalis*; (2) The yellow or Calisaya bark (*cortex cinchonæ flavæ*), the produce of *C. Calisaya*; (3) The red bark (*cortex cinchonæ rubræ*), derived from *C. succirubra*; and (4) Colombian bark, *C. lancifolia*, directed to be used as a source of quinine. These are the sources of the tinctures, extracts and other preparations, while, in common with several others, they also yield the alkaloids which now constitute the chief form in which the active principles of the barks are administered in medicine. Their great value depends upon the presence of these alkaloids, viz., quinine, quinidine, cinchonine and cinchonidine, which exist principally in the cellular tissue outside the liber, in combination with kinic and tannic acids. It is found that certain barks contain more of one principle than of another; hence their greater or less commercial value, and the skill and complex knowledge required by the manufacturer to distinguish the different varieties. The *C. Calisaya*, *C. officinalis* and *C. lancifolia* from Colombia are species rich in quinine, which, in the form of sulphate, is the alkaloid most extensively employed in medicine. Among the other barks used as sources of quinine, etc., the principal are:—Colombian bark, *C. lancifolia*; Pitayo bark, *C. Pitayensis*; grey or Lima bark, *C. micrantha*, *C. nitida* and *C. Peruviana*; and a variety of Carthagena bark, *C. lanceolata*. In addition to quinine the *C. Pitayensis* specially contains quinidine, the *C. succirubra*, cinchonidine, and the *C. nitida*, *C. micrantha* and *C. Peruviana*, from the Huanuco region, cinchonine. These alkaloids, extracted from the barks, are recognized by their several distinctive chemical characteristics, while the barks producing them are likewise distinguished by a careful scrutiny of their external appearance, the lichens, etc., growing on them, the way in which they break, their taste and odour, as well as by their microscopical and chemical characters. The manner in which barks break transversely, or their fracture, as it is termed, depends

* Paper read before the Chemists' Assistants' Association.

on their anatomical structure, and affords an important criterion of the quality of the bark, cellular tissue breaking with a short or smooth fracture, woody tissue with a fibrous fracture. The best characteristics by which barks containing much quinine may be distinguished are the shortness of the fibres which cover the transverse fracture and the facility with which they may be detached, instead of being flexible and adhering as in bad barks. Thus when dry Calisaya is handled a quantity of very small splinters run into the skin causing much irritation, and this forms one of its distinguishing marks. The importance of cinchona barks in medicine renders it necessary to give some account of the manner in which they are collected and dried in their native forests and prepared for exportation. The following notice has been extracted, therefore, chiefly from Weddell and Markham.

The hardships of bark collecting in the primeval forests of South America are of the severest kind, and undergone only by the half-civilized Indians and people of mixed race, in the pay of speculators or companies located in the towns. Those who are engaged in the business, especially the collectors themselves, are called *Cascarilleros,* from the Spanish word *Cascara,* meaning *bark.* A *major-domo* at the head of the collectors directs the proceedings of the several bands in the forest itself, where provisions, and afterwards the produce, are stowed away in huts of light construction.

The cascarillero, having found his tree, has usually to free its stem from the luxuriant climbing and parasitic plants with which it is encircled. This done he begins in most cases at once to remove, after a previous beating, the sapless layer of outer bark. In order to detach the valuable inner bark, longitudinal and transverse incisions are made as high as can be reached on the stem. The tree is then felled and the peeling completed. In most cases, but especially if previously beaten, the bark separates easily from the wood. In many localities it has to be dried by a fire made on the floor of a hut, the bark being placed on hurdles above, which proves a serviceable arrangement. In Southern Peru and Bolivia, however, even the thickest Calisaya bark is dried in the sun, without requiring the aid of a fire. The thinner bark as it dries rolls up into tubes or quills, while the pieces stripped from the trunks are made to dry flat by being placed one upon another and loaded with weights. The bark of the root was formerly neglected, but is now in several instances brought into the market. After drying, the barks are either assorted, chiefly according to size, or all are packed without distinction in sacks or bales. In some places, the bark is even stamped, in order to reduce its bulk as much as possible. The dealers in the export towns enclose the bark in *serons* of raw bullock-hide, which, contracting as it dries, tightly compresses the contents of the package (100 lbs. or more).

The ports to which bark is conveyed for shipment to Europe are not very numerous. Guayaquil, on the Pacific Coast, is the most important for produce of Ecuador; Pitayo bark is largely exported from Buenaventura in the Bay of Choco, further north.

Payta, the most northerly port of Peru, and Callao, the port of Lima, likewise export bark, the latter being the natural outlet for the barks of Central Peru, from Huanuco to Cusco. Islay, and more particularly Arica, receive the valuable barks of Carabaya and of the high valleys of Bolivia. Among other ports may be mentioned Santa Marta, Savanilla and Maracaibo.

Our imports for 1881 and 1880 were thus made up:—

	1881.	1880.	
Calisaya . .	7,020	6,580	serons and cases.
Soft Colombian, New Granadian Pitayo.	87,200*	44,500	„ „ bales.

* This includes cuprea, the imports of which, in 1881, were 60,000 packages.

	1881.	1880.	
Carthagena .	5,720	6,480	serons and bales.
East Indies and Ceylon	15,400	20,690	„ cases and ballots.

The receipts in America, mainly direct from Colombia and New Granada, were as follows:—

1881.	1880.	
31,400	32,800	serons and packages.

The imports into France were also thus made up:—

	1881.	1880.	
Calisaya . .	9,915	8,590	packages.
Colombian, etc.	16,550	11,580	„

From the above tables it is noticeable that the richer barks still continue to be consigned to England.

The reckless system of bark cutting in the forests of South America, which has resulted in the utter extermination of the tree from many localities, has, within recent years, aroused the attention of the Old World, and at length prompted serious efforts to cultivate the tree on a larger scale in other countries. The enterprise undertaken by Markham in 1859, of introducing the cultivation of Peruvian bark trees into British India and Ceylon, is now an assured success. During twenty years the enterprise has since steadily progressed. There are now more than 900 acres under cinchona cultivation in the Government plantations on the Nilgiri Hills, besides 4000 acres of private plantations on the Nilgiris, in Wainad, Coorg, and other hill districts of Southern India. In British Sikkim the Government plantations cover an area of 2242 acres. The annual bark crop from the Government plantations of British India alone is already 500,000 lbs. In 1879–80 the quantity of bark sold in the London market, from British India and Ceylon, was 1,172,060 lbs. Moreover, the East India source of bark supply is now a most important one as regards both quantity and quality. Thus the whole enterprise of introducing all the valuable cinchona species from South America into India, Ceylon and Jamaica, has been made complete in all its parts, and as at present *C. succirubra* and *C. officinalis* greatly preponderate, these species will form the main sources of the future bark supply from India.

The methods adopted in India of harvesting the bark are also worthy of comment, as they have proved a means of considerably increasing the yield of alkaloids. They comprise the two different systems known as "mossing" and "coppicing." The "mossing" system consists in longitudinally stripping eight-year old trees of their bark at intervals of about 2 inches apart, winding moss all round the decorticated parts and tying it on with fibre. At the end of six or twelve months the strips of bark left untouched at the first stripping are removed, and the intervals they occupied on the trunk are mossed. At the end of twenty-two months, on an average, the spaces occupied by the bark originally taken are found to be covered with *renewed* bark, much thicker than the natural bark of the same age, and this renewed bark can be removed and a fresh process of renewal again be fostered by moss. The enrichment of the renewed bark is said to be at the expense of the bark outside the mossed region; and also that the renewal is prevented or much retarded by the least injury to the cambium layer. The protection from light afforded by the moss also has been proved to increase the supply of alkaloid.

The "coppicing" system consists in cutting down the trees near the ground and allowing one or more of the young crops of the shoots which rise from the stumps to grow. The trees are barked at the proper season by coolies, to whom the felled stems and branches are made over as soon as they are cut. Provided with a stout knife, the coolie first marks the bark off into long narrow strips by putting his knife under it and pressing upwards. The end being freed, the remainder of the strip readily comes off; the bark is then laid to dry in sheds fitted with open shelves made of split bamboo.

Of the barks used in pharmacy, as before stated, four in number are official in the British Pharmacopœia. Of these, *C. officinalis*, *C. succirubra* and *C. Calisaya* are the sources from which the pharmaceutical preparations are directed to be made, while *C. lancifolia* is alluded to as a source of quinine. The following is a brief description of the distinguishing characters of these important barks:—

Cinchona Officinalis, Pale Cinchona, Loxa or Crown Bark (*Cortex Cinchonæ Pallidæ*).—This species is a native of Ecuador and Peru, existing under several varieties. It forms a large tree having lanceolate leaves, usually pointed, glabrous and shining on the upper surface. The flowers are small, pubescent, and in short panicles and are succeeded by oblong or lanceolate capsules, ½ an inch or more in length. The bark yielded by this tree, which formerly was the ordinary Peruvian bark of English medicine, is only found in the form of quills, which are occasionally as much as a foot in length, but more often in fragments of a few inches. The quills are from ⅜ to ¼ of an inch in diameter, having a blackish-brown or dark-grey external surface, variously blotched with silver-grey, and frequently covered with large and beautiful lichens. The surface of some of the quills is longitudinally wrinkled and moderately smooth, but in the majority it is distinctly marked by transverse cracks. The inner side is closely striated and of a bright yellowish brown.

The bark breaks easily with a fracture which exhibits very short fibres on the inner side. Though chiefly afforded by *Cinchona officinalis*, other species occasionally contribute to furnish the Loxa bark of commerce, as shown in the table above. Owing, however, to the bark having become nearly extinct in its native regions, at the present day it is scarcely possible to obtain genuine Loxa or crown bark from South America; the immense plantations on the Nilgiri Hills of Madras, in the Sikkim Himalayas and elsewhere in India, Ceylon, and Jamaica, are at present the chief sources of the bark in commerce.

The analyses of Howard show that the different varieties of crown bark vary much in the proportion of alkaloids they contain, South American bark yielding on an average ·5 to 1 per cent. of alkaloids, while the Indian bark yields as much as 4·30 to 5 per cent., consisting principally of quinine, and next in order cinchonidine and cinchonine. It might also be noticed here that the official pale bark of the United States Pharmacopœia also includes the kind of bark which is derived from *Cinchona micrantha*, a bark which was formerly official in the Edinburgh and Dublin Pharmacopœias under the name of *Cinchona cinerea*, and which is known to commerce as grey or Huanuco bark.

Cinchona Succirubra, Red Bark (*Cortex Cinchonæ Rubræ*). The tree yielding this species, although formerly growing in all the valleys of the Andes, is now almost entirely confined to the forests of Guaranda on the western declivities of Chimborazo, at 2000 to 5000 feet above the level of the sea. The tree has broadly ovate leaves attaining about a foot in length, nearly glabrous above, pubescent beneath, and large terminal panicles of rose-coloured flowers, succeeded by capsules from 1 to 1¼ inch long. Red cinchona bark occurs in quills and flat pieces. The quills vary in diameter from ¼ to 1½ inch, and in length from 4 to 12 inches or more. The so-called flat pieces are frequently slightly incurved, from 1 to 5 inches broad, ⅝ of an inch in thickness and about 2 feet in length. Red cinchona bark is generally coated and consists of liber, the cellular and tuberous coats, and usually more or less of the epidermis; its outer surface is generally rough, furrowed and frequently warty. The colour of the epidermis varies; in the thinner quills it is reddish-brown; in thick quils and flat pieces it varies from a reddish-brown to a chestnut-brown, frequently with a purplish tinge. Cryptogamic plants are not so frequent on this as on some other kinds of bark. The cellular coat of the flat pieces is very thick and spongy, much more so than in yellow cinchona bark. The inner surface of the quills is finely fibrous, giving a comparatively smooth fracture, while the fracture of the flat pieces is both fibrous and splintery. As to the proportion of alkaloids in red bark, the thick flat sort contains only 3 to 4 per cent. of alkaloids, but a large amount of red colouring matter. In reference to the brick-red colouring matter which, as Ruiz observes, is not found in the growing plant, but in the dried bark, Mr. J. E. Howard considers that it is really an excretory product of vegetation, a part used up and brought by contact with the air into a state in which it can no longer be serviceable to the living plants, and from which it still degenerates by a still further degeneration into *humus*. The pieces of flat red bark possessing the finest colour are generally remarkable for their specific lightness, having a texture analogous to that of wood that has lost its firmness by incipient decay. Indeed, it is by a process of *eremacausis* that the red bark acquires its colour, the cinchotannic acid in which it abounds having become oxidized and changed into cinchona red, and under these conditions the alkaloids also appear to undergo some corresponding alterations. They are now implicated with resin, which appears to have also become oxidized so as to act the part of an acid, and is with difficulty separated. But the most remarkable feature is the altered conditions of the alkaloids themselves. Quinine, which formed a considerable portion of the whole, is now greatly diminished, while cinchonine and cinchonidine remain much the same. The quill red bark of the Indian plantations is a much better drug, some of it yielding 5 to 10 per cent. of alkaloids, less than a third of which is quinine and a fourth cinchonidine, the remainder being cinchonine and sometimes traces of quinidine.

The experiments of Mr. J. E. Howard and others have also proved that the bark of the root contains a larger proportion of alkaloids than that of the stem; and further that the proportion of alkaloid diminishes as we go up the stem to the branches.

Mr. David Howard has also shown that the nature of the alkaloid varies according to the part of the tree from which the bark has been taken.

Cinchona Lancifolia, Soft Colombian.—Of the barks not used in pharmacy the most important are afforded by *C. lancifolia* and *C. Pitayensis*, natives of the Cordilleras of Colombia. These barks are largely imported and used for making quinine, the former under the name of soft Colombian, Carthagena or Caqueta bark. The bark of *C. lancifolia* varies much in appearance, but is generally of an orange-brown; the corky coat, which scales off easily, is shining and whitish. It also often occurs in more or less curved or quilled pieces of tolerable thickness, having externally the remains of a whitish silvery epidermis; but their greatest distinguishing character is their very fibrous fracture. Their anatomical structure, according to Hanbury, agrees, in all varieties, in the remarkable number of thick-walled cells of the middle cortical layer and the medullary rays. In percentage of alkaloids, Carthagena barks are liable to great variation.

The *Pitayo* barks are restricted to the south-western districts of Colombia, and are usually imported in short flattish fragments or broken quills. The middle cortical layer exhibits but few thick walled cells; the liber is traversed by very wide medullary rays, and is provided with but a small number of widely scattered liber fibres, which are rather thinner than in most other cinchona barks. The Pitayo barks are usually rich in alkaloids, quinine prevailing. *Cinchona Pitayensis* is one of the hardiest species of the valuable cinchonas, and is, therefore, particularly suitable for cultivation, which, however, has not been carried out as largely as that of either *C. officinalis* or *C. succirubra*. The hard Colombian bark of commerce, which occurs usually in flat pieces and also in quills, is obtained from *C. cordifolia*. The quills are usually large, heavy and without periderm, with a fracture not so fibrous as that of *C. lancifolia* (soft Colombian bark). The flat pieces are thin, hard, somewhat curved, with the remains of a white periderm.

In reference to the *grey* barks of commerce, *C. micrantha, C. nitida* and *C. peruviana*; they abound in the province of Huanuco, which is their principal source, and are all imported under the name of Huanuco or grey bark. The name of grey bark refers to the striking effect of the overspreading thallus of various lichens belonging to the order *Graphideæ*, forming groups, and indicating that the trees have grown in an open situation, exposed to rain and sunshine. These barks occur in quills and flat pieces; the former are eagerly sought after by manufacturers on the continent, while the flat pieces are just as readily sought for here, because they very much resemble in appearance the flat calisaya, for which at present they are very extensively substituted on account of the great scarcity of the latter. They each yield from 2 to 3 per cent. of cinchonine and cinchonidine, with scarcely any quinine.

Cinchona Calisaya, Yellow Bark (Cortex Cinchonæ Flavæ).—This valuable species was discovered by the late Dr. Weddell in 1847. It grows in the valley forests on the borders of Bolivia and South Peru (Carabaya). The bark was formerly imported in serons, principally from Arica, the nearest port to the Bolivian district of La Paz, where it was chiefly collected; but the supply of calisaya bark from its natural habitats is at the present time very uncertain. The cultivation of this bark in India has not been hitherto so successful as that of *C. succirubra* and *C. officinalis*, although recent accounts have been more favourable. For its introduction to India, as well as that of other species of Cinchona, we are more particularly indebted to Mr. Markham. Two varieties of this bark are distinguished in commerce—flat and quilled.

Flat Calisaya.—The pieces of this bark are flat, or nearly so, as their name implies. They are generally uncoated, consisting almost entirely of liber, which is sometimes ⅓ or nearly ½ an inch thick. Their texture is compact and uniform; the transverse fracture is finely fibrous, the fibres being short and readily detached, so that when this bark is handled it causes much irritation. Externally the colour is slightly brownish-tawny yellow, frequently interspersed with darker patches; the surface is marked by shallow longitudinal depressions, commonly termed digital furrows, which are caused naturally on separating the periderm from the liber, and not by the instrument used in detaching it as formerly supposed. Internally the surface has a wavy fibrous appearance; the taste is very bitter—the bitterness being gradually developed on chewing. The bark of the root is readily known from that of the trunk and branches, by occurring in short more or less curved or twisted pieces. Calisaya bark is the best of all the cinchona barks; but little, however, is now obtained from South America, our supplies being chiefly derived from plants under cultivation in India and Java. One variety of *Cinchona Calisaya*, which has been more especially cultivated in Java, and known as var. *Ledgeriana*, yields a bark of extraordinary richness in alkaloids.

Calisaya bark is remarkable for the large amount of quinine it contains, good qualities yielding at least 5 or 6 per cent. of this alkaloid.

Amongst other valuable barks which occur extensively in the market must be mentioned cuprea bark and the bark from *C. pubescens*, a variety of *C. robusta*.

The *cuprea bark*, which of late has been imported in enormous quantities, is furnished by two very distinct regions, viz., the base of the great eastern branch of the Cordillera of the Andes, and the valleys of the Rivers Meta and Guavire, affluents of the Orinoco. The centre of exportation is Bacaramanga, in the State of Santander. Cuprea bark is yielded by trees belonging respectively to at least two distinct species which, though nearly allied, are yet different from each other, and belong to the genus *Remijia*, which comes very near that of *Cinchona* and to the closely allied genus, *Cascarilla*. These species are *Remijia Purdieana* and *Remijia pedunculata*, Triana. The resemblance between the barks of the two species is very great and it would be difficult to find characters sufficiently marked to distinguish them. They are both, in fact, hard, very compact, relatively heavy, the inner surface smooth and of a wine-red colour; the epidermis is thin and striated longitudinally. The cuprea bark which yields cinchonamine is, however, heavier and more compact and more filled with red resinous colouring matter, and its fracture generally appears to be horny. The yield of quinine from cuprea barks varies between 1 and 2 per cent., according to the conditions of vegetation of the trees, which have not yet been sufficiently studied. From a chemical point of view, the characteristic and remarkable feature which distinguishes the cuprea barks from the true cinchonas is the absence of cinchonidine and the presence of a peculiar alkaloid called homoquinine or ultra-quinine, the salts of which very closely resemble those of quinine.

Cinchona pubescens.—This valuable bark is taken from a hairy leaved tree, believed to be a hybrid between *C. Calisaya* and *Cinchona officinalis* and on that account was at one time called *C. officinalis*, var. *pubescens*. The tree produces enormously thick bark and is one of very rapid growth. In a letter to Mr. Howard, Mr. McIvor writes, "If under all conditions this bark be found to yield 12 per cent. of alkaloids consisting of 6 per cent. quinine sulphate, it is certainly the best plant we can grow, being hardy and of rapid growth, and perfectly free from canker and other diseases to which the *Calisaya* and *Officinalis* are liable." The appearance, therefore, of these extraordinary plants, with their enormous yield, indicates the importance of cultivators paying close attention to the phenomena of hybridization and of studying the subject with a view of further improvement.

Pharmacy.—In the opinion of pharmacists the bark most suitable for medicinal use is the *Cinchona succirubra*, and as I have the privilege of addressing those directly or indirectly connected with pharmacy, it would not, perhaps, be out of place to mention the cause of this preference and the names of the writers who speak the strongest in its favour.

Mr. Holmes, in a paper read some time ago, pointed out that the red bark supply would in all probability be always equal to the demand on account of its growing at a much lower elevation, and consequent distribution over a much wider area, the amount of that bark grown was greater comparatively than of the other cinchonas. Mr. Holmes also pointed out that it could be procured of good quality, that it contains all the alkaloids with the exception of aricine, and that it was less liable to be mixed with hybrids, on account of its characteristic appearance.

Professor Flückiger also suggests the use of *Cinchona succirubra*, in 'Pharmacographia;' and both Mr. Umney and Mr. R. W. Giles have repeatedly pointed out the unsatisfactory results of using the yellow barks for pharmaceutical preparations.

Dr. de Vrij, some months ago, published a form for the preparation of red bark extract; the advantages it claims over most of the extracts now met with are its easy mode of preparation, and especially the production of a clear solution when it is mixed with water.

In conclusion, I have to thank Mr. Holmes for much valuable information and for the use of the Museum specimens, also Mr. W. E. Crow, one of the present Bell Scholars, for many useful suggestions. For much of the information contained in this paper I am also indebted to the following works:—Howard's 'Nueva Quinologia,' Markham's 'Peruvian Bark,' Bentley and Trimen's 'Medicinal Plants,' Flückiger and Hanbury's 'Pharmacographia.'

The Pharmaceutical Journal.

SATURDAY, DECEMBER 2, 1882.

Communications for the Editorial department of the Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE ABUSE OF NARCOTICS.

THE report on page 456, of an inquest held a few days since at Croydon, furnishes another instance of the lamentable spread of the habit of opiate drinking to which we have frequently called attention in these columns as having undoubtedly been greatly fostered by the present lax state of the law in regard to the sale of poisons under the guise of patent medicines. If, too, it correctly represents what took place at the inquest it well illustrates the mischievous rubbish which is sometimes talked when witnesses and jurymen are under the temporary excitement caused by such an inquiry. For, supposing that the statement of the medical witness be correct, that the bottle found near the deceased originally contained one hundred grains of chloral hydrate, as well as his speculation that the deceased had made up this quantity by going to different chemists and obtaining small quantities from each, apparently by the use of a prescription, it is not evident how this warrants the denunciation of chemists or the assumption that they supply drugs of the description of chloral in a wholesale fashion to any person who asks for them. It seems to us to be rather a matter for comment that a woman known to have been in the habit, for several years past, of taking chloral hydrate "to quiet her nerves" should have been in possession of a prescription ordering an indefinite quantity of that narcotic. Certainly if, armed with such a document, the deceased had to go to several chemists before she could make up the hypothetical one hundred grains, it cannot be justly said that the dispensers did not exercise the "discretion" which seems to have been wanting in the writer of the prescription.

But quibbling as to whether as much as one hundred grains of chloral hydrate was or was not jointly supplied on a prescription by several chemists is mere child's play in the face of actual facts. It is well known that under the cover of the patent medicine stamp narcotics quite as powerful and dangerous may be bought in unlimited quantity, even from grocers, drapers and "stores." An important paper upon the subject, recently read before the Border Counties Branch of the British Medical Association by Dr. HENRY BARNES, and published in the *British Medical Journal* last week, opportunely illustrates the growth of this traffic. A hospital nurse, aged twenty-four, who came under the author's notice, was suspected of indulging in some narcotic in excess. Upon being questioned she admitted that she was in the habit of taking chlorodyne, and that in less than seven weeks, during which she had been employed in the hospital, she had squandered nearly twenty pounds on its purchase. This confession was confirmed by the presence in her box of fifty-four empty chlorodyne bottles, and she admitted having thrown away half as many more. Those found consisted of one of the 11*s.* size, thirty of the 4*s.* 6*d.* size, fifteen of the 2*s.* 9*d.* size, and eight of the 1*s.* 1½*d.* size, representing together 91½ ounces. She stated that the 11*s.* bottle lasted little more than twenty-four hours, and that her usual dose was a 4*s.* 6*d.* bottle. With this experience, Dr. BARNES calls attention to the fact that this preparation, extensively advertised as it is and having a large sale as a patent medicine, is "said to consist of morphia, hydrocyanic acid, "chloroform and probably also Indian hemp and "belladonna, or its alkaloid, atropia, with some "other ingredients of a less active nature, used to "disguise its real nature and make it palatable." And yet this preparation, containing, if this statement as to its composition be true, five poisonous ingredients, four of which are scheduled poisons, is not even labelled as being poisonous in its nature, and is sold not only by druggists, but even by grocers and miscellaneous patent medicine vendors. Indeed, Dr. BARNES mentions that he recently obtained a specimen from one of the latter class, in whose trade list he found, as an additional recommendation, a statement that he sold it at lower prices than were charged by his neighbours, the duly qualified pharmacists. Of course, the value of the particular preparation referred to in this case, when properly used, is not in question, and the fact that it is issued under the auspices of a gentleman whose name is on the Medical Register, and that it has received a *quasi* endorsement in the prescriptions of other medical gentlemen, is a mere accident. Its position in respect to the law regulating—or rather not regulating—its sale would be the same if it were any one of the numerous class of compounds with eccentric names, which are so extensively advertised as soothing syrups, cordials, carminatives, cough tinctures and essences, though it might be the poisonous concoction of the most ignorant charlatan, and its proprietor a bootmaker or tailor, whose only evident skill was shown in his success in hiding its capability for harm. The point is that the trade in these preparations—whether skilfully prepared or not—is at present carried on under conditions that not only favour, but invite, the widest and most indiscriminate use of powerful opiates by the public.

Impressed with the great increase in the number of victims to the habit of taking narcotics, Dr. BARNES, in his paper, discusses what steps should be taken to aid in weaning them from their be-setting vice, and with this object he passes in review the poison clauses of the Pharmacy Act, 1868, which he says "was intended to prevent the public from obtaining unlimited supplies of poisonous drugs." Without quite accepting this statement as to its *raison d'être*, we feel warranted in saying that those entrusted with the carrying out of the provisions of the Act will be glad if it can be utilized in combating the growing evil. Dr. Barnes appears to think that the provisions of the Act with respect to the sale of poisons should be made more stringent, and that the distinction as to the two parts of the schedule of poisons should be abolished, or at least that the regulations enforced in the sale of poisons in Part 1 should be extended to chloroform, chloral hydrate and preparations containing morphia. It is not, however, at all clear how this would affect the sale of narcotic "patents." His remarks appear to us to be more to the purpose when he refers to the necessity—which we have before alluded to in speaking of the Croydon poisoning case—for watchfulness on the part of physicians as to the purposes for which their prescriptions may be used. He refers to a prescription of his own, for a mixture of equal parts of spirit of chloroform and tincture of cardamoms, which he was startled one day to find had been repeated to the extent of fifty ounces in eighteen days, when his attention appears to have been drawn to the matter by a pharmacist. Dr. Barnes is, in consequence, disposed to urge that prescriptions containing narcotics should not be repeated more than a certain limited number of times without revision by the prescriber. We have already expressed our opinion that, considering the general feeling of the public in regard to this question, the first step in this direction must be taken by medical men, and that it is especially within the province of prescribing medical practitioners to impose such limitations upon the use of their prescriptions as they may deem fitting and may be able to obtain their patients' assent to.

It may be remarked in conclusion that a parliamentary return, just issued, showing the quantity of opium annually imported into the United Kingdom, has considerable significance in respect to this question. It shows that the quantity of opium imported during the year 1881 was 793,146 lbs., or nearly double as much as was imported in 1880 and nearly four times as much as in 1860. Of this rather more than one half (401,833 lbs.) was re-exported, so that the quantity retained in this country nearly equalled the entire imports of the preceding year.

PHARMACY IN TASMANIA.

A correspondent, writing respecting the laws regulating the practice of pharmacy in Tasmania, informs us that the sale of poisons and all medicines in that colony is carefully restricted to the registered chemists, the only exemption made being in favour of the wholesale vending of medicines. Possession of the Minor qualification of the Pharmaceutical Society of Great Britain entitles the holder to registration; otherwise a person has first to pass an examination conducted by a medical board, acting under the provisions of the Tasmanian Medical Act; this is described as a tolerably good practical examination. Our correspondent adds: "It is quite refreshing to escape the contagion of the "'stores,' and to feel once more that he is getting "a decent remuneration for his exertions."

EXPLOSION IN AN ETHER FACTORY.

On Sunday evening last a tremendous explosion, followed by a fire, occurred at Mr. Polglase's Tyneville Chemical Works, Newcastle, due to the boiling over of a still containing ether, which appears to have been the principal article manufactured in the works. The effects of the explosion were felt over an area covering more than a mile in each direction from the point at which it occurred, but fortunately no lives were lost. The building was entirely demolished, and Mr. Polglase has been compelled to issue a circular explaining that he will be unable for the present to execute orders.

THE NEW UNITED STATES PHARMACOPŒIA.

The great interest excited among United States pharmacists in respect to the new national Pharmacopœia is manifest from the fact that the whole of the first issue was sold before the work was published. A second issue has been prepared, but we understand that copies are not expected to be in the hands of the booksellers in this country for another fortnight.

THE NEXT EVENING MEETING.

An Evening Meeting of the Pharmaceutical Society will be held on Wednesday next, the 6th inst., when the following papers are to be read:—"The Crystalline Constituent of Jafferabad Aloes," by Mr. W. A. Shenstone; "The Sale by Public Auction of Spurious and Worthless Drugs," by Mr. E. M. Holmes, and "Further Observations on Arsenic," by Messrs. W. A. H. Naylor and J. O. Braithwaite.

CHEMISTS' ASSISTANTS' ASSOCIATION.

We are requested to say that in consequence of the Evening Meeting of the Pharmaceutical Society there will be no meeting of the above Association next Wednesday.

THE CHEMISTS' BALL.

We learn from a circular that has been issued in respect to stewards to the Chemists' Ball, that the date fixed for it is Wednesday, the 10th of January. As the Ball has always hitherto taken place on the third Wednesday in January, it may be convenient to some readers to point out that the next one will take place a week earlier than usual.

Provincial Transactions.

EDINBURGH CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The third meeting of the present session was held in the Pharmaceutical Society's rooms, Edinburgh, on Wednesday evening, November 22, Mr. Peter Boa, President, in the chair.

The minutes of the former meeting having been read and confirmed,

The Chairman called upon Mr. Peter MacEwan to read a paper on—

Alkali Manufacture.

BY PETER MACEWAN.

A change for the better in the chemical industry a few years ago tempted the late Lord Beaconsfield to predict that the general trade of this country was on the eve of improvement. The country smiled at the noble lord's prediction, for it assumed that the basis of it was an unimportant factor in our commerce; but, nevertheless, there was much truth in the forecast of the far-seeing statesman; he knew that most of our important industries are dependent upon the chemical industry for some of their supplies, that increased demands for chemicals means greater activity in textile industry, for instance, for the alkali manufacturer supplies cleaning and bleaching agents to this and allied industries. The manure manufacturer cannot make his superphosphates without sulphuric acid, and if he make greater demand for that article, we must infer that agricultural districts are brisk. Alkali manufacture is the back-bone of the soap trade, and soap is so important an article in the world's commerce, that someone has given it as a truism that a country's position in the scale of civilization may be judged by the quantity of soap which it consumes. I hope, therefore, that apart from the purely technical nature of the subject which I bring before you to-night, there is in it something interesting and of general importance to occupy your thoughts.

The alkali industry is a large one; its products are many, and the methods of production numberless. But our time will only permit us to consider the production of the ordinary soda compounds, and the recovery of useful materials from waste products.

Previous to the French Revolution, the greater part of the carbonate of soda used was obtained from Spain as *barilla*. For the production of this various algæ (salsola, salicorna, etc.) were cultivated. The dried plants on burning yielded an ash consisting of from 5 to 20 per cent. of soda carbonate, with chloride and sulphate, the carbonate being a product of combustion. This ash was the barilla of commerce; its production was necessarily limited, hence industries dependent upon it were conducted on a small scale, and their products were correspondingly dear. The commerce between France and Spain being shaken during the Revolution, barilla reached a high figure, and the industries requiring supplies were almost at a stand-still. Napoleon, therefore, offered a high premium for the invention of a process which would utilize French resources in the manufacture of alkali. Many chemists entered the competition, and the adjudicating committee awarded the premium to M. Le Blanc, a pharmacien, who submitted details of a process which he had already in operation. This was in the year 1794, and the process was one of such merit, that it served not only the purpose of its day, but is now in use and is likely to be for many generations.

A word in passing of M. Le Blanc. The premium which his invention gained he spent in improvements upon his working plant; this soon exhausted his resources, and as his works were not conveniently situated for supplies, he could not compete with others more favourably located. Thus he failed commercially, and his works passed into the hands of the Government. Le Blanc deserved well of his country in his day. Life fame should have been his; but he was permitted to end his days in an almshouse, and a pauper funeral was his reward. Many pharmacists have been èminent men of science, but few of them have done so much benefit to their fellow-men as Le Blanc has done by his alkali process.

Starting with common salt, as required by the French Commission, Le Blanc converted this into carbonate of soda by a method involving at least three distinct reactions or, more properly, stages. These I shall describe in their rotation.

First Stage or Salt-Cake Process.—Common salt is acted upon by sulphuric acid, sulphate of soda ("salt-cake") and hydrochloric acid being produced. In Le Blanc's time and for many years thereafter, this operation was performed in an ordinary reverberatory furnace, but owing to the utter destruction of vegetation for many miles around alkali works, it was found expedient to adopt means for the condensation of the hydrochloric acid gas. The discovery of the bleaching properties of chlorine pointed to the utilization of hydrochloric acid as a means for its production; this helped to hasten on the universal condensation of the acid, and finally, the Alkali Act enforced the condensation of 95 per cent. of the noxious vapours of alkali works. All salt-cake furnaces are now, therefore, built in connection with towers for the condensation of the acid vapours discharged from them. These towers are constructed of Yorkshire flags, filled with coke or flint, down which water trickles, thus dissolving the gas as it ascends, the acid liquors being drawn off at the bottom of the towers. The salt-cake furnaces consist of two portions (diagram shown), first an iron pan, in shape like an evaporating dish, the common diameter of which is about 9 feet, and the thickness of the metal from 3 inches to 7 inches in the centre. This is securely built into brickwork. Beneath it there is an ordinary coal furnace as the source of heat. The pan has a strong iron cover, through which a funnel passes for the exit of hydrochloric acid. There are also two doors, one to admit the charge, the other to withdraw it to the second portion of the furnace called the "roaster." This is merely the hearth of an ordinary reverberatory furnace. Into the pan 10 cwt. of common salt and 80 gallons of sulphuric acid, sp. gr. 1·450, temp. 120° F., are introduced; the heat of the fire underneath ensures a decomposition, which may be fairly represented thus:—

$$NaCl + H_2SO_4 = NaHSO_4 + HCl.$$

In about an hour this change is effected, a third of the common salt being unacted upon. To complete the decomposition the charge is withdrawn to the roaster, when the strong heat present ensures the decomposition of the whole of the common salt, thus:—

$$NaHSO_4 + NaCl = Na_2SO_4 + HCl.$$

The salt cake which is thus produced contains 96 per cent. Na_2SO_4.

Many processes have been proposed for facilitating the production of salt-cake, and for conducting the process more economically. Beneficial modifications of the working plant are very numerous, but in the alteration of the method of production the only process which has been successful or is likely to supersede the old one is that proposed and carried out by Hargreaves. In this process bricks of common salt (artificially prepared) are exposed to the action of sulphurous acid, air and steam, at a temperature of 800° F. The following reaction takes place:—

$$2NaCl + SO_2 + O + H_2O = Na_2SO_4 + 2HCl.$$

The sulphurous acid for this purpose is conveyed direct from pyrites burners, so that it is at a high temperature, and this, combined with the heat of chemical action, economizes fuel greatly; indeed, the inventor anticipates such modifications on his salt-cake chambers as shall entirely do away with the use of fuel. This economy, together with the saving of soda nitre (used in sulphuric acid manufacture) and the use of rock salt, form very weighty arguments in favour of Hargreaves's process.

Second Stage or "Balling" Process.—In this salt-cake is fused with coal and limestone in a reverberatory furnace. The furnace is built of brick, lined with fire-brick, and, owing to the intense heat to which it is exposed, is securely bound with iron rods. From the sketch you will observe that it has two hearths, one a brick layer higher than the other; this is the "preparatory hearth;" the lower one nearest the fire is the "decomposing hearth;" communication with each is had by means of side openings, which are closed by strong iron doors having a vertical sliding movement. The construction of the furnace enables two charges to be wrought simultaneously, the weight of each charge being 5 cwts. (The composition of the mixture is:—Salt-cake, 10 parts; limestone, 10 parts; small coal, 7½ parts.) The charge is introduced and spread evenly over the preparatory hearth, and when it has become heated, it is pushed along to the "decomposing hearth," a fresh charge taking its place. In the decomposing hearth it is left undisturbed until surface fusion and formation of roundish clots take place; it is now ready to be carefully turned over so as to expose fresh surfaces, and when it becomes uniformly fused it is mixed dexterously and continuously, so that every portion of the mass may be exposed to the decomposing heat. While this is being done jets of inflammable gas are emitted, and when these fade it is time to withdraw the charge. The process lasts about two hours, and requires the constant attention of skilled workmen.

Improvements on the Process.—Many schemes have been proposed to substitute mechanical for manual labour, and as far back as 1848 Pattinson invented a furnace with mechanical stirrers; these proved more expensive than skilled workmen. In 1853 Elliott and Russel invented a revolving furnace, which, though not at first successful, has become so manageable and effectual in practice as to replace hand-furnaces to a great extent.

I may merely say of these furnaces that they are cylindrical in form, and revolve on large hollow axles which permit of the admission and exit of flame from the coal furnace in connection with them. The revolver is made of malleable iron plates, lined with fire-clay, and of a size sufficient to admit a charge of 5 tons being wrought. The motor of the revolver is a steam engine, capable of producing from one revolution in five minutes to five or more in one minute. The revolutions are slow at the beginning of the process and increase towards the end, about two and a half hours serving to complete the operation. The total substitution of revolving for hand furnaces is merely a question of time, the saving of labour and the advantage of working large quantities of material being fully recognized by the manufacturers.

The fused mass obtained during this stage is termed "black ash," and is a very complex mixture. The principal reactions occurring during its formation are—

First. The reaction between coal and salt-cake:—

$$Na_2SO_4 + C_4 = Na_2S + 4CO.$$

Second. The reaction between sodium sulphide and limestone:—

$$Na_2S + CaCO_3 = Na_2CO_3 + CaS.$$

It is possible that the limestone may be reduced to oxide of lime by the strong heat of the furnace, but the presence of carbon monoxide and air ensures a decomposition as represented. The following are the principal compounds present, together with the bodies present in the dried residue obtained from a solution of "black ash" (the consideration of which I shall return to):—

Black ash.	Per cent.	Solution residue. ("*Soda ash.*")	Per cent.
Na_2CO_3	36·88	Na_2CO_3	67·89
Na_2SO_4	0·39	$NaHO$	14·24
$NaCl$	2·53	Na_2SO_4*	4·57
$Na_2Si_4O_9$, $Na_2Al_2O_4$	1·87	Na_2S	0·55
		$NaCl$	3·50
CaS	28·68		
CaO	9·27		
$CaCO_3$	3·31		

Iron and cyanogen compounds are also present in minute quantity, and their presence is a source of great annoyance to the manufacturer, since they impart a yellow colour to the *soda ash.* It is believed that the cyanides are formed at the high temperature existing in the balling furnaces, the nitrogen necessary being principally atmospheric (Mactear).

Hand-furnace "black ash" does not (as a rule) contain so much cyanides as the black ash from revolvers. Mactear obviates the formation in a great part by working with only the theoretical quantity of limestone, adding 5 per cent. of quicklime towards the end of the process. The addition of sulphate of soda towards the end of the process is also recommended, and has proved efficacious, and the same result has been obtained by using a sulphate of any of the alkaline earths.

Third Stage.—It is now the object of the manufacturer to dissolve out the soluble constituents of the "black ash." This requires to be very carefully gone about, for although the lime compounds may practically be considered insoluble, yet that decomposition does take place is evident on comparison of the foregoing tables. In the second table ("soda ash") we find that caustic soda and sodium sulphide have come into existence, and that the percentage of sulphate of soda has very much increased. *These changes are the effect of the water of lixiviation.* Opinion seems to favour the following as the most probable decompositions which occur. In the first place the CaO (quicklime) present is slaked, and this reacts with a portion of the sodic carbonate thus:—

$$CaO + H_2O + Na_2CO_3 = 2NaHO + CaCO_3.$$

The caustic soda thus formed takes up about 15 per cent. of the available soda. The next reaction is one which is even less desirable than the foregoing, calcium sulphide and sodic carbonate undergoing decomposition:—

$$CaS + Na_2CO_3 = Na_2S + CaCO_3.$$

Another 5 per cent. of the available soda is thus changed into an undesirable compound, fully nine-tenths of which is oxidized to higher salts (sulphates, etc.). The investigations of Kolb have shown that these reactions are most energetic with the maximum of water, time and temperature. Taking advantage of this knowledge the manufacturer—with the object of obtaining a solution having a large percentage of sodic carbonate—uses the most expeditious means for lixiviating the black ash. In early days, I may remark, barrels served as plant for this purpose, but this method is both too expensive and slow for this age. The plant now used most commonly consists of a series of vats, provided with perforated false bottoms, and communicating with each other by means of an arrangement of taps and plugs, thus permitting of the liquor from one vat to be run into another as desired, or allowing circulation of the liquors (as a result of their different densities). The system was invented by Mr. Shanks, and is extremely well adapted to the purpose. Whenever the black ash is sufficiently cool to handle it is broken up into manageable pieces and the tanks filled with it; water being run in dissolves as much as it will, and is then withdrawn to settlers. When the ash has become exhausted it is removed from the tanks and set aside as waste. I shall say a few words about this later on. While the liquors are settling they get a preliminary

* Includes sulphites and lower sulphur salts.

surface heat, previous to evaporation; aluminates and silicates here separate, as well as part of the iron and lime sulphides. As it is necessary to oxidize the impurities in the liquors this is done either before or after evaporation. In the former case, the liquors are allowed to trickle down towers of a similar construction to hydrochloric acid towers, in which they meet a stream of air and carbonic acid as they descend, thus oxidizing and carbonating at the same time. By this process the metallic sulphides are reduced to oxides, and alumina and caustic soda are formed from the sodic aluminate.

Evaporation.—To utilize the waste heat of the balling furnaces evaporating pans are built in connection with them, and in such a manner as to enable the flame to pass over the surface of the liquors, or (in other cases) the heat is applied directly to the bottom of the pans. If the liquors have not been oxidized before evaporation it is the practice to mix sawdust with them; this enables drainage to be more readily carried out after evaporation, while the sawdust also acts as the carbonating medium in purifying such residues by roasting. An automatic arrangement keeps the liquors in the pans at a constant level, so that at the end of twenty-four hours a panful of deposit is obtained. This on drying constitutes "soda ash" of commerce, and is the alkali supplied to soap boilers.

Carbonating Process.—The ash being of a yellow colour, and containing much hydrate and sulphate, it is roasted in a reverberatory furnace with an equal bulk of sawdust or equivalent of small coal; much of the hydrate and sulphate are by this means converted into carbonate, and the resulting ash after lixiviation and evaporation is known as "white ash."

Soda crystals are obtained by dissolving white ash in boiling water to saturation nearly, and filtering through calico. The solution is then allowed to settle, a little lime or bleaching powder being added to clarify it. It is then transferred to the crystallizing vats, in which blocks of wood or bars of iron form crystallizing nodes. The mother-liquors from this process yield a weak white ash on evaporation.

Caustic Soda.—This is either prepared direct from the carbonate according to the B.P. process, or the mother-liquors got from the primary evaporation pans are utilized for its preparation. These liquors are of a red colour owing to impurities, such as ferrocyanide of sodium and a red compound (a double cyanide of iron and soda). The process is too long a one to describe at this stage. I may merely say that the sulphides are oxidized with air and superheated steam: ferrocyanides are decomposed by soda nitre, ammonia being evolved and graphite deposited in the pans. Any carbonate of soda present is hydrated by slaked lime. During evaporation it is necessary to withdraw any crystals which may separate; this process is termed "fishing," and is very often performed in the primary evaporation, thus saving much material.

So far I have described the principal features of the Le Blanc process. Much interesting matter has been left out, but sufficient has been given to show you that the process is an ingenious though an indirect one; one drawback to it is the loss of soda which it entails (13 per cent.) and the amount of waste material produced. Considering these drawbacks, the immense amount of labour, plant and fuel required for the process, it is not surprising that other processes have been proposed from time to time. Hitherto, only one of these has been at all successful, namely, the *ammonia soda process.* This was invented by Dyer and Hemming in 1830, and is based upon the double decomposition taking place between carbonate of ammonia and common salt. In practice it was found expedient to use ammonia gas (NH_3) and carbonic acid, which in the presence of water gave the following reaction:—

$$NaCl + H_2O + NH_3 + CO_2 = NaHCO_3 + NH_4Cl.$$

The advantages of any method of manufacture based upon this reaction would, amongst others, be:—

1. A direct product free from impurities.
2. Freedom from noxious vapours.
3. Less waste products.

The process as wrought by the inventors was not a success, the loss of ammonia and wear and tear of apparatus more than compensating for any benefit to be derived from it. During the past ten or fifteen years, more attention has been paid to it, and the improvements made upon working plant enable the process to be conducted without loss pecuniarily. Late improvements have been kept secret, so that I can only give a summary of the methods which were at one time in use. In one of these methods a revolving cylinder for the solution of salt (1 in 3) was used, which cylinder was divided into compartments, each one of which at a certain level was brought into communication with one of the apertures of the perforated axle, through which ammonia and carbonic acid gas were forced. The revolving nature of the vessel ensured thorough mixing, and full provision was made for collecting waste ammonia. By a later method the solution of salt is placed in tanks into which ammonia gas is introduced. The temperature of the mixture rises during this process, and it is necessary to cool it before proceeding further. Then it is withdrawn to cylinders about 30 feet in height and nearly the same in diameter; these are provided at the bottom with suitable apertures for the admission of carbonic acid, which is forced in under a pressure of from one to two atmospheres.

The manufacturer works with a small quantity of water, so that the mother-liquor may contain as little bicarbonate of soda as possible. To free the soda from any adherent chloride of ammonium it is washed with water and a weak solution of bicarbonate of soda. It is reduced to carbonate by roasting, the evolved carbonic acid being again used. There is no doubt about the purity of the resulting salt: it contains 99 per cent. of real carbonate, the 1 per cent. of impurity including water. A better salt for pharmaceutical purposes could not, therefore, be desired, although for some manufactures it is not so well adapted as ordinary alkali.

Our Society's reporters on the Paris Exhibition speak favourably of the new process and its progress on the continent. Much of this progress is due to Messrs. Solvay and Co., who have made many improvements, and turn out annually nearly 30,000 tons of alkali by the ammonia process. One matter which barred the progress of the process for many years was the loss entailed in recovering the ammonia. This was done by heating the chloride with lime, double decomposition taking place.

$$2NH_4Cl + CaO = 2NH_3 + CaCl_2 + H_2O.$$

There being no use for the chloride of calcium it had to be turned away as waste. Weldon patented the use of magnesia instead of lime, and the subsequent decomposition of the magnesic chloride with superheated steam thus:—

$$MgCl_2 + H_2O = MgO + 2HCl.$$

This invention has given a great stimulus to the ammonia process. The recovered magnesia is used again and again, the hydrochloric acid being condensed in the ordinary manner. Apart from all advantages, however, it is well to remember that 5 per cent. of the total ammonia used is lost during each operation. Ammonia is an expensive article and its production is limited. In Great Britain at present the annual production of ammonia is 9000 tons. So that the progress of the ammonia process in our country will only be possible with increased supplies of ammonia at or below present prices. Should the price of ammonia increase much, then it will not be safe to enter on the ammonia soda process as a monetary speculation.

Recovery of Sulphur from Tank Waste.—Time will only permit me to say a few words on this subject. For every ton of alkali produced there is $1\frac{1}{2}$ ton of waste; this contains all the sulphur derived from the sulphuric acid. It is a nuisance in alkali districts, sulphuretted hydrogen being given off from the waste heaps. To recover the sulphur the most successful method is to treat solution of the oxidized waste with hydrochloric acid; sulphuretted hydrogen is evolved, part of which is burnt into sulphurous acid, which again acts upon the remainder of the sulphuretted hydrogen, thus:—

$$2SH_2 + SO_2 = H_2O + S_3.$$

Upon this principle Mr. Ludwig Mond and Mr. Mactear, of St. Rollox Works, Glasgow, have both devised processes, and it is satisfactory to know that both of them recover a good percentage of sulphur, while they are a success commercially.

The paper was fully illustrated by diagrams of working plant and sheets of equations, showing the decompositions occurring during the various stages; also specimens illustrating the production of common salt from rock salt. Specimens showing the sequence of manufacture of alkali by the Le Blanc process with bye-products and recovered material, and specimens of. B.P. alkali were also exhibited. The production of alkali by the ammonia process was experimentally illustrated.

On the motion of the Chairman, seconded by Mr. Crowden, the thanks of the meeting were heartily accorded to Mr. MacEwan for his paper.

A discussion followed the reading of the paper, in which Messrs. Adamson, Crowden, Boa, Hill, and Turnbull took part.

Several queries when then submitted and answered.

Before the meeting adjourned the President announced that the next meeting would be held on December 6, when a debate will take place on the question, "Does a Necessity Exist for Further Legislative Restriction as to the Sale of Poisons?" The affirmative will be taken by Mr. C. F. Henry, and the negative by Mr. W. S. Adamson.

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

The first meeting of the session was held at the Mechanics' Institute, on Monday evening, November 27, the President, Mr. R. Fitzhugh, F.C.S., in the chair.

The meeting was fairly attended by both members and associates.

The President opened a discussion on the present state of the Association, with respect to the great want of interest and general apathy shown by the non-attendance of members and associates at the monthly meetings and classes, and remarked that unless more personal interest was shown in it, it would eventually collapse.

An animated discussion followed, in which most of the members and associates took part, all urging that the work should be continued, and eventually a proposition was carried that the usual social meeting be held next month, and the future prospects of the Association be further discussed at it.

During the evening Mr. M. Handford was admitted as a member and Mr. Greaves as an associate.

A vote of thanks to the President concluded the meeting.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

On Tuesday evening, November 28, a lecture was given in connection with the above Association, at 4, Halford Street, by Mr. J. Garrett, on "Mercury."

After treating of the heads of the subject, Mr. Garrett went on to speak of the different reactions of mercury, drawing special attention to the change which takes place when a piece of white paper, smeared with the red iodide, is held before the fire, consequent it is supposed upon the conversion of the rhomboidal crystals of the red iodide into octohedra with a square base. Other interesting features of the subject were touched upon, and an instructive lecture was at length brought to a close.

Mr. E. Brice proposed and Mr. Broof seconded a vote of thanks, which was accorded to the lecturer.

CHEMISTS AND DRUGGISTS' TRADE ASSOCIATION OF GREAT BRITAIN.

A meeting of the London Committee of this Association was held at the Inns of Court Hotel, High Holborn, London, W.C., on November 24, at 8 p.m. The President in the chair.

The appointment of local secretaries of the Association in London having been discussed, it was moved by Mr. Long, seconded by Mr. Urwick, and unanimously resolved:—"That the appointment of Local Secretaries in the Metropolitan districts be left in the hands of a subcommittee consisting of Messrs. Andrews, Long and Urwick, with power to add to their number."

It was decided to add the name of Mr. C. B. Allen, of Kilburn, to the London Committee.

The desirability of holding a meeting of the London members of the trade was then considered. On the motion of Mr. Andrews, seconded by Mr. Urwick, it was resolved:—"That the Secretary be instructed to convene a general meeting of the members of the trade resident in London to discuss matters of trade interest; the meeting to be held at the Arbitration Rooms of the Inns of Courts Hotel, Lincoln's Inn Fields, on Wednesday, December 13, 1882, at 8 p.m., prompt."

It was decided that a circular convening the meeting should be sent to the whole of the London trade seven days prior to the meeting and that the agenda should be as follows:—

"1. To consider desirable amendments in the Pharmacy Act, 1868.

"2. To take into consideration the advisability of holding periodical meetings of the members of the Association resident in London.

"3. To discuss generally matters affecting trade interests."

Proceedings of Scientific Societies.

CHEMISTS' ASSISTANTS' ASSOCIATION.

A Conversazione, in connectionwith this Association, was held at St. James Hall, on Wednesday, November 22, and was well attended by the members and their friends, and also by many of the leading pharmacists of London and the provinces. The excellent programme, which included both vocal and instrumental music, was extremely well rendered, and met with the hearty approval of the audience. In addition to this, through the kindness of the Council of the Pharmaceutical Society, an interesting collection of specimens was lent from the Museum, also a collection of rare chemicals was exhibited by Messrs. Hopkin and Williams. Messrs. Beck and Co. exhibited electrical apparatus, including a powerful plate electric machine, vacuum tubes, etc. Electric bells and telephones were exhibited by Messrs. Mayfield and Co., and also by Mr. W. H. Kerr. Messrs. Swift and Sons again exhibited some of their well-known microscopes.

From the feelings of pleasure expressed by visitors during the evening, the efforts of the Council seemed to be thoroughly appreciated, and a most enjoyable evening was spent.

Parliamentary and Law Proceedings.

Death through an Overdose of Chloral.

On Tuesday, Mr. W. Carter, coroner, held an inquest at the "Alma" Inn, Lower Addiscombe Road, upon th body of Mrs. Eliza Ann Walmsley, aged 48, the wife o Mr. John Walmsley, a commercial traveller.

Mr. Walmsley was the first witness. He said that on Saturday last at about 7 a.m. he went into the deceased's bedroom and saw her lying in bed on he left side apparently asleep, and there was a pocket-handkerchief over the upper part of her face. He spoke to her but she did not reply, and he then told his son, who had slept with his mother, to get up, after which witness placed a pillow against deceased's back for the purpose of keeping her warm, this being his habit. After witness had had his breakfast he went upstairs again for the purpose of wishing deceased good-bye prior to going to business. Deceased was then lying in the same position, and witness pulled the clothes down a little way, whereupon he discovered that his wife was dead. Witness immediately fetched Dr. Thompson who examined the body and pronounced life to be extinct. Witness had last seen his wife alive at 10 o'clock on Friday night, he not having returned home from business until 9. She was then in the bedroom seated in a chair by a small fire, and she seemed to be in her usual state of health.

Dr. Thompson deposed to being called to Mr. Walmsley's house, and finding the deceased lying in bed dead. The witness's opinion was that deceased must have then been dead for some hours. The left side of the face was in a congested condition. There was no distortion of the features, but they were perfectly placid. Witness could detect no marks of violence. A white medicine bottle was found under the body, and it contained about 3 drachms of liquid, which witness tasted and found to be hydrate of chloral. Witness concluded that deceased had taken this poisonous medicine which produced suffocation. Nothing was found to lead it to be supposed that deceased contemplated committing suicide. Witness had attended deceased for the last twelve months. She suffered from extreme nervous debility, caused by habits of intemperance. Deceased was at times very hysterical, and had bordered upon an attack of *delirium tremens.* Witness was of opinion that deceased took an overdose of chloral. The ordinary number of grains of chloral to be taken by an adult ranged from 10 to 13 grains, but it was clear to witness that the bottle found in the bed had contained at least 100 grains, and he was of opinion that deceased, having found that the ordinary quantities taken by her for several years past to quiet her nerves did not have the desired effect, had gone to different chemists and obtained small quantities, which she had put together in one bottle and taken as a dose, which caused sudden stoppage of the heart's action.

A Juryman asked whether chemists were justified in selling such a medicine as chloral to any persons who asked for it.

Dr. Thompson said there was no quantity specified on the prescription, and a chemist would have to use his own discretion. The question raised by the juror was a very important one, and one which, no doubt, would be ere long inquired into by a Royal Commission.

The Jury, after brief consultation, returned a verdict of "Death through misadventure."

Mr. Walmsley asked the Coroner to kindly add to his deposition his protest against chemists selling drugs of the description of chloral in the wholesale way it had evidently been supplied to his wife. With regard to this particular dose it seemed deceased sent her little boy for it, and he had not the least difficulty in obtaining it.

The Coroner said he was sorry, but under the peculiar circumstances of this case he did not see how he could comply with his request.—*From a Local Paper.*

Attempt to Poison with Iodine Liniment.

On Thursday, November 23, Elizabeth Taylor, aged 13 years, was brought before Messrs. Coleridge and Toller, Ottery St. Mary magistrates, charged on remand with administering poison to Norman Skinner, a child 13 months of age.

On Wednesday week Taylor fetched the child from her bedroom in the morning, and about ten minutes afterwards she came back exclaiming, "I've been giving baby some liquorice." Mrs. Skinner then noticed something brown running from the child's mouth, and on closer inspection she saw it was iodine. Upon asking Taylor what she thought would become of her, she replied, "I shall not be hung, as my father will pay some money." The girl then ran into a front room, took a vase from the mantelpiece, and threw its contents into the grate, wiping out the vase with her apron.

Sarah Jane Sanford said that Elizabeth Taylor was her fellow servant, and they slept in the same room. The bottle containing iodine, now produced, was hers (witness's). She had been using it for a swollen knee. On the Wednesday she found that some of the stuff was gone, and the label had been moved further down. She saw dark marks on the child's clothes.

Dr. Pullin, of Sidmouth, said that he saw the child and noticed that its chin and clothes were discoloured with a brown colour. The lips were as if burnt, and the inside of the mouth was also brown. The prisoner and Mrs. Skinner were present. He told the girl she ought to say what she had given the child. He asked this so that he might know how to treat the case. Taylor then said, "I first gave him benzoline and then some stuff that Jane uses for her knee." Mrs. Skinner then fetched the bottle produced, and the prisoner said, "Yes, that's the stuff." On the bottle was a red label marked "poison." He asked her how she gave it to the child, and she replied, "Out of that," pointing to a vase on the mantelpiece. Iodine was a poison; its action was scalding, and thirty drops given to a child would prove fatal. He did not think the child had swallowed any. The spots on the child's dress and girl's apron now produced were caused by iodine. On his asking the girl if she knew what "poison" meant she replied in the affirmative.

Prisoner reserved her defence, and was committed to take her trial at the ensuing Quarter Sessions at Exeter. —*Western Weekly News.*

Poisoning by Carbolic Acid.

The Plymouth Borough Coroner (Mr. T. C. Brian) on Monday, November 20, investigated the circumstances attending the death of Lawrence Charles de Vries Hall, aged 4 years, son of Captain Hall, late of the Royal Mail Steamship service.

Emily Roose, under nurse, stated that on the previous afternoon the deceased went from the dining-room into one of the spare bedrooms. She heard him scream, and she immediately ran upstairs, and found him standing foaming at the mouth. Mr. Budd, surgeon, was sent for, but before he arrived Captain Hall concluded from the smell that the deceased had taken carbolic acid. Witness on again going to the spare bedroom found a 12oz. bottle containing carbolic acid on the washing stand. The acid was kept as a disinfectant, and was last used about two months ago on the occasion of a death occurring in the house. On Sunday evening the child appeared to be much better, but on Monday morning he grew worse, and died about eleven o'clock.

Mr. George Budd stated that he found the deceased in a state of extreme collapse. The odour of carbolic acid was very strong, and in fact anyone standing three yards from the child could smell it. He administered about a quart of olive oil, as well as a quantity of ipecacuanha wine, to induce vomiting. The child vomited very freely, and witness thought all the acid had been removed. The child's face presented a better colour; but from the first he (the doctor) had no hopes. If he had been in attendance even immediately after the child had taken the poison the result would have been the same, for the acid was so strong. It was his opinion that a blue bottle with a red label, though the orthodox pattern for poison bottles, was too attractive for children.

The Jury returned a verdict of "Death from accidental poisoning," adding that in their opinion there was no blame due to any person.—*Western Weekly News.*

Obituary.

Notice has been received of the death of the following:—

On the 10th of November, Mr. John Tombs, Chemist and Druggist, Burlington Street, Liverpool. Aged 60 years.

On the 20th of November, Mr. John Taylor, Chemist and Druggist, of 14, Clarence Road, Leytonstone, E., formerly in business in Wakefield for many years. Mr. Taylor was a Member of the Pharmaceutical Society from 1853 to 1876, and for several years held the post of Local Secretary at Wakefield.

On the 27th of November, Mr. John Stone, Pharmaceutical Chemist, Fore Street, Exeter. Aged 85 years. Mr. Stone had been a Member of the Pharmaceutical Society since 1853.

Notes and Queries.

[744]. Potash Powders.—I frequently make "potash water" by adding to the ordinary charge of bicarbonate of soda and tartaric acid, ℈iij pot. bicarb. for Oij and ℈iv for Oiij size.—W. Lee.

[744]. Potash Powders.—If "Pulvis" would procure a circular sent out with Fevre's seltzogenes, he will find a good deal of information, and the following appears to be an answer to his query. "To make potash water add to the lower globe 4 scruples of bicarbonate of potash for 3 pint size," that will be to the upper globe in Briet's gazogene. I think "374" must have misunderstood the query when he says, "Substitute pot. bicarb. for sodæ bicarb. in ordinary gazogene charges." What is the use of that when all that gets into the finished water from the charges is the evolved gas?—J. H.

[745]. Boracic Lint.—W. L. P. will find in Squire's 'Companion,' 13th edition, p. 7, under Acid. Boracic., the following:—"Lint, dipped in a boiling saturated solution (of boracic acid) and dried, is used as an antiseptic dressing for wounds and ulcers."—J. H.

Correspondence.

The Proposed Pharmacy Curriculum.

Sir,—Although the present date may seem a late one for a contribution to the discussion of a subject prominently brought forward some months back, yet the importance of that subject will, I trust, render excusable my request for a space in your Journal for the insertion of this letter, my tardiness in writing arising from my inability to do so before, since Professor Attfield's pamphlet and the *Pharmaceutical Journals* containing the proposed innovations were received by me, some in Australia, some in New Zealand, and my desire to give fair and unbiassed thought to the subject before venturing to express an opinion was the reason of my not inditing an epistle from those antipodal lands.

Before offering any criticisms or suggestions concerning the proposed innovations, I would like to state that, in the main, I am thoroughly at one with the projectors of a pharmaceutical curriculum; the more perfect harmonizing of pharmaceutical education to examination is in my opinion desirable, I would even add, under the present state of affairs, necessary. But if a curriculum is to be established, it should certainly be a compulsory and not a permissive one. The recognition of a permissive curriculum by the Boards of Examiners would be an act of injustice, in that it would give an unfair advantage to those schools which would be officially recognized for the purpose; it would be almost enticing students to those schools by the offer of a power, viz., a schedule detailing that they had passed through a curriculum, which would act as a lever in assisting them through their examinations. Such a plan would mean the establishment, not of a permissive curriculum, but of a morally compulsory one on a basis the fairness of which would certainly be questionable. If a system inimical to true pharmaceutical education does exist, then no half measures should be employed in dealing with it. The recognition of permissive curricula would either attract the majority of or all students to the schools recognized for the purpose, in which case a compulsory system might have been established at once, or the system inimical to true education would still flourish, in which case a compulsory system would have to be adopted. I infer—perhaps wrongly—from Professor Attfield's arguments, that he reasoned to himself that the recognition of permissive curricula by the examiners would bring about a gradual and lingering death of the system he deprecates, by wounding it in an unguarded quarter, and so placing it *hors de combat*. But such an action would be an ungenerous one; in instituting reforms, common fairness and feeling for others should always be considered.

I certainly agree with Professor Attfield, that the recognition of compulsory curricula is to be desired for the furtherance of true pharmaceutical education; if the pharmaceutical body, as a whole, is of the same mind, I, for one, cannot see the impracticability of carrying out such a step.

In connection with the adoption of a compulsory curriculum, it is important that due weight should be given to the opinions of the teachers concerning the actual work done by the students whilst under their guidance, otherwise the system will be labouring under the same ban as that with which the English medical educational system is afflicted; for that system provides that a student must attend a certain number of lectures, demonstrations, etc., but does not require to know that he has benefited by such attendance or taken advantage of his opportunities, previous to presenting himself for examination. The consequence is that many a student goes up for examination in a far worse condition than if he had not passed through a compulsory curriculum at all, for the attendance at the requisite number of lectures, demontrations, etc., will probably have imbued him with the false idea that he is, of necessity, ready for the examination. I have spoken with many of the lecturers and teachers at the medical schools, concerning their compulsory curriculum, and they all agreed in deploring it in its present condition, maintaining that unless weight is given to a teacher's opinion of a student's fitness for presenting himself for examination, the mere attendance at a certain number of lectures, etc., is useless, nay, even detrimental. It is true that at most of the medical schools the teachers, from time to time, examine their pupils, so as to gauge their knowledge, and will, if they find them deficient, refuse them their schedules, without which they cannot present themselves for examination. Such refusal, however, is not, I believe, legal, provided the student has simply attended the requisite number of lectures, etc. I, therefore, most strongly urge that in the event of a compulsory pharmaceutical curriculum becoming established, due power be given to the teacher to ensure thoroughness of work in his pupils, and so prevent the frittering away of a certain length of time, which by the unthinking medical student is often regarded as a purgatory to be endured previous to the examination. In the present state of pharmaceutical education, it would be utterly out of the question to think of delegating to pharmaceutical teachers the additional duty of acting as public examiners, even supposing the present paucity of eminent teachers did not render such a scheme impossible, but I must certainly dissent from Professor Attfield's statement, on p. 88 of his pamphlet, "that with regard to the question of education and examination being carried on by one and the same man, or body of men, the general impression is that certain weaknesses of human nature render such a course undesirable," for how is it that the plan works so admirably in connection with the various medical examining bodies, where, as a rule, the examiners are selected from the professors and lecturers actually engaged in teaching at the different medical schools?—the logical inference being employed, that the man engaged in teaching is the man best fitted to examine. At such examinations a teacher does not examine his own pupils, that task being delegated to the other examiners, and as is well known, such a system works perfectly, an accusation of unfair bias on the part of any of the examiners never having been made.

The late President of the Pharmaceutical Society, in discussing the proposed curriculum at the April Council Meeting, said, "He believed a large portion of the change had been made with a view to abolish what was termed cram, but he thought it was to a great extent a bogus, and that there was a great deal more noise about it than it really deserved." That cram does exist to some extent cannot be denied, but I also think that to a great extent it is a phantasm, existing in the minds of those who so fiercely denounce it. Special, conscientious, and thorough preparation for examination has no association whatever with cramming, for it is the same kind of teaching that is employed, in the scientific subjects at least, at all the recognized medical schools. Moreover, special preparation for examination by tutors who to some extent know from experience the areas to be covered in connection with the different subjects is the necessary outcome of the want of a comprehensive syllabus defining the range of the examinations. Deploring, as I do, the absence of such a guide, both to the teacher and the student, for the syllabus at present issued in connection with the Major and Minor examinations is all but useless, I should welcome some such a syllabus as that detailed in the Report of the Special Committee appointed to consider the inter-relation of pharmaceutical education and examination, allied with, if necessary, a compulsory attendance at lectures and laboratory work, since it would greatly lighten the burden of the teacher, rendering his work much more satisfactory both to himself and to his pupils.

I emphatically and honestly deny that preparation for examination necessarily consists, as Professor Attfield asserts, in the tutor getting hold of the examination questions and wrapping their answers up in a course. To teachers who endeavour to conscientiously prepare their pupils for examination such an assertion is ungenerous.

In my opinion nothing has contributed more to the fostering and development of preparation, and also of cramming, in connection with the pharmaceutical examinations, than the absence of a comprehensive syllabus indicating the range and limits of the various subjects. In the absence of such a guide a teacher is compelled, even against his inclination, to watch the examinations in order to gain an idea of the areas covered by the different subjects, the boundaries to which are to a great extent left to the will and fancy of the examiners. In making this statement—that the examiners possess the power of fixing or extending at their will the limits of the various subjects,—a statement which I believe no one who gives serious thought to the matter will contravene,—I wish to record that no disrepect nor impliance of want of faith is intended, either towards the examiners as a body or to any of them personally; that they endeavour to perform their duties conscientiously I am confident, my feeling is only that of commiseration for them that their duties are rendered so onerous, so tormenting and so perplexing, by the absence of a sufficiently comprehensive syllabus, indicating the range of the different subjects in which they examine. The absence of such a syllabus not only puzzles the teacher as to the exact nature and area of the ground over which his teaching must be spread, but is the cause of the frequent cavilling heard amongst candidates as to the right of such and such a question being asked, remarks equally unpleasant for both examiners and teachers to hear. Why have the pharmaceutical examinations been rendered conspicuous by the absence of a syllabus fitted to guide examiners, teachers and students? In connection with other examinations to which no compulsory system of education is attached, a comprehensive syllabus is issued, definitely indicating the range and limits of the subjects of the examination.

Of the recommendations suggested by the Special Committee appointed to consider the inter-relation of pharmaceutical education and examination, I only now wish to make a few remarks concerning "recommendation 4." That the examination should be divided is much to be desired, but the division proposed in recommendation 4 is, in my opinion, a most unfortunate one. I perfectly agree with Mr. Carteighe's remarks at the April Council meeting, "that it is quite practicable for the first part to consist of prescriptions, practical dispensing, and pharmacy, and then for the candidate to go in for five months' study and come up at the end for the three scientific subjects," and I go further in thinking that such a division of the examination would be the only harmonious one that could be effected. It seems to me a perfect anomaly that a man should attend lectures, etc., on scientific subjects for five months, and then be compelled to wait six months before he could present himself for examination in those subjects. At the same Council meeting Mr. Symes said, "that the Committee found it was only following the practice of other bodies to give a young man his scientific training somewhat before they gave him his technical training." If the members of the Committee had in their minds at the time the system of medical education, I can only reply that though the deduction is correct, the application is both untenable and illogical. It is true that in the medical system of education the scientific training does precede the technical, but the medical student has not passed through a long period of technical training such as that undergone by the pharmaceutical student during his apprenticeship; the medical student commences his scientific training with no technical knowledge whatever. Moreover, as soon as the medical student has received his scientific training, he can go up for examination in the scientific subjects, and as soon as he has received his technical training, he is examined in the technical subjects. If, therefore, the medical system of education is to be taken as a guide, it would be but logical to say that when a pharmaceutical student has received his technical training, that is, when his apprenticeship is finished, he should be examined in the technical subjects, and that his examination in the scientific subjects should immediately follow his scientific training, without the unparalleled institution of an unseemly gap of six months between his scientific training and his examination in the scientific subjects.

Singleton's Ointment.

Sir,—Having at last an opportunity, I will endeavour to answer the letters respecting citrine ointment which have appeared in the Journal during the past three weeks.

The points at issue seem to be:—

1st. What is the composition of Singleton's eye salve? and

2nd. Has that ointment always been prepared from the same formula?

Before answering these questions, I should like to refer incidentally to two minor subjects Mr. Henry Brown mentions. If he will be kind enough to refer to the old London Pharmacopœia, he will find the ung. basilicon and all the ointments of which I gave the formula in my paper are called by the name ung. citrinum; and also if he will carefully read the title of my paper he will probably see that it is 'The History of Citrine Ointment,' not 'The History of Eye Ointments in general, and Plato's in particular.'

Having myself examined Singleton's ointment, I can decidedly state that it is an ointment of HgO, without a trace of As_2S_2 or As_2S_3, although I am ready to yield the point of yellow or red oxide to Mr. Tanner.

In respect to the second point, I think it is very easy to argue, as Mr. Saul has done, on the assumed infallibility of Dr. Paris and others, but I ask, does Mr. Saul think it likely that Dr. Paris analysed, or even prepared, one-half of the preparations mentioned in 'Pharmacologia?' Indeed, I think it very probable that some of the formulæ may have been written on the authority of others, as almost every author of such a book would do more or less.

Again, the very fact of Christison and others, looking upon it as citrine ointment, shows clearly, either that they often jumped at conclusions without any sound foundation, or, if they did examine "eye salve," that it was mercurial.

For my own part, I do not see how the old composition can be arrived at with any degree of certainty; but I ask, would the proprietor of "Singleton's Golden Eye Salve" have altered the composition, considering what a large sale his preparation had gained? Again, arsenious sulphide in the proportion of 2 or 3 grs. to 1 ounce (as used for the eyes) would not give sufficient colour for it to be mistaken for citrine ointment, unless some further colouring matter were added.

R. A. Cripps.

Sir,—The paper on "Singleton's Ointment," to which Mr. Tanner probably refers, was read by Mr. W. Jardine, at a meeting of the Glasgow Chemists' Association. in February, 1867, and was printed in the *Pharmaceutical Journal*, [2], vol. viii., p. 591, and shows very clearly that whatever Singleton's ointment may have been originally, it is now an ointment of red oxide of mercury.

Manchester. W. Wilkinson.

Sir,—I think Mr. J. E. Saul may be congratulated on having made out a pretty strong case in favour of his theory that Singleton's golden ointment, as originally prepared, was an ointment composed of yellow sulphide of arsenic; at least this is the conclusion one must almost inevitably come to in the face of such testimony as he brings forward in his letter on p. 140. It is inconceivable certainly that an eminent authority, as Dr. Paris undoubtably was, should make such a definite statement as to its composition, on mere conjecture and without having seen the ointment in question. But what shall we say of Dr. Christison ('Dispensatory,' 1st ed., p. 531), who, in speaking of citrine ointment, says it was introduced for the purpose of "imitating as exactly as possible a nostrum well known by the name of the golden eye ointment?" Now if the golden ointment of that period were really an ointment of arsenious sulphide, surely there would have been no difficulty in determining that fact and framing the formula accordingly; we must, therefore, either look upon the efforts of the compiler at imitating it as futile, or suppose that this Proteus had again changed its shape. It would be an interesting, but perhaps difficult task to trace out when it first differentiated and subsequently became what we now find it.

Mr. Saul must pardon me for reminding him that the object of my letter to the Journal was not so much to show what golden ointment was, as what it is, and he will find that the latter portion of my letter indicates an explanation of the discrepancies which have arisen as to its composition. Cooley, in 1855, appears to have been the first to show that it is composed of red oxide of mercury and not arsenious sulphide as generally supposed. In 1877, Mr. R. J. Downs, in a paper read before the Irish Pharmaceutical Society, and published in abstract in the *Chemist and Druggist*, of April 14, 1877, p. 138, gives the result of his examination of a pot of Singleton's golden ointment, which establishes its almost perfect identity with the ung. hydrarg. oxid. rub. of the B.P.

Mr. Cripps will, I am sure, pardon me for taking up the cudgels on his behalf, but before concluding I should like to point out that both your correspondents, Mr. Henry Brown and Mr. Saul, have, unintentionally perhaps, misquoted him. Mr. Cripps nowhere says "Singleton's eye salve was an ointment of yellow oxide of mercury" (Mr. Brown); nor, again, "was the same at the time to which Mr. Cripps referred in his paper" (Mr. Saul). What he did say was that citrine ointment was not satisfactory as an imitation of golden ointment, this latter "being an ointment of yellow oxide of mercury." The difference in meaning is sufficiently apparent.

Tottenham High Cross. Alfred E. Tanner.

The composition of this preparation has also been the subject of some correspondence in the *Lancet*, to which journal Mr. Napier, of Guildford, has forwarded the following "original receipt," which he says was obtained about forty years since from the occupier of the house in Fleet Street, nearly opposite St. Dunstan's Church, where Singleton lived:—

℞ Hydrargyri, ℥ss.; acid. nitric., ʒvss.; butyri (without salt), ℥vj.; oleum olivæ, ℥iv. Hydrargyrum in acido primum liquus; dum liquorum adhuc calentum, butyro et oleo simul liquefactes: misce.—N.B. This is half diluted.

Mr. Napier says, "It requires care in making and to be well stirred until cool, when it will come out of a brilliant golden colour. To make the ointment full strength the butter and oil must be reduced one-half."

[*$_*$* We think that sufficient space has now been accorded to the discussion of this subject, and as it is not probable that any greater certainty will be attained as to the original composition of the ointment the controversy may well be dropped.—Ed. Ph. J.]

Impure Ammonium Bromide.

Sir,—A somewhat curious case of poisoning having come under my notice a few months since, it has occurred to me that a short account of it might be of interest to your readers and also be a warning to pharmacists of the necessity of assuring themselves of the purity of the chemicals they purchase.

A prescription (written by a physican known to me) consisting of ammon. bromid. and sal volatile in ordinary doses, was dispensed at a continental pharmacy. The first dose, instead of producing the usual effects, caused violent sickness, the vomit being of a peculiar red colour, accompanied by all the symptoms of irritant poisoning. A portion of the mixture was brought to me by the doctor in question, who went over to investigate the matter. Upon making an examination of the mixture, I found, in addition to ammon. bromid. in solution, there was an insoluble precipitate, amounting to about 1 grain per fluid ounce of the mixture, which, upon analysis, I proved to be carbonate of cadmium. This result seemed so improbable, that a further portion of the mixture was taken by the physician to a well-known analyst, who confirmed my report.

Subsequent inquiry has brought to light the following facts:—That the principal fault lay with the manufacturers, who have since acknowledged that they found the whole batch of ammon. bromid., of which that used by the continental pharmacist was a part, had through the carelessness of their workmen become contaminated with a cadmium salt of which they were large makers.

I have since learnt that cases of poisoning by cadmium are rare. In several books that I consulted, I could find nothing about its physiological effects. I am told the colour of the vomit is highly characteristic.

A Point in Ethics.

Sir,—On page 379 you quote from the *Standard* a report in which the Assistant Secretary to the Chemists and Druggists' Trade Association is represented to have said that he "was obliged to tell an untruth in order to detect the defendant." I have looked in vain in the succeeding numbers of the Journal for any contradiction or explanation of this curiously bald statement. That some satisfactory account of the matter will be forthcoming is, I take it, beyond doubt; for the suggestion implied, that when the interests of the Association conflict with truth, it is truth that must yield, is too monstrous to entertain. Without judging this case, it may not be out of place to affirm that a good cause cannot be served by untruth. Of that I am sure the officers of the Trade Association are as fully convinced as I am.

THE CRYSTALLINE CONSTITUENT OF JAFFERABAD ALOES.*

BY W. A. SHENSTONE.

It will be remembered that at the Evening Meeting of the Society held in March, 1881, Mr. Holmes brought forward a specimen of aloes known in the Bombay market as Jafferabad aloes, which he had received from Dr. Dymock. Shortly afterwards I proposed to Mr. Holmes that an examination of its crystalline constituent would perhaps be interesting, and he very kindly obtained a supply of the drug for me, which I received during the first half of the present year.

I found in a preliminary examination of the substance that although the method employed for obtaining aloin from Barbados aloes was not without result when applied to the Jafferabad aloes, yet that a better result could be obtained by Histed's method.

Accordingly about 1½ pound of the powdered aloes was treated with enough proof spirit to make a thin paste, and after standing for a few hours was enveloped in folds of stout calico and submitted to powerful pressure, by which means I found that a yield of about 28 per cent. of crude aloin could be obtained.

This crude aloin was purified by twice crystallizing from water, then by crystallizing several times from dilute spirit and finally by crystallizing twice or thrice from rectified spirit. Portions of the crops of crystals thus obtained were burnt with the following results:—

I. ·1104 gram of aloin which had been once crystallized from rectified spirit and dried *in vacuo* over sulphuric acid gave ·2438 gram of CO_2 and ·0561 gram of H_2O.

II. ·1380 gram of aloin which had been twice crystallized from rectified spirit and dried *in vacuo* over sulphuric acid gave ·3042 gram of CO_2 and ·0696 gram of H_2O.

Corresponding to—

	Carbon.	Hydrogen.	Oxygen.
I. . . .	60·22	5·64	34·14
II. . . .	60·11	5·60	34·29

The aloin was therefore evidently in a pure state. 1·2375 gram of pure air-dried aloin dried over sulphuric acid in a vacuum lost ·1987 gram of water, corresponding to 16·0 per cent.

When bromine water was added in excess to an aqueous solution of the aloin a copious yellow precipitate fell. This was collected after having been in contact with excess of bromine water for an hour, washed, dried and crystallized three times from spirit. The brominated aloin was in beautiful yellow crystals, which were rather soluble in cold alcohol, and were somewhat more stable than the aloin itself. It retained only a trace of water when dried in a vacuum over sulphuric acid, which was given off on heating to 100° C. to 110° C. ·2526 gram of the perfectly dry substance gave ·2539 gram of silver bromide, corresponding to 42·75 per cent. of bromine.

In 1875 Dr. Tilden proposed, as the result of the consideration of a number of analyses of aloins and their derivatives made by himself and others, that the aloins obtained from Barbados and Zanzibar aloes might be considered isomeric bodies, with the empirical formula $C_{16}H_{18}O_7$, which also agrees closely with the results of his analyses of nataloin. This formula requires 59·62 per cent. of carbon and 5·59 per cent. of hydrogen. Its tribromo derivative requires 42·93 per cent. of bromine.

It will be seen that of the numbers obtained in my analyses those for the hydrogen and bromine agree very closely with these, and that the proportion of carbon, though a little high, also agrees fairly well.

The water of crystallization found, 16 per cent., is rather more than the amount which would correspond to three molecules, *i.e.*, 14·3 per cent. The difficulty of getting air-dried aloin of constant composition, however, is so great that the result is not of much value.

Dr. Tilden found that air-dried zanaloin when dried over sulphuric acid in a vacuum gave off about 14 per cent. of water.

In addition to the above work the following comparative observations were made; in making them some of my aloin from Jafferabad aloes and a portion of Dr. Tilden's zanaloin, which he kindly gave me for the purpose, were employed.

There is no distinguishable difference in the crystalline form of the two aloins.

No. 1*a*.

No. 1*b*.

No. 2.

In the above engravings, which are from photographs and, therefore, absolutely trustworthy,† 1*a* and 1*b* are of the aloin of Jafferabad aloes,‡ and 2 is of zanaloin of Dr. Tilden's preparation. Two photographs were taken of my aloin, as with the available slide it was not possible to get good pictures of both the large and small crystals at once.

Neither of them gives any change of colour in the cold when moistened with ordinary strong nitric acid; both of them are reddened by fuming nitric acid. And the Jafferabad aloin, by prolonged treat-

* Read at an Evening Meeting of the Pharmaceutical Society, December 6, 1882.

† These were kindly taken for me from microscopic slides by Mr. Woollet, of Colchester, who, with my brother, has lately taken a good deal of interest in such work.

‡ The magnification in each case is about 180 diameters.

ment with nitric acid, yields chrysammic, aloetic, picric, and oxalic acids, as zanaloin and barbaloin do.

Jafferabad aloin, when treated with potassium chlorate in a hydrochloric acid solution, yields a chloro-body resembling that given by zanaloin, and when heated with acetic anhydride gives an acetyl compound similar to acetyl-zanaloin.

Both of them, when treated with strong sulphuric acid and potassium bichromate, give a violet coloration closely resembling that given by strychnia, but quickly fading to *green*.

These results seem to leave no doubt that the aloin of Jafferabad aloes is identical with that from Zanzibar aloes, though I should state that the colour of the former is distinctly a lighter shade of yellow than that of the latter.

Up to the present time four aloins have been examined somewhat minutely, viz., those known as barbaloin, zanaloin, nataloin, and that which is the subject of the present communication. In addition socaloin has been partly examined and is believed to be identical with zanaloin.

As the adoption of a new name for every fresh variety of aloin examined is likely to be a source of some inconvenience, and as there is an obvious advantage in adopting a nomenclature which will group together those aloins which are most nearly alike, and also because the aloins seem likely to fall into a few groups, I venture, in concluding this paper, to make the following suggestion, which I think will make a comprehension of the sources and properties of these bodies a little more easy to attain than it is at present.

Since nataloin differs so distinctly from all the rest it will be convenient to retain that name for that substance.

And, since zanaloin, socaloin, and Jafferabad aloin differ so little from barbaloin, they may be conveniently classed together as "barbaloins," distinguishing the aloin of Barbados aloes, which was first discovered, and differs in a few particulars from the others as α-barbaloin, and the later discovered aloins, between which no distinct differences are known, as β-barbaloin. The main points of difference among these bodies could then be tabulated thus:—

1. Nataloin, obtained from Natal aloes, yields only picric and oxalic acids by treatment with nitric acid. Is not reddened, even on heating, by that reagent.

2. Barbaloins, yield chrysammic, aloetic, picric and oxalic acids by treatment with nitric acid.

They may be divided into—

a. α-barbaloin, obtained from Barbados aloes. Is reddened in the cold by ordinary strong nitric acid.

b. β-barbaloin, obtained from Socotrine, Zanzibar, and Jafferabad aloes. Is not coloured by cold nitric acid, but gives an orange red coloration when heated with it, and also gives a coloration in the cold with fuming nitric acid.

The point is not one of great importance, but I think this, or some similar system, might now be conveniently adopted, in place of giving a new name to each aloin even when it is in no way different from others already known.

Clifton College, 1882.

[*The discussion on this paper is printed at p.* 475.]

THE SALE BY PUBLIC AUCTION OF SPURIOUS AND WORTHLESS DRUGS.*

BY E. M. HOLMES,

Curator of the Museum of the Pharmaceutical Society of Great Britain.

Since its incorporation in 1843, the Pharmaceutical Society of Great Britain has taken every opportunity of making as widely known as possible, through the columns of its Journal, all cases of spurious or worthless drugs that have been brought under its notice.

It is much to the credit of the retail trade, that in a large number of cases these falsifications have been detected and pointed out by its members. This statement naturally implies that in such cases the samples have passed undetected through the hands of the wholesale dealers. To assume that this is always the case, however, would be unjust to a considerable number who have, especially of late years, called attention to the very unsatisfactory state of the drug market, and who have on various occasions pointed out the occurrence of adulterations or of very inferior qualities of drugs.

The term "adulterated" is sometimes erroneously applied to crude drugs which do not consist wholly of the article of which they bear the name. Strictly speaking, only those drugs can be said to be adulterated in which there is evidence of some substance being added with fraudulent intention.

In many cases roots, etc., collected by peasants, have other kinds mixed with them, either through the ignorance of the collector, or through carelessness in collecting and drying; or the mixture may occur when the cases containing the drugs are opened at the custom house. I believe, in all wholesale houses of any reputation, these admixtures are removed during the processes of screening, fanning, or picking over, to which crude drugs are subjected before being distributed. The fact of these admixtures not being adulterations is obvious from their occurrence in very small percentage, and from their not bearing a close resemblance to the drug in which they occur.

There is another form of so-called adulteration of drugs of very common occurrence, which consists in the substitution of an unknown drug for the genuine article. This arises in the following way. A merchant abroad sends to the English market, on speculation, a drug which is used in his own country, and which he, in his ignorance of the drug trade, supposes will obtain a remunerative price in this country. The consignee being unable to sell the drug, in consequence of it being unknown, puts it up to auction. At the sales it appears under the name of the drug which it most nearly resembles. In some cases the resemblance is very striking, so that it is quite possible for even a practised eye to be deceived, and the substitution is only discovered when the drug is used in pharmacy. This is notably the case with calisaya bark, cusparia and pareira brava, so much so, indeed, that the description of the last-named drug in the British Pharmacopœia is obviously taken from a mixture of the false and genuine drug.

Those who are acquainted with the wholesale trade are aware of the extent to which different samples of the same drug may vary in size, colour and general appearance, *e.g.*, anise, fennel, cusparia

* Read at an Evening Meeting of the Pharmaceutical Society, December 6, 1882.

bark, liquorice root, aloes, etc., and how easy it is to believe that slight differences merely indicate that the drug comes from a new locality or has been grown in a different climate.

It is very creditable to the members of the wholesale trade that, notwithstanding these difficulties, the substitutions are, in most cases, detected by them before the drugs are sold.

There is, however, a great disadvantage attached to this custom of offering one drug under the name of another in the drug sales. The spurious drugs which often come over in large quantities are purchased at a low price, I believe, by continental dealers known as "mixers," and after being mixed with genuine drugs are sent back to this country with the view of underselling dealers in the legitimate article. Such admixtures are constantly cropping up either in this country or on the continent. This practice cannot fail to exert a baneful influence on the trade, since those who sell the best quality cannot compete with those who sell adulterated drugs.

It would obviously, therefore, be a gain if drugs unknown in this country were not permitted to be sold under the name of those they most resemble, but were obliged to be sold under their real name. To prevent altogether the sale of drugs for which some use might be found would be an act of injustice.

The term "adulterated drugs" may, I think, be limited to those in which there is evidence of an intent to defraud—

1st. By the addition of any substance of less value to increase the weight, such as the addition of sulphate of barium to cochineal and saffron.

2nd. By the admixture of cheaper drugs having a great similarity of appearance, *e.g.*, marshmallow with belladonna root.

3rd. By the addition of a colouring matter to enhance the value, *e.g.*, aniline dye to rose leaves.

4th. By the exhaustion of their active principles before being offered for sale as the genuine article.

Under these headings I wish to direct attention to a few cases of recent occurrence.

1. *Saffron.*—The sample of saffron which I have placed on the table was purchased in London and contains sulphate of barium. To the naked eye it presents the colour and appearance of a fine sample of saffron, but under a hand-lens some threads are seen to be coated with some kind of paste in which occur little holes formed by the bursting of bubbles of air. When stirred in water that liquid becomes immediately coloured and a white powder settles down to the bottom of the vessel. This powder, which is insoluble in nitric acid, having been examined in the laboratory by Mr. W. E. Crow, proved to be sulphate of barium.

2. *Senega.*—In the November number of the *Répertoire de Pharmacie*, M. Charbonnier mentions that in the town of Calvados a number of the pharmaciens have received, from Paris, senega adulterated with white ipecacuanha, *Ionidium Ipecacuanha.* As this root was offered in the London market a year or two ago and disappeared, it has apparently found its way to France and has been used for the purpose above stated. When an adulterated drug is made known in one country, it soon appears in another; hence it behoves the druggist in this country to be on his guard against this adulteration. The rough surface, woody fracture and absence of keel, sweet taste and bright yellow meditullium will serve to distinguish the root of *Ionidium* from senega.

Arnica.—The flowers of *Inula britannica*, which have already been described in the Journal of this Society, as a substitute for arnica, have now been offered in England, and a sample of them is placed upon the table.

3. *Rose Petals.*—Rose petals coloured with rose aniline are still to be met with in this country, although the fraudulent coloration was exposed by Mr. T. E. Greenish in March, 1881.

4. *Jalap.*—The specimen of exhausted jalap root, which has already been alluded to in the Journal as having been deprived of its resin in Paris and offered and sold in London, has been examined, and apparently contains no resin. It behoves the members of the trade, therefore, to examine their jalap powder as to the percentage of the resin it contains and as to the insolubility of the latter in ether or otherwise.

Having recently, while going through the Hanbury collection, observed a curious specimen of jalap, labelled "Peculiar form of Jalap, imported in 1861," 100 grains of it were boiled in alcohol and the tincture poured into water. As in a previous experiment with the specimen presented by Mr. Williams, no trace of resin was precipitated. The jalap had been cut longitudinally in the same way, and had a very similar appearance, except that it looked blacker externally. Internally, it was extremely tough and as difficult to cut as powder of squills when it has caked together, in which point alone it seemed to differ from Mr. Williams's specimen. The root was evidently that of true jalap exhausted of resin. It would appear, therefore, that the practice which is now made known is not new, but was carried on twenty-one years ago.

Ipecacuanha.—The sample of mouldy ipecacuanha mentioned in the *Pharmaceutical Journal* was found to give evidence of the presence of emetine, when the process described in 'Pharmacographia' was adopted. A sample which I received this month, as being undoubtedly the same article after having been washed and dried, when subjected to the same test seemed to contain less alkaloid. This root was much darker in appearance and had a cleaner surface than the ordinary drug. A sample is laid before the meeting for inspection.

It may be of some interest to call attention to the fact that the publication of cases of adulteration of drugs is not sufficient to act as a deterrent. It is true that in some cases, such as senna and pareira brava, the quality has much improved of late years, but these are exceptional cases, and senna mixed with argel leaves is still procurable. A few remarks concerning the adulteration of saffron with mineral matter will show that some more stringent method is required in order to stop the fraud.

Saffron.—In 1869, the *Répertoire de Pharmacie** described an adulterated saffron met with in commerce, which had a very rich colour and fine appearance, the colour having been heightened with about 5 per cent. of a fixed oil, while about 12 per cent. of mineral matter was found in it.

In August, 1870, M. Constantine, of Brest, called attention, in the *Union Pharmaceutique*,† to the adulteration of saffron with 15 per cent. of chalk, stating

---

* *Pharm. Journ.*, [2], xi., 231.

† *Pharm. Journ.*, [3], i., 266.

that it had been obtained from a drug house of good repute.

In September, 1870, Mr. D. Hanbury* gave an analysis of some samples of adulterated saffron, containing carbonate of lime to the extent of from 7 to 22 per cent. All the samples containing this adulteration were from Alicante. He remarked that saffron adulterated in this manner is for the most part *undistinguishable to the eye* from the drug in a state of purity.

At the same date Professor Maisch remarked, in the *American Journal of Pharmacy*, upon the occurrence of the same adulteration in the United States.

In February, 1871, Mr. J. Ingham† described a sample of saffron which he had "obtained from a drug firm in London, whose drugs are generally to be relied upon for purity as much as any other," and which had been purchased as *Crocus sativus, opt.*, at 56*s.* per lb., as containing 40 per cent. of the same impurity.

In 1874, J. Mueller,‡ of Breslau, stated that he found 9 per cent. of sulphate of barium in one sample of saffron, and 25 per cent. of carbonate of calcium in another.

In 1879, M. Boutet published in the *Journal de Pharmacie*, vii., p. 669,§ an account of the adulteration of saffron of a similar character, the substances added in this case being 25 per cent. of sulphate of lime and 20 per cent. of glucose.

In the same year Herr Johanson, of Dorpat (*Pharm. Zeit. für Russl.*, October 15), stated that he found a commercial specimen of saffron to contain 39 per cent. of calcium carbonate.

It thus appears that, notwithstanding the publication of the adulteration of saffron with mineral matter in the Journal of this Society and in various continental journals, saffron is still to be met with in commerce, adulterated in the same manner that it was thirteen years ago.

[*The discussion on this paper is printed at p.* 476.]

FURTHER OBSERVATIONS ON ARSENIC.||

BY W. A. H. NAYLOR AND J. O. BRAITHWAITE.

At its last meeting the Society was honoured with a contribution from a distinguished French pharmacien, in which oxalic acid was recommended to be used as a test for arseniates in alkaline salts. It will be remembered that this note of M. Patrouillard was submitted as a rejoinder to an unfavourable criticism we had ventured to offer upon a previous communication which he had published in the *Bulletin No.* 1 *de la Société des Pharmaciens de l'Eure.*

In this paper we understood the author to express the opinion that oxalic acid exercised a reducing action upon arsenic acid. This view being contrary to that held by one of us, we conjointly investigated the subject, the result being that our experiments led us to adopt a conclusion the opposite to that at which he had arrived. A summary of our work on this inquiry was embodied in a paper read before the Conference at Southampton, in August last.

In his rejoinder, M. Patrouillard courteously reminds us that in every place in his memoir where mention is made of arsenic acid, "it is always understood that it is the acid combined with alkalies that is referred to, and that the idea never occurred to him to examine the action of oxalic acid upon uncombined arsenic acid; *à priori* he would have thought that it was the same as upon arseniates."

The point at issue then is clearly this:—Does oxalic acid, when boiled with a solution of arseniate of sodium, exercise a reducing action upon it, either *per se*, or through the intervention of sulphuric acid and sulphuretted hydrogen? To the settlement of this question the following experiments are directed:—

Experiment 1.—1·0 gram of disodic arseniate and ·50 gram of oxalic acid were dissolved in 50 c.c. of water, and boiled for half an hour. When cool the oxalic radical was removed by barium nitrate, filtered, the filtrate decomposed by sodium bicarbonate, and the solution divided into four portions. These were severally examined for arsenite after the manner described in our previous paper; the reagents applied being mercuric oxide, our modified Fehling, iodine and permanganate of potassium. In each case no evidence of a reduction was obtained.

Experiment 2.—This differed only from No. 1 in that oxalate of ammonium was substituted for the free acid. Here also no evidence of a reduction was traceable.

Experiment 3 was identical with No. 1, except that the arseniate was mixed with nine times its weight of sodium nitrate. Search for an arsenite was attended with negative results.

If to the sum of these experiments be added the further fact that a solution of arseniate and oxalic acid on prolonged boiling evolves no carbonic anhydride, we deem the evidence sufficient to warrant the assertion that oxalic acid *per se*, under the conditions now described, exercises no reducing action on disodic arseniate.

Experiment 4 consisted in passing sulphuretted hydrogen through a solution of disodic arseniate containing half its weight of oxalic acid, it having been previously boiled for half an hour. It was observed that no turbidity was produced in the liquid until a steady stream of gas had flowed through it for three minutes; at the end of five minutes little reddish-yellow pellets had formed, and in fifteen minutes a flocculent precipitate had appeared. For the purpose of comparison a second solution was prepared, to which was added sufficient arsenite of sodium so as to contain the equivalent of ·25 per cent. of arsenious oxide. On passing the gas through it a precipitate of tersulphide was produced in a *few seconds.*

Notwithstanding the strikingly convincing character of these experiments it was thought desirable to go a step farther, and to ascertain if the oxalic acid influenced to any extent the composition of the precipitated sulphide.

Experiment 5.—2·0 grams of disodic arseniate and ·5 gram of oxalic acid were dissolved in 50 c.c. of water, and the solution boiled for half an hour. When cool it was strongly acidified with sulphuric acid. Sulphuretted hydrogen was passed through the liquid until no more precipitate fell. The precipitate was collected, thoroughly washed, pressed between bibulous paper and dried in a current of

§ *Pharm. Journ.*, [3], x., 422.
|| Read at an Evening Meeting of the Pharmaceutical Society, December 6, 1882.

dry carbonic anhydride first at normal temperature, and subsequently at about 90° C. until the weight was constant. It was then digested repeatedly in carbon bisulphide and filtered. The united filtrates left on evaporation and drying a quantity of sulphur equal to 3·5 per cent. on the dry sulphide. A second experiment, conducted in precisely the same manner, omitting the oxalic acid, gave a quantity of sulphur equivalent to 3·8 per cent. on the dry sulphide. On the assumption that the sulphur resulted from the decomposition of the higher sulphide the two results would represent 13·45 per cent. and 14·60 per cent. of tersulphide of arsenic respectively. As this line of procedure held out no promise of obtaining a reduction which might legitimately be attributed to the oxalic acid, we determined to ascertain what action, if any, took place between the sulphuretted hydrogen and oxalic acid.

Experiment 6 consisted in passing sulphuretted hydrogen through a solution of oxalic acid. At the expiration of one hour, the liquid was filtered. The filtrate on examination was found to contain a small quantity of a substance which, on boiling, reduced silver nitrate solution. The experiment was repeated, but this time the gas was passed through a solution of the acid kept boiling, and the vapour was condensed. The resulting distillate gave proof of the existence of the reducing substance, and in much larger quantity. From the solubility of its barium, calcium and magnesium compounds, from the readiness with which on boiling it converts mercuric chloride in solution into calomel, and reduces silver nitrate to the metallic condition, there can be little doubt that the body in question is formic acid. Here it may be mentioned that Carle and others have detected it as a product of decomposition on passing hydrogen and nitrogen gases through oxalic acid. Parenthetically we may state that sulphuretted hydrogen obtained from native sulphide of antimony was alone used throughout our experiments. It now became a point of interest to know if formic acid would reduce alkaline arseniates. The test was applied by boiling a solution of disodic arseniate with a little of the acid. No carbonic acid gas was given off, and at the end of one hour there was no reduction. The solution was then evaporated on a water-bath to dryness ; still it afforded no evidence of an arsenite.

And now having regard to the whole of our experiments, we conclude that oxalic acid *alone* exercises no reducing action, either on arsenic acid or on disodic arseniate. Further, that the oxalic acid cannot be credited *indirectly* with the reduction which results from the transmission of sulphuretted hydrogen through the solution of arseniate and oxalate previously boiled and acidified with sulphuric acid.

There now remains to us the pleasant duty of acceding to a request, expressed privately by M. Patrouillard, in which we are asked to make the following correction. That in the sentence "l'acide oxalique semble donc agir sur l'acide arsenique aussi bien lorsqu'il est combiné que lorsqu'il est à l'état libre," the words *combiné* and *l'état libre* refer to the oxalic and not to the arsenic acid as interpreted by one of us. The passage then should be so construed as to imply that the oxalic acid, whether free or combined, acts equally well on the arsenic acid.

[*The discussion on this paper is printed at p.* 478.]

MARGARINE MANUFACTURE IN SCOTLAND.*

There are few subjects on which so much popular delusion prevails as in connection with the manufacture of butterine. A large section of the community will purchase almost any kind of mixture so long as it is placed before them in an attractive manner, and labelled pure butter; while they shrink with a feeling almost akin to horror from the artificial substitute, no matter how superior it may be in quality, if it is presented to them under its proper name. The most preposterous stories are circulated about butterine being manufactured from the fat of all conceivable kinds of animals—stories whose only foundation is in the imagination of their originators.

There is only one substance from which butterine, or margarine as it is called in the earlier stage, can be manufactured—that is, pure fresh beef-suet and fat, or what is known in the trade as tallow. The latter name must not be confounded with that applied to the coarser article used in the manufacture of soap and candles. The tallow is principally purchased at auction sales held in Edinburgh, Glasgow, and Aberdeen towards the close of each month, conducted by limited companies. The catalogue contains the names of the principal butchers slaughtering in the local market, with an approximate estimate of the probable quantity each will produce during the month. Each butcher's lot is knocked down separately at a certain price per cwt., and charged at that rate. The tallow is paid for after delivery, generally at the close of each week. An ox will produce, on an average, about 56 lbs. of tallow, and a sheep about 7 lbs. or 8 lbs. The quantities sold for the present month were—at the Glasgow tallow sales, about 140 tons for the month, and the top price realized was 44*s*. 3*d*. per cwt.; Edinburgh Hide, Skin, and Tallow Market Company's sale, about 40 tons, with a top price of 44*s*. 9*d*.; and the Aberdeen Tallow Market Company, about 60 tons, with a top price of 48*s*. 9*d*. The principal manufacturers in Scotland are—Messrs. A. and J. Beveridge, Leith; Messrs. Thomas Dickson and Son, Edinburgh; Messrs. Alexander Ogston and Sons, and Mr. Alexander Lyon, Aberdeen.

The process of manufacture is conducted throughout with the most scrupulous attention to cleanliness, and great care is taken that no stale pieces of tallow are introduced into the margarine, as they at once make their presence known, and taint the article both in taste and smell. When the animals are slaughtered the tallow is hung up in well-ventilated apartments at the slaughter-house for a night, in order to clear off the animal heat and the moisture. Next morning it is taken to the premises of the manufacturer, and spread out upon tables, where all extraneous substances and dirty and stale pieces are carefully cut off the tallow. The selected tallow is then hung up for another night in cool apartments, after which it is cut into small pieces by hand or machinery, and passed through a crushing machine, whence it falls into a large vat. This vat is placed within another vat, and into the intervening space steam is introduced at a gentle temperature. The fat, to which a small quantity of acid has been added to aid in its refinement, is repeatedly stirred, until it has all been exposed to the action of the heat and melted. It is then allowed to settle, after which the oil is drawn off into iron pans, each holding several hundredweights, where it remains for several days, until it has attained a pasty consistency. At this stage the fat still contains its natural quantity of stearine, and is technically known as *premier jus*, or first juice. The fat, having been taken from the pans, is folded up in clean linen cloths and placed in a hydraulic press, in alternate tiers, between iron plates, where it is gradually subjected to enormous pressure. The oil, or oleo-margarine, thus extracted, is drawn off

* From the *Grocer*, Nov. 25, 1882.

into settling pans, where it remains over-night, after which it is placed in casks usually containing about 3 cwts. each. It is then ready for export.

The substance remaining in the cloths is known as "pressed tallow," and after undergoing further pressure and a process of distillation it yields glycerine and stearine. The latter substance is used for the manufacture of a very fine description of candle, which if properly made is able to resist even the heat of tropical climates. Although the greater part of the tallow purchased at the auction sales is that of oxen, and of a character suited to the manufacture of margarine, yet there is always a considerable proportion of refuse and sheep-tallow. The latter contains a much larger proportion of stearine than ox-tallow, and is therefore unsuitable for the manufacture of margarine. It is, however, used along with marrow and the parings from the fat of roasts, in the manufacture of cooking or, as it known in the trade, marrow-fat. It is melted in a large pan placed over a fire, and in consequence the flavour is more agreeable for the purposes for which the fat is used than if it were melted by steam. The oil is strained off, and the remaining crackling, after having been subjected to hydraulic pressure, is made into "greaves," which form admirable food for animals, and are usually sold at about 14*s.* per cwt. Marrow-fat is sold in 1½-cwt. casks, firkins, and half-firkins, at about 50*s.* per cwt., in 56-lb. tins at 51*s.* per cwt, and in 28-lb. tins at 51*s.* 6*d.* per cwt. Oleo-margarine is at present worth about 70*s.* per cwt., and *premier jus* about 10*s.* per cwt. less. The price of both articles is extremely fluctuating, and occasionally falls considerably below the above figure, as two years ago, when oleo-margarine sold at much less than the cost of the raw material. Inferior and refuse tallow received from the slaughter-house, after having been melted in vats by steam, is made into tallow for soap making, and for the composition of "inspector's grease" for the axle-bearings of railway waggons. At present it is worth about 43*s.* 6*d.* per cwt. It is also made up into bars for "cup tallow" for the bearings of steam-engines.

Such is the process of manufacturing margarine generally followed out in Scotland. The manufactured article is exported principally to London, Holland and Belgium. Coming into the butterine manufacturer's hands, the margarine is churned up with sour milk, coloured with annatto, and placed in a tub of pounded ice, where it solidifies. It is then made up in ½-lb., 1-lb. and 2-lb. rolls, covered with muslin, and placed in boxes, or placed solid into tubs or firkins containing from 28 lbs. to 56 lbs. each. The latter class of packages are the more popular in this district. It is extensively sold in Glasgow, and to a considerably less extent in Edinburgh, and appears to give general satisfaction to those who use it. The market price at present ranges from 68*s.* to 92*s.*, and the article is retailed at from 10*d.* to 1*s.* 2*d.* per lb. On the whole, it is as nutritious as the genuine article, but rather deficient in flavour and smell—defects which will no doubt in course of time be remedied. It is, however, to be regretted that shopkeepers do not see their way to offer it to the public under its proper name, a proceeding which would be not only more honest, but which would ultimately tend to the more general adoption of butterine as an article of daily consumption. It is only public prejudice that can hinder its adoption; and this is being rapidly overcome, as is evidenced by the steadily increasing demand, wholesale houses all over the country being forced into selling the article by the demands of their customers. Practically there is little difference between it and fine butter. The one is made from the fat in the cow's milk, the other from the fat on the cow's back, and the chemical constituents are similar.

A NEW AND EXPEDITIOUS METHOD FOR THE DETERMINATION OF THE NITRITES, UNDER DIFFERENT CIRCUMSTANCES.*

BY EDMUND W. DAVY, A.M., M.D., M.R.I.A.,

Professor of Forensic Medicine, Royal College of Surgeons, Ireland, etc.

As the existence of nitrites and nitrates in different natural waters has been regarded (under certain circumstances) as affording evidence of previous sewage contamination, the determination of the presence or absence of such compounds, and their quantitative estimation when present, in the waters employed for domestic purposes, may be a matter of much importance in a hygienic point of view; and though we have some delicate tests for the detection in such of the presence both of nitrites and nitrates, as well as different methods for their conjoint quantitative determination, there is no very simple or expeditious method for the separate estimation of nitrites in waters, which may sometimes be required, if we except that not long since proposed by P. Griess, which method I shall presently describe, and compare with the one I have myself devised, and which I shall now lay before the Academy.

In making lately some experiments on certain nitrites, I observed a reaction, which, as far as I am aware, has not hitherto been described; and this being one of extreme delicacy, I have founded on it a new method not only for the detection of the presence, but likewise for the quantitative determination of the nitrites under different circumstances, but especially in the case of natural waters, for which it is peculiarly suitable. The reaction referred to is that of nitrous acid, or of a soluble nitrite, on the well-known substance, gallic acid; thus when an aqueous solution of that latter acid is brought in contact with a soluble nitrite, the mixture, unless the amount of the latter present be very small, will soon acquire a yellow or yellowish-brown tint, which will increase in depth up to a certain point, after which the colour remains permanent, whilst, at the same time, minute globules of gas make their appearance in the mixture. If, however, the quantity of nitrate present be exceedingly small, it will require several hours, or even some days, to complete the reaction at the ordinary temperature. By the application, however, of heat,† and bringing the mixture to the boiling point, even in the case of the most dilute solutions, the reaction will be completed in a few moments. This development of colour under the circumstances stated is evidently due to the oxidation of the gallic acid, at the expense of the nitrous acid, whereby the compound known under the name of tanno-melanic acid seems to be formed, whilst nitric oxide and carbonic acid gases are evolved. The following equation represents the changes which occur in the reaction:—

Gallic acid.	Nitrous acid.	Tanno-melanic acid.	Carbonic acid.	Nitric oxide.	Water.

$$C_7H_6O_5 + 2HNO_2 = C_6H_4O_3 + CO_2 + 2NO + 2H_2O.$$

These changes, with the development of colour, take place in neutral as well as in acid solutions, but more readily in the latter, and when they are heated, than at the ordinary temperature, as already observed. The colouring principle which is so produced seems to be the same substance that is formed by the gradual oxidation of gallic acid in aqueous solution by exposure to the air; or when this takes place more rapidly, by the solution being rendered alkaline by the addition of one of the alkalies before exposing it to its influence. The colouring matter so formed is unaffected by diluted acids—at least diluted sulphuric, nitric, and hydrochloric

* A paper read before the Royal Irish Academy, April 24, 1882. Reprinted from the 'Proceedings,' [2], vol iii. (Science), No. 9, December, 1882.

† The continual application of heat has the effect of slightly diminishing the depth of colour developed in this reaction.

acids had no apparent effect on it; and the organic acids, acetic, oxalic, and tartaric, even in a concentrated condition, did not seem to produce any change. It is also very permanent, and does not appear to be affected by exposure to air and light, even after being a long time subjected to their influence.

The depth or intensity of the colour produced being in direct proportion to the amount of nitrite reacting on the gallic acid, a ready means is afforded for the quantitative determination of the nitrites. Thus, if a standard solution be prepared, containing a known quantity of nitrite, and if a given amount of water or solution under examination yielded with gallic acid a certain shade or depth of colour, and if the same bulk of the standard solution, or of a mixture of it with distilled water in known proportion, developed the same tint, the former would be considered to contain the same amount of nitrite as the latter, and by thus comparing the tints produced by the waters under examination with those caused by solutions containing known quantities of nitrite, the quantitative estimation of such may be quickly accomplished, just as in Nessler's process (now so much employed by chemists) the determination of ammonia is so readily effected. Indeed, the colour which is developed by the action of the nitrites on gallic acid most closely resembles that produced by ammonia on Nessler's reagent. The process, too, is conducted pretty much in the same way, except that we have a standard solution of an alkaline nitrite, instead of one of ammonia; and the test reagent is one containing gallic acid, instead of Nessler's solution; and finally, that the water or mixture, after the addition of the gallic acid solution, and a few drops of either sulphuric or hydrochloric acid, is heated to boiling in a test-tube and allowed to cool; after which it is placed in a cylindrical flat bottomed glass, to compare more accurately the degree of colour produced by the water under examination with that containing some known quantity of nitrite.

The gallic acid solution which I have employed for the determination of nitrites is a strong or saturated aqueous one, which, if not colourless, can be easily made so by boiling it for a few minutes with animal charcoal, filtering the mixture whilst still warm, and then adding immediately to the filtrate sufficient sulphuric or hydrochloric acid to render it strongly acid, which addition I have found prevents, to a great extent, the tendency of aqueous solutions of gallic acid to become of a yellow or brownish tint on keeping, which well-known property is due, as already observed, to the tendency of that acid to oxidize under such circumstances; but by the addition of the acids stated, I have kept solutions of gallic acid, which were even exposed to the air in open vessels, for over two months without undergoing any change in colour.

As to the standard alkaline nitrite solution, it may be readily prepared by decomposing a hot aqueous solution of silver nitrite with potassium or sodium chloride, and after the subsidence of the silver chloride formed, diluting the solution to the required amount. The one I employed was made, as Dr. Frankland directs, in his 'Water Analysis,' for the preparation of the standard alkaline nitrite solution to be employed in Griess's method for the determination of nitrites, which is prepared as follows:—0·406 gram of pure silver nitrite is dissolved in boiling distilled water, and pure potassium or sodium chloride added, till no more silver chloride is precipitated. The solution is made up to 1 litre, and the silver chloride being allowed to settle, 100 c.c. of the clear solution is made up to 1 litre, of which 1 c.c. is equivalent, as he says, to 0·01 milligram of nitrous anhydride (N_2O_3); and he further adds, that this solution should be kept in closely-stoppered bottles, quite full. A solution at least double this strength will, however, be found more convenient for my test. I may also observe that I have likewise used a standard solution made by taking the commercial potassium nitrite and boiling it along with alcohol, which will dissolve out the potassium nitrite, leaving undissolved the nitrate and other impurities; and this alcoholic solution, on evaporation and drying the residue, will furnish the nitrite suitable for this purpose.

In using this test a convenient quantity of water to employ is 25 c.c., which can be easily heated in a test tube of somewhat larger capacity, along with 1 or 2 c.c. of the gallic solution, and a few drops of sulphuric or hydrochloric acid, and, when the mixture has cooled, transferring it to a flat-bottomed cylindrical glass, where the depth of colour can be more readily determined and compared with that yielded by equal bulks of different mixtures of the standard solution with distilled water. But where the amount of nitrite is very minute, it will perhaps be better to use at least 50 c.c. of the water under examination. I should observe that the nitrates do not produce the reaction described with gallic acid, and, unless they are present in large quantity, do not affect the test; and that it (the reaction with the nitrites) appears to be uninfluenced by the presence of the different saline and earthy salts that occur in natural waters, as well as by the organic matters that may be there occasionally. It might be naturally supposed that soluble salts of iron (which are sometimes present to some extent in certain waters), producing as they do the well-known black or ink-like reaction with gallic acid, would preclude its employment as a means of estimating nitrites, where the former salts were present; but this is not the case; for the iron may be separated by the addition of ammonia and filtration, after which I have found that the filtrate, having been acidified, may be treated with gallic acid, for the estimation of nitrites. It appears, therefore, that none of the substances which would be likely to occur in natural waters interfere with the employment of this test.

As to what may be the exact limits of its indications, I have not yet been able to determine; but I have readily detected, by its use, an amount of nitrite in water equivalent to 1 part of nitrous acid in about 20,000,000 parts of water.

I have made a number of comparative experiments with this test of mine and those hitherto proposed for nitrites, but chiefly with that of P. Griess, already referred to, as Dr. Frankland (who is one of the first chemists of the day) has stated, in his 'Water Analysis,' that it is the only trustworthy means we have for the estimation of nitrites.

This test, I may briefly say, depends on the reaction of nitrous acid on metaphenylene diamine, or meta-diamido-benzol, a derivative of benzol, whereby an orange-coloured compound is produced, by the oxidation of this complex basic substance. This reaction is one of extreme delicacy, and the test is carried out pretty much in the same manner as the well-known Nessler's method for the determination of ammonia; or of mine, just described, for that of nitrites; the depth of colour produced by the test solution, with the water under examination, being compared with that of one containing a known quantity of nitrite; the details, however, of the method will be found fully stated in Dr. Frankland's 'Water Analysis.'

From several comparative experiments I have made with Griess's method and that of my own, I have come to the conclusion that the latter is almost, if not quite, as delicate a test for the nitrites as the former. I have, however, observed this difference between them, that when the proportion of nitrites present was considerable, that then Griess's test gave a more decided reaction, or that the colour produced was of greater intensity than in the case of the gallic acid test; but that when the amount of nitrite was exceedingly minute, that then there was but little or no difference in the delicacy of their indications. In some other respects, however, the test which I have proposed, possesses advantages over that of Griess; thus the metaphenylene diamine is at present a compound very difficult to be procured; so much so that though I applied twice, lately, to one of the best-known firms in London for the manufacture of chemicals, they were unable to procure me a little of that substance; and that which I operated on was kindly given to me by my friend Dr. Tichborne, who procured it direct from Berlin. On the other hand, the reagent used in my test may be got for a few pence at any druggist's shop. Again, Griess's test solution will not keep, as it quickly acquires the same coloration that is produced by the reaction of nitrous acid or a nitrite on it, even when it is kept in closely-stoppered bottles, and therefore requires to be freshly made and titrated almost every time it is employed; whereas the gallic acid solution which I have recommended will, I find, keep for a very considerable time without apparently undergoing any alteration requiring its fresh titration, which is an important advantage. In conclusion, I may add, that whatever may be the comparative merits of the two tests contrasted, I have but little doubt that the one I have proposed will be found to be a useful and expeditious method for both the qualitative and quantitative determination of the nitrites under different circumstances.

SYRUP OF LACTUCARIUM.*

BY FRED. HOHENTHAL.

The chief difficulty in obtaining a syrup of lactucarium of good appearance is the resinous matter present in the lactucarium. In the U.S. Pharmacopœia process this substance is extracted along with the other constituents, but on the evaporation of the alcohol it separates almost wholly, and that with the small part remaining in solution gives the syrup mixed with it an unsightly appearance, although the finished product possesses the virtues of the drug in the fullest degree. There have been remedies proposed for this unsightliness, chief among which are those looking towards a total removal of this obnoxious resinous matter, which, it is claimed, has no medicinal effect, and many methods have been devised to remedy this evil. It was proposed, among others, to extract this resinous matter (caoutchouc) by means of petroleum benzine, and then make the remainder of the drug into syrup. In my experience, thus far, I have found this way to be the best I have yet operated with, although excellent results have been obtained by other processes, prominent among which is that recommended by Professor Balfour, of rubbing the evaporated percolate of lactucarium with carbonate of magnesia and water, filtering, and adding the requisite quantity of sugar, as in the process for syrup of tolu. This is an excellent method, and is used in many laboratories, but is objectionable, inasmuch as alkalies destroy some of the bitter principles of lactucarium.

In the process recommended for the new U.S. Pharmacopœia, a fluid extract is made by depriving the lactucarium of its resinous matter by means of benzine, and extracting the residue with diluted alcohol, and evaporating the percolate to the proper strength, so that 1 minim represents 1 grain of the drug. The extract is then mixed with the proper quantity of syrup, and gives an effective syrup of lactucarium of good appearance.

But the long continued heat necessary to evaporate the percolate down to the proper bulk required for a fluid extract is objected to by many, and I have, therefore, devised a formula intended to do away with as much of the heat as possible, as follows:—

Macerate 1 ounce of lactucarium with 3 or 4 ounces of benzine for twenty-four hours, decant the benzine solution, dry the residue, mix it with an equal bulk of clean dry sand, and exhaust with diluted alcohol to 8 fluid ounces; evaporate this tincture to 6 fluid ounces (instead of to 1 fluid ounce as in the other process), add water enough to regain the measure of 8 fluid ounces, then add sugar 12 troy ounces, and afterwards again water, or preferably glycerine enough to bring the measure to one pint.

By evaporating the percolate from 8 to 6 ounces, and adding water to regain the measure, we do away with so much alcohol, which is often objectionable, and is easily dissipated at a very gentle heat, whereas in the fluid extract method a higher and longer continued heat is necessary to drive off the water. I believe my formula will be found as desirable as any heretofore offered.

* From the 'Eleventh Annual Report of the Alumni Association of the College of Pharmacy of the City of New York,' 1882.

PHOSPHORUS PILLS.*

BY ALONZO ROBBINS.

What is the best formula for extemporaneously preparing phosphorus pills?

In reply to this query, the following formula is presented, and, although I cannot assert it is the "best" formula, it is certainly the most satisfactory that I have ever used:—

Take of Phosphorus	1 grain.
Chloroform	1 fluid drachm.
Balsam of Tolu	30 grains.
Wheat Flour	70 „

Rub the tolu with the flour until it is reduced to a fine powder; put the chloroform into a test tube, add the phosphorus and warm the tube until it is dissolved, pour the solution on the contents of the mortar, rub until a pilular mass is obtained, which divide into one hundred pills.

I found it convenient to have a solution of 6 grains of phosphorus in a fluid ounce of chloroform, of which solution 80 minims would be required in the above formula, each 100th of a grain of phosphorus; for one hundred pills each to contain the 60th of a grain, 134 minims of the solution would be required; and so on for any strength or number of pills.

No powder of any kind is needed in rolling out and dividing the mass. When finished, the pills may be moistened with a strong solution of tolu in ether, and immediately thrown into powdered liquorice root, or other suitable powder, rotated for a few moments, and the excess of powder removed, when they will be ready for delivery. But the additional time and labour required is so small, and the appearance of the product so much more creditable to the skill of the pharmacist, that it is strongly recommended that the pills be gelatin coated, and for this process either of the following formulas answer very well.

The first is a modification of a formula published in the *American Journal of Pharmacy*, 1879, p. 435. It possesses the advantage of being always ready; but the coated pills are rather slow in drying. The second requires to be heated when used, and needs the occasional addition of water; but when a considerable number of pills are to be coated, it is much to be preferred to the other, as the pills can be removed from the needles in a few minutes, and another lot put on and coated.

No. 1:—

Take of Gelatin	℥j.
Acetic Acid	f ℥xx.
Spirit of Nitrous Ether	f ℥xii.
Oil of Gaultheria	♏x.

Dissolve the gelatin in the acetic acid with the aid of a water-bath, then add the other ingredients, and mix. To be used cold.

No. 2:—

Take of Gelatin	℥j.
Sugar	ʒss.
Water	f ℥ij.

Dissolve with the aid of a water-bath, and use while hot, adding a little water occasionally to make up for the loss by evaporation.

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE SALE OF SPURIOUS AND WORTHLESS DRUGS.

THE report of the discussion which, at the Evening Meeting last Wednesday, followed Mr. HOLMES'S communication on the sale by public auction of spurious and worthless drugs, will be read with interest, and cannot fail to assist the Committee specially charged with the consideration of the subject in drawing up its report. We think it will be recognized that the general tone of the discussion was eminently satisfactory, and that the position taken up by the different speakers was one strictly consistent with the claim of pharmacists to recognition from the public as a body of men who have been specially educated and trained to enable them to deal intelligently in drugs. It will be seen that, in compliance with a suggestion made by the PRESIDENT at the commencement of the discussion, the purely trade aspect of the question was kept in subjection, and the speakers chose for topics rather their experience as to the occurrence of adulterated, inferior and substituted drugs in this country, and the best method of preventing their introduction into the pharmacy.

Mr. HOLMES, in his paper, very properly drew a distinction between cases where a partial or entire substitution of one substance for another is the result of ignorance or mistake and others where there is evidence of sophistication with intent to defraud; but with respect to both these classes he appeared to suggest that there should be some kind of legislative interference on behalf of the retail dealer. He said he considered it would be a gain if drugs unknown in this country were prohibited from being sold, as they sometimes now are, under the name of those they most resemble, on the ground that these spurious drugs are purchased at a low price by continental dealers known as "mixers," by whom they are used for deliberate adulteration of the genuine drug. With respect to drugs adulterated with intent to defraud, Mr. HOLMES called attention to the fact that exposure by publication has not in the past had a sufficiently deterrent effect to make them disappear, and he quoted several recorded sophistications of saffron especially as showing that some more stringent method is required in order to stop the fraud.

It may be said at once, that if this be a correct interpretation of the views of the writer of the paper, they found no support whatever in the discussion. Mr. SCHACHT thought that if exposure were not a complete remedy it was the first step in the only process which commended itself to his mind for the solution of the difficulty. Mr. GREENISH recommended pharmacists to take care of themselves in respect to the drugs which entered their establishments. The VICE-PRESIDENT pointed out that one of the fundamental principles of the Pharmaceutical Society is the condemnation and extermination of drug adulteration, and said that this could be best accomplished as the result of a perfected education, and the dispersion throughout the country of a trained body of pharmacists who would not only decline to receive a spurious article, but would make it unprofitable to a dealer to offer one. Mr. UMNEY justly remarked that already wholesale druggists carry on their business under considerable responsibilities, since retailers have their remedy against them under the Sale of Food and Drugs Act if they supply any article that is not of the nature, substance and quality demanded by the purchaser. Mr. UMNEY claimed that members of the wholesale trade generally are anxious to prevent adulteration, and Professor BENTLEY testified to the skill and care which they exercise to attain this object. In fact, there appeared to be a general agreement that the best means of overcoming the difficulty are to be found in the will and ability of both wholesale and retail dealers to detect and expose substitutions or admixtures of drugs, whether effected intentionally or as the result of ignorance, and that there is nothing to indicate that either class is incompetent or adverse to the task. Even if it were not so, it is not quite evident why the sale of a drug under one name rather than another should have a reformatory effect upon a "mixer," who buys it knowing it is not what it is called and with a deliberate intention of using it for a dishonest purpose.

The time and care that have been devoted to the consideration of the subject will not, however, have been wasted. Every now and then more or less justifiable sensational statements are made with respect to the adulteration of drugs, and these are revivified time after time by every reporter on adulteration in want of material, until the features of each case become quite familiar. Although, therefore, those conversant with the subject know that few of these alleged sophistications would escape the notice of the skilled pharmacist, it will be well that it should go forth that the Pharmaceutical Society is watchful in this respect also of the interests of the public. On this account it appears worth considering whether the Committee which is now engaged upon the subject might not be made a permanent one, to which information respecting substitutions and adulterations might be communicated with a view to their exposure.

IMPORTS OF CHEMICALS INTO JAPAN.

A REPORT by Mr. Consul ENSLIE on the trade of the port of Kanagawa during the year 1881 gives fuller particulars than usual respecting the importation of drugs, chemicals, pharmaceutical preparations and dyes into Japan. So much has this trade developed during recent years that whereas twelve years ago it was carried on by a single firm, during the last three years nearly every mercantile house in Japan has more or less dabbled in it. The result has been that notwithstanding a much increased demand, following upon the successful efforts of the Japanese Government to introduce Western medical and other sciences into the country, the market has been somewhat over-supplied. The trade in chemicals for medicinal purposes is, however, described as having recently undergone considerable modification in consequence of the encouragement given to attempts at home manufacture, so that whereas in former years these goods were imported ready made and put up in convenient packages ready for dispensing, the Japanese are now in a position to prepare many of them themselves. The trade in pharmaceutical extracts, tinctures, scale preparations, etc., has in fact come to an end, only the raw materials being now required, and these are imported in bulk, in many cases direct from the producing countries instead of, as formerly, from England. In addition, German manufacturers are said to enjoy an increasing share of the remaining trade in chemicals used in medicine. Santonin, for instance, one of the most important imports of this kind, amounting to from 120,000 to 180,000 ounces annually, is derived almost entirely from that country. The consumption of quinine is not so large as might be expected, it being replaced by the cheaper cinchona alkaloids, but the principal supply is from Milan. The consumption of morphia has largely increased, and in this case the superiority of the English manufactured article has gained for it almost a monopoly of the market. A large quantity of potassium iodide is used, chiefly of English and French make, whilst potassium bromide is one of the few chemicals principally imported from the United States to the extent of about 25,000 lbs. annually. Tartaric acid, alcohol, bismuth and chloroform are also in steady demand. But the trade in alkalies and heavy chemicals used for manufacturing purposes is far more important than that in medicinal chemicals, and of this English manufacturers have at present the entire control. German manufacturers, on the other hand, monopolize the trade in dyeing materials, one of the principal in demand being aniline violet, which is used in conjunction with logwood for dyeing silk. The Japanese appear, as a rule, to show a preference for goods of English manufacture, but it is evident, from Mr. ENSLIE's report, that in the East, as at home, our countrymen find the Germans to be keen competitors.

PROPOSED INTERNATIONAL PHARMACEUTICAL EXHIBITION IN VIENNA.

A MEETING of representative pharmacists, convoked by the Austrian Pharmaceutical Society, was recently held in Vienna, for the purpose of considering whether it was practicable to have an international pharmaceutical exhibition in that city in the course of next year. The meeting appears to have been well attended, not only by members of pharmaceutical associations having their head quarters in Vienna, but also by representatives from associations in Styria, Austrian Silesia and other provinces. After discussion, an affirmative decision was arrived at, and it was resolved to organize such an exhibition, to be kept open throughout the month of August next. The rooms of the Vienna Horticultural Society are to be rented for the purpose, and a wish was expressed that the principal pharmaceutical bodies in Vienna (the General Austrian Pharmaceutical Association, the Austrian Pharmaceutical Society and the Vienna Pharmacists' Chief Centre) should each select five of its members to act together as an executive committee. The subject came under the consideration of the General Austrian Pharmaceutical Association at its last meeting, when it was decided to support the project and to subscribe one hundred florins towards the expenses. A similar amount had been previously subscribed by the two other bodies mentioned.

COLLEGE OF PRECEPTORS' EXAMINATIONS.

A SHORT time ago we referred to some of the statistics in the official Report on the Oxford and Cambridge Local Examinations. Further evidence of the growing tendency to submit the outcome of middle class education to the judgment of an independent and impartial body is found in the fact that the entries of candidates for the half-yearly examinations conducted under the superintendence of the College of Preceptors, which began on Tuesday last and have been carried on simultaneously in fifty-five local centres, exceeded eight thousand three hundred, making, with those examined at midsummer, a total of nearly thirteen thousand for the present year. We are informed that a supplementary examination for the preliminary literary subjects required by various bodies by whom the certificates of the College are recognized, among which is the Pharmaceutical Society, will be held in March next in London and at four provincial centres,—University College, Liverpool; the Leeds Medical School; Queen's College, Birmingham; and University College, Bristol.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A MEETING of this Association will be held on Thursday, December 14, when a paper will be read on "Original Investigation in Pharmacy," by Mr. E. M. HOLMES, F.L.S. The chair will be taken at 8 p.m., by the President, Professor ATTFIELD, F.R.S.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, December 6, 1882.

MR. MICHAEL CARTEIGHE, PRESIDENT.

MR. SAMUEL RALPH ATKINS, VICE-PRESIDENT.

Present—Messrs. Andrews, Borland, Bottle, Butt, Churchill, Gostling, Greenish, Hampson, W. Hills, Radley, Richardson, Robbins, Savage, Schacht, Symes Williams, Woolley and Young.

The minutes of the previous meeting were read and confirmed.

THE LATE MR. ALLCHIN.

The PRESIDENT read a letter from Mrs. Allchin, thanking the Council for the resolution of sympathy passed at the last meeting.

APPOINTMENT OF EXAMINERS FOR 1883.

The Council went into committee to consider nominations, and upon resuming the following pharmaceutical chemists were appointed to act as Examiners for the ensuing year, subject to the approval of the Privy Council:—

England and Wales.

Barnes, James Benjamin, 1, Trevor Terrace, Knightsbridge, S.W.
Benger, Frederick Baden, 7, Exchange Street, Manchester.
Brady, Henry Bowman, Hillfield, Gateshead-on-Tyne.
Corder, Octavius, 31, London Street, Norwich.
Ekin, Charles, 2, Lampton Road, Hounslow.
Fletcher, John, Montpellier Avenue, Cheltenham.
Gale, Samuel, 225, Oxford Street, W.
Greenish, Thomas Edward, 20, New Street, Dorset Square, N.W.
Linford, John Samuel, 5, Gladstone Street, Anlaby Road, Hull.
Plowman, Sidney, 2, Residence, St. Thomas's Hospital, S.E.
Southall, William, 17, Bull Street, Birmingham.
Tanner, Alfred Edward, High Cross, Tottenham.
Taylor, George Spratt, 13, Queen's Terrace, St. John's Wood, N.W.
Thresh, John Clough, 11, Eagle Parade, Buxton.

Scotland.

Ainslie, William, 58, George Street, Edinburgh.
Baildon, Henry Bellyse, 73, Princes Street, Edinburgh.
Clark, William Inglis, 26, South Back Canongate, Edinburgh.
Gibson, Adam, Leven.
Gilmour, William, 11, Elm Row, Edinburgh.
Kinninmont, Alexander, 69, South Portland Street, Glasgow.
Nesbit, John, 162, High Street, Portobello.
Stephenson, John Bertram, 48, North Frederick Street, Edinburgh.

It was resolved—

"That the Board of Examiners for England and Wales shall meet in the months of February, April, June, July, October and December in 1883."

The cordial thanks of the Council were unanimously voted to the Boards of Examiners for their services during the present year.

ELECTIONS.

ASSOCIATE.

The following, having passed the Minor examination, and paid, as an Apprentice or Student, his subscription for the current year, was elected an "Associate" of the Society:—

Norman, William Francis......Towcester.

A former Apprentice or Student was restored to his former status in the Society upon payment of the current year's subscription and a fine.

The name of the following person, who had made the required declaration and paid a fine of one guinea, was restored to the Register of Chemists and Druggists:—

James Gater, 22, Victoria Road, Peckham, London, S.E.

Mr. John Munday was appointed Local Secretary and Superintendent of Written Examinations at Cardiff, in place of Mr. A. B. Hollway, who has resigned in consequence of ill health.

ADDITIONS TO THE REGISTER.

The Registrar reported that—

George Gibbons, Adwy, near Wrexham,
James George Hole, Westbury, Wilts,

having severally made the statutory declarations that they were in business before the passing of the Pharmacy Act, 1868, and these declarations having been supported by duly qualified medical practitioners, their names had been placed on the Register.

REPORTS OF COMMITTEES.

FINANCE.

The report and recommendations of this Committee were received and adopted, and various accounts were ordered to be paid.

BENEVOLENT FUND.

Legacies.

Previous to the reading of the report of this Committee,

The SECRETARY read a letter he had received from the executors of the late Mr. CHARLES JAMES PEARSON, of Swansea, stating that that gentleman had bequeathed £100 free of legacy duty to the Benevolent Fund.

He reported also that he had received a cheque for £100 from the executors of the late Mr. HOWDEN, in payment of the legacy previously referred to.

Donation from the Committee for Reception of the British Pharmaceutical Conference at Southampton.

The SECRETARY further reported that Mr. Chipperfield, Hon. Treasurer to the Local Committee of the British Pharmaceutical Conference at Southampton, had written that there had been a surplus of receipts over expenditure in connection with the recent meeting, and, in accordance with a resolution of the Local Committee, he had forwarded a cheque for £55 16*s*. 7*d*., the amount of the balance, as a donation to the Benevolent Fund.

The thanks of the Council were voted to the Local Committee for their donation.

The report of the Committee included a recommendation of the following grants:—

£15 to a former Member who was also a subscriber to the Fund.

£5 to a pharmaceutical chemist, who has been unfortunate and suffered from illness.

£5 to the widow of a registered chemist and druggist.

£5 to the widow, aged 68, of a registered chemist and druggist.

One case had been deferred for further inquiries, and two applications the Committee had declined to entertain.

The Secretary had submitted a statement with regard to the Isherwood orphans, showing that the fund subscribed for their support was exhausted. A letter had been received from the gentleman with whom the two boys were placed, saying he should be happy to wait on the Committee with the boys in January next.

With regard to Mr. Robbins's special donation the Secretary had reported that only one of the annuitants had subscribed to the Fund, and it had been therefore resolved to recommend that £5 be given to her before Christmas.

The report and recommendations were unanimously adopted.

Mr. Robbins said it was rather astonishing to hear that out of the thirty-six annuitants at present on the list only one had been a subscriber to the Benevolent Fund. He hoped this would not be found to be the case in future years.

LIBRARY, MUSEUM AND LABORATORY.

Librarian's Report.

The report of the Librarian had been received, and included the following particulars:—

Attendance.		Total.	Highest.	Lowest.	Average.
October . .	Day . .	592	32	11	23 nearly
	Evening	207	17	5	9

Circulation of books.	Town.	Country.	Total.
No. of entries . . .	199	164	363

Carriage paid, £1 10*s.* 5*d.*

The undermentioned donations to the Library had been received, and the Committee recommended that the usual letter of thanks be sent to the respective donors:—

Index-catalogue of the Library of the Surgeon-General's Office, U.S. Army, vol. 3.
From the Surgeon-General.

Flückiger (F. A.), Die Chinarinden, 1883.

Archiv der Pharmacie, Separat-Abdruck, 1882.
From Professor Flückiger.

The Committee recommended the purchase of the undermentioned books:—

Candolle (Alph. de), Origine des plantes cultivées, 1883.

Davies (T.), The preparation and mounting of microscopic objects, 1881.

Hager (H.), Commentar zur Pharmacopœa Germanica.

Lunge (G.), Treatise on the distillation of coal-tar and ammoniacal liquor, 1882.

— Theoretical and practical treatise on the manufacture of sulphuric acid and alkali, 1879–80. 3 vols.

Pomet (P.), History of drugs, 1748.

Sachs (J.), Text-book of botany, 2nd ed., 1882.

Curator's Report.

The Curator had reported the average attendance in the Museum to have been—

Attendance.		Total.	Highest.	Lowest.	Average.
October. .	Morning	410	25	2	16
	Evening	115	17	0	5

The following donations to the Museum had been received and the Committee recommended that the usual letters of thanks be sent to the respective donors:—

Specimen of *Humulus Lupulus* with monœcious flowers. From Mr. H. O. Huskisson.

An orginal bottle of Persian Rose Water.
From Messrs. Christy and Co.

Specimens of Crude and Pure Chinoline and Tartrate of Chinoline prepared from Cinchonine; Chinoline and Tartrate of Chinoline obtained from Coal-tar.
From Messrs. Hopkin and Willliams.

Specimens of the following Brazilian drugs:—Guaco, Jaquitiba Bark, Cipo Chumbo, Milhomens.
From M. Eugene Collin.

Specimens of Almasça (Brazilian Elemi), Oil of *Carapa guianensis*, Guassatunga Bark.
From Dr. Symes.

Specimen of Winter's Bark.
From Mr. G. B. Francis.

Specimens of Spurious Calumba Root and Bengal Cardamoms.
From Messrs. Burgoyne, Burbridges, Cyriax and Farries.

Specimens of Adonidin, Tannate of Cannabine, Convallarin and Convallamarin.
From Messrs. E. Merck and Co., Darmstadt.

A series of Herbarium specimens of various species of Aconite.
From Professor Maximowicz, St. Petersburg.

A series of packages of Cinchona bark from the Darjeeling Plantations.
From the Indian Government.

Specimens of False Buchu (*Empleurum serrulatum*), of *Barosma ericifolia* and of False Calisaya Bark.
From Messrs. Donald Gray and Son.

Specimen of False Buchu leaves.
From Messrs. Dalton and Young.

Specimen of False Senega root (*Polygala Boykinii*).
From Professor J. Maisch.

A letter of thanks had been received from the Director of the Royal Gardens, Kew, for duplicate specimens of drugs.

The Professors had attended and reported satisfactorily as to their respective classes.

Estimates for printing the Register and Calendar had been considered and were recommended for acceptance.

The Committee recommended that the list of subscribers to the Benevolent Fund be published in the Journal for the last week in February.

It was also recommended that the fire policies on the Society's premises and property be increased to £18,900 in the aggregate.

The Council went into committee to consider some parts of the above report.

On resuming, the report and recommendations of the Committee were received and adopted.

LAW AND PARLIAMENTARY.

The Council went into committee to consider this report. After considerable discussion the Council resumed and the report was received and adopted.

The President reported that, having taken steps to ascertain the views of the department in regard to further legislation, he had had an interview with Mr. Peel and the following correspondence had taken place since that interview:—

"17, Bloomsbury Square,
"*November* 13*th*, 1882.

"C. L. Peel, Esq.,
"Privy Council Office.

"Sir,—With reference to your letter of 29th July last, and the interview between yourself and the President of this Society on the 9th inst., I am instructed to inquire if their Lordships desire that the Council of this Society should prepare and submit to the Privy Council, in the form of a Bill, their views as to the amendment of the law in regard to the sale of poisons.

"I have the honour to be, Sir,
"Your obedient servant
(Signed) "Elias Bremridge,
"*Secretary and Registrar.*"

"Council Office,
"14*th November*, 1882.

"Sir,—I have submitted to the Lord President of the Council your letter of the 13th inst., and I am directed to request that you will inform the Pharmaceutical Society that his Lordship would be glad if that Society would submit their views, in regard to the sale of poisons, for the consideration of the Lords of the Council, in the form of a draft Bill amending the existing law.

"I am, Sir,
"Your obedient servant,
(Signed) "C. L. Peel."

The President announced that the Law and Parliamentary Committee was drafting a Bill, in response to the invitation of the Privy Council.

GENERAL PURPOSES.

The report of this Committee was taken in committee as usual. It included a letter from the Solicitor, stating the progress of cases which had been placed in his hands.

Several cases of alleged infringement of the law had been considered by the Committee, and legal proceedings were recommended in three cases.

The report and recommendations were received and adopted.

Report of the Board of Examiners.

Special Recommendation respecting the Preliminary Examination.

The President said the next business had reference to a recommendation made by the Board of Examiners in England, with regard to the Preliminary examination, which had been sent to the Board in Scotland, and partly, but not altogether, agreed to by the latter body. The recommendation referred to the Latin authors to be used in future, and also to the time over which the examination should extend. It was customary for some members of the London Board of Examiners, with the President, to attend once a year the College of Preceptors, to ask for information and to take counsel together as to whether the examination was doing its work properly, and whether any suggestions could be made as to its amendment. Accordingly, last July, he with other members of the Board attended at the College of Preceptors by appointment, and had a long conversation with the examiners and with the Dean of the College. The conclusion arrived at was that, having regard to the somewhat careless way in which the subject of English was dealt with in many of the papers, it would be wise to separate that subject from Latin and Arithmetic and to give a special and separate time to it; in other words, that the present three hours devoted to the three subjects should be devoted to Latin and Arithmetic only, and that after an interval of an hour there should be another hour and a half set aside for English. It was found that, in many cases, there was a disposition on the part of the candidates to use a large portion of the time for Arithmetic, and when they came to the English they had not the opportunity to show to what extent they could come up to the requirements of the examiners. The next consideration was with regard to the Latin author. The first book of Cæsar had been used ever since there was any Preliminary examination at all, and it was recognized that it was a book still read in a very large number of schools; but it was also recognized that there were a certain number of other schools in which Virgil practically took its place, and the examiners readily assented to a suggestion which had often been made that Virgil should be added to the subjects, and that the candidate should have the option of taking a paragraph from Cæsar or Virgil at will. Of course, the object was not to get a knowledge of any particular author's Latin, but an indication that the candidate had such a knowledge of Latin as that he might be able to conduct his business satisfactorily. If the examinations were restricted to one author, candidates were compelled to read that author; and, as was well known, the peculiarities of Cæsar were almost innumerable, so that a very good Latin scholar who had not read Cæsar might find very considerable difficulty in translating a paragraph and answering questions upon it. The Council did not desire to encourage men to prepare special books, but to obtain a general standard of education in Latin and other subjects. The examiners of the College of Preceptors thought, therefore, that Virgil might very well be added, and seeing that the first book of Cæsar had been used for so long they also acceded to the suggestion that the second book of Cæsar might be added. The general conclusion come to was that two books of Cæsar and two books of the Æneid should be the standard books, and that a year's notice should, in each case, be given as to which book of each author should be selected. This suggestion was sent to the Board of Examiners in Scotland, and substantially the members of that Board agreed with their London colleagues, except that they would limit the Latin to the first book of the Æneid and the first book of Cæsar. He must confess he agreed with the London Board that it was desirable that the recommendation should be adopted in full, and he would, therefore move a resolution as follows:—

"That in future the time allowed for the Preliminary examination be four and a half hours; three hours in the morning and one hour and a half in the afternoon, with an interval of one hour between the two portions of the examination.

"That in the morning the three hours be devoted to Arithmetic and Latin, and that in the afternoon the whole time be devoted to English.

"That in Latin the present regulation requiring translation into English of a paragraph from the first book of Cæsar (De Bello Gallico) be extended as follows:—

"Two Latin subjects shall be annually selected in December by the Council from the works of the undermentioned authors, and twelve months' notice shall be given in the *Pharmaceutical Journal* of such selection:—

"*Cæsar.*—One of the first two books of the Gallic War.

"*Virgil.*—One of the first two books of the Æneid.

"That in each examination paper a passage from both of the selected books be given, but that a candidate shall be required to translate one only of such passages.

"That the Latin subjects to be selected for 1884 be:—

"*Cæsar.*—Second book of the Gallic War.

"*Virgil.*—First book of the Æneid."

Mr. Andrews asked if this would not make the examination somewhat more difficult that the Oxford and Cambridge local examinations, which were now accepted as sufficient.

The President said he thought not.

The Vice-President said he had had a good deal to do for the last ten years with the Oxford and Cambridge University examinations, and he could say that this examination, even with the addition of Virgil, would be below that standard in Latin. He had much pleasure in seconding this motion. He thought it was a great boon to have the extension of time. He had superintended the Preliminary examination for some years in Salisbury, and he found that many youths occupied nearly the whole time in the two earlier subjects, and with regard to the English, which was, after all, about as good a test of a liberal education as could be, they had to apologize, because hardly the requisite number of lines were written. He was very glad to hear they were going to get away from Cæsar for a bit; long ago he had suggested that Cornelius Nepos should have a turn. Even if there were a slight increase of stringency in the Preliminary examinations, which there was not, he should heartily approve of it, because he thought it would be a wise and kind act to put such a barrier at the outset that only those could pass it who were likely to succeed in the subsequent examination. But there was no indication of this being so. The matter had been carefully considered by the College of Preceptors, and the intention was rather to vary the extent of the Latin information than to make it more stringent.

Mr. Symes said if the proposal were to increase the stringency of the Preliminary, he should take exception to it. He did not say it was not desirable gradually to increase it somewhat, and he agreed with the Vice-President that at present it was somewhat below the Oxford and Cambridge local examinations, but whilst there was such a large percentage of failures it would not be wise to increase the stringency. The chief point to which he wished to speak was the question of time, and he failed to see how this increase of time was at all necessary. His experience as a superintendent was that the greatest loss of time was at the beginning, and then many candidates spent a great deal of time over the first subject. He believed it would be found that the failures were very few comparatively in Latin. But assuming it was a want of time that caused them to come short in English, the conclusion would follow that the next proportion of failures would be in Arithmetic, and the larger proportion in English. But that was not so; the greatest percentage of failures was in Arithmetic, the second subject, and, therefore, it was not a question of time, but of capability. He admitted that English was often neglected for want of time, owing to too much being spent in the Arithmetic, but he thought the difficulty might be met by giving one hour to each subject. It might in some cases be objectionable to youths who had to come a long distance, to spread the examination over five and a half hours. Of course he assumed that an equal quantity of work would be put into each subject.

Mr. Hampson thought the experience of the officers of the College of Preceptors was very important. They had immense experience in this kind of examination, and they divided the subjects, and gave proper time to each. With regard to including two other books in Latin he did not see any great hardship in it. The first book of Cæsar had become so hackneyed that it was quite time to have a change.

Mr. Borland was glad to find there was a substantial agreement between the two Boards of Examiners with regard to the increased time given to Latin and Arithmetic, but he certainly thought that in the face of coming legislation and with the prospects of an enforced curriculum the Preliminary examinations should not be made any more stringent than at present, and the statistics did not appear to show that there was any great proportion of failures in Latin. He did not object to the introduction of another book in addition to Cæsar, which would to a certain extent be in favour of the candidates. In Scotch schools it was quite customary for the teachers to have a *penchant* for a certain author, and a boy after he had passed through the rudimentary stage was set to translate it, and if he had an aversion to Cæsar he was pushed on to Virgil. If the resolution come to by the Scotch Board were adopted it would give the candidate an opportunity of presenting himself at an earlier period than if he had to go on for another half year at school studying the second book of Cæsar, which might be selected by the Council for the year in which he was to come up. With regard to the Latin examination it should not be overlooked that the Board of Examiners had a double opportunity to examine the candidates in Latin, because this was a point in the Minor examination in reading prescriptions, and it had been noticed by Dr. Greenhow that many candidates failed in reading Latin prescriptions. During the time when he was examiner in Edinburgh he was often obliged to remit candidates back to their studies from the imperfect knowledge of Latin which they exhibited in reading prescriptions. They could tell what was meant, but could not read the numerals or give the terminations. He, therefore, thought it was rather too much, at the present time, to include two books in each author. There was great difficulty in Scotland generally to find apprentices to enter the business, and if the stringency of the examinations were in any way increased this difficulty would also increase. He had no doubt that the object of the examiners was to bring into the business a class of young men whose parents were in a position to keep them longer at school, but it was very doubtful whether a sufficient number of such youths was forthcoming.

Mr. Williams said he should support the proposition, because he did not see that it was at all objectionable, or that it would practically increase the stringency of the examination. He should only suggest an alteration of the wording of it, because he did not think it was the province of the Council to select the subjects; the examination was submitted to the Board of Examiners, to whom it ought to be left.

The President said it must be done by the Council ultimately, and it was much more convenient for the Council to act in the first place, otherwise there might be a delay of six months.

Mr. Borland said he should move as an amendment, that the recommendation of Board of Examiners in Scotland be adopted. He moved—

> "That the recommendation of the Board of Examiners in England be adopted, excepting in so far that the examination in Latin be confined to the first book Cæsar and first book of Virgil's Æneid."

Mr. Young seconded the amendment. He considered this was a very important matter; there had been frequent complaints made of the number of failures in connection with the Preliminary examination, and it appeared to him very strange in that state of matters that the stringency of the examination should be increased, and that would be the tendency, whatever might be said to the contrary. No doubt it was a good thing that there should be an option to take Virgil instead of Cæsar, but he saw no reason for going beyond the first book of each. One gentleman said the first book had been used so long that it was become quite hackneyed; but it must be remembered that it was a different set of boys who came up each time, and although the teachers might have got tired of picking out the paragraphs, they were quite new to the lads who had to translate them. For all the Latin which was really wanted in connection with the business, one who could translate properly the first book of Cæsar had a very fair knowledge, and it would entail a great deal of extra trouble if he had to make himself proficient in the second book. It took a good time at school to get through the second book of Cæsar, and therefore he thought at present the Council might be satisfied with adding the first book of Virgil, so as to give the youths an option and to increase the time so as to show there was really a desire that they should pass. He did not agree with Mr. Williams's suggestion, for he thought the Council should have the control of the whole matter.

Mr. Andrews thought anything which tended to bring the Preliminary examination on a par with the Oxford and Cambridge local examinations was decidedly desirable, as otherwise the candidates did not all start fair. He thought Mr. Borland and Mr. Young were rather opposed to each other as to one point. If Latin were properly taught, the boy ought to be able to translate the second book of a work as easily as the first. The fact was that now youths learnt the whole of the first book by heart, but did not learn the language properly, so that it was no test at all. If a boy knew Latin he could translate the whole of the Æneid properly as well as the first book. He thought it was a very good suggestion to add Virgil, because boys might be taught Latin very well and yet not be able to translate Cæsar, unless they had specially studied it. He had heard of one case in which a boy knew the first book of Cæsar so well that he translated a passage which was not set.

Mr. Radley suggested that the question of time was of great importance in some parts of the country, and he feared if it was extended as proposed, it might sometimes involve youths being away a night from home, which was rather objectionable.

Mr. Schacht said the scheme as put forward by the English Board contained a great deal with which he strongly sympathized. The enlargement of the scope over which the examination extended from one book of one author to two books of two authors was a decided improvement, nor did he fancy the extension to two books of either author was at all too much; but it did strike him there was a weak point in the recommendation of the English Board which, if removed, might possibly meet the objection raised by the amendment. The weak point in the recommendation was the suggestion that the Council should each year select the Latin subjects. Why should not the examination papers contain a set of questions from each of the authors, giving the candidate the alternative of answering whichever he pleased?

The PRESIDENT said that was intended.

Mr. SCHACHT asked, if that were so, where was the necessity for indicating the book selected. There was no doubt many preceptors trained their pupils in Virgil rather than Cæsar, and those who had been trained in Virgil would have to study Cæsar for a considerable time in order to be able to answer any questions upon it; but those who had been decently trained might be fairly supposed capable of answering questions on either of two books of the author they had studied.

The PRESIDENT said there would be an objection to having four passages on the examination papers. The examiners would have preferred only one.

Mr. SCHACHT said he did not propose that passages from all four books should be set, but that the examiners might choose from either.

The PRESIDENT said that would probably meet the views of the London Board entirely, but was not what Mr. Borland desired.

Mr. YOUNG said the amendment was simply addressed to confining the examination in Latin to the first book in Virgil or Cæsar, the candidate having the option of choosing a passage from one author or the other.

The PRESIDENT thought Mr. Schacht's view was the right one, and that eventually it must be adopted; but it was necessary to proceed gradually, and it had been long the custom in all examinations in which classics formed a part to give the actual book selected.

Mr. BOTTLE supported the amendment because he thought it extremely desirable that the two Boards of Examiners should act in perfect accord; and even if the Scotch Board had agreed with the recommendation of the English Board he should have accepted it with some compunction, because he thought it unwise at the present moment to even appear to increase the stringency of the examination. He also found that the preliminary examination for tho College of Surgeons only contemplated one Latin author.

Mr. SCHACHT remarked that it included Greek also.

The amendment was then put, and there were 7 votes on each side.

The President and one other member of Council did not vote.

The PRESIDENT said under these circumstances the only course for him to pursue was to vote for the minor proposition, although it was not in accordance with his own views. He must therefore declare the amendment carried.

The amendment was then put as a substantive motion and carried.

The following resolution, embodying the recommendations of the Board of Examiners as altered by the above amendment, was then put and carried unanimously:—

"That in future the time allowed for the Preliminary examination be four and a half hours, in two periods of three hours and one hour and a half, with an interval of one hour between the two portions of the examination.

"That the three hours be devoted to Arithmetic and Latin, and the one hour and a half to English.

"That in Latin the present regulation requiring translation into English of a paragraph from the first book of Cæsar (De Dello Gallico) be extended by the addition of Virgil—first book of the Æneid.

"That in each examination paper a passage from both of the authors be given, but that a candidate shall be required to translate one only of such passages.

"That this regulation shall come into force in January, 1884."

Mr. BUTT suggested that the Preliminary examinations in future should be held on Thursday, as it would in many cases be more convenient.

The PRESIDENT said that would have to be decided on a future occasion.

A NEW PHARMACOPŒIA.

Mr. HAMPSON said he noticed in the Journal for November 25, an article in reference to the appearance of the new German and United States Pharmacopœias, in which the Editor casually alluded to a rumour that a new edition of the British Pharmacopœia was in preparation. He was anxious to know if there had been any communication received by the President or the Secretary from the Medical Council with reference to this new edition, and whether in that communication any proposals had been made to include the Society in the preparation of this new pharmacopœia. It appeared to him that it was a most humiliating position for the Society which represented pharmacy to be utterly ignored in this matter.

The PRESIDENT said he could only reply that neither he, as President, nor the Secretary had received any communication from the Medical Council on the subject.

THE WEIGHTS AND MEASURES ACT.

The PRESIDENT read a letter which he had received from Mr. Keyworth, of Hastings, referring to the inspection of chemists' weights and measures.

The Council went into committee to consider the letter. On resuming,

The PRESIDENT said he gathered that it was the opinion of the Council that he should reply to Mr. Keyworth that in the present state of the law it was very important and desirable, wherever the Weights and Measures Act was in force, that every dispensing chemist should see not only that his larger weights and measures were correct and stamped, but that also his smaller weights and measures used in dispensing were also similarly stamped and verified; and that it was not expedient at the present moment to make any attempt on the part of the Society to alter the law on the subject.

EVENING MEETING.

Wednesday, December 6, 1882.

MR. MICHAEL CARTEIGHE, PRESIDENT, IN THE CHAIR.

An Evening Meeting of the Pharmaceutical Society was held on Wednesday last, the 6th inst. The chair was taken at half-past eight.

The minutes of the previous meeting having been read and confirmed, the PRESIDENT requested Mr. Holmes to read a paper on—

THE CRYSTALLINE CONSTITUENTS OF JAFFERABAD ALOES.

BY W. A. SHENSTONE.

The paper is printed on p. 461, and gave rise to the following discussion:—

Professor ATTFIELD said that Mr. Shenstone had obtained negative results, and an investigator never got so much credit for them as he did for discovering something new. At the same time it was quite clear that Mr. Shenstone had done most excellent, admirable and useful work, and he had clearly made out that the aloin obtained from the Jafferabad aloes was allied to barbaloin and not to nataloin, inasmuch as he got the chloro-, bromo- and acetyl derivatives which were obtained from barbaloin and not from nataloin.

The PRESIDENT said that one must always be struck with the tendency of investigations of this sort to show that most of the organic bodies of the same nature which yielded active principles yielded principles which were closely allied, if not identical. When a complete series of investigations should have been made into all the varieties of aloes, such as Dr. Tilden and Mr. Shenstone had already made into the more important varieties, it would be possible probably to come to some definite conclusion with regard to them, which would be of real practical value in pharmacy. Mr. Shenstone was a former distinguished student of the Society and was now teaching chemistry at Clifton College. The members of the Society were grateful to him for continuing to take an interest in materia medica and other matters connected with pharmacy.

The next paper read was—

On the Sale by Public Auction of Spurious and Worthless Drugs.

BY E. M. HOLMES.

The paper is printed at p. 462, and gave rise to the following discussion:—

The President said he would venture to suggest that in the discussion the speakers should avoid going into purely trade matters. He had no doubt that Mr. Holmes's object was to elicit information from the members about their experience in actual pharmaceutical practice, as to the extent of adulteration, and to assist buyers in detecting fraud. The difficulties which were so ably presented in the paper were difficulties which even the most practised eye could not at all times overcome, and there could exist no better proof than that fact of the necessity for there being a trained and educated body of pharmacists. Fortunately there was a very large staff of excellent pharmacists spread all over the country, and he thought that it was to the credit of the Pharmaceutical Society of Great Britain, that it had disposed and encouraged buyers in the sale rooms of the City of London to be as careful as such men could be. He hoped that the discussion would be confined as much as possible to a statement of further instances of detected adulteration. The purely trade side of the question was adapted rather for consideration by a small committee of half-a-dozen men, than for discussion at such a meeting as the present. Perhaps the paper might be taken to be a general comment upon the way in which things were bought in the City. He would ask Mr. Umney, who was in the habit of buying on the east of Temple Bar, to open the discussion.

Mr. Umney said that he felt that the paper was a most important one. It was important for the pharmacist, because he was watched on one side by the medical practitioner, and on the other side by the public, and he sometimes was blamed if the effects of the drugs he sold or dispensed did not answer the expectations of the medical man. He could conceive no better action on the part of a pharmacist than to point out adulteration and to hound it down unflinchingly. He knew that the members of the wholesale trade generally were quite as anxious as the retail pharmacist to prevent adulteration. The responsibility of the wholesale druggist was very great. There was an Act known as "The Sale of Food and Drugs Act," and retail traders had their remedy against the wholesale dealers for supplying them with anything which was not of the nature and character demanded. For officinal drugs and preparations wholesale traders were quite ready to be judged by the standard described under "Characters and Tests" in the British Pharmacopœia. Mr. Holmes had very properly alluded to impurities which could not be well avoided, as in the case of scammony and other drugs which were collected by peasants. Such things came into the market and they were an unavoidable evil. Cheap drugs were generally said to be an abomination, and while this was undoubtedly true of such bodies as saffron and other drugs which were adulterated to make qualities to be sold at lower rates, it was not strictly true that all medicinal substances can be so classed. Take, for instance, ginger, and contrast African or Bengal with fine Jamaica ginger. Both were equally genuine, but their prices varied from, say, £25 to £100 per ton. Pharmacists should not lose sight of these important differences, when, from economical points of view, they were making purchases. Again, saffron might be very fairly genuine as a commercial article and yet not genuine from a botanical point of view. Ten or fifteen per cent. of the stamens might be present in consequence of the drug having been gathered carelessly, but he did think that could be fairly called a gross adulteration. One bad form of drug to which Mr. Holmes had alluded was that known in trade as Alicante saffron. All good houses ignored such an article. They knew that it was loaded either with carbonate of lime or carbonate of baryta or, perhaps, sulphate of baryta made adherent by glycerine or some such body. He had again and again taken samples of saffron exposed on the brokers show-boards and infused them in water and obtained after a few hours a sediment which, upon being treated with hydrochloric acid and the solution examined, gave conclusive evidence of adulteration. No one who had been in the habit of using his other senses besides his eyes could be deceived. He, personally, could generally distinguish loaded saffron by the harsh feel which it presented to the touch. If pharmacists would avoid such drugs, they would very soon cease to exist in the market, because where there were no buyers there would be no sellers. Such drugs were sold to a less extent than they were eight or ten years ago. The Sale of Food and Drugs Act had done wonders both for druggists and for the community in general. As to Ionidium ipecacuanha, or white ipecacuanha, he saw some offered in London about two years ago. It was purchased by continental buyers. He was confident that none of it found its way into British pharmacy. He could not see that there was any reason for using it as an adulterant for senega, for the price of that drug was only 15 or 20 per cent. more than that of this particular ipecacuanha. Perhaps the adulteration arose from ignorance. As to rose petals, the adulteration of that article had been very ably exposed by Mr. T. E. Greenish. He (Mr. Umney) knew of no artifice which was so difficult to detect as one in which the chemist had applied his scientific skill for the purpose of deceit. He had not met with such jalap as that to which Mr. Holmes had alluded. The specimen on the table appeared to have been sliced. Perhaps this had been done for the purpose of better extracting the resinous principle, but the whole of the resin could not have been extracted from the specimen, sliced as it had been.

Mr. Cleaver said that with regard to ipecacuanha and jalap one important consideration was the small number of pharmacists who made their own preparations from those drugs. Excepting those who did make their own preparations, perhaps not one pharmacist in a hundred ever saw a sample of jalap root or of ipecacuanha root in its natural state. He did not suppose that such drugs as Mr. Holmes had exhibited would be used by any manufacturing pharmacist. Still there was no doubt that many preparations failed to come up to the mark, but they were not all of English manufacture. He had met with alcoholic extract of hyoscyamus and alcoholic extract of aconite, which came from the continent, and which were devoid either of hyoscyamine or of aconitine, though the manufacturer vouched for their being genuine. Easton's syrup also might be met with in this country, containing only one-fourth or one-fifth of the proper proportion of quinine. He had that week seen some which contained only about 2 grains of phosphate of quinine in an ounce instead of 8 grains. He had never met with adulterated saffron.

Mr. Urwick, referring to a remark of the preceding speaker, said he believed that there was scarcely a pharmacist in England who did not make his own ipecacuanha wine. As to Easton's syrup, he thought that Mr Cleaver must be in error. He could only account for what Mr. Cleaver had stated by supposing that the preparation had been procured from some co-operative stores.

Dr. Symes said that Mr. Urwick had said what he himself intended to say. He should not think that there was one pharmacist in a hundred who bought ipecacuanha wine and who did not have opportunities of seeing the ipecacuanha in its original condition and of judging of its character.

Mr. CLEAVER said that his remarks did not apply to those who made their own ipecacuanha wine. He should think that there was a very large number who did not do so.

Mr. GREENISH recommended pharmacists generally to take care of themselves in the matter of the drugs which entered their establishments. As to pharmaceutical preparations such as that to which Mr. Cleaver had alluded, if they went into that subject they would occupy many hours with the discussion. It was surprising that there should still be found in the market rose leaves dyed with aniline, since the fraud had been exposed in that room, and the detection of it was so easy and rapid. The adulterated saffron which Mr. Holmes had shown them was charged with a very large quantity of sulphate of barium, and more than he had seen in any previous sample. It had been stated that there was some glucose in connection with it; but from the cursory examination which he (Mr. Greenish) had made of it, he thought that the substance was honey and not glucose, for under the microscope he detected the pollen grains of other flowers than those either of saffron or calendula. He could not understand how it was that the jalap was in that sliced condition, or "slashed" as it was termed. The slicing must have been done when the jalap was quite fresh, and with some object. Judging from the appearance of the jalap under the microscope, he was disposed to think that this sample never had much resin in it; and he did not think that it could be exhausted of its resin by being boiled in alcohol in its present condition. He recommended pharmacists to use the microscope for the detection of the adulteration of drugs. It did not take three minutes to distinguish adulterated saffron.

Professor ATTFIELD said that he did not think that Mr. Holmes made any allusion, in reading his paper, to the use of glucose for the purpose of making the adulterants adhere to the saffron. He thought that if Mr. Crowe had been present he would tell them that he looked for glucose, and that he did not find more sugar in the so-called adulterated saffron than there was in the original article. Possibly gum or glycerine might have been used in this case, but not glucose or honey.

Mr. HOLMES said that Mr. Crowe at first thought that glucose had been used, but on experimenting further he failed to get absolute proof of the fact.

Professor BENTLEY said that he must add his testimony in confirmation of what Mr. Umney had said as to the very careful manner in which drugs were selected by the wholesale druggists before they got distributed among retail pharmacists. Cases of difficulty sometimes occurred, for drugs were bought from sample, but it was surprising how few mistakes were made. Some years ago a wholesale druggist bought in the market a very large quantity of chiretta, which was so perfectly like the official that he was deceived by its appearance. Upon some of it being supplied to a retail pharmacist it was noticed that the infusion was less bitter than usual. The wholesale buyer having been informed of the fact, he immediately sent a specimen to him (Professor Bentley) to be examined. He was himself almost deceived at first sight, but on a more careful inspection he detected certain differences, and ultimately he found that it was not true chiretta at all, but an entire substitution of a drug which in India bears the name of "hill chiretta." In India there were other substances bearing that name, and it was a wonder that the article he had just alluded to had never found its way into the market previously. Since that time it had often appeared, and it was a substance as to which he should recommend particular care. True chiretta had a thin stem and a continuous yellow pith, which was at once evident when the stem was broken. In the spurious article there was scarcely any trace of pith. Another drug which had been sent to him for examination was matico, an article which was first made official when the British Pharmacopœia was first brought out. At that time, there was no such thing as true matico to be got in this country, the whole supply being used up in connection with the civil war in the United States of America. The specimen which was sent to him he found had not been obtained from *Artanthe elongata*, but from *Artanthe adunca*. This was another substance which now occasionally appeared in the market. Almost all the specimens which he obtained of these spurious or adulterated articles were sent to him by wholesale druggists when they were in doubt as to their genuineness. Saffron was a thing which he had had frequently sent to him. It was very easy to be deceived as to this substance upon casual inspection. He did not agree, however, that the presence of stamens in saffron was due to carelessness in gathering; he had no doubt that they were introduced as a systematic adulteration and not through ignorance. He should like to ask Mr. Holmes whether he had tried the specimen of jalap with ether instead of alcohol, if not, the experiment would be well worth trying. The body might contain an active resin, though it might not be the resin of jalap. There was a jalap called woody jalap; and there was the common Tampico jalap, the active resin of which was soluble in ether. It must be borne in mind that the substance now called jalapin was obtained from woody jalap. The old jalapin of Pereira was derived from the true jalap, but this was now called convolvulin.

Mr. POSTANS said that the paper illustrated the practical character of many of the papers which were read at the Evening Meetings. At present no speaker had taken up the opposite side of the question. The President had told them that there were many well-trained pharmacists distributed throughout the country, but they were chiefly the younger men, and if a discussion of this sort was not conducted with great care it would tend to get up a cry of "pure drugs and pure chemicals," more especially among medical men. If he were asked why he should put in that plea, he would refer them to page 246 of 'The Progress of Pharmacy.' It would there be found that a similar discussion arose some years ago, and it tended to become rather a bore than anything else, inasmuch as it created a certain amount of want of confidence in pharmacists generally. The subject was one which ought to be considered very carefully by the Council. The pith of the whole matter seemed to be involved in that part of the paper which said, "to prevent altogether the sale of drugs for which some use might be found, would be an act of injustice." As a Society, they must draw the line somewhere. Would they draw it at best, or would they make the question one of price? As a Society, they would have to decide that very important question.

Mr. SCHACHT said he was anxious that an observation should be made upon the sentiment which seemed to pervade the paper. Mr. Holmes seemed to imply that very little real good would come of the exposure of the wrong-doings of which the paper spoke. He should be sorry that such a statement should pass unchallenged. If exposure were not a complete remedy he would venture to say that it was the first step in the only process which commended itself to his mind for the solution of the difficulty. He could conceive no other legitimate process than thorough exposure and the diffusion of information on the subject, such as would lead pharmacists to decline to buy an inferior or spurious article merely because it was low priced. Although Mr. Holmes hinted at something stronger, he (Mr. Schacht) believed that he was aiming at the impossible, namely, the making of men virtuous by Act of Parliament. The scientific portions of such papers as the present, and the raising of discussions upon them, would be of eminent practical good in bringing about the cessation of the evil which all so much deplored.

Mr. HAMPSON said that Mr. Schacht had almost taken from his lips the words which he had intended to say. He felt sure that if statistics could be obtained it would be found that adulteration had considerably diminished rather than increased; or else the Society would not have done any service by promoting and extending pharmaceutical education. It was perhaps desirable for pharmacists to have their attention called occasionally to the evils which existed, and such an exposure as this paper brought about was most important. Further, he had no hesitation in saying that exposure was the only remedy, especially where scientific men were concerned. They needed no other distinct influences than education and their own palpable self-interest. Considering the peculiar circumstances under which many drugs were collected it was a wonder that there was not more adulteration. When a pharmacist detected an adulteration let him add it to the chamber of horrors which already existed in the Museum of the Society.

Mr. PLOWMAN said that a case of complete substitution of one drug for another had recently come under his notice. A parcel of copalchi bark had been supplied instead of cusparia bark, and there was not a single shred of the latter present. It was only right to add that the wholesale house expressed its sense of obligation to him for pointing out the substitution.

Mr. LONG sympathized with the view expressed by Mr. Postans. He hoped that it would go forth that the adulterations which had been exposed were quite exceptional and were not the rule. The Society had done an immense work, and the present condition of things was very different from that which existed when he attended Dr. Pereira's lectures. The President had said that they ought not to talk about trade questions, such as the price of the drugs, but as pharmacists could not go and gather the drugs for themselves there was, fortunately, a systematized process for supplying them. A gentleman at an examination, when asked where jalap came from, said, "It comes from the wholesale druggist in 2-pound parcels." Pharmacists were supplied by the wholesale druggists, and he was glad to find that these matters were of sufficient interest to them to induce many of them to enter the ranks of the Society. The wholesale druggists were one with the retail pharmacists, and they knew their wants and endeavoured to supply them well. There would be much more difficulty if it was not for the discrimination and care exercised in the wholesale trade. There were many wholesale men now-a-days to whom it would be futile to attempt to sell the rubbishing things which used to be offered. The drug trade was as good in England as in any part of the globe, and better than it was in some places.

Mr. ATKINS thought that the introduction of this matter for discussion had been singularly fortunate. The whole discussion had tended to produce in his mind the conviction that there had been much more smoke than fire. He had a growing belief that there was much less adulteration of drugs than had been represented by medical journals both in England and abroad. If they could exorcise this "bogey" the discussion of the subject would be of great service. He might say, however, that one of the fundamental principles of the Society was the utter condemnation and extermination of adulteration. He knew of no better means of accomplishing that result than a perfected education. It might be asserted generally that, other things being equal, a higher moral sensibility was a collateral result of a more perfected education. He believed that in the dispersion throughout the country of a trained body of men, such as was now being rapidly accomplished by the Society, the end in view was being accomplished in two ways. Not only would the trained pharmacist himself decline to receive an imperfect article or expose it if he had received it, but, if there was a black sheep in the wholesale trade who would be willing to trade upon the ignorance of others, he would be deterred from doing so by the knowledge that his fraud would be exploded.

The PRESIDENT said that he would ask Mr. Holmes to reply to the materia medica aspect of the remarks which had been made. As the speakers had not confined themselves strictly to the scientific side of the question, but had unconsciously departed from the dictum which he had laid down at the commencement of the discussion, he might be allowed to point out that pharmacists were not the only persons who bought drugs, and it would be very wrong, in a moral sense, for them to be hasty in their judgment, or to express any harsh views against wholesale dealers or brokers. It should be borne in mind that the City of London was the drug market of the world, and that there were sold there, in quantities of hundreds of tons, many drugs of which educated pharmacists did not even know the name; and therefore, wholesale druggists might be excused if they were now and then deceived.

Mr. HOLMES, referring first to Mr. Cleaver's remarks, said that he had had some years' experience in the Museum, and he could say, unhesitatingly, that he had never met with a student, who did not know the appearance of ipecacuanha root or true jalap root before he came to the Society. But he had met with many who did not know the appearance of the inferior or Tampico jalap. With reference to the incisions which were made on the specimen of jalap, it appeared to him that they were made after the root had been soaked in water, and that afterwards the root had been exhausted with benzole or petroleum spirit or something of that kind. The outside appearance seemed to indicate that some solvent had been used. With regard to Professor Bentley's remarks on matico, only during the present month he (Mr. Holmes) had seen a specimen of matico mixed with the leaves of *Artanthe adunca*, just as it occurred occasionally in commerce. As to Mr. Schacht's remarks, he (Mr. Holmes) had found that short articles, published occasionally in the Journal, respecting adulteration, did not receive as much attention as was called to the subject when the spurious articles could be seen. He had, therefore, preferred bringing forward the subject at an Evening Meeting. The President had very justly remarked that London was the drug market of the world. That being so they ought to pay some attention to the mode in which adulterations occurred. He thought that wholesale druggists would bear him out in the statement that England had perhaps fewer drug adulterations than any other country in the world. He had been told that the adulterated drugs in the London market did not, as a rule, pass into use in this country, but that the greater proportion of them went either to the continent or to South America, or elsewhere. He might safely say that when they found their way among English pharmacists, it was rather from accident than from intention; but, be that as it might, it was important that the fact should be known, especially in those cases in which the adulteration was difficult to detect.

A paper was then read, entitled—

FURTHER OBSERVATIONS ON ARSENIC.

BY W. A. H. NAYLOR AND J. O. BRAITHWAITE.

The paper is printed on p. 464 and gave rise to the following discutsion:—

The PRESIDENT said that these analytical subjects were of extreme importance both to pharmacists and to chemists generally. The statements of observers with regard to analytical results were frequently copied from manual to manual, so that if an error once crept in, it might be perpetuated for many generations. Personally, he felt very much indebted to the authors for having given them an opportunity of listening to the paper, and for having, in a former paper, discussed the action of oxalic acid upon arsenic acid. They had now somewhat completely, as he thought, dealt with the action of oxalic acid upon alkaline arseniates.

Professor ATTFIELD said, with regard to the general question which the President had just raised, that authors of manuals were the very men who would most thank gentlemen like Mr. Naylor for doing work of the kind described.

The PRESIDENT said that if there was a paucity of discussion on the present paper it must be understood to arise from the very completeness of the investigation, and not from any lack of interest in the subject. The style of work described in the paper was just that which, as President, he liked to see brought forward. It consisted of a series of experiments performed under the most careful conditions, accurately observed and thoroughly and conscientiously worked out. He was happy to say that this was the general character of that work of Mr. Naylor with which he was acquainted, and the same was true, in a minor sense, of Mr. Braithwaite, although he was a comparatively young worker in original research.

Mr. HOLMES called attention to certain specimens which were exhibited on the table. In the first place, there were some very perfect crystals of tartrate of soda prepared by a gentleman in the laboratory, whose father, Mr. Reynolds, of Leeds, was well known wherever pharmacy was known. There were also some new preparations on view, presented by Mr. E. Merck, of Darmstadt, including a sample of adonidin, the active principle obtained from *Adonis vernalis.* This substance was said to have the active properties of digitalin, but not its cumulative action. There was also a sample of tannate of cannabine, the active principle of Indian hemp. There were also two principles obtained from the lily of the valley. One, convallarin, was said to be inactive, and the other, convallamarin, was said to be the most powerful diuretic known. There was also a specimen of a new kind of eucalyptus oil. He believed the great bulk of what had been sold as the oil of *Eucalyptus globulus* was not obtained from that species, but from *Eucalyptus amygdalina.* There was now a great demand for the oil for dissolving india-rubber for making varnishes and other purposes, and the supply from that source was not equal to the demand; hence it was now proposed by Mr. Bosisto to prepare it from the species from which the oil exhibited had been distilled, *Eucalyptus dumosa*, which could be obtained in unlimited quantity. This oil possessed the same solvent properties as that from *E. amygdalina.* There was also a specimen, presented by Mr. Warrick, of the oil of *Eucalyptus globulus*, prepared from the leaves of the plant at Grasse. He had also to call attention to some specimens which consisted of some species of cuprea bark, presented through Dr. Paul, by Mr. Parisot, a gentleman who had recently brought them to this country from Columbia. They came from a new district, from which, probably, much larger quantities would come by-and-by. There was also on the table a specimen of the Dyak arrow poison used in Borneo. He believed that there was some difficulty in obtaining it. The present samples came from Mr. Jamie, of Singapore, who took much interest in the work of the Society. He had sent with the specimens an interesting note, in which it was stated that the poison was prepared, as far as could be learnt, from the leaf of a creeper in Borneo. The leaf was rubbed down in water into a sort of paste, and mixed with a kind of gum. All the tribes did not prepare it in the same way. Many of them used the poison of snakes in connection with this poison. Mr. Jamie stated that the late Rajah Sir James Brooke, when cases of poisoning occurred to his soldiers, used to give them intoxicating liquor until they were drunk, and that treatment generally saved their lives. The same remedy was also used in Mexico as an antidote. Perhaps there was no better antidote for snake poison than alcohol.

The PRESIDENT announced that the next meeting would be held on February 7, 1883.

Provincial Transactions.

BRISTOL PHARMACEUTICAL ASSOCIATION.

A meeting of the pharmacists of Bristol and the neighbourhood was held at the Museum and Library on Friday, November 24, for the purpose of discussing the recent action of the Pharmaceutical Society of Great Britain in respect of certain proposed modifications in the conditions for examination of future candidates for for pharmacy. Mr. Schacht, the President of the local Association, occupied the chair.

The Chairman, in opening the proceedings, explained that the cause which had forced the Council of the Pharmaceutical Society to a consideration of this subject was the continually recurring evidence of the deficiency of proper training with which so many candidates presented themselves for the examinations, and which rendered the conduct of those examinations so difficult and so unsatisfactory to all concerned in them. He begged the meeting to believe that the single idea in the mind of the Council throughout all its inquiries and deliberations had been to devise a scheme which should promote a more general state of efficient qualification amongst those who aspired to the important work of pharmacy; and as a necessary consequence to enable the student to regard the pharmaceutical examinations no longer as a stumbling block in his path, but simply as the stamp of his qualification. It had not aimed at any undue exaltation of the standard of scientific attainment in the pharmacist, but rather that the standard now admitted to be requisite for the proper fulfilment of duty should be more generally achieved and more certainly secured. Many of the details of the proposed scheme were, as they knew, published in the *Pharmaceutical Journal* of April 15th of this year, and the chief points of the scheme as at present matured were:—1st. That one of the recognized examinations in arts be passed by the candidate prior to the commencement of his apprenticeship or pupilage. 2nd. That a period of at least three years be then spent as pupil to a registered pharmacist; after which, the first portion of a technical examination be passed. 3rd. That at least one year more be then spent in further work and laboratory practice. 4th. That during these four years (or more) certain courses of lectures on chemistry, botany, and materia medica, and a practical course of instruction in a chemical laboratory—as defined by the Council, and for convenience called "a curriculum of study"—be attended. 5th. That when all this has been fulfilled, the candidate present himself for the final portion of the qualifying examination. He did not mean to state that every point he had named had, as yet, been fully adopted by the Council, but that such was the direction in which opinion was moving, and he should be glad to hear what was thought of the whole matter by those then present.

Mr. Berry inquired if the Council of the Pharmaceutical Society, in view of its own efforts to enforce a compulsory curriculum, was prepared to offer substantial aid to provincial centres of education.

Mr. Towerzey thought that most probably ample instruction in chemistry and botany could be obtained at the scientific institutions already established in many of the larger provincial towns; but he was afraid the subject of materia medica was nowhere taught out of London as the Council required it to be taught.

Mr. Toone (of Bath) wished to urge a consideration which had long occupied his thoughts. It seemed to him unfortunate that the authorities should so completely lose sight of the student during the three years of his pupilage. He felt inclined to urge that a students' examination be held annually, as a method of keeping alive their interest in scientific knowledge and as an inducement to work.

Mr. Keevil regarded such duties as belonging rather to the master than to any outside authority. He was afraid the contemplated changes would press hardly upon country apprentices, nevertheless he was bound to admit them to be changes in the right direction. It would certainly be a great convenience to all provincial students if the first portion of the pass examination could be held at certain provincial centres as well as in London.

Mr. Isaac supported the idea that the Pharmaceutical Society should assist in providing, if it did not altogether provide, good lecture teaching at a certain number of well-selected centres in the provinces.

Mr. Wretts was of the same opinion, especially in regard to the subject of materia medica, which he thought was little likely to be taught at ordinary science schools or colleges unless subsidised and supervised by the Pharmaceutical Society.

Mr. Towerzey repeated the opinion that the Society ought to endow a certain number of chairs of materia medica throughout the provinces. It appeared to him that unless it was prepared to do something of this sort for the general benefit of pharmacy its plain duty was to discontinue its endowment of the School at Bloomsbury Square.

Mr. White warmly advocated the institution of a "curriculum." He could not admit that its being made compulsory inflicted hardship upon anyone, not even the country apprentice; for it would be strange to call that a hardship which entailed upon its supposed victims nothing but benefit. With regard to the supply of provincial teaching he thought they might fairly expect that to appear when the requisite demand arose.

Mr. Keevil suggested that the work in the practical laboratory might with advantage be distributed over a longer time than laid down in the syllabus; it might be well to say the time should not be less than four months, but he thought that should be the only limiting expression.

Mr. Algernon Warren expressed approval of the changes proposed by the Council, and thought that any possible increase of difficulty they might entail on the country apprentice would be compensated by the arrangement suggested, of dividing the examination into two portions and holding the former at a number of provincial centres.

The Chairman replied generally to the several speakers upon the points raised, and answered a number of questions.

The following resolutions were then proposed, seconded and carried unanimously:—

"1. That this meeting approves the principle of a compulsory curriculum of study for all future candidates for pharmacy."

"2. That this meeting approves the action of the Council of the Pharmaceutical Society of Great Britain in respect of the proposed modifications of the conditions for the examination of future candidates for pharmacy, as far as that action has been made public."

"3. That this meeting is of opinion that it would add greatly to the convenience of examinees if such portions of the examination as can be properly conducted by the written process were held at certain provincial centres as well as in London and Edinburgh."

A vote of thanks to the Chairman concluded the proceedings.

Erratum.—On p. 406, col. ii., line 11 from bottom, as the name of the gentleman appointed Sheriff of Poole, *for* "Mr. T. W. Atkinson" *read* "Mr. T. W. Atkins."

Mr. Rotter.—Your letter, which should have been sent direct to the Editor instead of through the Publishers, was received too late to allow of dealing with it in the present number.

A Proposal as to Lectures.

Sir,—Now that the business of the various societies in London has fairly commenced, is it too much to ask that our professors should entertain the members occasionally with lectures on some popular topic connected with science; or are such discourses left entirely in the hands of the Committees of the Royal Institution and the Society of Arts? Surely it is time that the theatre at Bloomsbury Square and the latent power at number seventeen should be turned to use on behalf of the members in some such manner as that described. This, I believe, would be wise; and I will add still more, that, in my opinion, such reunions would tend greatly to cement together in the kindly feeling of one common brotherhood many who might not otherwise be drawn within the circle of membership. Cowper says:—

> "Knowledge and wisdom, far from being one,
> Have oft times no connexion. Knowledge dwells
> In heads replete with thoughts of other men;
> Wisdom in minds attentive to their own.
> Knowledge is proud, that he has learnt so much;
> Wisdom is humble, that he knows no more."

35, *Baker Street, W.* A. W. Postans.

The Death of Mr. Cyrus Buott.

Sir,—It is my melancholy duty to announce the death of Mr. Cyrus Buott, late Secretary of the United Society of Chemists and Druggists. He was released from his sufferings on November 26, at the ripe age of 82 years.

Both he and his devoted daughter frequently expressed their gratitude for the kindness and generosity of those who contributed to their support during a period of struggle and distress. And Mr. Buott, shortly before he died, earnestly requested that I should give public expression to those feelings. I, too, have to express my gratitude that I have been privileged, by the sympathetic co-operation of many generous friends, to give kindly aid to Mr. Buott. Appended is a final statement of the donations I have received since my last acknowledgment. I need scarcely say that all sums that have been sent have been safely and carefully disbursed.

I most sincerely thank all those who united with me in this benevolent transaction. They with me have experienced the joy of doing a little good.

205, *St. John Street Road, E.C.* Robert Hampson.

T. P. Jones.—By keeping them for a time in a closed space together with some odorous substances, such as are used in the preparation of sachets.

Communications, Letters, etc., have been received from Messrs. Hayward, Abraham, Shenstone, Bell, Spiller, Ward, Law, K. K., E. T. D., D. M. P., 1878, Sinapis, Subacet., Suburban.

THE NEW PHARMACOPŒIAS FOR THE UNITED STATES AND GERMANY.

Either of the two pharmacopœias that have been almost simultaneously issued, one for use in Germany and the other in the United States, is of sufficient importance and interest to British pharmacists to justify its being considered separately, and indeed in some aspects they have so little in common that they cannot be treated other than independently. Nevertheless, as there exists just now some desire for the greatest possible approximation to uniformity in the different pharmacopœias, at least in respect to the more potent drugs and preparations, it seems desirable to utilize the opportunity for observing what, if any, progress has been made in this direction in these two works, and whether they present any common ground which is favourable to further advance in connection with the preparation of other works of a similar nature. It is therefore proposed to discuss the principal features of the two pharmacopœias in one series of papers, this plan appearing to be the most convenient for those parts which allow of comparative treatment.

Before proceeding to consider in detail the contents of the new volumes, it will be as well to notice the conditions under which they have been produced, and this will involve a brief historical sketch, not without significance in relation to the very important subject of the supervision of pharmacopœias generally.

The first national United States Pharmacopœia was published in December, 1820. Before that time, as we learn from the Preface of that work, a number of pharmacopœias, and "dispensatories" founded upon them, had been produced in different parts of the Union, and various foreign works of the kind had been imported, some of which had become naturalized by republication in the country. The medical practitioners and druggists had supplied themselves with one or other of these books, and as a consequence the character of medicinal preparations was liable to vary in every state and city in the Union. Moved by this condition of affairs, Dr. Lyman Spalding, in the year 1817, submitted to the New York County Medical Society a project for the formation of a national pharmacopœia based on the authority of all the medical schools and medical societies in the United States. As a first step he proposed that the States and territories should be divided into four districts,—northern, middle, southern and western,—and that in each district a convention should be held, consisting of delegates from all incorporated medical bodies, or, failing the existence of any such in a state, from voluntary associations of physicians and surgeons; the primary business of each convention was to be to form a pharmacopœia, and then to select delegates to attend a general convention in Washington and aid in compiling from the four district pharmacopœias one national work. This plan was in the main adhered to, and the general convention entered upon its task on the 1st of January, 1820, under the presidency of Dr. Samuel L. Mitchell. Only three out of the four districts,—the northern, middle and southern,—appear to have been represented, and only the northern and middle districts submitted pharmacopœias. These, however, were compared, supplemented, and consolidated into one work, which was published at the end of the year. It was written entirely in English; but the nomenclature and all the essential parts were presented also in Latin, on the ground that, as no well-educated physician or apothecary was unacquainted with that tongue, the book might thus be rendered more intelligible to foreigners, and more useful in those districts of the United States where the French and German languages were spoken. From the foregoing it will, therefore, be seen that the United States Pharmacopœia was at its inception under purely *medical* auspices. Moreover it was and has continued to be a volunteer work, not having its origin in any legal enactment and not having any authority beyond what it may derive through the measure of acceptance granted to it by medical practitioners and pharmacists throughout the country, and the reference to it as a standard for the purity of drugs in Adulteration Acts that have been passed in some of the states.

Before adjourning, the Convention, having in view the revision of the work that would become necessary with the lapse of time, instructed its President to take preliminary steps in 1828 for holding a General Convention in Washington in 1830, to consist of three delegates from each of the four divisions, chosen by the medical colleges. Through some misunderstanding of the rather elaborate provisions as to the election, delegates from the northern and middle districts only were duly returned, and these formed the nucleus of a Convention which prepared a revised pharmacopœia that was published in New York in 1830. But the medical interests in the middle district being still unsatisfied, a fresh Convention was called, which authorized the publication of another revised pharmacopœia in Philadelphia in the following year.

The next Pharmacopœia Convention was held in Washington in 1840 and consisted entirely of delegates from incorporated medical societies and colleges. But a communication from the College of Physicians of Philadelphia having been accepted as a proper basis for a revised pharmacopœia, it was referred to a committee consisting of seven members to be worked out, with authority to the committee to request the co-operation of *colleges of pharmacy.* Invitations were accordingly addressed to the Presidents of the Colleges of Pharmacy of Boston, New York and Philadelphia, and these were responded to favourably; indeed the contribution offered by the Philadelphia college was so important that its proper consideration involved a delay in the publication of the new work until 1842. One notable point in which the United States Pharmacopœia of 1849—the first in which the pharmacists of the country took part—differed from its predecessors, was the abandonment of the duplicate descriptions in Latin, as presenting "no sufficient practical advantage to counterbalance the inconvenience of attempting to present ideas in a language which has no appropriate words to express them, and the labour and expense incurred in printing twice as much matter as is necessary to convey the meaning intended." The then recent publication of the French Codex and the Edinburgh Pharmacopœia in the vernacular languages of their respective countries was quoted as giving sanction to this course. Another point was the introduction of the "mode of filtration denominated as *displacement*" as an alternative process in the preparation of some of the vinegars, extracts, infusions and tinctures.

In making arrangements for the Convention in 1850, it was decided that invitations to send delegates should be forwarded to the incorporated colleges of pharmacy at the same time as others were sent to the medical colleges. Consequently, the New York and Philadelphia colleges were represented in the General Convention as well as in the committee entrusted with the work of revision and publication. A similar course was adopted in 1860, when the number of colleges represented was four, whilst the American Pharmaceutical Association contributed some suggestions. In the fifth decennial Convention, held in 1870, the number of colleges of pharmacy represented was further increased to eight.

But on no previous occasion have pharmacists taken so prominent a share in the revision of the United States Pharmacopœia as in the work just completed. No less than twenty-six delegates from eleven incorporated colleges of pharmacy attended the Convention; from these were selected fifteen out of twenty-five members of the committee appointed to carry out the work, the Chairman of the Committee, Dr. Rice, the two Vice-Chairmen, Messrs. Remington and Diehl, the Secretary, Mr. Bedford, and the Treasurer, Mr. Doliber, being all pharmacists. No doubt this pharmaceutical preponderance is attributable to some events that had taken place in the interval between this and the previous Convention. In 1876, Dr. Squibb, considering that the work necessary for the proper revision of a pharmacopœia could not be done by a special Convention, meeting at intervals of ten years, and moreover thinking that body, as hitherto constituted, was not sufficiently representative to be the fit custodian of the interests involved in the preparation of a national pharmacopœia, advocated an entirely new departure. The proposition of Dr. Squibb was that the revision should henceforth be placed under the charge and authority of the American Medical Association, as the representative body of the medical profession in the United States, with the understanding that the Association, whilst maintaining the control, should invite the active co-operation of the American Pharmaceutical Association. The Medical Association however declined to undertake the task, and in consequence the subject subsequently came under the consideration of the American Pharmaceutical Association during its meeting in Toronto, in 1877, when a committee was appointed to consider the advisability and feasibility of the Association arranging to draw up a complete pharmacopœia, which might be submitted to the criticisms of the medical and pharmaceutical professions and proposed to the final committee of revision. The report being in the affirmative a committee was appointed to carry out the work; but it eventually became evident that the original plan, to construct a complete pharmacopœia, was impracticable. A large quantity of valuable material was, however, collected, and this was presented at the meeting of the Pharmaceutical Association in 1879 in the form of a report, which was printed at the expense of different colleges and societies there represented. This report exercised a considerable influence upon the revision which has just been completed, and Dr. Charles Rice, who in his capacity as Chairman of the Committee drew it up, was also chosen to preside over the Committee of Revision appointed by the Convention. It is this report that is occasionally referred to in the succeeding articles.

Turning now to the European work under notice, it may be said that all the inconveniences arising from a multiplicity of pharmacopœias existed in Germany long after a national work had been accomplished in the United States. For as recently as twenty years since there were no less than ten different pharmacopœias, each being an authoritative text book in one or more German-speaking states. Indeed the first edition of the official 'Pharmacopœa Germanica' did not appear until 1872, having been drawn up by a committee acting under the authority of a decree of the Federal Council, issued immediately after the establishment of the German empire. This Pharmacopœia was not, however, original in the full sense of the word; nor was it the intention of the Committee to produce a new work. According to the Latin Preface, the main object of the Committee was to collate the formulæ in the different pharmacopœias existing in Germany, to remodel the 'Pharmacopœa Borussica' and the 'Pharmacopœa Germaniæ,' and to take into account the recognized pharmacopœias of South Germany.

In order to trace the true origin of the 'Pharmacopœa Germanica,' it is necessary to go back to a scheme for replacing the ten existing pharmacopœias by one complete and inclusive work which was worked out by nine pharmacists belonging to North and South Germany and Austria, and laid before the First International Pharmaceutical Congress, held at Brunswick, in 1865. The Congress sanctioned the printing of the scheme as a 'Pharmacopœa Germaniæ,' and the cost was covered by subscriptions. The subject appears to have been afterwards taken up jointly by the Pharmaceutical Association of North Germany and the Pharmaceutical Association of South Germany, under whose auspices alterations and improvements were made and a work was drawn up intended to be used as a national pharmacopœia in the place of the diverse pharmacopœias that were then in use in the different German states. This work was published in 1867, under the title of 'Pharmacopœa Germaniæ: Editio Altera.' It of course had no legal authority, though copies of it were forwarded to the governments of the various states for consideration and formal adoption, if approved of. But the North German Confederation, having by this time taken the place of the more loosely bound Germanic Confederation, the authorities of Mecklenburg-Schwerin called the attention of the Federal Council to the want of an authoritative national pharmacopœia, and that body in December, 1868, resolved that a committee of medical men and pharmacists should be charged with the execution of the work. The committee met in May, 1869, and determined to utilize the 'Pharmacopœa Germaniæ' which had been produced by the two great Pharmaceutical Associations of the country, together with the 'Pharmacopœa Borussica,' and to consult the medical men and pharmacists of repute and authority throughout the North German Confederation, as to the materia medica and preparations to be included. The work of the committee was, however, interrupted by the breaking out of the Franco-German war, and when this was over, the task that had to be confronted was the compilation of a national pharmacopœia for the whole of Germany, instead of for a part of it.

In 1871 a new committee was appointed, consisting of representatives of repute in the different departments of science from all parts of Germany. The work was commenced in September and brought to a close in December of the same year, and under the title of the 'Pharmacopœa Germanica,' by virtue of a resolution of the Federal Council of the Empire, passed in May, 1872, it took the place of the different pharmacopœias in use in the several states of the empire from the first day of November following. It will, therefore, be seen that from the very commencement of its history pharmacists played a very important part in the production of the first authoritative 'Pharmacopœa Germanica.'

But the interests of German pharmacists in the national pharmacopœia did not cease with its official recognition. Six years afterwards, the necessity for revision having become apparent, the German Pharmaceutical Association,—having then become the representative of the two separate associations for North and South Germany,—during its meeting at Coblentz, in 1878, nominated a Committee, of which Dr. Brunnengräber was chosen chairman, to consider suggestions for the improvement of the 'Pharmacopœa Germanica.' In the same year the Federal Council decided that a revised edition of the pharmacopœia should be published in 1882, or ten years after the publication of the original work, and that the task of preparing it should be entrusted to a Commission consisting of twelve physicians, six pharmacologists, six chemists, and six pharmacists, aided by two military doctors and a military pharmacist of superior rank, deputed by the Prussian War Office. About the same time the Imperial Chancellary sent out invitations to the different governments to obtain opinions from persons interested as to deficiencies that had become manifest during the use of the work, and after some negotiations a report drawn up by the Committee appointed by the Pharmaceutical Association was, at the request of the Government, placed at the disposal of the Imperial Sanitary Department. It is the result of the labours of the Commission thus appointed and assisted that has been recently issued under the title of 'Pharmacopœa Germanica: Editio Altera,' and which is to come into force, by Imperial decree, as the official *Arzneibuch* in the German Empire from the first day of January next.

(*To be continued.*)

A NEW METHOD OF MANUFACTURING SODIUM SULPHIDE.*

BY W. WELDON.

The question of how to manufacture sodium sulphide has occupied the attention of industrial chemists from almost the dawn of what we now understand by industrial chemistry down to our own time. Till recently, the object with which this question was studied was that of modifying the Leblanc soda-process in such wise as to avoid the production of the very undesirable residue of that process, and at the same time to permit of the sulphur of the sulphuric acid used in that process being perpetually recovered for use again. All attempts, however, so to modify the Leblanc process that sodium sulphide shall be its intermediate product, instead of "black-ash," have been unsuccessful; and although for nearly a century every successive failure to do that was followed, after a short interval, by fresh efforts to the same end, it is probable that the idea of converting sodium chloride into sodium carbonate by way of the intermediate production of sodium sulphide has now at last been definitively abandoned. On the one hand, the success of what is known as the "ammonia process," and, on the other hand, the probable realization of new methods of dealing with the residue of the Leblanc process for the recovery of sulphur therefrom, together with the discovery, made by myself some years ago, of the unexpected fact that sodium sulphide, pure enough to yield by treatment with CO_2 sodium carbonate uncontaminated with free sulphur, is absolutely infusible by any method which can be applied industrially, would seem to render all further attempts to realize a sodium sulphide soda-process quite out of the question.

Meanwhile, a demand has arisen for sodium sulphide as a substantive product. There is a demand for it for use in connection with tanning, for use in connection with bleaching jute, for use in the manufacture of pigments consisting in part of sulphide of zinc, and for various other purposes; and this demand has led to the realization of the method of producing it industrially by the wet way which I will now proceed to describe. The method in question is due to Mr. Helbig, of the great chemical works of Aussig, in Bohemia, the co-inventor with Dr. Schaffner of the method of recovering sulphur from alkali-waste. It is already in industrial operation at Aussig, and will shortly be in industrial operation in this country also, at the works of Messrs. J. C. Gamble and Son, at St. Helens.

When the residual product of the Leblanc process, known as "alkali-waste," is digested with water under a pressure of about five atmospheres, reaction takes place between some of the water and the greater portion of the calcium sulphide of the alkali-waste, in accordance with the equation:—

$$2\,CaS + 2\,H_2O = CaH_2O_2 + CaH_2S_2.$$

There is thus obtained a solution of calcium sulphydrate, capable of reacting on sodium sulphate, to give calcium sulphate and sodium sulphydrate:—

$$CaH_2S_2 + Na_2SO_4 = CaSO_4 + 2\,NaHS.$$

Up to this point I managed to get myself, some years ago, in some experiments conducted at Mr. Brock's works at Widnes; but I could not see how to get any further. That is to say, having obtained a solution of sodium sulphydrate by heating with water under pressure a mixture of alkali-waste and sodium sulphate, I did not see how to convert the sodium sulphydrate into sodium sulphide. The reaction so constantly in use in laboratories,

$$NaHS + NaHO = H_2O + Na_2S,$$

was of course obvious enough; but I could not see how to apply it except by using previously manufactured caustic soda, and to use previously manufactured caustic soda as a raw material for the production of sodium sulphide for industrial applications was, of course, out of the question. Mr. Helbig, however, does use caustic soda to react upon his sodium sulphydrate; but he does not use previously manufactured caustic soda. He obtains what he calls "a passing formation" of caustic soda in what seems to me a very ingenious and elegant and at the same time a very simple way.

Crude Leblanc soda, or "black-ash," as it is called in this country, consists essentially of a mixture of sodium carbonate and calcium sulphide. We have seen that calcium sulphide, when heated with water under pressure, gives two products, one of which is calcium hydrate; and we know that calcium hydrate can react on sodium carbonate to form calcium carbonate and caustic soda. Mr. Helbig takes advantage of this last mentioned fact by adding a certain quantity of black-ash to the mixture of sodium sulphate and alkali-waste which he digests with water. The reactions which then take place no doubt take place practically simultaneously, but they may be most readily explained by supposing them to take place successively: by supposing, that is to say, that water and calcium sulphide first react on each other, producing calcium hydrate and sulphydrate, that the

* From the *Journal of the Society of Chemical Industry*, November 29, 1882.

calcium sulphide so produced then reacts on sodium sulphate, giving calcium sulphate and sodium sulphydrate, that the calcium hydrate, which is one of the products of the first reaction, then reacts on the sodium carbonate of the black-ash, producing calcium carbonate and caustic soda, and that the caustic soda so produced and the sodium sulphydrate previously formed then react on each other and are both converted into sodium sulphide. The sum of these reactions may be represented by the equation:—

$$2CaS + Na_2SO_4 + Na_2CO_3 = CaCO_3 + CaSO_4 + 2Na_2S.$$

The operation is performed in iron digesters furnished with mechanical agitators—which are kept in motion throughout the operation—and heated by injection of steam. What is drawn off from the digesters when the operation in them is complete is a solution of sodium sulphide holding in suspension various solid matters. These having been separated by filtration, the solution is evaporated till its density has become about 32° Beaumé. During this evaporation any salts other than Na_2S which may have been originally present fall and are fished out. The concentrated solution is then allowed to cool, when it gives crystals of the hydrated salt, $Na_2S,9H_2O$.

Just two points more require to be mentioned. It is obvious that in the process just described the sodium sulphate might be replaced by sodium carbonate—in other words by more black-ash. The reactions in that case would all be the same as those I have enumerated, except that the sodium sulphydrate would be formed by the reaction of sodium carbonate upon calcium sulphydrate. As the value of sodium carbonate in the state of black-ash is not very much greater than that of sodium sulphate, Mr. Helbig at present prefers that all the sodium used in the process should go into it as carbonate; so that he now really uses, not a mixture of sodium sulphate, black-ash, and alkali-waste, but a mixture of black-ash and alkali-waste only. The reason for this preference is that a much lower pressure suffices to bring about the required reactions when using the latter mixture than when using the former.

The other point is curious. Just as the text-books say that sodium sulphide is a readily fusible body, so they say that crystallized sodium sulphide readily absorbs oxygen on exposure to the air; and just as I have found that pure sodium sulphide cannot be fused at all, on the large scale, in closed vessels made of a material on which Na_2S has no chemical action, so Mr. Helbig has found that crystallized sodium sulphide, as produced by his method, absorbs oxygen on exposure to the air only very slowly indeed. The difference between its behaviour in this respect and that of sodium sulphide made in other ways Mr. Helbig attributes to the latter always containing small quantities of caustic soda, whereas his crystals are quite free from caustic soda.

ATOMS AND MOLECULES.*

BY BARNARD S. PROCTOR.

The most important function of the President of a Chemical Society is to stimulate the chemical activity of the members by an action parallel to catalysis.

By his own molecular activity he should bring into play the affinities which are capable of developing new matter, without himself entering into combination with other molecules, in such a way as to deprive them of their individuality.

This function of your leading officer is much more easily exercised when his habitual work is intimately associated, either practically or theoretically, with the daily occupations of the members in general.

Unfortunately this is less the case with me than with any of the gentlemen who have filled this office before me. On this account I shall have to claim a large share of your indulgence and assistance.

Looking back a year, our society has lost two of its most eminent members, one distinguished for his extensive acquaintance with the chemical resources of the district, and the readiness with which he became the exponent and historian of its technology. The other, pursuing the paths of pure science, occupied a position of vantage not practically within the reach of technical chemists. A position which enabled him to meet each of us as an equal on our own ground.

It will be impossible for me to interest you as the former would have done by reviewing the technical changes of the past, and the prospects of the future for chemical manufacturers, or to trace the development of chemical laws, and recount the discoveries of recent years as would have been an easy task to the latter; but as every man's experience, and every man's train of thought has necessarily something of individuality to distinguish it from that of his fellows, and as each may profit to some extent by noting the facts or the fancies of his fellows, I will endeavour to lead you as it were on a holiday excursion, away from the technical department of our studies, where everything turns on the pivot of cost, and away from the purely scientific side, where all is excluded but experimental investigation and mathematical law.

I desire for the present to get beyond the walls of the shop, and the boundaries of the college. I desire to feel the freedom in which the schoolboy rejoices who has escaped from the customary restraint. I wish to be at liberty to say things which may be fanciful or imaginative, but I trust not foolish. Fancy has its duties in philosophy, though not in science. Fancy developes a multitude of half-truths, which by the treatment of science are decomposed, evolving an atom of truth and eliminating an atom of error; so truth is established, which would have lain dormant had not fancy thrown down the gauntlet to science. Our speculations are evolved by the philosophical use of the imagination, from the unsystematized truths which may be regarded as the waste material of science. Professor Mills says:—"The roadway on which chemistry now runs has been elevated by the rubbish of at least two thousand years."* It is my ambition now to scrape together a little heap of such rubbish.

It seems to be the natural desire of a chemist to see with his mind's eye the atoms and molecules, which can no more be seen through the microscope than by the unaided eye. While endeavouring thus to see the constitution of matter, we are told on the one hand that we may relieve ourselves from the idea of matter altogether, and be content with resolving all things into force;† and on the other hand we are told that force, in all its many manifestations, may be resolved into matter and motion. We are told at one time that force cannot act at a distance, that attractions are all resolvable into the effects of impacts of molecules in motion; and at another we are told that the molecules of solid bodies do not touch one another, the space occupied by the actual matter being small compared with the space separating the atoms from one another. We are told that attraction, as hitherto understood, is irrational because it is inconceivable. It is pointed to as an absurdity that force should throw out its boat-hooks, and draw two masses of matter together. To my mind the conception of a repelling force is just as difficult as an attracting, and I am compelled to admit that, where both are inconceivable, there is not much to determine us in rejecting one if we cannot equally do without the other. But we may dismiss them both, repulsion most simply by supposing it to result from the rebounding of atoms in collision; and we get rid of the idea of

* Presidential Address delivered before the Newcastle-upon-Tyne Chemical Society.

* *Phil. Mag.*, January, 1876.

† *E.g.*, Sir W. G. Armstrong, British Association Address, 1863, etc.

attraction by a speculation just one step more complicated, in supposing it to be caused by the collisions of atoms preponderating in one direction, the attracting bodies shielding one another on one side, and so being forced together by the impact of atoms on the opposite sides; but for these speculations to be entertained, we have to assume that atoms can pass through masses with nearly perfect freedom, which does not accord with our usual ideas of matter. To help us in our craving for an explanation of everything, the existence of a luminiferous ether is assumed, and it is endowed with hypothetical properties to suit every difficulty. It is assigned a position intermediate between matter and force. It is supposed to fill all space, and penetrate all bodies. It is supposed to be the basis, the physical basis perhaps we might say, of heat, light, electricity, magnetism, etc. Its movements are supposed to be the cause of polarity and induction. Perhaps they *are*, if the ether has any existence. On the present occasion, as I have stipulated for a full play of the imagination, we will assume the existence of the ether, the existence of matter, of atoms, of molecules, of spaces between them, of repulsions, attractions, polarities, molecular movements, and whatever else the exigencies of the moment demand.

The middle-aged chemist of the present day was taught in his youth that the general properties of matter included ponderability, size, shape. etc. That matter was distinguished from immaterial forces by its ponderability, the forces being spoken of as imponderable agents, though the expressions were often used somewhat indefinitely.

Gmelin ('Handbook,' page 2) speaks of the imponderables as *bodies*. Miller, without making the statement in so many words, evidently assumes that "bodies" or matter must be possessed of weight. ('Elements of Chemistry,' 1865.) In looking over these and other books which I reverenced as unquestionable authorities, quarter of a century ago, I feel tempted to put marginal queries to many paragraphs which point to questionable conclusions.

I propose to take as my starting point two or three of these marked passages—passages which will probably retain their position and authority for many years to come, but which, nevertheless, do not harmonize with more recent experience or modes of thought.

Turning to Miller's 'Elements' (vol. i., page 65), the phenomena of solution are explained as the result of the adhesion of the solvent to the solved, overcoming the cohesion of the latter. This can scarcely be regarded as an explanation, but even if viewed simply as a statement it is far from being satisfactory. If we accept the common meaning of the word adhesion, that is "sticking to," it can scarcely be admitted that a liquid sticking to a solid explains its disintegration. Nor is it much more satisfactory as an explanation, though it may be more correct as a statement, to say that the force which commonly manifests itself as cohesion is overcome by another force which commonly manifests itself as adhesion. Cohesion and adhesion may fairly be regarded as effects or manifestations of some form of force, but in a critical inquiry it is necessary to avoid confusion between a force itself and the phenomena by which that force is made manifest. It is scarcely a philosophical statement to say that a powdered substance dissolves more quickly "from the partial destruction of cohesion." Nor can we very readily admit that there is less adhesion between a crystal of sugar and a saturated syrup than between the same crystal and water, how then can we say that solution of the crystal takes place in consequence of the force of adhesion between it and the water in which it is immersed, and that the crystal remains unacted on by the syrup from the absence of adhesion between a material and its saturated solution?

When a supersaturated solution deposits a crystal, the cohesion is said to overcome the adhesion acting between the solvent and the substance of the crystal, but it can scarcely be admitted that cohesion proper comes into existence till the separation has taken place, though it might be correct to say that the *force which causes cohesion* has caused the separation of the solid from its solvent.

This would naturally lead to the question—"What is the nature of the force which causes cohesion?"

Gmelin ('Handbook,' i., 38) says, "If the insolubility of crystallized alumina arose from its cohesion being greater than its affinity for the acid, it ought not to dissolve in the acid after being ignited with potash, but to separate in consequence of its greater cohesion after the potash has been dissolved in the acid." In such a case as this I should say the cohesion of alumina no longer existed. It had been destroyed by the potash; not that any matter nor any force had been destroyed, but that one effect of a force had been destroyed by the diversion of the force to the production of another effect.

We may suppose the crystalline cohesion of the alumina was the effect of a polarity of its molecules which determined their set in the regular crystalline form; a polarity which is not destroyed by fusion with potash, or by union with acids, but which is satisfied or temporarily neutralized by any of these conditions. The polarity which causes crystallization at one time effects union with acids at another. A confusion arises through regarding cohesion as a force, rather than the effect of a force. Probably cohesion and adhesion differ only in name, the force being the same. We call it cohesion when it causes two molecules of the same nature to join, and adhesion when the effect is the joining of two molecules of different natures. Let us assume that molecules are endowed with polarities, which are the cause of crystallization, cohesion, adhesion, solution, etc.,—polarities which, like magnetism, are satisfied by meeting with equal and opposite polarities. Let us assume that molecules may have several axes of polarity which may differ much or little in intensity; we may speculate that viscosity is caused by a *multipolar* attraction of approximately equal intensities in different axes, and of a strength intermediate between those existing in solid and liquid states. We may suppose that mobility is the result of equality and feebleness of multipolar attractions; that the colloid state is consequent on equality with strength of multipolar force; that a crystalloid has strong and unequal polar forces which determine the arrangement of the molecules in the lines of their strongest polarities. We may suppose, when sulphate of soda or any other salt dissolves in water, that the polarity of its molecules is satisfied by the attraction of so much water as is required to make a saturated solution; and this polarity being satisfied, further water is miscible with it in all proportions. The greater solubility at higher temperatures probably arises from a weakening of the polarities as the effect of heat, an effect which is evident to us in the case of magnetism in iron. The stronger polarities probably diminish in greater degree than the weaker till fusion takes place, when the forces are approximately equal in all directions, and further diminish as temperature rises, till volatilization is effected, when molecular attraction seems to vanish altogether. This all appears reasonable enough in the case of sulphate of soda and water where the proportion between the salt and the solvent is such that we may suppose the molecules engaged on the phenomena are within the sphere of probable attraction; but when we come to such salts as chloride of silver, sulphate of baryta, etc., how can we suppose that one molecule of the salt can come within the sphere of attraction of so many molecules of water as are required for its solution? This has appeared to me a difficulty in all the theories of solution commonly propounded. If 100 molecules of water by their adhesion cannot overcome the cohesion of 2 molecules of sulphate of baryta, how is it likely that 1000 or 10,000 can attack the particle at the same moment?

How can we conceive of 1 molecule of chloride of silver being maintained in solution by its adhesion to 100,000 molecules of water? And the adhesion of 50,000 molecules of water is insufficient to restrain it from union with some other molecule of chloride of silver which may be adhering to 50,000 contiguous molecules of water?

Hydrogen dissolves in 50 volumes of water, or by weight, 1 in 12,500, or by atoms, 1 in 1400; probably this is much the same as saying that the molecules find freer space for their movements between the molecules of fluid water, than between those of the atmosphere of gaseous hydrogen from which the solution is taking place. The active movements in the hydrogen atmosphere tend to throw out molecules into any space freer than the atmosphere, and will so throw hydrogen into the water till the water is as crowded with hydrogen molecules as the hydrogen atmosphere itself, and then it is probable that interchanges will take place, but the number of molecules thrown into the water will be just equal to those thrown back from the water into the hydrogen atmosphere, and so there will be maintained a definite relationship between the proportion of hydrogen "absorbed" or "dissolved" by the water, and the temperature and pressure of the hydrogen atmosphere in contact with it. This doctrine is so nearly the common one in reference to gas and water that my statement is like an oft-told tale. But if we apply the same idea to the solution of chloride of silver it affords us at least some material for thought and speculation. The quantity of chloride of silver in its saturated solution in water is less than the quantity of air in an equal space of an ordinary air-pump vacuum, but more than in the high vacua used for radiometers or Swan lamps.

A cubic inch of air, attenuated to the thousandth of an atmosphere contains $\frac{3}{10000}$ of a grain of N and O. A cubic inch of saturated solution of chloride of silver contains about $\frac{2}{100000}$ of a grain of Ag Cl. But the highest authorities tell us that even in the most perfect vacua attainable, the molecules are crowded almost inconceivably closely together and in numbers quite beyond our powers of thought. The limit of solubility seems more probably determined by the relation of the molecular motions of the Ag Cl to this state of crowding than to any adhesion between the salt and its solvent, using the word adhesion in its customary sense. The flight of molecules of Ag Cl through the water would give them mean free paths of appreciable length before coming into contact with others, or within influence of their polarities and movements.

The movements of the Ag Cl in relation to those of the water may be compared to the movements of a comet in relation to a planetary system. The comet comes in and obeys the central commanding force and is temporarily part of the system, but is whirled away again into space, so the mass Ag Cl, by a temporary influence of the water, throws off an atom which, passing through a cometic orbit, having too distant a harmony with the aqueous sun to be retained in its system, passes into the aqueous space till it comes under the influence of a molecule or a mass of its own nature, with which it unites and passes out of solution.

The effect of heat is no doubt to weaken the molecular polarities, thus facilitating the disintegration of solids, but at the same time weakening the polar attraction between the solid and the solvent. The increased or decreased solubility with a rise of temperature will depend upon whether the polar attractions among the molecules of the solid diminish more or less rapidly, in proportion to the increased temperature, than the polar attractions between the solid and the solvent. Of course we expect the molecular movements of one drop of water to be just the same as of another, and we know they unite instantly and perfectly. The molecular construction of oil of turpentine or other essential oil we believe to be very different, and probably their molecular movements are inharmonious with those of water, resulting in the small degree of solubility between them, while the complicated and heavy molecules of the volatile oils having sluggish movement dissolve freely among one another.

To be continued.)

COTTON SEED OIL: SOME OF ITS USES IN PHARMACY, AND ITS DETECTION WHEN MIXED WITH OLIVE OIL.*

BY S. S. BRADFORD, PH.G.

Having had occasion during the last six years to manufacture lead plaster in considerable quantities, it occurred to me that cotton seed oil might be used instead of olive oil, at less expense, and with as good results. The making of this plaster with cotton seed oil has been questioned, as according to some authorities the product is not of good consistence, and is apt to be soft, sticky, and dark coloured, but in my experience such is not the case. If the U. S. P. process is followed in making this plaster, substituting for the olive oil cotton seed oil, and instead of ½ pint of boiling water 1½ pint are added, the product obtained will be equally as good as that from olive oil. My results with this oil in making lead plaster led me to try it in making the different liniments of the Pharmacopœia, with the following results:—

Linimentum Ammoniæ.—This liniment, made with cotton seed oil, is of much better consistency than when made with olive oil. It is not so thick, will pour easily out of the bottle, and if the ammonia used is of proper strength will make a perfect liniment.

Linimentum Calcis.—Cottonseed oil is not at all adapted to making this liniment. It does not readily saponify, separates quickly, and it is almost impossible to unite when separated.

Linimentum Camphoræ.—Cotton seed oil is far superior to olive oil in making this liniment, it being a much better solvent of camphor. It has not that disagreeable odour so commonly found in the liniment.

Linimentum Chloroformi.—Cotton seed oil being very soluble in chloroform, the liniment made with it leaves nothing to be desired.

Linimentum Plumbi Subacetatis.—When liq. plumbi subacet. is mixed with cotton seed oil and allowed to stand for some time the oil assumes a reddish colour similar to that of freshly-made tincture of myrrh. When the liquor is mixed with olive oil, if the oil be pure no such change takes place. Noticing this change, it occurred to me that this would be a simple and easy way to detect cotton seed oil when mixed with olive oil. This change usually takes place after standing from twelve to twenty-four hours. It is easily detected in mixtures containing 5 per cent. or even less of the oil, and I am convinced, after making numerous experiments with different oils, that it is peculiar to cotton seed oil.

CATTLE CONDIMENT.

"In the preparation of cattle food the main object is to make the food palatable. The animal is more contented, it eats with a contented relish, and a greater thriftiness is the result. I am not a believer in the condimental value of these foods, for I believe that in our grasses we have all the condimental elements required. But should my correspondent desire to make his own cattle food, here is a common formula:—Locust bean, 6 cwts.; Indian corn, 9 cwts.; best linseed cake, 3 cwts.; powdered turmeric, 40 lbs.; sulphur, 40 lbs.; saltpetre, 20 lbs.; liquorice, 27 lbs.; ginger, 3 lbs.; aniseed, 4 lbs.; coriander, 10 lbs.; gentian, 10 lbs.; cream of tartar, 2 lbs.; carbonate of soda, 6 lbs.; levigated antimony, 6 lbs.; common salt, 30 lbs.; Peruvian bark, 14 lbs.; fenugreek, 22 lbs. This will make as good a cattle spice or food as any that can be bought. But my own opinion is that food can be made very palatable by simply mixing with it a small proportion of locust bean meal and a little salt; and locust bean meal can be purchased at about £8 10s. a ton just now, so that it is not very expensive."—*Correspondent of the Morning Post.*

THE JUBILEE OF M. DUMAS.

THE French Academy of Sciences was last week the scene of a graceful and well-deserved compliment to one of the ablest of living chemists, in the presentation to M. DUMAS of a medal which had been struck specially to commemorate the fiftieth anniversary of his election as one of its members. Science is too cosmopolitan to limit the faculty of admiration for such a career as that of M. DUMAS to one country, and therefore, notwithstanding his countryman's arrogant boast that chemistry is a French science, there is not an English chemist who would grudge to join in according to the veteran scientist a full meed of honour, in the same catholic spirit as permeated his own panegyric a few years ago of our great countryman, FARADAY. But beyond a share in this general sympathy, the readers of this Journal may claim to have a special interest in M. DUMAS, arising from the fact that he is one of the band of famous men who began their scientific career in the pharmacy.

Born in the year 1800, M. DUMAS, shortly after the battle of Waterloo was fought, became an apprentice to a pharmacist in his native town of Alais, in the department of the Gard. Not satisfied, however, with his prospects there, he in 1816 travelled on foot to Geneva, where he attended lectures on botany by the elder DE CANDOLLE, on physics by PICTET, and on chemistry by DE LA RIVE. He, moreover, had the good fortune to secure there the superintendence of a large laboratory, which had previously been used for courses of practical chemistry, but then belonged to the pharmacy of M. LE ROYER. We learn from the eloquent biography from the pen of Dr. HOFMANN, which, about three years since, was published in *Nature,* that his fellow pharmaceutical students, who frequently united in botanical excursions during the summer, started the idea of winter meetings for scientific studies, and it was proposed that as young DUMAS had a laboratory at his disposal he should give them a course of experimental chemistry. Much patience and ingenuity were required before the apparatus absolutely necessary was constructed; but all difficulties were overcome, and thus early he made his *début* in the professorial career, which he afterwards followed with so much success in Paris at the Athenæum, the Polytechnic School, the Sorbonne, the School of Medicine and the College of France. It was, however, in connection with work strictly pharmaceutical that the name of DUMAS first appeared in scientific literature, and mention of the subject will assist in conveying some idea—though still a very vague one—of the enormous strides that have been made in scientific pharmacy since that time. DUMAS was eighteen years of age when he detected the presence of iodine in carbonized sponge, and in consequence Dr. COINDET, at whose request the examination had been made, announced iodine as a specific against goitre. This led to further inquiries as to the most convenient mode of administration, and DUMAS suggested the trial of a tincture of iodine, potassium iodide and iodized potassium iodide. But only about six years had elapsed since COURTOIS had first separated iodine from the waste liquor in the manufacture of soda ash from seaweed, and still more recently had it been recognized as an elementary body by GAY-LUSSAC; the iodides were then unknown to trade, and iodine was the only commercial article available. The discovery of Dr. COINDET, however, originated a great demand for iodine preparations, and for many years their manufacture proved a source of wealth and reputation to the pharmacy of LE ROYER. After this, DUMAS' association with pharmacy was not so close, although nearly fifty years subsequently he presided over the Commission entrusted with the revision of the French pharmacopœia. But he now joined PREVOST in those physiological investigations which for a time diverted his attention from more purely chemical studies, though they brought to him a reputation that eventually led to his migration to Paris, where chemistry again resumed its sway.

We must be content with having thus briefly sketched DUMAS' early work whilst engaged in a pharmacy; it would be impossible in these columns even to mention his multitudinous subsequent investigations. In the words of the President of the Academy, M. JAMIN, he went to Paris with no other wealth than a brave heart, a resolutely fixed programme, the will to carry it out, and confidence in himself, but still unconscious of the future that awaited him. To-day, with the progress of time, his dreams have been realized, his hopes surpassed, and he has attained the highest pinnacle of honour that a scientific man can hope to attain. Like FRANKLIN, he might say, "If I had to recommence life, I could not ask for more!" Looking back upon the brilliant services to science which M. DUMAS has rendered since he first took his seat in the Academy half a century ago, it is not difficult to understand the feeling which impelled M. JAMIN, who had himself sat under the famous teacher he addressed, to say: "The pupil cannot "assume, without irreverence, the right to praise or "to criticize; face to face with his master, he has "only the duty of respect."

DEFECTIVE WEIGHTS AND MEASURES.

We regret that circumstances appear to us to make it desirable that we should once more direct the attention of chemists and druggists to the imperative necessity, if they wish to avoid annoyance and loss, that they should satisfy themselves as to the weights and measures used by them coming within the requirements of the law, and that they should exercise care in the purchase of new ones. But we think that a sufficient justification will be found in a statement of the results of a week's inspection in one of our cities, which has been placed at our disposal by a correspondent whose good faith and capability of forming a correct judgment are beyond challenge. The shops visited were twenty-four in number; in only four instances were all the weights and measures found correct, and in sixteen cases summonses were issued and convictions followed. Altogether 1207 weights and 127 measures were examined. Of the weights 128 were found too light, 97 were too heavy, and 59 were illegal only in being unstamped. Of the measures 31 were found incorrect. There were also 54 scales tested and 17 proved untrue. The nature and extent of the default may be seen from the following table, setting out the amount of error in the weights seized in two cases in which convictions were obtained:—

First Case. Denomination of Weight.	Error.	*Second Case.* Denomination of Weight.	Error.
6 grains	$\frac{9}{10}$ gr. light.	6 grains	$\frac{9}{10}$ gr. light.
5 grains	$\frac{2}{10}$ gr. light.	5 grains	$\frac{4}{10}$ gr. light.
4 grains	1 gr. light.	4 grains	$\frac{4}{10}$ gr. light.
2 drachms	$1\frac{1}{2}$ gr. heavy.	3 grains	$\frac{7}{10}$ gr. light.
2 scruples	$\frac{3}{10}$ gr. heavy.	1 grain	$\frac{3}{10}$ gr. light.
1 scruple	$\frac{3}{10}$ gr. heavy.	2 drachms	$\frac{5}{10}$ gr. heavy.
$\frac{1}{2}$ scruple	$\frac{6}{10}$ gr. heavy.	1 drachm	$\frac{4}{10}$ gr. heavy.
		$\frac{1}{2}$ drachm	$\frac{5}{10}$ gr. light.
		1 scruple	$\frac{6}{10}$ gr. heavy.
		$\frac{1}{2}$ scruple	$\frac{3}{10}$ gr. heavy.

THE PARIS SCHOOL OF PHARMACY.

It may interest some of our readers to learn that an excellent full page engraving of the new buildings of the Ecole Supérieure de Pharmacie, which have recently been erected in Paris at the expense of the French nation, was published in *The Builder* for November 25. The view is taken from the rear of the buildings, near the junction of the Rue Michelet and the Rue d'Assas, and consequently it does not show the principal façade in the Avenue de l'Observatoire; but this is more than compensated for by the greater extent to which the details of the different buildings are disclosed. Looking across the ample botanical garden, with its hot house accommodation, the eye rests on two handsome horseshoe shaped buildings, each containing an amphitheatre capable of accommodating an audience of six hundred persons. These lecture theatres are connected by vestibules and galleries with the main building, portions of the back of which are seen, and in which are situated the examination hall, the residences of the officials, the professors' laboratories, the museums, reading rooms, library, etc. On the left hand of the picture, running back from these, and with an outlook towards the north over the Rue l'Abbé de l'Epée, is a long three-storied wing, devoted to practical work, the ground floor containing the chemical laboratories for the first year's students, the second floor those for the second year's students, whilst in the upper floor micrographic work is carried on by the more advanced pupils.

PHARMACEUTICAL INSTRUCTION IN DUBLIN UNIVERSITY.

It may be useful to some of our readers to learn that in the Experimental Science School, Trinity College, University of Dublin, there are now courses of instruction, specially arranged for pharmaceutical students to meet the requirements of the Pharmaceutical Society of Ireland, which may be attended by persons otherwise unconnected with the College. The lectures are delivered twice a week, Tuesdays and Thursdays, the course extending from November 1st to March 31st, and on an additional day in each week illustrative experiments are conducted in the Laboratory. The necessary three months' practical course in the Laboratory may be commenced on the 1st of January or the 1st of April, and is under the joint supervision of the University Professor of Chemistry (Professor J. Emerson Reynolds), and the King's Professor of Materia Medica (Dr. W. G. Smith). It comprises instruction in the qualitative testing and volumetric analyses of the Pharmacopœia and in the examination of drugs for pharmaceutical purposes. Pharmaceutical students are also allowed to attend the summer course of lectures delivered in the Medical School by the Professor of Materia Medica and Pharmacy.

DEATH OF MR. S. U. JONES.

Our readers will read with regret the announcement made at the meeting of the Chemists and Druggists' Trade Association, on Wednesday evening, of the death of Mr. Samuel U. Jones, of Leamington, who took an active part in the formation of that society and was unanimously elected its first President. Mr. Jones was also an esteemed member of the Pharmaceutical Society, which he served during many years as Local Secretary.

CHEMISTS' ASSISTANTS' ASSOCIATION.

A meeting of the above Association will be held on Wednesday next, December 20, at the new rooms, 53, Conduit Street, W., when a paper will be read on "Plant Names," by Mr. C. E. Stuart.

Mr. Robert Gibson, Pharmaceutical Chemist, of the Carlton Medicated Lozenge Works, Hulme, has been elected without opposition Alderman for St. George's Ward, Manchester.

Chemists and Druggists' Trade Association of Great Britain.

MEETING IN LONDON.

A general meeting of the members of the trade resident in London, convened by the Executive of the Chemists and Druggists' Trade Association, was held on Wednesday last, at the Inns of Court Hotel, for the purpose of considering what amendments are desirable in the Pharmacy Act, 1868, the desirability of holding periodical meetings, and to discuss matters generally of trade interest. Mr. Robert Hampson, President of the Trade Association, occupied the chair.

The Chairman, after expressing regret for the absence of Mr. Urwick, who had gone to Leamington to attend the funeral of Mr. Jones, the first President of the Association, said the London Committee of the trade had for some time thought that it would be a good thing to have a meeting of the members of the Association to take into consideration trade questions, and the result was that the members had been asked to attend that evening. There was no organization, except the Pharmaceutical Society, in London, which could call the members of the trade together, and it seemed to be a fit thing that they should meet occasionally to discuss trade matters. London was so vast that it was almost impossible to get that spirit of union which places such as Manchester and the like found it possible to do. Unless there was some burning or political question, it was very difficult to get many members together in London; but he hoped that in course of time chemists would find it to their interest to meet as other bodies of men would when anything of importance was in possession of their minds, and that they would meet to discuss their own interests, and that larger meetings would be assembled than they had that evening. There was one special subject mentioned upon the agenda which made it almost imperative that the chemists of the metropolis should meet together, and that was the prospect—it might be a remote prospect, though he was disposed to think it was not quite remote—of having an amended Pharmacy Bill. But that question was ripening. Some time ago a Draft Bill was sent to the Government Office for consideration, but no social or home legislation had lately had any chance whatever, though it was to be hoped now that Parliament had consented to organize itself as it were as a body capable of doing political work, that it would be able to enter upon a period of practical legislation, and that the question of pharmacy would receive proper attention at its hands. If chemists and druggists went before Parliament for a Bill, it was essential that they should know what they wanted, and that they should agree upon certain main points which they thought it desirable to have in the Bill. It was most essential that they should not indulge in Utopian proposals or vague grumblings, but they should be prepared with a Bill suited to public wants as well as their own wants. He was quite sure that it would be of no use asking for anything that was incompatible with the public interest. Their interest after all was the public interest; they had no right to special legislation except in the public interest; but he was firmly convinced that the legislation they already had, or which the State had inflicted upon them, had been of public benefit, and that if they proceeded upon the lines of qualification and education they would obtain what they required. The first thing to be done in any new Bill was to repair the great breach which had lately been made at Westminster, and by that expression he referred, of course, to the decision of the House of Lords. It was no use giving them any Bill without that breach was repaired. It was possible that the decision of the House of Lords was technically right and that the framers of the Pharmacy Act might not have contemplated limited liability companies carrying on the business of chemists and druggists. The law might be good, but certainly no justice had been obtained at Westminster. The decision was contrary to the spirit of the old Act, and certainly no Bill would be acceptable to the chemists or compatible with public interests unless that breach was repaired. Was it an advantage to the public that pharmacy should receive the countenance of the State at all and was it desirable that chemists should be thoroughly qualified? Of course every one was agreed upon that. But then came the question whether it was desirable that pharmacy should receive any further recognition from the State. They would all agree that certain things required alteration, and they could only hope that when the time arrived they would at any rate amend the Bill in all the main points. He maintained that if pharmacy was not worth following, owing to the business being diminished and rendered worthless, the public would suffer along with the chemists. It was not simply their own loss, but the public loss and the loss which medical men must sustain. The interests of chemists were bound up with those of the medical faculty, and anything which injured them injured the medical profession, and therefore that profession ought to unite with the chemists in obtaining what was considered right. He also considered that an Englishman was quite as good as an Irishman, but by the provisions of the Irish Pharmacy Act, pharmaceutical chemists alone had the right of dispensing prescriptions. In all Colonial Bills there was a similar clause, and he maintained that an English pharmacist ought to have the same right. What were they educated for? Not simply to have attached to their names some useless title. What would a mariner think if, after receiving an excellent education in navigation and all that applied to the safe care of a vessel, he was never allowed to enter a ship and sail a voyage? The thing was utterly absurd. Take the case of a student in music; if he were constantly engaged in rehearsals and never allowed to sing in public his qualifications would be of no use at all. The education of a chemist was utterly useless unless he was able to exercise it in true pharmacy. They heard a good deal of talk about imposing a curriculum upon students, but it was all perfectly useless, unless they could make use of their sharpened qualities. There would be no lack of zeal in the students if they found during their apprenticeship that pharmacy was a thing really required; but of course students received a damper directly they found that dispensing was an unimportant and minor thing. He thoroughly agreed with the imposition of a curriculum, as it would bring about the establishment of educational centres. Then again, they must bear in mind that unless they had the pharmacy of the country and the sale of drugs in their hands, in consequence of the very quick vanishing of miscellaneous trade owing to the terrible competition which prevailed, there would be nothing left to them. They must stick to their proper calling, viz., pharmacy, and endeavour as much as possible to obtain a fair recognition of it. The next question for consideration was that of patent medicines containing poisons, and he hoped that in any future Bill there would be a provision that these medicines should only be sold by pharmacists. The wholesale patent medicine vendors ought not to utter any protest about this. At one time these gentlemen only sold to chemists, but now they did not care to whom they sold, though he thought that chemists being independent people might be able to take care of themselves in this matter. The most important thing after all, after knowing what they wanted, was to become thoroughly organized either by that Association or the Pharmaceutical Society, so that when the time came to urge upon the Legislature their claims, they might be able to carry through a Bill. If they did not know what they wanted, they would have no chance of carrying any Bill, but if they did know what they wanted, and their wants were reasonable and they were zealous in representing their views, he had no hesitation in saying that they would carry a satisfactory Bill.

Mr. Holmes moved the first resolution as follows:—

"As it is likely practical legislation will be possible in the next session of Parliament, this meeting expresses an earnest hope that a Bill may then be passed to amend the Pharmacy Act, 1868."

He thought everyone would rejoice in seeing that the Privy Council had at last requested the Pharmaceutical Society to send in a Draft Bill for an improved Pharmacy Act. After the remarks which had been made by the Chairman it was hardly necessary for him to state in what respects the Pharmacy Act required amendment, but his own opinion was that the sale of patent medicines require special attention. In the neighbourhood of Pimlico, where he resided, he suffered from competition not only from co-operative stores, but from oilmen and grocers, who sold patent medicines at the price which he (Mr. Holmes) had to pay for them to the wholesale house. There was no Act of Parliament to prevent chlorodyne or solution of chloral being sold by an uneducated person, and he thought that as a chemist was obliged to pass a certified examination before he could sell poisons, that the same law should apply to the sale of patent medicines. With regard to dispensing by co-operative stores, that was, in his opinion, a very iniquitous thing, because the Act of Parliament provided that no person could keep an open shop unless he was qualified by having passed the requisite examination, or was on the register. A chemist and druggist could not take into partnership any person not upon the register, therefore it followed that it was unlawful for certain persons to enter into partnership for the sale of patent medicines by merely employing a qualified assistant. If co-operative stores could be put upon the same basis as chemists and druggists an amendment might be made in the Pharmacy Act.

Mr. Woolings, in seconding the motion, said he thought that registered chemists and druggists, as well as pharmaceutical chemists, should be exempt from serving on juries.

Mr. Nicholls wished to be informed of the salient points upon which they desired to have some alteration in the Act.

The Chairman said the second resolution covered that ground.

The motion was then put and carried unanimously.

Mr. Long moved the second resolution as follows:—

"That whilst leaving with confidence to the Executive Committee of the Chemists and Druggists' Trade Association the consideration and careful watching of any Pharmacy Bill brought into Parliament, this meeting is of opinion that unless it contains the following or equivalent provisions it will not be consistent with the public safety nor adequate to the just claims of pharmacy and of legally qualified registered persons practising the same: (1) To insure that all persons, without any distinction whatsoever, keeping open shop for the dispensing of medicine and the sale and dispensing of poisons should be legally qualified and registered; (2). That patent medicines containing scheduled poisons should be sold only under the same or similar restrictions as are already applied to the sale of other poisons enumerated in the schedule of the Pharmacy Act."

As reference had been made to the decision given by the House of Lords with regard to what constituted qualification, he might perhaps be permitted to point out that the Act itself said that it was expedient for the safety of the public that all persons who sold medicines should be qualified. That was a proposition which no sane person would attempt to dispute, and he could not see that there was any difficulty about the subject at all. With all due deference to the decision of the House of Lords, it was not, to his mind, English law. There was no reason whatever why a corporate body should not be composed of qualified people. Of course, it would be perfectly impossible to have a dozen people up, unless they were going to catechise them as a class; but they could take each individual separately and examine him, and if he was not competent to pass the examination then he was not qualified to carry on business according to the Act, because the Act most decidedly gave a definite status and conferred certain rights and privileges on chemists and druggists, and it was not customary in England to abolish rights and privileges without compensating those who possessed those rights. The law did not say that the servant qualified the master; in everything legal, medical and pharmaceutical, it was necessary for the master to be qualified, and the sense of that was evident, as the directing mind ought to be able to know what was right and what was wrong. A manager might be a very good man, but unless he was able to direct and decide, the thing was perfectly futile. He did not think there would be any difficulty about the first proviso of the resolution. The Pharmaceutical Society had been established for more than forty years, and there was now no one in business who had not had the opportunity of joining, either by free admission or examination, and it was evident that a large amount of skilled technical knowledge was necessary to conduct the business of a chemist. Cutting out of the Pharmacopœia the common family requisites, such as carbonate of soda, arrowroot and essence of lemon, he thought that all drugs of curative or active properties should only be sold by the men who had qualified themselves to know their properties and could dispense them with safety to the public. The act of dispensing did not merely mean mixing together a doctor's prescriptions, but giving a certain amount of advice, and therefore their aim and object should be, the Pharmacopœia for the pharmacist. There was no difficulty in defining who should sell, and what they should sell. Pharmacists ought to be the only makers of patent medicines; he knew they were only the makers of respectable patent medicines; because the makers now were so anxious to procure a large sale that, like traitors in the camp, they did not care whether they sold to friends or enemies. It would not be at all difficult for chemists to keep their preparations to their own profession, and it would be better for them if they did. With regard to the powerful patent medicines the resolution was absolutely necessary, because it was perfect nonsense to expect a man to go through the education required of a pharmacist and then to allow an incompetent man to sell side by side with him the same articles.

Mr. Nicholls, in seconding the motion, said there was scarcely a patent medicine which did not contain poison, and therefore the sale of these articles should be relegated solely to pharmacists. He was sure nobody would be better pleased if this could be brought about than the medical faculty. As a matter of fact it was necessary to give a certain amount of advice upon the sale of any patent medicine, and it was not to be expected that a person in a grocer's shop could tell a customer as to how the medicine should be administered to a child. He was strongly of opinion that most of the homœopathic medicines were dangerous in the hands of shopkeepers, and that these medicines should be included in the category of patent medicines.

The Chairman pointed out that at the present time homœopathic medicines containing an appreciable amount of poison were within the Act, and it was illegal for an unregistered person to sell them.

Mr. Horncastle thought it was very important that chemists should be united before going to Parliament for any Bill, and such meetings as the present were likely to go a long way towards accomplishing that object. It had been suggested that chemists should take out a licence, but he thought they were sufficiently saddled at the present time. Pharmaceutical legislation hitherto had done a great deal for the public, much more for the public than the trade, and now the time had arrived when chemists might very well come forward and ask for something for themselves, but in doing so they should try to draw a distinct line between chemists and druggists and the ordinary trade. He saw no difficulty in restricting the sale of compounds mentioned in the Pharmacopœia to chemists and druggists, though the case was entirely different as regards simples and trade chemicals. The sale of all patent medicines ought to be confined exclusively to them, and the only way to secure the interest of the public was the one which would secure the interest of the trade. Many could remember the time when the first Pharmacy Act was brought forward, and how it was mutilated and crippled by the division in the trade, and, therefore, he hoped there would be no personal bickerings when the next Bill was brought forward.

Mr. Wightman Cooper thought the last speaker had enunciated the feeling of pharmaceutical chemists, though he was not so sure that he had expressed the opinion of chemists and druggists. A glance at the poison schedule to the Bill of 1868 would show that the gentlemen who legislated for the trade at that time knew nothing about the matter, or if they did, they had sadly neglected their duties. They should have included some two hundred or three hundred things called drugs, and so have made it worth the while of many persons to pay attention to the trade. At the present time the schedule was so cramped that anyone was able to open shop, and to set the chemist at defiance. He was glad to think that there was a sensible feeling at last that chemists should combine for their mutual benefit, but he was afraid it was now too late. Free trade was very good in many things, but there could be no free trade in a restrictive business, and he was sorry that the leaders of pharmacy had made the mistake of restricting without giving sufficient compensation. Now if they had found out their mistake he hoped they would be able to rectify it.

Mr. Lawrence asked whether the views expressed at that meeting would be brought before the Pharmaceutical Society.

The Chairman said it was competent for the meeting to do so. The last speaker seemed to imagine a great mistake had been made because the earlier movers in pharmaceutical politics did not include drugs in the schedule, but the Privy Council would not accept such an enlarged schedule. To have done so would have been to destroy the use of the word "poison" altogether. As a pharmaceutical chemist he did not take any share of the blame which had been attached to that small body, and the meeting should remember that the chemists and druggists outnumbered the pharmaceutical chemists, and if they had chosen, when they had the opportunity, to join the Society they might have manipulated it as they wished. The folly entirely rested with them for not having taken advantage of their opportunity. Inasmuch as they did not join the Society the subject of legislation had been left in the hands of a small number who had done a great deal of good for the trade.

Mr. Cooper asked whether the meeting had been called by the Chemists and Druggists' Association of Birmingham, or by the Pharmaceutical Society.

The Chairman replied by the Chemists and Druggists' Association of Great Britain.

Mr. Cooper thought the motion did not go far enough, because it did not state sufficiently the alterations required. They had had many additions to the poison schedule, and certain tinkerings with the Pharmacy Act, and the time had now arrived for them to act, once for all, and to say that everything which came under the word "drug" should be included in the schedule. If that were done, the public would know what drugs were. As an amendment to the second provisio, he begged to move—

"That every article which could be enumerated as a drug should be included in the new Pharmacy Act, and sold only by chemists."

Mr. Henchley seconded the amendment.

Mr. Nicholls hoped that the amendment would be withdrawn, because if they went for too much they would not get anything.

Mr. Reid asked whether the motion which had been put forward could be amended or enlarged by the Committee, which would be afterwards appointed.

The Chairman said, Certainly. He might point out that application had been made to the Privy Council to add mineral acids to the schedule, and he did put it to the meeting, whether it was expedient to try and include all drugs in the schedule. To his mind it was not only inexpedient, but unwise, because he was sure that no Government would grant such a thing.

Mr. Allen thought that if they went to Parliament for anything unreasonable they would fail altogether, and therefore he hoped Mr. Cooper would not press his amendment.

Mr. Barnard was of opinion that it would be absurd to ask Parliament to give them an Act embodying everything which could be classed under the name of "Drugs."

Mr. Cooper said the time had now arrived when they should make a stand as to whether they should live or die, and therefore he could not withdraw his amendment.

The amendment upon being put to the meeting was lost by a large majority.

The motion was then put and carried.

Mr. Allen moved the next resolution as follows:—

"That it is advisable to hold periodical meetings of the members of the Association resident in London, and that the London Committee be requested to make the necessary arrangements for the same."

The reason for this resolution was that the London members did not possess the opportunity of meeting together to discuss trade questions in a purely commercial or trade manner. He was old enough to remember the agitation prior to 1868, when certain gentlemen were always ready to come forward to discuss questions relating to their business, and the result of their meeting was the establishment of the Pharmaceutical Society, which had done so much for the trade. There were many subjects which could be discussed at these meetings, for instance, the copying of prescriptions, for which chemists were not paid, the long hours of business, and the sale of patent medicine.

Mr. W. Cooper, in seconding the motion, said he thought it would be a great advantage to hold sectional meetings in London.

Mr. Andrews agreed that one meeting would not be sufficient for the whole of London, but if they commenced with one meeting, it would not be long before many district associations sprang up.

The motion was put and carried unanimously.

On the proposition of Mr. Long, a cordial vote of thanks was passed to Mr. Hampson for presiding, and the meeting separated.

Pharmaceutical Society of Ireland.

MEETING OF THE COUNCIL.

The monthly meeting of the Council of the Society was held on Wednesday, the 6th instant, in the College of Physicians, Kildare Street, Dublin. The President, Dr. Charles Tichborne, in the chair.

The other members of the Council present were the Vice-President, Dr. Aquilla Smith; Dr. Montgomery, Dr. Collins, Mr. Brunker, Mr. Allen, Mr. Hayes and Mr. Hodgson.

Mr. Hugh Fennell, the Registrar, read the minutes of the last meeting, which were confirmed.

A letter was read from Mr. John Patrick Henry, L.P.S.I., of Belfast, in which the writer complained of some remarks made in reference to him by Dr. Dill, Coroner of Belfast, at a recent inquest. Mr. Henry stated that in reference to the case to which the inquest related he had done more than the law required, and yet the coroner said that he had "evidently looked on the matter as a business transaction and sold laudanum without caring whether the man poisoned himself or not." Mr. Henry referred to an editorial article which had appeared in the *Pharmaceutical Journal* of October 28, 1882, on the subject, and asked whether or not the Society would protect its licentiates from such language as that used by the coroner.

Dr. Montgomery moved that the letter be marked "read." There was nothing in it that they could take notice of.

The President said no doubt the coroner did make a slip and his law was not very good; but the subject had been already thoroughly ventilated in the newspapers and he did not see that the Society could do anything in the matter.

The motion of Dr. Montgomery was agreed to.

A letter was read from Mr. James H. Haslett, of Belfast, inquiring whether candidates who passed their Preliminary examination before November 1, 1882, would be exempt from the operation of the new rule passed on that day, which fixes the time to be spent in learning practical pharmacy at four years.

The President read the rule as follows:—"That all candidates for the licence shall be required to produce a certificate signed by a pharmaceutical chemist or apothecary keeping open shop, stating that he has served a *bonâ fide* engagement with him as either apprentice or assistant, in his sole employment, for a term of four years. To come into force on January 1, 1884."

Mr. Hodgson said that, according to that rule, before the writer of the letter could come up for his Major examination he certainly would have to serve four years. But the rule would not be law without the consent of the Privy Council; and any member of the Council of the Society going before the Privy Council and objecting to the rule could upset it. He was not clear that he himself would not do so, for he had the strongest objection to the rule. He believed it was contrary to the principle of the Pharmacy Act, and at variance with the opinion of their late lamented President, Sir Dominic Corrigan, who always objected to apprenticeship, and maintained that it was enough for a man to show by examination that he knew his business.

The President said the question of apprenticeship was not raised by the letter. The real point was as to time. The rule made it four years instead of two. He certainly thought the rule would prevent the writer from coming up for his Major examination on two years' study or service. But the only question now before them was, what reply was to be given to the letter.

Mr. Hayes said the application of the rule would be hard upon men who had passed their Preliminary examination under the old rule.

Mr. Allen said notice might be given of a motion to exempt from the operation of the rule those gentlemen who should pass the Preliminary examination before January of next year.

The President said the best course would be to inform Mr. Haslett that the new rule was under the consideration of the Privy Council.

The Registrar stated that on the previous Saturday he had received a letter from Dr. Kaye, Q.C., Clerk to the Privy Council, enclosing for the approval of the Council of the Society the rule in question amended as follows by the law officers of the Crown:—

> "That every candidate for the licence shall be required to produce a certificate, signed by a pharmaceutical chemist or apothecary keeping open shop, stating that such candidate has served a *bonâ fide* engagement as apprentice or assistant, with and in the sole employment of such pharmaceutical chemist or apothecary, or a firm of which he is a member, for a term of four years. To come into force on January 1, 1884."

The President said the last part of the amended rule would require consideration.

Mr. Hodgson said there were two hundred and eighty-seven young men, every one of whom had passed his Preliminary examination under the impression that when qualified by two years' practical pharmacy he would be able to pass the Major examination. If this rule, which had been adopted in a crude manner, should be enforced, it would be a breach of faith with them.

The President: I think there has been only an oversight that can be easily remedied.

Dr. Montgomery: The Council did not adopt the rule hastily. It was a long time under consideration. The only mistake was that they did not define the time more accurately.

The President: It will meet the case for us to reply to Mr. Haslett that the matter is under consideration, and no final decision has been arrived at.

A letter was received from Mr. J. B. Fisher, making inquiries as to certain legal proceedings.

The Registrar was directed to reply to Mr. Fisher, stating that as he was not a member of the Society, the Council could not continue to correspond with him on the subject.

A letter was received from Mr. Hatchell Whitby in reference to the conference of four members of the Council with four members of the Society, stating that it would be out of his power to undertake to arrange with any of the members of the proposed committee.

The letter was marked "read."

A report of the Law Committee, making a recommendation as to the course of action to be taken with reference to a letter from Mr. Daniel J. McGrath, L.P.S.I., of Carlow, as to the sale of poisons, was adopted.

The Council then adjourned.

Provincial Transactions.

BRIGHTON ASSOCIATION OF PHARMACY.

A meeting was held in the ante-room of the Town Hall, on December 1, when Mr. W. D. Savage read a paper entitled—

Some Thoughts suggested by Professor Attfield's Address to the British Pharmaceutical Conference at Southampton.

The many and important subjects alluded to in the admirable address of Professor Attfield, at the opening of the Conference at Southampton, may fairly claim from us some consideration, and as the subject has been suggested to me as an appropriate one for opening our local session, I readily avail myself of this opportunity of congratulating the Professor on his happy selection and systematic arrangement of subjects. Exhaustive research, careful manufacture, and thorough distribution, or the collection, preparation, and distribution of drugs, embrace a wide field for discussion, and although they have at his hands had great consideration, yet there are some points on which we may, some of us, differ, and it is well on such occasions as the present that we should freely discuss the various subjects brought before us, and ascertain thereby how far our views accord with those of the worthy Professor.

With respect to the first heading "Collection," it is suggested that flower culture, and medicinal plants might with advantage be more extensively cultivated in our own country, and if we might infer from the success which attends the culture of lavender and peppermint—at Mitcham, and other places—it would seem desirable, in the present depressed state of agriculture, that an experiment in this direction should be tried. Of course it would, in the first place, be necessary to know what conditions of soil are suitable; and what counties, in the second place, are best likely to fulfil those conditions; and now that scientific farming is exciting considerable interest, and is in our own country being practically carried out by Professor Jamieson, of Aberdeen, the time seems appropriate for considering this important subject. It is true that our climate is not very favourable for the production of many plants yielding the finer perfumes, but still much might be done to meet climatic difficulties. Look for instance at the obstacles which the farmers in Kent have to encounter in the cultivation of hops, and whilst they have not lately been very successful, times have been when their care and expensive culture has been well rewarded. And under the head of "Collection" might not some of our indigenous plants be made more available that they are at present? Indeed, there does seem a tendency in this direction. We have in "The Month" of the October number of the *Pharmaceutical Journal*, reference to fool's parsley, burdock (*Arctium Lappa*), etc.; and if we go back to the time of John Gerarde, 1633, we there find, in his 'General History of Plants,' a valuable collection of remedies; and again, in 1653, our old friend Dr. Culpepper,—in his 'Complete Herbal' we have a marvellous revelation of remedies associated with astronomy, and what is called the 'Doctrine of Signatures,' implying that nature herself indicated, by unmistakable signs, the appropriate remedies for certain diseases. Thus we are told that turmerick was good for jaundice, and saffron for measles, and these remedies are now very generally used by the poor people in the country; indeed saffron finds many patrons amongst the poor of the cities and towns. Now, however, without believing in the efficacy of plants, either from their colour or from planetary influences, there are no doubt many that would yield satisfactory results. I might enumerate many plants growing on our downs, such as the scabious and the different orchids, that are worthy of investigation; but I have said enough on this subject.

With respect to the preparation of drugs, Professor Attfield gives some excellent advice relative to the importance of doing as much at home in this way as you can. For obvious reasons it is well to be able, from one's own knowledge, to certify as to the quality; at the same time it is the duty of those who take apprentices, to make many things which are more cheaply bought, if for no other purpose than to enable them to know how to do it. But, as the Professor himself says, "Some preparations will doubtless always be better made by one man than by another, or by few persons rather than by many." In the very nature of things this must be so. In most retail establishments, the tendency of the age is to award the preference to certain makers of well-established reputation,—for instance, Howard's Quinine, Morson's preparations, and others I might enumerate. But apart from these special preparations, there are other reasons why many things are better made on a large scale; indeed some of them, such as the mineral acids, acetic and citric acids, can only be made well and profitably in large quantities and on premises specially adapted for them. Then, again, gamboge, scammony, guaiacum and other gum resins cannot, except on a very limited scale be powdered at home. The mercurial preparations, the vegetable powders, and many other articles of a like kind, cannot well be done by an ordinary retail druggist. Leaving out of consideration the advantages which result from a division of labour, the cost of preparation is an important factor not to be lost sight of. The druggist has now a hard fight against competitors, and whilst I am fully convinced that success or non-success in business is largely dependent on the quality of goods which are sold, there are well-known manufacturers whose reputations for years have placed their names above suspicion, and therefore, without hesitating, the retailer orders of them with as much confidence as if all the articles were prepared by himself, although I must say that tinctures, syrups, ointments and such articles as can readily be made in large or small quantities on your own premises should be prepared there. The mere trader, not being a druggist, cannot compete with one who knows his trade, who can tell a good article from a bad one, and if his requirements necessitate his going to the wholesale dealer, his knowledge would teach him where he would be best served. Here the educated druggist has an advantage over the medical man, for it is a well-known fact that as a rule the profession have a very limited knowledge of drugs. A young man probably enters into some arrangement with a medical man, or he becomes a pupil of a provincial hospital; in the former case, if his master sends out his own medicines, his experience of drugs is very limited,—he has some dozen or two bottles which supply all his requirements. How can such a system convey anything like an adequate knowledge of the materia medica of the Pharmacopœia? And if the future medical man begins his career at the hospital he is supposed to learn of the dispenser a knowledge of drugs and dispensing. But what is the fact? Nine-tenths of the dispensers have in their ordinary daily duties more to do in exercising necessary care with quick dispensing, to be able efficiently to teach others, so that, with few exceptions, the knowledge thus acquired can never enter into competition with that of the well-informed druggist, and he has little to fear from competition in this quarter. Another source of evil may, and no doubt does, to a limited extent, now exist, and that is the wholesale houses becoming retailers. As a rule the more respectable houses confine their dealings to the retailer; but there are many small establishments, calling themselves wholesale dealers, that put up ounce bottles of tinctures and other things to supply grocers and small country shopkeepers in wide-spread districts with sparse populations insufficient to maintain a druggist. Such a system has its advantages; but when the population is sufficiently large to maintain what may be called a composite druggist, the employment of grocers and others not specially educated for the trade is an innovation that the legitimate druggist has to contend with. But I cannot entertain the thought, that such second-hand dealers in drugs have any chance of superseding the better-informed dealer, although he may charge a little less for his drugs; and however much we should like to adopt the suggestion of Professor Attfield, and have the sale of drugs confined to the druggist, and mere vendors not being druggists to receive drugs in "unbroken packets supplied by a not-far-distant registered and responsible pharmacist," I very much fear the unrestrained freedom of trade is an insuperable barrier to the adoption of any system for exclusive trading. Indeed, every day more and more illustrates what I have said on more than one occasion before, that no distinctive trade seems to exist; every tradesman poaches on his neighbour, and one of the last of these encroachments is to be seen in the stationer and bookseller's windows. Since taking 20 and 25 per cent. off new books, the provincial book shop exhibits cheap American clocks, watches and jewellery, so that, what with the toy and fancy trade displays of the draper, the multifarious exhibits of the grocer, the druggist is forced to do much that he otherwise would be glad to avoid. In a struggle for existence, pure pharmacy and scientific chemistry will, I fear, be delegated to the few, with the survival of the fittest.

Another and very important subject is now, and has been for some time, exciting considerable interest. I allude to the patent medicine trade. The only probability of practically placing this branch of trade in the hands of the pharmacist, is confined to those articles said to contain poisons; and it becomes a matter of great difficulty to control the sale of such articles as chlorodyne, soothing syrups and powders, aniseed balsam, and others of a like kind, although well known to contain a certain portion of some poisonous substance. They are not, as a rule, when given according to directions, dangerous, and it will, therefore, be a difficult matter to convince the Legislature that the exclusive sale of these articles should be in the hands of the druggist. Government will not forego the large sums which they now receive for stamp duty, nor will they readily make any concession likely to diminish their interest. The counteracting influence suggested is the extension of our own proprietary articles. This course of action may, to a certain extent, succeed, but it can never displace those secret remedies which extensive advertising has impressed on a gullible public for effecting cures of real or imaginary maladies; the conscientious pharmacist would never condescend to recommend his preparations as *infallible* remedies, whilst the anxiety of the invalid often tempts him to forsake his medical adviser and seek alleviation from one or other of these sources—patent medicines or the pharmacist—and it is here that a difficulty arises, for, however much we may be disposed to avoid counter practice, we cannot, in justice to ourselves, do it, a demand is made for a certain remedy advertised, and the druggist supplies it, unless the applicant asks, as is frequently the case, "Can you suggest anything better?" Under the circumstances, surely we should be justified in exercising our judgment in giving something suitable, always taking care as far as possible to confine the practice to simple cases, or as Professor Attfield says, "Any trespassing on the purely medical domain would necessarily sooner or later involve commensurate punishment."

With respect to legislation the Pharmaceutical Society has certain powers conferred upon it; but it has been found in practice, like most parliamentary measures, defective, and the Council of the Society is most anxious to remedy many obvious defects. But when the subject is fairly considered in all its bearings two important problems present themselves—Can the well-being of the pharmacist be made to dovetail with the well-being of the public? Here difficulties present themselves; for whilst the trade coincide with Professor Attfield's views, that not only poisonous articles but the sale of compound drugs should be placed in their hands as being most likely to conduce to the health and welfare of the community, can the Legislature be induced to adopt this view? From the evidence we have already obtained I very much doubt it, and supposing the suggestion of Professor Attfield to schedule such innocuous drugs as might with safety be entrusted for sale to other hands than those of druggists could be carried out, I fear much difficulty would arise in producing such a classification as would satisfy the public and the Legislature. And I do not think that the suggested curriculum, if adopted, would influence the Legislature, and induce them to give us greater privileges. At the same time there is the startling fact that 56 to 58 per cent. of the Preliminary candidates and 50 to 56 per cent. of the Minor failed during last year. Something must be done to remedy the evil, and the excellent paper read in February last before this Association, by Mr. Hornsby, coincides closely with the views expressed by Dr. Greenhow, in his report of the examinations, which states "the very inadequate early education of the large majority of the candidates" causes the failures. It therefore would indicate that the course adopted by the Council of the Pharmaceutical Society is the right one, viz., apprentices to pass the Preliminary before they are apprenticed, or at any rate that the three years of pupilage as a necessary condition shall date from the passing of the Preliminary, and without this the candidate cannot pass the Minor. To ensure the accomplishment of these objects the curriculum, requiring attendance on courses of suitable lectures at certain centres, seems necessary, notwithstanding that the evidence of Dr. Greenhow goes to establish the efficiency of the present examinations by asserting that in his opinion those who pass them are competent to be registered under the Pharmacy Act. Our friend, Mr. Hornsby, has so ably written on the subject of education that I need not refer to it further.

Before I conclude my paper I must advert to the reiterated statements in the Journal, asking what has the Pharmaceutical Society done? I contend that it has done very much to raise an institution which is generally recognized as a power both at home and abroad. Any matter connected with pharmacy of a public character is invariably remitted by the executive of the Government to the Society for its opinion and advice. Should a vacancy occur in any department requiring an efficient dispenser, those holding our diplomas are preferred. The very fact of appointing a worthy representative (Dr. Greenhow) to attend our examinations and report upon them is sufficient evidence of the interest which Government takes in our proceedings; and in order that our statutes may not be a dead letter, every coroner is annually supplied by the Government with a copy of the Register. I only regret that they too often, by their remarks, show a disregard for its contents. These are only some of the results of having an organized well-established institution to fall back upon. What would have been our position had there been no Pharmaceutical Society when legislative measures inimical to our interests were introduced? But there are unfortunately some individuals—like Sydney Smith's lemon-juice squeezers—who expect the Council of the Society to do improbable things, irrespective of Acts of Parliament and the loss of influence which would follow injudicious action. Having travelled somewhat from my text, I may be permitted, before I conclude, to go a little further, and I do so with the conviction that all those connected with or outside the Society will agree with me—that our Benevolent Fund is entitled to the support of *all*. The Committee, in the distribution of this fund, does not stop to ask if the candidate has directly or indirectly contributed anything to it; but in the spirit of true benevolence it aids the most needy, and I do think principals and assistants should readily respond to appeals which are continuously made for increased means.

A discussion ensued, in which Messrs. Padwick, Marshall Leigh and others took part, and a vote of thanks to Mr. Savage closed the meeting.

LIVERPOOL CHEMISTS' ASSOCIATION.

The fourth general meeting of this Association was held at the Royal Institution, on Thursday, November 24.

In the absence of the President, the chair was occupied by the Vice-President, Mr. A. H. Mason.

The minutes of the last meeting were read and confirmed, and the following donations announced:—The *Pharmaceutical Journal* and the *Canadian Pharmaceutical Journal*.

Mr. Conroy brought before the meeting the results of an examination of one of the class of spurious temperance beverages to which reference was made in the last report of the Commissioners of Inland Revenue. He reported that he had found it to contain alcohol equal to 25 per cent. of proof spirit.

A discussion followed, in which Mr. E. Davies, Mr. T. Fell Abraham and Dr. Symes took part.

The following paper was then read:—

Notes upon the Action of Glycerine on some Ferric Salts.

BY F. O. BROWN.

Often having had to dispense prescriptions containing tincture of perchloride of iron, or sometimes solution of perchloride of iron, in which glycerine has usually been ordered, I was led to make the following experiments. I commenced by making two mixtures as follows, viz.:—

No. 1.

℞ Tr. Ferri Perchlor. . . . . . . ℨiss.
Glycerini . . . . ℨvj.
Aquæ Destill. . . . . ad ℥vj.

No. 2.

℞ Liq. Ferri Perchlor. . . . . . . ℨiss.
Glycerini . . . . ℨvj.
Aquæ Destill. . . . . ad ℥vj.

Having dispensed the mixtures, I next proceeded to ascertain whether the preparations of iron I had used were in the ferric or ferrous state. On applying my reagents to a small quantity of each preparations, taken from the ordinary dispensing bottle which I had used in making the mixtures, I found both preparations to be in the ferric state.

The first reagent I applied was ferridcyanide of potassium, which gave a dark-green colour with both the liquor and tincture.

$$Fe_2Cl_6 + K_6Fe_2Cy_{12} = Fe_2Fe_2Cy_{12} + 6KCl.$$

Then to another portion of each, I added a solution of sulphocyanide of potassium, which gave a deep blood-red colour—

$$Fe_2Cl_6 + 6KCyS = Fe_2\ 6CyS + 6KCl.$$

Both mixtures, when first dispensed, were of a pale sherry colour, No. 1 (containing tincture) being slightly darker than No. 2, which I account for by the tincture being slightly darker than the liquor, no doubt owing to the presence of rectified spirit.

At the end of fourteen days, I noticed that both mixtures were paler in colour, but on applying the same reagents which I have mentioned in the previous part of my paper there was still a quantity in the ferric state, although the colour on applying my reagents was not so intense as when the mixtures were first dispensed. Up to this time the mixture had been well corked and in a shaded position. I then placed what was remaining of both mixtures in a window subject to a strong light and left them both loosely corked for fourteen days more, after which I found both mixtures were considerably paler in colour, in fact almost colourless, and on applying my reagents, I found a still greater proportion had been reduced to the ferrous state; in fact there was scarcely any remaining in the ferric.

On applying a solution of sulphocyanide of potassium a slight coloration was visible, owing to the presence of a little ferric. On the addition of ferridcyanide of potassium to another portion, I had a dark-blue precipitate of Turnbull's blue ($Fe_3Fe_2Cy_{12}$), showing the presence of a large quantity of ferrous salt—

$$3FeCl_2 + K_6Fe_2Cy_{12} = Fe_3Fe_2Cy_{12} + 6KCl.$$

Both mixtures showed the same results.

My reason for subjecting the same mixtures to the two experiments is that it is not an unfrequent occurrence that a customer gets a prescription dispensed, and whilst taking the first doses the bottle is kept securely corked and in a shaded place; after taking a few doses the patient feels considerably better and the mixture is put on one side, loosely corked, or perhaps without a cork and exposed to a strong light; after a while not feeling quite so well, the patient decides to try the remaining part of mixture which previously had done a great amount of good, not knowing whether the mixture (although exactly the same to look at) is the same as when first dispensed, or whether it is quite a different preparation.

On looking over the *Pharmaceutical Journal*, for September 23, on page 257, I find Mr. Schacht, in his valuable paper on the action of glycerine on some salts of iron, says "I found it necessary to record as the first memorandum, that the *tincture* of perchloride of iron taken from the ordinary dispensing bottle was no longer what it was when originally mixed, for it gave an emphatic bright green colour with ferricyanide of potassium." If I am not mistaken this reaction shows that the tincture of perchloride of iron *was* what it *was* when originally mixed, as Professor Attfield, in his 'Manual of Chemistry,' says:—"To a ferric solution add solution of ferridcyanide of potassium; no precipitate occurs, but the liquid is darkened to a *greenish* or olive hue, according to the strength."

Some discussion took place upon this paper, and a vote of thanks having been passed to Mr. Brown the proceedings terminated.

REGISTERED CHEMISTS' TRADE ASSOCIATION OF LIVERPOOL.

The members of this Association held their annual supper at the "Bear's Paw," Lord Street, on Thursday, November 30. It was numerously attended by the chemists of Liverpool and suburbs. Dr. Charles Symes occupied the chair, and Mr. A. Redford the vice-chair, in the temporary absence of the Vice-President.

After the usual loyal toasts had been given, the Chairman proposed "The Registered Chemists' Trade Association of Liverpool," and remarked that the Association had existed long enough and had done sufficient useful work to justify them in looking back with some amount of satisfaction at the past, and to encourage the members with bright hopes for the future. They would still welcome a large number of their brethren if they could prevail upon them to join the Association and accord their willing help. The Association was not a mere trades' union organization pledged to support and carry out selfish objects, but was a body willing to take the broad and most comprehensive view of whatever lay within their province. They would soon have to deal with a Pharmacy Act, as it seemed the Government was now fully prepared to support a Bill so long as it was just to the public. That was all the Association wanted, fairness to themselves and justice to the public.

Mr. Hocken, the Hon. Secretary, in responding said that kindred associations had taken the scientific part and this one the trade portion. He stated that during the past year a fifth edition of the 'Price List' had been issued, copies of which he had sent to all parts of the country. At some of the recent meetings, novelties in the trade and new remedies had been placed upon the table, attracting considerable attention and discussion. He also intimated that, during the coming season, it was intended to continue this and to have short papers on trade subjects. He promised that the Committee would do everything in its power to increase the credit and usefulness of the Association, and hoped it would continue to be an advantage to the city.

"The Pharmaceutical Society and the Chemists and Druggists' Trade Association of Great Britain," was proposed by Mr. Dickins and responded to by Mr. Mackinlay.

"The Liverpool Chemists' Association and Kindred Societies," was proposed by Mr. Parkinson, who specially urged the claims of the Benevolent Fund.

Mr. J. Woodcock, as President, responded for the Liverpool and Mr. Nicholson for the kindred societies.

The other toasts were "The Wholesale Trade," by Mr. Warhurst, and "The President" (given with musical honours), by Mr. Wyatt.

LEEDS CHEMISTS' ASSOCIATION

The first meeting of this session was held in the Library, on Monday, November 27, 1882. The President, Mr. G. Taylor, in the chair.

The minutes of the last meeting were read and confirmed, after which the President delivered an address.

After some preliminary remarks, he said: "In considering how I should proceed with my task it seemed to me that my first and foremost duty, and it is a very melancholy one, is to pay my humble tribute of praise to the memory of my much lamented predecessor. In the death of Mr. Stead this Association has lost one of its oldest and staunchest supporters. He was one of its founders, worked for it steadily and persistently, and died its President. His business tact and sage councils contributed largely to keep it afloat when threatened with wreck by the desertions of its members, and by his cheery good humour and buoyant spirits he has often sustained the courage of his fellow-workers amid very dark and gloomy surroundings. The same characteristics which made him so welcome a member of this Association rendered him equally useful in the management of town's affairs. He represented the West Ward in the Municipal Council for a number of years, was a regular attender of its meetings and faithful in the discharge of his duties, and whether sitting in committee or in full Council he was, I believe, equally esteemed by his brother councillors. . . .

"I shall not attempt anything like a *résumé* of phamacy since you listened to the last presidential address, neither shall I attempt to describe to you the many interesting researches of many very clever men, both English and Continental, into the composition and decomposition, combinations and derivatives, characteristics, conversions, and, I know not what else of the vegetable alkaloids, and other abstruse chemical subjects, for I am quite unable to do so, but shall content myself by passing a few remarks upon some of the recent experiments or discoveries described in the Year-Book, having a practical bearing upon our calling. For instance, we are all more or less interested in teething powders, some of us perhaps in their personal administration, but all of us to some extent in their sale. It is pretty generally known that the basis of these powders is calomel, rendered palatable by the admixture of sugar. It is difficult, however, to reconcile the fact stated by a French pharmacist, M. Verne, that a mixture of this kind undergoes no change, and that, therefore, the asserted danger of prescribing calomel with sugar is fictitious, with the opinion of an English chemist, Mr. P. Hoglan, that sugar greatly promotes the conversion of calomel into corrosive sublimate, and is hence more or less dangerous when present in the system with calomel, and that the latter even at the temperature of the human body is an unstable compound. Practically I think the Frenchman is in the right, though probably in theory the Englishman is more correct. However, it is a subject worthy the attention of chemists, especially of those who sell large quantities of these powders, whether some substitute for the sugar cannot be found about the harmlessness of which there can be no doubt.

"M. Tedenat, I see, suggests phosphate of bismuth as a substitute for subnitrate in medicine on account of its stability. Whether this form is the best in all cases to substitute for the bismuth. alb. of the Pharmacopœia, I will not venture to affirm, but that the latter is a very troublesome customer to deal with when prescribed, as we so often find it, along with bicarbonate of potash or soda, I think there can be no doubt."

The President then referred to the various compounds of bismuth used in medicine, the ready way of preparing ferric hydrates suggested by Mr. P. Hodgson, in which, however, the author erred in suggesting the use of a carbonate instead of a caustic salt, the liquor sodæ or potass. of the B.P. being quite as easily obtained in the pharmacy and producing a better preparation as an antidote for arsenic.

"What is liq. opii sed.? or in other words, if a physician prescribes liq. opii sed. what preparation bearing that name should be used? If 'Battley' is mentioned no difficulty arises; but in nine cases out of ten no indication is given of the particular preparation required, and with the great number of different makers it is quite impossible to ensure a similar medicine from a prescription whose owner is continually passing from town to town, and consequently having his prescription dispensed at different establishments. It would be a great advantage to the retail trade if a form for the preparation of the well-known (at least in name) sedative was introduced into the Pharmacopœia under its proper appellation.

"Mr. D. B. Dott's interesting paper on 'The Solubility of the Salts of Morphia' is very instructive, and will repay a careful perusal. I have always found a difficulty in getting the commercial acetate of morphia to dissolve without the addition of a little acetic acid, whilst the bi-meconate I have always regarded as a very soluble and stable salt; further experiments are evidently needed to give more light upon the subject.

"The various pepsines now met with in the trade have a peculiar tarry odour, which I have been unable to account for; this must be due to some peculiar process of manufacture, as some prepared by myself, according to the B.P. process, has not this disagreeable smell, but, on the contrary, quite a savoury fragrance; perhaps it is due to the use of methylated spirit by other makers.

"The best method of coating pills does not appear to me by any means settled as yet, and affords a fair field for the display of original invention amongst chemists. All the modes hitherto adopted seem to be open to some objection. In one, the coating is too thick and increases the size of the pills too much, besides rendering them difficult to get perfectly round; another is too thin, resembling varnish; another not sufficiently soluble, and all cumbersome and tedious in manipulation. What is wanted is a coating that shall be elegant in appearance, readily soluble, thin, and yet durable, and that can be put on as readily as a coating of silver leaf. Some of those introduced into this country from America are certainly specimens of very elegant pharmacy, and some of those turned out on a large scale by our English makers are certainly very pretty; but what we want is something that a man can do in his own pharmacy, behind his own counter, in small quantities and well. How very common it is for medical men to put 'coated' after writing a prescription for pills, just as they used to put in 'argento rotundo.' These remarks have been suggested by M. Ditten's 'new method of coating pills' by rolling them in melted cocoa butter in a plate or flat-bottomed dish, then shaking them in a large proportion of starch powder and allowing them to cool. Coating in this way is said to protect the pills from the action of air and moisture, to prevent the evaporation of volatile ingredients and to give them in some degree the pleasant aroma of chocolate; but whether they would stand the test of a journey across the burning plains of Egypt and through the heart of Central Africa is doubtful.

"Leaving the region of pharmacy I should now like to make a few very brief remarks upon one or two burning questions. And first and foremost comes the question, the great question of co-operation *versus* individual enterprise. To those who are lifted out of the strife either by having already realized a competence or by having inherited a fortune it must be very interesting to watch the struggle and speculate upon the issue of the great battle now waging betwixt these two great forces, but to us, whose means of securing our daily bread hangs on the result, why we are very much in the position of the frogs against whom the boys were throwing stones; it may be sport to them, but it may be death to some of us. If co-operation in trade, call it by what name you will, Co-operative Societies, Mutual Supply Associations, Civil Service Supply Associations, is to succeed, and be pushed to its ultimate issues, I can see nothing else for it but that the small retail dealer, the man with small capital, must in the end be pushed off the face of the earth. In all large towns and centres of population those who live long enough will see some dozen gigantic stores with outlying branches erected and conducted by means of immense capital subscribed by different classes of society, and all the small shopkeepers merged in these colossal concerns as employees. A very miserable prospect. And whether it would be for the well-being of society that this state of things should come about is exceedingly doubtful, for long before Napoleon uttered his famous saying about the English being a nation of shopkeepers, those very shopkeepers were and have continued to be the backbone of England, and if you take out the backbone the whole body politic must come tumbling down.

"But, I said, *if* co-operation succeeds, and that is a very important reservation. The retail dealer, as a rule, cannot compete with these accumulations of capital, cannot write to the makers of all advertised patent medicines for a large parcel of their preparations and enclose a cheque for the amount in such letter. Probably his capital to commence business with is only £500; out of which he may pay £150 for fittings, another £200 or £250 for stock, and the balance left will be none too much to meet current expenses; he may go on for years, perhaps for life, just able to keep his head above water, and in a general way the utmost he can do is, to pay cash for small quantities as he wants them from the wholesale dealers, and then he loses the first-hand buyers' extra discount.

"If, however, the retailer cannot compete in the matter of capital with these concerns, there are other points in which I think he has the advantage. Personal supervision perhaps is the most telling. Wherever you have divided responsibility, as in a board of directors or managers, buyers for this department and buyers for that department, with numbers of employees not under the immediate supervision of a personally interested head, the door is open for any amount of bribery, corruption and waste; and if all be true one hears of co-operative societies they are not exceptions to this rule. Whereas the small dealer has his little store all around him; his one or two helps are immediately under his eye; he saves one person's wages by his own hands, and in some cases is still further assisted by his wife, and perhaps one or two members of his family. Well, then, in the next place he takes his little store, be it drugs, grocery or drapery, with himself as the presiding genius, and drops it down, so to speak, just under the noses of his customers, whilst his colossal opponents must plant themselves in a central position (of course they may and do throw out branches, but these lack the personal supervision element more than the other), and so in this way he catches many a rainy day customer. Then, lastly, there is the incentive to enterprise which every man must feel more or less who knows himself to be his own master, and that the making or the marring of his fortune rests in his own hands.

"These remarks do not apply to large retail establishments of various trades, or even some of the leading men in our own business, excepting so far as they go to prove the success attainable by individual enterprise, for they are quite capable of taking care of themselves and competing with any corporation. In fact I am disposed to think that we retail druggists have more to fear from these pushing private individuals with capital at their backs than we have from associations.

"This brings me to another burning question, the sale of patent medicines containing poisons by unregistered men. Here, gentlemen, I think we have a real and tangible grievance. That a man, simply because he buys a 5*s.* licence and puts a 1½*d.* piece of diverse coloured paper over the top of a bottle or a box, should be allowed to ride right through the spirit of the Pharmacy Act is not only absurd but unjust. It is absurd, because through this loophole in the Act the country is being flooded with poisons under insidious names, from which it was one of the principal alleged reasons for the passing of the Act it was necessary the public should be protected. And it is unjust, in that whilst a chemist before ever he can sell a pennyworth of laudanum or dispense a grain of morphia must now pass a couple of stiff examinations, have his name kept on the register, and be subject to all the pains and penalties attaching to any infringement of the law, his next door neighbour, be he bookseller or barber, can, by the simple proviso before named, sell any quantity of morphia, prussic acid, chloral, chloroform or other poison which any adventurous maker may think fit to put up and christen a patent medicine. I think that any one putting up a proprietary article containing a scheduled poison should be compelled to state on the label the name of such poison, together with the word "poison" and his own name and address, and that the retailing of such proprietary poisons should be confined to the hands of registered chemists, who should in their turn also affix their names and addresses. This would ensure the public being properly forewarned of the nature of the article they were purchasing and restrict the sale of poisons to those who are alone qualified by Act of Parliament.

"I intend bringing this subject before the Committee of this Association shortly, when I hope they may see their way clear towards taking some steps for bringing this question under the notice of the proper authorities, or for getting up an agitation throughout the country against the law as it now stands.

"Before closing I should like to say a very few words to the young men just coming into our calling. Do not slip the days of your apprenticeship as a time for study and observation. Whether a few months' cramming at some of the establishments in London, or even at the Pharmaceutical Society's rooms, be the quickest and easiest way of getting through your examinations or not I will not say; but this I will venture to affirm, that the amount of information required of you at those examinations, if acquired by a steady day by day reading and observation during the term of your apprenticeship, and by availing yourselves of such courses of instruction or lectures during the time within your reach, will be far more likely to stick to you and remain ready at your beck and call in future years, than the same amount thrust into your head at high pressure, for the moment the pressure is removed and your diploma obtained, then off goes your rapidly acquired knowledge, and you are left very much where you were before you went up for examination."

Mr. Reynolds had much pleasure in proposing that the best thanks of the meeting be given to Mr. Taylor for his interesting address. With regard to one of the questions brought forward, namely, What is meant by liq. opii sed.? he might say that in compounding medicines he always used Battley's preparation unless it was otherwise ordered, as this was the first introduced; but there were many medical men who bought cheaper preparations under a similar name, and it would be better if pharmacists had a guide to assist them in solving this and many other problems presented in connection with their business.

Mr. J. Abbott thought the want of solubility in the morph. acet., referred to by the President, was due to the gradual vaporization of the acetic acid, and it was necessary to add a little acetic acid to get a clear solution; with this addition he had been able to dissolve 1 part of the salt in 3 of water.

Mr. E. Yewdall had much pleasure in seconding the motion proposed by Mr. Reynolds. He thought the danger threatened by co-operative societies would soon be a thing of the past. Quite recently a customer at one of these stores had been supplied with saltpetre in place of carbonate of soda, and he felt quite sure that if chemists and druggists paid careful attention to the requirements of customers so as to avoid mistakes, they would be able to maintain their position. He thought, however, they were making a great mistake in taking apprentices for short periods of servitude. Formerly seven years was the time a youth had to serve, and now they took them for four years, thus producing five generations of chemists instead of three in nearly the same time.

Mr. Branson thought that recently prepared and neutral acetate of morphia would dissolve readily in 3 parts of water, but it was so apt to change by keeping, that most commercial specimens contained a basic salt.

Mr. P. Jefferson had pleasure in supporting the motion, and referred to the special advantages offered to the youths of the present day to those which existed fifty years ago.

The resolution was carried with applause, and having been acknowledged by the President, the meeting separated.

HULL CHEMISTS' ASSOCIATION.

The annual meeting of the above Association was held at the Cross Keys Hotel, on Thursday evening, November 23. In the unavoidable absence of the President (Mr. Councillor Myers), the Vice-President, Mr. George Hayles, presided.

The Secretary gave an epitome of the proceedings during the past year, which was accepted as the report.

The balance sheet for the past year, having been audited, was read and approved of.

The following were elected as office bearers for the year ensuing:—President, Mr. Councillor Myers, re-elected; Vice-President, Mr. George Hayles, re-elected; Secretary and Treasurer, Mr. C. B. Bell, re-elected. Committee: Mr. James Oldham, re-elected; Mr. W. H. Hammond, re-elected; Mr. W. Price, re-elected; Mr. T. W. Ellis, elected.

Votes of thanks to the various officers for the valuable services they had rendered during the past year was accorded.

BLACKBURN CHEMISTS' ASSOCIATION.

One of a series of lectures for this season was delivered on Friday evening, December 8, 1882, by Mr. J. G. Tier, on the subject of "Acetone, its Manufacture, History, etc." Mr. Joseph Hindle, President.

There was a good attendance, and votes of thanks were accorded unanimously to the lecturer and chairman.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on Thursday, December 7, Dr. Gilbert, F.R.S., President, in the chair.

The following certificates were read for the first time:—G. Chandra Basu, W. R. Flett, E. C. Gill, J. Hunter, T. Jenner, W. W. J. Nicol, F. W. Richardson, E. S. Spencer, C. A. Serre.

During the evening a ballot was held and the Scrutators, Messrs. Greenaway and Kingzett, declared the following gentlemen to be duly elected Fellows of the Society:—J. S. Bishop, E. E. Berry, F. W. Branson, R. Blair, T. R. Cowie, R. Carruthers, R. Coulthard, W. J. Chrystal, E. G. Clayton, J. T. Dunn, H. L. Dampier, A. G. Earl, G. Gray, A. G. Howard, W. A. L. Hammersley, J. L. Howe, H. Hotblack, A. E. Johnson, E. Jackson, A. Keen, J. Kilner, J. D. McCarthy, H. C. Newton, S. G. Phillips, R. H. Parker, T. F. Peppe, S. Rideal, G. M. Taylor, T. E. Vasey.

The two following papers were read by the Secretary:—

On the Condensation Products of Oenanthol. By W. H. Perkin, jun.—Much work has been already done on the condensation products of isobutyric, isovaleric and œnanthylic aldehydes, but in many cases only the formulæ of the products obtained have been given. The author therefore undertook the present research to obtain, if possible, some clue as to the constitution of the bodies formed especially from œnanthol. In the first section of the paper the action of alcoholic potash on œnanthol is studied. Dilute potash was used and two acids were found (heptylic acid and an acid, $C_{14}H_{26}O_2$, boiling between 270° and 290°) in combination with the potash. From the oily condensation products two bodies were isolated. The principal one being an aldehyd, $C_{14}H_{26}O$, a colourless oil boiling 277°–279°, the second condensation product is a thick light yellow oil with disagreeable smell and burning taste, boiling at 330°–340°; it was probably an aldehyde having the composition $C_{28}H_{50}O$. The second section of the paper refers to the action of zinc chloride on œnanthol. The reaction is violent. The œnanthol was agitated with water and a very small quantity of zinc chloride used. The principal product is again the body $C_{14}H_{26}O$. The action of acetic anhydride on the aldehyde $C_{14}H_{26}O$ is then examined; it acts simply as a dehydrating agent, $2\,C_{14}H_{26}O = C_{28}H_{50}O + H_2O$. On fusing this substance, $C_{28}H_{50}O$, with caustic potash, heptylic and hexylic acids were formed. Nascent hydrogen converts the body $C_{14}H_{26}O$ into an alcohol, $C_{14}H_{28}O$, boiling at 280°–283°; it is not a saturated body, and by the further action of nascent hydrogen it is converted into another alcohol, $C_{14}H_{30}O$, boiling at 270°–275°. The author then studied the oxidation of the body $C_{14}H_{26}O$, but heptylic and hexylic acids were the chief products. Small quantities of an acid with a high boiling point were produced, which probably had the composition $C_{14}H_{26}O_2$. Alcoholic potash acts upon $C_{14}H_{26}O$, forming heptylic acid and an acid, $C_{14}H_{26}O_2$, boiling at 275°–280°. From a general consideration of the various reactions the author concludes that this body, $C_{14}H_{26}O$, has the constitution—

$$\begin{array}{l} CH_3-(CH_2)_5-CH \\ \qquad\qquad\quad\ \| \\ CH_3-(CH_2)_4-C-COH \end{array}$$

or hexyl pentyl acrylic aldehyd.

On the Condensation Products of Isobutyl-aldehyd. By W. H. Perkin, jun.—A short time since there appeared in the *Berichte* an abstract of a preliminary notice by Fossek, from the *Monatshefte der Chemie*, on the action of an aqueous solution of caustic potash on isobutyl-aldehyde. As the author has for some time been working on these condensation products, he felt himself compelled to publish his results, although at present not quite complete, especially as they are quite different from those obtained by Fossek; the action of alcoholic potash seems to be quite distinct from that of aqueous potash. The author first describes his method of preparing the isobutyl-aldehyde; 50 grams of this substance are first diluted with 100 c.c. of absolute alcohol, and 40 c.c. of 10 per cent. solution of alcoholic potash slowly added, the temperature never being allowed to rise above 30°; after standing twelve hours the mixture is warmed to 50° for a few minutes and then left to cool. The potash solution contained isobutyric acid and a new acid, $C_{12}H_{22}O_3$, boiling at 245°–255°, distilling without decomposition, not solidifying at −10°. Fossek, with aqueous potash, obtained an acid melting at 75°, with composition $C_8H_{16}O_3$. The oily product of the above reaction, after fractionation, gave a distillate boiling between 154° and 157°, having the formula $C_{12}H_{22}O_2$. Much residue of a higher boiling-point was left in the retort. Fossek, by the action of aqueous sodic acetate on isobutyric aldehyde, obtained a body $C_8H_{14}O$. By the action of nascent hydrogen on the aldehyde $C_{12}H_{22}O_2$, an alcohol, $C_{12}H_{24}O_2$, was formed, boiling at 170°–175°; it is a colourless oil, which does not solidify at −10°; it has the same formula as ethyl propylpinakone, but a different boiling point. This alcohol when treated with acetic anhydride gives a diacetate, $C_{16}H_{30}O_4$. A vapour density determination gave numbers about one-half of those required by theory. The higher condensation products of isobutyl aldehyde were next studied by using twice the above-mentioned quantity of alcoholic potash and heating the mixture nearly to the boiling point for ten minutes. Oily products were separated and contained small quantities of the bodies $C_{12}H_{22}O_2$ and $C_{16}H_{30}O_3$, but the principal portion distilled over at 223°–225°, and had the composition $C_{20}H_{38}O_4$; it is apparently an aldehyde; a vapour density determination gave about half the calculated density. By the action of acetic anhydride a mono and a diacetate were formed. After this body, $C_{20}H_{38}O_4$, had been distilled off, a body boiling at 250°–255° was obtained, having the composition $C_{24}H_{44}O_4$. Another body, boiling under 100 m.m. pressure at 227°–229°, had the formula $C_{28}H_{48}O_3$.

Dr. Japp then read a paper—

On a Condensation Product of Phenanthraquinon with Ethylic Aceto-acetate. By F. R. Japp and F. W. Streatfeild.—By heating a mixture of phenanthraquinon and ethylic aceto-acetate with a solution of caustic potash, the authors obtained a condensation product of the formula $C_{20}H_{16}O_4$, crystallizing from benzene in white silky needles fusing at 185°. They ascribe to it the constitution—

$$\begin{array}{l} C_6H_4—C=C\begin{cases} CO—CH_3 \\ COOC_2H_5 \end{cases} \\ \ \ |\qquad\ \ | \\ C_6H_4—CO \end{array}$$

and the name ethylic phenanthroxylene aceto-acetate. By treatment with fuming hydriodic acid in the cold this compound parts with one atom of oxygen, and is converted into ethylic-phenanthroxylene-isocrotonate—

$$\begin{array}{l} C_6H_4—C=C\begin{cases} CH=CH_2 \\ COOC_2H_5 \end{cases} \\ \ \ |\qquad\ \ | \\ C_6H_4—CO \end{array}$$

which is deposited from light petroleum in groups of colourless crystals, fusing at 124°. This compound dissolves in dilute caustic potash on warming, and on acidifying with hydrochloric acid a new acid is precipitated, which by recrystallization from boiling phenol is obtained in short colourless needles, fusing at 295°. This acid is formed from the preceding compound by replacement of the ethyl group by hydrogen, and simultaneous assumption of the elements of water. The formula is therefore $C_{18}H_{14}O_4$. An examination of its salts showed that it was dibasic. The authors assign to it the constitution—

$$\begin{array}{l} C_6H_4—CH=C\begin{cases} CH=CH_2 \\ COOH \end{cases} \\ \ \ | \\ C_6H_4—COOH. \end{array}$$

Both the reduction product and the dibasic acid derived from it yield on destructive sublimation long colourless needles of a new compound, fusing at 213°, which gave on analysis figures agreeing with the formula $C_{14}H_{10}O$. The authors suggest that this compound may be the desoxybenzoïn of phenanthrene $\begin{array}{l} C_6H_4—CH_2 \\ \ \ |\qquad\quad | \\ C_6H_4—CO \end{array}$ but the quantity obtained was insufficient for further investigation.

Dr. Armstrong then gave a short communication—

On the Constitution of Lophin.—This was a criticism of Dr. Japp's paper read at the last meeting. The author claimed that Radziszewski's formula, and especially his own modification of it $\begin{array}{l} Ph—C—N \\ \quad\ \ | \qquad\ \ >CHPh \\ Ph—C—N \end{array}$ was applicable in explanation of the reactions of lophin. He objected to Dr. Japp's use of the argument from analogy, on the ground that the bodies obtained by the action of aldehydes on phenanthraquinone were not analogues of lophin, and, he urged, that since in the great majority of cases in which aldehydes enter into reaction with other bodies, the radicle CHPh of the aldehyde remains intact, the argument from analogy would lead us to prefer the symmetrical rather than the unsymmetrical formula adopted by Dr. Japp. The formation of benzamide and dibenzamide on the oxidation of lophin, it was pointed out, is not difficult to explain, and the production of benzoic acid on heating lophin with hydriodic and hydrochloric acids is probably a consequence of a purely hydrolytic action. Incidentally, Dr. Armstrong objected to Dr. Japp's use of the term "intramolecular change" in cases involving no transposition of atoms.

Dr. Japp briefly replied to the criticisms of Dr. Armstrong, and reiterated his conviction that the formula proposed by him agreed best with the known decompositions, etc., of lophin, and he failed to see how Radziszewski's formula accounted for some of the known reactions of that body.

Mr. S. U. Pickering then read a paper—

On the Constitution of Molecular Compounds: the Molecular Weight of Basic Ferric Sulphate.—Two methods of notation are commonly employed to represent basic compounds. Thus with basic ferric sulphate, $2Fe_2O_3\ SO_3$, or $Fe_2(SO_4)_3\ 5Fe_2O_3$; in this latter an analogy between a basic salt and a hydrated salt is hinted at. If the first formula is correct, the molecular weight is 400; if the latter, m.w. = 1200. The author has, in the present paper, endeavoured to determine the molecular weight of basic ferric sulphate by ascertaining the unit of water removable from a hydrated specimen of it. The author gives details as to the preparation of the sulphate, the hydration of it and the loss of water under different conditions. If the molecular weight be 1200, thirty-three different hydrates are possible; he obtained fourteen hydrates, all of which indicate the number 1200, and he concludes that it is practically a certainty that the molecular weight of basic ferric sulphate is 1200 and its formula $Fe_2(SO_4)_3,5Fe_2O_3$.

Mr. Toms then read a paper on—

The Chemistry of Hay and "Ensilage."—The author has analysed various samples of hay and contrasted them with analyses of "ensilage," *i.e.*, grass buried whilst green in a water-tight pit or "silo," and subjected to pressure. It is well known to chemists that haymaking is not a mere drying of grass, but that a fermentation, during which the grass loses its green colour, also takes place, which developes the well-known perfume of hay. A specimen of good hay, dried, contained:—Fatty matters, 2·17 per cent.; free acetic acid, 1·89; sugar, 3·42; starch, 12·46; gum and mucilage, 27·25. A specimen of brown hay from the same rick as the last, but from a portion of the stack which had heated, contained:—Fatty matters, 4·26; aldehyde, which formed a mirror with ammonio silver nitrate; free acetic acid, 5·38; sugar, 6·94; starch, 3·42; gum and mucilage, 24·77. More than two-thirds of the starch had thus disappeared and apparently had been converted into sugar, etc. Three specimens of ensilage were analysed; one differed very little from ordinary grass. The second was brown and smelt strongly of tobacco; it contained more acetic acid and sugar, but less starch. The third specimen represented fodder, which had been buried eighteen months; it still contained starch sugar, but was not acid and was mouldy.

Mr. O'Sullivan did not think that the author had proved the presence of starch in the hay or ensilage, because other substances, such as gum and mucilage, when boiled with dilute sulphuric acid, furnished cupric oxide-reducing substances.

Dr. Gilbert said during his recent visit to America he had heard a good deal about "ensilage," and the process seemed to be thought much of in that country. The crops, too, of succulent maize, etc., seemed well suited for it. It was essential for a good result to put all the materials as quickly as possible in the "silo," and put on a pressure of 100 to 150 lbs. per square foot almost immediately. He suggested that unless samples of ensilage taken for analysis were kept under pressure during transit the product might be completely changed. The process was very suitable for the preservation of the pulp from the sugar beet.

The Secretary then read a paper on—

Certain Brominated Carbon Compounds obtained in the Manufacture of Bromine. By S. Dyson.—The author has separated from a liquor obtained as a bye-product at the North British Chemical Company's Works, carbon tetrabromide, bromoform and chlorobromoform; these substances were identified by analysis, boiling point and vapour density determinations.

Mr. W. H. Perkin then read a note on—

The Preparation of Diphenylene Ketone Ether.—A quantity of salicylic acid was heated with acetic anhydride, the mixture was boiled and the excess of acetic anhydride distilled off. The residue, consisting chiefly of salicylide, was distilled, and an oily product came over which solidified to a crystalline mass. On purification pale yellow needles were obtained, having the composition $C_{13}H_8O_2$, fusing at 170°. The yield is 30 to 40 per cent. The author's son, Mr. A. G. Perkin, is engaged in a study of the derivatives, etc., of this substance.

CHEMISTS' ASSISTANTS' ASSOCIATION.

A meeting of the above Association was held on Wednesday, November 29, when a paper on "Pharmaceutical Politics" was read by Mr. R. Winfrey.

The author divided the subject into three parts:—(1) The preparation and elaboration of drugs; (2) prescribing simple remedies by chemists; (3) the necessity of further pharmaceutical legislation. With regard to the first, he held it as very desirable that all preparations should be made by the chemist himself, but practically this could not be entirely carried out; in many cases things could be bought much better than they could be made on a small scale. On prescribing he could not do better then endorse the remarks of Professor Attfield. He thought that in cases where a druggist was free to sell a patent medicine he should be equally free to sell a remedy of his own. This sale of simple remedies would do much to prevent the sale of patent medicines. At present both those chemists and doctors who hold extreme views play into the hands of the patent medicine makers. With regard to further legislation he did not think it reasonable or even desirable to expect a monopoly in the sale of drugs; the superior knowledge of the chemist, when that could be used, would prevent his suffering from severe competition, and ordinary trading he must be content to conduct on trade principles. The only protection he thought just or desirable was in dispensing, and this he thought would before long be granted.

A long discussion took place, in which Messrs. Wrenn, Parkinson, Kerr, Cooper, Hartridge, Woods, Palmer, Alcock, Phillips, Millhouse, Wyatt and Hadfield took part, after which a hearty vote of thanks to Mr. Winfrey brought the meeting to a close.

Parliamentary and Law Proceedings.

Alleged Defective Sweet Spirit of Nitre.

The following case came before the South Shields bench of county magistrates on November 7:—

John Atkinson, general dealer, Harton Colliery, was summoned and charged by Superintendent Scott with selling to him sweet spirit of nitre, not being of the nature and quality asked for.

Superintendent Scott deposed that he bought three ounces of sweet spirit of nitre of Mr. Atkinson, which for analysis he divided into three parts, one he gave to Mr. Atkinson, one he took to the county analyst, and the other he kept himself. The analyst's report was now before the bench, and stated that its gravity was a little too low, that it was totally wanting in nitrous ether, and therefore of no medicinal value.

Mr. G. R. Duncan defended, and called Mr. Atkinson, who, being sworn, said that he sold the nitre pure, just as he got it of Messrs. Mays and Son.

Mr. Sergent was then sworn, and said that he was a chemist by examination, an assistant of Messrs. Mays and Son, that he in presence of Mr. Mays tested the spirit of nitre, and found its specific gravity ·850. He also tested it for nitrous ether, and found it present.

Mr. Mays was then sworn, and said that he was a pharmaceutical chemist, and had been more than forty years in business. He bought the sweet spirit of nitre of one of the first makers in London, Messrs. Davy, Yates and Routledge, and had always found their preparation good, and as for his firm, they sold it undiluted, as they got it. He had examined the sample left with Mr. Atkinson by Mr. Scott, and found it of gravity ·850, and that it did contain nitrous ether. As to the last, the gentlemen on the bench could judge for themselves, for the sample before them spoke for itself as to that—to anyone whose senses of smell and taste were not impaired. It was the spiritus ætheris nitrici dulcis of the London Pharmacopœia—the sweet spirit of nitre which it was the allowed usage of the trade to sell, as they had done many years before the British Pharmacopœia was written, and which the public liked better than the British Pharmacopœia preparation, which always tasted rather sour, but which last it was the duty of chemists to use in prescriptions.

The scientific evidence being contradictory, Mr. Duncan asked to have Superintendent Scott's sample sent for examination to the Government analysts at Somerset House. This was ordered, and their report, being now before the court, was read, and as it agreed with Mr. Mays's evidence *in toto*, the case was dismissed.—*Shields Daily News.*

BOOKS, PAMPHLETS, ETC., RECEIVED.

Elements of Dental Materia Medica and Therapeutics, with Pharmacopœia. Third Edition. By James Stocken, L.D.S. Assisted by Thomas Gaddes, L.D.S. London: J. and A. Churchill. 1882. From the Publishers.

The Chemists and Druggists' Diary, 1883. London: Office of the Chemist and Druggist. From the Publishers.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

The Extract of Meat Case.—We have received from Mr. Charles Rotter, Secretary to the Liebig's Extract of Meat Company, a letter in which, at the desire of the Board, he refers us to Liebig's paper in the Annals of Chemistry, for 1847 (vol. lxii., p. 361), stating that Proust had many years before described extract of meat, and recommended the use of it to the French Government. Mr. Rotter appears to be under the impression that we were not aware of this publication, or of the precise nature of Liebig's claims with regard to the extract of meat, and refers to our editorial comments on this subject (before, p. 406) as supporting his assumption. We believe that it is unnecessary in reply to do more than say that those comments merely had relation to the statements brought forward in evidence at the trial, and in so far we fail to perceive that they stand in any need of correction.

J. Richardson is recommended to send his question to one of the Dental Journals.

Sarsæ.—Other things besides the name would have to be taken into account. The question is one for a solicitor.

J. K.—Coffin's Composition Powder is not the subject of a patent. The following recipe, taken from one of Dr. Coffin's works, has already been published in this Journal:—"Bayberry bark, 4 oz.; Pinus Canadensis, 2 oz.; Ginger, 2 oz.; Cayenne, $\frac{1}{4}$ oz.; Cloves, $\frac{1}{4}$ oz.; all finely pulverized and well mixed. Ordinary dose, a tea-spoonful in a cup of hot water, sweetened." Other recipes may be found by referring to the General Index.

Lignum.—We are unable to identify the wood, but might, perhaps, if you could furnish any information as to its history.

M. P. S.—Several recipes for Ung. Rumicis c. Sulph. will be found in the *Pharmaceutical Journals* for Oct. 23 and 30, 1880, pp. 346 and 367.

J. Robertson.—*Amomum angustifolium.* See the Museum Catalogue.

Communications, Letters, etc., have been received from Messrs. Hickling, Palmer, Wells, Richardson, Hill, D. G.

THE PHARMACOPŒIAL EXTRACTS OF ALOES AND THEIR PREPARATION.*

BY ROBERT AITKEN.

The above subject was brought under my notice in the following manner. A short time ago a friend of mine complained that a prescription which had been made up in different towns varied very much in effect. The prescription was for 1 grain pills of extract of aloes, combined with a little capsicum. As the variation evidently lay with the extract of aloes, I procured a sample from a firm who had dispensed the prescription, and was rather surprised to find it contain about 30 per cent. of resin, which no doubt accounted for its weak action. A second sample procured from another firm who had also dispensed the prescription gave about 8 per cent. of resin. These experiments led me into an examination of several samples of extract, and I found that all those tested gave evidence of the presence of resin, some in large proportion, some in small.

To elucidate the matter further, twelve samples of extract (both Socotrine and Barbadoes) were procured from Edinburgh, London and Dublin, and examined with the following results:—

No. 1. Socotrine, gave 20 per cent. of resin.
No. 2. Barbadoes, gave 25 per cent. of resin.
No. 3. Socotrine, gave 25 per cent. of resin.
No. 4. Socotrine, gave 25 per cent. of resin.
No. 5. Socotrine, gave 10 per cent. of resin.
No. 6. Barbadoes, gave 8 per cent. of resin.
No. 7. Socotrine, gave 8 per cent. of resin.
No. 8. Barbadoes, gave a trace of resin.
No. 9. Barbadoes, gave 6 per cent. of resin.
No. 10. Socotrine, gave 8 per cent. of resin.
No. 11. Socotrine, gave 15 per cent. of resin.
No. 12. Barbadoes, gave 20 per cent. of resin.

The method I employed was as follows:—A certain quantity of the extract was weighed out, powdered, and dissolved in boiling distilled water; on allowing it to cool, the resin gradually deposited on the sides and bottom of the mortar; stirring seemed to facilitate the separation. The resin was collected on a weighed filter and well washed with cold distilled water, until the washings were colourless. The filter was then dried and weighed; the difference between the gross weight and the weight of the filter giving the amount of resin present.

In most of the samples which contained a large quantity of resin, the latter separated in a sticky mass; in those which contained least, the resin was suspended in the solution as a fine brown powder, in some instances so fine as to run through a paper filter.

The different varieties of aloes as prepared for the market contain a considerable amount of resin, caused by the heat employed in evaporating the juice; and in order to free the aloes from this and other inert matters the Pharmacopœia orders the preparation of the extracts of Socotrine and Barbadoes aloes. Consequently one would expect these extracts to be perfectly free from resin. The Pharmacopœia recommends two methods of evaporation, either by means of a water-bath or a current of warm air. In order to ascertain whether the first process would yield an extract free from resin, I prepared some extract from Socotrine aloes, and evaporated the liquid by means of a water-bath. I obtained about 50 per cent. of extract, and on testing it found resin even in portions which had not come much in contact with the sides of the porcelain vessel used for evaporation. I then made another sample of extract, but used a current of warm air instead of the water-bath. The result was an extract perfectly free from resin. Some of this last sample was then exposed to an increased heat on the top of a boiler, and, after a short exposure, showed the resin in the form of a fine brown powder, thus showing how prone the drug is to change under the influence of heat.

From these experiments it will be seen that in order to procure the extract free from resin, the second method alone ought to be used, and even that carefully attended to.

The causes of so much difference in the extracts is owing, I consider, to careless preparation, very few evidently choosing to prepare them by the slow process, and those who are in the habit of making large quantities are more likely to adopt the quicker method of the water- or steam-bath, though, as I have shown, such a method would lessen considerably the activity of the extract by the formation of resin.

* Read at a Meeting of the North British Branch of the Pharmaceutical Society, Wednesday, December 13, 1882.

PREPARATION OF SYRUPUS FERRI PHOSPHATIS BY A NEW METHOD.*

BY DANIEL GORRIE.

Of all the pharmacopœial syrups none are so unsatisfactory as those of iron, and the literature which has been written upon them is able and voluminous; it is with considerable diffidence, therefore, that I submit this paper. In syrupus ferri phosphatis there are two sources of dissatisfaction, (1st) in its preparation and (2nd) in its tendency to spoil by keeping. The official method of preparation favours oxidation, while the ferrous phosphate cannot be entirely washed free from impurities which tend to favour subsequent coloration of the syrup. The method which I now bring before you is intended to overcome these objections, and has as its main feature *the constant retention of the iron in solution*, thus saving the trouble of precipitating, washing, draining, drying and redissolving a ferrous compound, which is very prone to oxidation. My formula is based upon the quantities given in the official formula and is as follows:—

Take of—

Granulated sulphate of iron	224 grs.
Syrupy phosphoric acid† (sp. gr. 1·500) 9 drachms, 56 grs. by weight.	
Pure carbonate of baryta	159 grs.
Distilled water	6 ozs. or q.s.
Refined sugar	8 ozs.

Mix the phosphoric acid with three ounces of water and in the mixture dissolve the sulphate of iron with the aid of heat; add the baryta carbonate and, when effervescence has ceased, continue the heat for a few

* Read at a Meeting of the North British Branch of the Pharmaceutical Society, Wednesday, December 13, 1882.

† Acid of this density contains, omitting a fraction, 50 per cent. of phosphoric anhydride and the calculation is based upon this percentage. The additional quantity of acid, 76 grs., required to unite with the Fe, to form $Fe_3P_2O_8$, is also included.

minutes, to allow the precipitate to aggregate, then allow to cool. Filter when cold and wash the precipitate with three ounces of cold distilled water; in the filtrate dissolve the sugar without heat and make up to 12 ozs. if necessary.

I may be allowed to give the rationale of the process:—In the first instance, the baryta carbonate will react with phosphoric acid to form baryta phosphate, carbonic acid and water, thus:—

$$2H_3PO_4 + 3BaCO_3 = Ba_3P_2O_8 + 3CO_2 + 3H_2O.$$

Double decomposition will then take place between the iron sulphate and baryta phosphate, thus:—

$$Ba_3P_2O_8 + 3(FeSO_4 7H_2O) = 3BaSO_4 + Fe_3P_2O_8 + 21H_2O.$$

Although baryta phosphate is insoluble in water it is easily held in solution by the excess of acid present. The sulphate, you are aware, is almost insoluble, 1 part only being soluble in 400,000 of water; and it is concluded that it is not more soluble in cold phosphoric acid, but the solubility is rather more at the boiling point. It will be obvious, therefore, that boiling should be prevented, and that the solution be quite cold before filtration; the total separation of the baryta sulphate is thereby secured. To prove this I have several times made an estimation of the precipitate by heating till it ceased to lose weight and weighing: in all cases the theoretical quantity, 188·05 grs., was found; the working loss scarcely interfered with the estimation. In every case I ascertain by the ordinary tests whether the solution contains either undecomposed ferrous sulphate or baryta phosphate previous to the addition of the sugar. The finished product is beautifully transparent and colourless, and infinitely less liable to oxidation than syrup prepared by the official method.

Since writing the foregoing, Mr. MacEwan has drawn my attention to a discussion on this subject at the Pharmaceutical Conference, held in Glasgow. In this discussion Mr. Borland suggested a method based on the same principle which has guided me in drawing up a formula, namely, the precipitation of the sulphuric instead of the ferrous radicle. Mr. Borland gets this result by dissolving lime phosphate in phosphoric acid, and adding a solution of sulphate of iron; double decomposition ensuing. This method is objectionable in so far that lime phosphate to be soluble requires to be freshly precipitated (thus entailing considerable time), and besides the finished product is contaminated with lime sulphate. The objections against the lime phosphate can be obviated by adopting my method and substituting precipitated chalk for baryta carbonate, 81 grains of the former being equal to 159 grains of the latter. If the precipitated chalk be used it is necessary to allow the solution to stand for twenty-four hours to allow sulphate of lime to separate as far as possible. Again, when the sugar has been dissolved in the solution, more lime sulphate separates, due no doubt to its inferior solubility in a saturated saccharine solution; hence the necessity of a few days' rest for deposition.

I am conscious that objections may be urged against the baryta method, lest baryta phosphate should be held in solution by the free acid present; but it is evident that with pure materials, and careful and intelligent manipulation, the process will commend itself as being simpler, speedier and less objectionable than the official method, or than the very slow method of dissolving iron filings in syrupy phosphoric acid.

PRELIMINARY NOTE ON GELSEMINE AND ITS SALTS.

BY A. W. GERRARD, F.C.S.

Up to the present time, that is thirty years after its isolation by Kollock, no crystalline ordinary compounds of the alkaloid gelsemine have been described, although it has been investigated by several chemists, notably, Professor Sonnenschein and Dr. Wormley.

During the year 1881 I prepared a small quantity of gelsemine, having mainly the characters hitherto ascribed to it, only differing so far that microscopic crystals were noticed. This observation was sufficiently interesting to determine me to further investigate the subject, and I have met with considerable success, having prepared the pure alkaloid and a number of its compounds with acids in the crystalline form.

The pure alkaloid is a colourless substance, having properties in many and important respects, especially its behaviour with acids, different from those hitherto described. The hydrochloride and hydrobromide are the best crystallizing salts, their form being prismatic.

In a future paper, and I trust at the next Evening Meeting of the Pharmaceutical Society, I propose to describe in detail the method of preparation and properties of the above compounds. The main object of the present communication is to reserve the right of such work.

THE NEW PHARMACOPŒIAS FOR THE UNITED STATES AND GERMANY.

(*Continued from page* 483.)

LANGUAGE, NOMENCLATURE, ETC.—The text of the new edition of the United States Pharmacopœia is—was as the case in the previous four editions—written in the English language, whilst that of the 'Pharmacopœa Germanica' is entirely in Latin. So strictly is this carried out in the latter work that the German synonyms, which in the first edition were placed under the respective Latin titles, are now remitted to an index at the end of the work. On the other hand, in the United States Pharmacopœia, the titles are given in Latin and in English. It is understood, however, that the adoption of the vernacular tongue in the German work also would have been in accordance with the opinion of the majority of those who carried out its revision, but that in this they were overruled by the Government department, which, indeed, is responsible for the translation into Latin of the original German manuscript presented by the Commission. This decision has given rise to some discontent, and insinuations have not been wanting that it will be necessary to consult the original in some cases in order to understand the newly-coined technical expressions in which the classical philologists have wrapped up the "clear German words." From an international point of view, however, perhaps, even barbarous Latin will, as a rule, be thought preferable to the most crystal German. But, be this as it may, the Imperial Government has thought proper to meet the objectors half-way, and has announced its intention to publish the work in its original German form also, though this is not to be considered the official pharmacopœia.

The *nomenclature* of the United States Pharmacopœia, in respect to the main principles followed, is the same as that of the previous edition; but in some details it has undergone considerable modification, which, whatever may be the effect in furnishing common ground for agreement at some future time, has the present result of making it less like that of the British Pharmacopœia without making it more like that of the German. For the chemical compounds, the unitary method, advocated by Professor Attfield, is retained, and this method, it has been stated on good authority, will be probably adopted in the next edition of the British Pharmacopœia. But it has been deemed advisable to treat the Latin nouns of salts in *-as* and *-is* as of the masculine gender, on the ground that "the alteration to the feminine gender, made in 1860, was based on error;" *e.g.*, "Calcii Carbonas Præcipitat*us*," "Ferri Sulphas Exsiccat*us*," etc. An argument in favour of this alteration, put forward some time since, was based on the supposed necessity that the adjective should agree with the word "*sal*," understood; but this would seem to involve a further alteration, in which the terminations *-as* and *-is* would disappear altogether. The necessity for the alteration may well be doubted, but it only affects a very few names. A much more important alteration has been made in respect to the names of alkaloids, which in the last edition corresponded with those in the British Pharmacopœia, both in Latin and English. In Latin they are now made to terminate in *-ina*, giving rise to quite a new series of terms—morphina, strychnina, quinina, etc.,—an alteration, which, although advocated by Professor Oldberg, in a paper read before the International Pharmaceutical Congress, hardly appears to present advantages that will compensate for the introduction of another element of confusion in alkaloidal names, especially as in prescriptions the patience of prescribers is hardly equal to the task of writing in full the shorter forms at present in use. On the other hand, the abandonment of the termination *-ia* for the English names, in favour of *-ine*,—for instance, strychnine for strychnia, quinine for quinia,—is a step in the right direction; it being the orthography adopted officially and universally in France, whilst it is in accord with the practical tendency in this country. In Germany, also, where the terminations *-inum* in Latin and *-in* in the vernacular,—which in the United States and Great Britain are confined to the names of neutral principles,—are used for both alkaloids and neutral principles, the adoption of the change would involve only a slight alteration, and one that would be convenient and natural if it were thought advisable in that country to draw an orthographical distinction between the two classes. There are also a few other alterations in the Latin terms of minor importance, some of them tending towards uniformity, and others not. "Glycerina" is abandoned in favour of "glycerinum," the form adopted in the British and German Pharmacopœias; "iodum" takes the place of "iodinum;" "sulphidum" of "sulphuretum;" "cambogia" for "gambogia," etc. 'Manganesium" has been curtailed to "manganum," which is the German official form.

In the 'Pharmacopœa Germanica' the chemical nomenclature has been modified so as to bring it into accord with the principle followed in the United States work, the name of the metal instead of its oxide being now used to indicate the basic portion of a salt. But this affords no approximation to the form adopted in this country and the United tates on the one hand or that in France on the other. "Natrum nitricum" has become "natrium nitricum," "magnesia carbonica" has become "magnesium carbonicum," and so on, but the form remains equally unfamiliar to English eyes. One peculiarity of this nomenclature may, indeed, warrant the repetition of a word of caution. The occurrence of the particle *-at-* in the adjective applying to the non-basic radicle does not indicate that that portion of the compound has anything to do with an acid bearing a name ending in *-ic*, but that it belongs to the haloid class. Thus "ferrum iodatum" does not mean iodate of iron, which has been recently recommended for medicinal use, but our old friend "iodide of iron;" the other class being represented by adjectives constructed on the model of "kalium chloricum" for "potassium chlorate." The "liquor kalii bromati" is, therefore, a solution of potassium bromide, whilst "liquor kalii bromici" stands for the solution of potassium bromate.

Turning again to the United States Pharmacopœia, the rule has been followed, as before, with a few exceptions, of using the botanical genus name of a vegetable drug as its official Latin title; alone, when only one part of the plant is official, but when more than one part is official then the respective parts are indicated. Thus, "sambucus," U.S.P., is equivalent to "sambuci flores," B.P., and "sambuci flores," P.G.; "carum," U.S.P., to "carui fructus," B.P., and "fructus carui," P.G., etc. In the 'Pharmacopœa Germanica' the plan is adhered to, of indicating the part at the commencement of the title,—differing in this from the British Pharmacopœia,—so that the cortices, foliæ, herbæ, radices, etc., occur together in groups. It will, therefore, be apparent from the foregoing, although it may be a minor point, that no great advance has been made towards uniformity in nomenclature.

Arrangement.—In respect to arrangement the United States Pharmacopœia has undergone a great change. Hitherto the materia medica has been kept separate from the preparations and the articles in it have been enumerated in two divisions: a "primary list," which included what were considered to be the more important drugs, and a "secondary list," which included less important drugs and others that were yet on their trial. The plan has had its admirers in this country, but it is open to the objection that the object of a Pharmacopœia is to define medicines rather than to indicate their relative value. It has, however, been abandoned and all the articles of materia medica and preparations are now included in one series, arranged alphabetically. The arrangement, therefore, of the three Pharmacopœias is now practically the same, being subject only to variations arising from differences in the nomenclature. In the United States Pharmacopœia, after the description of each of the crude drugs, are also given the names of the preparations in which it forms a constituent of importance, an addition which, although not carried out so fully as in the British Pharmacopœia, obviates an inconvenience that must have been felt by any person who has had to consult former editions of the American work. In the 'Pharmacopœa Germanica' this plan is not followed.

Descriptions, Chemical Formulæ, etc.—Both the United States and the German Pharmacopœias now differ from the British in omitting processes for chemical bodies; except in cases where difference in processes produces different results, they are simply described according to their physical characteristics, and tests are given for their identity and purity. This is done very fully in the United States Pharmacopœia, and a large number of solubilities have been added. Definite chemical compounds are represented in the United States Pharmacopœia according to both the old and the new notations. Atomic and molecular weights are also given; but the atomic weights of the elements, which are given to the first place of decimals and are said to have been "selected with care from what appeared to be the most reliable determinations," represent the results of some of the most recent work: aluminium, 27; antimony, 120; bismuth, 210; cerium, 141, etc. The German Pharmacopœia gives neither chemical formulæ nor atomic weights. Temperature is indicated in both the United States and the German Pharmacopœias in degres Celsius; but in the former the equivalents are also given in every case in degrees Fahrenheit. Specific gravities in both works, where not otherwise expressed, are to be understood as taken at 15° C.

Quantities.—The instruction of the Convention to substitute in the United States Pharmacopœia parts by weight (except in certain cases) for actual weights and measures, which was ignored in working out the previous edition, as being then impracticable, has now been effected, and the work has been in this respect brought into accord with the German one. In doing this, care has been taken to adjust the proportions of the new formulæ so as not to affect materially the strength of the preparations. In the case of the pill masses where the quantities of ingredients ordered are for a definite number of pills, they are given side by side in grains and in grams.

Alterations in the Materia Medica and Preparations.—The alterations due to omissions and introductions are in both works very considerable. Taking first the United States Pharmacopœia, the number of articles omitted is 229, consisting of 78 crude drugs (almost all of vegetable origin), 28 inorganic drugs or chemicals, 106 pharmaceutical preparations and 17 miscellaneous substances. Among the dismissed pharmaceutical preparations, etc., are:—2 waters, 3 cerates, 3 confections, 10 decoctions, 2 plasters, 13 solid extracts, 2 fluid extracts, 5 glycerites, 29 infusions, 4 solutions, 5 oils, 2 juices, 3 pills or pill masses, 9 suppositories, 7 tinctures, 7 ointments and 3 wines. The following list of the articles of materia medica omitted will show that whilst a few dismissals are due to the abandonment of processes of manufacture a much larger number are articles of the indigenous materia medica that have become obsolete:—

Acetum.
— destillatum.
Achillea.
Acidum oxalicum.
— phosphoricum glaciale.
— valerianicum.
Aconitia.
Aconiti folia.
Alcohol amylicum.
Aloe barbadensis.
— capensis.
Angustura.
Antimonii oxysulphuretum.
Apocynum androsæmifolium.
Aralia nudicaulis.
— spinosa.
Argentum.
Asarum.
Asclepias incarnata.
— syriaca.
Avenæ farina.
Barii carbonas.
— chloridum.
Berberis.
Bismuthum.
Cadmii sulphas.
Cadmium.
Caffea.
Canella.
Carota.
Carthamus.
Cassia marilandica.
Castoreum.
Cinchona pallida.
Conii folia.
Coptis.
Cornus circinata.
— sericea.
Cotula.
Creta.
Cupri subacetas.
Cuprum ammoniatum.
Curcuma.
Delphinium.
Digitalinum.
Diospyros.
Dracontium.
Elaterium.
Erigeron.
— canadense.
Euphorbia corollata.
— ipecacuanha.
Fermentum.
Ferri ferrocyanidum.
— subcarbonas.
— sulphuretum.
Frasera.
Gentiana catesbæi.
Geum.
Gillenia.
Granati fructus cortex.
Helianthemum.
Helleborus.
Hepatica.
Heuchera.
Hordeum.
Hyoscyami semen.
Iris florentina.
Juniperis virginianus.
Lini farina.
Liriodendron.
Lycopus.
Maranta.
Marmor.
Monarda.
Mucuna.
Nectandra.
Os.
Ovum.
Panax.
Papaver.
Petroselinum.
Polygala rubella.
Quercus tinctoria.
Ranunculus.
Rubia.
Ruta.
Sabadilla.
Sabbatia.
Sago.
Sesamum.
Simaruba.
Solidago.
Spiræa.
Statice.
Tapioca.
Testa.
Tormentilla.
Triosteum.
Uva passa.
Veratrum album.
Vinum portense.
— xericum.
Viola.
Xanthorrhiza.
Zinci oxidum venale.

The newly added articles comprise 30 crude drugs derived from the vegetable kingdom, 60 inorganic drugs or chemicals, 150 pharmaceutical preparations and 16 miscellaneous substances. Among the new pharmaceutical preparations are:—11 abstracts, 10 solid extracts, 35 fluid extracts, 11 syrups, 22 tinctures and 6 wines. As these preparations will be referred to sufficiently under their respective headings, it will only be necessary, in order to give an idea of the new remedies incorporated in this Pharmacopœia, to give a list of the crude vegetable and inorganic drugs and chemicals that have been added:—

Acidum aceticum glaciale.
— boricum.
— hydrobromicum dilut.
— oleicum.
— phosphoricum.
— salicylicum.
Æther aceticus.
Aluminii hydras.
Ammonii phosphas.
Amyl nitris.
Amylum iodatum.
Antimonii sulphidum pur.
Apomorphinæ hydrochlor.
Argenti iodidum.
— nitras dilutus.
Arnicæ radix.
Auri et sodii chloridum.
Benzinum.
Bismuthi citras.
— et ammonii citras.
Bryonia.
Caffeina.
Calcii bromidum.
Calendula.
Calx sulphurata.
Camphora monobromata.
Carbonei bisulphidum.
Caulophyllum.
Chelidonium.
Chinoidinum.
Chysarobinum.
Cinchonidinæ sulphas.
Cinchonina.
Codeina.
Cupri acetas.
Elaterinum.
Erythroxylon.
Eucalyptus.
Fel bovis.
— inspissatum.

Fel purificatum.
Ferri carbonas saccharatus.
— iodidum saccharatum.
— oxidum hydratum cum magnesia.
— sulphas præcipitatus.
— valerianas.
Frangula.
Glycyrrhizinum ammoniat.
Grindelia.
Guarana.
Hamamelis.
Hyoscyaminæ sulphas.
Illicium.
Lithii benzoas.
— bromidum.
— salicylas.
Magnesia ponderosa.
Magnesii citras granulat.
— sulphis.
Maltum.
Menispermum.
Mucilago cydonii.
Oleatum hydrargyri.
— veratrinæ.
Oleum adipis.
— aurantii cortices.
— aurantii florum.
— coriandri.
— eucalypti.
— gossypii seminis.
— lavandulæ florum.
— myrciæ.
— phosphoratum.
— picis liquidæ.
— santali.
— sinapis volatile.
Opii pulvis.
Opium denarcotisatum.
Pepsinum saccharatum.
Petrolatum
Physostigminæ salicylas.
Picrotoxinum.
Pilocarpinæ hydrochloras.
Pilocarpus.
Piperina.
Pulsatilla.
Quillaia.
Quinidinæ sulphas.
Quinina.
Quininæ bisulphas.
— hydrobromas.
— hydrochloras.
Resina copaibæ.
Rubus idæus.
Salicinum.
Sapo viridis.
Sodii benzoas.
— bisulphis.
— bromidum.
— chloras.
— iodidum.
— pyrophosphas.
— salicylas.
— santoninas.
— sulphocarbolas.
Staphisagria.
Sumbul.
Thuja.
Thymol.
Triticum.
Ustilago.
Viburnum.
Vinum album.
— album fortius.
— rubrum.
Viola tricolor.
Vitellus.
Zinci bromidum.
— iodidum.
— phosphidum.

The net result of the omissions and additions in respect to the number of articles in the United States Pharmacopœia is an increase of 27, the total number of titles in the present edition being 997.

The Pharmacopœa Germanica, on the contrary, has undergone a decrease of about one-third, for whilst 360 articles have been omitted, only 48 new ones have been inserted. Amongst the articles of the materia medica that have been omitted are the following:—

Aconitinum.
Æther petrolei.
Alumina hydrata.
Ammoniumphosphoricum.
Amylum marantæ.
Atropinum.
Aurum foliatum.
Balsamum tolutanum.
Bismuthum valerianicum.
Cadmium sulphuricum.
Carboneum sulphuratum.
Caricæ.
Castoreum sibiricum.
Chininum.
— tannicum.
— valerianicum.
Chinoidinum.
Cinchoninum.
— sulphuricum.
Coccionella.
Colla piscium.
Conchæ præparatæ.
Coniinum.
Cortex fructus juglandis.
— mezerei.
Cuprum aceticum.
— aluminatum.
— subaceticum.
Dextrinum.
Elemi.
Faba calabarica.
Farina hordei præparata.
Fel tauri.
Ferrum chloratum.
— citricum ammoniatum.
— citricum oxidatum.
— oxidatum fuscum.
— phosphoricum.
Flores aurantii.
— chamomillæ romanæ.
— malvæ arboræ.
— millefolii.
— primulæ.
— rhœados.
Folia aurantii.
— laurocerasi.
Folia rosmarini.
— rutæ.
— toxicodendri.
Fructus anisi stellati.
— cannabis.
— ceratoniæ.
— coriandri.
— myrtilli.
— petroselini.
— sabadillæ.
Fungus laricis.
Gelatina.
Herba chenopodii ambrosioides.
— galeopsidis.
— gratiolæ.
— lactucæ.
— linariæ.
— majoranæ.
— millefolii.
— polygalæ.
— pulsatillæ.
— spilanthis.
Hydrargyrum sulphuratum nigrum.
— sulphuratum rubrum.
Kino.
Lignum campechianum.
Macis.
Magnesia lactica.
— usta.
Manganum hyperoxydat.
Manna.
Mastix.
Mel.
Morphinum.
— aceticum.
Natrum pyrophosphoricum.
— santonicum.
— subsulphurosum.
Oleum animale æthereum.
Oleum aurantii corticis.
— bergamottæ.
— chamomillæ æthereum
— majoranæ.
— menthæ crispæ.
— phosphoratum.
— sabinæ.
— succini.
— valerianæ.
Olibanum.
Radix alkanæ.
— arnicæ.
— artemisiæ.
— asari
bardanæ.
— belladonæ.
— carlinæ.
— hellebori viridis.
— pyrethri.
— saponariæ.
— scammoniæ.
— serpentariæ.
Resina draconis.
— guaiaci.
— pini.
— scammoniæ.
Rhizoma caricis.
— chinæ.
— curcumæ.
Sandaraca.
Semen cydoniæ.
— quercus tostum.
— stramonii.
Stipites dulcamaræ.
Strychninum.
Succinum.
Sulfur iodatum.
Zincum ferrocyanatum.
— lacticum.
— oxydatum sulfocarbolic
— valerianicum.

The dismissal of the above substances involves the omission also of a large number of their derivatives, and these are augmented by many antiquated preparations that are now dropped out. Amongst these are:—2 vinegars, 27 waters, 5 cerates, 16 plasters, 27 extracts, 8 liquors, 4 powders, 3 soaps, 4 spirits, 10 syrups, 22 tinctures, 4 troches and 22 ointments.

The additions are as follows:—

Acidum carbolicum liquef.
Acidum formicicum.
— pyrogallicum.
— salicylicum.
Aluminium sulfuricum.
Ammonium bromatum.
Amylium nitrosum.
Apomorphinum hydrochl.
Aqua carbolisata.
Calcium phosphoric. crud.
Charta sinapisata.
Chrysarobinum.
Cortex condurango.
Folia jaborandi.
Gossypium depuratum.
Hydrargyrum cyanatum.
Kalium bichromicum.
Linimentum terebinthinat.
Liquor aluminii acetici.
— corrosivus.
— ferri oxychlorati.
— natrii silicici.
Manganum sulfuricum.
Natrium benzoicum.
Natrium bromatum.
— iodatum.
— salicylicum.
Oleum cantharidatum.
— olivarum commune.
— rapæ.
Paraffinum liquidum.
— solidum.
Pepsinum.
Physostigminum salicylic.
Pilocarpinum hydrochloric.
Plumbum aceticum crud.
Podophyllinum.
Pulv. salicylicus c. talco.
Resina dammar.
Sal carolinum factitium.
Sapo kalinus.
Species lignorum.
Spiritus vini cognac.
Talcum.
Thymolum.
Tinctura veratri.
Unguentum paraffini.

(*To be continued.*)

A PROCESS FOR COATING PILLS WITH GELATINE.*

BY CLAY W. HOLMES.

Much has been written on the preparation of gelatine-coated pills, and various contrivances have been made and offered to pharmacists, protected by patents, and at an exorbitant price, so that few attempt the extemporaneous preparation of coated pills. Like all other manipulations in the laboratory, the coating of pills requires some experience, yet a reasonable amount of practice and patience will enable any pharmacist to devise means by which, at a minimum outlay, he can make a pill equal in appearance to those offered by the large manufacturers. It is the writer's desire to lay out the practical points in such a manner that any one can proceed intelligently, and without difficulty. The first point which presents itself is the pill to be coated. Pills composed entirely of dry powders offer little difficulty. Those containing a large proportion of extracts may occasion trouble. Much depends upon the excipient employed. Simple syrup is the best whenever it will make the mass sufficiently adhesive. In case this fails, confection of rose, or ext. gentian may be employed. Glycerine should never be used. If the mass is too soft, owing to the presence of a large portion of extract, stiffen it with sugar of milk or powdered gum arabic. The mass having been carefully prepared, the pills may be made either oval or spherical. The writer prefers the oval.

In making granules of arsenious acid, strychnia or other active remedies requiring minute doses, add enough sugar of milk to give the desired size, and make the mass with simple syrup. The pill being properly made, the next point is the apparatus for coating. The writer has made use of a round tin cup, about three (3) inches in diameter, in appearance like an ordinary blacking-box cover. The needles used were "No. 1 sharps," ordinary make. A thin layer of paste of plaster of paris and water is poured into each cup, and the needles set in the plaster. Each cup will hold twenty-five (25) needles. Place one in the centre, and around that run two circles—the first, half the distance between the centre and the edge of the cup; this circle to contain eight (8) needles. The outer circle, within one-eighth (1-8) of an inch of the edge; this circle contains sixteen (16) needles. If the distances are properly divided the needles will be far enough apart to hold the largest pill without fear of contact. After the plaster has set make more paste, thin enough to pour, then fill the cup. Let it stand until the plaster is firm, and then the cup is ready for use. The pills are readily stuck on the needles by hand, transfixing them as lightly as possible. The pill is now ready for coating. The coating solution is prepared as follows:—

℞ Gelatine, French (gold label) . . .	℥iv.
Gum arabic	℥j.
Sugar	ʒj.
Water	q. s.

Dissolve the gum arabic and sugar in eight (8) ounces of hot water in a capsule by means of a water-bath. Then add the gelatine and stir it until dissolved, Should the water have evaporated to such an extent that the solution is apparently too thick, add water gradually until it has the consistency of hot syrup. Continue the heat until a pellicle forms on the surface, then pour into a cold dish. A sixteen (16) ounce porcelain-covered casserole, with handle and lip, is a convenient dish to use, or a tin vessel may be made use of, a pint cup with a lip being about the size. Let the solution stand until the temperature is somewhat lowered, stir up the solution to break pellicle, and then dip the pills into the solution, lowering carefully until completely immersed. Pull them out slowly, that the surplus gelatine may run off, and then bring the needles to a horizontal position and rotate slowly for half a minute, when the cup may be set down. As soon as the coating is sufficiently set to prevent adhering to the fingers when touched, the pills are ready to come off.

Take an alcohol lamp with a small flame, and let the needle strike the flame about ½ inch from the pill. As soon as the needle is heated the gelatine begins to swell. Twist the pill off carefully, before the needle gets sufficiently hot to soften the pill, and with the finger stop the hole while the gelatine is hot. The pill is then ready to dispense.

If it is intended to keep the pills in stock they should be exposed to the air for a few hours before bottling. After the process is finished pour the coating solution into a wide-mouth pint bottle, and when cold pour on sufficient alcohol to make a strata ½ inch deep on the surface of the gelatine, and cork tightly. In this way the gelatine will keep for any length of time. When necessary to use again pour off the alcohol into a smaller bottle (kept ready for that purpose), place the gelatine bottle in a ½ gallon tin measure, putting a large piece of cork in the bottom to protect the bottle from direct heat, fill the measure nearly to the neck of the bottle with cold water and put over the gas flame or on the stove. Continue the heat until the gelatine is thoroughly liquified, and then pour into the coating-dish previously used. Place the empty bottle in the measure to keep it hot. As few or as many pills as you wish may be coated, and then the solution at once returned to the bottle. After the pills have been removed from the needles the next consideration is to restore the needles to their original condition.

A tin pan, or any convenient vessel having a flat bottom, is filled to the depth of an inch with hot water, and the cup is set in, the points being placed downward, the water not being deep enough to reach the cup. As soon as the gelatine is soft take the cup out, and with a small notched stick push the gelatine bulbs off, and then plunge the points into a bag of coarse emery a few times. This polishes the needles, and they are then laid aside until wanted again.

The only points of difficulty in the process, to the average pharmacist, will be the making of the pill and the proper consistence of the coating solution. Both must be learned by experience. If the coating is too thin on the pill, or does not cover it perfectly, evaporate the solution somewhat. Should it form too thick a coat, add a little hot water, and stir well. A pellicle forms rapidly, and it is necessary to stir frequently to prevent the pellicle from adhering to the pills as they are drawn out of the solution.

The difficulty in regard to the consistence of the pill shows itself in the bursting of the coating, and the exudation of the mass, when too soft, as is often the case in pills made largely from solid extracts. To remedy this, the mass must be made harder by the addition of gum arabic, or some other inert powder. Like all other labours in the laboratory, this process is open to the prospect of failure unless some degree of patience is exercised. The general working points are simple, the process does not require any elaborate machinery or contrivances, which might open a legal question as to "rights of protection," and anyone can, without fear of trouble, prepare for himself the simple apparatus described in this paper, and make any pills for which he may have a demand.

* Reprinted from the 'Proceedings of the New York State Pharmaceutical Association,' 1882.

RESEARCHES ON TARCHONANTHUS CAMPHORATUS.*

BY F. CANZONERI AND G. SPICA.

This plant, belonging to the Composite order, sub-order *Asteroïdeæ*, is indigenous at the Cape of Good Hope. On exhausting its dried leaves with warm alcohol in a percolator, and leaving the alcohol to cool, a greenish-white

* From the *Gazzetta*, 1882, pp. 227 to 231. Reprinted from the *Journal of the Chemical Society*, October, 1882.

gelatinous substance is deposited, which may be purified by washing it on a filter with alcohol as long as the filtrate exhibits a green colour, then drying it in the air, twice crystallizing it from alcohol, washing the waxy substance thus obtained with ether, and finally crystallizing it from alcohol.

The substance thus purified crystallizes in white light scales, having a silvery lustre, melting at 82°, solidifying at a slightly lower temperature, and afterwards melting at 72°. It is tasteless, burns with a bright flame, leaving no residue, and emitting the characteristic odour of burnt wax. It is insoluble in water, slightly soluble in cold, freely in hot alcohol; not attacked by strong sulphuric or hydrochloric acid or by strong potash-ley, and not sensibly altered by fusion with potash. Its analysis gave, as a mean result, 83·66 per cent. carbon and 14·44 hydrogen, and the chloride obtained by treating it with phosphorus pentachloride gave 80·77 per cent. C, 11·12 H and 4·17 Cl. These results, together with the resistance of the substance to the action of melting potash, lead to the idea that it might be a higher homologue of myricyl alcohol, $C_{32}H_{66}O$, which is also unattacked by potash; if so it must contain 50 or more atoms of carbon, and might be represented by either of the formulæ, $C_{50}H_{102}O$, $C_{51}H_{104}O$, $C_{52}H_{106}O$. The corresponding chloride melts at 67° to 68°; myricyl chloride at 64·5°.

It is not yet decided whether this alcohol, which the authors propose to call tarconyl alcohol, exists in the leaves in the free state or is produced by the action of the alcohol used in its preparation on a wax contained in the leaves. The solution from which the alcohol has been separated yields on evaporation a heavy, dark-coloured, pungent oil, consisting for the most part of an ether of an aromatic acid not yet examined.

ATOMS AND MOLECULES.*

BY BARNARD S. PROCTOR.

(*Continued from page* 486.)

In the various alcohols we have a step by step increase in complexity of molecular structure, with a like increase in density and decrease in mobility; at the same time we find the light mobile alcohols miscible with water in all proportions, the heavy alcohols insoluble in water but soluble in oils; the light alcohols standing between water and the heavy alcohols, and having considerable inter-solubilities with both.

The molecular motions and polarities of water are probably considerably influenced by most substances which may be dissolved in it, especially in those cases where one body has a conspicuous influence on the solubility of another, with which it does not enter into combination or decompose. Such, for example, as ammonia, which when present in large proportion has power to throw out of solution the double sulphate of copper and ammonia. The molecular relationships of the water are evidently much influenced by the great affinity of the ammonia; they are also much influenced, though in a different direction, by the great affinity of carbonate of potash when added to saturation, the saturated solution not being miscible with a strong solution of ammonia. On the other hand the sparingly soluble bodies probably have their molecular movements and polarities comparatively little influenced by the water, as in the case of hydrogen and oxygen, which may both be dissolved in water, though only to a small extent, and yet not enter into combination with one another. We regard the liquid condition as that most favourable to the combination of bodies having a tendency to unite, and yet the great affinities of O and H fail to bring them into union. Probably the affinity between the water and these two gases is so small as to exert very little influence on their movements, and leave them virtually in the free and gaseous state, occupying as it were only the interstices of the water. The case is necessarily different with ammonia, where the proportio is so great that we cannot suppose it to retain a molecular condition or mobility in any degree approaching that of its gaseous state. And the case is also very different when O and H are condensed upon the surface of platinum, where the amount of condensation is so great as to preclude the idea of a truly gaseous condition of the molecular movements, and where the affinities are brought into effective play. The great affinity of ammonia for water is seen not only in its abundantly taking the liquid form by their union, but also by its power to throw the carbonate of potash out of solution, when passed in the gaseous state through a saturated solution of this salt. Ammonia very much diminishes the solvent power of water for many other salts, but has no appreciable action on the solubility of ether, chloroform, sugar or gum.

I am not prepared to suggest any more definite relation between a substance and its solvent, than a harmony of molecular movements, and the existence of molecular polarities acting between the solid and the solvent, which enable the movements of the solid to throw off molecules under the influence of the motions and polarities of the solvent, with rates of frequency peculiar to the solid and solvent under consideration, and allow the re-attachment of the molecules of the solid to one another when the number of molecules of the solid to those of the solvent is beyond a ratio peculiar to themselves.

I think there is every reason to believe that the polarities of crystalline bodies by their inequalities cause the set of the matter in the crystalline form. I think there is also probability, though not yet so strong, that in amorphous or less crystalline bodies the intensities of the molecular polarities are more equal, and that bodies which are capable of taking both forms have polar intensities differing to so small an extent that a slight change of circumstances may determine the orderly or the heterogeneous arrangement of their molecules. It would be reasonable if such were the case, that the amorphous condition should be the less resistant to mechanical or chemical change, *i.e.*, should be softer, more soluble, more prone to enter into chemical combination. To illustrate my meaning, some substances may be thrown down as amorphous precipitates, becoming crystalline by time; the polarities being weak or of nearly equal strengths, the molecules attach themselves together in heterogeneous contact of those points which were nearest at the time of the formation of the new compound, and, being thus less combined, they are more readily dissolved by the mother-liquor. But some crystalline particles get formed, and are always surrounded by mother-liquor holding in solution more than the normal proportion of the salt. The crystalline particles are, therefore, always in circumstances to grow in size by attachment of more molecules drawn to them by the crystalline polarity; this reduces the solution to a strength below that at which it is capable of taking up the amorphous salt. The crystalline part of the precipitate is thus always growing, and the amorphous is constantly being dissolved till all has become crystalline. The whole phenomenon is very beautifully seen by aid of the microscope in the process for detecting traces of strychnine by precipitation with ferricyanide of potassium.

A drop of solution of strychnine on the microscope slide, being touched with a minute fraction of a drop of a solution of the ferricyanide, and the precipitate immediately examined under a half-inch objective, shows an amorphous cloud which quickly commences to exhibit a few crystals of a beautiful star-like shape. Around these the nebulous precipitate rapidly dissolves, leaving a clear space into which the stars expand, while the clouds clear away till all is bright and beautiful. Unless care be taken, it is sometimes difficult to repeat this experiment, as a trace of crystalline salt determines the rapid

* Presidential Address delivered before the Newcastle-upon-Tyne Chemical Society.

and less regular crystallization of the whole precipitate at once.

In this and many other cases the substance is capable of taking either of the two conditions distinctly. There are many in which a precipitate is apparently amorphous, though probably only so in appearance, from being in too minute a condition for its crystalline form to be noted under the microscope, and a considerable number of bodies exist in which no trace of crystalline property has yet been discovered, the most perfect of these being the gelatinous or colloid bodies.

The gelatinous state itself is probably due to polarities in the molecules acting equally in all directions. The hydration of colloid bodies has always appeared to me to be a subject worthy of speculation and of experiment. Its study relates to a debateable condition between the solid and the liquid state. We can trace every degree of change without any clear separation, from the most perfect fluidity through a great variety of watery combinations to the most perfect solidity and the most perfect insolubility, without losing the connection between the water and the solids with which it is brought into operation.

There is the most perfect gradation from the solution of ammonia, which is lighter and more mobile than water itself, through the solutions of crystalloid solids which add but little to the viscosity of the water, to solutions which are syrupy, to solutions of gums which are mucilaginous fluids or gelatinous semi-fluids, to combinations of water with gelatine or albumen, which by change of temperature become fluid in one case or lose fluidity in the other; to silica, which may be precipitated as a transparent gelatinous mass from a dilute solution, or as a pulverulent and opaque precipitate from a concentrated liquor, to clay which in small quantity remains diffused through pure water, with a persistency suggesting a union approaching that of solution, and from which it may be precipitated by hydrochloric acid, and to clay in its plastic state which presents some analogies to hydrated colloids; thus through many links till at the end of the chain we come to pure silicious sand and other pulverulent bodies, which retain the one remnant of analogy to solubility, that they are always left in a more coherent state by evaporation of water in which they have been immersed, than by lying in dry contact during any observable time.

I cannot at present enlarge upon more than one or two of the many suggestive links which merit study in this chain, first, as to the great force (molecular polarity I will assume) by which the gelatinous colloids are held together, and how great a force is represented by their union with water, and then to the adhesion, or cohesion of precipitates on the evaporation of water in comparison to the adhesion of the same substances under dry pressure. As regards the coherence of gelatinous colloids glue affords a convenient illustration. One part of gelatine dissolved in 100 of hot water makes a jelly on cooling. One molecule of gelatine confers proximate solidity to 100 times its weight of water; the molecules of gelatine may be regarded as separated from one another by this large proportion of water intervening, and still to have so much hold upon one another—still to be so strongly under the influence of one another's polarities, that they are held in position and not free to move, though the jelly is tremulous and easily broken. We might expect the polarities to increase inversely as the squares of the distances of the molecules, and to become something considerable as the water is diminished, and this is the fact to a larger extent than is often supposed. A solution of gelatine evaporated in glass or porcelain vessels contracts so much, and with so much force, as to tear away the surface of the vessel, thus indicating that the molecular attraction of the gelatine is at least as great as that of glass or porcelain. I have here specimens of glass and porcelain thus fractured. I had long ago heard of such results, but heard of them with a reservation of faith, till a few years ago, when experimenting with gelatine, my beaker fell a victim to this adhesive, cohesive, and contractile force. The effect on the evaporating dish is equally interesting. The force evidently exceeds the tensile strength of glass and porcelain, and if measured by pounds per square inch must be something considerable; but probably all the molecular forces would be large—indeed ungovernably violent, if our engineers were reduced to the size of molecules.

If the molecules of gelatine are held together with this great force, the force with which water attacks them must be equally great to enable it to penetrate the gelatine on immersion and expand it as it does. The swelling of a substance by becoming damp is frequently spoken of as the result of capillary attraction. I believe, however, that in most cases, if not in all, where swelling action takes place, it is the result of colloid hydration rather than capillarity. It is worthy of a passing remark, that while gelatine diffuses to a small extent only in water, water penetrates to a large extent into gelatine, and in contrast to this crystalloids diffuse freely in water, but water does not penetrate into a mass of solid crystalloid, though it diffuses into a solution of the same.

Turning now to another point, which I can do no more than touch upon, we may take pure silicious sand and wash it with the greatest care in distilled water, finally decanting the water and drying a small quantity of the sand in a beaker by evaporation. The particles of sand adhere to one another and to the beaker with sufficient force to permit of the inversion of the beaker without the sand falling out, though, if once disturbed after it has become dry, the adhesion instantly disappears, and does not show itself again after a long period of rest in the dry state. What is the nature of this adhesion, and what part the water takes in bringing it about is, as yet, problematical. We note the same effect in all bodies in varying degrees, from gelatine down to sand; it is not proportionate to the solubilities of the bodies in which it takes place. No doubt solubility has an effect of this kind, but we cannot regard the phenomenon as simply dependent on partial solution and the cementing of the undissolved particles, by means of the dissolved portion, left as a residue on evaporation.

The effect is variable in amount among bodies nearly equally soluble—for example, sand and clay—sand having the loosest possible adhesion, and clay a considerable one. It is more likely that the superficial molecules in a particle of sand or clay have one side of the molecule free to exert an affinity on the water, and that one side of the molecule is thus in the condition of hydration, the difference being that in hydrated colloids both sides of the molecule have water attached, and the action extends to every molecule in the mass. On this supposition when the water is evaporated, adhesion should take place wherever two molecules of silica come in contact, and the amount of adhesion should be proportionate to the relation between the size of the particles and the size of the molecules.

In a very interesting paper on regelation and the uniting of powders into masses under pressure, Professor Spring notices incidentally the disposition of powders, kept in bottles undisturbed for a length of time, to become united into masses which are more or less strongly coherent as they have been undisturbed for a longer or shorter time, and he attributes this result to a disposition possessed by most substances, but he thinks by crystalline substances especially, to weld when submitted to pressure —to unite promptly and perfectly under powerful pressure, or slowly and imperfectly under the pressure of their own weight. That many powders do agglomerate in our bottles is well known to us all, but the cause of their agglomeration I should think is mainly due to the action of moisture and change of temperature. The tendency to absorb moisture is not confined to deliquescent substances, or to substances commonly known as hygroscopic, but is probably possessed by all matter which has been carefully dried. In non-deliquescent salts the absorption of moisture ceases before the salt becomes palpably moist, but not before the particles are coated with an infinitesimal film of saturated solution of the salt. This film increasing in moist states of the air, and evaporating under the reverse circumstances, is sufficient to cause the agglomeration of the powder by a species of crystalline soldering of one particle to another. The same result would be produced by changes of temperature increasing or diminishing the solubility of the salt in its watery film. There is scope here for a series of careful observations which could not fail to be instructive. Professor Spring's results have had a great interest for me, perhaps the more so, as his conclusions are in some points opposite to my prejudices. He thinks that softness and a crystalline nature are, if not essential, at least favourable to this welding by pressure, Some years ago when Professor Brayley was lecturing on Physical Geography to our Literary and Philosophical Society, I performed for him an experiment in regelation, in illustration of his remarks upon glaciers, the point being the uniting of two pieces of ice while immersed in warm water. He expressed to me his conviction that it would ultimately turn out that regelation or welding could only take place with the matter in a colloid state. That ice, though crystalline in freezing, was probably colloid in melting, that iron, though feebly crystalline while cold, became colloid at a welding heat, and so on. He did not consider these points sufficiently mature for publication, but we discussed them as matters of interest to be kept in view as the subject of regelation and welding might develope, and I must say I felt strongly inclined to his view. I anticipated that the condition of matter which facilitated welding—using the word in a wide sense—was the reverse of that which is most favourable to, and most characteristic of, crystallization. My idea of crystalline matter was that the molecules had such polarities as caused their arrangement in a regular crystalline form, and the molecules would have little or no tendency to unite unless presented to one another in the position of this normal arrangement, and that colloid bodies consisted of molecules which cohered together in obedience to polarities which were not selective in their action, but which would cause the molecules to unite and cohere in any position or arrangement: and that welding or cohesion should take place when, by mechanical means, the masses can be brought together as closely as are the molecules within the masses. On this supposition welding should be a general property of such amorphous bodies as are soft enough to admit of their surfaces yielding so as to adapt themselves perfectly to one another. Practically, however, we had only a very limited experience of this till Professor Spring announced the success which he had achieved in uniting a great variety of powders by submitting them to pressures varying up to 20,000 atmospheres. I repeated a number of his experiments, and added others, and have now the pleasure of laying before you a few typical examples of the results. I had intended embodying, in the present address, some account of these experiments, but I find time will not permit me to do so at present, though it is possible I may find another opportunity of giving you a few details.

If we take a comprehensive view of welding, it is evident (without recourse to Professor Spring's experiments) that it accompanies a soft or semi-fluid condition rather than either a crystalline or colloid nature. The running together of two dew drops on the petal of a flower is the same thing in principle as the union of zinc filings under the pressure of 10,000 atmospheres in Professor Spring's apparatus, or the welding of the coils of a 100-ton gun in Sir W. G. Armstrong's works. Solidity and fluidity are but the different parts of an unbroken chain. The dew drop on a rose retains its rotundity against the force of gravity, in obedience to the greater force of its molecular attractions. On the other hand, the molecular attractions of the metal, great as they are, yield to the greater force of mechanical pressure, and zinc flows under the force of 10,000 atmospheres, or iron welds under the combined forces of the furnace and the forge. The probability is that all things would weld under circumstances such as would make them flow; that is, the molecular forces within the mass must be reduced or the external forces must be increased till the latter are at least equal to the former.

Pharmacists have long been familar with the welding tendency of powdered camphor, aloes, and other soft bodies of either a crystalline or amorphous nature. I should have felt considerable surprise if there had been a general difficulty in causing the welding of amorphous or colloid bodies, and among the first experiments I tried, after ascertaining that I could really obtain Professor Spring's general results, were those to determine the welding powder of sundry familiar colloids. Gums, sugar, gelatine, resins, and amorphous salts were tried with the general result that the amorphous bodies unite in a very similar degree and manner to the crystalline.

Amorphous sugar welds rather more easily and rather more perfectly than crystalline sugar under the same pressure. With crystalline and amorphous chrome alum there was no appreciable difference. The double citrate of ferric oxide and ammonia, though an amorphous salt, unites perfectly and readily; so does the double sulphate of the same bases which is a crystalline alum.

Though I have ceased to believe with Brayley that the colloid condition is an essential preliminary to a good weld, I have not learned to think with Spring that it is less favourable than the crystalline state; a definite judgment upon this point must be reserved for a much more extended evidence.

Professor Spring has obtained several other results no less interesting; he has shown that sulphur, in whatever condition it is put into the press, assumes its densest condition under pressure. Whether amorphous or prismatic in the first instance, it becomes octahedral by compression. Thus pressure is capable of producing molecular change, and the allotropic condition which is possessed of the greatest density. He has also submitted a mixture of copper filings and sulphur to a pressure of 5000 atmospheres, and obtained a block of sulphide of copper, showing that the pressure which suffices to cause the welding together of the particles of sulphur, or the particles of metal if applied to them separately, has the power of facilitating their chemical union if applied to them when mixed; but he thinks that such chemical union only takes place when the resulting compound occupies less space than the two elements in the separate state. In illustration of this I have upon the table a little block obtained by the same treatment of a mixture of sulphur and powdered tin, in which mechanical union and cohesion have been obtained, but not chemical union, the sulphur being still visible with the aid of a lens. There is here a resistance to blending, which we may compare to the immiscibility of oil and water, or to the aqueous solutions of ammonia and carbonate of potash previously noted, a resistance which we may suppose to be due to a want of harmony in the molecular movements of the bodies concerned, a discordance which is not removed by pressure such as we can apply, but which is removed by an increase in temperature. We may suppose the discordance to be similar to that of phosphorus and oxygen in the cold, where the union is retarded by pressure, and expedited by the reduction of pressure, or the increase of temperature. If the molecular movements of two elements in the separate state take place in one plane, the composition of these motions may result in a motion occupying more space, less space, or the same space as that occupied by the sum of the original elementary motions, but if the elementary motions are in different planes the result is a movement occupying more space than the sum of the previous movements. Under these circumstances there is a natural obstacle to this composition of forces, if the elements are brought together in a space too small to allow of the resultant motion. This is probably another way of putting the conclusion at which Professor Spring had arrived, *i.e.*, that combination takes place when the resulting compound has a greater density than the mean of the two elements, and does not take place if the density is less than the mean.

(*To be continued.*)

THE UNITED STATES PHARMACOPŒIA SYRUPS.

The following formulæ are taken from the new edition of the United States Pharmacopœia:—

Syrupus Calcii Lactophosphatis.

Syrup of Lactophosphate of Calcium.

Precipitated phosphate of calcium, *twenty-two parts*	22
Lactic acid, *thirty-three parts*	33
Orange flower water, *eighty parts*	80
Sugar, in coarse powder, *six hundred parts*	600
Hydrochloric acid,	
Water of ammonia,	
Water, each, *a sufficient quantity,*	
To make *one thousand parts*	1000

To the precipitated phosphate of calcium, mixed with *three hundred* (300) *parts* of cold water, add enough hydrochloric acid to dissolve it. Filter the solution, dilute it with *twelve hundred* (1200) *parts* of cold water, and then add water of ammonia, until it is slightly in excess. Transfer the mixture at once to a fine, wetted muslin strainer. As soon as the liquid has run off, return the magma to the vessel, mix it quickly with *twelve hundred* (1200) *parts* of cold water, and again transfer it to the strainer. When it has drained, mix the magma at once with the lactic acid, and stir until it is dissolved. Then add the orange flower water and enough water to make the solution weigh about *three hundred and fifty* (350) *parts*, filter, and pass enough water through the filter to make the filtrate weigh *four hundred* (400) *parts*. Lastly, add to this the sugar, dissolve it by agitation, without heat, and strain.

Syrupus Ferri Bromidi.

Syrup of Bromide of Iron.

A syrupy liquid containing 10 per cent. of ferrous bromide [$FeBr_2$; 215·5.—*FeBr;* 107·75].

Iron, in the form of fine wire, and cut into small pieces, *thirty parts*	30
Bromine, *seventy-five parts*	75
Sugar, in coarse powder, *six hundred parts*	600
Distilled water, *a sufficient quantity,*	
To make *one thousand parts*	1000

Introduce the iron into a flask of thin glass of suitable capacity, add to it *two hundred* (200) *parts* of distilled water and afterwards the bromine. Shake the mixture occasionally, until the reaction ceases and the solution has acquired a green colour and has lost the odour of bromine. Place the sugar in a porcelain capsule and filter the solution of bromide of iron into the sugar. Rinse the flask and iron wire with *ninety* (90) *parts* of distilled water, and pass the washings through the filter into the sugar. Stir the mixture with a porcelain or wooden spatula, heat it to the boiling point on a sand-bath, and having strained the syrup through linen into a tared bottle, add enough distilled water to make the product weigh *one thousand* (1000) *parts*. Lastly, shake the bottle and transfer its contents to small vials, which should be completely filled, securely corked, and kept in a place accessible to daylight.

A transparent, pale green liquid, odourless, having a sweet, strongly ferruginous taste, and a neutral reaction. With test-solution of ferricyanide of potassium it yields a blue precipitate. If a little disulphide of carbon be added to the syrup, then a few drops of chlorine water, and the whole agitated, the disulphide will separate with a yellow or brown colour. It should not deposit a sediment on keeping, and should not tinge gelatinized starch yellow (abs. of free bromine).

Ten gm. of the syrup should require for complete precipitation not less than 1·57 gm. of nitrate of silver (corresponding to 10 per cent. of ferrous bromide).

Syrupus Ferri Quininæ et Strychninæ Phosphatum.

Syrup of the Phosphates of Iron, Quinine, and Strychnine.

Phosphate of iron, *one hundred and thirty-three parts*	133
Quinine, *one hundred and thirty-three parts*	133
Strychnine, *four parts*	4
Phosphoric acid, *eight hundred parts*	800
Sugar, in coarse powder, *six thousand parts*	6000
Distilled water, *a sufficient quantity.*	
To make *ten thousand parts*	10000

Add the phosphate of iron to *twenty-five hundred* (2500) *parts* of distilled water, in a tared bottle large enough to hold the finished syrup, and agitate frequently until the salt is dissolved. Having added the phosphoric acid to the solution, triturate the quinine and strychnine gradually with the mixture, in a mortar, until they are dissolved, then return the solution to the bottle and add enough distilled water to make the liquid weigh *four thousand* (4000) *parts*. Lastly, add the sugar, dissolve it by agitation, without heat, and filter through paper.

Keep the syrup in small, well-stopped vials, in a cool and dark place.

Syrupus Hypophosphitum.

Syrup of Hypophosphites.

Hypophosphite of calcium, *thirty-five parts*	35
Hypophosphite of sodium, *twelve parts*	12
Hypophosphite of potassium, *twelve parts*	12
Citric acid, *one part*	1
Spirit of lemon, *two parts*	2
Sugar, in coarse powder, *five hundred parts*	500
Water, *a sufficient quantity,*	
To make *one thousand parts*	1000

Mix the hypophosphites, and dissolve them, by trituration, in *three hundred and fifty* (350) *parts* of water. Should there be a trifling residue undissolved, allow the solution to settle, pour off nearly all of it, and add the citric acid, so that the residue may be dissolved. Then, having mixed the liquids, add the spirit of lemon, and filter through paper, adding through the filter enough water to make the whole weigh *five hundred* (500) *parts*. In this liquid dissolve the sugar, by agitation, without heat, and strain.

Keep the syrup in well-stopped bottles.

Preparation: Syrupus hypophosphitum cum ferro.

Syrupus Hypophosphitum cum Ferro.

Syrup of Hypophosphites with Iron.

Lactate of iron, *one part*	1
Syrup of hypophosphites, *ninety-nine parts*	99
To make *one hundred parts*	100

Dissolve the lactate of iron in the syrup by trituration.

Keep the syrup in well-stopped bottles.

The Pharmaceutical Journal.

SATURDAY, DECEMBER 23, 1882.

Communications for the Editorial department of the Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

RHEUM OFFICINALE.

TEN years have now passed away since there appeared in the pages of this Journal the first printed account of a species of *Rheum*, which Professor BAILLON had then recently brought under the notice of a meeting, at Bordeaux, of the French Association for the Advancement of Science, as having been received from Thibet, with the claim that it represented the long-disputed source of official rhubarb. The plant was first cultivated at Montmorency; afterwards it was grown in the gardens of the Academy of Medicine, Paris, at Clapham, by the late Mr. DANIEL HANBURY, and in the Royal Gardens at Kew, where its noble proportions have no doubt excited the admiration of many of our readers. It proved to belong to an entirely new species, which Professor BAILLON described under the name of *Rheum officinale*. Since then its claim to be considered at least as one of the sources of official rhubarb has been fairly well established, and in the two new Pharmacopœias just issued that drug is described as being yielded by *Rheum officinale* and other unnamed species of rhubarb. As a natural consequence attempts have been made, both in this country and in France, to cultivate the plant on a commercial scale for the sake of its root, but it cannot be said that the results yet obtained have been satisfactory. For instance, the root of a plant of *Rheum officinale*, three years old, grown at Banbury, and examined in 1877, presented none of the characters of true Russian rhubarb, and gave rise to the impression that the drug was the product of a plant of much slower growth. But this may be attributable to the climatic and other conditions under which the plant grows in its native country, especially as the result was not quite in accord with the observations made upon a plant grown at Clapham. Efforts to secure the naturalization of the plant have also been made by the Paris Acclimatization Society, and this body has recently had placed at its disposal some interesting information from Herr HEUDER, German Consul at Shanghai, that may facilitate the making of future experiments under more favourable conditions.

Herr HEUDER states that for two years he was engaged unsuccessfully in attempts to obtain living plants of *Rheum officinale*, being foiled sometimes by the opposition raised by the natives, and at others by difficulties attending the transport of the plants, which always perished in the course of the long journey from the western parts of China to the seacoast. Eventually success was achieved by Herr FRANZENBACH, an interpreter to the consulate, who brought back from an excursion into Mongolia three specimens which were considered to represent the true rhubarb plant by the native doctors, and two of which appeared to correspond with the botanical description of *R. officinale*. On leaving Pekin, Herr FRANZENBACH had first taken a north-west course to Kalgan, and then, proceeding in a line due west, he crossed the Yellow River twice, and reached the Mongolian region situated on the northwest of the Chinese province of Shensi, where he discovered large quantities of the plant, and was assured by the Mongols living there that it was the source of the rhubarb sent into commerce. He himself pulled up four specimens, including apparently two varieties; these he planted in a wooden Mongolian milk pot, and, after encountering many perils during a journey of six weeks, brought three of them alive and in good condition into Shanghai. According to Herr FRANZENBACH, these two varieties or species of *Rheum* grow wild in considerable quantity upon the mountain slopes, but they are especially abundant in the alluvial lands which are saturated with water only in the spring. In this region the temperature falls in the winter to seventeen degrees below zero Fahrenheit; the hard weather lasts about eight months, but there is little snow. In summer, the average temperature is from 72° to 77 F.

When the roots are about six years old the Mongols extirpate them, like asparagus, to about four inches below the surface, leaving the stocks in the ground, where they throw out new shoots. The cut portions, after being dried carefully in the air, are sold to the Chinese, who send them into commerce after removing the cortical portion. The method of multiplying the plant adopted by the natives is curious. A piece, about an inch in length, is cut from the upper part of the root, where there are a number of small shoots, and this is again subdivided, taking care that each fragment contains a portion of root. At the end of the root an incision is made, into which a seed of any kind is introduced, and the fragment is then planted with the shoot pointing upwards. The process has been imitated by Herr FRANZENBACH, and he says that he has in this way succeeded in raising fine plants. With seed he was less successful, as it appeared to lose its germinating powers after an interval of a few months. Herr HEUDER adds that various species of *Rheum* appear to grow in Thibet and Siberia and other countries west of China and Mongolia.

PHARMACEUTICAL LEGISLATION IN QUEENSLAND.

The pharmacists of Queensland appear to be making a vigorous effort to get the management of pharmaceutical affairs in that colony placed in their own hands, the power of granting certificates to carry on the business being, as mentioned recently, now vested in a Medical Board. About two years since a Pharmaceutical Society was established with the object of obtaining reform in this and other directions. Last year a Bill embodying the views of the Society was introduced into the Colonial Parliament and passed the Lower House, but after reaching the Upper House it had to be withdrawn, apparently under pressure of medical influence. The Pharmacy Bill has, however, been reintroduced in the present session and at the time of our last advices it appears to be again encountering resistance from the same quarter. The opposition has indeed been carried so far that seven members of the Medical Board have published a notification to members of the Queensland Parliament that they consider this application for legislation premature, on the grounds that the present status of chemists and druggists in Brisbane is far too low to fit them to undertake the responsibility sought by them, and that two official boards, one medical and one pharmaceutical, would lead to antagonism and an undesirable state of things. There may be something peculiar in the atmosphere of Brisbane which creates an exception to the rule that pharmacists have proved themselves capable of managing their own affairs without becoming antagonistic to the medical profession, though we do not think it probable. Anyway the work done under present arrangements must be very perfunctory, if the Medical Board takes the position, as is asserted, that it has no power to examine pharmaceutical candidates, and has no option but to grant certificates to all who present themselves for registration with evidence of having served a three years' apprenticeship. It is not surprising to learn that under such a system a man has been registered as competent, who recently confessed at an inquest his ignorance of any difference between the two oils of almonds. Surely, any change in the law could hardly give a more unsatisfactory result.

THE ENFORCEMENT OF POISON REGULATIONS IN VICTORIA.

We learn from the Melbourne papers that the Pharmacy Board of Victoria has just won one of those Pyrrhian victories which too frequently fall to the lot of bodies that have to fight the battles of the public. It occurred in connection with a charge against a grocer for selling a rat poison consisting of coloured arsenic, in contravention of the colonial Act regulating the sale of poisons, which resembles the English law. The defendant, who was unregistered and sold the poison without making any inquiry or entry of sale, appears to have treated the business very lightly, making no defence beyond saying that he had bought the poison from the representative of an English firm and that he knew nothing about it, except that it killed rats in a remarkably quick manner. The police magistrate, sympathizing with the defendant in his ignorance, fined him only one shilling and limited the costs to ten shillings, thus practically imposing a fine upon the Pharmacy Board for carrying out a public duty, probably amounting to several times that imposed upon the offender. It is satisfactory to notice that the magistrate's decision has been subjected to sharp editorial criticism in the colonial press, and what is more the editors appear to have made themselves acquainted with the actual provisions of the law before writing upon the subject, an example that might be in many cases followed with advantage by the editors of the daily and weekly press in this country.

THE DANGERS OF PYROTECHNY.

By order of the Secretary of State for the Home Department an inquiry has been instituted in regard to the circumstances attending the explosion of fireworks at the Hull Botanic Gardens last September, and in the report furnished by one of the inspectors of explosives it is shown that it was due to the use of a mixture of chlorate of potash and sulphide of antimony in the preparation of stars intended to be fired out of a mortar loaded with gunpowder. These stars instead of being thrown up into the air and ignited at the moment of discharge, exploded within the mortar, bursting it and causing the death of two persons besides serious injury to several others.

Captain Cundill, the reporter, points out the danger attending the use of this kind of fireworks and insists upon the necessity of all possible precautions being taken to minimize that danger, one of the conditions requisite for this purpose being naturally the possession of chemical knowledge on the part of those who make fireworks. There is reason to fear that this is too frequently wanting, and in the case now referred to the pyrotechnist admitted he had no chemical knowledge whatever, making compositions simply by receipts without knowing anything of the results of putting the various ingredients together. The report states in reference to this confessed ignorance, which seems to prevail with all firework makers, that though there does not appear to be reason for complaining of the substantial justice of the verdict of "accidental death" given by the coroner's jury there is at least an opportunity afforded of profiting by the terrible lesson given to pyrotechnists by the sad results of this accident.

BRITISH MEDICAL ASSOCIATION.

According to an official announcement of the arrangements at present matured, the British Medical Association will hold its Fifty-first Annual Meeting next year, in the Liverpool College, Liverpool, commencing on the 31st of July, the President-Elect being Dr. A. T. H. Waters. The Address in Surgery is to be delivered by Professor Reginald Harrison, and the Address in Pathology by Dr. Charles Creighton.

Transactions of the Pharmaceutical Society.

GENERAL MEETING—BENEVOLENT FUND.
ELECTION OF ANNUITANTS.

A General Meeting of the Members, Associates in Business, and Associates of the Pharmaceutical Society, and of the Subscribers and Donors to the Benevolent Fund, was held at the house of the Society, 17, Bloomsbury Square, on Friday, December 15, at 12 o'clock, for the Election of Six Annuitants.

Mr. Michael Carteighe in the chair.

The notice convening the meeting was read.

Scrutineers were appointed, who examined the voting papers and brought up the following report:—

Scrutineers' Report.

We, the undersigned Scrutineers, appointed at the eighteenth election of Annuitants on the Benevolent Fund of the Pharmaceutical Society of Great Britain, do hereby certify that we have examined the voting papers committed to us and report the following result:—

Dixon, Mary Elizabeth	6914
Rowlands, Amelia C.	3030
Sutterby, Catharine M.A.	2786
Henly, Mary Ann	2768
Davies, Henry Edward.	2753
Broadwater, Elizabeth	2278
Wavell, John	1687
Taylor, Henry	1094
Powell, Mary Jane	1018

3556* voting papers were received, of which number 64 were informal (54 unsigned) and were disallowed.

J. Robbins, *Chairman.*

Charles J. Mead.
T. Howard Hall.
E. N. Butt.
W. H. Ferguson.
Charles E. Turner.
J. T. Tupholme.
W. Inchle Gulliver.
R. Fisher Young.
Thomas Rich.
Walter Hills.
W. Toogood Frost.
R. A. Robinson.
Robert Rowe.
J. O. Braithwaite.
W. Smith.
Robert H. Davies.
George S. Taylor.
W. H. Symons.
Chas. B. Allen.

December 15, 1882.

The Chairman declared the following six duly elected Annuitants:—

Broadwater, Elizabeth.
Davies, Henry Edward.
Dixon, Mary Elizabeth.
Henly, Mary Ann.
Rowlands, Amelia C.
Sutterby, Catharine M. A.

On the motion of the President it was resolved—

"That the best thanks of the subscribers are due, and hereby tendered, to the Scrutineers for their valuable services."

A vote of thanks was also given to the Chairman.

* 5742 voting papers were issued by the Secretary.

EXAMINATIONS IN LONDON.

December 13, 1882.

Present—Mr. Carteighe, President; Mr. Atkins, Vice-President; Messrs. Barnes, Benger, Brady, Corder, Ekin, Gale, Greenish, Linford, Martindale, Plowman, Southall, Taylor and Thresh.

Dr. Greenhow attended on behalf of the Privy Council.

MAJOR EXAMINATION.

Six candidates were examined. *Four* failed. The undermentioned *two* passed, and were declared qualified to be registered as Phamaceutical Chemists:—

Fowler, George ....Tewkesbury.
Marshall, Joseph Jewison ......Beverley.

MINOR EXAMINATION.

Nineteen candidates were examined. *Twelve* failed. The undermentioned *seven* passed, and were declared qualified to be registered as Chemists and Druggists:—

Armstrong, Frank ....Workington.
Bing, Charles ....Canterbury.
Blackham, William George......Liverpool.
Brisley, George......................Margate.
Carr, Percy ....Sheffield.
Chater, Arthur Brand.............Elmdon.
Clague, Thomas Maltby ....Douglas.

December 14, 1882.

Present—Mr. Carteighe, President; Mr. Atkins, Vice-President; Messrs. Barnes, Benger, Brady, Corder, Ekin, Gale, Greenish, Linford, Martindale, Plowman, Southall, Taylor and Thresh.

Dr. Greenhow was also present.

MAJOR EXAMINATION.

Seven candidates were examined. *Three* failed. The undermentioned *four* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Burton, Walter.......................Mansfield.
Nichol, Anthony ....Carlisle.
Richards, Thomas..................St. Clears.
Williams, William Jesse ....Crickhowell.

MINOR EXAMINATION.

Eighteen candidates were examined. *Eleven* failed. The undermentioned *seven* passed, and were declared qualified to be registered as Chemists and Druggists:—

Collins, Herbert Sleight ....Bradford.
Cox, Webster ....Liverpool.
Critchlow, Henry...................Oldham.
Doo, James Emile ....Atherstone.
Eastwood, Thomas Earnshaw...Skelmanthorpe.
Freeman, John Henry............Ipswich.
Goodwin, Walter Frederick ...Norwich.

December 19, 1882.

Present—Mr. Carteighe, President; Mr. Atkins, Vice-President; Messrs. Barnes, Benger, Brady, Corder, Ekin, Gale, Greenish, Linford, Martindale, Plowman, Taylor and Thresh.

MINOR EXAMINATION.

Twenty-four candidates were examined. *Twelve* failed. The undermentioned *twelve* passed, and were declared qualified to be registered as Chemists and Druggists:—

Harvey, Frederick ....Margate.
Holwell, Alfred ....Loughborough.
Hopkins, William Richard ......Aberystwith.
Houfe, Robert William ....York.
Hurcomb, Lawrence Edmund...Nottingham.
Isaac, James Griffith ....Strood.
Jenkin, William John ....Plymouth.
Lambert, John Thomas ....Hoyland.
Langley, Frank Collins ....Ashford.
Luxmoore, Charles Mann ......Bristol.
Marsh, Edward......................Luton.
Oldershaw, John ....Nottingham.

December 20, 1882.

Present—Mr. Carteighe, President; Mr. Atkins, Vice-President; Messrs. Barnes, Benger, Brady, Corder, Ekin, Gale, Greenish, Linford, Martindale, Plowman, Southall, Taylor and Thresh.

MINOR EXAMINATION.

Twenty-four candidates were examined. *Ten* failed. The undermentioned *fourteen* passed, and were declared qualified to be registered as Chemists and Druggists:—

Hopkinson, Harry ....Grantham.
Jones, William......................Carmarthen.
Neve, Annie..........................London.
Parker, Charles Henry Mitchell.South Molton.
Pask, Thomas Edward ....Newark.
Perkins, Charles Lynham ......Plymouth.
Pope, Albert Harry...............Southport.
Pridmore, Sydney Spencer......Hinckley.
Puckey, Courtenay ....Herne Hill.
Rednall, William Rush ....Northampton.
Rees, John Arthur ....Cardiff.
Ridgley, Cromwell ....Huntingdon.
Rigden, George ....Folkestone.
Ryley, Edward......................Louth.

December 21, 1882.

Present—Mr. Carteighe, President; Mr. Atkins, Vice-President; Messrs. Barnes, Benger, Brady, Corder, Ekin, Gale, Greenish, Linford, Martindale, Plowman, Southall, Taylor and Thresh.

MINOR EXAMINATION.

Twenty-four candidates were examined. *Fifteen* failed. The undermentioned *nine* passed, and were declared qualified to be registered as Chemists and Druggists:—

Gulliver, Walter Frederick......London.
Sharpe, William Cecil............Madeley.
Skyrme, Henry Edward ....Cardiff.
Smalley, Arthur William ......Stamford.
Smith, William Thomas ....Bath.
Steward, Henry Clarke ....Ludlow.
Walton, Frederick Miles.........Reading.
Whiffin, Henry.......................Market Harborough.
Young, Robert John ....Bideford.

PRELIMINARY EXAMINATION.

The undermentioned certificates were received in lieu of the Society's examination:—.

Certificates of the College of Preceptors.

Arnison, William S. ....Sunderland.
Baker, Sydney George ....High Barnet.
Hayward, Savill ....Trowbridge.
Humphreys, Thomas H. P. S...Denmark Park.

Certificate of the Faculty of Physicians and Surgeons of Glasgow.

Parkinson, James..................Oldham.

Certificate of the Royal College of Surgeons in Ireland.

Dodd, Richard Jefferson.........Sunderland.

Certificates of the University of Cambridge.

Everett, John Garwood ....Ipswich.
Everett, Walter Edes ....Colchester.

Certificate of the University of Edinburgh.

Cockburn, David ....Dunse.

Certificate of the University of Oxford.

Palmer, Charles Joseph ....Wingham.

Resolved—"That the Board of Examiners desire to convey to Mrs. Allchin and family the assurance of their sincere sympathy in the severe loss they have sustained through the decease of the late Mr. Allchin.

"Mr. Allchin had won and retained, during a lengthened career on the Board, the confidence and esteem of his co-examiners, and in this expression of condolence with the family, they also bear testimony to their own loss of a valued friend and colleague."

Resolved—"That Mr. Martindale, having expressed his intention to retire from the Board of Examiners in consequence of the increasing claims of his own business, the Board desires to record its appreciation of the valuable services rendered by Mr. Martindale during the ten years he has been an examiner, and its regret at losing an esteemed colleague."

Resolved—"That the foregoing resolutions be entered on the minutes of the Board."

NORTH BRITISH BRANCH.

EVENING MEETING.

The second meeting of the present session was held in the Society's Rooms, 119A, George Street, Edinburgh, on Wednesday evening, December 13, at 9 o'clock.

Mr. Alexander Napier, President of the Branch, in the chair.

The minutes of the former meeting were read and confirmed.

The Secretary to the Branch then announced the following donations;

To the Museum:—

Specimens illustrating the manufacture of soda, consisting of the following:—

Salt Cake, Black Ash, Diamond Soda, Soda Crystals, Caustic Soda, Hydrochloric Acid, Bleaching Powder, Black Oxide of Manganese (recovered), and Crystal, Rock and Roll Sulphur (recovered from Alkali Waste by Mactear's process).

From Messrs. Charles Tennant and Co.

Twelve specimen bottles for the above.

From Mr. Alexander Kinninmont.

Capsicum annuum, fructus, and
Convolvulus scammonium, radix.

From Messrs. T. and H. Smith and Co.

A piece of Spurious Opium.

From Messrs. J. F. MacFarlan and Co.

In calling attention to these donations, the Secretary remarked that the specimens of alkali products had come through the Glasgow Apothecaries' Company. The specimens of recovered sulphur were very pretty, and they were of interest from the fact that a waste material was utilized in their production. The specimens of scammony root exhibited had been selected from a large bale; the roots were very typical. The donors, he understood, went through large quantities of scammony in manufacturing the resin; a specimen of which would be exhibited at a future meeting. The piece of spurious opium was one of twenty-five pieces which had been picked out of six cases of opium imported from Smyrna. The weight of the twenty-five pieces was 16 lbs. 12 ozs. With the exception of the covering, the specimen in no way resembled opium; internally it was of a lighter colour, of a tough and glutinous consistency, and it had a faintly aromatic odour somewhat like Socotrine aloes. The specimen contained no morphia.

On the motion of the President a vote of thanks was given to the various donors.

Mr. Robert Aitken, then read a paper on "The Pharmacopœial Extracts of Aloes and their Preparations," which is printed on p. 501.

The President said that aloes was an important drug, and one of great antiquity; indeed, our knowledge did not seem to grow with the length of time in which it had been in use. The late Professor Christison had shown that prolonged heat greatly deteriorated the drug, and it was his opinion that it is better to use the purest samples of aloes as imported in preference to aqueous extracts of the drug. The investigations of Mr. Aitken showed that aloes is subject to very great change when converted into extract by the pharmacopœial method; and it was gratifying to know that he had prepared an extract free from resin. In moving a vote of thanks to Mr. Aitken he remarked that the paper was one of practical utility. It was such papers, more especially from young pharmacists, which proved interesting, and he hoped that there would be many more of the same kind.

Mr. Young said that the meeting was indebted to Mr. Aitken for having drawn attention to the matter. From the circumstance which led him to institute the experiments it was well to suppose that there was some difference in the preparations, and he deserved commendation for having acted as he did. The paper would direct attention to the subject, he hoped, and manufacturers would probably act upon the suggestions which had been thrown out.

Mr. Aitken stated, in reply to Mr. Young, that he had been particular in selecting good samples of Barbadoes and Socotrine aloes. He had made extracts with both of these and he got the best results by evaporating with hot air.

Mr. Hill said that he had much pleasure in listening to the paper, which dealt with a practical question and pointed out a discrepancy which, he was afraid, occurred with other official preparations than extract of aloes. Manufacturers were apt to adopt expedients by which they could produce preparations more rapidly than by the official process, without a due regard to the properties or efficacy of the resulting products. He hoped that the method of evaporation by hot air would commend itself to manufacturers.

The next paper read was on "The Preparation of Syrupus Ferri Phosphatis by a New Method," by Mr. Daniel Gorrie. The paper is printed on p. 501.

The President said that he had not found much difficulty with the official process; however, Mr. Gorrie's method seemed to be simpler and the syrup more permanent than the ordinary preparation. He had much pleasure in moving a vote of thanks to Mr. Gorrie.

Mr. Nesbit said that although the method proposed was a very simple one, yet he did not think that it would ever come into general use; for although it might answer very well in the hands of a careful and competent person, yet if entrusted to some one not so competent there would be liability of contamination with baryta, the poisonous nature of which, he maintained, precluded its use.

Mr. Stephenson said that he held much the same opinion as the previous speaker, and he could only add that he had found the syrup by the official method to keep for a long time; still the method proposed was an ingenious one and as such the author deserved credit for it.

This being all the business the meeting adjourned.

Provincial Transactions.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION

A lecture was delivered at the rooms of the above Association, on Wednesday evening, December 13, by Mr. J. E. Weatherhead, on "Teeth." Mr. J. J. Edwards presided. There was a good attendance.

The lecturer having described the substances, number and form of the teeth, pointed out the peculiarities in dentition of the different species of animals, showing skulls and teeth belonging to the orders Mammalia, Quadrumana, Rodentia, Carnivora, Proboscidia, Ungulata, Cetacea, Reptilia, Amphibia and Fishes. The lecture was illustrated by a quantity of beautiful diagrams and specimens, and was delivered in a highly interesting and instructive manner, and appeared to be thoroughly enjoyed by the audience.

Mr. Edwards proposed a vote of thanks to Mr. Weatherhead, which was seconded by Mr. Shirlby and carried.

BLACKBURN CHEMISTS' ASSOCIATION.

The annual meeting was held at the rooms, Exchang Street, on Monday, December 11. Mr. W. Farnworth presided.

The balance sheet was read and approved of.

The following are the officers for the ensuing year:—President, Mr. A. P. Garland; Secretary, Mr. J. W. Clayton; Assistant-Secretary, Mr. Jowett; Librarians, Messrs. W. C. Rundle and J. Hindle.

Votes of thanks to the various officers for their services during the past year were passed.

On Friday, December 15, in connection with the Improvement Class, Mr. S. Kirklan delivered a lecture on "Arsenic." Mr. J. G. Tier presided.

EDINBURGH CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The fourth meeting of the session was held on Wednesday, December 6, in the rooms of the North British Branch. Mr. P. Boa, President, in the chair.

The minutes of the previous meeting having been read and adopted, the Chairman called upon Mr. C. F. Henry to open, on the affirmative side, a debate on the question, "Does a necessity exist for further legislative restriction as to the sale of poisons?"

Mr. Henry first gave a brief historical *résumé* of the legislation in regard to poisons which had taken place during the last thirty years. He then proceeded to argue:—1st. That that part of section I. of the present Poison Act should be more definite which stipulates the drawing up of regulations for the keeping, storing, dispensing and selling of poisons. No regulations at present existed for the storing of drugs. Mistakes often occur through the too close proximity of poisonous to harmless drugs, and he thought that some regulations were imperatively required. Cases of accidental poisoning had increased 15·3 per cent. during the last five years, and he thought this indicated a necessity for some regulations in regard to the way in which poisons were placed in the hands of the public. 2nd. That the present poison schedule is far from complete. He suggested that the following should be added to the second part of it, viz.:—phosphorus and its medicinal preparations, carbolic acid and vitrio in quantities under one gallon, the salts of lead, copper, and zinc, croton oil and tincture of hyoscyamus. A reference to the Registrar General's Reports for the last ten years showed that some of the foregoing were far oftener the cause of fatal poisoning than many of those at present in the poison schedule. For instance, in one thousand cases of poisoning, 30·8 were caused by vitriol; 17·5 were caused by phosphorus; 94·2 were caused by carbolic acid; 1·7 was caused by hellebore; 1·2 was caused by cantharides; 4·8 were caused by aconite; 39·8 were caused by arsenic, and 12·3 were caused by chloroform, chloral and chlorodyne. 3rd. That legislative restriction should be imposed on the sale of poisonous patent medicines. Coroners had over and over again expressed an opinion to this effect and their opinion had been unanimously endorsed by juries. It short, it was admitted on all hands that something ought to be done to bring the sale of these articles under some control. The fact that a 1*s.* 1½*d.* bottle containing a solution of some powerful scheduled poison could be purchased from many country grocers, as easily as a pound of cheese or a couple of farthing candles, he thought sufficient to convince anyone that these poisonous patents ought to be included in the Poison Act. 4th. That no child under sixteen years of age should be supplied with any scheduled poison. 5th. That the sale of poisons should be restricted not only to pharmaceutical chemists and chemists and druggists, but also to qualified assistants, and that no others should be allowed to sell or retail them by any means. He knew that here he was treading on delicate ground, but he trusted he would not offend anyone if he stated his humble opinion on this matter. He reminded them of the argument which was used with great force against the Pharmaceutical Society by the law agent of a cooperative company in London who had been prosecuted for retailing and dispensing poisons,—the argument, viz., "That the public were safer in going to a co-operative store for poisons than to the branch shops of chemists, as most of these shops were conducted by unqualified assistants, whereas at the store the company kept a qualified assistant." It seemed to him that the time had come, if it was not far past, for this flaw in the Pharmacy Act to be remedied. No doubt the framers of the Act never intended that such a state of matters should be possible, and no doubt also in the existence of such a state of matters the spirit, if not the letter of the Act, was broken. In addition to the foregoing arguments he might, he said, have gone into the question of transferring the duties at present discharged by the Pharmaceutical Society to a public prosecutor, but he thought he had said enough to prove that the present legislation restricting the sale of poisons was incomplete, and that a necessity existed for further restriction.

The negative side of the question was opened by Mr. W. S. Adamson, who contended that no necessity existed for further legislative restriction, because, 1st. In the law, as it at present stood, there was sufficient power to cope with any emergency that might arise, and that it only rested with the Council of the Pharmaceutical Society to exercise the powers conferred upon them by clause 2 of the Pharmacy Act, 1868. 2nd. Any further restriction would tend to embarrass the seller. This point was illustrated by one or two incidents typical of what took place even under the present regulations, and he contended that any further restriction would only increase this embarrassment without conferring any advantage either on the public or on the chemist. 3rd. He concluded by saying that in agitating for further restriction on the sale of poisons they were doing that which would lower the standing of the chemist in the estimation of the public, and confessing that they were not competent to discharge the responsibility which at present rested upon them in connection with this matter. He, therefore, hoped that the majority of those present would agree with him that no necessity at present existed for any further legislative restriction.

The debate was continued by Messrs. Boa, Low, Maben, MacEwan, Robertson and Turnbull. The opener having replied, a vote was taken, and the affirmative declared carried by a majority of 14.

The Chairman, having intimated that the next meeting would be on Wednesday, December 20, when a paper on "The Haloïd Elements," would be read by Mr. J. Suttar, the meeting was closed.

MIDLAND COUNTIES CHEMISTS' ASSOCIATION.

The annual meeting was held at 23, Burlington Chambers, New Street, Birmingham, on December 13. The attendance was very fair, considering the inclement state of the weather. The chair was occupied by Mr. Barclay.

The Chairman, after some remarks, moved the adoption of the balance sheet, which showed a satisfactory balance of over £39 in the treasurer's hands.

This having been carried, the meeting proceeded to the election of officers, Mr. Lucas being appointed President, Messrs. Barlow and Brown accepting the Vice-Presidentships, the Treasurer, Auditors and Committee being re-elected.

The question of publishing a revised edition of the Price List aroused considerable discussion, and was decided in the affirmative; a sub-committee was then formed for that purpose.

It was then, on the motion of Mr. Barclay, resolved to appoint a sub-committee to carry out the arrangements for the annual *soirée*, the profits of which are devoted to the Benevolent Fund of the Society. It was also decided to resume at an early date the meetings for the reading of papers, and several gentlemen were reported as willing to give their services.

A sum of £5 was voted for the further increase of the Library, which the Librarian reported was being more appreciated by members.

It was then resolved, upon the motion of the Chairman, that a sum of £5 be voted from the profits of last year's *soirée* to the Benevolent Fund of the Pharmaceutical Society, the proposer testifying to the very able and careful manner in which that Society disbursed the money at its disposal.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

A meeting of the Executive Committee was held at 17, Bloomsbury Square, on Wednesday, December 20, 1882, at 4 p.m.

Present—Professor Attfield, F.R.S., President, in the chair; Messrs. Brady, Ekin, Naylor, and Messrs. Benger and Plowman (Hon. Secretaries).

The minutes of the previous meeting were read and confirmed.

Letters of apology for non-attendance were read from Messrs. Ashton, Kinninmont, Payne and Radley.

A letter was read from the printers saying that the whole of the matter of the 1882 Year-Book was in type, and that copies would be ready for delivery during the last week of the year at the rate of about two hundred and fifty per day. Members who have paid their subscriptions will be supplied in alphabetical order. Although the publication has been delayed, owing to domestic affliction of the editor, the Year-Book will nevertheless be in the hands of members somewhat earlier than usual.

Mr. Siebold was appointed editor of the Year-Book for 1883.

The following gentlemen were elected to membership: Mr. J. Clower (Leamington); Mr. F. Hole (Mansfield); Mr. C. J. Mead (London); Mr. S. C. Nicholl (Belfast); Dr. F. Taylor (London); Mr. R. Berkley (Brisbane); Mr. B. Fawcett (Sydney); Mr. T. Ingham (Rockhampton); Mr. O. J. Kempthorne (Dunedin); Mr. E. Taylor (Brisbane).

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association was held on Thursday, December 14, Professor Attfield, F.R.S., President in the chair.

The following paper was read on—

THE PRESENT STATE OF ORIGINAL INVESTIGATION IN PHARMACY IN THIS COUNTRY.

BY E. M. HOLMES, F.L.S.,

Curator of the Museum of the Pharmaceutical Society of Great Britain.

The title I have chosen for this paper will perhaps be understood to mean the examination for the first time of substances used in pharmacy, which never before have had the light of science thrown upon them from a chemical, histological or botanical standpoint.

But as I am addressing gentlemen of whom many have but recently commenced a course of study, and who therefore are not in a position to do this, who have, in fact, as yet to acquire the necessary knowledge and skill, it is obvious that another meaning must be sought in these words.

The true meaning of language becomes apparent only when the derivation of words is traced out. Now original is derived from *origo*, a beginning, and investigation from *in*, in or upon, and *vestigium*, a footstep. The idea, then, which seems to be conveyed by the word "investigation" in the first place was probably the following up or tracing a person or animal by the footsteps, and this meaning would naturally be afterwards applied to inanimate objects, and ultimately to abstract ideas. As applied to pharmacy, it would also signify the following of footsteps, and the word "original" would imply that this following must have a beginning with the one who undertakes it.

Having, then, the opportunity of observing footsteps, numerous and varied, imprinted on the many divergent ways which lead to and from the home of pharmacy in this country, I will endeavour to direct you along the right path and to advise you in which footsteps to follow.

The majority of those who visit Bloomsbury Square appear to be travelling on the road which may be named prosperity in business; a lesser number along one which may be called a scientific career, and apparently very few indeed who have before them the long, straight, and apparently difficult road of a life successful in a moral sense.

Let us, then, in the first place, look around to observe traces left by those who have already made their mark, or left their imprint on the road before us, *as successful men of business*, and trace back as far as we can their previous footsteps, so that we may learn the secret of their prosperity. In one or two cases which have come under my own notice, it may be interesting to direct your attention to some of the footsteps which I have been able to trace back. In conversation with Mr. T. N. R. Morson, in the Museum of this Society, a few years ago, he informed me that he usually obtained from opium a much larger percentage of morphia than that mentioned in books, and it is well known his aconitine and creasote for many years defied competition. Now this implies scientific chemical knowledge in advance of his compeers. Such knowledge is obtained only by hard work and careful observation and experiment.

Mr. Peter Squire himself informed me that his success in life was largely due to the hard work and careful observation and experiment bestowed on the preparation of extracts of good quality at a time when it was almost an impossibility to obtain such an article in the trade. He had purchased some hemlock brought to the door by a countryman, and knowing that it would heat and spoil if kept until the next day, he sat up until three o'clock a.m., to transform it into extract. On examining it by daylight, he found it so superior in colour, odour and taste to any he had been able to purchase, that from that day forth he determined to make all his own extracts. These, exposed on his counter, attracted the attention of the Royal Physician, so that it shortly after became true of him, "He that is diligent in business shall stand before kings."

Those who have read the 'Progress of Pharmacy" will remember that Thomas Herring, of the firm of Herrings and Co., was the first to introduce vegetable powders of good quality ground on his own premises.

I need only recall the names of others, such as Howard and Huskisson, to remind you that scientific knowledge and manipulative skill have a great deal to do with success in business.

The reputation of most of the celebrated firms, both wholesale and retail, whose names are inseparably connected with the history of pharmacy in this country, rest upon the same foundation.

We may next trace the footsteps of *scientific men* who have been connected with this Society. Take, for instance, Dr. Pereira. His work on materia medica remains unsurpassed at the present day as a monument of industry and thorough mastery of detail. He allowed no obstacle to stand in his way; whether a foreign language, crystallography, or polarization of light,—every subject connected with his work was thoroughly mastered. His mantle, so to speak, fell upon one of his favourite pupils, Daniel Hanbury. When 'Pharmacographia' appeared it was felt at once that a new era in the history of materia medica had begun; that here was a book which was not made with scissors and paste, into which no errors of preceding authors had been copied with unquestioning faith, but one in which no statement was made which had not been verified by the personal experiments of the authors; in fact that it was the outcome of the patient research of a lifetime.

Mr. Hanbury was in the habit of carrying with him wherever he went a note-book in which to copy memoranda derived from books, information given him by travellers, or the results obtained by his own experiments. These note-books were of quarto size, and carefully indexed, fifteen of them being filled during his lifetime; the sixteenth was left unfinished.

These I have recently had the privilege of examining with a view to extract remarks which might throw light on the specimens in the rich and interesting collection of materia medica subsequently presented to this Society by his brother, Mr. Thomas Hanbury. I have been struck on going through them by the pertinacity with which he followed up any clue, the unsparing and yet gentle hand with which he corrected errors, and the conscientious striving for accuracy and exact truth which characterized all his investigations. Thus his inquiry into the botanical source of liquid storax necessitated correspondence in Europe, Asia, and America, extending over a considerable time. Yet he would never accept a statement as fact unless he obtained corroborative evidence from an independent source, although in some cases he had to wait weeks, months, or even years for it. It is this "veracity" as Carlyle would have called it, this love of truth, which gives such a high value to 'Pharmacographia.' Every fact there stated is vouched for by the author's well-known character as an accurate scientific observer, this feature being as it were stamped upon every page.

Some of the entries in the first book show that when any new statement was made in the *Pharmaceutical Journal* he at once tested it by experiment, and recorded the result in his book. Others show that he examined carefully such chemicals as aconitine soon after they were bought. These experiments seem to have been carried on contemporaneously with his attendance at the lectures, and indicate that he was not content with merely reading and hearing, but as far as possible followed out the apostolic injunction to "prove all things and hold fast that which is good."

Our honoured Chairman, Professor Attfield, must indeed have traced with pleasure the footsteps of several of his pupils who have held the enviable position of Bell Scholars, and especially of the first one. No one could write such lucid and yet concise papers as those which appeared from Dr. Tilden's pen in the *Pharmaceutical Journal*, unless he had a clear conception of the facts in his own mind, such a conception, indeed, as could only have been acquired by the habit of doing thoroughly everything he took in hand.

But there are, I am happy to say, footsteps still more recent. I allude to Dr. Thresh. It must have required an indomitable determination and no small degree of courage to attack such a subject as capsicum; for so penetrating and irritating is the effect even of the crystals of capsaicin, that in moving it from one bottle to another with the greatest care severe coughing is sure to ensue. But it is this same faculty of perseverance and courage in overcoming difficulties that has enabled Dr. Thresh to attain the high scientific degree he now holds.

It is scarcely within the scope of my subject to allude here to those few who travel along the road of life with the aim of living a life successful in a moral sense. There have been and are those who have placed this aspiration first, and who have been none the less successful business men and have had no less a brilliant scientific career in consequence. But of the satisfaction which rewards the travellers on this road, none can judge but those who experience it.

Having, then, endeavoured to trace the secret of success from the "footprints in the sands of time," may we not reasonably conclude that the qualities with which it is necessary to start on an equally successful journey are the capability of working hard and systematically, of exercising a close observation, a wise scepticism, followed promptly by experiment and by a record of the results obtained; and to crown all, the invincible resolution to overcome all obstacles in the path entered upon?

Underlying all there must be the golden maxim, "Whatsoever thy hand findeth to do, do it with thy might," and a conviction of the truth of the motto, *Labor omnia vincit.* These qualities should have been formed during apprenticeship, so as to have developed into habits by the time that a course of scientific study has to be begun; they do, in fact, constitute what are commonly known by the name of business habits.

When these habits are once formed and applied to study, all difficulties vanish and success is morally certain.

Unfortunately it needs but little observation to see that all have not received this necessary training, but that some, on the contrary, have developed habits of indolence, procrastination, superficial observation, carelessness of detail, and want of earnestness; in fact, an almost entire absence of the qualities essential to manhood or self-mastery, on which success in life largely depends.

This is due no doubt in some measure to want of careful parental training, and in no less a degree perhaps to the absence of conscientious supervision on the part of the business employer.

It is the absence of business habits, which should have been formed during the period of apprenticeship, and not the acquisition of scientific knowledge, that makes bad assistants. It is the same cause which gives rise to so many failures at the examinations; in other words business habits have not been applied to the study of science.

To those who have not had the advantage of this kind of training I would especially point out that the way in which work is done is far more important than the work itself; that, just as muscular strength is the result of physical labour, so mental and moral strength are the result of intellectual and moral exercise. Just as surely as it is true that he that will not work, neither shall he eat (because he cannot), so is it the fact that valuable habits will not be formed without regular exercise of the intellectual faculties. The true balance of the mind, like the balance of the body necessary to skating or tricycling, can only be obtained by practice.

If business habits and manipulative skill have not been obtained during apprenticeship, they will have to be gained during the subsequent course of study. Let your studies be mapped out for each day during the whole course and then carried out systematically with all the thoroughness and earnestness of which you are capable, and with the determination to leave no difficulty unsolved, and to know not merely all that is in the Pharmacopœia, but everything that is likely to be met with in any branch of the business, so that you can conscientiously feel that wherever you may be engaged no more competent assistant or more thoroughly equipped man of business can be found. This thoroughness is absolutely essential to success in any career. This is as true of nations as of individuals; it was this feature developed, in the almost microscopical character of national education, that made all the difference between defeat and victory to the German people in the late Franco-Prussian war.

I shall probably be expected to make a few remarks concerning original investigation in pharmacy in the ordinary acceptation of the term, and these must be addressed more particularly to those who have already formed business habits, and having applied them to their subsequent course of study have passed their examinations with flying colours.

In glancing through the index of the *Pharmaceutical Journal,* I have been struck with the comparatively small number of papers by English authors on subjects connected with the business of a pharmaceutical chemist, and with the fact that the greatest number as well as the majority of the best and most thorough articles have been written by German, Russian or French chemists. This may arise from the fact that, on the continent, graduates in pharmacy are required to write a thesis on a subject as yet untouched. This, however, cannot be the only reason since the inaugural essays published in the *American Journal of Pharmacy* by intending graduates are almost entirely wanting in the thoroughness and completeness which characterize those produced on the European continent. Nor does it arise from lack of subjects. To take a few instances:—Is there no room for improvement in decoct. aloes co., and pil. aloes co., ext. calumbæ or liquor taraxaci? Are there none of the numerous species of Eucalyptus that will yield a more satisfactory kino than that at present in use, or is it impossible to prevent the gelatinization of the tincture and yet preserve its activity? Is the present formula for ipecacuanha wine the best that could be devised? Is not the relative activity of the two resins of jalap worthy of investigation? Is it impossible to devise more economical processes for the extraction of alkaloids and active principles? Are there no vermifuges used in other countries possessing the advantages and none of the disadvantages of santonin. Are the preparations of aconite as satisfactory as they might be? Preparations of eserine keep very badly and a readily soluble salt that will keep well is still a desideratum. The purity of olive oil and of essence of lemon is always questionable, and no good test for the purity of either has yet been made known. Exact information is wanting also concerning the relative value and purity of artificial chemicals, such as benzoic acid, salicylic acid, chinoline, etc., as compared with the natural products.

These are a few points which occur to me as an outsider. But there are innumerable ones which must occur in daily business which need investigation, and on which the mental powers might be sharpened like iron on a whetstone. The *eye trained to observe and the hand to experiment and the spirit of thoroughness* are all that are needed to take away this reproach to pharmacy in this country. If I may venture to illustrate my meaning by alluding to a member present, I would point out the admirable investigations by Mr. R. H. Parker of some crystals found in furniture-polish; these crystals might have been thrown on one side, and an example of a research carried out in a most thorough and business-like manner might have been lost. In this case the only reward seems at present to be in the feeling that his example may lead others to attain equally valuable habits, and that thus he may benefit humanity. But this is not always the case. There are many points to be met with in the ordinary work of a pharmacist which, if followed up by experiment, will as surely lead to success in business and in benefit to humanity at large as Watt's observation of the lifting of the kettle-lid and his experiments thereupon. Those who have formed the habits I have alluded to cannot help applying them in their daily lives, and many a fortune has sprung out of a simple investigation. It was the search after a method of making quinine artificially that led to the discovery of the aniline dyes. It was the examination of seaweed at

Worthing, by a former student of this Society, Mr. E. C. C. Stanford, that led to the establishment of one of the largest manufactories of iodine in this country.

If my remarks have been rightly understood they will indicate that unless the habits of observation and experiment are formed in early life, it is vain to hope for an increase in original investigations in pharmacy, and that success in business, in science and in life, is dependent upon the possession of certain sterling qualities, of which knowledge is merely the instrument. That there is room enough in pharmacy for those who will take the trouble to cultivate these, I entertain not the slightest doubt; they have commanded success before and always will. Let the pharmacist be a pharmacist and not a grocer, a perfumer, or a drysalter, and he will no longer have to compete with those trades to his disadvantage. The only points upon which you can lay claim to public consideration and to proper emolument rest on special knowledge and skill.

A discussion followed, in which the President, Secretary, Messrs. Alcock, Giles, Greenish and Parker took part.

A vote of thanks was passed to Mr. Holmes.

The Secretary then announced that the Executive Committee had appointed the following gentlemen to act as a Committee of Reporters for the ensuing session:

Pharmacology	Mr. H. G. Greenish.
Materia Medica	Mr. W. Elborne.
Botany	Mr. J. O. Braithwaite.
Physics	Mr. H. Allen.
Organic Chemistry	Mr. W. R. Dunstan.
Inorganic Chemistry	Mr. F. W. Short.
Analytical Chemistry	Mr. C. Thompson.

The Executive Committee had also drawn up the following constitution and rules for the administration of the Research Fund:—

1. The fund shall be called "The Research Fund of the School of Pharmacy Students' Association," and its object shall be to encourage research in pharmacy and allied subjects by the defrayment of expenses incurred by members in the investigation of subjects forming the bases of communications to the Association. The balance in the hands of the Association shall be applied for this purpose and the administration of the fund shall rest with the Executive Committee.

2. The maximum grant for one subject in any one year shall be £2.

3. No grant shall be made for the payment of personal expenses.

4. Any member desirous of obtaining a grant from the fund shall submit a written statement of his application to the Secretary, specifying the nature of the investigation, the probable length of time which will be occupied by the same, and the amount of the grant applied for; also furnishing any other information which is likely to be of assistance to the Committee in considering the application. The Secretary shall then bring the application before the Executive Committee at its next meeting.

5. Members holding grants from the fund shall once a year forward to the Secretary a statement of the progress made with the investigation and of the expenses incurred since the grant was made. The Secretary shall then bring the statement before the Executive Committee, who shall report the same to the Association at the Annual Meeting.

6. When a grant is made to more than one member, the first member named shall be considered the secretary, unless a specific nomination is made, and he will be the only person entitled to receive the payment of the grant from the Treasurer.

Parliamentary and Law Proceedings.

Defective Measures.

At the Clerkenwell Police Court, on Thursday, December 14, Mr. William Davies, chemist, of 292, Gray's Inn Road, was summoned for having, on December 4, had in his possession three glass measures which were not stamped according to statute, one of them being 10 per cent. over measure.

The Defendant, in answer to Mr. Barstow, said he used the measures for poisonous drugs, but he knew his business and it made no difference whether the measures were stamped or not. He did not sell laudanum or any such drugs to the public in poisonous doses. He knew how to make the exact quantities with the glasses complained of. He had, however, had them replaced by stamped measures.

Mr. Barstow said that the defendant could not seriously allege that it made no difference whether glasses in which he measured poisonous drugs were right or wrong, and ordered him to pay a fine of 20*s.*—*Daily Chronicle.*

Alleged Acceleration of Death by an Opiate.

On Friday, December 15, Dr. Danford Thomas opened an inquiry, at the Islington Coroner's Court, on the body of Mary Wemhurst, aged 43.

Dr. George Brown, of Gibson Square, said that he was called to see the deceased by Mr. Burt, who stated that the deceased had taken a sleeping draught, and could not be awakened. He at once went to the house and found the deceased dead. He was handed a prescription written by Dr. O'Connor, dated 1876, each dose of which contained a sixteenth part of a grain of opium, in addition to other drugs. He had made a *post-mortem* examination, and had no doubt that death had been directly produced by an overdose of opium. In her condition such a draught should never have been given. All the evidences were those of opium poisoning.

By the Coroner: The dose she took would probably cause sleep in a healthy person, but undoubtedly death in a person suffering as the deceased did.

Dr. Alexander Wynter Blyth, the Public Analyst for Marylebone, said that he agreed with the last witness, but would not like to say that the death had been actually caused by the narcotic. He had no doubt whatever as to the inadvisability of giving any narcotic to a lady suffering as the deceased did. He held that a chemist had no right whatever to prescribe for a patient.

Mr. William Armstrong, of No. 33, Liverpool Road, deposed that he was a chemist's assistant, in the employ of Mr. Wootton. He was in the habit of putting up prescriptions for Mrs. Wemhurst, and did so on Monday evening. That was the prescription of Dr. O'Connor. At nine the same night, a young lady and gentleman came to him for an opiate, and he gave them 6 minims of tincture of opium and 10 grains of bromide of potassium. It was measured in a minim glass, and witness told Mr. Wootton of it then and there. The dose was made up to 1½ ounce by adding water. There was no prescription brought from Mrs. Wemhurst.

The Jury returned a verdict of death from bronchitis, accelerated by an overdose of opium, and blamed the chemist's assistant for prescribing.

Alleged Infringement of Trade Rights.

In the Chancery Division of the High Court of Justice, on Friday, December 15, the case of Smith *v.* Surfleet was heard before Mr. Justice Chitty. The plaintiff is a pharmaceutical chemist carrying on business in the Walworth Road and formerly in the Brixton Road, London, and the defendant is a chemist carrying on business in the Brixton Road, having purchased the plaintiff's business there. The plaintiff has for upwards of thirty years prepared and sold "Smith's Dr. McCann's Diarrhœa Mixture" and "Tasteless Dandelion Pills," and he has been in the habit of enclosing the mixture in a buff-coloured wrapper and the pills in blue wrapper. He alleged that the defendant, who sold similar compounds, had used labels which were a fraudulent imitation. The plaintiff accordingly asked that the defendant might be restrained from continuing the use of the labels in question. The defendant denied that the labels were in any way an imitation of the plaintiff's and contended that even if they were he had a perfect right to use them as they formed part of the good-will of the plaintiff's business, in the Brixton Road, which had been sold to him. The defendant in order to make his labels distinctive had placed his name in large letters upon them and had also used other distinctive marks. In addition, he produced evidence to show that it was the custom of the trade to use blue wrappers for pills.

His Lordship, after comparing the two labels upon the mixture, held that the defendant's was not a fraudulent imitation of the plaintiff's, and with regard to the wrapper on the pills said that although there seemed to be some similarity between the two he could not in the present conflicting state of the evidence decide the matter upon interlocutory motion, and therefore he must decline to make any order upon the motion. The question as to what passed to the defendant by the sale of the good-will of the Brixton business was a matter which could very well be decided at the hearing of the action.

Obituary.

SAMUEL URWICK JONES.

Mr. Samuel Urwick Jones, to whose death reference was made last week, began business as a chemist and druggist on his own account in Bath, about the year 1840. From that city he removed four years afterwards to Leamington, where he carried on business successfully for thirty years. In 1845 he joined the Pharmaceutical Society, and for many years filled the office of Local Secretary to the Society in the Leamington district. When the Conference of chemists and druggists, held at Birmingham in July, 1876, decided upon the formation of a Chemists and Druggists' Trade Association, Mr. Jones was unanimously requested to become its first President, and he continued in that office until May, 1879. In Leamington, Mr. Jones's business ability and sound judgment were much appreciated; he was twice chosen to be Chairman of the Local Board of Health, and he besides served his townsmen in several other offices. A few months since he removed to Budleigh Salterton, where he died on the 9th inst.

Notice has also been received of the death of the following:—

On the 24th of October, Mr. Albert Edward Newbery, Chemist and Druggist, Ramsgate. Aged 33 years.

On the 20th of November, Mr. William Fox, Chemist and Druggist, Pontefract. Aged 79 years.

On the 30th of November, Mr. Alexander Gorrie, Chemist and Druggist, Kirkcaldy. Aged 43 years.

Subacet.—Add half an ounce of mucilage to the water before the quinine is mixed with it.

J. B. A.—Yes; the formula is borrowed from the German Pharmacopœia, where the liquorice is directed to be decorticated.

"*Pertinctus.*"—The three simple tinctures are not official; but if a prescription ordering one of them was of recent date, it would be generally assumed that the compound and official tincture was intended by the writer.

D. M. P.—Tinct. digitalis gives a slight opacity and a little colour to the mixture. A dark flocculent deposit will form after twelve hours' standing.

D. G.—A separation of matter, having the colour of yellow bark, takes place in this mixture and is gradually deposited. The quantity will vary with different samples of ext. cinch. flav. liq. used.

Correspondence.

The Election of Annuitants.

Sir,—The recent election of annuitants presents such an anomalous and inexplicable result, that I think the attention of the subscribers to the Benevolent Fund should be directed thereto.

In nearly every benevolent society, it is a fundamental axiom that those who have subscribed to its funds should have the first claim to its benefit, whenever adverse circumstances unfortunately render it necessary for them to participate therein, and provided they are found deserving.

On a reference to the *Pharmaceutical Journal* of December 9, at the bottom of page 471, will be found the following:—"The Secretary reported that only one of the thirty-six annuitants then on the list had ever subscribed to the Fund," therefore, voters at previous elections had little opportunity to elect other than non-subscribers; but at the recent election, out of nine candidates no less than five had been subscribers, and in virtue of such subscriptions were entitled to be credited with an aggregate of 375 votes. Naturally one would think these five were more entitled to our sympathy from their having been "one of us," yet of the three unsuccessful candidates, two had been subscribers for many years, while a third subscriber was only elected by the addition of votes obtained at a previous election, when the preference was again given to non-subscribers.

Last week the total number of votes polled by the five subscribers was only 2088 more than the votes polled by one non-subscriber, a result certainly not in accordance with what might have been expected.

Now a few words to the voters on another subject. On the last polling day, for nearly five hours twenty gentlemen were engaged in examining the voting papers and counting the votes. These gentlemen found their work unnecessarily increased by the great difficulty many of the voters experienced in following the very plain and explicit directions which were given to enable them to fill up their papers correctly, non-compliance with which caused the rejection of many of the papers and the loss of a large number of votes. This occurs every year, both at the election of annuitants and at the election of the Council.

I will give a few illustrations. Printed on the voting paper is a column headed "Insert votes here in figures," an instruction which one would think was plain enough for anyone to comply with; yet some *write* the number of their votes in words, others put *crosses*, others again put the number in the wrong columns, and even to the left of the list of names. Some only give away a portion of their votes; others are much more liberal, for having, say, only two votes to dispose of, they give votes to each of four, five, and even six candidates; one gentleman with seven votes, kindly distributed twenty-eight votes as follows:—1, 2, 3, 4, 5, 6, 7, whilst another with ten votes gave one to each of eight candidates and two to the ninth, thus he nullified all his votes except one, but caused the scrutineers to make twenty-seven separate entries. Finally no less than fifty-four voters neglected to sign the voting paper with their name and address and 2186 omitted sending in their papers at all.

In conclusion, I may say I have no especial interest in either of the candidates but have been

A Scrutineer for several Years.

W. F. G.—See before, pp. 90, 156, and 510.

J. Hickling.—(1) Fresenius's 'Quantitative Chemical Analysis' (Churchill's). (2) Distil the ammonia into pure water.

X. Y. Z.—The article you refer to is a proprietary arsenical preparation; the London agents for it are Messrs. Schacht and Co., Finsbury Pavement.

Y. L.—The mixture should be perfectly clear and colourless. The precipitate can be accounted for only on the supposition that the liq. ammon. acet. was so alkaline as to neutralize the acid in which the quinine had been dissolved.

Communications, Letters, etc., have been received from Johnson, Hunn, Barnard, Clayton, Finch, Wells, Garry, Proctor, C. E., Ajax, Nemo.

"THE MONTH."

The recent work on 'The Colours of Flowers,' by Mr. Grant Allen, could hardly fail, from the elegance and clearness of his style, to attract considerable attention; but the position he assumes of taking useful theories as established truths naturally gives rise to scientific criticism. The editor of the *Gardeners' Chronicle* points out that the great mass of the facts of evolution militate against the acceptance of Mr. Allen's theory that petals are merely flattened out filaments and are developed subsequently to the stamens. Specialization and adaptation do not necessarily indicate lateness of origin in point of time, but are, in fact, the outcome of arrest of development, of a check to progress rather than an advance. Mr. Allen's theory that yellow was the colour of the earliest flowers, and that then in order of time came the white, red, purple and blue flowers, the last-named being the most highly organized, has no better basis than his theory concerning the origin of the petals. In the genus *Linum*, for instance, in which yellow, white, red and blue flowers occur, the blue-flowered species can scarcely be said to be more highly organized than the yellow.

Mr. Meehan, in the 'Proceedings of the Philadelphia Academy of Natural Sciences' (*Gardeners' Chronicle*, Nov. 25, p. 683), makes some interesting observations concerning *Acer dasycarpum*. During a period of fourteen years he found that a female tree would sometimes change the sex and bear only male flowers; also that this change resulted from a greater check to the vegetative force than that required to produce female flowers, and therefore signified exhaustion of vital power. Pursuing his researches he found that although at the time of the fall of the leaf there is little to distinguish a flower bud from a leaf bud, yet the former grows at a comparatively low temperature at which the leaf bud remains stationary, also that male flowers expand at a temperature at which the female flowers remain quiescent. Probably it is for this reason that some trees, like birch, which in countries where vegetation is suddenly developed during the short summer produce both kinds of flowers at the same time, rarely ripen fruit in more temperate climates because the male flowers are likely to be expanded long before the females. It is somewhat remarkable that the trees of *Acer dasycarpum* bearing male flowers were never observed by Mr. Meehan to change their sex to female. These observations may perhaps lead to some practical means of improving the culture of nutmegs, of which, owing to the uncertain sexual character of the trees, the crop is very precarious.

At the meeting of the Royal Horticultural Society, on December 12 (*Garden*, Dec. 16, p. 542), the Rev. G. Henslow gave a lecture illustrating the power of plants to render themselves attractive, independently of, or in addition to the corolla, in proof of which he exhibited various species of *Salvia, Poinsettia, Epiphyllum, Cornus* and *Euphorbia jacquinæfolia*, etc.

An interesting account of a spectroscopic study of chlorophyll, by Messrs. W. J. Russell and Lapaiche, will be found in *Nature* (Oct. 26, p. 637). These observers find that a mixture of 2 parts of alcohol and 1 of ether will extract from green leaves a substance which they regard as normal chlorophyll. The green substance so obtained is a body which very easily undergoes two modifications. Since these are produced by acids, heat and metallic solutions, they are regarded as the result of a molecular change, and not of a chemical one. Weak organic acids such as tartaric, oxalic and citric, cause a change in the spectrum, but this change does not go beyond a certain point. When strong acids, such as sulphuric, nitric or strong hydrochloric acid, are used a further change in the spectrum is produced. The modification produced by vegetable acids is distinguished by the authors as α-chlorophyll, and that produced by strong acids as β-chlorophyll. The authors state also that the spectrum remains unchanged after the yellow body, described by Conrad, has been extracted by benzene, and that hence this substance cannot be considered as a constituent of their normal chlorophyll. Some leaves, such as those of the vine, yield the α-chlorophyll to the alcohol and ether mixture, but this has been found to occur when the leaves are acid through being bruised; if carbonate of calcium or sodium be added, the normal chlorophyll only is detected by the spectroscope. The change from normal to α-chlorophyll takes place naturally in leaves after being gathered, whether in light or darkness. In some leaves, such as those of rhubarb, the chlorophyll evidently undergoes decomposition, the extract becoming of a tolerably bright red colour, and no longer giving the chlorophyll bands. Neither this red substance nor the majority of colouring matters in flowers give visible spectra. When to a solution of normal chlorophyll hydrochloric acid is added it has apparently considerable power of destroying certain bodies which absorb the blue ray, since after its addition blue rays come through where before it was quite dark. When a strong chlorophyll solution is very considerably diluted a striking change of tint from a dark to a light yellowish-green takes place; to this fact, viz., the greater or smaller amount of chlorophyll in a given area, is probably due the difference in shade between young and old leaves. The action of alkalies on chlorophyll produces a modification in which only the dominant band remains visible in the spectrum. This one-banded chlorophyll is much more permanent than the α and β modifications, solutions exposed to the sunlight for three months remaining unchanged in colour and constitution. This modification is also formed when a small quantity of sulphate of copper is added to an alcoholic solution of normal chlorophyll.

It is not unusual to see violets and primroses and other spring flowers blossoming in the mild weather of late autumn, especially if they have been prevented from flowering by having been transplanted at the period of flowering. From some interesting facts stated by Dr. Brandis, in the *Indian Forester* for July, 1882 (communicated by Mr. W. T. Thiselton Dyer to *Nature*, November 23, 1882), it would appear that similarity of season has more to do than the time of year with the time of flowering. Dr. Brandis observed that, from 1845 to 1850, *Acacia dealbata*, one of the Australian wattle trees, flowered in India in October; in 1860, it was observed to flower in September; in 1870, in August; in 1878, in July; and in 1882, in June. In Australia the tree flowers in October, which is the spring month there. In Ootacamund, the corresponding month is June. The tree has thus gradually worked back its time of flowering from October to June, from Indian autumn to Indian spring, during a period of forty years. *Acacia decurrens*, in the same way, appears to have flowered, during May to July, at Kew, in 1790, but now blossoms in February.

At a meeting of the Royal Horticultural Society, on November 16 (*Nature*, November 30, p. 119), some singular monstrosities of flowers were exhibited by the Rev. G. Henslow. One of these was a specimen of Solomon's seal (*Polygonatum officinale*) in which the normal flowers were developed as leafy racemes; another was a violet in which the sepals bore abortive ovules on the margins and midribs. Mr. Henslow also exhibited some drawings illustrating various stages of ovuliferous stamens in the alpine poppy.

In the same Journal Mr. A. M. Stapley, of Owens College, describes the fertilization of *Veronica officinalis*. According to his observations a fly trying to alight on the flower is obliged to clasp the two divergent stamens on account of the vertical position of the flower; this brings the two anthers close together below the pistil, where the front of the fly's head becomes dusted with pollen. The stigma, when mature, droops a little (the flower is proterandrous), so that it receives the pollen deposited on the insect's head. In another species, *V. hederæfolia*, in which the corolla is not so easily detached, the stamens and pistil are close together and self-fertilization appears to be the rule.

Dr. T. F. Hanausek, of Krem, describes (*Zeits. d. allg. öst. Apot.-Vereins*, xx., 465) a new kind of ginger, said to be of Japanese origin, in which the starch grains differ very considerably in appearance from those found in *Zingiber officinale*. This ginger is met with in commerce in the form of compressed pieces, with the flat side pared as if the root had been sliced longitudinally. The colour of the ginger is a light slaty grey or dirty greyish white. At the edge a grey corky bark remains, but sometimes this is absent. The freshly cut surface shows numerous yellow streaks or dots, indicating the vascular bundles, consisting chiefly of scalariform reticulated vessels, and small brown points which are resin cells. The taste and smell resemble those of ginger but are weaker. The starch grains are broadly oval or elliptical, without the point which forms such a marked feature in ordinary ginger, and the concentric rings and hilum are well marked and easily seen. Mixed with these are numerous compound starch grains, with their component parts sometimes separated; these somewhat resemble those of the nutmeg. Nothing resembling these starch grains has ever been found by Dr. Hanausek in Bengal, Jamaica or Africa ginger, and hence he thinks that Japanese ginger mnst be produced by another species.

In a note read at the Linnean Society, on Nov. 16, by Mr. W. T. Thiselton Dyer "On the Origin of *Cassia lignea*," he remarks that the want of exact evidence as to the botanical source of this spice is now cleared up. Mr. C. Ford, Superintendent of the Botanical Department at Hong Kong, has made an expedition to the districts in which the cassia tree is cultivated, and has brought back herbarium specimens in flower, which prove to be those of *Cinnamomum Cassia*. So far as Mr. Ford could ascertain, cassia buds and leaves as well as barks are obtained from this tree only. The leaves are sent to Canton for the distillation of oil of cassia, and the buds are gathered when about one-eighth grown. The thick bark, so much valued by the Chinese, is obtained from trees reserved for seedbearing, when such can conveniently be spared for the purpose.

Some interesting results concerning the germination of seeds have been obtained by Dr. Liebenberg, and published in the *Journal of the Vienna Academy of Sciences* (*Garden*, Dec. 2, p. 480). He finds that many plants require the presence of lime in the soil during the germination process, and that the seedlings die if it is not present. On the other hand, there are some plants which germinate freely without it. The cinchona trees are known not to require lime, but the frequent failure in Jamaica to raise seedlings, may, perhaps, be due to the soil not containing the other ingredients necessary to their healthy growth.

Several valuable memoirs have recently been presented to the Academy of Sciences upon points connected with the chemistry of vegetation. M. Leplay (*Comptes Rendus*, xcv., 1133) has given the conclusions he has drawn from the analysis of the different organs of maize at three different periods of its vegetation. He has found that at the end of the first period of vegetation (1st July) potash and lime are present in all parts of growing maize, in the soluble state in combination with vegetable acids in the juices, and also in the insoluble state in the tissues. From this time, however, no more potash appears to be taken up from the soil; but that already present in the plant in soluble organic combination undergoes an extraordinary migration from one part of the plant to another. During the second period the growing ear is supplied with potash entirely at the expense of the stalks, which lose as much as 39 per cent. of the quantity present in them at the end of the first period; but in the third period the proportion of this base in the stalks is restored to the extent of about 25 per cent., the reserve drawn upon now having previously been stored up in the leaves. The quantity of potash in the roots is not affected or only very slightly diminished during these movements. On the other hand whilst the total quantity of potash in the plant remains stationary, the amount of lime in organic combination in the different parts of it is increased during the second and third periods (July 1st to September 1st) by about 140 per cent., the first augmentation taking place in the stalks, from whence as the plant approaches maturity it passes in considerable quantity into the ear and especially into the seeds. During the formation of the reproductive organs the potash in organic combination with the tissues is gradually diminished and disappears entirely from the stalks, being replaced by lime. The vegetable acids combined with the potash and lime are considered to have their origin in the carbonic acid taken up by the plant from the soil in the form of carbonate or dissolved in water. According to M. Leplay (*Comptes Rendus*, xcv., p. 895) this transformation is effected by (1) reduction of carbonic acid or elimination of oxygen; (2) condensation or assimilation of carbon; (3) assimilation of the elements of water in the same proportions as they exist in water. Equations representing the manner in which these changes are supposed to take place are given in the paper.

Another memoir, by M. Leplay (*Comptes Rendus*, Nov. 27), throws some light on the relations between the presence of starch and sugar in plants. He found that sugar occurs in the leaves and accumulates in the stem until the moment of the formation of starch in the seeds. It then passes first into the inflorescence to support it, and subsequently into the seeds themselves, where it is replaced by starch. The function of the sugar would appear, therefore, to be that of furnishing the seeds with the elements of starch.

At a meeting of the Linnean Society on November 2, Mr. W. E. Armit, of Queensland, contributed a paper on "The Native Medicinal Plants of North-West Australia." Among these he enumerated *Erythræa australis*, used as a tonic in febrile complaints; *Careya arborea*, a myrtaceous plant, the leaves of which are used as an application to ulcers; *Grewia polygama*, a tiliaceous plant, said by the author to be very useful in dysentery, he having "never known it to fail in any case, however serious;" *Petalostigma quadriloculare*, a euphorbiaceous plant, the bark of which is used as a tonic in fevers in doses of 10 grs. three times a day; *Datura australis* and *Euphorbia pilulifera*, remedies for asthma. Of the two last, the former is said to be fatal to horses and cattle, the latter has recently been introduced into this country, and appears to be valuable as a remedy for bronchitis as well as asthma.

Dr. A. F. Currier, of New York, has published in the *American Journal of Medical Sciences* (October, 1882) an article on the use of *Eucalyptus Globulus* (*Med. Times and Gaz.*, Dec. 2, p. 666). The oil is said to diminish the action of the heart and the blood pressure, and to act as a stimulant, astringent and antiseptic on mucous membranes. It is also said to destroy entirely the unpleasant smell of iodoform. Dr. Currier speaks highly of its use as a disinfectant and antiseptic in chronic ovaritis and tumours of the breast in removing the fœtor of the discharges and relieving the pain and discomfort.

Doubts have from time to time been expressed as to the solubility of dialysed iron in the juices of the stomach. Dr. Prosser James, in the *Medical Times and Gazette* (December 2, p. 660), remarks "that the metal is really taken into the blood is not to be doubted," and that in five cases of anæmia with diminished corpuscles, as determined by the hæmatocytometer the globules increased rapidly under the use of 90 drops daily, and general improvement went on *pari passu* with this increase.

In the *Therapeutical Gazette* (p. 401), J. M. Blackerly speaks very highly of *Chionanthus virginica* as a remedy in chronic cases of enlarged and indurated liver. He states that in his hands it has proved superior to iridin, leptandrin, euonymin, podophyllin, or phosphate of sodium.

Dr. C. H. Ralfe, in a paper read before the Royal Medical and Chirurgical Society (*Brit. Med. Journ.*, p. 1095), gave an account of the results obtained by the use of nitrite of sodium in epilepsy. This remedy is stated by him to possess the advantage over nitrite of amyl and nitroglycerine, of more slowly producing effects which are more permanent. The author remarked that it is necessary to ascertain the purity of the drug, as some samples contained an admixture of nitrate. The dose that is usually given appears to be from 10 to 20 grains. Judging from the discussion which followed the reading of the paper, the new remedy does not seem likely to be received with much favour, and its usefulness would appear to be confined to a certain number of cases in which bromide of potassium is of little service and in which there is a state of low vascular tension.

A remarkable case in which the administration of pilocarpine cured a severe attack of pleurisy is described in the *Practitioner* for December (p. 453). A puncture and three blisters having failed to effectually reduce the pleuritic effusion, a hypodermic injection of two centigrams of nitrate of pilocarpine caused such a violent perspiration and salivation that the patient was entirely relieved in an hour and a quarter.

Some excellent results appear to have been obtained by Dr. Seifert in the treatment of diphtheria by chinoline (*Practitioner*, December, p. 447, from *Berl. klein. Woch.*). Dr. Seifert prefers the pure chinoline to the tartrates, on account of the bad taste and smell of the latter. The chinoline is prescribed in a 5 per cent. solution for painting the fauces, the solvent being a mixture of equal parts of alcohol and water. A new brush of hair or cotton wool is used each time, the old ones being burned. The stinging pain at first produced is succeeded by a sense of comfort and by the ability to swallow, if the throat is washed out with cold water after being painted. The following formula is the one which is prescribed for a gargle:—Pure chinoline 1 gram, distilled water 500 grams, sp. vini rect. 50 grams, and menth. pip. gtt. ij.

Dr. P. Miall (*British Medical Journal*, December 10, p. 1206) recommends the use of sulphocarbolate of sodium in the vomiting of pregnancy, in doses of 7 grains in half an ounce of water.

A French correspondent of the *Medical Press and Circular* (December 6, p. 485) speaks very highly of the local application of chlorate of potash in cancroid affections, such as epithelioma, lupus, etc. He states that a medical man has just treated, in a very effectual and rapid manner, a case of the latter by the application of the salt in powder. The cure was effected in a month although the disease was of five years' standing, and no other treatment was used, although previously many other things were tried.

In an interesting note on "epidermic medication" (*Ephemeris*, p. 152), Dr. Squibb calls attention to the facilities which the oleates dissolved in oleic acid present for this form of treatment and the desirability of more systematic experiment as to their mode of action. He points out that an oleate of glycerine,—olive oil, for example,—when used as a solvent or vehicle for an active medicine, is absorbed or passes through the skin very slowly and imperfectly; but that when the glycerine radical is replaced by a basic medicinal agent and the resulting soap is dissolved in excess of oleic acid, the whole passes rapidly through the skin and the local effect is correspondingly prompt and certain. As illustrating the affinity which oleic acid appears to have for the skin, he states that wood, porcelain and cloth coated with oils, glycerine or oleic acid retain a greasy appearance indefinitely, but that if the skin be similarly treated the oleic acid disappears much more quickly than oils or glycerine. This observation appears to have some bearing upon a recommendation, recently made, to use the definite oleates with heavy petroleum oil for a vehicle.

In connection with this subject it may be mentioned that in consequence of a failure to effect solution of a specimen of Duquesnel's "aconitine cristallisée" in oleic acid, and from the fact that he found it to be soluble in water, Dr. Squibb was induced to examine it more closely. Some of the crystals were dissolved in water and the solution was precipitated with slight excess of normal solution of sodium; the precipitate when carefully washed and dried at about 44° C. weighed only 80·7 per cent. of the weight of crystals used. The mother liquor, tested physiologically, gave no indications of aconitine, but contained nitric acid equal to about another 8 per cent., making together 88·7 per cent. The other 11·3 per cent. was not accounted for. Dr. Squibb is therefore of opinion that "Duquesnel's crystallized aconitine is not what it purports to be, but is a nitrate of aconitine containing not more than 80·7 per cent. of the hydrated alkaloid."

At a recent meeting of the Berlin Pharmaceutical Association, Dr. Carl Schacht called attention to some specimens of formamide of mercury, a new mercurial preparation recommended by Dr. Liebreich for use in subcutaneous injections (*Pharm. Zeitung*, December 16, p. 764). Formamide is a colourless liquid, boiling at about 195° C., which is a product of the reaction of the ethylic ether of formic acid upon ammonia; it is neutral when pure, but easily becomes acid, and it can only be distilled without decomposition in a vacuum. When a dilute solution of formamide is heated in a water-bath with precipitated mercuric oxide a clear colourless solution of formamide of mercury is obtained, in which sodium hydrate causes no precipitate, and which does not produce a precipitate in a solution of albumen. A solution for subcutaneous use, each cubic centimetre of which represents one centigram of mercury, is prepared by gradually adding 10 grams of formamide to 10 to 13 grams of freshly precipitated well-washed mercuric oxide, gently heated with some water in a water-bath, and as soon as solution takes place, filtering the colourless liquid into a litre flask and filling this up with distilled water. The solution of formamide of mercury keeps well in brown glass and is therefore dispensed in bottles of that colour.

According to the *Sanitary Engineer* (December 14, p. 31) the distilled extract of hamamelis is chiefly prepared in the States of Massachusetts, Connecticut, and New York. For this purpose the small twigs of the witch hazel are collected, preferably in the fall, when the leaves are off, and sold by the farmers to the distillers. Some of the stills employed hold more than a ton of these twigs, together with sufficient water to cover them. Steam heat is used, and from a ton of twigs fifty to eighty gallons of distillate is produced, to which 5 to 10 per cent. of alcohol is added to prevent change. The composition of the volatile substances thus separated has not yet been determined. There remains in the still a dark-coloured very astringent liquid, which is said to be available as a source of tannic acid. The leaves and not the twigs of hamamelis have been made official in the new edition of the United States Pharmacopœia, and the single official preparation is a fluid extract made by percolation with a mixture of alcohol and water.

M. Pasteur has communicated to the Academy of Sciences some interesting results of an investigation he has carried out together with M. Thuiller in connection with a serious epidemic of *rouget* or pneumo-enteritis among pigs in Bolène (*Comptes Rendus*, xcv., 1120). These investigators have arrived at the conclusion that the disease is the product of a special microbe, of such tenuity as to be easily overlooked, which can be readily cultivated outside the animal. In appearance this microbe approaches most nearly to that to which the "chicken cholera" is attributed, but it differs essentially in its physiological properties, since it is without action upon fowls, whilst it is fatal to rabbits and sheep. The inoculation of pigs with an almost inappreciable quantity of the microbe is promptly followed by the appearance of the disease, followed by death. The most important statement is that animals inoculated by a benign modification of the microbe, resulting from suitable cultivation, are not liable to a fatal attack of the disease.

The synthesis of uric acid, which foiled the best efforts of Wöhler and Liebig, has just been effected by Dr. Johann Horbaczewski, of Vienna (*Monatshefte*, iii., 796). It was known that when uric acid is treated with hydriodic acid it splits up into glycocoll, ammonia and carbonic acid. Dr. Horbaczewski has succeeded in reversing this process. Pure glycocoll was finely powdered with ten times its weight of urea (the diamide of carbonic acid), and heated rapidly in a retort on a metal-bath to a temperature of 200° to 230° C., until the liquid, at first perfectly clear and colourless, became yellow and turbid. After cooling the fused mass was dissolved in dilute potash solution, and the resulting clear reddish-yellow solution, after supersaturating it with ammonium chloride, was precipitated with a mixture of ammoniacal silver solution and magnesia mixture. The precipitate was washed with dilute ammonia, and decomposed with potassium sulphide, the silver sulphide filtered off and the filtrate acidulated with hydrochloric acid. Upon concentrating it in a water-bath there was a separation of uric acid, which after purification was obtained as a yellowish crystalline powder, presenting all the characters and having the elementary composition of that body.

Difficulty has been experienced by some experimenters in obtaining the alkaline potassium permanganate solution required in the analysis of water by the ammonia process free from ammonia. Mr. J. Stapleton (*Chemical News*, December 22, p. 284) is decidedly of opinion that the chief source of the ammonia evolved during the preparation of this solution is nitrogenous matter which is present in most commercial specimens of potash and cannot be entirely removed, even by fusion at a low red heat. As a serviceable device for overcoming the difficulty he recommends first that in preparing the potash solution a "hard" water should be used, as the precipitate of calcium carbonate formed by the neutralization of carbonic dioxide in the water apparently carries down with it a large proportion of the organic matter. The solution is allowed to clear by subsidence during twenty-four hours, or if necessary filtered through asbestos. The potassium permanganate is dissolved in a separate quantity of hot distilled water, and the solution when cold is added to the potash solution and the mixture brought up to half the proper bulk with distilled water. The alkaline permanganate solution thus prepared requires further purification, as it is still capable of yielding a comparatively large quantity of ammonia. This is most conveniently effected by distillation, by means of a current of steam generated from non-ammoniacal water passed at atmospheric pressure through the liquid heated on a water-bath, the steam being led almost to the bottom of the retort. The distillate is nesslerized after a few c.c. have collected, and this is repeated until the solution contains not more than 0·005 milligram of ammonia per litre.

Mr. Shelford Bidwell has given an account before the Physical Society (November 25) of some experiments he made to test the theory of Dr. James Moser that the action of a selenium cell under light is due to the heat rays making a closer microphonic contact between the selenium and the metal electrodes by expanding the material. He has submitted selenium cells to dark heat rays and found their resistance to *rise*. Under light rays, however, their resistance fell. He, therefore, considers that Dr. Moser's theory is erroneous, and that the fall in resistance due to the light rays is the differential result of the rise due to heat and the fall due to the light. He also explained the fatigue of a selenium cell by use as caused by its increase of temperature. When the cell cools again the fatigue disappears.

An interesting account of a selenium photometer constructed by Messrs. Siemens and Halske, of Berlin, appears in the *Electrician* (December 16, p. 100). The idea embodied in the instrument is to get galvanometer readings from optically excited selenium. If experience should prove the reliability of this method of photometry, a valuable instrument will result, free from the "personal" uncertainty that attaches to the best of those in use at the present time.

Professors Ayrton and Perry, at a meeting of the Physical Society, held on December 9, read a paper "On the Resistance of the Voltaic Arc, or the Opposition Electromotive Forces set up." The electromotive force was measured by a voltmeter connected between the terminals of the lamp. Keeping the width of arc constant the electromotive force was found to diminish as the current increased. Keeping the current constant the electromotive force increased rapidly at first with an increasing width of arc, and afterwards more slowly. The authors gave a curve representing the change. About 80 volts are required to produce an arc of $\frac{1}{3}$rd of an inch. For further increase of arc electromotive force is therefore proportional to increase of length of arc.

Professors Ayrton and Perry also read a paper on "The Relative Intensities of the Magnetic Field produced by Electromagnets when the Current, Iron Core, and Length of Wire, etc., are Constant, but the Wire differently distributed." In (*a*) case the wire was wound uniformly from end to end; in (*b*) case it was wound from the middle to one end; in (*c*) case it was wound only at both ends; in (*d*) case it was wound only at one end. The field was measured along a line running through the axis of the poles beyond the magnet. Of the above plans, (*a*) gave the strongest field, except at short distances, when (*b*) was best.

ATOMS AND MOLECULES.*

BY BARNARD S. PROCTOR.

(*Concluded from page* 510.)

Chemical action is probably the influence or effect of the force exerted by molecules of one nature upon the motions of molecules of a different nature, and having different kinds of movement; the resulting motion determining the nature of the resulting compound, and the action taking place when the differing molecules come in contact. Or, if we accept the current theory, that the spaces between the atoms in solid bodies is large in comparison to the size of the atoms, instead of saying when the atoms come in contact, we must say when the ethereal atmospheres which surround them, come in contact. The idea that combination is the result of a harmony of some of these molecular movements is supported by the fact, that mechanical union takes place when powdered sulphur and chlorate of potash are powerfully compressed, and that chemical union takes place when they are powerfully rubbed together, the harmony of their molecular motions not being close enough to cause chemical union till the mechanical motion of friction assists, probably by altering one or both of the molecular motions, in such a way as to make them harmonize more closely, or by the mechanical disintegration of particles disturbing the polarities of the simple body, as chemical decomposition effects the nascent state of molecules liberated from chemical union. Friction is said to ignite a match by causing heat. Why not say it causes chemical action directly? We have no evidence that heat is produced *before* the chemical action, except the general experience that heat is one of the results of friction; and no evidence at all that the chemical action observed is due to the heat produced by the friction. We also know that light and electricity are results of friction, and though light is said to be one of the evidences, or consequences of a certain degree of heat, we cannot for a moment admit that light is invariably an evidence of heat or at least of that degree of heat which is said to be luminous, and when, by rubbing two quartz pebbles they shine in the dark, there is scarcely a possibility that any portion of the stone has been raised to the temperature of incandescence. Again if, instead of quartz, we take loaf sugar for the experiment, the sugar would not bear a temperature capable of producing light through the development of a luminous heat. Is it not more philosophical to say—*friction produces molecular motions of various degrees of intensity, which manifest themselves as heat, light, electricity, or chemical action?* In the friction light of quartz the yellow rays preponderate, while in the friction light of sugar the blue rays predominate, and both are no doubt accompanied by that lower grade of molecular motion which is known as non-luminous heat, and possibly also by electricity. The odour of the rubbed quartz may be the result of chemical action, though of what nature we have no evidence; it does not resemble ozone, though it might be a silica compound of a parallel nature.

Assuming that all bodies are endowed with molecular movements, and that their disposition to unite depends upon the harmony of those movements, we may naturally conclude that chemical change will be facilitated by change of temperature. It has been a common saying that heat was promotive of chemical change, but that is a one-sided statement, true only in relation to certain degrees of heat. If we were inhabitants of the sun or some other very hot place, we might note that chemical action was promoted by a reduction of temperature, and that few combinations could be produced without it. The fact is, while a low temperature usually adds to the stability of a compound, when once formed, a high heat prevents the majority of combinations taking place. The aqueous zone, that is the temperature between the freezing and boiling points of water, is the fertile land of chemical change; here combinations and decompositions in infinite variety take place.

It being admitted that the contact of one body will communicate to others of a different temperature, some of its molecular movements—that harmony of these movements causes combination, and want of harmony causes separation, it is not unnatural that the presence of one body may cause sympathetic vibration in another of the same temperature, but of different normal velocity of vibration, and thus bring about combination or decomposition in the manner long known as catalysis. The surface action of charcoal and spongy platinum effecting the union of H and O, is probably of this nature, and the reverse of the way heat effects the same; the latter increasing the molecular movements till they come into

---

* Presidential Address delivered before the Newcastle-upon-Tyne Chemical Society.

harmony, the former retarding them till another harmony; a different chord produces a like result. The doctrine of catalysis is going out of favour. Fermentation was formerly spoken of as a catalytic process; then it was attributed to the force of vegetable life, but to call it vital force instead of catalytic is only moving the difficulty from one place to another, not getting rid of it. There is too much disposition to get difficulties put a little further away, just out of sight for the time being, and then neglecting them; such, for instance, as the recent endeavour to explain the process of digestion by saying that solution of the food in the stomach is principally due to the action of the living vibrios which always abound under these circumstances; and omitting to explain at the same time what aids the digestion in the stomachs of the vibrios. Perhaps they have no stomachs, so the difficulty of explaining their digestion disappears. There are, however, a number of cases in which the presence of one body affects the chemical action of another, where we have not the opportunity of hiding our ignorance under the statement that the phenomena are due to vital force. The decomposition of peroxide of hydrogen by oxide of silver. The more ready decomposition of chlorate of potash when mixed with oxide of manganese. The decomposition of chlorate of silver into chloride and oxygen by the action of nitric acid. The increased explosiveness of fire-damp in the presence of non-combustible dust, such as calcined magnesia. The solubility of platinum in nitric acid, if first alloyed with a large proportion of silver, and many other cases which will readily occur to you. In some of these there is probably no explanation more ready or more rational than the supposition that the contact of one body influences the motions of the others, and by this means influences their tendencies to combine or separate.

Johnstone Stoney, in the *Philosophical Magazine*, vol. xxxvi., p. 134, estimates the velocity of the oxygen molecules. The pressure of the gas on its containing vessel equals its weight multiplied by the velocity of its molecules. He goes on to say if oxygen be replaced by hydrogen, which has only $\frac{1}{16}$th of the weight under the same pressure, the velocity must be square 16, (16^2) times as great, that is 256 to 1, to account for the same pressure. Feeling conscious of my own deficiency in mathematical training and experience, it is with some hesitation that I criticise this latter statement. If the momentum of O equal 16, that of H at the same velocity equals 1. At 4 times the velocity it equals 4 for each impact; but at 4 times the velocity it makes 4 times the number of impacts in an equal time, and so brings up the resultant force to 16, the force being proportionate to the *square root* of the velocity instead of the square. This velocity is that of the molecule through space from one part of the vessel to another, however small the movement may be; but the internal molecular movements are more regular and minute, and more ready to act upon the waves of light, causing bright spectral lines or absorption lines. The regularity of the motion is shown by the *narrowness* of the spectrum lines; and the complexity of the motion, by the number of lines belonging to any gas, by how many different velocities of undulations are interfered with, and how sharply the interference is limited. He quotes Maxwell to the effect that the free path of a molecule of air equals 7 "eighth metres." That is, a molecule of air between its collisions, moves on the average $\frac{7}{10^8}$ (7—one hundred-millionths) of a metre, that is $\frac{1}{8}$th of the wave length of the ray D.

The molecule is deflected 7×10^9 (7 thousand million times) in a second, and each free path lasts $\frac{14}{10^{11}}$ (14 thousand millionths) of a second. This is 50,000 times the double vibration of a red ray, and 100,000 times the double vibration of a violet ray. All the molecular motions affecting light must, Stoney says, vary in velocity only between these limits.

Clausius estimates that the mean distance between the molecules of a gas equal about $\frac{1}{60}$ of the length of their free path. Stoney concludes from Maxwell's experiments that the normal distance is probably about $\frac{1}{10^9}$ (1 thousand millionth of a) metre, consequently there are about 10^{18} (a trillion) molecules in a cubic mm. of gas. These statements and such as these may be regarded as knowledge in the nascent state, knowledge which scarcely yet exists, but which is to be. We have been taught that heat is a great promoter of chemical change, but the greater part of the chemical processes with which we are acquainted can only take place at moderate temperatures, that is between the freezing and the boiling points of water. The vital zone of temperature bears a luxurious growth of chemicals. The zone higher is characterized by decomposition and dissociation, the lower zone by stability of compounds, and the formation of some which are easily decomposed by heat.

In physical conditions also the middle or liquid state is the zone of chemical activity; it is here that molecular movements are sufficiently active to facilitate change, and yet kept within the bounds in which the motions of heterogeneous atoms have a probable chance of harmonizing.

Hardness is a physical obstacle to the act of combination of solids, elasticity equally so in the case of gases, though neither of these obstacles are insuperable. Increased temperature (and consequent increased elasticity) facilitates the combination of some gases, probably by bringing their molecular movements into harmony with one another. If an equal number of vibrations per second be added to the motions of two inharmonious musical strings, a point may be reached at which they harmonize. If one string vibrates forty-five times, while the other vibrates ninety-five, they will produce a discord, but if we add five vibrations to each, making fifty and a hundred respectively, the one will sound the octave above the other. An analogous action may enable the movements of two uncombined gases to become so harmonious as to result in their union. The compound motion resulting would then be constant in its character, unless the action of heat be increased so much that dissociation ensues, which would take place if the motion of one of the atoms was acted on by a rythmical heat vibration, which would so far enlarge its orbit as to set it flying off from its companion atom.

The harmony of vibration may be brought about by other agencies than heat or light, such as pressure: increased pressure tending to combine sulphur and copper; reduced pressure facilitating the union of oxygen and phosphorus.

The molecular motion of a compound is probably the result of the composition of the forces of the molecular movements of its elements, but it is not probable that it is so in the simple mechanical sense in which we represent the composition of two forces as the diagonal of their parallelogram; the elements no doubt retain some of their individuality. Professor Mills, of Glasgow, objects to our saying that water contains H_2O (*Phil. Mag.*, January, 1876). He prefers to say that water plus energy equals $H + O$; and that $H + O$ forms water plus energy. He thinks we might with equal exactness say that water is a simple body intermediate between H and O. If matter were only directed motion as he suggests, the compound water might be only compound in the same sense as the diagonal is the compound in a parallelogram of forces, a simple line intermediate between the two forces H and O; but the conception of motion or force without matter seems to me to require a new definition of matter, or else to require the resolution of both force and matter into motion of luminiferous ether, the existence of which is hypothetical, and the nature of which we assume to be any that suits the requirements of our hypotheses. Had water been a force or motion as simple in its nature as the diagonal in a parallelogram of force, or as any simple force resulting from the combination of two forces acting in different directions, it would not necessarily be resolvable only into the two forces from the union of which it resulted. The fact that no application of force, varying in kind or quantity, has resulted in the production of anything but H and O from water supports the view of the elements of water retaining their individuality, to some extent at any rate, while in combination, and does not encourage us to regard Aq as a simple body or a simple force intermediate between H and O.

In Ag_2O the union is feeble because the normal movements of the elements are not closely harmonious. In H_2O the union is stable because of a closer harmony. In H_2O_2 the second equivalent of O is feebly held, because the normal movement of O is not closely harmonious with that of H_2O. And Ag_2O, we may suppose, decomposes H_2O_2 because of the harmony between the loosely attached oxygen atoms, continuing in their combination, and because the polarities of these atoms are not better satisfied by association with silver or water than they are by the union of two atoms of oxygen into one molecule, which constitutes oxygen in the free state. This partial satisfying of the polarities by the union of two or more atoms into one molecule, constitutes the difference between the chemical activity of free and nascent elements.

Dr. Siemens has recently propounded a theory of the sun's heat, based upon the fact that the radiant heat and light have the power of dissociating the elements of water when they pass through its vapour in a highly rarefied state, and that the dissociated elements, when drawn down to the denser atmosphere of the sun, reunite, giving out again the heat which had effected their separation. A reasonable objection has been raised to this theory, that is, that the heat which we estimate as the sun's loss is only that which escapes this trap to catch the sunbeams. But, however much heat may escape from the sun into space, it does not seem necessary that we should establish new laws for the conservancy of the solar system. If force radiates from the sun as heat and light against space, diminishing in proportion to the square of the distance from the sun, the same force reflected back from space as from a hollow spherical reflector would come back directly to the sun undiminished. But as space is not a reflector of heat and light, may we not speculate on these overflowing vibrations causing a mechanical reaction, the backward flow of some other force, say gravity? Is it not a more reasonable speculation that gravity should be convertible with the other forces and keep up the cycle of natural change, than that all the stars are pouring forth their heat and light into infinite space, receiving nothing in return, and so to go on till, in the lapse of countless ages, all comes to utter darkness and inconceivable cold? Our common experience is that a hot body tends to become cold, but he would be a bold physicist who would assert that the universe as a whole had the same tendency. On the one hand we have no experience of the universe as a whole, and on the other we have experience of numberless cases where, in ignorance, it was supposed that force was lost, but in which further knowledge showed that it was not lost, but converted into another form. We are as yet unacquainted with any means by which gravity may be converted directly into any force except mechanical motion, but the conversion of the forces is a subject so new, in comparison with the length of time during which the forces have been studied as separate and unconvertible agents, that it would be unreasonable to assume that because we have not yet seen the means of converting the force of gravity into heat or light except through the intervention of mechanical motion, we are not likely to do so. We have converted heat into electricity and electricity into heat—magnetism into electricity and electricity into magnetism, and so on in many other cases, which have been among the most interesting achievements of science during the last half-century.

If the action of gravity be reduced to that of radiant force acting in all directions, the apparent attraction being the subtraction of impacts on that side of a body to which the action of gravity tends to move it, then all bodies must have a diadynamous property at least as perfect as the diaphanous and diathermanous property of air. The proportion of impact force a body transmits, compared to that which it intercepts, gives the difference in weight of a second body weighed above and below the first. The proportion of impact force which a body intercepts, compared to that which it transmits, gives its mass, and the excess of impacts it receives in one direction over the other, multiplied into its mass gives its weight. One very marked difference between gravity and other forces, is that the relationships which an element bears to all the other forms of force are changed by chemical combination, while its relation to gravity remains constant. When iron combines with chlorine, its relations to heat, light, electricity and magnetism are essentially changed, but its weight remains the same. On this exceptional constancy in the relationship between gravity and matter in its different states of combination depends the possibility of exactness in chemical science.

It is with pleasure, not unmingled with reverence, that we feel our views of force and matter extending and promising that we shall see the unity and harmony of all nature. It must be regarded as a narrow view, a small-world prejudice, to look upon our solar system as a centre, radiating force upon all creation, giving out force in the form of heat and light, in quantity inconceivably greater than it receives. Our common experience is that there is a general tendency in all nature to the restoration of physical equilibrium, the bent spring tends to relax, the suspended weight to come to the ground, the hot or cold body to come to the temperature of the bodies surrounding it, and we have naturally assumed, though with too little reason, that a state of rest, of inactivity, of monotony, and of death, is the natural goal to which all things tend.

We do not *know* that our system is becoming colder, and the sun less luminous; and if we did, we still do not know that we are not accumulating some other force, at present beyond our discovery.

On the other hand we are daily becoming more convinced—more *certain* that force is not destroyed.

We are learning to count the atoms, to weigh the imponderable, and to measure that which has neither size nor shape; and we may with hopeful anticipation look for the laws which govern the chemical action of heat and light, and bring gravity into close relationship with the other forces of nature.

THE MEDICINAL OLEATES.*

BY DR. SQUIBB.

Chevreul ('Recherches sur les Corps Gras') discovered oleic acid about 1811, and notices of medicinal oleates may be found in the chemistry and pharmacy of France about that time. The first paper met with in the English language, however, is by Professor Attfield. This is "On a Method of Dissolving Alkaloids in Oils," and is published in the British *Pharmaceutical Journal and Transactions*, for 1862-63, vol. iv., p. 388. This paper refers mainly, but not entirely, to the use of oleates for the purpose of rendering these bases soluble in oil, and both in the paper and in the discussion which followed the reading of it, this use of the oleates was discouraged as tending to useless polypharmacy. From this time nothing very definite has been met with until

* Reprinted from *An Ephemeris of Materia Medica, Pharmacy, Therapeutics and Collateral Information* November, 1882.

the publication of the paper of Mr. John Marshall, in 1872. Since 1872, very general notice has been taken of the subject, in a casual, inexact way, by authors on therapeutics and materia medica, and several papers have appeared upon the chemistry and pharmacy of the oleates. Various methods of preparation have been advocated, but none so good as the direct union of the acid with the dry base without heating. The preparation should always be either a liquid or a semi-solid which is easily and completely liquefied by the natural temperature of the surface to which it is to be applied, and hence normal oleates undiluted are not applicable to therapeutic uses, but only solutions of the oleates, and these solutions should always be in oleic acid as the solvent rather than in oils, because the acid is more readily absorbed than the oils. In the rare cases where the excess of acid as a solvent of the oleates proves irritant to the skin, dilution with a bland oil becomes admissible. A paper has appeared recently by Dr. John V. Shoemaker (see the *Medical Bulletin* for July, 1882, p. 153), in which it is stated that the oleates as commonly prepared and used are not chemically true oleates, but merely solutions of oxides in oleic acid, and as such will often give negative results. This is a mistake, and is as great an error as it would be to say that mercuric nitrate, made by dissolving mercuric oxide in nitric acid, was not a chemical nitrate, but only a solution of the oxide in the acid. This author also states that the best method of making oleates for medicinal uses is by double decomposition; and this, as a general statement, is also a mistake, as very few oleates are well made in this way, and it is doubtful whether any are best made by double decomposition between solution of oleate of sodium and solution of salts of the bases. At least this is neither the simplest nor the easiest way of making the solutions of the oleates in oleic acid as required for the best and the easiest absorption through the sound or unbroken skin, and it is incorrect to write of preparations made by direct union of the acid and base as "supposed oleates" of "indefinite and unstable character."

The oleates which, up to this time, appear to have been most used, are oleates of aconitia, atropia, mercury, morphia, quinia, strychnia, veratria and zinc. These are for general or epidermic use through the skin, while for special or dermic use in diseases of the skin, oleates of copper, lead and zinc are those most frequently heard of.

Oleates of the more active alkaloids, namely, aconitia, atropia, strychnia and veratria, are usually and properly made of the strength of 2 per cent. of the alkaloid. The oleate of morphia usually contains 5 per cent. of that alkaloid, while the oleate of quinia is made as strong as is practicable, and usually contains 20 per cent. of the alkaloid.

All of these are very simply and easily made by putting the weighed quantity of the alkaloid into a mortar, adding a small quantity of the oleic acid, little by little, and triturating until the alkaloid is completely dissolved. The strong solution thus made is then poured into a tared bottle, and the mortar and pestle rinsed twice into the bottle with small quantities of oleic acid. The proper weight is then made up by the addition of oleic acid. No heat is needed, nor should any be used in the preparation of many oleates, but in some of these the digestion is prolonged, and intervals of trituration are needed. All heating has a great tendency to change their molecular constitution. If well-made oleate of morphia be shaken with dilute sulphuric acid, the morphia should be washed out as a sulphate, but it is a singular fact that it cannot all be so recovered as morphia; yet the morphia effect of the oleate is prompt and decided. This appears to show that some change is effected in the alkaloid even by combining it without heat, while if heated the changes are destructive.

The molecular or combining weight of oleic acid is high, namely, 282, but the weights of the alkaloids are still higher. That of aconitia is 645, atropia 239, morphia 285, quinia 324, strychnia 334, and veratria 592. Hence the molecule of the respective oleates would be very complex and very easily split up by any forces tending to decomposition, as heat, light, etc., or by oxidation from undue exposure to air. Hence it is that oleates may not keep well, but should be as freshly made as practicable, and should not be relied upon for their full effect when more than a year old, even if they have been carefully kept in a cool place.

The normal oleates—that is, when the oleic acid is fully saturated by the base—contain the following percentage of the respective bases:

Oleate of aconitia,	about	69·6	per cent.	of	aconitia.
Oleate of atropia,	„	50·6	„	„	atropia.
Oleate of morphia,	„	50·3	„	„	morphia.
Oleate of quinia,	„	53·5	„	„	quinia.
Oleate of strychnia,	„	54·2	„	„	strychnia.
Oleate of veratria,	„	67·7	„	„	veratria.
Oleate of bismuth,	„	22·2	„	„	Bi_2O_3.
Oleate of copper,	„	12·7	„	„	CuO.
Oleate of iron,	„	11·7	„	„	FeO.
Oleate of lead,	„	29·	„	„	PbO.
Oleate of mercury,	„	28·4	„	„	HgO.
Oleate of zinc,	„	1·29	„	„	ZnO.

A brief notice of the therapeutic application of some of these oleates may not be without use. In epidermic medication it must be borne in mind that the skin, in common with the mucous membranes of the primæ viæ, does not absorb with equal facility or rapidity at all times. As was forcibly said by Professor Charles D. Meigs in regard to the occasional inactivity of powdered ergot in parturient women: "There are conditions of stomach in which you might as well put your medicines in a bladder and hang it up on a nail." So there are conditions of skin wherein absorption is slow and difficult, and in all such, hypodermic medication has great advantages, and it is highly probable that the hypodermic use of these oleates would be effective in such cases.

In reviewing the principal oleates somewhat in detail, it may be useful to begin with oleic acid.

Oleic Acid.—This is made from the so-called "red oil" of the makers of stearin candles. The other fatty acids are separated from the oleic by solidifying at higher temperatures, when they can be filtered out. But they are never completely separated, nor is it necessary they should be, since this oleic acid for medicinal uses does not aim at a high degree of chemical purity. The crude oleic acid is next washed with solution of sulphurous acid, and finally is repeatedly washed with water, and carefully filtered in the cold with the least practicable exposure to air.

It is then an oily liquid of the colour of pale sherry wine, having a faint, peculiar, indescribable odour and taste, free from acridity. Its specific gravity is ·898 to ·900, at 15·6° C. = 60° F. It is thinner than the oils, and much more easily wiped off from surfaces without leaving them greasy. Applied to the skin, it wets it almost like water, and if very thinly applied it is so quickly absorbed that it seems as if it had evaporated like water; and it leaves the skin as clean and free from greasiness as though it had been wet with water. The peculiar odour of the acid is much stronger when it is spread upon the skin than when in a bottle. It should be kept from the light and air as much as practicable, although it does not appear to rancidify as easily as fats and oils do. As it has not yet been determined how the oleates keep, it is very good practice to keep the oleic acid on hand, and from it make the oleates as they are required for use—not necessarily each time they are prescribed, but every month or two.

Oleate of Aconitia.—This is made by simply putting the dry alkaloid and the acid together, when the alkaloid, if pure, instantly dissolves and disappears.

This is, however, only the case with the alkaloid precipitated from the "aconitine" of Duquesnel.* With the other aconitias of the market the solution is not quite so prompt, and a little residue is often left undissolved, and has to be filtered out. The oleate should, however, always be made from the best aconitia, although it be thus rendered very expensive. The increased cost is, however, rather apparent than real, since half a drachm of such an oleate is more effective than an ounce made from ordinary aconitia.

There is no pharmacopœial authority for the strength of this oleate, but usage has started it at 2 per cent. That is, 2 grains of aconitia in 98 grains of oleic acid. Then, as the aconitia precipitated from "Duquesnel's aconitine" costs at least forty cents a grain, the 100 grains of this oleate would cost say eighty-two cents. But the preparation is an exceedingly active and potent one, and is, therefore, required in very small quantity. Remembering that the dose of this aconitia for internal administration is from the one-hundredth to the two-hundredth of a grain there will be at least three hundred doses in 100 grains of the oleate. Hence it will be required, in any probable use of it, in very small quantity, and as it must be a very dangerous substance, it should never be put up or dispensed in larger quantity than about the sixteenth of a fluid-ounce, or 2 cubic centimetres, and this quantity would contain the eighth of a grain. Each minim weighs eight-tenths of a grain, and contains about one-sixtieth of a grain of aconitia. A drop from the thin lip of the vial in which it is dispensed is about half a minim.

This oleate should be applied by means of the end of the cork which stops the bottle containing it. If twice the quantity which the end of the cork will carry be spread over about half a square inch of the skin on the back of the hand, a glow of warmth in the part is almost immediately felt. This will continue for some minutes, then become intermittent, and in a half hour will have entirely disappeared. If twice this quantity be then applied to about a square inch of surface, including the first portion, the glow will be more pronounced, and there will be prompt tingling in the nerves which pass under the part down to the ends of the fingers. In a few minutes the glow will have increased to a sense of heat and pricking in the part, and the tingling along the course of the nerves will have increased. In a quarter of an hour there will be slight numbness in the ends of the fingers to which these nerves are distributed. All these sensations will increase slightly and steadily for about half an hour, and will then subside, becoming intermittent with longer intervals, until they disappear at about the end of an hour, when the oleate will have nearly disappeared from the surface. If, however, at the end of half an hour the dose be repeated on the same surface, all the sensations are promptly increased and extended to the whole hand. In a quarter of an hour a slight glow of warmth is felt throughout the arm, with just perceptible intermittent tingling. This tingling was noticeable with widening intervals for at least ten hours, and on the following day there was itching of the surface.

This much may serve to show the potency of the preparation, and to indicate both the dose and the use. If in trigeminal neuralgia such an application of this oleate be made over the course of the branch involved, or over the point of emergence and distribution of the nerve, it will probably soon do all that aconite can do for the case in a better, safer and more manageable way than by internal administration. The active medication of the whole organism to get at a local nerve at a point of pain seems to be a roundabout way when access can be had directly to it by such means as this oleate, while at the end of a few hours of the above-mentioned experiments it seemed quite plain that the aconite influence had extended to the entire organism, for the sensations were distinctly felt in the opposite hand, and although the temperature and pulse were not taken, they were evidently both reduced.

Oleate of Atropia.—This oleate is made in exactly the same way as the oleate of aconitia, and by general usage is of the same strength, namely: 2 per cent. Although an active and potent preparation, it is by no means so active or dangerous as the oleate of aconitia. It has been said that the application of 5 minims of this oleate to a knee-joint of a adult patient has produced dilatation of the pupils within a quarter of an hour just as a very good belladonna plaster should do, with prompt relief of pain, and if this be true it serves well to indicate the power and the dose of this oleate. There is, beside, considerable loose and scattered testimony to its steady though slow effect upon the pupil when applied in the neighbourhood of the eye. It would seem that it ought to be very manageable and very useful in ophthalmology as a substitute or alternate for instillation of the watery solution, but up to this time it has not attracted much attention so far as any published statements go. Yet there is a good deal of it sold, and judging by the sales its use is increasing, probably mainly as an application to painful joints as a substitute for belladonna plasters.

Each minim contains about one-sixtieth of a grain of atropia, and a drop from a common 1-ounce vial is about two-thirds of a minim, or from a homœopathic vial with thin lips about half a minim, or one one-hundred and twentieth of a grain.

Oleate of Morphia.—This is made precisely as the preceding oleates, except that as the morphia of the markets is in crystals, their solution in oleic acid is slow, unless the crystals be rubbed into powder before adding them to the acid in the bottle in which the solution is to be made. A little agitation is then all that is needed. This is the only one of the oleates of the alkaloids that within a short time changes much in keeping. When the elements of it are first put together the solution begins to grow darker, and this change progresses until within a year it becomes very dark indeed. This change in keeping does not destroy its efficacy, but whether it diminishes it or not has not been shown. This oleate was introduced by Mr. John Marshall, who made it of the strength of 5 per cent., or 5 grains of morphia to 95 grains of oleic acid, and this strength has now been generally adopted. This oleate is quite largely used, and yet very little accurate information or observation in regard to it has been published in the ten years that have passed since its introduction. Several good observers within the writer's personal knowledge have occasionally used it for some years past in special cases, and with alleged success, especially as an anodyne and sedative in infants and children. Five to ten minims applied to the abdomen under oiled silk seems to be about the usual dose for children of one to four years.

As a simple sedative hypnotic it is often applied to the inside of the thighs and arms of infants, one or two drops spread over a large area in each locality so as to get not more than four or five drops in all for infants of six months. It should be dropped on to the surface with care, and be spread by the ball of one finger, and as sometimes the absorption is slow the dose should not be repeated within an hour if the first one be insufficient. It is said to have less tendency to constipate than any other opiate. Each ordinary drop contains nearly $\frac{1}{20}$ of a grain of morphia. It is probable that this oleate should be doubled in strength.

Oleate of Quinia.—This, although it has not attracted general attention, is probably one of the most important of the oleates. From the larger quantity of quinia needed in medicine this oleate is made as strong as possible. While a normal oleate of this alkaloid would by calculation contain about 53 per cent. of the alkaloid

* This "aconitine" is a nitrate of aconitia, and requires to be precipitated and dried. As sold under the name of "Duquesnel's aconitine" it is entirely insoluble in oleic acid.

it has been found impracticable to dissolve that quantity in the acid. In a series of experiments made some years ago when this oleate was introduced, it was concluded that 25 per cent. was the best proportion. But as the quinia of the market holds some hygrometric moisture, it is better to take 26 grains of the alkaloid and 74 grains of oleic acid as the formula. The alkaloid is simply rubbed to powder, and added to the acid in a bottle. Like the other alkaloids this dissolves so readily that, being in much larger proportion, it is liable to clog together and be slow in dissolving. But this clogging together is easily broken up by means of a glass rod. Or the solution may be effected in a capsule and the clogging be prevented by a pestle. In this way it is easily made in a very few minutes. A fluid ounce of this oleate weighs about 410 grains, and, therefore, contains about 102 grains of quinia, which is equivalent to about 140 grains of the ordinary sulphate of quinia. Therefore, a fluid drachm contains the equivalent of about 17 grains of the sulphate, and a minim is equivalent to a little more than a $\frac{1}{4}$ of a grain. A hypodermic injection of a fluid drachm will, therefore, carry the equivalent of 17 to 18 grains of sulphate of quinia.

It happens, perhaps oftener with the administration of quinia than most other medicines, that the physician wants to save the stomach. And many conditions need quinia when the stomach will not accept it, or will not utilize it if given by the mouth. These circumstances have long indicated the hypodermic use of quinia, but up to this time no solution has been proposed that is well adapted to hypodermic use, first, because of the large dose required, and again, because of sparing solubility of available quinia salts. Hence this oleate has been sometimes used hypodermically, but with what success is unknown to the writer. The epidermic use, however, is of late not uncommon, and since it was first proposed occasional trustworthy testimony from private sources has led the writer to consider it an important adjunct to the more common methods of using quinia. The quantity of oleate needed here is considerable, often amounting to 1 or 2 fluid drachms. Hence it should always be applied under oiled silk or gutta percha tissue. When put directly on the skin a minim will require about 4 square inches of surface or it will run, and a fluid drachm would require about 2 square feet of surface, an area hardly accessible under ordinary circumstances. But two pieces of very thin fine old muslin or linen, 6 by 9 inches, will easily hold $\frac{1}{2}$ a fluid drachm each, and may be applied to the insides of the thighs, covered by oiled silk. This leaves the abdomen available for another similar application if desirable, and the oleate can be renewed on these places as rapidly as it is absorbed. Another good way of applying it, especially in walking cases, to get a moderate continuous effect, is to anoint the spinal tract for an inch or more on each side of the spinous processes morning and evening with a $\frac{1}{2}$ fluid drachm, and cover it with a strip of oiled silk under the clothing. The writer has heard of several instances in which ringing in the ears was speedily produced by such applications of the oleate.

Oleate of Strychnia.—This is made exactly in the same way as the oleate of quinia, the crystals of the alkaloid being simply rubbed to powder and added to the acid in a bottle, the solution being promptly and easily effected.

In strength this oleate has been generally made 2 per cent., that is, 2 grains of strychnia to 98 grains of oleic acid; but of course it may be as easily made of any desired strength, short of the saturation of the acid.

When of 2 per cent., each minim will represent about $\frac{1}{60}$th of a grain of strychnia, and a drop will represent from one-half to two-thirds of this quantity, according to the thickness of the vial lip from which the drop falls.

This should be a very effective way of using strychnia, but it has not yet come into use to any extent. For application to the temples in the treatment of some eye diseases, it would seem to be better adapted than the present mode by hypodermic injections, because the effect would be more prolonged and more permanent. That is, the strychnia would remain in the neighbourhood of the nerves to be affected by it for a longer time, and the application could be more easily made.

The general effects of strychnia would doubtless be as easily obtained by this oleate as in the instances of the other alkaloids.

Oleate of Veratria.—Made in exactly the same way as oleate of strychnia and of the same strength, namely: 2 per cent., the minim representing the $\frac{1}{60}$th of a grain.

This oleate has been more used than many of the others, and generally as a local application in the various forms of neuralgia. It is much weaker than aconitia, and as it is applied to similar uses much more of it is required. It should, therefore, be made much stronger or as strong as the skin would bear it. Probably 10 per cent. would be much better than 2, and would make the preparation more serviceable, as then a sufficient dose could be applied without involving too great a surface. If of the strength of 10 per cent. the effective dose would be much more manageable, and more nearly parallel with the oleates of aconitia and atropia; and it would then have more chance of sustaining its reputation for controlling some cases of neuralgia which resist the action of aconitia.

These oleates of the alkaloids are all fluids and should be, as their application demands an accuracy of dose easily attained by minims or drops, but not so easily attained if they were semi-solids; but the oleates with metallic bases do not need such accuracy of dose, and are best dispensed and applied as soft ointments.

Oleate of Copper.—This should be made to contain at least 5 per cent. of oxide of copper, but it may be made of normal strength, that is, containing 12·7 per cent. of oxide. The 5 per cent. oleate is liquid when first made, but soon acquires a kind of semi-gelatinous consistence. It is very easily made by simply adding the oxide and acid together in a bottle. In the cold the solution of the oxide is slow, requiring two or three weeks and frequent agitation. When warmed, however, a few hours only is necessary. The resulting oleate is of a beautiful dark-green colour, and appears to keep well.

It has been used solely in dermic medication, that is, in treating skin diseases, so far as is known to the writer, and its value is not known.

Oleate of Lead.—This oleate, in order to be of a proper consistence, should contain 20 per cent. of oxide of lead. The oxide dissolves slowly in the cold, but more easily and rapidly when warmed to about 66° C. = 150° F.

It forms a yellowish unguent, and is used only in skin diseases, so far as is known to the writer, and very little testimony in regard to its uses or value has been met with.

Oleate of Mercury.—This is the oldest and, perhaps, the most important of the oleates, perhaps because it has been most used, and, therefore, its effects and uses are best known. As introduced by Mr. Marshall it contained 6 per cent. of oxide of mercury, and this strength is still the one most requently used; but a strength of 10 per cent. has also been largely used, and more recently one of 20 per cent., which latter should and probably will soon supersede the others. Either strength is easily made by simply putting together the yellow oxide of mercury and the acid in the cold, and waiting until the solution takes place, stirring occasionally. All heating should be avoided in making this oleate, even the heat of the combining elements being probably hurtful. Time and patience easily effect the combination, but even with the greatest care the weaker or more liquid preparations do not keep well. In a few weeks a film of metallic mercury shows itself at the bottom of each vial, and in a few months this film will represent about 1 per cent. of the mercury used. From this circumstance it has been the practice of the writer to always put up both the 6 per cent. and the 10 per cent. with 1 per cent. excess of the oxide to compensate for this decomposition, so that the practitioner will really get the strength called for by the label if the preparation be not very old, and be well protected against heat and light. These strengths can, however, never be very accurate, because the decomposition though slow begins early, and probably continues indefinitely or until all the mercury is reduced. When made of the strength of 20 per cent. however, this decomposition does not occur, or at least does not occur to any practically hurtful extent. Of a sample that had been made three years 19 per cent. was soluble in ether, thus showing that it keeps well, while the others do not. It is a very soft solid, like very soft butter, but yet solid enough to prevent all circulation among its particles, and it is probably to this condition that its superior keeping properties are due. Because it keeps so well and the other strengths do not, it is the only oleate of mercury that should be used. Its greater strength is no valid objection to its application, as it is only necessary to apply so much less of it. Or if not easily enough controlled in that way, it can be diluted at the time of using to any definite strength with olive oil, or preferably with oleic acid.

No reduced mercury has ever been noticed in any well made oleate of this strength.

The uses and applications of oleate of mercury are now too well and too generally known to need repetition here. Suffice it to say that by its epidermic use the most prompt, the best and the most easily controlled mercurial impression can be obtained, whereby a remedy often dangerous has been rendered, under proper skill and care, comparatively harmless or altogether beneficent in a very large number of cases which cannot be very successfully treated without mercurials.

Oleate of Mercury and Morphia.—This double oleate was also introduced by Mr. Marshall, and, therefore, is among those which are oldest and best known. The formula generally adopted and most used has been 10 per cent. of the oxide and 2 per cent. of morphia. The morphia was at first used to correct or control the irritation of the skin from the application, but it was found to give a decided anodyne effect in painful joints, etc., while the tendency to irritate has been largely corrected by the use of a better oleic acid. The preparation, however, does not keep well. A specimen made in 1878 is now almost black in colour, with a very considerable film of reduced mercury at the bottom of the vial. It is highly probable, however, that a 20 per cent. oleate of mercury would dissolve 5 per cent. of morphia and make a better preparation which would keep much better. Small quantities of such a preparation could be much better applied than the larger quantities of the weaker one.

Oleate of Zinc.—A 20 per cent. oleate of zinc is not unfrequently spoken of and asked for of late, and a preparation is sold as such. But as a normal oleate of zinc only contains the equivalent of about 13 per cent. of the oxide, such a preparation can only be a mixture of oleate and oxide. It is generally in the condition of a dry, soapy, granular powder, and not susceptible of easy application for absorption even in skin diseases, but only applicable as a surface powder. For appropriate therapeutic use as a zinc preparation it should not be stronger than 5 per cent. When of this strength it is a soft solid of proper consistence for easy application in diseases of the skin. Of this strength it is well adapted to become a very useful preparation, but as yet its uses have not been very definitely stated.

Several other oleates have been mentioned as available for medicinal uses, and possibly some of them may be found useful, but as yet there is no accumulation of testimony in regard to them. Those occasionally heard of are oleates of aluminium, arsenic, bismuth, iron, nickel and silver, but the latter is an impracticable, if not an impossible, oleate.

COMMERCIAL OIL OF THYME.*

BY J. S. LEMBERGER.

Oil of thyme of commerce is said to be very often deprived of its thymol. Is this statement true?

In experimenting with oil of thyme, in answer to this query, we have taken for granted that the declaration made by A. W. Gerrard, who ably investigated thymol, its sources, manufacture and application as an antiseptic agent, was justified by his researches. He is credited with saying, oil of thyme is said to yield as much as 50 per cent. thymol on the Continent. We, therefore, hoped to obtain from pure oil of thyme, if not 50 per cent., at least a considerable percentage of thymol. The writer purchased nine separate lots of oil of thyme from as many different houses in New York and Philadelphia. Only one of these, however, is known to have been distilled in the United States, and this one only we feel warranted in vouching for as a pure distillate of *Thymus vulgaris.* The experiments we conducted in the following order:—

No. 1 was bought as pure red oil of thyme, and yielded 1·67 per cent. of dark crystals.

No. 2 was bought as pure white oil, and yielded 6·67 per cent. lighter coloured crystals.

No. 3 was bought as pure red oil, and yielded 16·67 per cent. of dark crystals.

No. 4 was bought as pure white oil, and yielded ·80 per cent. of light-coloured crystals.

No. 5 was bought as pure white oil, and yielded ·42 per cent. of light-coloured crystals.

No. 6 was reported as very old white oil, and yielded also only ·42 per cent. of light-coloured crystals.

No. 7 was bought as pure French red oil, and yielded 7·92 per cent. dark crystals.

No. 8 was the undoubted American white oil, four months old, distilled from dried French herb, and yielded ·84 per cent.

No. 9 was a dark red oil, rich in colour and very odorous, obtained direct from the importer, and this yielded 38·75 per cent. dark-coloured crystals.

The process used by the writer for separating the thymol consisted in treating the oil with a twenty per cent. solution of pure caustic soda, and, after separating the solution of thymolate of sodium formed, treating this with ether, which, on evaporation, yielded the thymol in the form of irregular crystals. That obtained from the dark oils was dark in colour; that from the white oil much lighter.

Another process was employed upon portions of the same oils to prove the former experiments, viz.: that of treating the oil with caustic soda, then separating the alkaline solution and adding to this hydrochloric acid so long as the supposed thymol separated or rose to the surface as a float. The float was separated by filtration, and weighed after drying; the estimate made appeared to be about the same.

The last process is not so satisfactory, although undoubted crystals were detected as in the first, and numerous minute crystals were found adhering to the vessel, which appeared to be the same under the microscope as those obtained by the former process. The odour of this float in some cases, and more so that obtained from the oils yielding the least percentage of the crystals, was very suggestive of the action of acids upon turpentine, giving rise to a peculiar empyreumatic odour, and corresponds closely with a product described by Gerrard as obtained by him, as being "12 per cent. of oily matter, differing to such an extent in colour, odour, and look from thymol that he could not pronounce it as such."

We observe that the dark oils seem to be the richest in thymol.

---

* Read at the meeting of the American Pharmaceutical Association held at Niagara Falls, 1882.

The experiments as made seem to justify the declaration suggested by the query that very little of the oil of thyme of commerce is pure, but in all probability is first deprived of its most valuable constituent by manipulations before it is thrown upon the market.

In the discussion which followed the reading of this paper, Mr. Sloane, of Indianapolis, mentioned that thymol is excellent to disguise the odour of iodoform.

Professor Maisch stated that a considerable proportion of the thymol remains in the terbene. It should be produced by fractional distillation. It can be obtained from the American product in considerable quantities.

Mr. J. A. Lloyd said he had failed to get enough thymol from the commercial oil of thyme to pay for the trouble of preparation.

Professor Remington stated that possibly the manufacturers found the sale of thymol so profitable that they make that and sell the residue as oil of thyme.

Professor Bedford stated that the price of oil of thyme is so low that there is now no pure oil of thyme on sale except a brand known as white oil, which is sold at four times the price of the ordinary, the one selling for 55 cents and the other at 2 dollars.

Professor Maisch stated that the herb should yield a larger proportion of thymol than can be obtained from oil of thyme. It may be that the plants grown in different localities yield a different amount of thymol. The amount of thymol does not increase with the age of the oil of thyme.

CURCUMIN.*

BY C. L. JACKSON AND A. E. MENKE.

This substance, the yellow colouring matter of turmeric, has been examined by several chemists, whose experiments have led to the conclusion that its formula is either $C_{10}H_{10}O_3$ or $C_{16}H_{16}O_4$; that it melts at 172°; forms red-brown salts with alkalies; is converted by boric or sulphuric acid into rosocyanine; by reduction with zinc-dust into an oily body; by oxidation into oxalic or terephthalic acid; and by fusion with potash, into protocatechuic acid. The experiments of Jackson and Menke have, however, led to results differing in many respects from those above detailed, which were probably obtained with impure preparations.

The curcumin used in the authors' experiments was prepared by treating ground turmeric root (Bengal or Madras) with light petroleum to remove turmeric oil, and then with ether, which dissolves the curcumin together with a large quantity of resin; and it was finally purified by crystallization from alcohol. The quantity of curcumin thus obtained was only 0·3 per cent. of the root; the total quantity contained in the root is, however, much larger, as a considerable amount remains mixed with the resinous impurities, and some also in the oil.

Curcumin thus prepared crystallizes from alcohol in stout needles, appearing on microscopic examination to be made up of well-formed prisms with square ends, or in spindle-shaped crystals often arranged in radiate groups. It has an orange to yellow colour, according to the size of the crystals, with a beautiful blue reflex: its solution in ether exhibits a strong green fluorescence. It is inodorous when pure; melts at 178°, apparently with decomposition. It is nearly insoluble in water, somewhat soluble in cold, more readily in hot ethyl and methyl alcohols, more soluble in glacial acetic acid, less in ether, very slightly in benzene and carbon bisulphide, and all but insoluble in light petroleum. Strong sulphuric acid dissolves it with a fine reddish-purple colour, gradually changing to black from charring; the same effect is produced, though more slowly, by strong hydrochloric acid. Curcumin dissolves readily in alkalies and alkaline carbonates, to a slight extent also when boiled with water and calcium carbonate. Its ammoniacal solution gives off ammonia when boiled, and deposits unaltered curcumin. Baryta-water converts it into a blackish-red powder, but lime-water gives a red solution like that obtained with calcium carbonate. Curcumin is not affected by acid sodium sulphite.

Pure curcumin gives, as the mean of several analyses, 68·30 per cent. carbon and 5·63 hydrogen, leading to the formula $C_{14}H_{14}O_4$, which requires 68·29 C, 5·69 H, and 26·02 O; and this formula has been confirmed by the analysis of several derivatives.

The *dipotassium salt*, $C_{14}H_{12}K_2O_4$, prepared by adding a large excess of strong alcoholic potash to a hot alcoholic solution of curcumin, separates in flame-coloured crystals, and may be precipitated from weaker solutions by addition of ether. When first formed, it consists of globular radiate groups of flame-coloured needles, but assumes a deep claret colour on drying. It is freely soluble in water, somewhat less so in alcohol, and nearly insoluble in ether. The alcoholic solution assumes a magenta colour on exposure to the air, probably from oxidation. The *monopotassium salt*, $C_{14}H_{13}KO_4$, is formed on adding an excess of potassium carbonate to a hot solution of curcumin in absolute alcohol, and separates on addition of ether in crimson-black flocks, having the lustre of rosaniline and a somewhat blacker green colour. It is very soluble in water and in alcohol. It may also be made by adding an excess of curcumin to the dipotassium salt, or by adding potash, not in excess, to curcumin suspended in alcohol. The *calcium salt*, obtained by precipitation from the monopotassium salt, is flame-coloured, and slightly soluble in water. The *zinc salt* appears to be soluble, the *barium salt* insoluble; the *silver salt* appears to be very unstable.

The fact that only 1 atom of the hydrogen in curcumin can be replaced by the potassium in potassic carbonate, seems to indicate the existence of one, and only one, carboxyl-group in its molecule, whilst the replacement of a second H-atom by the action of an excess of potassium hydroxide points to the existence of a hydroxyl-group, probably a phenolic hydroxyl, and leads to the inference that curcumin is a diatomic monobasic acid.

Parabromobenzyl-curcumin, $C_{14}H_{13}(C_7H_6Br)O_3$, is formed by adding an excess of *p*-bromobenzyl bromide to an alcoholic solution of monopotassium-curcumin and separates in pale yellow crystals, which, after purification, melt at 76° to 78°. It is more soluble in glacial acetic acid than in alcohol, but crystallizes better from the latter; readily soluble in ether and in benzene, slightly in carbon sulphide, nearly insoluble in light petroleum; it is not attacked by potassium carbonate, but dissolves in caustic potash, though without the red colour characteristic of curcumin.

Oxidation of Curcumin.—By oxidation with chromic acid mixture, curcumin is wholly converted into acetic acid and carbonic anhydride, not a trace of terephthalic acid having been found in the product; by incomplete oxidation with potassium permanganate in alkaline solution, it yields vanillin,—

$$C_8H_8O_3 = C_6H_3\overset{1}{(CHO)}\,\overset{3}{(OMe)}\,\overset{4}{(OH)}.$$

Hence, and from the fact previously established that curcumin contains a carboxyl-group, the authors infer that its constitutional formula is—

$$C_6H_3\overset{1}{(CH.C_5H_5.COOH)}\,\overset{3}{(OMe)}\,\overset{4}{(OH)}.$$

The structure of the group C_5H_5 will be made the subject of further investigation.

ANNUAL REPORT ON THE ROYAL GARDENS AT KEW.

THE Report on the Progress and Condition of the Royal Gardens at Kew, during the year 1881, which has just been issued, shows that whilst they are becoming increasingly important to all interested in botanical science, they fully maintain their popularity as a place of public resort. In fact, the number of visitors reached a higher point in the year 1881 than in any previous twelve months, amounting to 836,676, or 111,254 in excess of the year 1878, which had up to that time remained the maximum. The largest number of visitors admitted in any one day in the year was reached on Whit Monday, when it was over 50,000. But the work carried on in connection with these gardens, under the superintendence of Sir JOSEPH HOOKER and his able assistant, Mr. W. T. THISELTON DYER, is not confined to catering for holiday folks, but it also includes much that is of special importance to our readers, and as usual many of the passages in the report furnish matter suitable for quotation in this Journal.

Kew has now become the centre of botanical correspondence, and the authorities of the gardens actively participate in nearly all the experiments in acclimatization or the utilization of vegetable products that are made throughout the world. Hence these annual reports are always extremely rich in information as to the success or non-success of such attempts, many of which are made with a view to securing the better supply of drugs. In the present report, for instance, there is much interesting information respecting cinchona cultivation. We learn that a great deal of attention has been attracted, in India and Ceylon, to a cinchona which is supposed to be a hybrid between *C. officinalis* and *C. succirubra*, and to which reference has already been made in this Journal. Next to the *Ledgeriana* variety it is considered to be one of the most promising kinds. In Darjeeling it grows splendidly at an elevation where *C. succirubra* does not do well, and where *C. officinalis* will not grow at all, and it yields a bark which chemically resembles that of *C. officinalis.* In habit of growth this plant resembles *C. succirubra*, though at a distance it has more the appearance of *C. officinalis*; it never comes true to seed, the seedlings resembling as a rule nearly pure *C. officinalis.* The valuable cinchona associated with the name of Mr. LEDGER, which has recently been described as a distinct species by Dr. TRIMEN under the name *Cinchona Ledgeriana*, Moens, and a figure of which accompanies the report, is now being cultivated in India, Ceylon and Jamaica. As the bark yielded by this species is so rich in alkaloid it is satisfactory to read that, after a visit to the Dutch plantations in Java, Dr. KING is satisfied that the plants cultivated under this name at Darjeeling, seeds from which have also been sent to Jamaica, are true *Ledgerianas.* Satisfactory information has been received also respecting the Santa Fé plants, yielding "Columbian bark," which were sent to the Nilgiris in 1880. The present financial success of cinchona cultivation is illustrated by the fact that England now takes all the Jamaica bark that can be shipped and at remunerative prices, whilst it is thought probable another market for the bark will be found at no distant date in the United States. A paragraph is devoted to the Sikhim febrifuge, and, according to a quotation from a report by Dr. KING, the quantity used as a substitute for quinine in Government hospitals and dispensaries during the year ending May, 1881, was so great as to represent a saving of more than four and a half lacs of rupees, or a sum nearly equal to half the total expenditure on the Darjeeling plantations, including compound interest at 4 per cent., since their commencement.

Jalap is another drug the cultivation of which is said to have given rise to some inquiries, and to answer these an interesting account of the method adopted for the propagation of the tubers in the Ootacamund gardens is quoted from an official report. According to this, one acre of land should at the end of three years produce five thousand pounds of green tubers, which will yield when dried one thousand pounds of jalap powder. The cost of cultivation, collection and drying of the root during the same period is said not to exceed three hundred rupees, and it is therefore estimated that dried jalap tuber can be produced at Ootacamund at a cost of 4 annas and 10 pies (about 6*d.*) per pound.

A drug, known under the name of "waras," is exported in considerable quantity from Aden, and is said to be used as a substitute for kamala. Its origin being unknown, Captain HUNTER, Assistant-Resident at Aden, obtained specimens of the plant said to yield it in Arabia, and sent one to Kew, with a note stating that it had been gathered at an elevation of six thousand feet, on Jebel Dthubarah, sixty miles due north of Aden. The plant was immediately identified with *Flemingia congesta*, Roxb., a leguminous species, and of course, therefore, having no affinity with *Mallotus philippinensis.* Kamala yields to alcohol a splendid red colour, whilst the name "waras" signifies "saffron;" and it is mentioned in support of the notion that a substance similar to kamala is yielded in Arabia by perhaps one or more species of *Flemingia* that dried specimens belonging to this genus stain paper in the herbarium a bright yellow colour when washed over with the alcoholic solution of corrosive sublimate used to protect them from the attacks of insects. *Flemingia rhodocarpa*, from the Mozambique district, has its pods covered with a bright red resinous pubescence.

The cultivation of various medicinal plants in the Government Botanical Gardens at Saharunpore, and the preparation from them of extracts for the use of the Indian medical department, has been the subject of some correspondence. Roots and seeds of English taraxacum have been sent to the gardens, and samples of extract have been prepared from plants raised.

The foregoing represents the principal subjects in this Report which are directly allied with medicine, but it does not by any means include all the matter of economic interest. The information respecting the plants yielding caoutchouc and gutta percha, for instance, is of great importance, considering the fact that we are believed to be within measurable distance of the exhaustion of the natural supplies of the latter of these substances at least. There is also good news for coffee drinkers in connection with results obtained with the "wild coffee" from *Cassia occidentalis*. But to these subjects we hope to have another opportunity of referring.

SIR JAMES PAGET ON UNEXPECTED THERAPEUTICAL EFFECTS.

When it was known that Sir James Paget had undertaken the task of initiating a new annual "lecture," instituted in memory of the late Mr. William Wood Bradshawe, and that he had chosen for the subject of his discourse "Some Rare and New Diseases," it needed no prophet to foretell the success of the experiment. The topics discussed were, however, so purely medical in their character that notwithstanding many portions of the argument were capable of apprehension and enjoyment by any well-educated person, we should not under ordinary circumstances give the address more than a passing notice in these columns. But one passage in it so well illustrates the tendency of a master to question where a novice would dogmatize that we feel warranted in referring to it somewhat more fully, because it has some bearing upon what we have always considered to be an injustice done to pharmacists. In the sensational ebullitions which are periodically manifested in our medical contemporaries in respect to the alleged adulteration of the medicines supplied by pharmacists one allegation which is ever present is that a proof of sophistication is to be found in the failure of medicines sometimes to produce the therapeutic effects expected. Of course, if it were the business of this Journal to bandy vulgar charges with such persons as the writers of these statements, the retort would be obvious; but nothing is gained by such personalities, and it is not in this spirit that we call attention to the words of the eminent lecturer on the subject.

We may premise that Sir James Paget throughout his discourse laid emphasis on the probability that different diseases are continually undergoing more or less modification due to heredity and other causes; some diseases in the form in which they were formerly known becoming exceptional, whilst others which a century ago were considered rare or had not yet been observed are becoming more and more frequent. This he attributes partly to the previous oversight of what existed, but he also considers there is sufficient evidence that new diseases are in progress of evolution and that some that are now looked upon as rare diseases are simply the earliest instances of new ones. He points out that the study of these variations of diseases is not one of mere pathological curiosities, but might be made of great practical utility, and he urges that one direction in which it should be pursued vigorously is in relation to the frequently alleged uncertainty of medicines and the disappointments in the use of supposed remedies that have caused substances long in good repute for the treatment of particular diseases to be spoken of with disrespect. Whilst in many cases it cannot be questioned that the belief in the utility of a medicine has been maintained by completely erroneous observations, yet in others uniform effects are not produced although the diseases treated seem to be the same. Referring to these disappointing results, which he illustrates as occurring sometimes during the use of bromide of potassium in epilepsy, of guaiacum in chronic rheumatic arthritis and of arsenic in lymphadenoma, Sir James says:—"I suppose there is not a "medicine in the Pharmacopœia which does not "sometimes disappoint him who gives it hopefully; "not one which is not therefore spoken of with "contempt or blame, as if it were a responsible "agent convicted of default. But here is an unfair "imputation. It is not these medicines which are "in fault, but ourselves. That which some call the "fallacy of therapeutics is generally the fallacy of "diagnosis. To state the facts roughly, we suppose "cases to be alike which are really different, and "very naturally the medicine which does good in "some of them is useless in others."

We do not wish to place any strained interpretation upon these words; in fact their meaning is too clear to allow of it being obscured or quibbled over. We do not even wish that they should receive an application for which they were possibly not intended. But we do suggest that in future they should be allowed to have due weight with any medical practitioner who is disappointed in the results following the administration of a particular medicine, before he jumps to the conclusion that the pharmacist who dispensed it was either dishonest or incapable.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association will be held on Thursday, January 4, 1883, at 8 p.m., when the following papers will be read:—"Genius, Talent and Industry in Relation to Pharmaceutical Research," by Mr. R. W. Giles. "Some Hints on Practical Photography," by Mr. R. J. MacDermott.

The Lord Chancellor has been pleased to add the name of Mr. Charles James Blelock, Chemist and Druggist, to the Commission of the Peace for the city and borough of Chester.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The fifth general meeting of the above Association was held at the Royal Institution on Thursday, December 7, 1882.

In the absence of the President and Vice-President, the chair was occupied by Mr. T. Fell Abraham.

The minutes of the last meeting were read and confirmed, and the following donations announced:—The *Pharmaceutical Journal* and the *Canadian Pharmaceutical Journal.*

Mr. Edward Davies, F.L.S., F.I.C., delivered a lecture on "The Relation between the Physical Forces." The lecturer began with the consideration of chemical force, which was explained to be a form of cohesion, as illustrated by the experiments of Dr. Spring, who by means of enormous pressures brought about the chemical union of sulphur and copper, etc. The connection of heat and electricity with chemical action, as shown in a galvanic cell, was not a conversion of chemical force into heat and electricity, for the force which brought the elements together continues ever at work, keeping them together. They are produced during the impact of the atoms on one another, just as a bullet may by striking an iron target develope heat enough to melt it, but we cannot say that chemical action becomes heat or becomes electricity. The relation of electricity to magnetism was shown in the formation of an electromagnet, and by means of a Gramme machine the production of electric light by motion, and the reciprocal production of motion by electricity was strikingly illustrated. Thermo electricity, or electricity produced by heat, was then shown, as well as heat produced by electricity. The lecturer thought that it was too much to say that one kind of force could be transformed into another. Two forces might stand in the relation of cause and effect, but to go farther than this would naturally lead one to look for the transformation of matter of which we have no evidence. Some explanation of the telegraph, telephone and other applications of the physical forces brought the lecture to a close.

A vote of thanks, proposed by Mr. Birchall, and seconded by Mr. M. Conroy, F.C.S., was passed with acclamation, and Mr. Davies having briefly replied, the proceedings terminated.

YORK CHEMISTS' ASSOCIATION.

The first of a series of lectures was delivered before the members of this Association, at the rooms, 9, High Ousegate, on Wednesday evening, December 20, by Mr. Spencer, L.R.C.P., on "The Relationship between Medicine and Pharmacy," when there was a numerous gathering of the younger members of the trade.

The lecturer reviewed the ancient as well as the modern and scientific methods of the administration of drugs and chemicals, and gave practical information for the guidance of the rising students in pharmacy. After a brief reference to the antiquity of the use of drugs in the treatment of disease, Mr. Spencer observed that our present therapeutics were partially dependent on the results of clinical experience, and partly on a knowledge of the physiological action of drugs. Empiricism had been of great use to humanity, but was full of fallacies. The physiological action of drugs was studied partly by intentional experiments on both man and the lower animals, and partly by the results of poisoning. The advance of therapeutics meant the gradual inclusion of all remedies of which the physiological action was known. Having given several illustrations of this part of his argument, the lecturer dwelt upon the necessity of an advancing pharmacy; in the separation of active principles from drugs, and their preparation in shapes suitable for inhalation and injection under the skin as well as by the mouth. In the concluding part of his address he advocated the practice of pharmacy proper apart from a miscellaneous trade, and the abolition of dispensing by medical men and prescribing by druggists; the extension of provident and co-operative principles for the wants of the working class, showing that modern ideas of development and division of labour must be applied to medicine and pharmacy.

A vote of thanks was passed to the lecturer, and also to Mr. F. Slinger, who occupied the chair.

EDINBURGH CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The fifth meeting of the session was held on Wednesday, December 20, in the rooms of the North British Branch, Mr. P. Boa, President, in the chair.

The minutes of the last meeting having been read and confirmed, the Chairman called upon Mr. J. Suttar to read a paper on the "Haloid Elements."

Mr. Suttar having referred to the history of the discovery of the elements chlorine, bromine, iodine and fluorine, and to the strong family likeness that pervaded the group, proceeded to describe their various compounds, and point out their characteristic and distinguishing properties. The paper was illustrated by a number of interesting and successful practical demonstrations by Mr. Macfarlane.

The Chairman moved, and Mr. MacEwan seconded, a vote of thanks to Mr. Suttar, which was heartily awarded, as was also a similar vote to Mr. Macfarlane.

Mr. J. D. Robertson then gave notice of a motion in connection with the sale of poisonous patent medicines, and the Chairman having intimated that an open meeting would be held on January 10, 1883, the meeting was closed.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on December 21, Dr. Gilbert, F.R.S., President, in the chair.

The following certificates were read for the first time: H. C. Bond, J. T. Donald, A. H. Jackson, H. Jones, J. E. Johnson.

The Secretary then read a paper—

On the Condensation Products of Œnanthol. Part II. By W. H. PERKIN, jun.—When œnanthol is acted upon by nascent hydrogen it is well known that heptylic alcohol is produced, but, in addition, other products of higher boiling points are formed in some quantity, and the author has accordingly investigated them. The œnanthol was first dissolved in acetic acid and a sodium amalgam containing 2 per cent. of sodium added; when the action was finished, water was added and the oil which separated dried and distilled at 300 mm. pressure. The portion which distilled under 200° consisted chiefly of heptyl alcohol and œnanthol. The higher fraction contained the aldehyde $C_{14}H_{26}O$ and the alcohol $C_{14}H_{28}O$. The œnanthol was next dissolved in a large excess of ether, floated on water and treated with sodium. The aqueous solution contained some heptylic acid. The ethereal solution was distilled at 150°–200° when œnanthol and heptylic acid came over. The temperature then rose and between 250° and 310° most of the remainder came over. This distillate was refractioned and an aldehyde obtained in crystalline plates melting at 29·5, distilling between 266°–268°, and having the composition $C_{14}H_{28}O$; a second substance was also separated as an oil solidifying at $-10°$, boiling at about 320°, reducing ammoniacal silver nitrate and having the formula $C_{21}H_{40}O$. The author next studied the oxidation of the aldehyde $C_{14}H_{28}O$. The chief products (with chromic acid or silver oxide) were heptylic and hexylic acids, but with silver oxide an acid boiling 300°–310° was obtained in small quantity with the composition $C_{14}H_{28}O_2$. By acting on the aldehyde $C_{14}H_{28}O$, dissolved in acetic acid, first with zinc slightly coated with copper and subsequently with sodium amalgam, an oil was obtained boiling at 270°–275°, which analysis proved to be the alcohol $C_{14}H_{30}O$ already obtained in Part I. The author then discusses the constitution of these bodies; the solid aldehyde and the acid obtained from it are isomeric with myristic aldehyde and myristic acid, but myristic aldehyde fuses at 53·8°, the new substance at 29·5°. From the oxidation products the author considers that the acid must be heptyl-pentyl-acetic acid—

$$\begin{array}{l} CH_3(CH_2)_5CH_2 \\ \quad\quad\quad\quad | \\ CH_3(CH_2)_4CH-COOH. \end{array}$$

The next part of the paper refers to the polymerization of œnanthol. The solid polymer $(C_7H_{14}O)_n$ which had been previously obtained was distilled and from various experiments the author concludes that $n=4$ and the body has the composition $C_{28}H_{56}O_4$.

Dr. Armstrong congratulated the author on having completed an arduous piece of work, which was besides very interesting as it gave a synthetical method for preparing the normal paraffins.

Professor W. Foster then read a paper—

On the Behaviour of the Nitrogen of Coal during Destructive Distillation, with some Observations on the Estimation of Nitrogen in Coal and Coke.—It is usually stated in text-books that coal contains about 2 per cent. of nitrogen, which when the coal is heated in close vessels, usually comes off as ammonia. The author, however, finds that only a small fraction of the total nitrogen comes off as ammonia. A Durham coal was employed which contained 1·73 per cent. of nitrogen and left 74·46 per cent. of coke. A weighed quantity of the coal was placed in a combustion tube, sealed at one end, and the issuing gas was washed free from ammonia by hydrochloric acid. The gas thus freed from ammonia was passed through a second heated combustion tube containing slaked lime; the additional ammonia thus obtained came from the decomposition of cyanogen in the gas. Taking the total nitrogen in the coal as 100, only 14·5 per cent. is evolved as ammonia, 1·56 per cent. as cyanogen, 35·26 per cent. is present in the coal-gas as nitrogen, whilst 48·68 per cent. remains behind in the coke.

Dr. Percy Frankland said that Dr. Hofmann, in his report in connection with the Exhibition of 1862, stated that only one-third of the nitrogen was evolved as ammonia, two-thirds remaining behind in the coke, and as far as he knew nothing had been done with the subject until Mr. Foster had taken it up. He had made some combustions of the coal used by that gentleman, using the apparatus employed in the combustion of a water residue. About ·024 gram of coal was taken; great difficulty was experienced in gettting all the nitrogen off.

Dr. Armstrong suggested that as regards the results obtained everything would depend on the temperature and it would be interesting to know how the quality of the coal affected the results.

Professor Foster said that in his experiments he had endeavoured to imitate as far as possible the usual process employed in the manufacture of coal gas. He hoped to be able to make some experiments shortly, in which he should employ a Siemens regenerating furnace, and so have the temperature under control.

The Secretary then read a paper—

On the Absorption of Weak Reagents by Cotton, Silk and Wool. By E. J. Mills and J. Takamine.—The object of the authors was the quantitative measurement of such absorption. 250 c.c. of the weak reagent (dilute sulphuric acid, dilute hydrochloric acid or dilute caustic soda) were placed in a bottle and kept at a constant temperature; in the bottle was placed also a known weight of the tissue (usually 3 grams). After a week or more the tissue was removed and a known volume of the emaining liquid titrated. The diminution of strength gives, so the authors state, the amount of absorption. In the second part of the paper the authors have determined in a similar way the ratio of absorption from mixtures of the acids. The paper contains numerous tables giving the results calculated to five places of decimals and the mean probable errors. The paper concludes as follows:—"There is thus a very intimate relation between silk and cotton, a relation which, whatever it may be in part, is shown by the changes to be, to a great extent, of a strictly chemical nature. We have, in conclusion, to express the hope that an investigation, while bearing on the one hand on questions of great technical importance, may not be without its value in the profounder future study of cotton, silk and wool; three bodies of definite chemical composition, but the intimate constitution of which still remains obscure."

Mr. Cross said the subject was extremely interesting as bearing on the constitution of fibre. He had made experiments of a similar kind, but had found it very difficult to separate the various factors involved. He did not think that it was correct to assume that the loss in strength of the solution was an accurate measure of the absorption by the fibre, because the fibre might absorb a solution of a different density to that left outside the fibre. He had investigated the subject and could not satisfy himself that the fibre did not take up a solution of different density to that left outside the fibre. In some experiments with aniline dyes he found that asbestos gave results similar to these obtained with some of the fibres used. The effect of the constituents of the ash seemed to have been neglected by the authors.

Dr. Schunck said it was important to determine the absorption by different samples of the same fibre.

Mr. W. A. Shenstone then read a paper entitled—

The Alkaloids of Nux Vomica. No. 2.—On Brucine.—The author has made many experiments as to the limited oxidation of brucine and strychnine, but at present without any definite results. Strecker, Liebig and others state that brucine when treated with dilute nitric acid yields, amóngst other products, either methyl or ethyl nitrate or nitrite. As the formula of brucine suggested that it might be a dimethoxyl derivative of strychnine, the author proceeded to investigate the question. He finds that 1 gram brucine when heated with fifteen times its weight of hydrochloric acid for fourteen hours to 135°, then for thirteen hours to 145°, then seven hours to 150°, and finally seven hours to 160°, evolved 90·2 c.c. of a gas, which analysis proved to be methyl chloride; 1 gram of dimethoxystrychnine should give 113 c.c. During the analysis, after exploding with oxygen, much calomel was formed. It is probable, therefore, that brucine is strychnine in which two atoms of hydrogen are replaced by two methoxyl groups, and that it has the formula $C_{21}H_{20}(CH_3O)_2N_2O_2$. The contents of the sealed tubes after the escape of the gas were black and usually tarry; an examination led to no satisfactory results. The author also studied the action of hydriodic acid upon brucine, but the substances formed are unstable. The author intends to examine strychnine, and thus endeavour to make out the relations of the nux vomica alkaloids, since the removal of the methyl groups from brucine seems to give rise to bodies of such unstable character.

Dr. W. H. Perkin then read a preliminary note on—

Some Diazo-derivatives of Nitrobenzyl Cyanide.—When alcoholic solution of nitrobenzyl cyanide is mixed with an alcoholic solution of caustic potash, an intense crimson red colour is produced, which gradually changes through a brownish purple to a greenish blue colour. It appeared, therefore, that some definite though unstable compound was produced, and it seemed probable that it might yield a derivative with the diazo bodies. The alcoholic solutions of the above-mentioned bodies were mixed, and immediately afterwards an aqueous solution of diazobenzine chloride was added until the red colour disappeared; the product was further diluted and filtered, the precipitate washed, purified by recrystallization, and finally orange-yellow needles obtained melting at 200°–202°, having the formula $C_{14}H_{10}N_4O_2$. The constitution of this body has not yet been established, but it appears to be analogous to the phenylanilo-acetic nitryl, obtained recently by Tiemann.

The Secretary then read a paper on—

Researches on the Induline Group. By O. N. WITT and E. J. P. THOMAS.—The term induline is applied in commerce to a series of violet and blue dyes, distinguished by great fastness to light and atmospheric influences. Scientifically the term may be applied to all coloured compounds formed by the action of amidoazo compounds on the hydrochlorides of aromatic amines with elimination of ammonia. In the present paper the authors give an account of their researches on the formation of amidoazo-benzene and its action on aromatic hydrochlorides. It has long been known that amidoazobenzene, when treated with anilin hydrochloride or nitrate, produces a dark blue coloration. The authors find that invariably several colouring matters, differing from each other both in composition and properties, are formed, and that the nature as well as the quantities of the products depend largely on the temperature at which the reaction takes place, and the manner in which it is conducted. In this paper the authors describe these various compounds and their preparation, and promise, in a future communication, to explain the reaction and the constitution of the products.

The Society then adjourned till January 13, 1883.

CHEMISTS' ASSISTANTS' ASSOCIATION.

At a meeting of the above Association, held on Wednesday evening, December 20, an interesting paper "On Plant Names," was read by Mr. C. E. Stuart, B.Sc. The paper, which will be printed in a future number of this Journal, gave rise to a lively discussion, in which Messrs. Wrenn (President), Parkinson, Alcock, Dodd and others took part.

A hearty vote of thanks to the author was passed.

SUBNITRATE OF BISMUTH.*

BY F. HARRIS ALCOCK.

Some time ago, while engaged in examining a commercial sample of subnitrate of bismuth, I was led to collect a number of specimens and to investigate their general condition. The outcome was sufficiently important to induce me to review the history, general literature, modes of preparation, physical and chemical characters, impurities, and pharmacy of this remedial agent. I venture to think that an account of these several labours will be interesting.

HISTORY.

Basil Valentine, who lived 1413 (*circa*), says in his last testament "that bismuth is a bastard Jovis (Jupiter ♃ = tin)." Paracelsus (1493–1541) classed it amongst the semi-metals. It was for a long time known under the name of marcasite or pyrite, and had been confounded with tin and lead. But it is to Agricola, who lived about 1529, that we owe the first description and definite name of this element; he calls it bisemutum or plumbum cinereum, and says that it is a true metal which is usually added to tin in order to make it work better. This, however, does not seem to have been plain enough for those who were to come after, for we are told that Andrew Libavius (a German physician who lived 1550–1616) thought that the metal was the same as antimony, and Nicholas Lemery (1672) fancied that it was identical with tin. Boyle, the physicist (1626–1691), states, in one of his many dissertations, that the metal bismuth dissolves in aqua fortis (meaning thereby nitric acid), and that the resulting liquid, mixed with common water, was almost completely precipitated by its means. A. Libavius was cognizant of the fact that when a solution of the metal was made in nitric acid, and poured into water a precipitation occurred, but did not offer any remarks about its composition. Lemery describes the preparation (a translation of his original method, with remarks being given below), adding that the product weighs more than the metal used. He added common salt, and many chemists afterwards believed that it was essential to the process. This error was corrected by J. H. Pott (1692–1777), a German chemist, pupil of Stahl and Fr. Hoffmann, who made numerous experiments and increased the knowledge which was then possessed of this substance very much; they will be found in his 'Prima Collectio Observationum et Animadversionum Chymicarum' (1739).* Of the chemists who have contributed much to our information on this subject may be mentioned Geoffroy the younger (1753 *circa*), Stahl (1660–1734), Dufay (1698–1739), the Swede, Cronstedt (1722–1765), Kerwan (1750–1812), Bergman (1735–1784), G. Neumann (1683–1737), Hellot (1685–1766) and of those in this century, John Davy (1812); Jacquelin Berzelius, Phillips, Gmelin, Freundt, Lagerhjelm (1815), Stromeyer, Schneider, Nickles, Bechamp, Saint Pierre, Ritter, Ruge, Gladstone, Duflos, Muir, etc., and many others, and amongst them some eminent pharmacists of our own day.

MODES OF PREPARATION.

In honour of M. Lemery it may not be out of place to quote the method adopted by him. It will be found in his 'Cours de Chymie' (1675),† and as he was remarkable for a clear mode of expressing himself, and for his superior chemical skill, and also as he had gained considerable reputation for the manufacture of this article, you may rely on something useful as well as quaint. This is from a fair translation of his work by Dr. Walter Harris (1686):—

"Magistery of Bismuth is a tinn glass dissolved and precipitated in a very white powder. Dissolve in a Matrass, an ounce of Bismuth, grosly powdered with 3 ounces of Spirit of Niter,‡ pour the Dissolution into a clear Whiteware Vessel, and pour upon it 5 or 6 pints of Fountain water, in which you shall have dissolved beforehand an ounce of sea salt,§ you'l see a white powder precipitate at the bottom. Pour off the water by Inclination, and wash this Magistery several times, then dry it in the shade. It is an excellent Cosmetick, called Spanish White, that serves to whiten the complexion. It is either mixed in Pomatum (ʒi to ℥i), or Lillie water (ʒi to ℥iv)."

"*Remarks.*—You must use a large Bolt-head to dissolve the Bismuth in, because the great Ebullition that happens

* Read at a Meeting of the Association, November 8, 1882.

* Dr. J. H. Pott, 'Observationum et Animadversionum Chymicarum, præcipue circa Sal Commune, Acidum Salis Vinosum, et Wismuthum Versantium, Collectio Prima.' Berolini, 1739.

† This was a wonderful production by Lemery. Immediately after it was published it was received with general approbation and applause, and passed through numerous editions. Indeed, seldom had a work on a subject of science been so popular. Fontenelle said 'it sold like a satire.' New editions fol owed year by year, and it was translated into Latin and into various modern languages.

‡ "Spirits of niter" was prepared i Lemery's ay by mixing together 2 pounds salt-peter and 6 pounds of Potter's earth, dried, placed into an earthen or glass retort, luted and heated in a reverberatory furnace until nothing more would pass over.

§ J. H. Pott, 1739, shows in his work, previously referred to, that the sea salt is unnecessary.

as soon as spirits of niter is cast upon it requires room to move in. You must likewise have a care, as much as you can, of receiving the Vapours at your nose or mouth, for they are very offensive to the breast. This quick and violent ebullition proceeds from the acid's immediate penetration of the large pores of the Bismuth, so soon as thrown upon it, and the acid violently divides all that opposes its motion. It happens also that the Bolt-head grows so hot that a man can't endure the hand on it because the points of the Menstruum do chafe against the solid body of Bismuth with such force that you may observe from thence much the same heat as when two solids are rub'd against one another, add to this, that the great store of igneous particles contained in Spirits of Niter, may much increase this heat. If the Dissolution becomes turbid through some impurities in the Bismuth, you must pour into it about twice as much water and filter it, for if you should go to filter it without water, it would coagulate like salt in the filter and not pass through. This Coagulation proceeds from the acid Spirits of Niter that are included in the particles of Bismuth, which finding too little liquid to swim in and disperse do gather together into Crystals when the Dissolution is cold. The impurity which commonly swims upon the Solution of Bismuth is a fat or bituminous matter, which will not dissolve in the Spirit of Niter.* This Magistery may be made by pouring into great quantity of Fountain water without any salt, and the Precipitation is the better because salt does encounter and break some of the acids that pure water alone was not able to weaken sufficiently. Now some difficulty appears in conceiving how plain water alone comes to precipitate Bismuth, Lead and Antimony, which the acid has dissolved, and yet can do nothing at all to the precipitating Gold, Silver or Mercury, without the assistance of some salt or other body. I do imagine that the former having larger Pores the acids cannot stick so close in them, but that water is able to force them out; but Gold, Silver and Mercury having finer pores in comparison than the other, do retain the acids so very closely, that the weak impulses of water alone can make no separation: some more active body is required to do it.

"The augmention which happens to Bismuth when made into a Magistery, does proceed from some part of the Spirit of Niter that remains still in it notwithstanding the precipitation and lotion."

The following are the principal official processes for the preparation of subnitrate of bismuth:—

B.P.—Purified bismuth in small pieces 2 ounces av., nitric acid (1·420) 4 fluid ounces, distilled water a sufficiency. The acid mixed with 3 ounces of distilled water and bismuth gradually added. When effervescence has ceased, heat to nearly ebullition is applied for ten minutes and the clear solution decanted very carefully from the insoluble portion which may be present. Evaporate the clear solution to 2 fluid ounces and pour it into ½ gallon of distilled water. Let the precipitate subside, decant the clear supernatant liquid, add ½ gallon distilled water to the precipitate, stir well and after two hours decant off liquid, collect and drain the precipitate in calico filter, press with the hands and drain it at a temperature not exceeding 150° F.

Heavy white powder in minute crystalline scales, blackened by sulphuretted hydrogen, insoluble in water, but soluble in nitric acid mixed with half its volume of distilled water, forming a clear solution which poured into much water gives a white precipitate. It forms with sulphuric acid diluted with an equal volume of water a solution which is blackened by sulphate of iron. The nitric acid solution gives no precipitate with diluted sulphuric acid nor with solution of nitrate of silver.

U.S.P. (1882).—This, which was published November 1, does not describe the process for the preparation of this substance, the reason being given in negative form in the Preface to the work, viz., that in the case of those chemical preparations where different processes yield different results, the process to be followed in each case is described in detail; it is therefore presumed that bismuth subnitrate, however prepared, should be uniform in composition.

U.S.P. (1872, *i.e.*, 5th Decennial Revision).—Bismuth in pieces, 2 troy ounces, nitric acid (1·42), carbonate sodium, each 10 ounces, water of ammonia (·960), 6 fluid ounces, distilled water q.s. Mix 4½ troy ounces of the nitric acid with four fluid ounces of distilled water in a capacious glass vessel, and having added the bismuth, set the whole aside for twenty-four hours. Dilute the resulting solution with 10 fluid ounces of distilled water, stir thoroughly and at the end of twenty-four hours filter through paper. Dissolve the carbonate of sodium in 12 fluid ounces of distilled water with the aid of heat and filter the solution through paper. To this, when cold slowly add the solution of nitrate of bismuth with constant stirring. Transfer the whole to a strainer, and after the precipitate has been drained wash it with distilled water until the washings pass tasteless and drain again as completely as possible. Then place the moist precipitate in a capacious vessel, gradually add the remainder of the nitric acid and afterwards 4 fluid ounces of distilled water and set the solution aside. After twenty-four hours filter through paper, and to the filtered liquid previously diluted with 4 pints of distilled water, slowly add the water of ammonia with constant stirring. Transfer the whole to a strainer and after the precipitate has been drained, wash it with 2 pints of distilled water and drain it again. Lastly, dry it upon bibulous paper with a gentle heat and rub it into powder.

French Codex.—Purified bismuth, 200 grams; nitric acid (1·42), 450 grams; distilled water, 150 grams; mix the acid and water in a flask, add the metal in coarse powder gradually to prevent excessive action. When effervescence has ceased, heat to ebullition to complete the solution; decant clear liquid after a little rest, and evaporate in a porcelain capsule to two-thirds and then pour into 40–50 times its weight of distilled water with constant agitation. Let precipitate settle, decant supernatant liquid and wash several times by decantation, collect on a filter, drain and dry.

German P. (1882).—Bismuth, 2 parts; nitrate of sodium, 1 part; distilled water, 5 parts; solution of caustic soda, 3 parts (15 per cent. and S.G. 1·159–1·163); warm nitric acid (1·185) 8 parts. The metal is treated in an iron crucible with the nitrate of sodium in very much the same way as our Pharmacopœia directs, and the resulting mass treated with the water and solution of sodium hydrate, mixed together, boiled for a short time, and the insoluble portion collected on a filter, and washed until free from alkali. The dried residue is then dissolved in the nitric acid gradually, and after the solution has been kept for a short time at a temperature between 80°-90° C. it is filtered through asbestos and the clear solution evaporated until reduced to 6 parts. One part of the crystals which will form on cooling is washed several times with water acidulated with a little nitric acid, and then rubbed down smoothly with 4 parts of water, transferred to a vessel containing 21 parts of boiling distilled water and stirred. The sediment is allowed to subside and the supernatant liquor while still warm is removed and the precipitate collected on a filter. Then, as soon as filtration has ceased, wash with an equal volume of cold water and dry at 30° C. (86° F.).

German (1872).—Pure nitric acid (1·185), 9 parts; coarsely powdered bismuth, 2 parts; towards end of action apply gentle heat. When nitrous fumes cease to be evolved, add a quantity of distilled water equal to half the amount of liquid, or until a white precipitate begins to form. Let the liquid remain until precipitate has subsided, and pour off clear liquid and evaporate

* That bismuth did neither contain fat nor bitumen was shown by Pott in his work previously cited.

until it begins to crystallize or until the weight of the solution is three times the weight of the metal used. One part of these crystals, washed with a little water acidulated with a little nitric acid, is mixed with 4 parts distilled water and the mixture poured into a vessel containing 21 parts of boiling water and thoroughly stirred. The precipitate thus formed, after the whole has cooled, is poured on to a filter, and washed with a very small quantity of water (*ne nimis*) and dried at a temperature not exceeding 30° C.

Of the above methods which are official, three are in the main identical, viz., B.P., Codex and German, being solution in nitric acid and precipitation by means of water, washing by decantation and drying at a low temperature. The dilution of the acid is essential to prevent too violent action, with consequent development of much heat, and loss by spirting and evaporation.

The B.P. method orders too much acid and therefore when solution of the metal is effected the resulting solution is evaporated with loss of acid. Perhaps it would be better to add the bismuth to the acid until a point is reached when it ceases to dissolve the metal and then a small and definite quantity of the acid could be added to bring the product to the proper strength for producing the B.P. article. The residue, which varies in quantity and colour according to the purity of the metal used, is, after the solution has been boiled, decanted or diluted until it would not act on paper, and filtered, or better, filtered through powdered glass, glass wool, or gun cotton. Evaporation should not be carried too far, for crystals form and cake and are then difficult to wash. When, after pouring into the *stated* quantity of water and washed as directed, it is placed on calico filter and drained, it would shorten the drying process if the precipitate were strongly pressed under a wooden press, as is done when phosphate of iron is made. The drying may be conducted at 120° F. in air closet, the result being a *white* powder not too dense and not acid to litmus paper when moistened with cold water. The supernatant liquors must in every case be preserved, for they contain varying amounts of bismuth which is held in solution by excess of HNO_3. Care is to be taken that distilled water only be used, for some waters contain solids which are very liable to be carried down when the nitric acid solution is poured into the water. To obtain uniformity in results the method adopted, whichever it may be, must always be carried out strictly in accordance with the recipe; even different amounts of water used in washing, difference in strength of acid used, and temperature at which the product is dried, tend to alter the nature of the preparation. It should not be allowed to remain in contact with the calico longer than is absolutely necessary, for this is said to darken the product from contact with the small particles on the surface of the calico when exposed to light. Drying may be done by placing in flat glass dishes as clock dials, etc.

The United States method of 1872 was quite different to the methods which had been used for a long time, in fact since the substance was known. The difference consisted in the use of carbonate of sodium and the liquid ammonia.

Before the 1864 edition of the U.S.P. the process was the usual one, but in their fourth decennial revision in that year the 1872 process was first authorized. It was devised with the intention of removing all the arsenic which might exist in the metal. The arsenic becoming arsenic acid, and by the dilution process arseniate of bismuth being sparingly soluble in the liquid so diluted is deposited in the time stated and was then removed by filtration. Addition of filtrate to the excess of carbonate solution caused precipitation of bismuth as subcarbonate, together with other metals except arsenic, nearly the whole of which remaining in solution as arseniate of sodium and was removed by filtration and washing the precipitate with water. The bismuth subcarbonate, or rather oxycarbonate, by solution in HNO_3 became again nitrate, and this solution was again set aside for twenty-four hours to permit any more arseniate of Bi which might have escaped previous treatment to be deposited. The filtered liquid was then mixed with water, which gave the subnitrate free from arsenic. As the liberated nitric acid retained some bismuth in solution, the water of ammonia was used to nearly neutralize the acid, which caused the precipitation of more bismuthous nitrate. This operation required great care, for the least excess of ammonia water would cause the precipitation of other metals which might be present, and to redissolve them again would be a difficult and unsafe way of rectifying the possible source of much impurity by the excess of precipitant. The advantage of the B.P. process over this is now easily seen, and would impress the practical man more if he carelessly made his preparation by the U.S.P. method. The supernatant liquors are never thrown away, for there are other compounds of bismuth used in pharmacy and the arts besides the one under consideration, and these can be made from them, when required, so that it is a mistaken notion to suppose than any bismuth will be lost by the British process; the supernatant liquors could be precipitated by carbonate of sodium, and the precipitate washed, dissolved in HNO_3 and reprecipitated by water. Many methods have been described to prepare this compound, so that it shall be more constant in composition, and contain less impurities. A few may be briefly mentioned here, excluding the many methods for purification of metal.

Lalieu (1878).—Treatment of well-washed and still moist oxide obtained from 200 grams of the metal (by means of AmHO, wash, add NaHO, put on water-bath for short time), with nitric acid equal to 48·5 grams of nitric anhydride, adding it in small quantities, and then heating the mixture until it becomes limpid and white; after the addition of a little water the subnitrate is thrown upon a filter, washed with twice its bulk of water, expressed and dried; the yield is 265 grams.

Huskisson's Method (*P.J.*, 1860).—This, something like the German process, is, it is said, adopted by manufacturers, viz., evaporation of nitric solution until it begins to crystallize, set aside and removing supernatant mother-liquor and wash crystals with a little acidulated water and using these only. This process can be repeated as often as necessary to ensure perfect absence of impurity. This would certainly remove much silver, copper, lead and arsenic, if present.

Brownen suggests, for removal of copper, precipitation from nitric solution by means of carbonate of ammonium (its best precipitant); wash with liquor ammonia and reduce to metal or dissolve at once in nitric acid and proceed as usual.

Umney, during a discussion at one of the Pharmaceutical Society's meetings some years ago, suggested the use of bismuth oxide prepared by precipitation by caustic alkali, and although he spoke of it as applicable to the preparation of the "Liquor" yet it may with considerable advantage be used for the other compounds, especially when copper, silver, etc., are absent.

Julius Löwe recommends the washing water to be made of 1 part of nitrate of ammonium with 500 of distilled water. Fresenius adopts this suggestion in his 'Quantitative Analysis.'

Schneider (as also Duflos) recommends solution of 2 kilogrammes of Bi in 10 kilogrammes HNO_3, *hot*, and after solution decant from sediment which contains the arsenic; on evaporation, the crystals, which separate, are free from arsenic. Bismuth arseniate is formed, which is insoluble in strong solution of nitrate of bismuth, although more soluble in water. A safe method consists in the examination of the metal, and if any impurities are present, to reject the sample, and, as Professor Redwood said some years ago could be done, viz., seek and pay for good and pure metal.

(*To be continued.*)

Review.

THERAPEUTICAL REMEMBRANCER, PRESENTING IN DETAIL ALL MEDICAMENTS ACCREDITED BY THE BRITISH PHARMACOPŒIA, with copious supplementary tables, etc. By J. MAYNE, M.D., L.R.C.S.E., L.S.A. Second Edition, revised. London: J. and A. Churchill.

It is difficult to decide what to say concerning this little book. It only deserves notice from the fact that of the many similar compilations we have the misfortune to see, this is the most badly arranged, the most erroneous, the most useless. One cannot understand how it could possibly have reached a second edition, unless the first consisted chiefly of presentation copies.

The various drugs are arranged according to their therapeutic action, and the whole concludes with a few notes on poisons and their antidotes. Some curious things which we suppose are meant to be prescriptions are, without a word of explanation, tacked on to some pages. We select a few specimens;—

On page 5—

H. Subchlor.
Tr. Cinchonæ.
Solve. (A teaspoonful dose.)

Again on page 6.

℞ Pil. H.
Ext. Colcynth. co.
Ipecacuanhæ pulv.
Saponis.
F. massa in pil. div.
Liqu. H. perchlor.

On page 18—

℞ Cambogiæ.
Potassæ carb.
Theriacæ. q.s.
M. pro. re. nata.
M. take.

And on page 22—

℞ Hellebori.
Ext. aloes barb.
Ferri et ammoniæ cit.
Colocinth.
Opii pulv.
M. f. pil.

We admire the author's ingenuity in working so many errors into the following three lines:—

Chalk (calcis chloridum)
Use. To prepare the following
Liq. Calcis chloratæ.

According to Dr. Mayne, white marble is synonymous with creta, and is a valuable antacid for intestinal disorders; æther purus and spiritus ætheris are the same substances. Sabadilla is derived from *Veratrum Sabadilla*; saccharated *carbonate* of lime is an antidote. Pix Burgundica is the tar exudings from spruce fir and *Pinus sylvestris*. Sinapis is the seeds of *S. nigra* only; galls are *nuts* or excrescences; syrupus ferri iodidi contains 4·3 grs. *oxide* of iron in fluid drachm; phosphorus is *never* given *in the solid form* (author's italics); pareira root is of course still derived from *Cissampelos Pareira*; and the following is a full description given by the author:—"Canna (the tous-le-mois, not well authenticated)." The following is the formula given for Fowler's solution:—"Arsen. acid, powder, powdered carb. potash aa—grs. 80, tr. lavand. co., drachms V., aqua distil, q.s." This is all, but the reader naturally would like to know what the quantum may be. In this revised second edition we find such gross errors in orthography as antimonium sulphuretum, sp. ætherus, colcynth, colocinth, lequ (we presume this is meant for liquor), syrupus ramni, rincing, zinzib, strobules. We find such expressions as acid solution of nitrate of H., solution of perchlor. H., and we are fairly puzzled by the following:—"Iodum (emmenagoges)," "sodæ (sodæ acetas)," "rosa centifolia (*i.e.*, aqua rosæ)," and "cardamomum (capsules of Malabar [elettaria] dried)."

It seems scarcely credible that such drugs as the following should be omitted from a therapeutic remembrancer, but we have failed to find them mentioned:—Ergot, chloral hydrate, bismuth salts, areca, nitrite of amyl, pepsin, hypophosphites, chloroform; and all the notice of cinchonas, on page 78, is "cinchonæ (var.)."

It is not our province to criticise this extraordinary production in its medical aspect, but we notice that galls are not mentioned as being used externally; that sp. æth. nit. is said to have the same action as æther, and, therefore, according to the author, to be useful in tetanus, epilepsy, hysteria, asthma and other spasmi; that dulcamara is good for gout, rheumatism, eruptions of long standing, jaundice and scrofula (on another page it is stated that it is "*perhaps* serviceable to form an infusion);" and that veratria is given as an *errhine* in gout. We should think an hour or two's continuous sneezing would be calculated to exert a very soothing influence upon a patient suffering from an acute attack. Tonics are described simply as "those medicines which have power of enhancing the quality of tonicity in muscular fibre," and buchu is described as being "scarcely ever selected even as infusion or vehicle."

In the so-called index, which is miserably insufficient, there is no drug mentioned, although throughout the book the reader is constantly referred for the properties of one drug to the description of another—thus: "Alcohol (v. Vinum Xericum)," "Calomel (v. hydrarg. subchlor)." We have devoted this amount of space to this wretched book to indicate to our readers its absolutely worthless character. To be frank, we are surprised that an M.D., L.R.C.S.E., L.S.A., should publish such a thing with such a title page, and we hope that when the *cacoethes scribendi* next seizes him, he will turn his attention to some subject other than medicine or pharmacy.

BOOK RECEIVED.

THE BREWER, DISTILLER AND WINE MANUFACTURER, giving full Directions for the Manufacture of Beers, Spirits, Wines, Liqueurs, etc. [Churchill's Technological Handbooks.] London: J. and A. Churchill. 1883. From the Publishers.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

"*Wilton*" (who is requested to comply in future with the regulations as to anonymous communications).—(1) Any person whose name is on the Register of Chemists and Druggists may legally carry on the business of a chemist and druggist, whether he is connected with the Pharmaceutical Society or not, (2) Consult the indexes of this Journal.

J. Finch.—Our views as to the rights of chemists to prescribe have been expressed in this Journal in numerous articles, to which we must refer you for the information you require.

J. Gould.—We do not feel at liberty to ask for assistance in imitating a particular proprietary preparation.

C. Ellison.—The following recipe for "Pick-me-up" tonic has been published before in this Journal:—Cardamoms, 5 parts; caraways, 2; cochineal, 2; cinnamon, 10; raisins, 80; orange-peel, 56; ginger, 14; gentian root, 3; wormwood, 2; quassia, 1; alcohol (·838), 750; water, 750. Macerate for fourteen days, filter, and add syrup, 200 parts.

Nemo.—We cannot.

J. Ward.—We are unable, after the lapse of time, to comply with your request. Please address future communications direct to the Editor, 17, Bloomsbury Square, in accordance with the notice on p. 533.

Ajax.—We have been unable to obtain the information.

Junior.—The formulæ has been asked for on several occasions without success.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Short, Dyer, Scruton, and Incognito.

The Pharmaceutical Journal.

SATURDAY, JANUARY 6, 1883.

Communications for the Editorial department of the Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed " Pharm. Journ."*

1882.

THE year that has just closed has not, in its pharmaceutical aspect, been marked by any very stirring events. But even in this it may be said to have had an advantage over its predecessor; for if it has brought no International Congress, neither has it seen the retirement of honoured leaders or the frustration of carefully elaborated schemes for the improvement of the conditions under which pharmacy is practised in this country. On the contrary there has been a decided improvement in the general position, and the close of the year finds the Council engaged, at the request of the Government, in formulating its views as to amended legislation in the interests of pharmacy as well as of the public.

The Council of the Pharmaceutical Society, which may fairly claim to be by far the most important executive body in relation to all that pertains to pharmacy in this country, has not undergone any change in respect to its members during the past year. The fourteen gentlemen who, according to the bye-laws, retired from the Council in May were nominated for re-election, and were all returned by considerable majorities. At the first meeting of the new Council in June, the choice of officers for the ensuing year was made. Mr. THOMAS GREENISH, who for two years had filled the post of President with a success indicated by the fact that at the end of each year he had headed the poll in the election of members of the Council, retired from the chair, and his place was taken by Mr. MICHAEL CARTEIGHE. Mr. GEORGE FREDERICK SCHACHT, who for three successive years had been chosen Vice-President, gave up that post to Mr. SAMUEL RALPH ATKINS; whilst Mr. JOHN ROBBINS was again requested to act as Treasurer.

The Registrar's Report, which was presented as usual to the Council in February, showed an increase of 193 in the number of names on the Register of Chemists and Druggists. In contrast to this there was a decrease of 29 in the total number of persons connected with the Pharmaceutical Society as members and associates. This retrogression, and the fact that it was mainly due to a decrease in the class of Pharmaceutical Chemist Members, naturally formed the topic of some conversation at the Council, and it gave rise outside to some ill-concealed jubilation as to "the decay of the Pharmaceutical Society." That this assumption was somewhat premature is shown by the fact that the gross number of members and associates still reached 4607, a total that had only been exceeded in the previous year.

Amongst the earliest business that came before the Council last year was a motion of Mr. RICHARDSON to rescind some regulations passed in 1879, as to the conditions under which reporters should be allowed to attend the meetings of the Council. The general effect of the motion was to place all press reporters who might attend upon an equal footing, and to remove a somewhat anomalous distinction which had its origin in a desire to confer upon the representatives of another journal privileges we were erroneously supposed to enjoy. The Council also resumed the right to allow its own reporter to be present for the purpose of taking notes during the transaction of private business in committee, a right which, as Mr. RICHARDSON frankly admitted, had been relinquished under the temporary misapprehension that this reporter attended on behalf of the *Pharmaceutical Journal.* The fact is, as has been stated many times, the reports of the Council proceedings published in this Journal are the official reports, supplied under the authority of the Council itself. After the experience of the last three years it may be fairly assumed that they correctly represent all that portion of the business which the Council feels at liberty to transact in public. In addition to this, the Council, at its meeting in May, on the motion of Mr. RADLEY, passed a resolution authorizing the President for the time being to publish in the Society's Journal and Transactions so much of the proceedings of the General Purposes Committee as he might deem desirable.

Notwithstanding the wide-spread discontent that exists among those legally entitled to carry on the business of chemist and druggist, and their almost unanimous agreement that the emoluments arising from it are insufficient to repay the expenditure of time and money involved in securing the necessary qualification, there does not yet appear to be any indication of a falling off in the number of persons desirous of acquiring the right to practise pharmacy. The total number of candidates who came up at the different examinations during the year amounted to 2030, being 73 in excess of those of the previous year, and 13 more than in 1880. Taking first the initiatory stage, the number of candidates at the four Preliminary examinations reached 1269 against 1187 in the previous year. Of these 629 were successful; this represents 49·5 per cent. of passes, which is a result more satisfactory than in the previous year when only 512 or 43·1 per cent. passed. The number of certificates received in lieu of the Society's examination was only 50, showing a falling off as compared with the year 1880; but the net result was that 679 apprentices were registered, being 82 more than in the previous year. The number of candidates for the Minor examination was 650, or exactly the same number as in 1881, and two less than in 1880, so that very little variation is manifest in the numbers coming up for the qualifying examination. There has been, however, a very considerable falling off in the percentage of passes in this examination, for whereas in 1881 they equalled exactly 50 per cent., last year they only amounted to 286 or 44 per cent., showing a larger proportion of failures than has occurred in any year except 1874 since the passing of the Pharmacy Act in 1868. The number of candidates who presented themselves for the Major examination also was almost the same as in 1881, having been 103 against 107; but of these, too, a much larger proportion failed and only 40, or 38·8 per cent., passed and became entitled to registration as pharmaceutical chemists. Only 8 persons presented themselves for the Modified examination, and of these 5 passed.

The examinations and their relation to pharmaceutical education have again occupied a large share of the attention of the Council. The very large proportion of failures in the Preliminary examination in January induced Mr. Borland to raise the inquiry whether the questions in arithmetic had not been more difficult than usual, and Mr. Young suggested whether it might not become desirable to appoint a committee to watch the examination papers with a view to checking undue stringency. Undoubtedly the large proportion of failures in arithmetic which occur in the Preliminary examination, and which in 1881 nearly quadrupled the proportion of failures in Latin, is a very remarkable feature; but as the questions are always published, and this particular subject is one that does not admit of much variation of opinion in awarding marks, any person interested in the subject has an opportunity of forming his own judgment upon the subject. Still, we think that there will be a general agreement with an opinion expressed by Mr. Walter Hills, at the Council meeting in October, that the arithmetical questions set are not of such a nature as to explain this result, and that in a pharmacist's daily business questions quite as difficult often occur, so that a person unable to obtain 40 per cent. of marks in arithmetic in this examination would scarcely be qualified to dispense prescriptions. Unfortunately there can be little doubt that Dr. Greenhow, in his report to the Privy Council, correctly attributed the large number of rejections to the very inadequate early education of the majority of the candidates; it is to be hoped, therefore, that in an increasing proportion of cases this test may be applied before pupils have wasted some years of their lives in a calling for which they do not possess the elementary scholastic qualification. Evidently, however, there exists some difference of opinion among chemists and druggists as to the standard that should be adopted for this examination, and the Society may be congratulated that the questions are now set by an impartial body like the College of Preceptors. From this point of view interest attaches to a communication which was received in August from the honorary secretaries to the Oxford and Cambridge Schools Examination Board, in reference to an examination which it is intended to institute in connection with schools throughout the country, and asking if certificates granted in respect to it would be received in lieu of the Preliminary examination. Some points in the scheme gave rise to objection, but the general spirit of it was approved by the Council, and there is no doubt that the establishment by such unimpeachable authority of a standard that shall represent what may be considered a fair test of a sound middle-class education would be a great boon.

In December the subject of the Preliminary examination came again under the consideration of the Council in connection with a special recommendation contained in a report from the Board of Examiners in England. It was to the effect that the time allowed should be extended from one hour to one hour and a half for each of the three subjects, with an interval of one hour between the second and the third; also that instead of the examiners being limited to the first book of Cæsar for their selection of one passage for Latin translation, they should be at liberty to set two passages, one from one of the first two books of Cæsar's 'De Bello Gallico,' and the other from one of the first two of Virgil's 'Æneid,' the candidate only to be required to translate one of the passages, and notice to be given a year in advance as to the books from which the selections would be made. An objection was raised, however, representing the views of the Board of Examiners in Scotland, that the extension of the ground of selection to two books of each author would have the effect of unduly increasing the difficulty of the examination. Accepting the suggestion as to the increase in time allowed, the Scotch Board desired that in respect to Cæsar the examination should be still limited to the first book, and that, if Virgil were introduced, only the first book of that author should be used. After a discussion, an amendment in accordance with the views of the Scotch Board was carried by a bare majority of the Council, and future candidates for the Preliminary who have studied Virgil rather than Cæsar will, therefore, have an easier task and a longer time to perform it in.

But the interest of the Council in the examinations has been by no means confined to the Preliminary, and it appears probable that one of the results of the past year's labour has been to bring more clearly within the range of probability the establishment of a curriculum to be followed as an indispensable portion of the education of pharmacists in the not very remote future. In March a Special Committee on the relation to each other of pharmaceutical education and the pharmaceutical examinations, to which a preliminary report had been referred for the working out of details, laid the result of its labours before the Council. The fresh report fully endorsed the first two recommendations of the previous one, to the effect that candidates for the qualifying examination should be required to produce evidence of apprenticeship or pupilage of not less than three years, and that the Preliminary examination or its equivalent should be passed before the time spent in such pupilage should be allowed to count. The third recommendation, that the candidate should be required to produce evidence that he had attended since the date of his Preliminary examination a course of lectures on chemistry, one on botany, and one on materia medica, was also endorsed and a syllabus of the course of lectures on each subject was submitted. With respect to the authoritative recognition of such lectures and teaching the Committee recommended that the Council should, at its discretion, recognize and accept certificates from those public schools of science, the responsible authorities of which shall satisfy it that their scope of teaching includes the points enumerated in the syllabuses, or certificates from other schools in which it is shown that the teaching is of sufficient excellence and of the nature required. With respect to the fourth recommendation the Committee recommended an important modification of that in the previous report. It was still proposed that the Minor examination should be divided into two parts, between which it was suggested there should be an interval of not less than six months; but it was now recommended that the first portion, including the translation of prescriptions, pharmacy and theoretical chemistry, should be entirely a written examination and should be conducted under suitable regulations in London, Edinburgh, and certain provincial centres to be agreed upon by the Council. It was recommended that persons passing this portion of the examination should not receive a certificate, but should be entitled to present themselves, after an interval of not less than six months, for the second portion of the examination, which should be essentially *vivâ voce* and experimental, conducted in London and Edinburgh only, and consist of chemistry and practical chemistry, botany, materia medica and practical dispensing. Finally it was recommended that these regulations should come into operation on the 1st of January, 1886. The discussion of the report was postponed until the meeting in the following month, and a copy was ordered to be supplied to each member of the Council for consideration meanwhile.

In April, accordingly, the subject was brought formally under the consideration of the Council, upon a motion made by Mr. SCHACHT, and seconded by Dr. SYMES, that the recommendations of the Committee should be approved. The first three recommendations, as to pupilage, the Preliminary examination, and a curriculum, were again endorsed with great unanimity; but the modifications introduced into the fourth were sharply criticized. Granting the desirability of the division of the Minor examination into two parts, Mr. HAMPSON opposed the suggestion that there should be an interval of six months between them, as well as the rearrangement of subjects, and especially the proposition that the first portion should be conducted at provincial centres. In one or other of these objections he was supported by a majority of the members of Council, among whom were the President (Mr. GREENISH), Mr. WILLIAMS, Mr. BOTTLE, Mr. YOUNG and Mr. BORLAND. On the other hand the report was defended by the Vice-President (Mr. SCHACHT), Mr. CARTEIGHE, Dr. SYMES, Mr. ATKINS and others, it being argued that the interval and the local examinations were advisable in the interest of the candidates, whilst the placing of the theoretical subjects before the technical was the logical course, since after a candidate had satisfied the examiners as to his practical ability the prolongation of his scientific studies could not be so well demanded in the interest of the public. After a long debate an amendment to adopt the first three recommendations was carried unanimously, but a motion to adopt the fourth recommendation was lost by a majority of one. The fifth recommendation, as to the time when the new scheme should come into force, was therefore necessarily dropped; indeed it almost seemed as if some of the chief advocates of the scheme, in seeking to secure a minor point, had brought the whole movement to a dead-lock.

At the second meeting of the new Council, in July, however, the recommendations again underwent a long discussion. Mr. SCHACHT moved that a Committee should be appointed to consider and report upon the best method of giving effect to the resolution of the Council in April, and he pointed out that one of the first duties of such a Committee would be to inquire how far the present legislative power would enable the Council to carry it out. But the motion also included an instruction to the Committee to report any suggestions it might desire to advance as the result of its deliberations, which provoked considerable opposition, and Mr. HAMPSON moved its omission on the ground that it would probably reopen the question upon which the Council had already come to a decision. On the other side it was argued that the manner in which the Minor examination should be conducted would necessarily have to be considered by the Committee in connection with the third recommendation, which had been adopted, and that even without such an instruction the rejection of one plan would not have precluded the Committee from suggesting another; it was also pointed out by the President, Mr. CARTEIGHE, that the striking out of the instruction after it had been inserted might be construed as an indication that the Council wished to fetter the Committee in its deliberations. So evenly were opinions balanced upon this point that upon a division an equal number voted on each side, and the President having given his casting vote against the amendment, the motion of Mr. SCHACHT was afterwards carried by a majority of one.

It may be safely said that besides the prominent position this future of the qualifying examination has occupied in the deliberations of the Council it has given rise to more talking and writing than any other pharmaceutical topic during the year. Besides being discussed at the General Meeting of the Society, it has permeated presidential addresses, been the occasion of several meetings in the provinces, called forth special memorials to the Council, and provoked a mass of correspondence. Of course there has been diversity of opinion manifested, but the preponderance has been decidedly in favour of the establishment of a curriculum, which denotes a healthy recognition of the fact that such a course would not make the qualifying examination more stringent, but would lessen the proportion of rejections by promoting the better education of those who are to be examined. Among the expressions of opinion to which adventitious circumstances lend an additional importance, is that of Dr. GREENHOW, the Government Visitor at the examinations, who, in his last official report, whilst deferring detailed comments on the scheme as a whole, expressed his decided approval of the first two recommendations. Another occurred in a letter from Dr. W. B. CARPENTER, who, after many years' experience as Registrar at the University of London, considers that the regulation under which the attainment of medical degrees at that University is made exceptional by restrictions as to the mode in which candidates shall study is a wise one, and that a similar course should be followed with respect to candidates for a qualification to practise pharmacy. Again, Mr. ALEXANDER NAPIER, speaking as President of the North British Branch, two months ago, said, that no one could doubt that a course of compulsory and systematic instruction in theoretical chemistry, botany and materia medica, with practical instruction in chemistry, would be the best means of insuring thoroughly intelligent agents for the practice of pharmacy, and that the time must come when pharmaceutical students will have to devote a certain period exclusively to scientific education, since the present system, or no-system, of having an engagement in a pharmacy and attending lectures and studying in bye hours, is unsatisfactory to both employers and students. But perhaps one of the most encouraging expressions of opinion on the subject, outside the Council, took place at the Annual Meeting of the Trade Association, when a motion to the effect that at the present time it is not desirable to establish a curriculum was rejected by a majority of nearly three to one. It therefore appears evident that there has been recently a considerable development of opinion in favour of the adoption of a compulsory curriculum as a means of ensuring the systematic education of intending pharmacists, and it does not seem unreasonable to attribute this, in part at least, to the stimulus received through contact with pharmacists of other countries during the International Pharmaceutical Congress in 1880. Be that as it may, the hands of the Council will be strengthened by the knowledge that it has the support of the majority of pharmacists in respect to the principles laid down, and in working out the details it will no doubt bear in mind all the pecuniary and other interests involved, in which its own members are as much concerned as any.

Many circumstances combined early in the year to concentrate more public attention than usual upon the regulations under which dealings in poisons and preparations containing poisonous medicines are conducted. Especially some circumstances attending a case of criminal poisoning by means of aconitine, and representations made by coroners as to the numerous fatalities resulting from the use of preparations containing poisons which are now so widely sold under the cover of the patent medicine stamp, compelled the Government to take some action in deference to public opinion. Towards the end of January, the Director of Public Prosecutions took legal proceedings against the proprietor of one of the most notorious of these preparations, on the charge of having sold "solution of chloral" without affixing a poison label to the bottle in which it was contained. The case rested on the sale of two bottles of the solution, one of them containing equal to 284 grains, and the other 88 grains of chloral hydrate, and it was deposed that a dose of 30 grains—which would be exceeded in a teaspoonful and a half of the solution—had been known to prove fatal. On the part of the prosecution, it was argued that the exemption contained in the sixteenth section of the Pharmacy Act, 1868, in favour of "the making or dealing in patent medicines," only applied to the provisions "hereinbefore contained"—*i.e.*, the first fifteen sections of the Act—which restrict dealings in poisons to registered chemists and druggists, and that it does not relieve any seller of a scheduled poison from the necessity of complying with the provisions as to labelling, etc., in the seventeenth section. For the defence it was broadly contended that by the words in the sixteenth section, patent medicines are entirely withdrawn from the operation of the statute, and that this reading had the sanction of custom. The magistrate, however, decided against the defendant, though somewhat ambiguously, "on the larger word 'poison,'" because he thought the solution was a poison on the medical evidence, and he imposed a penalty of 40*s.* and costs. Notice of appeal was given at once; but it is instructive to note that it has never been carried out, neither has the Public Prosecutor shown any signs of following up his success by further proceedings in the same direction.

Before turning to the subject of projects for fresh legislation in respect to the sale of poisons, mention must be made of a signal failure in an attempt to extend the scope of the present law. It will be remembered that in the parliamentary session of 1881 a Bill was introduced to amend the law as to the sale of poisons, especially in relation to their administration to animals, which, if passed, would have caused much inconvenience and added largely to the list of scheduled poisons. The Bill was, however, withdrawn in deference to the wish of the Council of the Pharmaceutical Society, to give an opportunity for conference with the promoters. As a result, in February last, the Council resolved to exercise its statutory powers, and to recommend to the Privy Council the addition to the second part of the poison schedule of sulphuric, hydrochloric and nitric acids, butter of antimony, carbolic acid, hellebore, nux vomica and its preparations, and vermin killers containing phosphorus. After an unusually long interval, probably taken up in communicating with representatives of classes that would be affected by such a course, a communication was received in August from the Privy Council Office, containing a copy of an Order in Council by which nux vomica and its preparations were added to the second part of the schedule of poisons, and intimating that, pending the consideration of the expediency of further legislation with respect to the sale of poisons, their Lordships did not deem it desirable to add to the restrictions on the sale of the acids and other articles mentioned in the resolutions of the Council.

In March, in accordance with a promise made in reply to a question put in the House of Commons, the Home Secretary caused a communication to be sent inquiring whether the Pharmaceutical Society had any suggestion to make for the amendment of the law relating to the sale of poisons. In reply, and after consultation, the President (Mr. GREENISH) forwarded to the Home Secretary three definite suggestions as embodying the opinion of the Council. These were to the effect (1) that further restrictions on the sale of medicine containing poison, dispensed from ordinary prescriptions, are not necessary or practicable; (2) that the sale by wholesale of certain virulent poisons,—such as the poisonous vegetable alkaloids,—might with advantage be placed under greater restrictions; and (3) that the sale of patent medicines containing poisons should be placed under the same restrictions as the sale of other medicines containing poisons. It was also mentioned that the amendment of other sections of the existing Acts seemed desirable. In compliance with a wish expressed by Sir WILLIAM HARCOURT at an interview which took place subsequently between himself and the President and other members of the Council, these suggestions were afterwards amplified. The restriction on wholesale transactions proposed was that sales of poisons in the first part of the schedule should be recorded as to name of poison, quantity, name and address of purchaser and date of sale, and that the record should be kept twelve months. With respect to patent medicines, it was proposed that so much of section 16 of the Pharmacy Act, 1868, should be repealed as allows patent medicines to be sold without restriction, and to enact that all such medicines containing poisons should bear a notice to that effect and a warning that they should be used with care. The propriety of enforcing a certain course of technical education and training, prior to the qualifying examination of persons who are to be registered as authorized to sell and dispense poisons and poisonous medicines, was also urged in regard to the safety of the public. It would appear most probable, however, that any legislation on this subject undertaken by the Government will emanate from the Privy Council, and it is satisfactory to find that the postponement of the additions to the poison schedule proposed by the Privy Council "pending the consideration" of the subject was not meant as an empty phrase. Immediately after the summer vacation a request was transmitted from the Lord President that the Pharmaceutical Society would submit its views in regard to the sale of poisons, for the consideration of the Lords of the Council, in the form of a draft Bill for amending the existing law, and it will be seen from the report on another page that the Law and Parliamentary Committee is at present busily engaged on the work.

The Royal Commission on the Medical Acts, the appointment of which last year was the occasion of considerable discussion, if not anxiety, amongst pharmaceutical politicians, was published in June, but so far from presenting any features of special interest to pharmacists, such topics were only remarkable by their absence.

In August the subject of reciprocity in the recognition of certificates of qualification granted by colonial pharmacy boards was revived by the reception of a letter from the Pharmacy Board of Victoria. In this communication, it was stated that the course of study required by the Victorian Pharmacy Act is nearly identical with that required for the Major examination in this country, and it was urged that since the exemption from examination of holders of the British qualification is especially provided for in the Colonial Act, it would be equitable that there should be some recognition of the Victorian certificate in this country. The evident feeling of the Council in respect to this application was that at present it has no power to accept such certificates of qualification and that the time has not yet come when it would be justified in applying to Parliament for such power, since it would be difficult to draw the distinction between one colony and another. A significant commentary upon this decision has been furnished by the resolution of the Pharmacy Board of Victoria itself not to recognize the certificates of qualification issued by the Pharmacy Board of the neighbouring colony of New Zealand, and some of the incidents arising out of the resulting controversy between the two colonial Boards have not been devoid of the humorous element.

The disposition of different Government departments to consult the Council of the Pharmaceutical Society upon subjects connected with the practice of pharmacy in all parts of the British empire is evidently increasing. Besides the communications from the Home Office and the Privy Council Office, before referred to, there was in May transmitted to the Council a copy of an Ordinance of the Legislature of St. Lucia, for the regulation of the sale and dispensing of drugs and poisons in that colony, asking that it might be considered, and that the Secretary of State for the Colonies might be furnished with the views of the Council respecting it. The request was complied with and some alterations were suggested.

It may be here mentioned that, mainly through the efforts of Mr. Crossley, an Associate of the Pharmaceutical Society, two Ordinances have been passed regulating the dispensing of medicines and the dealing in poisons in the Island of Guernsey, by which the practice of pharmacy in that island, after saving the rights of those engaged in business at the time, is confined to persons holding the diploma of the Pharmaceutical Society of Great Britain or of one of the French faculties.

At the meeting of the Council in November the subject of the public sale in London by auction of spurious and worthless drugs was brought forward by Mr. Williams, who moved that a Committee should be appointed to consider the question and report to the Council what steps, if any, should be taken to check this practice. There was a decided feeling amongst the members of Council as to the necessity for caution in dealing with this subject, and a disinclination to assume the position that pharmacists are incapable of protecting themselves and the public from those practices without State aid. A similar feeling was manifested at the Evening Meeting in December, when the subject was brought forward in a paper read by Mr. E. M. Holmes. The Committee was appointed, but has not yet made a report.

Whatever else in connection with pharmacy may have been sluggish during the year benevolence has been active, and notwithstanding that pharmacists number among themselves a large share of the poor they have nobly striven to render to them adequate aid. Early in the year there were some indications of a falling off in the number of subscribers and that the Council would be left with a diminished income to meet increasing requirements. The subject was, however, taken up vigorously in the Council, and a resolution was passed expressing an opinion that the number of subscriptions would be much increased if a personal canvass were made by each Local Secretary, accompanied by one or more members of the trade. It was also resolved that with a view to facilitate this work a complete list of all the subscribers should be published annually in this Journal and that a copy of the number containing the list should be sent to every person whose name is on the Register of Chemists and Druggists. The response from Local Secretaries and others interested throughout the country has been very satisfactory, and as a result the year's subscriptions amounted to the sum of £1568, being £383 in excess of the sum received in 1881; besides which the unusually large amount of £388 was received in donations. Of the donations the sum of £100 was given by the Treasurer, Mr. Robbins, to be invested in gas shares, on the condition that the dividends should be applied in paying £5 each year to the annuitant who has contributed the largest amount to the Benevolent Fund. Donations of £50 each were also given by Mr. J. Richardson and Mr. E. N. Butt. There was a further accession to the Fund in the shape of three legacies of £100 each, under the wills of Mr. Arthur Lloyd, of Camden Square, Mr. Robert Howden, of Gracechurch Street, and Mr. Charles James Pearson, of Swansea. On the other hand the expenditure in the shape of annuities amounted to £1187 10s., and in casual grants to £461. Last month six fresh annuitants were elected, which brought the number up to forty-two, involving an expenditure of £1360 per annum.

Great attention has been paid during the year to the Library and Museum by the Committee charged with the task of keeping them in a state of efficiency. About 500 books and pamphlets have been added to the Library, and it is satisfactory to find that evidence of the esteem in which it is held has been afforded by a considerable increase in the number of persons using it both in the day-time and in the evening, the numbers having been, day, 4218, evening, 1510, against 3447 and 1249 in the previous year. This may be partially attributable to the increased number of students in the School of Pharmacy, but it is also noticeable that the circulation of books has been almost the same as in 1881, although that the Library was closed during the whole of September for cleansing purposes.

The Herbarium has been increased by a valuable series of medicinal plants from the Botanical Gardens at Ceylon; also by an excellent set of specimens of various species of aconite and by specimens of the plants yielding damiana and Japanese oil of peppermint. The collection of materia medica has been enriched by numerous contributions, notably by specimens of new alkaloids from Messrs. Merck, by a tolerably complete series of the cuprea barks from various donors, by a number of Madagascar drugs collected by Dr. G. W. Parker, the Physician to the Queen of that island, and by the scarce and not easily obtainable Dyak poison of Borneo. The catalogue of the Hanbury Collection has been prepared for the press, and has now only to be enriched by additional notes from the private MSS. of the late Mr. Daniel Hanbury before being published. The number of visitors to the Museum has shown a small increase, and many duplicate specimens have been distributed to local associations or lent for scientific purposes.

The Annual Meeting of the Pharmaceutical Society was held, as usual, on the third Wednesday in May, and was well attended. The address delivered on that occasion by the President, Mr. Greenish, was not wanting in plain speaking. Referring to the "deep and general discontent" prevailing throughout the country with regard to the condition of the chemist and druggist, he attributed it, firstly, to the state of trade generally, and, secondly, to excessive competition. Much of this competition he said was due to young men of deficient education being lured into an over-crowded trade; instead of being educated pupils, articled to learn a trade, they were admitted from a low social scale, with deficient early education and small premiums, mainly for the sake of their manual labour, the desire to obtain this chiefly being greater than is consistent with a due regard to the advancement of pharmacy. Another cause mentioned was that some pharmacists lend their names and influence to the flooding of the trade and harrying of the medical profession with secret nostrums. If this "negation of true pharmacy" be followed to its logical issue, Mr. Greenish thinks the result will be that "the medical profession will order medicines "by numbers and prescribe nostrums with obscure "names; prescriptions and pharmacists will disappear together, and the ordinary huckster may keep "a supply—a 'line' of remedies—on his shelves, and "sell them to the public just as he now sells Bath "bricks and hearth-stones." In the Report presented the Council enumerated the different subjects which had engaged its attention during the year, many of which have already been referred to elsewhere in a previous summary and the remainder in the present one. The Financial Statement showed that, although there had been a slight decrease in the receipts in subscriptions and examination fees, the income had exceeded the expenditure by more than eleven hundred pounds. In the discussion that followed several speakers expressed their agreement with the spirit of the Presidential Address, and although some of the points touched upon in the Report elicited a brisk criticism, this did not prevent the meeting from adopting it unanimously.

The usual number of Evening Meetings have been held, and whilst these have been only moderately well supplied with papers the proceedings have always been sufficiently interesting to well repay those who attended them. The following are the titles of the papers read:—"Does Cod Liver Oil contain ·05 per cent. of Iodine?" by Mr. M. M. Bird; "Iodine-yielding Algæ," by Mr. J. Wheeler; "Further Contributions to the Chemistry of the Rhizome of Zingiber Officinale," by Dr. J. C. Thresh; "Note on the Extract of Aconite and on the Alkaloid of Aconitum Paniculatum," by Messrs. E. L. Cleaver and M. W. Williams; "The Orchard Alum Spring," by Dr. J. C. Thresh; "Note upon the Use of Oxalic Acid as a Test for Arseniates in Alkaline Salts," by Mr. C. Patrouillard; "Note on Tinctura Camphoræ Composita," by Mr. J. Bland; "The Crystalline Constituent of Jafferabad Aloes," by Mr. W. A. Shenstone; "The Sale by Public Auction of Spurious and Worthless Drugs," by Mr. E. M. Holmes; "Further Observations on Arsenic," by Messrs. W. A. H. Naylor and J. O. Braithwaite. In addition to the foregoing, at the February meeting, Dr. Parker, Physician to the Queen of Madagascar, exhibited a series of specimens of the Malagasy materia medica and furnished some interesting information concerning them.

At the Evening Meeting in October the Professors, as usual, made their reports as to the doings of the students in the previous session of the School of Pharmacy. *Il va sans dire* that these reports were favourable, and it is some proof of the good work done in the School that the Pereira Medal,—the Blue Ribbon of Pharmacy, which is open to all who have passed the Major examination during the year, wherever they may have studied,—was once more won by one of its students, who had also distinguished himself by carrying off the three silver medals of the School. After the distribution of the prizes an admirable address was delivered to the students by Mr. Joseph Ince.

The Annual Meeting of the North British Branch was held in May, in the Society's rooms in Edinburgh, under the presidency of Mr. J. B. Stephenson. The Report presented was a favourable one, the operations of the Branch having been carried out with a gratifying amount of success. Many donations to the library and museum were acknowledged, and the attendance in the Society's rooms for the purpose of study was stated to be on the increase. Mention was made of the large proportion of failures—60 per cent.—in the Preliminary examination, among students who during the year had sat at the Scotch centres, as likely to draw attention to the elementary education of the younger members of the calling, and an opinion was also expressed that the curriculum scheme is fraught with issues of the greatest importance to the future of pharmacy in this country. The arrangement under which the duties formerly performed by the late Honorary Secretary, Mr. JOHN MACKAY, are now divided between an Honorary Treasurer, appointed by the Council in London, and the ordinary Secretary to the Branch, were reported to be working smoothly and satisfactorily. After the Annual Meeting the newly elected executive chose Mr. ALEXANDER NAPIER, President, and Mr. JOHN NESBIT, Vice-President, for the ensuing year.

The Chemists and Druggists' Trade Association of Great Britain held its Annual Meeting in London in May. The Report recounted a considerable amount of work done by the Association in the defence of some of its members, also in the prosecution of offenders under the seventeenth section of the Pharmacy Act, and in various other ways; but the balance sheet showed that notwithstanding this the receipts had been insufficient to meet the current expenses by about two hundred pounds. As no statistics are given as to membership, it is not quite clear whether this resulted from a falling off in the number of members or from the failure of members to pay their subscriptions promptly, which it was said by one of the speakers had reduced the income that should have been derived from this source by about 60 per cent. Suggestions were made as to the best means of increasing the number of members, and the more efficient collection of subscriptions. It is to be hoped that these measures may be successful, or else the Executive of the Association will become seriously cramped in the carrying out of the good work for which it is peculiarly fitted, if, indeed, the Association itself does not come within measurable distance of collapse. Last month the Association organized a meeting in London to give the chemists and druggists of the Metropolis an opportunity of conferring together on trade matters, but it cannot be said that the attendance was sufficiently numerous or the discussion of such a nature as to encourage the Executive to repeat the experiment.

The Annual Meeting in May and the presence of many members and friends of the Pharmaceutical Society in London at that time again afforded the occasion for a Conversazione in the South Kensington Museum and a Dinner at the Freemasons' Tavern. These festive meetings were as usual preceded by a "Chemists' Ball," in January. But last year the junior members of the calling also organized a Ball and a Dinner, with a success that warrants a repetition. Are these multiplied junketings, to say nothing of the "scientific outing" in connection with the British Pharmaceutical Conference, to be deemed signs of the times, and if so what may they be supposed to indicate in relation to the "deep and general discontent" spoken of by the late President? Certainly, according to the statistical abstract published in *Kemp's Mercantile Gazette*, only just over half as many chemists and druggists failed in business in 1882 as failed in 1881.

The proceedings of the Council of the Pharmaceutical Society of Ireland have been regularly reported in this Journal. This Society, like its sister Society in Great Britain, has had to regret a slight decrease in the number of its members, though unfortunately it is yet too young to be so well able to spare them. The attention of the Council has been devoted principally to the consideration of desirable amendments in the Pharmacy Act, Ireland,—especially with respect to the registration of "druggists," who are allowed to sell poisons but not to compound medicines,—and the nature and extent of the practical experience to be required from candidates for the examination. The Annual Meeting was held in October, when Professor TICHBORNE was unanimously re-elected President, Dr. AQUILLA SMITH, Vice-President, and Mr. HODGSON, Treasurer. Before the meeting broke up a committee was appointed to report on the best means of making the Society more attractive and of inducing licentiates to become members.

The British Pharmaceutical Conference met in Southampton at the end of August, under the presidency of Professor ATTFIELD, when a report was presented showing some falling off in the number of members, which, however, it was believed would prove to be only temporary. About the usual number of papers were read, most of which will be referred to elsewhere. But the feature of the meeting was undoubtedly an exceptionally able address delivered by the President, having for its subject the collection, preparation, and distribution of drugs. As usual, in the same week the British Association met in the same town, with Dr. C. W. SIEMENS as its President, whilst earlier in the same month the British Medical Association held its jubilee meeting in the city of Worcester. The German Pharmaceutical Association met in Berlin in the first days of September, under the guidance of its popular President, Dr. C. BRUNNENGRÄBER, and the meeting was attended by the President of the International Pharmacopœia Commission, Herr A. von WALDHEIM, who made a very satisfactory statement as to the progress of that work. Then, a few days later, the American Pharmaceutical Association held a successful meeting at Niagara Falls, its two Presidents being Professor P. W. Bedford and Mr. C. Heinitsh. Lastly, almost simultaneously, the Austrian Pharmaceutical Association met at Agram.

A large number of prosecutions for offences under the Pharmacy Act have been instituted during the past year. Those for a breach of the fifteenth section by the illegal assumption of a protected title were, of course, carried out in the name of the Registrar, acting under the instructions of the Council of the Pharmaceutical Society. Most of the prosecutions under the seventeenth section, for the offence of insufficient labelling of poisons, were undertaken by the Executive of the Trade Association, and only a few of them were initiated by the police. It is very desirable, however, as pointed out by Mr. Greenish at the Annual Meeting, it should be more generally understood that the provisions of the Act of Parliament do not throw upon the Pharmaceutical—or any other—Society the onus of prosecutions under the seventeenth section, since these can be instituted by any member of the public, and might, with advantage, be undertaken more frequently by the Public Prosecutor or the police.

The cases of death by poisoning during the year do not call for any particular remark, except that as usual several have been due to narcotic preparations, and a number more than usual to one or other of the poisons which the Privy Council has recently declined to include within the Schedule.

There have been a few cases of excise proceedings worthy of being mentioned briefly. One of the most noticeable of these was a prosecution by the Inland Revenue authorities of a person carrying on the business of a "Drug and General Supply Association," on the charge of having sold laudanum, a preparation capable of being used internally as a medicine, in the making of which methylated spirit had been used. The defence offered was the remarkable one that the laudanum had been made with duty-paid proof spirit, to which wood spirit had been added to make it clear and to give it the particular flavour preferred by the people of the district. The magistrates considered the case doubtful, and gave the defendant the benefit of the doubt. In another Excise prosecution for the sale of paregoric made with methylated spirit the offence was attributed to a mistake, but a modified penalty was inflicted. Another important Excise prosecution was for the several offences of using a still, compounding spirits in the preparation of "essences," and the separation of gum resin from methylated "finish." A conviction was obtained, and the penalties imposed amounted altogether to £1275.

The history of the sciences upon which the practice of pharmacy is based bears also the character of a quiet year. Many new remedies have been proposed, old ones have received new applications, discoveries of new principles have crowned chemical research, and numerous suggestions have been published having a bearing upon practical pharmacy; but there has been no one subject of greatly predominating importance, and, probably, no very momentous addition has been made to the materials previously in use for combating disease. Perhaps the most interesting fact of the year has been the reduction to a certainty of what had before been only a suspicion, that the barks which under the name of "cuprea" have, during the last two or three years, attained such importance as a source of quinine, are not derived from plants belonging to the genus *Cinchona*. This was first announced in a paper published in this Journal in April, the fact having been determined by the celebrated quinologist, Dr. Triana, as the result of an examination of specimens of the plants yielding the barks received from Columbia, which proved to belong to two species of *Remijia*. There appear to be at least three different varieties of bark which have been imported under the name of "cuprea." But the best known of these, and probably the richest in quinine, is that which was first introduced as coming from Bucaramanga, in the north of Columbia; this is said to be derived from plants growing in the mountainous regions of La Paz, which have been referred by Dr. Triana to *Remijia Purdieana*. Two other varieties derived from plants growing in a district further south, beyond Bogota, in the Orinoco basin, have been referred to *R. pedunculata*. The importance of this determination depends upon the fact that a new series of plants, which are said to be more hardy and easily cultivated than cinchonas, have been rendered available as a source of the important febrifugal alkaloids which had been previously supposed to be confined to that genus. Some interesting observations by M. Arnaud show that all these cuprea barks have a greater density than any of the cinchona barks, varying from 1·128 to 1·320, whilst the greatest specific gravity noticed in a cinchona bark was 1·077. According to analyses made by M. Arnaud, the Orinoco cupreas do not as a rule equal Bucaramanga bark in the quantity of quinine they contain; but all these barks are remarkable for the proportion of quinidine present, and the absence of cinchonidine. Amongst the bark from Bucaramanga a very dense variety is sometimes met with, which is nevertheless considered by Dr. Triana to be the product of the same species growing under different conditions. It is noteworthy, however, that it is from this variety that M. Arnaud claims to have separated a peculiar alkaloid which he has described under the name of cinchonamine. It may be here mentioned that the alkaloid, which under the names of "homoquinine" and "ultraquinine" was described simultaneously by three sets of observers at the close of last year, has been the subject of an investigation by Dr. HESSE, who has described its physical properties more minutely and attributed to it the formula, when dried at 120° C., of $C_{19}H_{22}N_2O_2$. The neutral sulphate is described as crystallizing with six molecules of water in short prisms. As homoquinine sulphate resembles quinine sulphate in its sparing solubility in water, Dr. HESSE thinks it is probably frequently present in the commercial salt; but "homoquinine" is markedly distinguished from quinine by its sparing solubility in ether. Herr KÖRNER has made the curious observation that during the manufacture of sulphate of quinine from cuprea bark a notable quantity of caffeic acid is formed, evidently as the product of the breaking up of a complex substance existing in the bark together with the alkaloid, and this is found in the mother-liquor in the state of caffeate of quinine. The genera *Cinchona* and *Coffea* both belong to the same natural order, although not to the same tribe, and this chemical confirmation of botanical relationship has its counterpart in a previous observation of quinic acid in the coffee plant.

One plant that promises to come into use is the well-known "lily of the valley," *Convallaria majalis*. It is said to exercise an action upon the heart similar to that of digitalis and also to be one of the most powerful diuretics known. From experiments made by M. LANGLEBERT it would appear that the best cardiac results are obtained with an aqueous extract prepared from the flowers and stalks with the addition of a third of their weight of the roots and leaves. The diuretic results appear to depend upon a resinous principle which is taken up in an alcoholic extract. Probably, however, the form in which this medicine will be most frequently administered will be by using "convallamarin," one of two glucosides present in the plant and which appears to be its active cardiac principle. Another plant yielding a glucosidal principle described as having an action similar to digitalin, but far more powerful, is the *Adonis vernalis*. The glucoside has been separated and described under the name of "adonidin" by Dr. CERVELLO, who claims for it that it has the advantage of not being cumulative.

The uncertain nature of preparations of aconite has been the subject of several papers. At the Evening Meeting in March, Messrs. CLEAVER and WILLIAMS called attention to an extract prepared from *Aconitum paniculatum* which failed to produce on the tongue the peculiar tingling sensation characteristic of the official extract, and contained a small amount of a very bitter alkaloidal substance, which they were disposed to think might be identical with the non-poisonous picraconitine observed on one occasion by Mr. GROVES. Mr. HOLMES afterwards referred to the non-production of the tingling sensation by varieties closely resembling the official aconite in a paper read before the Pharmaceutical Conference, and having expressed the opinion that the description of the official plant in the Pharmacopœia is insufficient, proposed to limit the official drug to home-grown aconite flowering in May and June and gathered when the plant is in flower. Dr. SQUIBB also looks upon the tingling indication as valuable and has suggested a rough standard for the strength of aconite preparations, based upon the time which elapses before it is produced by aqueous dilutions of them. The varying potency of different alkaloidal substances supplied under the name "aconitine" has also been illustrated by physiological experiments in connection with a legal inquiry in Holland, in which one preparation was estimated to be one hundred and seventy times more powerful than another. Some experiments made by Dr. SQUIBB also point in the same direction, and to this consideration no doubt is to be attributed the omission of aconitine from the new editions of the German and United States Pharmacopœias.

Mr. GERRARD has contributed further information as to the alkaloidal value of belladonna plants at different periods of their growth. His experiments with wild plants seemed to indicate that the development of alkaloid is favoured by a chalky soil, but that very little is formed in the first year. Those with the cultivated plant appeared to show that the greatest development of alkaloid takes place simultaneously in the root and the leaf at the flowering period and is maintained during the fruiting. The substitution of the root of *Medicago sativa* for belladonna root has been observed by Mr. HOLMES.

Under the name of "tambor," specimens of a tree growing in Central America were received by the late Mr. HANBURY with the information that its fruit yields by pressure a large quantity of a very fine oil, resembling castor-oil in its purgative effect, but rather pleasant to the taste, and with the advantage that it does not gripe. The herbarium specimens have now been described by Mr. HEMSLEY as belonging to a new species, to which he has given the name *Omphalea oleifera*. Another plant which has been identified as the source of a fragrant volatile oil, said to come from Jamaica under the name of "tobacco-bush oil," and may eventually be utilized, is the *Hedyosmum nutans*. The plant itself is popularly known as the "headache weed," and is said to be generally used by the natives for making tea and binding round their heads when in pain, whilst a preparation of the leaves and flowers is said to be used as a stomachic and spasmodic. An interesting description of the manufacture on a large scale of an essential oil from an American species of birch, the *Betula lenta*, has been given by Mr. G. W. KENNEDY. The whole plant is used for distillation, and the oil is sold as "oil of wintergreen," which it closely resembles. The production of peppermint oil on the large scale in New York State has been also described. It is said that this oil, as exported from Wayne county, is colourless and resembles the English oil, except that its odour and taste are somewhat less pungent and penetrating. With respect to the source of Chinese and Japanese peppermint oil, Mr. HOLMES, having made a curious observation that typical specimens of *Mentha arvensis*, var. *Javanica*, from which plant it has been said to be derived, had not the taste of peppermint, but a flavour similar to that of *M. viridis*, took the trouble to obtain from China and Japan specimens of the peppermint plants of those countries. Both plants were found to possess most of the characters of *M. arvensis*, but the Chinese plant was found to more closely resemble and indeed to be identical with *M. canadensis*, var. *glabrata*, specimens of which, obtained from different localities in the United States, were found to possess the flavour of peppermint in a feeble degree. As the chief point in which the Japanese plant differs from *M. arvensis* is in its flavour, Mr. HOLMES proposes to name it *Mentha arvensis*, var. *piperascens*. Mr. HOLMES raises the question whether these variations in the essential oil are dependent on development, climate, soil or sex, and whether the oil in each case is a mixture in which one ingredient is present in variable proportions in different plants. The increasing demand for a preparation known as "bay rum," which is made by the distillation of the leaves and berries of the bayberry tree (*Myrcia acris*) with rum, has directed some attention to other members of the Myrtaceæ yielding aromatic volatile oils, and an exhaustive enumeration of them has been supplied by Professor MAISCH. The botanical source of another essential oil, oil of cassia, would appear now to be satisfactorily cleared up. Herbarium specimens in flower, derived from the districts in China in which the cassia tree is cultivated, show that the plant is the *Cinnamomum Cassia*, and, as far as can be ascertained, "cassia lignea," cassia buds, and the leaves from which oil of cassia is distilled, are obtained from this tree only. It may be mentioned here that, according to a report presented by Mr. A. H. JACKSON to the Conference, although the oils of cinnamon and cassia may be distinguished from each other by their odour and taste, they have no other very characteristic physical property in which they differ, and a chemical examination indicated that any constituents in which they might differ from each other are present only in extremely small proportion.

One of those thorough investigations of crude drugs with which the name of Dr. HESSE is associated, has been carried out by him in respect to the barks and wood coming from the Argentine Republic under the name of Quebracho. From the bark derived from one of the Apocynaceæ, *Aspidosperma Quebracho*, besides the alkaloid aspidospermine, separated by FRAUDE, he obtained five other alkaloids, which he named aspidospermatine, aspidosamine, hypoquebrachine, quebrachine and quebrachamine, as well as a neutral substance which he called quebrachol. In the Quebracho wood from *Loxopterygium Lorentzii*, a terebinthaceous plant, which has been used in medicine, he could find no alkaloid at all, but in the bark of this wood he found indications of two alkaloids, one of which he named loxopterygine. The *Aspidosperma* alkaloids appear to have a physiological action similar to that of the *Strychnos* bases, but less powerful. Messrs. HECKEL and SCHLAGDENHAUFFEN have made a thorough investigation of "m'boundu," the Gaboon ordeal poison, which has been said to contain two special alkaloids, but they have come to the conclusion that strychnine, which is present in the root bark, stem bark and leaves, is its sole alkaloid and active principle. Another crude product, said to have an action similar to curare, and called "guachamacha," has been introduced from South America; it consists of an aqueous extract derived from one of the oleanders. Box-tree bark has been alleged to contain alkaloidal substances which are capable of being used as substitutes for quinine. The subject has been thoroughly investigated chemically by Mr. ALESSANDRI, who found that the *Buxus sempervirens* contains three special and distinct alkaloids, namely, buxine in the bark, buxeine in the leaves, and parabuxine in both the bark and the leaves. Buxine has been stated to be identical with bibeerine and also with pareirine and paricine; this point, however, and the physiological action remain yet unsettled. It may be mentioned here that Mr. ALESSANDRI used oxalic acid as a means of separating these alkaloids, and he has also applied the method to the separation of the cinchona and other bases.

A great deal of other interesting work was done last year in connection with the alkaloids. Revising the statements of previous experimenters, Mr. DOTT came to the conclusion that Dr. HESSE was mistaken in supposing that the methyl-morphine obtained by M. GRIMAUX in acting with methyl-iodide on morphine dissolved in alcoholic solution of soda was isomeric, but not identical with codeine. This was practically admitted by Dr. HESSE in a subsequent communication, he having apparently been misled by the formation at the same time of a di-methyl compound. Mr. DOTT has also done some very valuable work towards clearing up the confusion which existed respecting the solubility of salts of morphine, and in respect to this alkaloid he has further illustrated the untrustworthiness of many of the so-called colour reactions. Herr FISCHER, starting with xanthine has succeeded in introducing two methyl groups into it to produce theobromine, and this by the introduction of another methyl group has been converted into caffeine. M. Tanret has provided a convenient method of obtaining caffeine in solution by forming very soluble double salts with benzoate, cinnamate or salicylate of soda. Atropine has yielded two new bases by treatment with nitric acid, one by the loss of the elements of water, called "apoatropine," which is crystalline and forms crystalline salts, but does not cause dilation of the pupil; the other, called "nitroatropine," not forming crystalline salts, but dilating the pupil of the eye. Herr Ladenburg has made further progress towards the synthesis of atropine, starting from pyridine, whilst on the other hand the products obtained in the decomposition of atropine, of brucine, and other alkaloids, have given some confirmation to the suggestion of Dr. Königs that the pyridic nucleus should be considered analogous to the benzoic nucleus, and that under the name "alkaloid" should be understood organic vegetable bases which are pyridic derivatives. Erythrophleine, the alkaloid of sassy bark, has been found by Messrs. Gallois and Hardy to break up in a manner analogous to atropine into an acid and another base. Some further experiments by Mr. Shenstone on the nux vomica alkaloids appear to show that brucine is strychnine in which two atoms of hydrogen are replaced by two methoxyl groups. Dr. Hoffman has shown that the formula for coniine wanted amending by the addition of two atoms of hydrogen, and that it is correctly represented as $C_8H_{17}N$; consequently conydrine is not a hydrate of it as supposed.

Besides the investigation in respect to homoquinine, before referred to, Dr. Hesse has given further information respecting some of the more uncommon cinchona alkaloids, and has described a new one, which is liquid, volatile and odorous, and which he thinks may possibly play some part in the formation of quinine; this he has named "cincholine." Dr. de Vrij has defended from attack his process for the quantitative estimation of quinine by means of iodosulphate of quinoidine, and has brought forward strong evidence to show that the herapathite formed under the conditions laid down is very constant in composition. He has also described a modification of Prollius's process for the estimation of the total alkaloids of cinchona bark, in which a mixture of ether, spirit and ammonia is used to extract the bark. In a paper read by Mr. Giles before the British Pharmaceutical Conference, another process for the estimation of the total alkaloids, recommended by Dr. de Vrij, was described, in which the bark is exhausted with dilute hydrochloric acid. In the same paper Mr. Giles put forward a plea for a return to the use of pharmaceutical preparations of the bark. Quinine iodate and bromate have been recommended for therapeutic use by Dr. Cameron, and some attention has been paid to the preparation of a "tasteless" tannate. Among the substitutes for quinine, chinoline continues to hold a place, as well as its tartrate and salicylate; but early in the year Mr. Ekin gave some reasons that the substance supplied at that time as "pure chinoline" was more or less a mixture of homologous bodies. Being sceptical as to chinoline representing all the characteristic properties of quinine, Messrs. Fischer and Königs prepared for physiological experiment a number of compounds by the introduction of various hydroxyl and other groups into the chinoline molecule. It was found that the antipyretic property is possessed to the greatest degree by compounds in which the nitrogen atom is joined with two atoms of carbon in the chinoline ring and an atom of carbon in a methyl or other alcohol group. This occurs in three known compounds, but the most convenient for preparation is oxychinolinmethylhydride, which has been named more briefly "kairine."

Several new vegetable principles, besides those already mentioned, have been isolated during the year. Among the alkaloids are "oxyacanthine," which accompanies berberine in the root of the *Berberis aquifolium*; "sapotine," separated from the astringent and febrifuge bark of the West Indian sapotilla tree (*Sapota Achras*); "macleyine," from a Japanese papaveraceous plant (*Macleya cordata*); "nupharine," from the rhizome of the yellow water lily (*Nuphar luteum*); and an unnamed alkaloid from the bark of the white ash (*Fraxinus Americana*). A new poisonous glucoside has been observed in the *Thevetia nereifolia*; a poisonous neutral principle has been isolated from the Japanese ericaceous plant, *Andromeda japonica*, and named "asebotoxin," and quassiin has been found to be present in very variable quantities in the wood of both *Quassia amara* and *Picræna excelsa*. Salicylic acid has been found to be present in all parts of *Viola syrtica* and *V. tricolor*. Dr. Wormley has negatived the assertion that gelsemic acid is identical with æsculin. Mr. Shenstone has examined Jafferabad aloes and obtained an aloin from it apparently identical with the aloin from Zanzibar aloes, and Dr. Lenz has shown that what is known as Bornträger's test for aloes is untrustworthy, as the reaction is common to bodies containing chrysophanic acid. Herr Singer has found that lignin is a complex body, of which vanillin is an invariable constituent, and that probably this principle is present in minute quantity in all woody tissue. Lastly, the chemistry of bast fibres has been studied by Messrs. Cross and Bevan, who have not only rendered a service to science by explaining some of the causes of the tendency of jute goods to spoil, but have worked out the history of a number of new compounds formed by the action of chemical reagents upon vegetable fibre.

Synthetical chemistry has also made some progress during the year, perhaps the most interesting step being the very recent synthesis of uric acid from urea and glycocoll by Dr. HORBACZEWSKI. Thymol has been built up partially, starting with cuminol, the principal constituent of the essential oil of cumin. Lactic acid has been prepared artificially by heating dextrose with a caustic alkali, neutralizing with sulphuric acid and removing the sulphate by means of alcohol. Succinic acid has been produced by the fermentation of tartaric acid set up by a few drops of a fermenting solution of ammonium tartrate. Bromochloral, chlorobromal, and their hydrates and alcoholates, and bromochloroform and chlorobromoform, are the names of a number of allied compounds that have been produced by the action of bromine and chlorine upon alcohol. Here also may be mentioned an able paper on terpene hydrate read by Mr. R. H. PARKER before the Pharmaceutical Conference.

Turning to another class of chemical subjects, reference must be made to the masterly papers of Messrs. NAYLOR and BRAITHWAITE, which have disposed of a misstatement in chemical manuals and shown that neither oxalic acid nor oxalates exercise a reducing action upon arsenic acid or arsenates. Professor TICHBORNE has suggested a new method of making soap solution for testing the hardness of water, and also a new form of apparatus for preventing contamination from atmospheric impurities during the estimation of ammonia in water. The colour reaction between gallic acid and nitrous acid has been utilized by Dr. DAVY in the determination of nitrites in water. A method of preparing bismuth subnitrate free from arsenic has been recommended by Mr. SCHNEIDER, based upon the insolubility of bismuth arsenate in a concentrated neutral solution of bismuth nitrate. Mr. FLETCHER has observed a new very basic iodide of bismuth, simulating iodide of lead, and four salicylates of mercury have been described by Mr. LAJOUX.

Recently the hypophosphites have come much into use, and Mr. GIBSON has done useful service in working out and publishing a process for the preparation of the compound solution, which, although it has been subject to criticism, will probably yield a product sufficiently satisfactory to most prescribers. A useful formula for a soluble saccharate of iron has also been worked out by Dr. BRUNNENGRÄBER. Other pharmacists have furnished formulæ for ferrated albumen, albuminated ferrous borotartrate, and mercurial peptones. Ammoniated preparations of ergot have recently assumed some prominence, and a formula has been furnished by Mr. GERRARD. It has been suggested that the definite salts should be used in making preparations of the oleates, but Dr. SQUIBB has given reasons for preferring a solution of the oleate in oleic acid, based on the facility with which oleic acid is absorbed by the skin. Cotton seed oil has been recommended for pharmaceutical use in the preparation of lead plaster and different liniments. Chlorinated oil is a preparation that has been reported to be coming into use in the United States for chronic affections of the skin. The use of the heavier paraffins derived from petroleum has now received official sanction by the admission of a "petrolatum" into the United States Pharmacopœia; a considerable amount of information has been published respecting the melting points of these semi-solid hydrocarbons, and in the above work two melting points, 104° F. and 125° F. have been adopted. Mr. T. E. GREENISH has pointed out that if petroleum spirit be used to remove fat from nux vomica, it will carry with it also a considerable portion of the alkaloids, but that percolation with coal-tar benzol does not remove any. The influence of gum arabic in retarding certain chemical reactions has been described by M. LEFORT, and is evidently a property that can be utilized in the pharmacy. Gregory's powder has been the subject of further discussion in Scotland. Mr. MACPHERSON has arrived at the conclusion that the chief cause of immiscibility is added fatty matter, and Mr. NESBIT, who has examined samples of rhubarb for fixed oil, is of opinion that the practice of adding oil prevails to a considerable extent. Dr. CLARK, too, has found as much as 7 per cent. in one sample, and is of opinion that the presence of oil is the chief cause of the non-miscibility of Gregory's powder, but that even when it occurs in the powder exposure to moisture or the original presence of moisture is a necessity to the production of this condition. Apart from these interesting observations it may be mentioned that it has been pointed out that the immiscibility of Gregory's powder may be easily overcome by shaking it briskly with water in a bottle. Another pharmaceutical subject that has been brought before the North British Branch is the confection of sulphur, and Mr. PETER BOA has shown that the separation which takes place may be obviated by the addition of two grains of gum tragacanth in powder to the ounce. Mr. MACKENZIE also has suggested the use of a petrolatum in the preparation of cold cream, and his opinion has been confirmed by the experience of Mr. W. H. SYMONS. Mr. BLAND has recorded the observation that he has obtained better results in preparing tinct. camphoræ co. with the oil of *Pimpenella anisatum* than with the oil of star-anise. Lastly, Mr. A. C. ABRAHAM has pointed out the extent to which the preparation of lime water may be affected by temperature.

A great deal of interesting work has been done in investigations of the physiological effects of different ferments and micro-organisms, but although these may exercise much influence on the future of pharmacy they can only be mentioned here with the utmost brevity. The discovery by Dr. KOCH of the bacillus supposed to be the cause of phthisis, and the means of detecting it in the sputa; the researches as to the minute organism alleged to be the cause of paludal disease; the recent discovery by M. PASTEUR of the microbes which are supposed to produce rabies in dogs and pneumo-enteritis in pigs, are all full of promise in respect to the future treatment of disease. Many interesting contributions have also been made to the history of pepsine, diastase and similar ferments, and what has been observed as to the part which bacteria and similar organisms may play in the formation of peptones reveals a wide field of research. Nor is the subject wanting in technical interest, as is shown by the researches on the work done by ferments in the formation of nitrates or in their reduction to nitrites and in the communication of special properties to cheese.

The field of physics is a wide one and workers have been busy therein, but the predominant interest during the year has been devoted to subjects connected with the development, storage and application of electric energy. The magnificent exhibition of electrical apparatus at the Crystal Palace in the spring furnished the pretext for a series of articles in this Journal, in which the chief underlying principles were described with sufficient fulness to render further notice here unnecessary. Other subjects connected with physics have been referred to in "The Month," as they arose. Excuse may, however, perhaps be found for special mention of the interesting address on atoms and molecules, which Mr. B. S. PROCTOR recently delivered before the Newcastle-on-Tyne Chemical Society, on the ground that it was the effort of a well-known practical pharmacist.

The year that has seen the publication of two such important works as the new editions of the Pharmacopœias of Germany and the United States cannot be said to be poor in the production of books interesting to pharmacists. Besides this there have been Dr. WHITLA's little work on the 'Elements of Pharmacy, Materia Medica and Therapeutics,' numberless manuals of chemistry, good, bad and indifferent, and a new edition of BENTLEY's 'Manual of Botany.' Mr. ALLEN has supplied another volume of his important work on 'Commercial Analysis,' and Dr. PHILLIPS another of his 'Materia Medica.' Then, too, Dr. QUAIN's 'Dictionary of Medicine' is a book that will find its way to the bookshelves of some of our readers. Cinchona culture, also, is accumulating a literature of its own, and within the last few days we have received an English translation of a handbook on the subject, written by Mr. VAN GORKOM. Finally another 'Year-Book' is even now making its way into circulation.

The death roll of the year contains some names that lovers of science in succeeding generations will long hold in reverence. Greatest among them all stands that of our own countryman, CHARLES DARWIN, who has left such a mighty impress upon the study of natural history. Another name is that of ANTOINE BUSSY, whose researches upon sulphurous and sulphuric acids must remain a part of their history, and who for many years conducted the most important pharmaceutical journal in France. Germany contributes the name of FRIEDRICH WÖHLER, who by his synthesis of urea obliterated the distinction that had been set up between organic and inorganic compounds. America has lost the two DRAPERS, father and son, but not before each had won a niche in the Temple of Fame. Turning to men who have been more particularly lost to British pharmacy, place must be given to DANIEL BELL HANBURY, honoured for his own services as well as for the sake of those of his son. Sir ROBERT CHRISTISON, also, is a name of which Scotchmen are justifiably proud, bringing to memory good and sympathetic work done in the early days of the Pharmaceutical Society, of which he was an Honorary Member. The North British Branch has also lost in GEORGE BLANSHARD one of its former Presidents. In the North, too, at Leeds, TITUS BENNETT STEAD passed away whilst still holding office as President of the local association. In London the Board of Examiners has lost the genial presence of ALFRED ALLCHIN. Then among other names that will occur to memory are GEORGE HENRY THWAITES, the botanist, A. FREIRE-MARRECO, of Newcastle, SAMUEL URWICK JONES, of Leamington, and ROBERT HOWDEN.

Once more our yearly task is at an end. The subjects enumerated in our review will suffice to show that if pharmacy in Great Britain did not make any demonstrative progress last year it was not asleep. On the threshold of another year, which promises to raise issues of unusual importance to the pharmaceutical community, we venture to offer our wishes that they may be decided in accordance with its prosperity.

THE PROPERTY IN PRESCRIPTIONS.

IN the *Lancet* last week a case is put by a patient who received a prescription from his doctor, with an intimation that it could only be made up at a certain establishment. Some time afterwards, considering himself to be in need of the same medicine, he took the prescription to the same chemist, who, however, refused to make it up on the ground that he had been told by the doctor not to dispense it without his sanction, and this statement was confirmed on communicating with the medical man. The patient contends that the prescription is his property and that he is free to have it made up every day if he chooses, and asks the opinion of the Editor of the *Lancet* on the point. The answer given, which at any rate cannot be said to be wanting in "lucidity," is as follows:—"A medical "man is at liberty to make his own terms as to "attendance, but the system described in our cor- "respondent's letter is not generally practised or "approved. A medical man either dispenses or "prescribes. If he prescribes, the prescription "ought to be the property of the patient, to be "used when and how he pleases, and ought to be "written so that it may be compounded by any "legally qualified chemist."

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, January 3, 1883.

MR. MICHAEL CARTEIGHE, PRESIDENT.

MR. SAMUEL RALPH ATKINS, VICE-PRESIDENT.

Present—Messrs. Andrews, Bottle, Butt, Churchill, Gostling, Greenish, Hampson, W. Hills, Radley, Richardson, Robbins, Savage, Schacht, P. W. Squire, Symes, Williams and Woolley.

PUBLICATION OF THE LIST OF SUBSCRIBERS TO THE BENEVOLENT FUND.

The minutes of the previous meeting were read and confirmed, as also the minutes of the meeting of Subscribers to the Benevolent Fund for the election of annuitants.

Mr. SYMES drew attention to what he considered to be an omission from the minutes, as published in the Journal, viz., that after reading the Benevolent Fund minutes it was announced that the resolution of the Council passed in October or November was to some extent set aside. He then suggested that, as the date of publishing the list of subscribers to the Benevolent Fund had been postponed for the convenience of the office, some notice should be taken of it, in order that those who had seen the former resolution and were expecting the list might understand why it did not appear at the time named. He did not find any notice of the matter in the Journal, which appeared to him a little discourteous to the subscribers.

Mr. RICHARDSON said another matter of regret in connection with this subject was that no notice had been given to the publishers, Messrs. Churchill, that such publication was about to be carried out; and he feared some loss might accrue in consequence, as an extra number of advertisements might be expected for such special number, had due notice been given.

The PRESIDENT remarked that until the recommendations of the Committee were approved by the Council no formal notice of the matter could be given to the publishers. As soon as the Council had sanctioned the issue notice was given. With regard to Mr. Symes's remarks, the fact of the postponement was stated in the Journal in the report of the Library, Museum, Laboratory and House Committee to the Council last month.

Mr. SYMES, having referred to the report, said he found the matter was mentioned there, but he had overlooked it, having expected to find it after the report of the Benevolent Fund Committee.

THE BOARD OF EXAMINERS.

The SECRETARY read a letter which had been received from the Privy Council, approving the appointment of Examiners as reported last month.

DIPLOMAS.

The following, being duly registered as Pharmaceutical Chemists, were respectively granted a diploma stamped with the seal of the Society:—

Burton, Walter.
Fowler, George.
Marshall, Joseph Jewison.
Nichol, Anthony.
Richards, Thomas.
Williams, William Jesse.

ELECTIONS.

MEMBERS.

Pharmaceutical Chemists.

The following, having passed the Major examination and tendered their subscriptions for the current year, were elected "Members" of the Society:—

Jones, John ....London.
Knight, William Tomkinson ...Peterborough.
Thornley, Frederick...............London.
Williams, William Jesse.........Gloucester.

Chemists and Druggists.

The following registered chemists and druggists, who were in business on their own account before August 1, 1868, having tendered their subscriptions for the current year, were elected "Members" of the Society:—

Gilbert, Charles Edwin ....Dawley.
Kearnes, Robert Henry ....Bilston.

ASSOCIATES IN BUSINESS.

The following, having passed their respective examinations, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:—

Minor.

Buckley, James Julian ....London.
Lawrence, Samuel ....Oban.
Llewellyn, Lewis Herbert ......Bridgwater.
Milner, Thomas ....Consett.
Willet, John Algernon ....Port Elizabeth.

Modified.

Evans, Charles Edward ....Moretonhampstead.
Gooseman, William ....Grimsby.
Pooley, John Dingley S..........Wimbledon.

ASSOCIATES.

The following, having passed the Minor examination and tendered their subscriptions for the current year, were elected "Associates" of the Society:—

Cardwell, Augustus ....Derby.
Chater, Arthur Brand ....Elmdon.
Collins, Herbert Sleight ....Bradford.
Deacon, Frederick George ......Frome.
East, William Alfred ....Princes Risbro.
Fleming, Ebenezer ....Castle Douglas.
Jenkin, William John..... ......Plymouth.
Lambert, John Thomas ....Hoyland.
Langley, Frank Collins ....Ashford.
Luxmoore, Charles Mann ......Bristol.
Miller, William Philip F. ......Folkestone.
Pask, Thomas Edward ....Newark.
Perkins, Charles Lynham ..... Plymouth.
Pridmore, Sydney Spencer ......Hinckley.
Ridgley, Cromwell ....Huntingdon.
Sharpe, William Cecil............Madeley.
Whiffin, Henry.......................Market Harboro.

APPRENTICES OR STUDENTS.

The following, having passed the Preliminary examination and tendered their subscriptions for the current year, were elected "Apprentices or Students" of the Society:—

Baxter, William ....Bromley.
Bennet, Andrew Russell.........Uphall.
Black, Hugh Milner ....London.
Borthwick, Robert Waddell .. Bathgate.
Brett, William George ....Grantham.
Burnby, John James ....Bardney.
Clark, Alfred Turner Sims......London.
Cock, John Frederick .. ..Southsea.
Corder, Edward ....Norwich.
Crockett, Henry ....East Grinstead.
Dodd, Richard Jefferson.........Sunderland.
Dymond, Thomas Southall......Bristol.
Elliott, Stephen James ....Preston.
Foster, William ....Dewsbury.
Granger, Harold ....Nottingham.
Hendry, Robert Love ....Edinburgh.
Herbert, Sydney Reeves.........Cockermouth.
Hersant, Milton ....London.
Hine, Alfred Ernest...............Beaminster.
Howell, Alfred.......................St. Clears.

Jackson, Herbert .... Horncastle.
Lees, James .... Manchester.
Lewis, Alfred Wheatcroft ...... Swansea.
Lomax, William Henry .... Over Darwen.
McDonald, James .... Lochee.
McEwan, Donald................. Dunfermline.
Mack, George Henry .... Holt.
Marsh, Charles David .... Devizes.
Marsh, William Henry .... Old Catton.
Mason, John Henry............... Wirksworth.
Mathias, James Russell Hy. ... Tenby.
Midgley, Walter .... Keighley.
Morris, David Henry M.......... Sunbury.
Munkman, Robert Allen......... Boston.
Pickering, Charles Edward...... Stockton-on-Tees.
Pidgeon, Alfred .... London.
Porter, Caleb Thomas George... London.
Pottage, John Wm. Dick ...... Edinburgh.
Rees, David .... Newcastle Emlyn.
Roberts, James Frederick ...... London.
Rudd, Henry Bulmer .... Bradford.
Sowden, Joseph .... Bowling.
Sugden, William Allen .... Waterfoot.
Thompson, Abraham Lewis ... Birmingham.
Tilley, Joseph .... Chelmsford.
Wilkes, Thomas .... Shrewsbury.
Wilson, Richard .... Kidderminster.
Wright, William Charles ...... Stockport.
Zusman, Harry...................... Wolverhampton.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a fine.

The names of the following persons, who had made the required declarations and paid a fine of one guinea, were restored to the Register of Chemists and Druggists:—

Andrew Duncanson, 4, East Thomas Street, Edinburgh.

John Wilkins Hodgson, 28, Mariner Street, Swansea.

Reports of Committees.

LAW AND PARLIAMENTARY.

Draft Pharmacy Bill.

The Council went into committee to receive the report of this Committee and to discuss in detail a draft Pharmacy Bill which it had prepared. The discussion having lasted several hours,

The Council resumed, when the following resolution was adopted:—

"That the report of the Law and Parliamentary Committee of November 22, December 18 and December 28, be received and that the draft Pharmacy Bill be again referred to the Committee with power to confer with the Privy Council thereon."

Mr. Schacht said he must now ask that his name might be withdrawn from the Committee, as he should not be able to take any further part in its proceedings.

The President suggested that Mr. Schacht should defer this matter for another month.

Mr. Schacht said he could not allow the matter to be postponed. It was no spasmodic action on his part. He had resolved some time ago that if there were a definite expression of opinion on the part of the Council in favour of two particular clauses in the draft Bill, he could not continue to act on the Committee.

FINANCE.

The report of this Committee was received and adopted, and sundry accounts were ordered to be paid.

BENEVOLENT FUND.

The report of this Committee included a recommendation of the following grants:—

£10 to a former member, suffering from chronic disease, who has had eight previous grants of like amount.

£10 to the widow of a pharmaceutical chemist, who has had a previous grant.

£10 to the widow of a chemist and druggist and former member, and subscriber to the Fund.

£15 to the widow of a chemist and druggist, having six children dependent on her, who has had one previous grant.

£5 to the widow of a registered chemist and druggist, who has had three previous grants.

£10 to the widow of a registered chemist and druggist, who has had two previous grants of like amount.

£10 to the widow, aged 75, of a registered chemist and druggist.

One application which had been deferred twice for further information had been now definitely refused.

The gentleman who has charge of two of the Isherwood orphans (boys) had had an interview with the Committee, and had been requested to make some suggestion at an early date with regard to some employment for the elder boy, now in his fourteenth year.

The report and recommendations of the Committee were unanimously adopted.

Librarian's Report.

The report of the Librarian had been received, and included the following particulars:—

	Attendance.	Total.	Highest.	Lowest.	Average
November .	Day . . .	627	33	19	24
	Evening . .	243	19	6	11

	No. of Entries.		
Circulation of books.	Town.	Country.	Total.
	196	146	342

Carriage paid, £1 15*s.* 11½*d.*

The following donations to the Library had been received, and the Committee recommended that the usual letter of thanks be sent to the respective donors:—

Allgemeiner österreichischer Apotheker-Verein, Zeitschrift, 1882. From the Verein.

Alumni Association of the Philadelphia College of Pharmacy, Eighteenth annual report, 1882. From the Association.

American Journal of Pharmacy, 1882. From the Philadelphia College of Pharmacy.

American Pharmaceutical Association, Proceedings, vol. 29. From the Association.

Analyst, 1882. From the Editors.

Annuaire des Spécialités médicales et pharmaceutiques, 1882. From the Publishers.

Archiv for Pharmaci og technisk Chemi, 1882. From the Publishers.

Botanical Society [of Edinburgh], Transactions, vol. 14, part 2. From the Society.

Canadian Pharmaceutical Journal, 1882. From the Ontario College of Pharmacy.

United States Pharmacopœia, 1882. 2 *copies.*
Journal of the Chemical Society. Sundry numbers to complete.

An application for the loan of microscopic slides having been laid before the Committee, it was decided that it is not advisable that slides should be lent out of the Society's building.

Curator's Report.

The Curator had reported the average attendance in the Museum during November to have been:—

	Total.	Highest.	Lowest.	Average.
Morning .	395	26	2	15
Evening .	104	13	0	5

The attendance during the year 1882 showed a slight increase over that of the previous year:—

	1881.	1882.
Morning	3071	3089
Evening	774	894
	3845	3983

The following donations to the Museum had been received, and the Committee recommended that the usual letter of thanks be sent to the respective donors:—
Leaves of *Croton balsamiferum.* From Mr. EADE.
Unusually fine specimens of Orris Root, China Root and Zanzibar Amine. From M. CHANTRE.
Specimen of Spurious Opium found mixed with the genuine. From Mr. J. R. YOUNG.
Three specimens of *Endogenites erosa* from the Sussex Wealden. From Mr. G. A. KEYWORTH

Herbarium specimens of *Erigeron Philadelphicum*.

From the DIRECTOR OF THE ROYAL GARDENS, KEW.

Specimen of Aloin and Tribromo-Aloin from Jafferabad Aloes.

Crystalline mass of Xanthate of Potassium.

From Mr. F. H. ALCOCK.

The Professors had reported satisfactorily of their respective classes.

The Secretary had reported that he had written to the India Office asking that further specimens of Cinchona barks grown in India might be forwarded to the Museum, and had received a reply stating that his request had been forwarded to India with the desire that it might be complied with as fully as possible.

It was also reported that the President had been in correspondence with the Colonial Office respecting the forwarding of drugs, colonial products, and papers relating thereto, to the Museum of the Society, and had received a promise that it should be done.

The Committee had ordered the Library and Museum be closed for the usual period during the Christmas vacation.

The report was received and adopted unanimously.

GENERAL PURPOSES.

This report, which was taken in committee, consisted merely of the usual letter from the Solicitor respecting cases which had been placed in his hands. He reported that—

R. Preston, Bury, had paid the penalty and costs.

Thomas McCreath, Newton Stewart, had paid a penalty and costs; and

John Lawson, Newton Stewart, had also paid a penalty and costs.

The report was received and adopted.

CORRESPONDING MEMBERS.

The PRESIDENT then moved the following resolution:—

"That it is desirable to institute a class, limited in number, of Corresponding Members, to consist of such persons as have distinguished themselves in pharmacy, or any of the branches of knowledge embraced in the educational objects of the Society.

"The class of Corresponding Members shall consist of persons who reside permanently *outside* the limits of the United Kingdom.

"The election of Corresponding Members shall take place annually in the same manner and under the same conditions as Honorary Members.

"That it be referred to the Library, Museum, Laboratory and House Committee, to consider and report what limit should be fixed as the number of such Corresponding Members, and as to the best way of carrying out the foregoing resolutions."

He said he would remind the Council that in almost all societies interested in the advancement of science and knowledge generally there are two classes of non-paying members, men whom it is desired by the Executive of such societies to have within their fold, but who are not liable to pay the subscriptions of ordinary members. They are honorary members in the one case, and corresponding members in the other. Honorary members are men distinguished either at home or abroad, whilst corresponding members are drawn from countries outside that in which the society has its existence. The Pharmaceutical Society, at different times, had received very great encouragement from distinguished pharmacists abroad, some of whom were also eminent chemists, physicists and botanists, but it had been out of its power hitherto, except in a few cases, to show its appreciation of their interest in British pharmacy by conferring upon them any title. He felt sure that this resolution, which proposed to allow the Council the opportunity of doing so, would commend itself, not only to his colleagues, but to the Society at large. There were many distinguished men who had worked for pharmacy and sent papers to the Journal, and some of whom had actually come to the Society's house and taken part in the deliberations for the advancement of pharmacy, but who resided on the Continent, in the United States, India, Australia and other places. There were many, also, who correspond with the Society's officers, and who show generally an active interest in the efforts of the Society, and he felt that their co-operation would be fittingly acknowledged by enrolling them as corresponding members. To many of these distinguished men the privilege of an honorary member would be practically unavailable, but the status of a corresponding member would be applicable to a large number of them. Having regard to these facts, and also to the fact that the byelaws evidently contemplated the formation of this class, he begged to move the resolution standing in his name.

The VICE-PRESIDENT, in seconding the motion, said that as the list of honorary members was necessarily very restricted it became impossible to recognize the services of all the distinguished men whom the Society would like to honour. There were many gentlemen around the table and other members outside who had been recognized by continental and other societies, and it seemed to be only right for this Society to take the subject into consideration. He wished to know if it were intended to send any stamped document or diploma to the gentlemen elected—something beyond a mere letter of recognition from the office.

The PRESIDENT said the third paragraph of the motion was intended to convey that corresponding members would receive the same sort of respect as the honorary members and be furnished with a diploma, so that they would have a permanent record of the honour conferred upon them.

Mr. BUTT asked if it were proposed to restrict the number.

The PRESIDENT replied that a number would probably be fixed from time to time.

Mr. GREENISH said the motion met with his hearty approval, for he felt it was a movement in the right direction. Hitherto the two titles of honorary and corresponding members had been combined; but it was usual with foreign societies to confer honorary membership on some gentlemen and corresponding membership on others, and he was quite sure that a large number of foreigners, scientific gentlemen who had supported the Museum and the Society generally, would be gratified at having this title conferred upon them. He had a letter in his pocket from one resident in Belgium who had sent a large number of works from time to time to the Society, and such were the men on whom the corresponding membership should be conferred. It was perhaps unfortunate that the honorary membership should be limited to fifty, but it was certainly not desirable that the list should be too large. A few years ago it was almost entirely filled up, so that the Council could only elect additional honorary members as those already on the list died off. Just at the present time, when the Society had been honoured by the presence at the International Congress of so many gentlemen from abroad, it was particularly desirable that something of this kind should be done.

Mr. WILLIAMS said he had not the slightest doubt about the desirability of this resolution, but hitherto in electing honorary members the two titles had been united, and it was a question in his mind whether it would not be wiser to enlarge the number of honorary members and have only one list. He did not at all oppose the proposition that the number of honorary or corresponding members should be very much extended, but he thought it might be preferable to keep to one grade of honorary members.

Mr. BOTTLE asked if it were proposed that these corresponding members should be honorary members.

The PRESIDENT said they would not pay any subscription.

Mr. Bottle said in that case they would be honorary members. They must come within the category of those mentioned in the bye-laws as honorary and corresponding members.

The President said as he read the bye-laws he took them to be two separate classes, although it had been the practice hitherto to consider them as one.

Mr. Bottle said in one place in the charter they were spoken of as honorary or corresponding members, but everywhere else they were spoken of as honorary and corresponding members. He did not wish to oppose the motion in any way, but it appeared to him the fair construction of the bye-laws was that they applied to one class only.

The President said that in the diploma the title "honorary member" alone was used. Of course all corresponding members might be said to be honorary, and some of them might eventually be elected to the class of honorary members.

The motion was put and carried unanimously.

Report of Examinations.

December, 1882.

ENGLAND AND WALES.

	Candidates. Examined.	Passed.	Failed.
Major (13th)	6	2	4
„ (14th)	7	4	3
	— 13	— 6	— 7
Minor (13th)	12	7	12
„ (14th)	18	7	11
„ (19th)	24	12	12
„ (20th)	24	14	10
„ (21st)	24	9	15
	—109	—49	—60
	122	55	67

Preliminary Examination.

Ten certificates were received in lieu of the Society's examination:—

4 College of Preceptors.
1 Faculty of Physicians and Surgeons of Glasgow.
1 Royal College of Surgeons in Ireland.
2 University of Cambridge.
1 „ Edinburgh.
1 „ Oxford.

Sale of Patent Medicines.

The President reported that a communication had been received from the Honorary Secretary of the Nottingham and Notts Chemists' Association, enclosing a resolution passed at a meeting, held December 19, in favour of procuring a repeal of that portion of the Pharmacy Act which excluded stamped proprietary articles from the operation of the poison regulations.

Parliamentary and Law Proceedings.

Poisoning by "Syrup of Chloral Hydrate."

An inquest was held last week at Saxonbury Lodge, Ryde, on the body of Lady Petre, widow of the late Hon. Arthur Petre, and daughter of the late Earl and Countess of Wicklow. The deceased lady retired to rest on Wednesday evening in her usual good health. As she did not rise at her accustomed hour the governess went into her room and found her in a convulsed attitude on the bed. By her side was a bottle of chloral, which had been fetched for the deceased the day after Christmas Day, and from which no less than sixteen teaspoonfuls had been taken in two days. The bottle was labelled "Syrup of chloral hydrate, dose one teaspoonful."

The deceased lady's son-in-law, Mr. J. S. Powell, of Hamberton Park, Maryborough, Queen's County, said he was aware that Lady Petre took chloral for sleeplessness, but did not know whether she had been ordered to do so by a medical man. He did not think she was at all likely to commit suicide.

Mr. Rich, surgeon, Ryde, said he thought her ladyship died from heart disease while under the influence of chloral. Of course he could not say that was so without a *post-mortem* examination. He pointed out that people began with small doses of chloral, which they kept increasing till they could take as much as 80 grains, and that the practice of taking chloral to induce sleep weakened the heart.

The Coroner said he would order a *post-mortem* if the jury wished it, but he thought it unnecessary. It was, in his opinion, clear that the deceased took the chloral inadvertently.

In this view the Jury concurred, and returned a verdict to that effect, and expressed an opinion that the bottle ought to have been labelled "Poison."

Poisoning by Prussic Acid.

On Saturday, Dec. 30, the Coroner for Central Middlesex held an inquiry as to the death of John Maplestone, aged 51, which was supposed to have resulted from poisoning by prussic acid. It appeared from the evidence that deceased obtained from a medical friend some prussic acid in a bottle with the object of poisoning a cat. Some time after he was found in the pantry, lying on his back on the floor, as if he had fainted, whilst a cat was in the room in a very excited state. On medical aid being obtained he was found to be dead. There was a saucer on the table, which had contained sardine oil and prussic acid. The cat was known to be exceedingly fond of sardine oil, and it was subsequently discovered by the vomit about the floor that the sardine oil and prussic acid had been administered to the cat. On the shelf was the bottle which had contained the prussic acid. It was therefore suggested that if the death of the deceased was due to prussic acid it must have resulted from some misadventure, as he had no cause to destroy himself, but on the contrary, every reason why he should desire to live. He was on excellent terms with everyone.

Mr. Rayner, the summoning officer, stated that he had searched deceased's property and papers, and could find nothing to throw light on the matter.

The Coroner remarked that there was no doubt of the fact that deceased's death was from taking prussic acid, but what caused him to do so was a mystery. He had frequently held inquests where persons had committed suicide without any assignable cause.

The Jury ultimately returned a verdict "That the deceased died from the effects of prussic acid poisoning self-administered, but whether with the intention of suicide or otherwise there was not sufficient evidence to show."

Review.

The Year-Book of Pharmacy. Comprising Abstracts of Papers relating to Pharmacy, Materia Medica and Chemistry contributed to British and Foreign Journals from July 1, 1881 to June 30, 1882, with the Transactions of the British Pharmaceutical Conference at the Nineteenth Annual Meeting held at Southampton, August, 1882. London: J. and A. Churchill.

Not an unimportant measure of the success enjoyed by the British Pharmaceutical Conference is without doubt attributable to the annual publication of a Year-Book of Pharmacy, and its free distribution among its members. The reflex influence resulting from this act would alone form a necessary factor in any estimate of the numerical strength of the body. On the other hand the eagerness manifested on the part of its members to possess themselves of this work at an early date may surely be regarded as an indication of their appreciation of its worth.

In size, the present volume is within six pages of last year's issue, which it further resembles, both in regard to the subjects into which it is divided and the manner of their arrangement. The conventional sixteen pages at its commencement, though less closely printed than usual, take the form of an introduction. Although this constitutes mainly a connected summary of the scope of the work, it is perhaps the more valuable as affording a means by which the reader is enabled to judge of the advance which pharmacy and its allied branches have made during the past year.

The subject of "Chemistry," Part I., embraces one hundred and twenty-five pages. Here we are pleased to note the space which has been devoted a careful digest of the physiology and chemistry of chinoline and its compounds. No less than five abstracts, taken from the papers of eminent English and continental investigators, appear on this newly discovered medicament. Information not less helpful to the pharmacist will be found under pilocarpine, emetine, etc. The man, too, of more purely scientific tendencies will find his tastes gratified and a field for revelry in the contemplation of such products as monochlormethylnoropianic acid, a derivative of opianic acid, and pyroguajacol, a product of the dry distillation of guaiacum. The chemistry of the cinchona bases and the various products derivable therefrom also receive a large share of attention, and the results of the several workers will probably be studied with unabated interest by specialists.

Not a few, too, of the analytical methods which have been published during the year are here presented in a succinct form.

Part II. comprises "Materia Medica and Pharmacy," and is contained within the more moderate bounds of ninety-six pages. It is more particularly this section and the succeeding one on "Notes and Formulæ" that renders this book an indispensable desk companion to the busy pharmacist. As a work of reference we note with satisfaction that its usefulness has not been sacrificed by overloading it with *minutiæ* of detail pertaining to methods having reference to the extraction of plant principles. The results of the proximate analysis of plants are clearly expressed, while the processes employed are stated in general terms. We would suggest that to a description of those drugs more recently introduced into medicine should be appended a note upon their therapeutical action and dose.

Part IV. is entitled "Bibliography," comprising titles of books, pamphlets, etc., on chemistry, botany, materia medica, pharmacy and allied subjects, published between July, 1881, and June, 1882. This section, which now appears for the second time, undoubtedly supplies a demand, but it occurs to us that it might give the desired information without occupying a space of equal dimensions with materia medica and pharmacy. Adverting to the transactions, we have here given, in alphabetical order, the names and addresses of all the members of the Conference, but we nowhere find any mention of the exact number. From the report of the executive committee we learn that fifty-seven gentlemen have been elected members since the last year. It is gratifying to be told that as the result of an invitation issued to colonial pharmacists to become members, twenty have applied in the affirmative. The comparative freedom from clerical errors which characterizes the transactions is a continued proof of the great care with which it is edited; but on p. 446, four lines from the bottom, the word *not* is omitted in the sentence "there would be an equivalent quantity of iodine liberated," and again, on p. 471, the abbreviation *per cent.* is left out in the sentence reading "8 solution of caustic soda."

Obituary.

Notice has been received of the death of the following:—

On the 19th of December, Mr. William Hardcastle, Chemist and Druggist, Stockton-on-Tees. Aged 72 years.

On the 22nd of December, Mr. Alfred Driver, Chemist and Druggist, Royal York Crescent, Clifton. Aged 35 years.

On the 28th of December, at Sheffield, Mr. Edward Wilson, Pharmaceutical Chemist. Aged 57 years. Mr. Wilson joined the Pharmaceutical Society in 1853, and continued a Member up to the time of his retirement from business in the year 1877. He generously supported and took great interest in the Benevolent Fund.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

The Preliminary Examination.

Sir,—Although outside the pharmaceutical world, I frequently read your paper. I am a B.A. and L.C.P., and having been a tutor for many years I claim your indulgence in allowing me just a small space to make a few remarks on the Preliminary examination. My experience as a tutor is by no means limited, having followed my profession for nearly twenty years, during which time I have had scores of youths to prepare for the Preliminary examination. I contend that the fact of a boy passing the Preliminary is by no means a test that he has been properly educated, and especially in the Latin subject, and the only way by which this may be remedied is to adopt the plan used by the examiners for the legal profession, that is change the subjects twice yearly (the Latin authors). I have had a boy who could translate the first book of Cæsar well,—indeed, you need only give him the beginning of a chapter and he would say the rest off by heart,—still, if I were to ask him the simplest question about the grammatical construction of a sentence, he would be completely dumbfounded. On December 9, at a meeting of the Pharmaceutical Council, a gentleman remarked that the Preliminary examination of the College of Surgeons contemplated one Latin author only. This is true, but the examination is altogether different from the pharmaceutical, inasmuch as the 'Anab.' of Xenophon, Book I., has to be translated into English, or a passage from a French work into English, besides English into French, algebra, Euclid (books I., II.), geography and history, so that the two examinations cannot be well compared as regards severity. If, as suggested, the first book of the 'Æneid' were added, even then the examination would be far below the standard of the Oxford and Cambridge locals. It appears to me that the Council wish to make it equal to the two latter examinations, and I must express my entire concurrence, for any well-educated schoolboy should pass the Oxford or Cambridge examinations with ease. Taking into consideration that there is no French, German, or Greek to be learnt, as for the medical and legal examinations, I think two Latin authors should be taken at least, say—

January . . . . July	Cornelius Nepos. Cæsar D. B. G. Lib. I.
April . . . . . October	Cæsar D. B. G. Book II. Virg. Æneid, Lib. I.

And a wider range of arithmetic to compensate for the Euclid and algebra. A boy well up in his Latin grammar would be able to get up any two of the above books in eight or nine weeks. A good examination in analysis should be added to the English paper.

A. W. S.

Communications, Letters, etc., have been received from Messrs. Dewson, Radley, Sangster, Lime Juice, Sanitas, S. G., A. W. S.

THE NEW PHARMACOPŒIAS FOR THE UNITED STATES AND GERMANY.

(*Continued from page* 505.)

In commenting more in detail upon the articles contained in the two Pharmacopœias it is proposed to deal first with the animal and vegetable materia medica, then with chemicals and their preparations, and lastly with the galenical preparations. As a rule an alphabetical arrangement will be followed, and for convenience the sequence will be according to the actual name of the drug, as in the U.S.P., instead of according to that of the part used, as in the P.G. Exceptions to this rule, however, will be made in the cases of the balsams and essential oils.

I. Animal and Vegetable Materia Medica.

Absinthii, Herba, P.G.—The use of the cultivated as well as the wild herb is allowed. The time of collection is now omitted.

Aconitum, U.S.P., Tubera Aconiti, P.G.—The tuberous root is alone official, the leaves being omitted from the U.S.P. This is an advantage, since the leaves vary greatly in strength at different periods of their growth. The description now given in the U.S.P. permits the use of those roots only which are whitish internally and enclose a pith having about seven rays. This should ensure the rejection of horny and hollow roots, of which many are of uncertain value and doubtful botanical origin. The Japanese aconite (*Pharm. Journ.*, [3], xi., 1042), which is white and starchy internally, is also excluded, since the pith is not usually seven-rayed, but is surrounded by an irregular circle of vessels; even in the comparatively few specimens in which the pith is five-rayed, and which probably belong to a plant nearly allied to *A. variegatum* (the root of which has a five-rayed pith) the number of the rays and the smooth, plump appearance and more conical shape, will serve to distinguish it. Possibly it is with the view of excluding Japanese aconite, on account of its containing a distinct alkaloid and being more poisonous than the root of *A. Napellus*, that the P.G. now describes aconite as "tubera rapiformia," not "obconica" as formerly. The use of tubers that are brownish and hollow internally and of unequal size, which was permissible under the description given in the last edition, is now excluded by the simple statement that the roots are "farinosa vel granulosa" internally. In neither Pharmacopœia is it stated at what time of year the tubers should be collected, nor whether cultivated or wild plants should be used (*Pharm. Journ.*, [3], xiii., 234). It therefore remains for private enterprise to cultivate and supply a root which shall present the required characters, such being the exception rather than the rule in commerce at the present time.

Aconitine is omitted from both Pharmacopœias, possibly in consequence of the extreme variability in strength of the alkaloid as procurable in commerce, and of the deplorable results that have followed the use of a substance of which some samples are one hundred and seventy times as strong as others (*Pharm. Journ.*, [3], xi., 51; xii., 683). It may be hoped that the medical profession will also permit the alkaloid to drop out of use in this country and that thus the heavy responsibility which at present rests on the chemists who dispense it may be removed.

Adeps.—In the U.S.P. this is now directed to be kept in vessels impervious to fats, and directions are given for testing its freedom from alkalies, starch, common salt and water. In the P.G. the description is much longer than in the previous edition and directions are given for ascertaining its characters. The U.S.P. gives data as to the solubility of lard in benzine, ether and bisulphide of carbon. The P.G. directs that its character should be ascertained by the preparation with caustic potash of a soft soap, which should be soluble in 40 parts of warm water and in 10 parts of alcohol. The unguentum benzoini of the last edition of the U.S.P. is now placed under the better-known name of "adeps benzoinatus." Instead of being made with the tincture of benzoin it is now prepared of a strength and in a manner very similar to that of the British and Russian Pharmacopœias, the temperature not being allowed to rise above 60° C. (140° F.) during the process.

Allium, U.S.P.—A description of the bulbs is now given, followed by a sentence which is almost Irish in its incongruity, viz.:—"It should be preserved in a dry place and only used in the fresh state."

Aloe and Aloe Purificata, U.S.P.; Aloe, P.G.—Socotrine aloes is now the only kind official in the U.S.P., Barbadoes and Cape aloes having been discarded. It appears to have escaped the notice of the editors that Socotrine aloes is not produced, as was formerly supposed, by *A. Socotrina*, but by *A. Perryi*, Baker (*Pharm. Journ.*, [3], xi., 747). Socotrine aloes, as met with in commerce, varies so much, containing sometimes half its weight of mineral matter and sometimes as much as 25 to 30 per cent. of "resin," that the introduction of "aloe purificata" for use in the various preparations cannot be too highly commended as a step in the right direction, which might well be followed in the next edition of the British Pharmacopœia. The mode in which the purification is effected is, however, probably open to improvement, both as to the solvent and the temperature employed (*Pharm. Journ.*, [3], xii., 501). In the P.G., Cape aloes is still the only official kind. The tests now given are that a solution of 5 parts in 10 of boiling water, when cooled, should not yield more than 3 parts of deposit, that no colour should be given to boiling chloroform, and only a yellowish tint to ether. It should also be so free from moisture that it only softens, but does not melt at 100° C.

Althæa, U.S.P.—A description is now appended, from which it is evident that only the decorticated root is official. Marshmallow root is very apt to become mouldy and undergo change if kept in a damp atmosphere; directions to keep it in a dry place might, therefore, have been added with advantage.

Ammoniacum, U.S.P. and P.G.—In the P.G. the wording of the description has been altered. Specimens of a brown colour are not objected to. Two chemical tests are given, one with liquor sodæ, which should give a yellow and then a brown coloration to the aqueous emulsion, and the other with hydrochloric acid, which should not change the colour. The latter test distinguishes ammoniacum from galbanum, with which it gives a blue colour, but the former test might well be replaced by solution of chlorinated soda, which colours true ammoniacum but does not affect the African kind.

Amygdala amara and A. dulcis, U.S.P.; Amygdalæ amaræ and A. dulces, P.G.—The sweet almonds are now limited in the P.G. by given measurements, which seem to apply to Valencia rather than to Malaga almonds; but in neither Pharmacopœia is any commercial variety specified.

AMYLUM, U.S.P.; AMYLUM TRITICI, P.G.—The description given in the U.S.P. applies to wheat starch in its pseudo-crystalline state, and permits of the use of starch which forms a white jelly having a bluish tinge, but provides against the presence of acids or alkalies. The P.G. orders powdered starch, but enters more minutely than before into its microscopical appearance, describing the different aspect of the granules when examined in water or alcohol, and the means by which potato starch may be recognized if mixed with that of wheat. The mucilage is required to be free from taste and odour. It is difficult to understand why potato starch should alone have been specified, since maize and rice starch are quite as likely to be mixed with it or substituted for it. Mineral substances, as heavy spar, etc., are detected by estimating the ash, which should not exceed 1 per cent. This is a tolerably difficult process, which might, with advantage, be replaced by that of heating with dilute sulphuric acid and boiling and adding an equal volume of alcohol to a portion of the clear solution, which should not become turbid.

AMYLUM IODATUM occurs only in the U.S.P., and is of 5 per cent. strength, being thus only half that of the Belgian formula, and one quarter of the strength of that given by Dr. Buchanan in the *British Medical Journal* (May 1, 1880). According to Stillé and Maisch (U.S. Disp., p. 173), iodide of starch contains "not over 7·5 per cent. of iodine," and the formula now given is, therefore, safer for internal use for those unusually susceptible to the action of iodine. A distinction is made in the U.S.P. between the Latin name for starch and that of amyl nitrite by making the word amyl indeclinable, and in the P.G. by adopting the form amylium.

ANGELICÆ, RADIX, P.G.—Although placed under "*Radix*" the description now begins with the words *Rhizoma breve.* As other rhizomes are placed under "*Rhizoma*," it is difficult to understand why this is placed under "*Radix*." The measurement and description are now made more exact, by which the root of *A. sylvestris*, L., is excluded, being smaller than the dimensions given. For this reason, probably, it is not now alluded to. The directions to collect the drug in the spring of the second year of its growth, to reject specimens injured by insects, and to preserve it well dried in closed vessels, are now omitted.

ANISUM, U.S.P.; FRUCTUS ANISI VULGARIS, P.G.—In the last P.G. the fruit was described as about 2 millimetres long, which applies only to Russian anise. It is now directed to be 3 millimetres long and 3 broad, a description which admits only of the use of German and Maltese anise. The U.S.P. states that the fruit should be 4 millimetres long, which applies to the Alicant kind. It gives directions how to distinguish anise from conium fruit. As conium fruit rarely exceeds 3 millimetres in length, the official sort could not well be confounded with any but the Russian aniseed.

ANTHEMIS, U.S.P.—A description is now added by which the flower-heads may be distinguished from those of *Matricaria Chamomilla*, which was included in the secondary list of the last edition, and is retained probably in consequence of its preference by the German element of the population. The U.S.P. points out how the flower-heads may be distinguished from those of *A. arvensis* and *A. Cotula*, but the P.G., while mentioning neither these nor the two similar species, *Anthemis arvensis* and *Pyrethrum inodorum*, remarks that *M. Chamomilla* is distinguished from all the nearly allied plants by its hollow conical receptacle, the measurement of which it gives. (See "*Chamomillæ, Flores.*")

APOCYNUM, U.S.P.—This root is another remov from the secondary list and is now distinguished by the vernacular name of Canadian hemp, instead of Indian hemp as in the last edition, a precaution which will prevent confusion between this plant and *Cannabis indica.* It is undoubtedly a more active plant than *A. androsæmifolium*, which is no longer official, and, which moreover, is difficult to obtain in commerce in the United States, although easily procurable in Canada (*Amer. Journ. Pharm.*, [4], xi., 554.

ARNICA FLORES, U.S.P.; FLORES ARNICÆ, P.G.—The description in the P.G. now gives the measurement of the receptacle, of the fruit, and of the pappus, and a more full description of the flower, by which it may easily be distinguished from that of other Compositæ likely to be mixed with it. That given in the U.S.P. is not sufficiently definite to prevent admixture passing undetected. The P.G. directs the involucre and receptacle to be removed. The width of the receptacle "ad sex millimetros" is rather beyond that generally found in commercial samples, which are in most cases only 4 millimetres broad. The hairiness of the receptacle and the ten-veined ligulate florets, in conjunction with other characters, serve to distinguish it from *Inula britanica.* The description of the root in the U.S.P., in which it is said to be internally whitish, having "a rather thick bark, containing a circle of resin-cells surrounding the short woody wedges and large spongy pith," leaves it open to conjecture whether there is a second circle of resin-cells surrounding the pith. A more correct description would be:—The thin bark is brown internally and contains a circle of resin cells, the woody portion is whitish and consists of a single circular row of woody bundles surrounding a proportionately large greyish spongy pith." The rootlets are whitish internally, with a slender yellowish meditullium. The resin cells mentioned in the U.S.P. are not easily distinguished under an ordinary hand lens.

ASAFŒTIDA, U.S.P.; ASA FŒTIDA, P.G.—In both Pharmacopœias the names of the plants yielding it are changed to *Ferula Narthex* and *Ferula Scorodosma.* The U.S.P. states that 60 per cent. of the drug should be soluble in alcohol, and the P.G. directs that the ash should not exceed 10 per cent., that liquor sodæ should give a yellowish colour to it and that hydrochloric acid should not effervesce much nor become coloured when digested with it. Considering how frequently it is impure a strained preparation would be an improvement.

ASCLEPIAS, U.S.P.—This is one of the roots removed from the secondary list of the last edition. The reason for retaining *A. tuberosa* and discarding *A. syriaca* and *A. incarnata* is not very obvious, but is probably due to the properties of the former being better known and to popular prejudice in its favour. The vernacular synonym now adopted is "pleurisy root," instead of "butterfly weed," as in the last edition.

ASPIDIUM, U.S.P.; RHIZOMA FILICIS, P.G.—The name "aspidium" is now adopted in the U.S.P.

in preference to "*Filix mas*" and it includes also *A. marginale*, the rhizome of which is characterized by having six instead of about ten vascular bundles. The chaffy scales of the leaf-stalks and the dead portion of the rhizome and stipes are to be removed, the green portion only being used. In the P.G. the botanical name "*Aspidium*" is adopted instead of "*Polystichum*" as in the last edition, and the rhizome with the base of the leaves is to be collected towards the end of the year, the rootlets and "paleæ" being removed. The rhizome is not to be kept longer than a year and the transverse section of the leaf-bases should show a greenish colour, an angular outline and about eight vascular bundles, the number which appears to be most frequently present in *A. Filix-mas*.

Aurantii Amari Cortex, U.S.P.; Cortex Fructus Aurantii, P.G.—This is described in the U.S.P. as occurring either in thin bands or in quarters, the epidermis being of a dark brownish-green colour. The P.G. describes it as of a pale brown colour (subfusca), from which it would appear that it is not so carefully dried abroad as it is in this country. The Curaçoa kind rejected by the last edition is not now mentioned.

Aurantii Flores, U.S.P., are directed to be mixed with half their weight of chloride of sodium and preserved in a suitable jar in a cool place when it is desirable to keep them for some time.

Azedarach, U.S.P.—Removed from the secondary list. The description is apparently inaccurate in one part. In samples seen in this country the outer surface has not "blackish longitudinal *ridges*," but glossy patches of thin black epidermis more or less cracked and wrinkled.

(*To be continued.*)

THE SALT DEPOSITS OF DURHAM.*

People interested in the chemical trade in various parts of the United Kingdom will know that what may amount to a new departure in that very important industry has been taken on the north-east coast of England. About twenty years ago the late Mr. John Vaughan, of the firm of Messrs. Bolckow and Vaughan, the pioneers of the Cleveland iron trade, in boring for water at their Middlesbrough works, discovered an important bed of salt underlying their premises, close to the river Tees. A few years later Messrs. Bolckow and Vaughan converted their firm into a limited liability company, and shortly afterwards an attempt was made to win the salt by sinking a shaft. Unfortunately they met with insuperable obstacles in an abundant feeder of water, which caused them, after expending a very large sum of money, to abandon for the time their proposed salt pit, and for several years no further steps were taken in the matter. In the meantime the firm of Messrs. Bell Brothers (Limited), who had established iron works at Port Clarence, on the north bank of the Tees, opposite Middlesbrough, feeling that great inconvenience might arise to them if any one else were to become owners of the salt immediately adjoining their blast furnaces at Clarence, entered into negotiations with the owners of the minerals—the Crown and the Ecclesiastical Commissioners—for an extensive royalty, and began to consider in what way the salt could best be made available. The unfortunate experience of their neighbours Bolckow, Vaughan and Co., who had become large lessees of salt, partly from the Crown and partly from adjoining landowners, deterred Messrs. Bell Brothers from endeavouring to work the salt in the rock form, and induced them to seek some other method of winning the rich deposit. One of their partners, Mr. Thomas Bell, proposed a plan which was ultimately adopted. He suggested that a bore hole should be put down to the salt, that within this hole a tube should be inserted, and a pump placed at a proper depth, so that, availing themselves of the principle which governs the levels of liquids of different densities in tubes, it would only be necessary to pump the brine from such a depth as is represented by the difference between the specific gravity of water and fully-saturated brine.

On this suggestion being made to them Messrs. Bell Brothers proposed to inquire whether a similar plan had been carried out in any other region where salt is found, and speedily learned that in the eastern part of France, near the town of Nancy, a large bed of salt is so won, the only difference between the conditions of this deposit and that on the Tees being the much greater depth of the latter. They proceeded accordingly to sink a bore hole 16 inches in diameter to the salt, and for this purpose they availed themselves of the services of the Subaqueous Boring Company, who are the licensees of the well-known Beaumont boring machinery. Considerable difficulties of a practical character were met with in completing the bore hole, and it is impossible to award too great praise to the engineers of the boring company for the way in which they dealt with the various problems that arose. One instance was very interesting. It was found, for a variety of reasons, impossible to carry the hole down to its full depth, and the engineer of the company devised an instrument by which, after boring the hole 12 inches in diameter, he was able to bore it out to the full diameter of 16 inches, so that the lining tubes, which are essential to the carrying out of the plan, would follow the instrument to the bottom of the hole. The boring operations were begun on June 16, 1880, and completed on May 28, 1881. Simple pumping apparatus was then erected at the top of the bore hole, and on June 19, 1882, the first brine from the Middlesbrough salt pit was brought to the surface. It is peculiar that the salt is found at an entirely different geological horizon from that of the Cheshire beds, which occur at a much higher point in the strata than those at Middlesbrough. Although salt is a mineral of very wide distribution, it is chiefly found in the new red sandstone series. These rocks were probably deposited under conditions which caused the formation of large inland lakes, communicating, possibly, by narrow channels with the sea. It is surmised that those channels gradually became restricted, owing to the changes of levels, and the lakes thus formed full of salt water, by a process easily understood, in time became more and more concentrated. The Dead Sea is an instance of this geological change in our own time. No doubt the salt beds of Cheshire, as of Yorkshire, were formed in this way, the only difference between them being one of time, the Cheshire beds being created at a much later period than those of Yorkshire and Durham. It is interesting to note that the great German deposits are found at the same geological horizon as are the Middlesbrough beds.

Having won the brine on the banks of the Tees, the next question was how it should be utilized: The chief purpose for which salt is used in commerce is in the manufacture of alkali, and the main centres of this industry are Lancashire and the Tyne. The process at present in vogue in both these districts is known by the name of the great French chemist who invented it, Le Blanc, and is based upon the consideration that salt is decomposed by sulphuric acid to make sulphate of soda, which is subsequently treated so as to produce carbonate of soda. The most expensive and the most difficult part of this process consists in procuring sulphuric acid. This in olden days was got from native sulphur, but when the demand for this article became so great, a substitute had to be found, and pyrites or sulphide of iron was made to

* From the *Times*.

take its place. The immediate cause of chemical manufacturers seeking for another source of sulphur than the Sicilian mines was a great commercial blunder, committed by the Neapolitan Government some forty-five years ago. For a considerable sum of money they granted a monopoly for the export of the produce of the mines to a French company, who immediately used the power thus acquired to raise the price of sulphur to two or three times its former value. This continued for some little time until the British Government insisted upon the trade being relieved of such a burden. It was in operation, however, long enough to afford the soda makers of Great Britain an opportunity of finding a substitute in the mineral known as pyrites, which is a compound of sulphur and iron, from which the former element is easily separated as sulphurous acid by the heat evolved by its own combustion. Sulphur may be described as simply a vehicle to carry the metal sodium from the chloride with which it is found combined in common salt. The sulphate of soda obtained by the action of sulphuric acid on salt is subsequently decomposed, the sulphur becoming a waste product, by action of carbonate of lime and coal, when the soda, combining with the carbonic acid, affords the marketable article known as soda ash; pan and soda crystals are also produced. The sulphur, after having served its purpose, is all thrown away, and constitutes those unsightly heaps which are characteristic of alkali works all over the world. The salt required for the Le Blanc process must be in a solid form, and Messrs. Bell, looking to the Tyne as one of their chief markets, and believing by their favourable position that they can successfully compete with Cheshire, have erected pans to evaporate the brine and produce salt for the chemical manufacturers on the banks of the neighbouring river. The requirements of the Tyne amount to about 200,000 tons a year. It may be asked how it happens that an industry requiring so large an amount of material grew up at so great a distance from its source of supply. This is accounted for by the fact that at the time the Tyne became a great alkali producing place, small coals, which are largely used in the process, were exceedingly cheap. Indeed, the colliery owner was glad to have them taken off his hands, for it relieved him of the inconvenience of adding to the burning heap which was seen near every pit in the north, and the consumption of which subjected the coalowners to claims for damages from the neighbouring landholders. The changing circumstances of the coal trade, which have rendered small fuel a valuable article, have had a disastrous effect upon the soda trade of the Tyne. One establishment after another has been closed. While this has been going on, a new method of making soda has been introduced. Many years ago a plan was devised by Messrs. Heming and Dyar to take advantage of a well-known chemical reaction, by which, when a solution of common salt is mixed with bicarbonate of ammonia, decomposition takes place and bicarbonate of soda is precipitated. This reaction has been given a commercial value by Messrs. Solvay and Co., of Brussels, who are among the largest soda makers on the Continent, and, under licence from them, is employed by Messrs. Brunner, Mond and Co. (Limited), who have extensive works in Cheshire.

If the chemical trade of the Tyne is to be regarded to some extent as a dying industry the salt of the Tees must find another outlet. Salt as brine is requisite to the new process, and the alkali industry now located on the Tyne may have to migrate to the banks of the Tees, where it will find brine to its hand, or it will have to embark in an industry entirely different in character from that in which it is engaged at present. Probably it may be convenient that a half-way course should be adopted. A portion of the trade might remain where it is and continue to use salt in its solid form, drawing its supplies from Middlesbrough, and making either carbonate of soda as at present or sulphate of soda, which is extensively used in glass-making. This is likely to be so, as up to the present time no means has been discovered for obtaining chlorine cheaply by the ammonia process. This element is an active ingredient of the bleaching powder which is so largely used in many of our textile factories and mills. Chlorine is now procured from hydrochloric acid, produced by the action of sulphuric acid on salt in making sulphate of soda. It is that pungent destructive gas which renders the neighbourhood of chemical manufactories so distasteful to our senses of both sight and smell. The rest of the trade will, it may be predicted, migrate to the Tees, and, no doubt those who contemplate engaging in the salt industry will have to make arrangements for providing, not only the brine, but chemical works to absorb that product. We are able to state that Messrs. Bell Brothers, who are the pioneers in the salt trade of the Tees, which is of so much local and even national importance, intend to erect works near their salt pans for the manufacture of soda by the ammonia process. The royalty of salt held by Messrs. Bell Brothers extends over 2000 acres, half of which is from the Ecclesiastical Commissioners, and the other half from the Crown, the latter portion being situate under the bed and foreshore of the river.

The existing bore hole, which has attracted so much attention, is placed about the middle of the royalty held under the Ecclesiastical Commissioners, and is something like a mile distant from the banks of the Tees. The brine from the pumps runs in an underground conduit to a large reservoir, which holds about 500,000 gallons of brine, or, say, about 400 tons of salt. The reservoir, while serving as a place of storage in case of accident at the bore hole, collects any solid impurities which may have been carried into it by the water running through the pipes. By the aid of a pump the brine in the reservoir is delivered to the evaporating pans, which closely adjoin and are on a somewhat higher level. There are nine pans, all of which are of the form customary in Cheshire, each being about 65 feet long by 25 feet in width, and 18 inches in depth. Each pan is calculated to produce between 35 tons and 40 tons of salt per week. It will, therefore, be seen that Messrs. Bell Brothers (Limited) are already in a position to produce between 350 and 400 tons per week. Some very important experiments for utilizing the waste heat from the blast furnaces are being made by Messrs. Bell Brothers. They have erected experimental pans, and are producing over 20 tons of salt per week by using only the waste heat from the furnaces to accomplish the evaporation. The pans are so constructed that the number could easily be increased to twenty, which number would give a producing capacity of nearly 1000 tons per week. The salt from these works is being sent away by the North-Eastern Railway Company, whose lines immediately adjoin the pans, and close at hand is the river Tees, to which Messrs. Bell Brothers possess shipping access. The salt required for the chemical trade is somewhat coarse in the crystal, and is not usually employed for fish curing or ordinary culinary purposes. Should Messrs. Bell deem it advisable to embark in the manufacture of salt for other of its uses, they would require to make certain modifications in their present plant, but as long as the Tyne is in need of 4000 tons of salt per week, and while they are the only manufacturers on the Tees, it will not be necessary for them to look for any other market. The existing bore hole is sufficing for the present evaporating works, and they hope that, as the cavity formed by the solution of the salt obtained grows larger, they will get a greater quantity of brine from it. As the years of duration of such a bore hole are uncertain, they are about to put down another bore hole, and if the industry develops, as there is every reason to believe it will, they will put down a third and even a fourth hole. The site of the projected chemical works has been already determined upon, and is immediately adjoining the evaporating plant, where Messrs. Bell possess either as owners or lessees a large extent of land, and are, therefore, in a position to increase the size of the works to any dimensions that may be required.

It is almost needless to say that the success of Messrs. Bell Brothers has aroused a great deal of interest in the north of England, and the chemical manufacturers of the Tyne are on the alert and anxious to learn the results over a few months. Already one of the largest alkali manufacturers there is contemplating becoming the lessee of a royalty on the banks of the Tees. Messrs. Bolckow, Vaughan and Co., too, the iron and steel manufacturers at Middlesbrough have decided to put down a bore hole to win salt in the same way as that adopted by Messrs. Bell Brothers. The only chemical works at present on the banks of the Tees are those belonging to Colonel Sadler, at whose extensive premises at Middlesbrough are produced alkalies, oxalic acid, various tar products, potash, and Epsom salts. These works, unlike those on the Tyne, are exceedingly busy, and afford employment to many hundreds of workmen. The landowners, as might be expected, are very much interested in the new industry. Quite recently in *The Times* attention was drawn to the disastrous effects on the surface of Cheshire produced by salt winning, and some speculation as to the future of low-lying lands in North Yorkshire and South Durham in the salt district may not be out of place. At Middlesbrough the salt lies more than 1000 feet below the surface and is at least 100 feet thick. There are about 200,000 tons to every acre, and many years, perhaps even generations, may elapse before the salt works of the Tees produce any considerable effect. There can, however, be no doubt that ultimately an enormous cavity will be formed underneath Middlesbrough and its environs. Possibly this cavity will not occasion such disasters as have taken place in Cheshire, where the salt lies much nearer the surface. It is believed that at Middlesbrough the supercincumbent rocks will, in falling, pack themselves into the spaces left by the salt much less closely than that mineral, and possibly there may be a very slight subsidence on the surface. Whenever the surface subsides, the landowners will profit by their predécessors in Cheshire and make the best they can of the circumstances. We have said enough to show that there is opening out for the Tees an industry which, though it may not vie with that great iron trade which has grown to such gigantic proportions on its banks in so short a time, will, nevertheless, prove of enormous value in the development of that commercial centre. Probably nowhere in England are there to be found men more likely to take advantage of any circumstances which present themselves for the enlarging of the trade of Cleveland, or more able to cope with a new industry, than those who within a generation have created an iron trade which for extent and importance is not to be equalled in the United Kingdom.

BEE CULTURE IN INDIA.*

The following information respecting the bee industry in India, is gathered partly from the *Indian Agriculturist.* The details were obtained by Mr. John Douglas, Superintendent of Telegraphs, from Mr. Morgan, Deputy Conservator of Forests, and are noteworthy from the light they throw on the modes of collecting wild honey. The best honey-producing flower of Southern India is the strobilanthes, which not only forms the principal undergrowth of the *sholas*, both temperate and tropical, but spreads over the grassy slopes of the higher elevations. There are an immense number of species in this genus and they almost all flower once in seven years, dying down entirely, and afterwards a fresh growth springing up from seed. Whenever any species of strobilanthes flowers, colonies of bees migrate from all parts of the country to feast on the honey, and rear their young broods. At such times honey becomes plentiful and cheap, and as the strobilanthes honey is of the finest quality and flavour, even rivalling that from the famous Mount Hymettus, it is eagerly sought after by the Todas of the Neilgherry Hills, and in fact by all aboriginal tribes. The year 1879 was such a season for honey that it sold at the rate of 4 annas per imperial pint, whereas its usual price is from 8 to 10 annas. This honey, in the cold climate of the Neilgherries, crystallizes in from a fortnight to three weeks, when the flavour becomes richer and finer. In the Wynaad, as soon as the moon has waned sufficiently, great preparations are made to take the honey. Bamboo and rattan ladders are constructed, sometimes of astonishing length, and at nightfall, after 9 p.m.—for the bees do not go to bed till then, as you will find to your cost if you disturb them—the Jain (honey) Kurumbars proceed to the *burray*, and, having erected their ladders, if they have to climb upwards, or suspended their cane ladders, if downwards, arm themselves with torches and knives and sever the combs from the rock or branch. The drowsy bees meanwhile, roused by the glare of the torches, desert the combs, and buzz aimlessly about, even on the persons of those engaged in taking the combs, but never attempt to sting, unless crushed, or hurt. The combs are then lowered down in baskets, the Kurumbars feasting on the larvæ, which taste something like cream, while the fish, which swarm in thousands when the hives are built over a river, have a glorious feed on the grubs and bees that fall into the water and float helplessly down stream.
