these animals, there is a short fissure to be seen between them. This exists above and below in the *camelopard*, *stag*, and *gazelle*: only at the upper part of the bones in the *horse*, *sheep*, and *ox*, and is not perceived in the *camel* and *dromedary*; but in all these animals the original distinction between these bones is marked by a furrow or groove.

All the hoofed quadrupeds have the anterior extremities permanently in the state of pronation; that is, with what is called the back of the wrist turned forwards.

In the *bat* and *galeopithecus*, there is only one bone in the fore-arm, or at least a mere styliform rudiment of the other. This single bone Blumenbach has called the ulna, and Cuvier the radius. The latter is certainly the proper appellation. The motions of the anterior extremity, as a wing, require the part corresponding to the fore-arm to be constantly in a state of pronation.

In the *mole*, the olecranon is very long, and terminates in a transverse plate: the whole ulna is very thin. The edge of the head of the radius is prolonged under the little head of the humerus, and seems to be incapable of rotation. The position of the fore-arm and hand of the *mole* is singular. The elbow, as before observed, is turned upwards; the palm of the hand outwards, and the thumb downwards. This is pronation carried to an extreme, which is the most suitable position of the hand for its peculiar office in this animal of scooping out the earth.

The *seal*, instead of the concavity for surrounding the pulley of the humerus, has upon the ulna one surface, which forms a joint with the humerus, and another oblique one for the radius. This last has a large head, the inner edge of which runs in a pulley. The body of the radius is very broad downwards.

In the *lamantin*, the radius and ulna are anchylosed together at both ends.

In the *cetacea*, the bones of the fore-arm are placed close to each other, but not united by ossific substance: they are flattened, and connected so intimately with the humerus and the carpus by ligaments and cartilage, that they have none of the motions of a regular articulation. They merely admit of a degree of flexion, forwards and backwards, sufficient to communicate the necessary pliancy to the fin.

The number and the figure of the bones composing the *carpus* differ from what we find in the human subject, and amongst the different tribes of mammalia themselves.

In the *monkey tribe* there are nine bones in the *carpus*, which is one more than in man. According to Tyson, however, there are but eight in the *ourang-outang*. The *pisiform bone* of these animals is elongated, and appears like a heel when they walk upon all fours, or use the anterior extremities as feet. Certain ossified points of the tendons passing into the hand, have been mistaken for supernumerary bones in the *monkey* kind.

The *flying squirrel* is mentioned by Blumenbach as possessing a very curious sharp-pointed bone on the outer part of the carpus, connected to that part by two small round bones, and inclosed in the lateral expansion of the integuments.

In many *carnivorous* quadrupeds, the *scaphoides* and *lunare* are united into one. The *cat* has at the radial edge of the carpus a little supernumerary bone, similar in figure to the *pisiform* bone of the human subject. The real *os pisiforme* of the *digitigrade* is long, and serves as a sort of heel to the fore-feet. The *os magnum* is very small towards the back of the carpus. Those that have the thumb imperfect have also the *trapezium* much diminished. The *ursus gulo* has this bone also small, and a style-shaped process below the *os scaphoides*.

The *mole* has nine bones in the carpus, and an additional bone which resembles the blade of a scythe in its figure. It descends on the radial side of the hand, the surface of which it is designed to extend, in order to fit it for shovelling back the earth when this animal burrows.

Amongst the *saltigrada*, the *hare* has nine carpal bones. The *beaver*, *marmot*, *squirrel*, and *rat tribe* have the scaphoid and lunar bones formed into one. These animals likewise have, like the *digitigrada*, a supernumerary bone, which is often larger than the pisiform. In the *jerboa* and *marmot*, it bears upon it another supernumerary bone. In the *porcupine* there is an additional carpal bone, attached to the os unciforme, between the os pisiforme and the metacarpal bone of the small toe. The *cavy* and *guinea-pig* have one bone for the scaphoid and lunar; and the latter animal has a small supernumerary carpal bone.

The *two-toed ant-eater* has six bones in the carpus. There are seven in the *pangolin*. There are eight found in the *nine-banded armadillo*.

The *three-toed sloth* has but five carpal bones.

The *elephant* has eight bones. The os pisiforme is lengthened, and the other bones of a wedge shape.

In the *rhinoceros* the trapezium does not exist, but there are two supernumerary bones; one on the edge of the scaphoides, and the other upon the os unciforme.

In the other *many-hoofed* quadrupeds the trapezium is very small.

In the *cloven* and *solid-footed* quadrupeds the carpal bones are narrow. The first tribe have, in general, four bones in the first row, and two in the second. The *solipeda* have four in the first and three in the second row.

In the *cetacea* the bones of the carpus are flat-shaped, and intimately united to each other by cartilage and ligament. We have found the carpus of the *grampus* to contain a greater proportion of cartilaginous substance than of osseous, the bones appearing like spots of ossification in the centres of masses of cartilage. The surface of the carpus in *cetacea* is smooth on both sides. There are five carpal bones, three in the first row and two in the second.

The *metacarpus* consists of the same number of bones as the fingers, (or, as they are more commonly called, toes, in quadrupeds,) perhaps without exception; it being understood, that the *pollex* is not reckoned amongst the number of fingers, for it is a question amongst anatomists, whether the first joint of the thumb, in the human subject, should be considered as a metacarpal bone, or as a real phalanx. We believe it is the latter, which opinion seems to be supported not only by analogy of structure in mammalia, but in birds.

The *cloven* and *solid-hoofed* quadrupeds have been cited as giving examples of a difference in the number of the metacarpal bones and the digiti. This difference, however, is more apparent than real. The *cloven-hoofed* have, it is true, but one bone in the metacarpus after a certain age, which is called the *cannon* bone (*gamba* of Vegetius), but this bone is originally composed of two parallel pieces, which are formed into one by a curious process. The two sides of the pieces that are applied to each other are rendered thinner by being absorbed: these are next portions of the sides removed, leaving holes between the cavities of the two pieces; and ultimately the sides in contact disappear, forming a common medullary cavity, and a single bone, which remains grooved at the line of the junction of its original parts.

The *cannon bone* of the *solipeda* is composed of three pieces; the two lateral are slender and styliform, and are called, very appropriately, the *splent* bones. These have been considered analogous to the metacarpal bones of digiti which do not exist,

exiſt, but they ſhould rather, perhaps, be viewed as the rudiments of both metacarpal bones and digiti. In other caſes where there are veſtiges of digiti, they appear as ſtyliform bones.

The length of the metacarpal bones depends upon the offices of the anterior extremity. When it is employed ſolely for progreſſion, as in the true quadrupeds, the metacarpus is very long, but when uſed as a prehenſile member, this part is proportionally ſhort.

Cuvier ſtates, that in the *three-toed ſloth* there are three metacarpal bones united into one at their baſe, and that there is a rudiment of a fourth bone added to them.

The metacarpal bones of *cetacea*, from contributing to the formation of a fin, are much flattened.

The *digiti* of the *quadrumanous* mammalia, and all thoſe with claws, are five in number. In the firſt, the pollex is free in its motions, and capable of being brought oppoſite to the other fingers, which conſtitutes one of their moſt ſtriking reſemblances to man.

Even in the *monkey tribe*, however, the thumb is ſhorter and ſmaller, in proportion to the other fingers, than the thumb of the human ſubject; and a particular ſpecies of *monkey*, the *ſimia paniſcus*, has it imperfect, and concealed beneath the ſkin.

The *digitigrada* have the thumb parallel to the reſt of the toes: in many it is ſhort, and in the *hyæna* it is nearly obliterated, conſiſting only of one phalanx. In the *cat* genus, there is a peculiar ſtructure of the two laſt phalanges, by which the claws are thrown upwards in the extended ſtate of the toes. The deſign of this appears to be, to avoid the blunting of the claws againſt the ground. The laſt phalanx but one is three-ſided, having an inferior and two lateral ſurfaces; that on the inſide appears in ſome degree twiſted and hollowed out. The phalanx, which is terminated by the claw, is, of courſe, hooked at the end, but at its baſe, nearer the root of the claw, in a ſort of hood or ſheath. The poſterior part of the phalanx riſes almoſt vertically, and is only articulated at its moſt inferior part. Beneath the joint there are two appendices, in which the muſcles which bend the phalanx are inſerted. Theſe alſo bring the point of the claw forwards and downwards. The ſame muſcular power which puts the toes into a flex poſition, thus ſerves alſo to urge downwards the points of the claws into the prey of theſe animals. When the claws are retracted, the laſt phalanx is received by the lateral depreſſion on the radial ſide of the ſecond.

The *pollex* is ſhort in the *hare*, *beaver*, and *jerboa*. It is more diminiſhed in the *ſquirrel*, *rat*, *porcupine*, *paca*, and *agouti*. It is nearly loſt in the *cavy*, *marmot*, *guinea-pig*, &c.

Amongſt the *edentata* the thumb is obliterated in the *great* and the *four-toed ant-eaters*.

Both it and the little toe are loſt in the *three-toed ſloth*. In this animal the three perfect toes are often incorporated at their roots with the metacarpus. When they form a joint with the metacarpal bones, it is ſuch a one as does not permit any lateral motion. The phalanges themſelves likewiſe are articulated with each other by hinge-like ſurfaces, which only admit of flexion and extenſion. Another peculiarity of the hand of this animal is, the laſt phalanx being the longeſt.

In the *two-toed ant-eater* and *two-toed ſloth*, the thumb, fore, and little finger are the different parts.

The *multungulata* have either four or five toes. In the *elephant* there are five perfect, but they are nearly enveloped in the ſkin of the foot. There are but three perfect in the *rhinoceros*. The *hog* has but two perfect and two imperfect.

The *tapir* and *hippopotamus* have four perfect, and the rudiment of a thumb.

The *cloven-hoofed* have two perfect, and in ſome two imperfect toes.

The *ſolid-hoofed* have one perfect and two imperfect.

By imperfect toes, or digiti, are meant thoſe little horny excreſcences which do not reach the ground, but are placed at the back, and are ſometimes covered with nails or hoofs, and contain under the ſkin the proper bones of a toe.

The moſt remarkable deviations from the uſual ſtructure are found in the flying and aquatic mammalia. The very extenſive wings of the *bat* are ſupported upon the elongated phalanges of the four fingers, the thumb being ſhort, and armed with a hooked nail at the extremity.

In the *ſeal* and *lamantin* the fingers are elongated a good deal, and ſpread out, that the hand may the better perform the office of an oar. In the *cetacea* the digiti are rather elongated, and are much flattened. They are conjoined with the metacarpus and each other by cartilaginous ſurfaces, that do not permit any motion beyond the gentle waving one of the fin, in which they are concealed. The digiti are cloſe together at their baſes, but ſpread a little aſunder towards their extremities; but they are all bound together by means of the ligamentous ſubſtance which ſupports and ſtrengthens the different parts of the fin.

The *oſſa innominata* are more elongated and narrow in mammalia generally than in man. They do not in any inſtance form a baſon-ſhaped cavity, like the human pelvis. In many quadrupeds, the cavity of the oſſa innominata wants the diſtinction of the large and ſmall pelvis, and is placed in the direction of the ſpine; and in ſome this cavity looks obliquely upwards, that is to ſay, backwards, if we were ſpeaking of the human ſubject.

The *monkey* and *bear* moſt nearly reſemble man with reſpect to the form of the pelvis, but even they have the oſſa ilii elongated, and the cavity of the pelvis much narrower than in man, and not opening ſo much forwards. Thoſe *monkies* that have the calloſities on the buttocks, have the *tuberoſities* of the *iſchium* very large, and ſpread out.

In the *vampyre bat*, the tuberoſities of the iſchium and the extremity of the ſacrum are conſolidated together by anchyloſis, of which there is no other example in this whole claſs. The pelvic bones are leſs elongated in the *bats*, generally, than in quadrupeds.

The *digitigrada* have the abdominal ſurfaces of the ileum turned towards the ſpine, and ſo much narrowed, that the dorſum of the bone is not larger than the neck. The concavity is alſo upon the external ſurface. The criſta of the ileum is ſo ſhort, that it bears no reſemblance to that part in the human ſubject. The form of the pelvic bones is nearly ſimilar in the *plantigrade* and *ſaltigrade* quadrupeds, with ſome exceptions. In the *mole*, the oſſa innominata are nearly cylindric; they are long, and lie almoſt cloſe to the ſpine: the cavity of the pelvis is ſo very narrow, that it can only receive the rectum, the organs of generation and bladder being placed externally to it. The *beaver* and *kanguroo* have the oſſa pubis not united by cartilage, but are anchyloſed together.

In the *opoſſum* tribe and the *kanguroo*, the brim of the pelvis has but little extent, and there are two additional bones, the uſe of which is to ſupport the abdominal pouch. Theſe bones ſtand up from the edge of the pubis on each ſide of the ſymphyſis. They are, at leaſt in the *kanguroo*, of an elongated, tapering figure. They are connected with

the

the pubis by ligament, which allows the free extremities of the bones to be moved up and down upon the belly. Thefe bones exift alfo in the *ornithorhynchus*.

The *tardigrada* have the *offa ilii* broad, with a large circular *pubis*. The opening of their pelvis is, therefore, very wide, and but little oblique. In thefe animals, and the *armadillo*, *pangolin*, and *ant-eaters*, the tuber ifchii is placed near the facrum, and in fome cafes they are even offified together. In the *ant-eaters*, the *offa pubis* have no fymphyfis, but are feparate from each other, in which circumftance they refemble the bones of the pubis in birds. It is worthy of remark, that we difcern the moft frequent analogies of ftructure between the toothlefs tribe of mammalia, and the other claffes of animals.

In the *ruminating* quadrupeds the furface of the ileum, which in the human fubject is internal and anterior, has a contrary afpect, being turned towards the fpine. The ifchiatic notch excavates the ileum deeply. In the *ox*, *buffalo*, and other ftrong-backed *ruminants*, the anterior part of the ileum is very large. The fpine of this bone, and the tuberofity of the ifchium, are difcernible under the integuments, and produce that rugged outline of the rump of cattle.

The dorfum of the ileum is very large in the *horfe*, as in fome of the *ruminants*, and the neck of the bone is very fhort: in both, the external furface of the ileum is concave.

In the *elephant*, the furface of the ileum next the belly is hollowed; the crifta is round: both the anterior portion of this bone, and that which unites with the ifchium, are very large, and the latter moft fo. The *rhinoceros* has a fimilar pelvis, but the pofterior branch of the ileum is lefs in proportion.

There is a fimilitude in the pelves of the fwimming quadrupeds, as the *feal*, *otter*, &c. they are long and narrow.

In the *cetacea* there are two bones on each fide of the anus. They are conjoined by cartilage before that aperture. Thefe bones have a good deal the figure of two flat fhort horns united at their root. The ends of the horns are directed towards the fpine, and correfpond to the offa ilii: near the root there are two fmall conical projections which fupply the place of the ifchium of each fide, and the conjoined parts of thefe bones reprefent the pubis. Thefe bones are fufpended in the flefh, and have no connection with the fpinal column, and do not form any cavity; they, therefore, properly do not conftitute a pelvis. Their ufe is to give attachment to the penis and clitoris, and fome of the mufcles of thefe parts. Cuvier ftates, that the pelvic bones of *cetacea* are not united to each other, but we have found them as above defcribed in the *grampus*.

The *os femoris*, in the *monkey* tribe, refembles the fame bone in man. It, however, is fmoother and rounder, having fcarcely any *linea afpera* upon it.

In quadrupeds, generally, the femur has a fhorter neck, and the great *trochanter* is lefs eminent, and the bone altogether is fhorter in proportion to the other parts than in man. The femur is particularly fhort in the quadrupeds that have a long metatarfus, as the *cattle* and the *horfe*. In thefe the bone is enveloped fo much by the flefh of the buttock, that the part which is really the leg is commonly called the *thigh*. This bone is alfo remarkably fhort in the fwimming quadrupeds, as the *otter*, *beaver*, and *feal*. In the laft, Cuvier fays the articular extremities make more than half its length. The bone does not appear to be quite fo fhort, according to our obfervation.

Some quadrupeds poffefs a hook-fhaped procefs upon the external fide of the femur. It has been obferved in the *tapir*, *rhinoceros*, *armadillo*, and *beaver*. It is the termination of a prominent ridge of the bone about the middle. In the *rhinoceros* this unciform procefs and the great trochanter are much prolonged, and clofe again, fo as to have a hole between them and the body of the bone.

The *bones of the leg* are very fimilar in the *monkey* kind to thofe of the human fubject. In fome fpecies the tibia is a little bent anteriorly, and more round in its fhape.

In the *bats* the *fibula* is a delicate bone. The pofition of the bones of the leg is changed in thefe animals. The thighs are directed backwards, by which means the fibular, or external fide of the leg, is fituated internally.

The *tibia* in the *bear* is a little bent forwards: the anterior tuberofity is very prominent, and the furfaces for articulation with the femur are placed far back.

The pofition of the fibula is pofterior in the *faligrada*.

In the *opoffum* tribe, the *long-tailed manis*, the *armadillo*, and the *floth*, the fibula is large and curved outwards, by which fome fpace is left between it and the tibia.

The fibula has a fingular formation in the *wombat*, which has been defcribed by Mr. Brodie. It is proportionably larger, he fays, than in other animals. At the upper extremity it is broad and has two diftinct articulating furfaces; the anterior of which is joined to the tibia, and the pofterior to a fmall bone of a pyramidal fhape, which is connected to the tendon of the external head of the gaftrocnemius mufcle, like a fefamoid bone. The lower extremity of the fibula is large, and forms about half of the articulating furface for receiving the tarfus. An inter-articular cartilage is here interpofed between the tibia and fibula, and there is another between the fibula and the tarfus. The fibula has a flight degree of motion on the tibia at its upper end, and a half rotatory motion on it at its lower end. Mr. Home fuppofes, and we think with great probability, that this rotatory motion of the bones of the hind leg is defigned to enable the animal to bury itfelf in the ground.

The fibula in many quadrupeds declines in fize, and is anchylofed with the tibia, in which there is an analogy between it and the ulna in the fore-arm.

It is united to the tibia for about the lower third in the *mole*. It is connected to the tibia the whole length pofteriorly in the *dog*. It is offified with the tibia at the inferior third of the bone in the *rat* kind. The fibula is flat, and united throughout by offification with the tibia, in the *elephant*, the *rhinoceros*, and the *hog*. There is merely a rudiment of the fibula in the *horfe*, which is anchylofed with the top of the tibia after a certain age.

In the *cloven-footed* quadrupeds, there is a fmall bone fituated on the external edge of the aftragalus. It forms the external malleolus, and is the only veftige that exifts of the fibula in this tribe of animals.

The *bones of the tarfus*, and *metatarfus*, are analogous in their varieties to the carpus and metacarpus of the fore-arm of the fame animals.

The hind-feet of the *monkies*, *lemurs*, and *opoffums*, are really hands: the metatarfal bone of the great toe is, therefore, fhorter than the reft, and capable of being moved outwards. The projection of the *os calcis*, which forms the heel, and is fo ufeful to fome quadrupeds in walking, is alfo diminifhed in thefe animals, with the exception of the *Batavian pongo*. There are other peculiarities in their tarfal bones. The articulation of the aftragalus with the bones of the leg is fo conftructed in the *monkey* tribe, that the foot refts more on the external fide than what is called the bottom; a pofition of the member well adapted for its being employed in climbing, but unfavourable in walking.

In the *lemur tarfius* and *lemur galago*, the *os calcis* and *fca-*

phoides are extremely elongated, by which the foot affumes the appearance of a hand and fore-arm.

In the *opoffum* tribe, the *aftragalus* is very fmall, and articulated almoft exactly between the tibia and fibula. The *Virginian opoffum* has a little fupernumerary bone upon the edge of the firft *cuneiform bone.*

The os calcis is of a confiderable length in the common *bat.* It has a ftyle fhape, and is inclofed in the membranes of the wing at that part. In the *vampyre bat*, the part of the bone that forms the heel turns under the foot.

The os calcis is much elongated in the *faltigrada*, particularly in the *kanguroo*, in which the bone of the heel ftands back a confiderable way from the tarfus. The *beaver* has the os fcaphoides in two pieces; one is placed before the aftragalus, and the other at the internal fide of that bone. There is a flat fupernumerary bone upon the inner edge of the tarfus. A fimilar ftructure exifts in the *marmot*. The fcaphoides is divided alfo in the *porcupine* and *paca*, but the fupernumerary bone is wanting. In the *fquirrel* it is divided, but the inner portion is fmall. In all this order of quadrupeds, the fcaphoides forms a tubercle in the fole of the foot. This, in fome fpecies, is very long, as in the *jerboa* of the *Cape*, &c. Many of the *faltigrada*, that have only three or four toes, have fome fmall bones, which are the rudiments of thofe that are deficient.

In the *three-toed floth* the tarfus confifts of four bones, the aftragalus, os calcis, and the two cuneiform bones. There is a depreffion in the fuperior part of the aftragalus for the articulation with the lower end of the fibula, which is of a cone fhape. Upon the inner fide of the aftragalus there is a convex articular furface, which rolls upon the outer fide of the end of the tibia. The confequence of this fort of joint is, that the foot of the animal cannot be bent or extended in the ufual direction, but from the outfide inwards. The os calcis is articulated with the aftragalus by a fingle tubercle, which is received into a depreffion of the latter bone, which alfo facilitates the lateral motion of the foot.

The *elephant* has the tarfus and metatarfus both very fhort. In the *hog* there are three cuneiform bones, but in the *tapir* and *rhinoceros* only two.

In the *cloven-footed* order, the cuboides and fcaphoides are united together, except in the *camel*. There is a fmall bone on the outfide of the aftragalus, and articulated with the os calcis, which takes the place of the fibula, and correfponds with the one defcribed in the fore-foot as fupplying the ulna. There are only two cuneiform bones in this tribe, and even they are anchylofed in the *camelopard*. The metatarfus is formed of two pieces before birth, as the metacarpus.

In the *horfe* the metatarfus, as in the *cloven-footed* tribe of quadrupeds, is called the *cannon* bone. It has, like the metacarpus of the fame animal, two ftyles upon its fides, which are the rudiments of the metatarfal bones, and phalanges of the fecond and third toes.

In the *jerboa* (*mus fagitta*) and the *mus jaculus*, the three middle metatarfal bones are offified together, like the common bone of the *cloven* and *folid-hoofed* quadrupeds.

The orders of *quadrumanous* and *pedimanous mammalia*, as before-mentioned, have the power of moving the great toe in the manner of a thumb. Cuvier thinks the *aye-aye*, or *Madagafcar fquirrel*, can do fo likewife.

The number of the toes on the pofterior feet of quadrupeds varies from five to one. The great toe, or pollex, is the firft that difappears.

Some of the *digitigrada* have the great toe diminifhed, and a few, as the *cat* and *dog* genera, have it entirely obliterated.

Among the *faltigrada* there is confiderable variety in the number of the toes, and the fize of the great toe when it does exift.

Many of the *edentata* and the *tardigrada* receive fpecific names, according to the number of their toes, which in thefe are always lefs than five. In the *armadillos* the great and little toe are fhorter than the reft.

Amongft the *many-hoofed* quadrupeds, as they are called, the *elephant* has five toes, the *hog* four, and the *tapir* and *rhinoceros* three.

The *bifulca* have two perfect toes upon the cannon bone, and two imperfect.

The *folipeda* have one perfect and two imperfect: the latter are merely ftyloid proceffes.

It is hardly neceffary to obferve here, that the pofition of the toes gives the name to two orders of mammalia. Their number, and their fuftaining the animal in walking, or not, determine the character of feveral natural tribes of this clafs: the titles we have ufed for the orders of mammalia throughout the prefent article, are of themfelves explanatory of their foundation: for more full information, fee the article CLASSIFICATION.

In *Plate* X. of the *Anatomy of Mammalia*, there are figures given of the three moft diffimilar fkeletons found in the clafs. *Fig.* 1. is a front view of the fkeleton of the *bat*, which is taken as the example of a flying fpecies. *Fig.* 2. reprefents the fkeleton of the *mole*, the mechanifm of which is the moft curious found amongft quadrupeds. *Fig.* 3. exhibits the fkeleton of the *porpoife*, as an inftance of the aquatic tribe of mammalia. In each of thefe figures fimilar letters are employed to indicate fimilar parts, but when any of thefe parts are out of view, or do not exift in the fkeletons, the correfponding letters are of courfe omitted: *a* is the lower jaw; *b*, the upper jaw; *c*, the inter-maxillary bone; *d*, the malar bone; *e*, offa nafi; *f*, lacrymal bone; *g*, fphenoid bone; *h*, temporal bone; *i*, os frontis; *j*, parietal bone; *k*, occipital bone; *l*, cervical vertebræ; *m*, dorfal vertebræ; *n*, lumbar vertebræ; *o*, facrum; *p*, caudal vertebræ; *q*, fupernumerary bones on the lower furface of the tail; *r*, fternum, which is fingularly formed in the *bat* and *mole*; *s*, ribs; *t*, the clavicle, enormoufly thick in the *mole*; *u*, the fcapula, greatly elongated in the *mole*; *v*, the humerus, fhort in the *porpoife*, almoft fquare in the *mole*; *x*, the ulna, with an enormous olecranon in the *mole*; *y*, the radius, which makes the fingle bone of the fore-arm in the *bat*; *z*, the carpus; 1, the metacarpal bones; 2, the digiti, prodigioufly elongated in the *bat*; 3, the fupernumerary bone of the hand in the *mole*; 4, the os innominatum: the bones correfponding to the pelvis are very fingular in the *porpoife*; 5, the femur; 6, the tibia; 7, the fibula; 8, the tarfus; 9, the metatarfal bones; 10, the digiti of the pofterior extremity. There are no bones analogous to thofe of the pofterior member in the *porpoife*.

Mufcles.—The *mufcles* of the *head* and *face* are formed upon different plans in man and mammalia. In the former, befides moving the eye-brows, ears, cartilages of the nofe, and lips, they are defigned to exhibit the various expreffions of human fentiment. But in the latter, the mufcles of thefe parts are almoft exclufively confined to thofe motions which arife out of the mechanifm of the organs of fenfe in different kinds of animals, and are confequently very different in their formation: thus, fome mammalia have the external ears greatly developed, others the nofe, and others the lips.

The *occipito-frontalis* mufcle exifts in the *monkey*, *dog*, and other genera, without any remarkable variety, except that it is thinner.

The *corrugator fupercilii* alfo is found in thefe animals:

Monkies

Monkies very frequently move the ſkin of the forehead, and frown, without however ſeeming to intend to expreſs the ſame feelings which theſe actions indicate in the human ſpecies.

The muſcles of the cheeks and lips, which give the principal expreſſions of countenance in man, are often weak and indiſtinct in mammalia, or rather replaced by a layer of muſcular fibres, reſembling the *panniculus carnoſus*.

In the *monkey*, the ſubcutaneous muſcle of the face ariſes from below the orbit and the zygoma; it is continuous with the cutaneous muſcle of the neck. It envelopes longitudinally the ſnout, and terminates on the two lips, which it opens. Below this expanſion of muſcle the *buccinator* is very diſtinctly found, particularly in thoſe ſpecies that have jaw-facs. There are alſo to be perceived a *levator anguli oris*, an *orbicularis oris*, and ſometimes a *faſciculus* correſponding to the *zygomaticus*.

In the *dog*, the upper lip is moved by an expanſion of muſcular fibres which comes from the anterior angle of the eye, and ſpreads all over the upper lip, and by another little muſcle which deſcends from the ala of the noſe, near the ſeptum in the middle of the lip. Beneath this layer there are found the *orbicularis* and *buccinator*. The lower lip is depreſſed by a very thin muſcle.

The *ruminating* and *ſolid-footed* quadrupeds have the muſcles of the lips large and diſtinct. In the *ſheep* Cuvier reckons ſeven of them; *orbicularis*, *depreſſor labii inferioris*, *buccinator*, a very large *zygomaticus*, the *levator anguli oris*, a *naſalis* of the upper lip, and a *ſubcutaneous expanſion* of fibres ariſing in the neighbourhood of the orbit, and ſpreading over the *buccinator*.

In the *horſe*, in addition to theſe, with the exception of the two laſt, there are the *levator labii ſuperioris*; the *pyramidalis* of Bourgelat, or *ſupramaxillo-naſalis magnus* of Girard; a peculiar muſcle for raiſing the angles of the lips, and a ſhort muſcle to each lip, that are called by Bourgelat *medius ſuperior*, and *medius inferior*. It is unneceſſary to give any detailed account of theſe at preſent, as they are mentioned again, and are deſcribed under the ANATOMY *of the horſe* in this dictionary.

Theſe animals require an extenſive and varied action of the lips as organs of maſtication, but the form of their face in other reſpects prevents their having much expreſſion of countenance.

The *muſcles* of the *noſe* are ſubject to conſiderable variety in mammalia. In the *monkey* they appear to have their place ſupplied by the ſubcutaneous muſcle already mentioned.

In the *digitigrada*, of which we take the *dog* as an example, the *levator labii ſuperioris alæque naſi* is ſpread over the whole cheek, in a manner ſimilar to the ſubcutaneous muſcle of the *monkey*.

When the cartilages of the noſe and the lips are prolonged together, to form a ſnout, the muſcles have a peculiar form and arrangement.

In the *mole*, the muſcles which move the ſnout are eight in number, four on each ſide. They all ariſe from above the ears, and ſend off each a long tendon to the ſnout. The two deepeſt ſeated of theſe muſcles furniſh the tendons to the ſuperior part of the ſnout, upon which they unite and form a broad aponeuroſis that covers it for ſome diſtance. The two tendons that belong to the moſt ſuperficial of the muſcles unite in a band upon the inferior part of the ſnout. All the tendons are ultimately inſerted into the elaſtic fleſhy diſk, which terminates the cartilaginous tube of the ſnout. In addition to theſe there is a ſmall muſcle that ariſes from the alveolar edge of the intermaxillary bone, and depreſſes the ſnout. There are annular muſcular fibres ſurrounding thoſe already deſcribed: theſe ſeem to be the continuation of the *orbicularis oris*.

The muſcles of the ſnout in the *hog* are ſimilar to thoſe of the *mole*, but they are ſhorter, and ariſe from different places. The firſt two come from the lachrymal bone: their tendons do not unite. The next four ariſe from the ſuperior jaw before the zygoma; the two laſt are ſmall, and ariſe from the oſſa naſi: their tendons are not joined. There is alſo the circular muſcle, as in the *mole*.

The proboſcis of the *elephant* is moved by a very complicated muſcular apparatus, of which the beſt and lateſt deſcription has been given by Cuvier, in the additions to the 5th vol. of his "Anatomie comparée." It was compoſed from the diſſection of two *elephants*.

He divides the numerous muſcles found in this organ into two principal orders; *viz.* thoſe which form the body, or interior part of the trunk; and thoſe which envelope it. The firſt order are more or leſs tranſverſe, and interſect the internal part of the proboſcis in various directions. The ſecond have more or leſs of a longitudinal courſe, or that from the baſe to the point of the proboſcis.

Cuvier again divides the longitudinal muſcles into *anterior*, *poſterior*, and *lateral*. The *firſt* ariſe from the anterior part of the os frontis, above the cartilages, and proper bones of the noſe, by a large ſemicircular line, which deſcends on each ſide as far as before the orbits. They form an innumerable multitude of faſciculi, which all deſcend parallel to each other, and are contracted by tendinous interſections occurring at very ſhort diſtances. The *poſterior* diviſion of the longitudinal muſcles ariſe from the poſterior ſurface, and inferior edge of the intermaxillary bones. They form two layers, each of which is divided into a multitude of little faſciculi, which have an oblique direction. The fibres of the external layer are directed from above downwards; thoſe of the internal take a contrary courſe, that is, from without inwards; and the faſciculi of the two layers, when they meet, form a middle line, which extends along the middle of the under part of the proboſcis throughout its whole length. Finally, the longitudinal muſcles that make the *lateral* diviſion form two pairs, of which the one is in ſome meaſure a continuation of the *orbicularis oris*, or it might perhaps be rather conſidered as analogous to the naſal muſcle of the upper lip; it comes from the commiſſure of the lips, and deſcends between the anterior and poſterior muſcles as far as the middle of the proboſcis; it ſoon divides into ſeveral ſlips, which are inſerted obliquely between the lateral faſciculi of the inferior muſcles. The ſecond lateral muſcle is analogous to the *levator labii ſuperioris*; it ariſes from the anterior edge of the orbit, and proceeds, becoming broader, to be ſpread over the root of the preceding.

Blair has conſidered the zygomatic muſcle as a continuation of the firſt of theſe lateral muſcles; and becauſe the ſterno-cleido maſtoideus is attached to the zygoma alſo, in conſequence of the want of the maſtoid proceſs, Blair thought that theſe three muſcles were but one, and therefore pretended that the depreſſors of the proboſcis came from the ſternum.

The uſe of the longitudinal muſcles of the *elephant's* trunk is ſufficiently plain. When they all act together, they ſhorten the whole proboſcis. When thoſe of one ſide act, the trunk is bent towards that ſide. The diviſions and tendinous interſections of the anterior longitudinal muſcles, enable the animal to put particular parts of the trunk into a contracted or bent ſtate, whilſt other parts are elongated, or even bent in a different direction, and thus the prodigious

variety

variety of forms and curvatures that this wonderful inftrument affumes can be accounted for.

Perrault fuppofed that the interior tranfverfe mufcles proceed as rays from the circumference of the two canals to the external furface of the trunk. Cuvier has fhewn this to be incorrect. Thofe of the anterior part proceed nearly like radii from the centre to the circumference; in the region of the axis behind the two canals there are fome fafciculi which pafs directly from right to left; thefe are furrounded by others, which go more or lefs obliquely to the circumference. It is eafily perceived that the firft and laft tend much to diminifh the diameter of the external envelope of the trunk, without abridging the capacity of the canals; but when the mufcles of the region of the axis are put into action, they contract at the fame time the canals and the external envelope. Thefe laft feries of mufcles appeared not to have been known by Perrault; and Stukely did not defcribe them, although he delineated them in his figure of the *elephant's* trunk.

All thefe little mufcles which form the body of the probofcis are very diftinct from each other, and terminate each in flender tendons, of which fome pafs through the layers of the longitudinal mufcles to gain the external envelope, and others go to be inferted into the membrane of the canals. All thefe mufcles are imbedded in a cellular tiffue uniformly filled with a white and homogeneous fat.

The tranfverfe mufcles are evidently the antagonifts of the longitudinal, and in contracting the trunk they alfo elongate the whole, or parts of it, according to the animal's pleafure.

If the number of fhort mufcles be reckoned as they appear on a tranfverfe fection of the probofcis, and if the breadth of a line which is more than their thicknefs be allowed for the fucceeding ones, the total number may be in fome degree calculated, which, when added to the number of fafciculi compofing the longitudinal layers, will amount, Cuvier fays, to between 30 and 40,000. The ftrength, the variety, and the delicacy of the motions of the *elephant's* trunk, far furpafs thofe of any other organ with which animals are endowed, and are fully explained by the mufcular ftructure above defcribed. The aftonifhment of the vulgar in feeing *elephants*, that are exhibited by fhow-men, ufe their trunk in the manner of a hand, arifes from their conceiving this moft wonderful inftrument to be nothing but a common prolongation of the fnout, which, in quadrupeds, generally is a part incapable of performing any confiderable motion.

The probofcis of the *tapir*, although much fhorter than that of the *elephant*, is formed upon the fame plan. The longitudinal mufcles are in two fafciculi, and take their origin below the eye. The tranfverfe mufcles are attached to the membrane covering the tubes, and to the external envelope, as in the *elephant;* but the *tapir* has an additional mufcle, fimilar to the *levator labii fuperioris* of the *horfe*. It arifes from the neighbourhood of the eye, and unites above the noftrils in a common tendon with the fame mufcle of the other fide. The *occipito-frontalis* in the *tapir* alfo fends off a tendon to the bafe of the probofcis, which is thereby elevated.

The mufcles of the nofe in the *cloven-hoofed quadrupeds* are two on each fide. They arife from the inferior part of the os maxillare fuperioris above the anterior molar teeth. Two of them are fuperior, and two inferior; the firft fend off each two tendons, one to the upper edge, and the other to the pofterior angle of the noftril. The mufcles divide each into three portions; they are all inferted into the inferior edge of the noftril.

There is alfo a mufcle for depreffing the nofe; it is fituated anteriorly.

The mufcles which operate upon the nares of the *folipeda* are much more complicated than in the preceding tribe. The falfe noftril is dilated by a mufcle which veterinary anatomifts have called the *pyramidalis*. It arifes from the upper jaw, near the anterior part of the zygoma, by a fmall tendon. Its flefhy part becomes broader, and expanded upon the convexity of the falfe noftril, and in the orbicularis oris. There is another mufcle fituated above the preceding. It arifes from the maxillary bone near to the notch of the offeous part of the nares; it penetrates into the fold placed between the bone and the falfe noftril, and is inferted into a cartilaginous production of the inferior turbinated bone. The femilunar cartilage is made to approach the feptum, and the noftril is dilated by a mufcle which is common to both noftrils. This is the *tranfverfalis* of Bourgelat. It appears to be an extenfion of the orbicularis oris. Superiorly there are fome fibres which arife from the nafal bone, and are inferted into the fuperior convexity of the falfe nares; thefe are the *brevis* of Bourgelat. There is another mufcle called *maxillaris* by Bourgelat, which arifes from all the anterior part of the forehead, proceeds obliquely downwards, and divides into two branches. The external paffes over the pyramidalis, is intermixed with it, and is inferted in the external convexity of the falfe noftril.

The *levator labii fuperioris* alfo acts upon the noftrils: it arifes from the lachrymal bone. Its tendon unites with the one of the other fide, to form an aponeurofis, which covers the end of the nofe, and is inferted into the upper lip.

The mufcles which move the external ear in quadrupeds are much more numerous than in man. In the defcription which Cuvier has given from the *horfe*, *fheep*, *rabbit*, and *dog*, he reckons twenty-one, fome of which are peculiar to certain quadrupeds only. He divides them into four claffes: 1ft. Thofe which pafs from the head or neck to the third cartilage of the ear of quadrupeds, which he has called the *fcutum*. The 2d are thofe which arife from fome of the parts of the head, or the cervical ligament, and are inferted into the concha or its tube. The 3d clafs contains mufcles which unite the fcutum to the concha, or to the tube of the ear. The 4th clafs confifts of thofe that extend from one part of the concha to another.

In the firft clafs there are three mufcles: the *vertico-fcutalis*, the *jugo-fcutalis*, and the *cervico-fcutalis*. The firft comes from the crown of the head, and draws the ear upwards and inwards. The fecond arifes from the zygoma, and draws the ear forwards and a little upwards: it is wanting in the *hare* and *fheep*. The third comes from the cervical ligament, and makes the one ear approach the other pofteriorly: it is peculiar to the *dog* and *rabbit*.

The fecond clafs contains feveral mufcles.

1. The *vertico-auricularis* arifes from the vertex of the head, and is inferted on the concha, which it elevates and approximates to the other: it is peculiar to the *horfe* and *fheep*.

2. The *fupercilio-auricularis* takes the place of the preceding in the *hare* and *dog*. It arifes from the fuperciliary arch.

3. The *cervico-auricularis* arifes from the cervical ligament, and is inferted upon the concha, which it pulls backwards and to the other fide.

4. The *occipito auricularis* paffes from the occiput to the concha, which it draws upward and backward: it is not found in the *hare*.

5. The *cervico-tubalis profundus* paffes from the cervical ligament

ligament to the tube of the ear, which it draws backwards: it is double in the *horfe*, and wanting in the *hare*.

6. The *occipito-auricularis rotator* arifes from the occiput, and terminates in the concha, near its tube: it exifts in all long-eared quadrupeds, and turns the ear upon its axis.

7. The *parotido-auricularis* paffes from the parotid gland to the concha, near the tragus: it depreffes the ear, and is a mufcle conftantly found.

8. The *jugo-auricularis* goes from the zygoma to the concha: it is large in the *fheep*, double in the *dog* and *horfe*, and does not exift in the *hare*.

9. The *jugo-auricularis profundus* arifes from the pofterior part of the zygoma, and is inferted into the concha, near the tube: it fhortens the tube.

10. The *vertico-auricularis rotator* goes from the vertex of the head to the anterior part of the concha, near the tube: it rotates the ear, fo as to bring the hollow part forwards and inwards.

11. The *vertico-auricularis profundus* arifes along with the preceding, and is inferted into that part of the concha neareft the tube, which is inward when its concavity is directed outward: its ufe appears to elongate the tube of the ear. Thefe laft two mufcles Cuvier only found in the *horfe*.

The third clafs contains two fuperficial and one deep-feated mufcle.

1. The *fcutalis anterior* paffes from the lower edge and anterior angle of the fcutum, to the front of the concha: it turns the latter on its axis, and directs it upwards and forwards when horizontal. It does not exift in the *dogs* that have hanging ears.

2. The *fcutalis pofterior* has nearly the fame origin as the preceding, but is inferted into the back of the concha: it raifes the concha. The *hare* wants this mufcle.

3. The *fcutalis rotator* is deep-feated, and arifes under the fcutum, and terminates behind the concha next the tube: it rotates the concavity of the concha towards the earth, and backwards, when it is horizontal. This mufcle is double in the *hare*.

The fourth clafs of the mufcles of the ear do not exift in the *fheep;* and there is only one of them in the *horfe*, which is the *tragicus:* it contracts the opening of the external meatus. It is found in the *dog* and *hare*.

In the *hare* there is a mufcle which fhortens the tube: it is called by Cuvier *tubo-helicus*.

In the *dog* there is a mufcle analogous to thofe on the helix in the human fubject. Cuvier calls it *plicator auris*.

In the *dog* and *horfe* there are fome mufcular fibres upon the back of the concha, analogous to the *tranfverfus auris*.

By means of the mufcles above defcribed, quadrupeds are enabled to give almoft all poffible attitudes to the external ear, befides collecting the founds which approach in various directions. The external ear is fometimes employed in expreffing the fenfations of animals: thus, *horfes* throw back their ears, when difpleafed; and moft quadrupeds fhew their fatisfaction by an erect pofition of thofe parts.

The *mufcles which move the jaws* in mammalia are, except in fome of the *faltigrada*, the fame in number, and bear the fame names as thofe in man. They differ chiefly with refpect to their relative ftrength. This circumftance has been in a great meafure already explained, in defcribing the form and extent of the bones to which thefe mufcles are attached.

As a general obfervation, it may be ftated, that the *maffeter* and *pterygoid* mufcles are largeft in the *herbivorous* quadrupeds, and the *temporal* in the *carnivorous*.

In the *ant-eaters*, the pofition of the *maffeter* is very unfavourable to its action. The tubercle that fupplies the place of the zygoma is anterior to the part of the lower jaw, to which the other extremity of the maffeter is affixed; confequently the fibres of the mufcle pafs in a direction contrary to that in which their force is exerted.

In the *mus typhlus*, the *temporal* mufcle is very ftrong, although it is thin in this tribe generally. The *typhlus* has it fo much extended as to be intermixed with the one of the oppofite fide, upon the upper part of the head.

The *mole* has the temporal mufcles very thick and elongated, fo that their greateft extent is from behind forwards. They touch each other upon the crown of the head.

In the *carnivorous digitigrada*, efpecially the *cat* genus, the temporal mufcles have fo great a bulk in every direction, that they make up the chief part of the bulk of the head.

An additional mufcle on each fide, for raifing the lower jaw, has been difcovered in the *cavy*, and other *faltigrada*, by Mr. J. F. Meckel, which is defigned to aid thefe animals in their particular mode of comminuting their food. This mufcle has received the name of *mandibulo-maxillaris*. In the *cavy* it commences as a thick mafs, from the moft anterior part of the fuperior maxillary bone, proceeds backwards and downwards acrofs the great fub-orbitar foramen, which it fills, and changes there into a ftrong tendon, which defcends to the lower jaw, to be inferted on the outfide of the pterygoideus externus mufcle, oppofite the firft molar tooth, that is, in the moft anterior part of the canal, in which the pterygoid mufcles are inferted. Thefe mufcles are generally fimilar in the other *gnawing* quadrupeds: they are mufcular throughout in the *rats*, in whom they are very ftrong. The action of the mandibulo-maxillaris mufcle has a direct effect upon the incifor teeth, or upon the extremities of both jaws; and hence the exiftence of this mufcle in thofe *faltigrada* that gnaw hard fubftances. The mandibulo-maxillares are wanting in the *hare* and *marmot*, which live on foft herbs.

The *digaftric* mufcle, except in the *monkey*, is differently formed than in man. The name of *mafto-maxillaris*, impofed upon it according to the modern fyftem of nomenclature, is peculiarly proper. It generally wants the middle tendon, which forms it into a mufcle with two bellies, or a *digaftricus*. In the *mandril* (*fimia maimon*), the tendons of the maftoid portions of each fide become intermixed above the hyoides, fo that thefe two portions appear to make a digaftric mufcle.

In the *digitigrada* this mufcle has but one belly, and it is inferted into a procefs at the pofterior angle of the branch of the jaw.

In the *faltigrada* there are two portions.

This mufcle is wanting in the *ant-eaters* and *armadillos*. Thefe animals have its place fupplied by a long flender mufcle, that arifes from the middle of the top of the fternum, and is inferted at the inferior and middle part of the ramus of the lower jaw. This mufcle is called by Cuvier the *fterno-maxillaris*.

In the *floths* the digaftric is connected with the *fterno-hyoideus* mufcle.

The *ox* has the middle part of this mufcle covered above and upon the internal edge by an aponeurofis, which gives attachment to a fquare mufcle, that extends from one digaftric to the other.

The *mufcles of the os hyoides* exhibit no very ftriking peculiarities, except in fome of the *edentata*.

The *fterno-hyoidei* mufcles in the *lion* arife fo far within the fternum as the third piece compofing that bone. In the

fea-

feal they arife from the firft ribs, and are ftrengthened by a flip from the little tuberofity of the humerus, which correfponds to the *omo-hyoideus*. The fternum is narrow in thofe animals, to which Cuvier afcribes the fterno-hyoideus as having an unufual origin.

The *fterno* and *omo-hyoidean* mufcles are incorporated, and make a very large mufcle in the *dolphin*.

The *ftylo-hyoideus* is only perforated by the digaftric mufcle in the *monkey*, as in man.

In the *paca* the *ftylo hyoideus* is wanting: the ftyloid bone is not connected with the cranium; and the middle portion of the digaftricus adheres firmly to the body of the os hyoides.

The *mylo-hyoideus* is an active mufcle in bringing forwards the hyoides, when this bone is placed far back, and the jaw is much elongated.

The pofition of the os hyoides being fo near the fternum in the *ant-eaters*, the mufcles which act upon it have many peculiarities. There is a very fmall mufcle which is analogous to the *ftylo-hyoideus*: it arifes from the middle and anterior part of the ftyloid bone; it defcends inwards and backwards, to be united to the edge of the *genio-hyoideus*. The *mylo-hyoideus* is neceffarily very long: it does not touch the os hyoideus, but its laft fibres afcend to the bafe of the ftyloid bone, to which they are affixed; and, more anteriorly, fome of thefe fibres even afcend to be inferted into the tranfverfe proceffes of the middle cervical vertebræ. Thofe which precede the laft mentioned are inferted more internally, into the membrane of the bottom of the mouth. It is only the portion correfponding to the two anterior thirds of the jaw, that is attached to the edge of that bone. There is no middle tendinous line in this mufcle, and all its fibres are tranfverfe in their direction. The *genio-hyoideus* is a fingle mufcle: it is attached to the angle of the chin by a very thin tendon, which extends to the oppofite angles of the jaw, accompanying the middle of the *mylo-hyoideus*: its flefhy part commences there. It is very thin throughout, and is at firft narrow, but it afterwards enlarges, and then is compofed of two portions: it contracts again, before it is attached to the body of the hyoides. The *fterno-hyoidei* mufcles extend upon the fternum, as far as the middle of the bone.

In the *echidna* the *mylo-hyoideus* is attached in a great meafure to the palatine membrane: the moft diftant portion afcends upon the fides of the occiput.

In the *ornithorhynchus* the *mylo-hyoideus* has a tendinous line in the middle, from which the mufcular fibres depart on each fide, and proceed obliquely from behind forwards, and are inferted into the inferior border of the jaw. There is a fecond portion of this mufcle, which appears to fupply the place of the *genio-hyoideus* in this animal. Its fibres depart from the hyoides and the bafe of the tongue, and advance more obliquely outwards, as far as the moft diftant part of the branches of the jaw, to the lower edge of which they are attached. The *fterno-hyoideus* is prolonged upon the fternum, as far back as the middle of that bone, both in the *echidna* and *ornithorhynchus*. It is difficult to conceive the ufe of the extenfion of the mufcle in the latter animal. In the *echidna* and the *ant-eaters* it is fubfervient to the motions of their tongue.

The mufcle called by Cuvier *ftylo-maftoideus* is peculiar to mammalia, in which it appears to exift pretty regularly. It is a fmall mufcle, arifes from the external furface of the maftoid procefs, and is inferted upon the internal furface of the temporal end of the ftyloid bone. When the ftyloid bone, as in the *cloven-hoofed quadrupeds*, has an angle prolonged pofteriorly, this mufcle is inferted into it, and moves the ftyloid bone as a lever, and brings its lower end upwards and outwards. When the ftyloid bone is not attached to the cranium, this mufcle ferves to fufpend it.

In the *paca*, the *ftylo-maftoideus* feems to form a part of the digaftric, with which it defcends to the os hyoides, and is afterwards extended upon the fides of the pharynx, by which it fupplies the place of the *ftylo-pharyngeus*.

In the *digitigrada*, there is another additional mufcle: it is thin, flat, and fills up a part of the interval of the two horns of the os hyoides of the fame fide.

The *mufcles of the pharynx* refemble thofe of man fo much, that a defcription of them becomes unneceffary.

There is a *pharyngeus proprius* in the *elephant*, *bear*, &c. which has been already mentioned.

The *ftylo-pharyngeus* has fome peculiarity of direction and effect, in confequence of the horizontal pofition of the pharynx. It defcends almoft perpendicularly from the ftyloid procefs, or bone, upon the upper furface or fides of the pharynx, and it is only after it has paffed under the conftrictor mufcles that it proceeds backwards along the pharynx. Its operation is rather to dilate the bag of the pharynx than to bring it forwards.

The peculiarities of the mufcular ftructure of the tongue are already noticed in the firft part of this article, where that member is defcribed as an organ of maftication.

The *fubcutaneous mufcles* are much more remarkable in quadrupeds than the human fubject. In the latter, they are weak, and confined to particular places; but in the former, almoft the whole of the fkin can be moved; and in thofe fpecies that roll themfelves up when they are in danger, the fubcutaneous mufcles are of great magnitude, and complicated in their arrangement.

The *cutaneus* or *latiffimus colli*, (*thoraco-facialis* of Cuvier) is inconfiderable in many quadrupeds. It is intermixed with fome mufcular fibres that lie under the fkin of the face in the *monkey* kind, as already obferved. In the *marmot*, this mufcle has another placed under it, which is thicker, and extends to the fide of the head, and to the face and fnout.

There is a cutaneous mufcle upon the abdomen, and under the fkin of the thighs of quadrupeds, which is inferted, along with the pectoralis major, into the humerus by one or two tendons. Befides acting upon the fkin of the lower furface of the body, it concurs, with the actions of the pectoral mufcle, in bringing the arms inwards, and in the true quadrupeds is a mufcle of progreffion, by affifting to move the body forwards upon the anterior extremities. Cuvier gives the name of *dermo-humeralis* to this mufcle. In the *racoon* it is attached to the prepuce, which it retracts. Where it covers the belly of this animal, it is very thin. In the *marmot* this mufcle covers the back as well as the under furface of the body: it is inferted into the arm by two tendons; the one with that of the latiffimus dorfi; the other with the tendon of the pectoralis major.

Thofe animals that have the power of rolling themfelves up, poffefs a number of curious mufcles for the purpofe. Thefe are the moft numerous and ftriking in the *hedge-hog*.

In this animal there is a very extenfive fubcutaneous mufcle upon the back of the body. Its fibres adhere clofely to the fkin of the back and the ends of the fpines. The fhape of the mufcle is oval: the middle of it is thin, and has the fibres moftly arranged longitudinally; but around the edge they are thick, and have a circular direction, and refemble a fphincter mufcle.

In the ordinary pofition of the *hedge-hog*, the dorfal mufcle is contracted, and entirely carried upon the back; but when

when the creature is coiled up, the longitudinal fibres of the mufcle are fo much relaxed, that it is capable of being extended over the top of the head, the tail, and pofterior legs; after which the fphincter or marginal fibres are put in action, by which the whole body is inclofed, as it were, in a round bag.

There are feveral fmall diftinct mufcles which ferve to connect this flefhy oval expanfion to different parts of the body, and which contribute to bring the head and limbs into their proper pofition, after they have been doubled up by the mufcles fituated upon the inferior part of the body. Two pair of thefe mufcles arife from the anterior extremity of the oval mufcle. They are inferted into the nafal and intermaxillary bones, and the lateral parts of the nofe.

One pair of mufcles arifes from the pofterior part of the oval expanfion: they are broad, pyramidal, and inferted by tendon into the fides of the tail, near its end.

There are three diftinct portions of mufcles under the fkin, upon the lower furface of the body. The firft correfponds to the cutaneus colli: it arifes from the top of the fternum, and is inferted behind the ears. The fecond is pofterior to this; it arifes from the middle of the fternum; it paffes over the top of the fhoulder, and is inferted into the oval or orbicular mufcle of the back. Thefe two mufcles, with their fellows of the oppofite fide, produce the figure of two cones, having their points turned backwards, and the one being received into the bafe of the other. The third mufcle covers with its fellow the furface of the abdomen. It is attached to the tail, the top of the thighs, the arm, and the dorfal mufcles, by fo many diftinct flips or divifions. This mufcle is analogous to the *dermo-humeralis* of other quadrupeds.

There are, befides thofe already defcribed, fome deep-feated mufcles fituated under the great oval one of the back. One arifes from the pofterior edge of the meatus auditorius externus, and proceeds backwards to be loft in the fore-part of the orbicular mufcle. Another arifes from the laft cervical vertebræ, and is alfo inferted into the orbicular mufcle. Underneath the great oval mufcle there is a thin layer of tranfverfe fibres: the anterior ones are attached to the inner and upper part of the humerus, and the pofterior to the external procefs of the ventral or *dermo-humeralis* mufcle.

When the orbicular mufcle is entirely contracted, and carried upon the back of the *hedge-hog*, it ferves as the fixed attachment of the mufcles, which go from it to the head, neck, and tail; and thefe parts are confequently raifed or fuftained by them; but when the animal wifhes to roll itfelf up, it relaxes the orbicular mufcle, and puts into operation the flexors of the head and limbs, by which they become fixed points, and all the ftraight mufcles connected with the oval or orbicular mufcle of the back are enabled to act upon it, and fpread it over the body; and when the latter is brought over the head and tail, the margin of it contracts feparately from the reft, by which even the head and feet of the animal are completely inclofed. The connection which the great oval mufcle has with the roots of the fpines of the fkin, puts the fpines into a ftate of erection in different directions, which renders the animal unaffailable at every point. See Himly's account of the rolling up of *hedge-hog*, printed at Brunfwick, 1801, 4to.

The *mufcles* that act immediately upon the *ribs* have no peculiarities in mammalia worth remarking.

The *abdominal* mufcles are longer and narrower in mammalia than man. This depends, in fome degree, upon the difference in the fhape of the trunk, but not entirely, as the *ftraight* and *pyramidal* mufcles are generally the moft elongated. In many of the *digitated* quadrupeds the *pyramidales* are wanting, and the *recti* extend as far as the anterior part of the fternum.

The *diaphragm* exhibits, in general, no difference of ftructure in mammalia from what is defcribed in man. According to Cuvier, it has in the *bats* two very ftrong crura, which form a kind of flefhy feptum placed longitudinally on the fpine within the abdomen.

Thofe animals that have an abdominal pouch for containing the mammæ and the young during the period that they are fuckled there, have two additional bones attached to the pelvis, as already mentioned. Thefe bones are moved by two mufcles, long fince defcribed by Tyfon, and called by him *triangulares*. Thefe fibres arife in different directions from the fide of the marfupial bones next the fymphyfis pubis, and both mufcles unite with each other, in the middle of the interval, between the two bones, by means of a tendinous line. Thefe mufcles fuftain, elevate, and approximate the marfupial bones, in doing which they are affifted by the abdominal mufcles, which are likewife connected with thefe bones. The mufcles which move the head upon the fpine, and the different vertebræ upon each other, exhibit but few deviations from the ftructure defcribed in man, that are worthy of remark.

In moft mammalia, the *obliquus capitis inferior*, and the *rectus capitis pofticus major*, are much larger than in man, in proportion, on account of the magnitude of the two firft vertebræ of the neck being greater. The *monkey* and *cetaceous* tribes, however, form exceptions to this obfervation.

The *biventer cervicis* is commonly not divided by tendon into two bellies: the new name of *trachelo-dorfalis* given to it by Cuvier is particularly proper. In the *digitigrada* it is interfected by tranfverfe tendons throughout. It is quite diftinct from the *complexus*, although it lies upon it. The *horfe* has thefe two mufcles joined together at the upper part.

The *fplenius* is larger in mammalia than in man, and is particularly ftrong in the *mole*. In thofe that have the ligamentum nuchæ elevated above the vertebræ, the *fplenius colli* is inferted into it. There is no part of the mufcle inferted into the tranfverfe proceffes of the cervical vertebræ in the *digitigrada*.

The mufcles of the dorfal fpine conform ftill more clofely in general, than thofe of the cervical, to the plan obferved in man. In the *bat*, however, thefe mufcles are nearly obliterated.

The *mufcles* of the *tail*, in almoft all mammalia, are larger and more complicated than they are in man, but in particular fpecies they are very remarkable for their number, or their ftrength. Cuvier has reckoned eight pair of mufcles in mammalia, but if the portions of which thefe are compofed be counted in any of the long-tailed fpecies, they will be found to be vaftly numerous. Mery ftated that he met with 280 caudal mufcles in a *prehenfile-tailed monkey*. The *cetacea* have the mufcles of the tail fo large as to give to thefe animals the figure of fifhes. The *beaver* has the flexor mufcles of the tail prodigioufly ftrong, in order that it may be able to employ that member in the manner of a trowel for plaftering its habitation. The *kanguroo* has the extenfors very ftrong, as the animal ufes the tail to project the whole body from the ground in its fingular mode of progreffion by leaps.

In defcribing the caudal mufcles we fhall follow Cuvier and Vic d'Azir.

The *facro-coccygei fuperiores* of Cuvier, or *lumbo-fupra-*

caudales

caudales of Vic d'Azir, are fituated upon the upper fide of the tail. They arife, by flefhy flips, from the three or four laft lumbar vertebræ, the facrum, and from thofe caudal vertebræ that have proceffes. Small tendons pafs off from the common mafs oppofite to the flefhy digitations. The firft tendon is the fhorteft, and is inferted into the bafe of the firft caudal vertebra. The fecond tendon to the next vertebra, and fo on to the end. There are thirteen of thefe tendons. They enter ligamentous grooves or fheaths, which are connected together by a ligamentous web that inclofes them in a fort of cafe. Thefe mufcles have the effect of directly raifing the tail.

The *interfpinales* (*fpinales obliqui* of Cuvier,) (*lumbo-facro-coccygei* of Vic d'Azir), fhould be confidered as the continuation of the *inter-fpinal* mufcles of the back. They cooperate with the laft defcribed in the elevation of the tail.

There are four pair of mufcles for depreffing the tail.

The *ilio-fubcaudales* (*ilio-coccygei* of Vic d'Azir) arife from the internal part of the ileum; form two long flefhy maffes in the pelvis; and are inferted into one of the V fhaped bones of the under furface of the tail. Sometimes they are inferted between the fifth and fixth of thefe bones, at others between the feventh and eighth.

The *facro-fubcaudales* (*facro-coccygei inferiores* of Vic d'Azir) refemble exactly the facro-coccygei fuperiores, except that they are placed upon the oppofite fide of the tail. They arife from the facrum, and from the tranfverfe proceffes of the fuperior caudal vertebræ. Their tendons are long and numerous, and inclofed in a fheath, like thofe of the facro-coccygei fuperiores. They begin in the long-tailed fpecies to be inferted into the feventh caudal vertebra, and fo on.

Thefe mufcles, with the *fuperior coccygeal*, operate upon the tail, even to its point, and have exactly the oppofite effects of each other. They are particularly employed in all the more delicate motions of the tail.

The *fubcaudales* of Cuvier (*inter-coccygei* of Vic d'Azir) are fituated under the middle of the tail. They arife at the articulation of the firft and fecond caudal vertebræ. They are firft inferted into the V fhaped bone of the fourth, fifth, and fixth vertebræ; they further receive little flefhy flips, which gradually diminifh, and go on to be inferted into the bafe of each bone of the tail.

The *pubo-fubcaudales* of Cuvier (*pubo-coccygei* of Vic d'Azir) arife broad and thin from the upper part of the pelvis, and proceed to terminate in points which are inferted into the proceffes or tubercles at the bafe of the fourth and fifth vertebræ, upon the inferior furface of the tail. They bring the tail clofe to the body. Thefe mufcles are wanting in the *racoon*.

There are two mufcles on each fide of the tail for producing the lateral motions of it.

The *ifchio-caudalis* of Cuvier (*ifchio-coccygeus externus* of Vic d'Azir) arifes from the internal furface of the ifchium, and paffes backwards over the tranfverfe proceffes of the tail. In the *racoon*, it is inferted into the feven caudal vertebræ that fucceed the third, by feven flefhy digitations. In the *opoffum*, into the four firft vertebræ of the tail. In the *dog*, it is a mere flip of flefh, and is inferted into the fourth vertebra.

The *intertranfverfalis* paffes from one tranfverfe procefs to the other on each fide, as far as they go. This mufcle is fimilar to the one of the fame name in the other parts of the fpine.

It is fcarcely neceffary to obferve, that the combined actions of thefe mufcles, or their contractions in oppofition to each other in different parts of the tail, are capable of communicating to this member all poffible directions. The effects of this co-operation are ftrikingly difplayed in the tails of certain *monkies*, *marfupial animals*, *ant-eaters*, &c. in which this member is capable of performing moft of the operations of a hand.

There are feveral peculiarities to be noticed in the *mufcles* of the *anterior extremity*, particularly thofe of the fhoulder and upper arm of quadrupeds.

The *ferratus major* has not only the digitated attachments to the ribs, but to fome or all the tranfverfe proceffes of the cervical vertebræ. In the *dolphin*, and probably in all *cetacea*, this mufcle has no attachment to the cervical vertebræ; the greater extent of the ferratus major appears to be required for progreffion on four feet.

The *pectoralis minor* does not exift in the *digitigrade* and *hoofed quadrupeds*. Another mufcle fupplies its place in the *horfe*. This is united to the pectoralis major, and is in part inferted into the humerus. The pectoralis minor of the *dolphin* is narrow, and arifes by one digitation from near the top of the fternum, and is inferted at the glenoid cavity of the fcapula.

The *levator fcapulæ* is inferted into the fpine of the fcapula in the *monkey*, the *digitigrade* and *faltigrade* quadrupeds. In the *dog* and *bear* it arifes from the firft cervical vertebra only, and in the *rabbit* from the cuneiform procefs of the caput, and has been called by Vic d'Azir *acromio-bafillaris*. In the *fheep* it arifes from the firft cervical vertebra, and is inferted into the pofterior part of the fpine of the fcapula. The *levator fcapulæ* is wanting in the *horfe*. In the *dolphin* it comes from the firft cervical vertebra, and its tendon is fpread over the whole external furface of the fcapula.

The *trapezius* and *fterno-cleido mafloideus* are generally confounded with each other, or with fome of the other mufcles of the neck. In the *carnivorous*, and thofe *faltigrade* quadrupeds that have an imperfect clavicle, the clavicular portions of the *fterno-cleido mafloideus*, and of the *deltoides* and of the *trapezius*, make but one mufcle, to which Cuvier gives the name of *mafto-humeralis*, and which has been called by other anatomifts *communis capitis*, *pectoris*, and *brachii*. The clavicular portion of the *trapezius* is diftinct from the fcapular portion; and the levator fcapulæ paffes between them. In the *bear*, the anterior portion of the *trapezius* is again divided into two mufcles, one of which fends a tendon to the top of the fternum. In the *fheep*, there is a mufcle which arifes from the maftoid procefs; it divides into two; one goes to the fternum; and the other is incorporated with the clavicular portion of the *trapezius* and of the *deltoid*. In the *horfe* there is a diftinct *fterno-mafloideus*, but the *cleido-mafloideus*, *levator fcapulæ*, and the clavicular portions of the *trapezius* and *deltoid*, are fupplied by one mufcle, which arifes from the maftoid procefs, and the tranfverfe proceffes of the fuperior cervical vertebræ, and paffes down the internal fide of the arm to be inferted inferiorly. In the *dolphin*, the clavicular portion of the *trapezius* is wanting: the *fterno-mafloideus* of this animal is very ftrong, and there is another mufcle external to it, which arifes from the maftoid procefs alfo, and is inferted below the head of the humerus.

There is a mufcle of the fhoulder apparently peculiar to the *rabbit*: it is thin, and arifes from the fpine of the fcapula, and is inferted into the clavicle.

The *rhomboides* is a larger mufcle in quadrupeds, in proportion, than it is in man. It is even in the *monkey* tribe extended to the occiput. The portion arifing from the fkull is diftinct in the *digitigrade* quadrupeds, and is the

 mufcle

mufcle which has been called the *levator fcapulæ magnus*. This portion of the *rhomboides* arifes from the ligamentum nuchæ in the *horfe*, and has been called by the veterinary anatomifts *levator fcapulæ proprius*. The rhomboides has no divifion, and is a fmall mufcle in the *dolphin*.

The *fubclavius* is of courfe wanting in thofe quadrupeds that have imperfect clavicles, or none.

We have referved the account of the mufcles of the fhoulder in the *mole* and *bat* for feparate confideration, as the motions of the anterior extremity in thefe animals are fo very peculiar.

In the *mole*, the *ferratus major* is extremely large, but fimple in its form; it arifes from only the laft cervical vertebra. The *trapezius* has no anterior origin; there are only two fafciculi from the lumbar region to the pofterior angles of the fcapulæ, which would draw thefe bones afunder, if they were not bound together by a ftrong tranfverfe ligament. The *rhomboides* is attached pofteriorly almoft entirely to this tranfverfe ligament of the fcapulæ, and anteriorly to the offified ligamentum nuchæ. The chief ufe of this mufcle is therefore to elevate the head. The mufcle correfponding to the occipital portion of the *rhomboides* arifes from the middle of the head, has its fibres parallel to the cervical fpine, and paffes through the *rhomboides*, properly fo called, to be attached to the tranfverfe ligament of the fcapulæ. This mufcle operates with great power in raifing the head, which is a neceffary exertion to the *mole* in burrowing. This animal has two mufcles to the clavicle: one of thefe Cuvier calls *fuperclavius*: it arifes from the firft bone of the fternum at the anterior angle of the great head of the clavicle. The other arifes lower down on the fternum, and is inferted near the firft.

In the *bat*, the *ferratus major* is fituated before the *pectoralis minor*. It is only attached to the ribs, and is inferted into the inferior and external edge of the fcapula. The *fubclavius* is very large. The *trapezius* arifes from the eleven firft dorfal vertebræ, and is inferted into the triangular furface of the cervical angle of the fcapula. The *maftoid* mufcle is only attached to the fternum.

The *mufcles* of the *humerus* appear all to exift in mammalia, but frequently under different conditions than in man.

The *pectoralis major* is commonly compofed of feveral diftinct fafciculi, or portions. In thofe fpecies which have not a perfect clavicle, there is a portion of this mufcle arifing from the fternum, and inferted into the linea afpera, which, with the portion of the oppofite fide, makes a common mufcle for both arms, to which Cuvier gives the name of *ambibrachialis communis*. It has the effect of croffing the fore-legs. In the *fheep*, there is a fecond common mufcle, which paffes from the fternum to the ulna, completely inclofing the humerus with the trunk. It is defigned to crofs the fore-legs, and has been called by the veterinary anatomifts, in the *horfe*, *ambibrachialis communis*. It fhould rather, perhaps, be confidered a fubcutaneous mufcle than a portion of the pectoralis major. In the *bat*, the *pectoralis major* is divided into three diftinct mufcles. The laft lies partly under the firft. This is inferted into the great anterior tubercle of the humerus. The fecond is inferted above the firft, behind the great tubercle; and the third mufcle terminates upon the fpine of the humerus. Thefe mufcles deprefs the wing in flying, and therefore require to be very ftrong.

The *latiffimus dorfi* of the *bat* is a flefhy ftripe from the fpinous tubercles of the two laft dorfal vertebræ.

The *fupra* and *infrafpinatus* of quadrupeds have a different relative fize to each other than in man. In the former, the fupraspinatus is the larger mufcle. In the *cetacea*, the mufcles on the back of the fcapula are nearly obliterated.

In thofe fpecies that want the clavicle, there is only the fcapular portion of the *deltoides*, the other part being, as before defcribed, continued into the *trapezius*. There is a diftinction of two parts alfo in the fcapular portion, the *acromial* and *infra-fpinal*. In the *horfe*, the acromial attachment is wanting, and the deltoid having the fame direction as the infrafpinatus, it is diftinguifhed by the peculiar name of *abductor longus brachii*.

The *coraco-brachialis* confifts of two parts in the *monkey*, *bear*, &c. one of which extends the whole length of the humerus. In the *bear*, the inferior portion is inferted into the external condyle. When there is no coracoid procefs of the fcapula, this mufcle arifes from a little eminence on the upper edge of the fcapula.

In the *dog*, *cat*, *rabbit*, and *horfe*, the *biceps* arifes by one head, and is unconnected with the coraco-brachialis.

In the *bat*, there is no *coraco-brachialis* nor *teres minor*.

The mufcles which move the humerus are of an extraordinary bulk in the *mole*. The *pectoralis major* is almoft as large as the pectoral mufcles of *birds*. It confifts of fix portions: four of thefe arife from the fternum, and are inferted into different points of the humerus; the fifth comes alfo from the fternum, and covers the whole furface of the humerus; the fixth is extended from one humerus to the other. The *latiffimus dorfi* is alfo very ftrong; it is divided into two parts. The *teres major* is prodigioufly ftrong. Upon thefe three mufcles chiefly depend the rotation and the retraction of the anterior limbs of the *mole*, the motions by which it excavates the earth with fuch extraordinary force and rapidity.

The *fupinators* and *pronators* of the fore-arm are not found in thofe fpecies of mammalia which either have the ulna immoveable, or obliterated. The *cat* and *dog* have the *fupinator brevis*, but not the *longus*. The *rabbit* has only the *pronator teres*.

Monkies, the *cat*, and *bear*, have the fame number of flexors and extenfors of the *carpus* as the human fubject. In the *cloven* and *folid-hoofed* quadrupeds, the *external radialis* is inferted anteriorly into the bafe of the cannon bone, which it extends; this is the *extenfor rectus anticus* of Bourgelat. The *radialis internus* is the *flexor internus* of Bourgelat. The *ulnaris internus* is the *flexor obliquus* of the fame author; it is inferted into the bone that correfponds to the *os pififorme*. The *ulnaris externus* is inferted likewife into the fame bone, and is called by Bourgelat the *flexor externus*. The mufcle analogous to the *ulnaris externus* in the *bat*, arifes from the os brachii, and from the radius as far as its middle. Its tendon is inferted into the upper and internal part of the carpus, which it abducts. The mufcle correfponding to the *ulnaris internus* arifes from a flefhy portion common to it, and the other mufcles of the fore-arm, and is inferted into the external fide of the firft phalanx of the laft finger. It adducts the carpus. The *adductor pollicis* has the fame common origin, and fends its tendon obliquely acrofs that of the *ulnaris externus*, and is inferted into the internal fide of the carpus at the bafe of the thumb.

The *extenfor communis digitorum* exifts in all quadrupeds. Its tendons correfpond to the number of fingers. The portion, which merely extends the little finger in man, is of greater fize, fupplies more fingers, and is more diftinct in many mammalia. In the *monkey* and *rabbit* it has two tendons, and fends one to the fourth finger. In the *dog* and *bear* it furnifhes a tendon alfo to the third and middle fingers.

The

The *cat* has two mufcles in place of this divifion of the extenfor communis. In the *cloven-footed* cattle this mufcle extends the outer toe, and the *extenfor indicis* the internal.

There are two mufcles in the *horfe:* one is called by Bourgelat *extenfor lateralis*, and by La Foffe the *extenfor of the paftern.* It fends the tendon to the fide of the firft joint of the toe.

The other mufcle is fituated between the preceding, and the one analogous to the *extenfor communis*, of which it is confidered by fome anatomifts as making a part.

The *indicator* has two tendons in the *monkey*, one of which goes to the middle finger: this mufcle does not exift in the *rabbit*, the *folid* and *cloven-footed quadrupeds.*

The *extenfor brevis pollicis* is not found in the *cat, dog, bear*, and *rabbit*. The *extenfor longus* fends a tendon to the firft finger in the *bear.*

The *flexor longus pollicis* is wanting in the *monkey*, and its place fupplied by a fifth tendon from the *flexor profundus communis.*

In the *dog*, the *flexor profundus* unites with the *flexor pollicis*, and the latter feparates to go to the thumb. The *flexor fublimis* fends a tendon to the thumb.

In the *cat*, the *flexor profundus* confifts of five diftinct flips, and fends off as many tendons. The *fublimis* alfo fends a tendon to the thumb.

In the *rabbit*, the *profundus* furnifhes a tendon to the thumb, but the *fublimis* not.

The flexors furnifh fewer tendons, of courfe, where there are fewer digiti; for inftance, they fend off but two in the *cloven-footed*, and one in the *folid-hoofed* quadrupeds. The *bat*, which has fo many peculiarities of the anterior extremity, has only one *extenfor* of the digiti: its fine tendons run along the back of each of the elongated fingers that fuftain the membrane of the wing, to the extenfion of which they contribute. The *flexor communis* arifes from the common mafs of mufcle upon the infide of the fore-arm: its delicate tendons unite with the *flexores proprii* of the joints of the wing. Thefe laft mufcles are four in number; they form a flefhy mafs where they arife from the carpus; become connected with the tendons of the *flexor communis*, and are extended to the ends of the joints of the radii of the wing. Some fhort fibres arife from the carpus, and are inferted into the root of the pollex.

The mufcles of the fingers are obliterated in the *cetacea.*

The mufcles of the *inferior*, or, more properly, *pofterior* extremity, that arife within the body, are, in general, fimilar in man and mammalia. The *pfoas parvus* has been obferved to be wanting in the *rat.*

The *bat* wants the *quadratus lumborum, pfoas magnus, iliacus internus, pyriformis, gemini, obturator internus*, and *quadratus femoris.* The *pfoas parvus*, is, however, very ftrong in this animal, and its aponeurofis broad; the *pectineus* and *obturator externus* are long and flender. The *pectineus* of the *dog* fends its tendon to the lower part of the femur. Quadrupeds, in general, have the *pfoas magnus* and *iliacus* more elongated in their figure than they are in man.

There is a ftriking difproportion in the *gluteal* mufcles of mammalia. The *external*, called in man *gluteus maximus*, is in all quadrupeds the fmalleft of the three. In the *horfe*, it is little more than an aponeurotic expanfion, and is called by Bourgelat the *gluteus minimus.* The diminifhed fize of this mufcle, proves that its chief ufe in the human fubject is to move the pelvis upon the thigh, and to maintain the erect pofition of the body. In the *horfe*, this mufcle has, in addition to the thin flefhy head from the facrum and back of the ileum, another thin flip from the top of the ileum.

The *gluteus medius* and *minimus* are found much larger in proportion in quadrupeds than man. The *medius* in the *horfe* is very large: it arifes from the facrum, all the membrane between that bone and the ileum and ifchium, and is inferted into the procefs of the femur that Cuvier has been inclined to call a third trochanter. This mufcle draws the limb backwards, as in the action of kicking In the *bat*, the *gluteus minimus* defcends almoft perpendicularly from the ileum to the femur. This animal has but one *adductor* femoris, or head of the *triceps:* it goes from the fymphyfis of the pubis to the femur, about one-third from its top.

The fhape of the thigh is rather flat in the true quadrupeds, and even in the *monkey* it is lefs round than in man. The mufcles are thrown forwards and backwards, which is the moft convenient pofition for progreffion on four feet. The great fize of the mufcles upon the internal part of the thigh of the human fubject is not defigned, as anatomifts generally ftate, to bring the legs together, or to beftride a horfe, or, in cafe of fhipwreck, the maft of the veffel, but in the ordinary progreffion, on two feet, to transfer the weight of the body from one fide to the other.

The *fartorius* and *gracilis* are placed upon the anterior part of the thigh in the *digitigrade* and *faltigrade* quadrupeds. The *fartorius* is called in the *horfe adductor longus.* The *gracilis* is large in all quadrupeds, and efpecially in the *hoofed* orders. It is called by Bourgelat the *adductor brevis.* He gave the name of *gracilis* to the mufcle correfponding to the *femi-tendinofus.*

This laft mufcle, and the *femi-membranofus*, are inferted into the tibia by a broad aponeurofis, lower down than in man, by which means the hind legs are always, in a degree, bent, a circumftance favourable to progreffion on four feet, but very inconvenient in the erect pofition of the body. Even the *monkey* has this form of the limb, and for that reafon, as well as others, cannot remain long ftanding, without fupporting itfelf by the anterior extremities. In the *bat*, there is one mufcle which fupplies the place of the *fartorius, gracilis, femi-tendinofus*, and *femi-membranofus.* It arifes by two portions: the one from the fore-part of the ileum, the other from the pubis and ifchium. The *adductor femoris* paffes between them. The common tendon produced by thefe two mufcles is inferted below the head of the tibia, on what is the fore-part of the leg in the *bat.* This mufcle bends the leg. There is but one mufcle alfo for extending it, which arifes from the upper part of the femur, and is a flender tendon, which is inferted into the tibia.

The mufcles compofing the calf of the leg are much fmaller in mammalia than man, in proportion to the fize of the animals. The *foleus* arifes from the head of the fibula: it is peculiarly flight in the *cloven* and *folid-hoofed* quadrupeds.

The *tibialis anticus* is inferted into the anterior furface of the lower part of the *cannon* bone in thofe quadrupeds that have this bone.

The *tibialis pofticus* of the *monkey* has a large fefamoid bone in its tendon. In quadrupeds that want the great toe, the tendon is inferted into the metatarfal bone of the firft toe, which it abducts or feparates from the reft. This mufcle does not exift when there are cannon bones.

The *peroneus longus* in the *monkey* adducts the great toe to the others. The other peroneal mufcles of the *monkey*, and of the quadrupeds with claws, refemble the fame mufcles of the human fubject. The *rabbit*, however, is an exception. The *peroneus medius* fends a tendon to the laft toe but one. In the *cloven-footed* order, the *peroneus longus* croffes below

below the joint of the cannon bone to be inserted into the firſt os cuneiforme. The tendon of the *medius* extends to both the toes, and the *peroneus brevis* does not exiſt. There is only one peroneal muſcle in the *horſe:* its tendon joins that of the extenſor of the ſingle toe.

The *plantaris* muſcle, which terminates upon the os calcis in the human ſubject, is a ſtronger muſcle in mammalia: it ſupplies the place of the *flexor brevis digitorum perforatus* in quadrupeds. It is continuous with the *plantar faſcia* in the *monkey*, from the diſſection of which animal this muſcle probably received the name it bears.

In the *wombat*, according to Mr. Brodie, there is a peculiar muſcle of the leg. It is ſituated between the tibia and fibula throughout their whole length. The fibres have their origin from the inner edge of the fibula, and paſs obliquely, inward and downward, to be inserted into the oppoſite ſurface of the tibia. The operation of this muſcle is to bring the fibula forwards, and produce a degree of rotation on the tibia which turns the toes inwards. This muſcle is oppoſed in its action by the one that correſponds to the *biceps*, and which is inſerted into the poſterior part of the fibula. It brings the toes back into the ſtraight line, but does not turn them outwards.

There are ſeveral peculiarities in the arrangement of the flexor muſcles of the toes in the *monkey*. The part of the *flexor brevis* that goes to the firſt toe only is attached to the os calcis. The ſhort flexors of the great and little toes reſemble that of the human ſubject. The *flexor pollicis longus* gives a tendon to the pollex, or great toe, and two perforating tendons to the third and fourth toes. The *flexor longus digitorum* ſupplies two perforating tendons to the ſecond and fifth toes. The three perforating tendons of the third, fourth, and fifth toes do not come from the bone of the heel, but have their fleſhy fibres ariſing from the *flexor longus digitorum*. The tendons of the long flexors are united together. The *acceſſory flexor*, or *maſſa carnea*, has an aponeurotic attachment to the tendon of the *flexor longus pollicis*, and ſends a ſtrong tendinous band to the tendon of the *flexor longus digitorum*.

The *flexor longus pollicis*, when there is no great toe, has its tendon incorporated with that of the flexor longus digitorum, as in the *dog*, &c.

The *monkey* has a *long abductor* of the great toe; it is ſituated upon the inner ſide of the extenſor longus pollicis.

The *extenſor pollicis* is wanting in thoſe that have not the great toe, ſuch as the *dog* and *rabbit*.

In the *cloven-hoofed* quadrupeds, the inner toe has an *extenſor proprius*, which repreſents the *extenſor pollicis*. This is wanting in the *horſe*.

The quadrupeds that have cannon bones in place of metatarſal, have the muſcle correſponding to the *ſhort extenſor of the toes* ariſing from the cannon bone, and inſerted into the tendon of the long extenſor.

Plate XI. of the *Anatomy of Mammalia*, exhibits the muſcles which move the integuments of the *hedge-hog*. *Fig*. 1. is the *hedge-hog* in the coiled ſtate, and covered by the orbicular muſcle, which is expoſed by diſſection. *Fig*. 2. ſhews the animal in the relaxed ſtate: *a a* is the orbicular muſcle contracted, and carried upon the back; *b b*, its marginal part, reſembling a ſphincter; *c*, *c*, two muſcles going from the orbicular muſcle to the top of the head; *d*, the muſcle of the left ſide, which is one of another pair that extends from the orbicular to the head; *e*, *e*, the two muſcles from the orbicularis to the tail; *f*, part of the muſcle which correſponds to the cutaneous colli, ſeen going to be attached behind the ears; *g*, a portion of the muſcle which comes from the middle of the ſternum to the orbicularis; *h*, the cutaneous muſcle of the belly; *i*, the portion of the ſame muſcle which paſſes over the ſhoulder to be inſerted into the humerus. There are other deep-ſeated muſcles which connect the orbicularis with the body and neck, that are concealed by thoſe indicated in this figure.

Plate XI. and *fig*. 3, is a portion of the trunk of an *elephant*, cut in different directions, in order to expoſe its ſtructure. A is the horizontal ſection, in which are ſhewn the little tranſverſe muſcles, *a*, cut croſs-ways, and ſome others cut longitudinally (as indicated by *b*); B is the vertical ſection made lengthways, by which the naſal canal of the left ſide at C is divided. The little tranſverſe muſcles are, by this ſection, cut longitudinally at *b*, and tranſverſely at *c*. Some other little analogous muſcles are ſhewn in their length by *d*; and *e* points out the longitudinal muſcles of the proboſcis, which antagoniſe theſe laſt. D is the vertical ſection made croſs-ways. The little tranſverſe muſcles are ſeen in their length, paſſing in different directions, with reſpect to the axis and circumference of the trunk, but always tranſverſely. They are ſituated within the longitudinal muſcles of the trunk, which laſt are ſeen divided croſs-ways by this ſection, around the circumference of the trunk, as pointed out by the letters *f*, *f*: in this ſection are ſeen alſo many veſſels and nerves cut croſs-ways. Some large nerves, with blood-veſſels accompanying them, are ſhewn running in the direction of the ſection A, as pointed out by the letter *g*. C, C, are the two naſal canals which run in the interior of the trunk, ſomewhat nearer the lower ſurface than the centre.

Brain.—This viſcus is formed upon the ſame plan in *man* and *mammalia*. The chief differences conſiſt in the figure and ſize of the parts, in relation to each other, to the reſt of the nervous ſyſtem, or to the entire body.

The relation with reſpect to bulk, between the brain and the whole body, has been generally conſidered as determining the degree of intelligence poſſeſſed by an animal. That the mental character ſhould be indicated by the proportion which the organ of perception bears to the parts which exerciſe the other functions of life, ſeems to be almoſt ſelf-evident; and is conformable to common opinion and obſervation, with reſpect to the intellectual powers of different individuals of the human ſpecies. Nevertheleſs it ſhould be obſerved, that ſome differences muſt ariſe from the age and the degree of fatneſs of an animal, which cannot be ſuppoſed to affect materially the powers of the mind, although they do the weight of the body.

A compariſon of the weight of the cerebrum with that of the cerebellum, is another mode employed by anatomiſts for aſcertaining the degree of intellect an animal enjoys, and is more accurate and preciſe than the preceding. In the inferior claſſes of animals, the diminution of the cerebrum in proportion to the cerebellum is very ſtriking, and forms a very correct index of the gradations of intellect. But for the purpoſe of fixing the mental rank of the different tribes of mammalia, it is beſt to compare the brain with the medulla oblongata, or the nerves that ariſe in the cranium. This may be done, after the manner of Soemmerring and Ebel, by meaſuring the diameters of each at their thickeſt part. This laſt mode ſeems to ſhew, with tolerable accuracy, the intellectual endowment of the different genera of mammalia, except in the *whale* tribe, which have the brain ſo very broad in proportion to its length. The ſame rule alſo ſerves to correct the concluſions that would be drawn from comparing the weight of the brain with that of the whole body, in ſome of the *monkey* kind, and the very ſmall quadrupeds, which have as large a brain in proportion to their body as man.

In

In judging of the capacities of animals, we ſhould carefully diſtinguiſh between the operations of intellect and of inſtinct. Theſe are often miſtaken for each other in animals, and, we believe, are more frequently confounded in the workings of the human mind than people in general are aware of. The brain is the ſeat of reflection, and of *ideal* knowledge: the nerves and organs of ſenſe are but its agents; they are incapable of performing any intellectual operation of themſelves. The perfection of the organs of ſenſation determines, however, in a great degree, the *inſtinctive* faculties of animals, independently of the influence of the brain. Indeed the intellectual and inſtinctive powers are found, like the organs upon which they depend, to exiſt in an inverſe ratio to each other. Man, who has the higheſt mental character, has the brain largeſt, and the nerves ſmalleſt in relation to each other; and in the inferior claſſes of animals, whoſe actions are almoſt entirely governed by inſtinct, the nerves are uncommonly large, and the brain extremely ſmall; and even in ſome genera hardly diſtinguiſhable.

To illuſtrate this ſubject, the following tables have been extracted from Cuvier's "Comparative Anatomy," vol. ii.

Table I. exhibits the proportion of the ſize of the brain to that of the whole body.

Man, according as he is young or old	$\frac{1}{22}$ $\frac{1}{25}$ $\frac{1}{30}$ $\frac{1}{35}$
Long-armed ape, or *gibbon*	$\frac{1}{48}$
Orange monkey (*ſimia ſciurea*)	$\frac{1}{22}$
Capucin monkey (*ſimia capucina*)	$\frac{1}{25}$
Striated monkey (*ſimia jacchus*)	$\frac{1}{28}$
Four-fingered monkey (*ſimia paniſcus*)	$\frac{1}{41}$
Malbrouck (*ſimia faunus*), young	$\frac{1}{24}$
The *green* and *red monkies*	$\frac{1}{81}$
Varied monkey (*ſimia mona*)	$\frac{1}{24}$
White-eye-lid monkey (*ſimia æthiops*)	$\frac{1}{46}$
Hare-lipped monkey, or *macaque*	$\frac{1}{96}$
Barbary ape	$\frac{1}{105}$
Great baboon	$\frac{1}{104}$

Lemurs.

Ring-tailed maucauco (*lemur catta*), young	$\frac{1}{61}$
Vari (*lemur macaco*)	$\frac{1}{44}$

Cheiroptera.

Great bat (*veſpertilio noctula*)	$\frac{1}{96}$

Plantigrada.

Mole	$\frac{1}{36}$
Bear	$\frac{1}{265}$
Hedge-hog	$\frac{1}{168}$

Digitigrada.

Dog	$\frac{1}{47}$ $\frac{1}{50}$ $\frac{1}{57}$ $\frac{1}{153}$ $\frac{1}{161}$ $\frac{1}{305}$
Fox	$\frac{1}{205}$
Wolf	$\frac{1}{230}$
Cat	$\frac{1}{82}$ $\frac{1}{94}$ $\frac{1}{156}$
Panther	$\frac{1}{247}$
Martin	$\frac{1}{315}$
Ferret	$\frac{1}{135}$

Saltigrada.

Beaver	$\frac{1}{290}$
Hare	$\frac{1}{228}$
Rabbit	$\frac{1}{140}$ $\frac{1}{152}$
Ondatra, or *muſk beaver*	$\frac{1}{124}$
Rat	$\frac{1}{76}$
Mouſe	$\frac{1}{43}$
Field mouſe	$\frac{1}{31}$

Multungulata.

Elephant	$\frac{1}{500}$
Hogs — *Wild boar*	$\frac{1}{672}$
Hogs — *Domeſtic hog*	$\frac{1}{512}$ $\frac{1}{212}$
Hogs — *Siameſe hog*	$\frac{1}{451}$

Bisulca.

Stag	$\frac{1}{290}$
Roe, young	$\frac{1}{94}$
Sheep	$\frac{1}{351}$ $\frac{1}{192}$
Ox	$\frac{1}{860}$
Calf	$\frac{1}{219}$

Solipeda.

Horſe	$\frac{1}{400}$
Aſs	$\frac{1}{254}$

Cetacea.

Dolphin	$\frac{1}{25}$ $\frac{1}{36}$ $\frac{1}{66}$ $\frac{1}{102}$
Porpoiſe	$\frac{1}{93}$

Table II. ſhews the proportion that the cerebellum bears to the brain. In *man* it is as 1 to 9

In the *Orange monkey*	1 : 14
Capucin monkey	1 : 6
Barbary ape	1 : 7
Varied monkey	1 : 8
Dog	1 : 8
Cat	1 : 6
Mole	1 : $4\frac{1}{2}$
Beaver	1 : 3
Rat	1 : $3\frac{3}{4}$
Mouſe	1 : 2
Hare	1 : 6
Wild boar	1 : 7
Ox	1 : 9
Sheep	1 : 5
Horſe	1 : 7

Table III. is to point out the relation between the breadth of the medulla oblongata behind the pons Varolii, and that of the brain. In *man* it is as 1 to 7

In the *Short-tailed macaque*	1 : 5
Chineſe monkey	1 : 4
Dog	6 : 11
or	3 : 8
Cat	8 : 22
Rabbit	3 : 8
or	1 : 3
Hog	5 : 7
Ram	5 : 7
Stag	2 : 5
Roe	1 : 3
Ox	5 : 13
Calf	2 : 5
Horſe	8 : 21
Dolphin	1 : 13

The

The brain of the *monkey* refembles moft clofely that of the human fubject; but is neverthelefs diftinguifhed by certain differences, which form, as it were, the firft fteps in the gradations of ftructure in this organ.

The fuperior furface of the *hemifpheres* is fomewhat flatter in the *monkey* than in man; but in *quadrupeds* it is confiderably flatter. In fome of them alfo, as moft of the *digitated*, the anterior part of the cerebrum is much narrower than the pofterior. The *hoofed* quadrupeds generally have the brain nearly oval in its circumference, as it is in man and the *monkey*.

In quadrupeds the *middle lobes* of the cerebrum are flattened upon the inferior furface, and the pofterior lobes do not exift; confequently the cerebellum is not concealed by the cerebrum, as in man and the *monkey*.

The brain of the *porpoife*, *dolphin*, *grampus*, and moft probably others of the *whale* kind, has a figure different from that of any other animal: it is rounded at every part. Its greateft diameter is acrofs, yet it covers the fuperior part of the cerebellum: it has numerous and deep convolutions.

In mammalia, even in the *monkey*, the middle lobes of the cerebellum are larger, in proportion to the lateral ones, than they are in man. Thefe lobes are of the fame fize of the others in the *faltigrada*.

The divifion of the external furface of the brain into *convolutions* takes place to a lefs extent in mammalia than in man. There are few convolutions in the *monkey* tribe, particularly in thofe with prehenfile tails, which have the pofterior lobes nearly fmooth. The *jacko* and *Barbary ape* are exceptions, and have the pofterior lobe feparated from the others by a diftinct tranfverfe fiffure.

In the *digitigrada* and *plantigrada* the furrows upon the furface of the brain are tolerably numerous, and are arranged in a regular order.

The *faltigrada* have no convolutions, properly fpeaking, but very faint grooves: their brain is almoft fmooth upon the furface. There are deep convolutions on the brain of the *hoofed* quadrupeds, efpecially the *cloven* and *folid-footed* tribes.

The lower furface of the brain of mammalia is lefs unequal; the different prominences not projecting fo much as in man.

The *olfactory* nerves of quadrupeds are of an enormous fize, and contain a cavity which communicates with the lateral ventricles: they are compofed of cineritious fubftance externally, and medullary internally. They were defcribed by the early anatomifts under the names of *carunculæ mammillares*, or *proceffus mammillares*. They are found of the greateft fize in the large herbivorous quadrupeds.

There are no olfactory nerves in the *cetaceous* animals.

Except the peculiarities we have juft mentioned, the origin of the nerves is the fame in man and mammalia.

The *lateral ventricles* have lefs extent in all mammalia, except the *monkey*, than in man. That portion of their cavity which is called the *pofterior horn*, or *digital cavity*, is only found in the *monkey*, in which the pofterior lobes exift.

The *tubercula quadrigemina* become larger, in proportion as the animals are removed from man. They are of the greateft fize in the *faltigrada*, *bifulca*, and *folipeda*. There is a very fingular proportion obferved between the fuperior and inferior of thefe tubercles. In all the *herbivorous* tribes of quadrupeds, the *nates*, as they have been called, exceed very much in fize the *teftes*; and in the carnivorous quadrupeds, whether *digitigrade* or *plantigrade*, the inferior tubercles or *teftes* are larger than the *nates*; from which it might be fuppofed that the relative magnitude of thefe parts indicate the difpofition of the animal. Cuvier ftates, that the teftes are three times the fize of the nates in the *dolphin*.

But few obfervations have been made upon the comparative ftructure of the *pineal gland*. The gritty or earthy fubftance of this body has been difcovered in the *fallow deer* (*cervus dama*) by Soemmerring; and in the *goat* by Malacarne. It is not known in what number of quadrupeds the earthy matter exifts in the pineal gland: it may be prefumed, from its being found in the fpecies above mentioned, which are lefs allied to the human fubject in general ftructure than many others of this clafs, that the fandy matter would be met with generally in the pineal gland of mammalia.

The *corpora candecantia* are fmall in the carnivorous quadrupeds: there is but one large eminence of this kind in the herbivorous tribes.

The other eminences and cavities of the brain of mammalia exhibit no peculiarities worthy of notice.

The *tentorium cerebelli*, in many mammalia, is fuftained by a thin plate of bone, which projects from the inner furface of the cranium in one or three pieces.

In fome inftances the tentorium is an uniform bony partition, which leaves a quadrangular opening into the lower part of the cranium This is the cafe in moft fpecies of the *cat* and *bear* genera; in the *martin* and in the *coati* (*fimia panifcus*).

The *falx*, which divides the hemifpheres of the cerebrum, is alfo fuftained upon a bony plate in the *ornithorhynchus*. Blumenbach ftates, that fomething of the fame kind exifts in the fkull of the *porpoife*; but the fpecimen to which he refers, appears to have been an irregular formation of the bones of the cranium.

The *membranes* of the brain do not exhibit any other peculiarities of much importance in mammalia.

The *blood-veffels* of the brain have been defcribed already under the heads of *Arteries* and *Veins* in this article.

In *Plate* XII. of the *Anatomy of Mammalia*, *fig*. 1. is a lateral view of the external appearance of the brain in the *rabbit*. The anterior part of the cerebrum is feen to be fmaller than the pofterior. The middle lobes are flattened upon their inferior furface; and the pofterior lobes are wanting: *a a* fhew the cerebrum; *b*, the cerebellum; *c*, the medulla oblongata. *Fig*. 2. is a view of the under furface of the anterior part of the cerebrum of the *fheep*: *a*, *a*, the olfactory nerves; one of which is laid open to expofe its cavity, which is traced to the lateral ventricle, by cutting through the fubftance of the cerebrum. *Fig*. 3. is a tranfverfe fection of the brain of the *monkey*: *a a*, the corpora ftriata; *b b*, the thalami nervorum opticorum; *c c*, the cavities of the lateral ventricles laid open; *d d*, the digital cavities; *e e*, the nates; *f f*, the teftes; *g g*, the pineal gland; *h*, *h*, the cut furfaces of the hemifpheres. *Fig*. 4. is a view of the tubercula quadragemina in the *fheep*: *a a*, the nates; *b b*, the teftes; *c c*, the furrounding portion of the brain. *Fig*. 5. is a fimilar view of thofe parts in the brain of the *dog*, which are indicated by correfponding letters.

Nerves.—There is no part of the anatomy of mammalia in which there is fo clofe a refemblance to the human, as in the diftribution of the nerves. Where differences do occur, they are in general plainly referrible to the difference in the figure of the neighbouring parts, and not to any phyfiological reafon.

The *firft pair of nerves*, or the *olfactory*, afford a ftriking exception to the foregoing obfervation. In all mammalia which poffefs them, except the *monkey* kind, they are large, hollow proceffes of the anterior lobes of the cerebrum, the cavities of which communicate with the lateral ventricles of the brain, as already defcribed. This peculiarity of ftructure, however, does not appear to produce much effect upon them after they have paffed through the ethmoid bone into the nafal cavity. The only difference to be remarked between the branches of the olfactory nerves of quadrupeds and thofe of man, is, that they are ftronger, and more eafily demonftrated in the former.

The *fecond pair of nerves*, or *optic*, have precifely the fame ftructure in mammalia and man before their entrance into the globe of the eye. The medullary tubes of which they are compofed, are more plainly fhewn in the larger quadrupeds.

The *third*, *fourth*, and *fixth pair of nerves*, exhibit no peculiarities.

The *fifth pair of nerves* fhews fome difference in its ramification, and the ganglia it forms, although its diftribution is, as nearly as may be, the fame in mammalia and man. Cuvier has given fome account of the three principal branches of the fifth pair of nerves, taken from diffections of the *dog*, *rabbit*, *fheep*, and *calf*.

According to Cuvier's defcription, the firft, or *ophthalmic* branch of the fifth pair, is divided within the cranium, but does not form its three branches until it arrives in the orbit.

The firft, which is analogous to the *nafal* branch of the ophthalmic, is the largeft. It is divided into five or fix fmall nerves. Some of thefe pafs through the vault of the orbit to the frontal finufes: others, which are larger, enter the nafal cavity by the internal orbitar foramen. They afcend in an offeous canal, and pafs into the cranium by the large foramina of the cribriform bone, and pafs down again through the ethmoidal foramina, to be diftributed, as in man, to the pituitary membrane of the nofe. Thefe branches are very plain and eafily traced in the *cloven-footed* quadrupeds: one of them feems to have been miftaken by Cuvier for a branch of the olfactory in the *fheep*. One or two of the branches into which the nafal divides, go to the levator palpebræ fuperioris. One of thefe twigs affifts in forming the *lenticular ganglion*, which in the *dog* gives off two *ciliary* nerves that divide before they enter the eye, and in the *calf* it fends off four ciliary nerves. Finally, the nafal fends filaments to the obliquus inferior mufcle, and the glandula Harderi.

The *fecond*, or *frontal* branch of the *ophthalmic*, is fituated fuperiorly under the roof of the orbit. It divides into two nerves; one is external, and furnifhes two filaments to the rectus fuperior and the levator palpebræ; the other is internal, and fupplies the internal ftraight mufcle of the eye, and gives off the frontal branch which paffes through the fuperciliary notch, to be diftributed to the integuments of the forehead.

The *third*, or *lacrymal* branch of the *ophthalmic*, furnifhes a great number of filaments that are expended upon the lacrymal gland.

The *fecond* branch of the *fifth pair*, or the *fuperior maxillary* nerve, when it arrives on the outfide of the cavity of the cranium, becomes confiderably enlarged. Its fibres feem to crofs each other in fuch a manner, that the two branches which it foon after forms appear to be produced by oppofite filaments: thus, the pofterior, or *fub-maxillary* branch, feems to be compofed of the anterior filaments, and the anterior or fupra-maxillary branch of the pofterior fibres. This difpofition is very remarkable in the *dog*, but lefs fo in the *calf*.

The fupra-maxillary branch proceeds almoft horizontally from behind forwards. Having reached the anterior and inferior parts of the temporal foffa, it divides into a great number of fafciculi: one bundle, which confifts of four or five filaments, proceeds towards the fpheno-palatine foramen. This fafciculus then divides into two; one branch is fent into the nafal cavity, and furnifhes a confiderable nerve, which is fpread out upon the flefhy fubftance of the palate. Sometimes, as in the *calf*, this branch feparates from the trunk, even before it enters the fpheno-palatine hole.

The other branch of the fuperior maxillary nerve, which enters by the fpheno-palatine hole, paffes into the body of the fuperior maxillary bone, detaches filaments to all the teeth, and goes out by the fub-orbitar foramen, where it expands into a great number of branches, which fupply the mufcles and integuments of the face, and anaftomofe with the branches of the facial nerve. The *fub-orbitar nerve* and its branches are of a prodigious fize in all mammalia with whifkers; in thefe animals its anaftomofes are more intricate than ufual, and from the net-work under the fkin about the lips, the bulb of each whifker receives one or more large nerves.

There are fome other filaments given off from the fuperior maxillary nerve. The firft is a fmall one, which, after anaftomofing with a ganglion, paffes into the fubftance of the temporal mufcle, to which it gives branches. It afterwards perforates the orbit, and from thence goes into the nofe. Another more remarkable filament arifes from the fpheno-palatine branch; it forms a ganglion, which is joined by the preceding nerve, as already mentioned, and feveral other twigs. A flat nerve proceeds from this ganglion, which appears to be the continuation of the nerve that formed it, although larger. It paffes between the palatine and the convexity of the pterygoid procefs, in the fubftance of the bone: amongft other branches it fends one down to the floor of the noftrils.

The *third*, or *inferior maxillary* branch of the *fifth pair* of nerves, produces, almoft immediately after its feparation, a pretty large branch, which is diftributed to the parotid and maxillary glands. It afterwards divides into two other branches; one which is internal, and is loft in fmall filaments in the mufcles, and even in the fubftance of the tongue; the other is external, and fends a number of branches to the pterygoid mufcles, and thofe of the cheeks and lips, on their way to the fkin of the face on which they are loft, anaftomofing with the other facial nerves. The continuation of the fuperior maxillary nerve paffes, as ufual, into the canal of the lower jaw, fupplies the teeth, and emerging at the foramen mentale, fpreads in branches upon the foft parts in the neighbourhood.

In the *calf*, the inferior maxillary nerve, foon after leaving the cranium, divides into four branches.

The moft pofterior of thefe branches goes backwards, and below the condyle of the jaw, where it forms two branches; one is flender, and enters the parotid gland, to which it gives filaments, which anaftomofe with thofe of the facial nerve: the other takes the circuit of the jaw, and advances in the front of the mouth; it unites, as it paffes along the cheek, with the middle branch of the facial nerve, from which it previoufly receives feveral anaftomofing branches.

The next branch of the four is very long, flender, and follows the ramus of the jaw to be expended upon the buccinator mufcle and the glands.

The third branch paffes into the dental canal, and fupplies the teeth as ufual.

Laftly,

Laftly, the fourth branch is the lingual: it is ftrong and flat, and terminates in radiated filaments.

The *facial* nerve, commonly called the *portio dura* of the *feventh pair*, arifes in the *calf*, according to Cuvier, by two roots; the one is really the portio dura: the other appears to proceed from a confiderable ganglion of the pofterior part of the *par vagum*, which is fituated in a particular depreffion of the inferior furface of the bone of the tympanum: this root alfo appears to unite with the great fympathetic nerve, which has almoft the firmnefs of cartilage. Two or three fhort filaments concur in the formation of this root. It afterwards becomes thicker, and paffes into the fiffura Glafferi to meet the other roots of the facial nerve, to which it tranfmits a filament, and continues to proceed outwards before and below the ear.

The magnitude of the branches of the facial nerves varies in mammalia, but with refpect to number, they fcarcely differ from thofe of the human fubject. In thofe quadrupeds that have large ears, the branch of the facial nerve, which unites with the firft cervical pair, is of much greater fize than ordinary. In the carnivorous kinds, alfo, the nerves going to the temporal mufcle are particularly large, and in all mammalia with whifkers, the branches that anaftomofe with the facial nerves of the fifth pair have a confiderable fize.

There is nothing peculiar to be obferved with refpect to the *portio mollis* of the *feventh pair*, or the true *auditory nerves*.

The fpecies that Cuvier had diffected for the *par vagum*, or *pneumo-gaftric* nerve, were the *calf*, *dog*, *racoon*, *hog*, and the *porcupine*, in all of which, its diftribution and ramifications bore the greateft refemblance to the fame nerve in the human body. The connection it has with the facial nerve in the *calf* already mentioned, was the chief peculiarity obferved.

The *gloffo-pharyngeal*, and the *hypo-gloffal* nerves, exhibit no deviation from their difpofition in the human body, as far as they have been examined.

The *hypo-gloffus* was found by Cuvier to have a blueifh colour in the *calf*, until it arrives on the infide of the ramus of the lower jaw.

The *fub-occipital* and the *cervical* nerves alfo appear to be formed exactly as in man. They are of courfe in fome quadrupeds larger in proportion than in others, on account of the fize of the mufcles on the neck. In the *three-toed floth*, there are probably nine cervical nerves correfponding to the number of vertebræ in that animal.

The *phrenic* nerves differ in no refpect from thofe of man.

The *dorfal* and *lumbar* nerves vary only in regard to their numbers, which may be reckoned by the vertebræ. The *nerves* of the *pelvis* alfo exhibit no peculiarity in mammalia.

The nerves which fupply the tail are of fome confequence in this clafs, and do not exift in the human fubject. The following defcription has been given of them in the *rabbit* by Cuvier.

The *firft pair* of caudal nerves comes out between the laft piece of the facrum and the firft vertebra of the tail, and proceeds by the ifchiatic notch. It divides into two branches, one of which is united to the fchiatic nerve, and the other continues to advance between the pelvis and the tail, until it enters a gland fituated under the fixth pair of caudal nerves, where this branch terminates: but in its way thither it forms feveral anaftomofes with the other caudal nerves, and gives off branches, by which there is a remarkable plexus formed, which Cuvier calls the *caudal*.

The firft branch fent off by this nerve is diftributed among the gluteal mufcles. The nerve is afterwards joined on the inner fide by a fmall filament, that feems to be derived from the fecond pair of caudal nerves, and on the outer fide by three or four filaments, which make a plexus, from whence feveral branches go to the mufcles; one, which is very confiderable, and eafily traced, is fent to the penis. Afterwards the third, fourth, and fifth pair of caudal nerves fend filaments to the inner fide of the branch of the firft pair: then five or fix branches are given off from the external fide of the mufcles of the penis, and thofe which arife from the ifchium. Finally, the trunk of the firft caudal pair terminates in the gland, as above-mentioned.

The *great fympathetic*, or *intercoftal* nerve, has been defcribed by Cuvier from diffections of the *wolf*, *racoon*, *porcupine*, *fheep*, and *calf*. He found it to form a very remarkable anaftomofis with the fifth and fixth pair of nerves. On entering the cranium through the foramen lacerum, the intercoftal is diftinct from the par vagum, and adheres very clofely to the periofteum of the temporal bone. If the cord of the nerve be ftretched, it is feen to be divided into fix or feven filaments, that form a clofe network. A few lines farther, thefe filaments approach each other, and become confolidated into a ganglion, which, from its great firmnefs, appears like cartilage. Many filaments depart from this ganglion: fome are fhort, and proceed to the nerve of the fifth pair: others are long, fmall, and are interwoven with the blood-veffels, fo as to form a reddifh-coloured plexus, which was confidered by Willis as a little *rete mirabile*. The communication with the fixth pair is by means of this plexus, which furrounds the nerve on every fide, and is hardly to be feparated from it. There is not any remarkable anaftomofis obferved in the *calf* and *ram*.

The great intercoftal, while paffing through the foramen lacerum, detaches a filament to the cavity of the tympanum. At the fame place alfo it is united with the eighth pair of nerves.

The *fuperior cervical ganglion* is formed fome lines from the cranium. It has a reddifh colour, and an elongated oval figure. It forms the fame communication with the neighbouring nerves as in man.

In front of the laft cervical vertebra the intercoftal nerve forms a curve from within outwards, towards the firft rib, on the head of which it joins the firft thoracic ganglion. Several filaments from this curve go along the mediaftinum to the pericardium: others form a plexus around the fubclavian artery.

The *firft thoracic ganglion* is a femilunar figure. Some filaments go off from one of its edges; the uppermoft of which is fent to the vertebral artery, around which it forms a plexus, and appears to accompany the veffel into the cranium. The other filaments unite with the laft cervical, and with the two firft dorfal pair of nerves.

The concave edge of the ganglion detaches two or three filaments, which defcend obliquely to the root of the pulmonary arteries, where they unite with the par vagum, to form the *pulmonary* and *inferior cardiac plexufes*.

The intercoftal, in its paffage through the thorax, produces a ganglion upon the head of each rib, which is joined by a filament from each of the dorfal nerves.

The intercoftal, on entering the abdomen, forms a fingle cord, which is the *fplanchnic nerve*. It paffes into the middle, under the ftomach, where it frequently feparates into two cords, which are afterwards joined together again. From this fort of nervous ring, there arifes either a principal trunk, or four or five filaments, which, uniting together near the cœliac artery, form a ganglion, that is frequently of a femilunar

lunar figure. The filaments that produce the *ſtomachic*, *ſplenic*, and *hepatic plexuſes*, ariſe from the ſemilunar ganglion, and correſpond to the *ſolar plexus*. There are alſo filaments detached to form the *renal* plexus.

The intercoſtal, as it proceeds along the lateral parts of the bodies of the vertebræ, gives origin to *ganglia* of an elongated quadrangular figure: one of the ſuperior angles of theſe receives the continued trunk of the nerve; the other the lumbar pair. The internal inferior angle ſends a branch to the aorta, to concur in the formation of plexuſes, which encompaſs each of the branches of that veſſel. The external inferior angle furniſhes the continuation of the trunk.

Except the variations above-mentioned, there does not appear to be any material difference between the intercoſtal or great ſympathetic nerve in man and animals.

Scarcely any peculiarity is to be perceived in the diſtribution of the nerves of the extremities in mammalia. The *articular* nerve is excluſively formed in the *rabbit* by the fifth cervical pair of nerves; only one of its filaments is derived from the axillary plexus.

The *thoracic* nerves are furniſhed by the axillary plexus.

The *median nerve*, about the middle of its courſe, ſends off a branch, which is analogous to the *external cutaneous* nerve.

The *ulnar* nerve alſo, about the middle of the arm, gives off a branch, that appears to take the place of the *internal cutaneous* nerve: it ſupplies the extenſor muſcles of the elbow and the ſkin.

Both the origin and diſtribution of the nerves of the poſterior extremity appear to correſpond with what has been deſcribed in man.

Organs of Touch.—The general ſurface of the body in mammalia is better calculated for receiving external impreſſions than it is in any other animals, except thoſe that have naked and ſoft ſkins, ſuch as certain reptiles, and ſome of the inferior claſſes. The ſkin of mammalia is well ſupplied with nerves; the cuticle is thin, and the hairs, having their roots buried in the ſkin, rather facilitate than impede the ſenſation of touch.

The *cuticle* has the ſame ſtructure in man and mammalia. It is moſt delicate in the ſmaller quadrupeds, and in thoſe that have their body well defended by other coverings, as very thick hair or ſpines. The cuticle is particularly thin in the *porcupine*.

It is dry, and conſiſts evidently of ſcales, on the tail of the *beaver*, *rat*, *ondatra*, &c. and upon the ſurface of the bodies of the *pangolin* and *armadillo*.

In the *large many-hoofed* quadrupeds the cuticle is thick, and is covered with ſmall plates, that ſeparate from it like ſcales. It ſinks into the furrows of the true ſkin. On the ſoles of their feet it is very remarkably formed. It appears externally to be divided by deep impreſſions, nearly circular, with ſix or eight ſurfaces, ſome more regular, others leſs ſo, each of which contains an infinite number of ſmall polygons, that are very irregular. Theſe polygons, both the large and ſmall, correſpond to furrows in the true ſkin, into which internal projections of the cuticle are inſerted.

The cuticle of the *cetacea* is not thick in proportion to the other parts of the ſkin. It is free from folds or wrinkles; the ſurface of theſe animals being ſmooth, to facilitate their progreſs through the water. It is alſo beſmeared with oil, which not only is of uſe in ſwimming, but prevents the maceration of the cuticle in the water.

The *colouring matter* of the *ſkin*, or *rete mucoſum*, as it is commonly, though improperly, called, is uſually thin, and of a light colour in thoſe parts of the bodies of quadrupeds which are covered by hair: on particular parts, however, and in certain animals, it is various in its colour. It is generally black upon the uncovered parts of the ſkin, as the ſnouts of quadrupeds, the hands of *monkies*, &c. It has but rarely very vivid colour, as in the other claſſes of animals. The *monkey* kind ſhew examples in which the cheeks have a painted white or blue colour, and the noſe or iſchiatic calloſities are red, violet, or carmine.

The pigment of the ſkin of the *cetacea* vaſtly exceeds in thickneſs that of all other animals. It is about the tenth of an inch thick in the *porpoiſe*, and in the larger ſpecies of the *whale* tribe it is proportionably thicker. It appears like a ſolid ſubſtance, which divides very readily after maceration into layers, and alſo in the vertical direction into fibres, like the pile of velvet. This laminated and fibrous ſtructure is only the particular arrangement of the ſubſtances of the pigment, and not a texture compoſed of different parts, for the whole is ſoluble, or rather miſcible, in water after maceration. The rete mucoſum of the *cetacea* is black upon the ſuperior ſurface of the body, but is a ſilvery white on the belly.

The pigment of the ſkin is found within the cavities of the mouth and noſe in many quadrupeds, in which places it has a dark colour.

The *cutis*, or *true ſkin*, varies of courſe very much in thickneſs in different animals of this claſs: as a general obſervation, we may ſtate that the ſkin is thick in proportion to its nakedneſs, and its expoſure to external friction or preſſure. It is therefore moſt ſtrong in *many-hoofed* quadrupeds, to whom theſe circumſtances belong, as well as great bulk of the animals themſelves. The ſkin is always thickeſt upon the back of the body and outſide of the limbs. The thickneſs of the ſkin may be increaſed to a very extraordinary degree by artificial preſſure, as is ſeen in the *boar pigs* that are uſed for making *brawn*. In theſe animals, the ſkin upon the ſhoulders is ſometimes above an inch thick.

The ſkin is peculiarly tough in thoſe animals that burrow in the ground. In the *mole*, although it is thin, it is ſo tough, that it is difficult to cut it with a pair of ſciſſors.

The ſkin of *cetaceous* mammalia is peculiar in its ſtructure. The ſurface next the rete mucoſum is ſmooth, and when examined under water, floats like a villous texture. We could not readily detect any diſtinct villi upon the ſkin of the *porpoiſe*, or *grampus*, they are ſo fine and ſo cloſe to each other; but Hunter has deſcribed them as being very plain in *whales*. It is ſcarcely poſſible to calculate the thickneſs of the ſkin of *cetacea*, as it is gradually loſt in the cellular texture which contains the oil, but it appears to be peculiarly thin, according to the ſize of the animals, unleſs we conſider the cellular ſubſtance that is filled with the oil as making a part of the ſkin, which appears really to be the caſe. Every part of the ſkin of the *whale* tribe is penetrated by the oil.

The ſkin of *cetacea* appears to be leſs ſenſible of external impreſſions than that of any other ſpecies of mammalia. The ſmoothneſs, and ſtretched ſtate of the cuticle; the thickneſs of the rete mucoſum; the abſence of thoſe ſmall eminences of the cutis called papillæ, which are peculiarly endowed with blood-veſſels and nerves, and the interpoſition of ſo great a quantity of oil in the interſtices of the ſkin and cellular ſubſtance, all contribute to obſcure the impreſſions of foreign bodies.

Certain parts in the other mammalia, from their ſituation, figure, and intimate ſtructure of the ſkin covering them, are fitted to receive peculiar impreſſions, and are, properly ſpeaking, the *organs of touch*. The moſt delicate inſtruments of this kind are, the *hands* of the *quadrumanous* mammalia; the *lips* and *ſnouts* of many quadrupeds; the *prehenſile tails* of *monkies*, *opoſſums*, *ant-eaters*, *pangolins*, &c.

The

The under surfaces of the hands and feet of *monkies* are organized like those of the human subject, but have not the nervous papillæ so eminent as they are in the human hand.

The feet of *digitated* quadrupeds also are capable in a degree of the sensation of touch, particularly the under surface of the front toes in the *racoon.*

The lips of many quadrupeds form a very delicate sense of touch. They are largely supplied with nerves and blood-vessels, and the papillæ of the skin are very eminent. The superior lip of the *rhinoceros* forms a process which is moveable in various directions, and is used by the animal as a prehensile member.

The snouts of the *hog*, *mole*, *desman*, and *tapir*, are extremely well constructed for feeling with; being very moveable by the muscles already described, highly elastic in themselves, and their extremity having, like a lip, a papillated surface, which is richly endowed with nerves and vessels. But the proboscis of the *elephant*, as being capable of embracing bodies entirely, in addition to the great sensibility of its extremity, constitutes, perhaps, the most perfect organ of touch with which we are acquainted.

The inferior surface (which is the one applied to bodies) of the prehensile tails of mammalia, is divested of hair, and the skin is papillated as upon the end of snouts, &c. Cuvier states that he found the papillæ very distinctly upon the under surface of the tail in the *Cayenne opossum.*

In some cases, foreign impressions are conveyed by the medium of insensible parts. This may be observed with respect to whiskers, nails, hoofs, and horns, which are intimately connected with parts so extremely sensible, that the slightest impression upon them in an uncovered state would be highly painful. The vascular and sensible substances, which we find clothed by these horny integuments, are better calculated for producing the perception of the mere existence of solid or resisting bodies, than any of the other organs of touch; but are incapable of furnishing any idea of the figure of foreign substances. The insensible integuments and appendages of different animals are described under their proper heads in this dictionary; and there is also a plate allotted to the illustration of their structure and mode of growth.

In the *ornithorhynchus paradoxus* the external branches of the fifth pair of nerves are very large, and are distributed on the integuments of the bill of this curious animal, precisely in the same manner as in the broad bills of the *anserine birds*, and thus produce a very nice organ of touch. See *Anatomy of* BIRDS, in this dictionary.

The peculiar muscles, which move the skin and the organs of touch in mammalia, are already described, along with the other muscles of the body.

The integuments of the wing of the *bats* are so thin, that they are transparent, and permit one to see the distribution of the nerves, which form between the membranes of the wing a beautiful plexus. A contemplation of this structure should have taught Spallanzani and Jurin that *bats*, when flying, must be advertised of the existence of any resisting bodies, on approaching them, by the difference in the impulse of the air upon the concave surface of the wing; and have rendered the cruel experiments of these physiologists upon *bats*, in order to discover their sixth sense, unnecessary. From the first time we dissected this animal, we were convinced that it directed itself altogether by means of the sensibility of the wing. The mode of flying observable in *bats* appears to be perfectly consistent with this notion. They usually proceed as if they had no perception of objects, until they arrive within a near distance of them, when they either suddenly turn aside, or directly round, as if to avoid being dashed against them. Blind men are known to direct themselves by means of the feeling of resistance in the air, on approaching walls or houses, &c.; and even a person, whose sense of feeling has never been practised to discriminate so nicely, can discern the walls in a dark room, on approaching them very nearly, without touching them with any part of the body.

Organ of Taste.—The sense of taste is generally supposed to reside altogether in the tongue; but some substances excite particular tastes, in passing over the inside of the lips and the fauces. The irregular denticulated folds which the lips form in the *cloven-footed* quadrupeds, the *dog*, &c. seem particularly well calculated for receiving the impressions of sapid bodies.

Blumenbach mentions a man who was born without a tongue, yet could discern the taste of sapid substances, when passing over his palate.

The muscular structure and mechanism of the tongue have already been described, under the heads of the *organs of mastication* and the *organs of motion:* it, therefore, only remains to consider some peculiarities in the form of this member, and the organization of its integuments, which alone possess the sense of tasting.

The tongue in the *monkey* kind has not quite the same figure as in man; it is longer and thinner: even in the *ourang-outang* it is three times as long as it is broad. In the *digitigrade* quadrupeds it is long, thin, and flexible: it is so also in the *cloven* and *solid-hoofed tribes.* The *hog* has a short tongue, with the edge divided into a number of processes like fringe. The tongue of the *seal* is thick and short, and has on each side of the point a ragged notch, or deficiency, having the appearance of a piece being bitten off. The singular long-shaped tongue of the *ant-eaters* has been already mentioned, and the mechanism on which it depends described. The tongue of the *cetacea* is short, flat, and smooth, and bears considerable resemblance to that organ in fishes.

The three kinds of papillæ observed in the integuments of the human tongue, *viz.* the *conical*, *fungiform*, and *incupped*, exist in mammalia. Their varieties in different genera relate principally to the form and covering of the conical, and the number of the other sorts of papillæ.

In the *prehensile-tailed monkies* the conic papillæ are but small: they have but three incupped papillæ, which are arranged like the three points of a triangle. The *mandril* (*simia maimon*), and the *simia cynocephalus*, have also three incupped papillæ in the same position. The *simia cynomolgus* has four incupped papillæ arranged in the form of a portion of a circle. The *Chinese monkey* has seven, making an elongated triangle, with two before it in a line. Several other *monkies* have been observed to have fewer incupped papillæ than the human subject.

The tongue of the *common bats* has the conical papillæ very fine and long, somewhat like hairs, particularly on the back part. The inside of the mouth also has some of these papillæ upon it. In the *ternate bat* the conic papillæ are horny, and at the extremity of the tongue are divided into several points.

The whole of the *cat* genus (*felis*) have the conical papillæ, that are on the middle of the tongue, clothed with horny integuments. These are little hooks or claws, sharp pointed, and when on the tongue, are inflected backwards; so that when any of the larger animals of this genus employ the tongue in licking the human hand, they tear off the skin. When the papillæ of the tongue are covered by a horny substance, they seem to be insensible to the impressions of sapid bodies; we therefore find, in the *cat* kind, soft round papillæ interposed between the horny ones, upon the middle

 of

of the tongue. Thefe two kinds of papillæ are placed alternately in a quincunx order, fo that there is an equal number of both upon the tongue. There are foft, conical, fungiform papillæ upon the edges of the tongue. Upon the back part of the organ the horny papillæ difappear; and there are fome fmall incupped papillæ arranged in two lines, that approach pofteriorly. In the *common cat*, Cuvier ftates that there are on the fides of the back part of the tongue fome fungiform papillæ, which are pendent from long pedicles. The tongue of the *civet* refembles that of the *cat* genus.

In the other *digitigrade* and *plantigrade* quadrupeds the tongue is foft and flexible. The only variations are with refpect to the number and pofition of the incupped papillæ, which are fcarcely worth detailing.

The tongue of the *opoffums* has the anterior and middle part covered with horny fcales inflected backwards, which terminate in wedge-fhaped or rounded edges: the point of the tongue is fringed: there are but three incupped papillæ. The tongue is, however, foft in the *phalangers*.

The *porcupine* has the upper furface of the tongue like that of the other *faltigrada;* but upon its fides, and at the end, there are fome large fcales terminating in two or three points of a wedge-fhape. There are but two large incupped papillæ. The other animals of this order have alfo fewer incupped papillæ than man.

The conical papillæ are fo minute, as to be fcarcely difcernible in the *armadillos* and *Cape ant-eater* (*orycteropus*). Thefe animals have the tongue long, narrow, and very fmooth: they have alfo only two or three incupped papillæ.

In the *American ant-eaters* the tongue is without papillæ, and is therefore not an organ of tafte. Indeed in all the *edentata* or *infectivorous* quadrupeds, this member feems to be merely a mechanical inftrument for taking and fwallowing their prey.

The *floths* have the conic and fungiform papillæ but little developed, and only two papillæ in cups.

The *many-hoofed quadrupeds* have all the papillæ of the tongue fmall.

The *cloven-footed* order of mammalia have the conic papillæ upon about the anterior half of the tongue, terminating in flexible horny filaments. They are bent backwards, and end in a point. In the fmaller *bifulca* the horny coverings of the papillæ are fo fmall, as to be feen with difficulty; but in the larger fpecies, particularly the *camel*, thefe filaments are long, and give the touch of the tongue fomething of the feeling of velvet. The back part of the tongue, in the *bifulca*, is covered by thick tuberculated papillæ, which fometimes are cone-fhaped, and at others femi-fpherical, and which become fmaller towards the fides. The incupped papillæ are numerous, and fituated on the fides of the back of the tongue. They are not eafily diftinguifhed from the fungiform, except in the *camel*, in which they are very large, and concave on their furface.

The conical papillæ are very fmall and compact in the *horfe*, and the fungiform papillæ are confined to the fides of the tongue. There are but three of the incupped papillæ, and the furface of thefe is irregularly tuberculated.

There do not appear to be any conical papillæ on the tongue of *cetacea*. Cuvier ftates that they cannot be obferved, even with a glafs, on the tongue of the *dolphin* and *porpoife*. There are on it fome eminences like pimples, and at the bafe of the tongue there are four fiffures: the edges of the extremity of the tongue form fmall fhreds. Hunter compares the tongue of the large *whales* to a feather bed.

In *Plate* XIII. of the *Anatomy of Mammalia*, *fig.* 1 is a view of the tongue of the *cat: a*, the part covered with the fpiculated papillæ; *b*, the pendent fungiform papillæ; *c*, *c*, the two rows of incupped papillæ. *Fig.* 2 is one of the horny hooks removed from the tongue of the *leopard*, and magnified to about four times the natural fize. *Fig.* 3 fhews the tongue of the *porpoife: a*, the point of the tongue terminating in fhreddy proceffes; *b*, *b*, *b*, the pimple-like eminences upon the upper furface of the tongue.

Organs of Smelling.—The apparatus for receiving the impreffions of odorous effluvia is much more complicated in mammalia generally than in man, which is confiftent with the great excellence of the fenfe of fmelling in many of the former.

The parts of the *ethmoid* bone, which enter into the compofition of the orbits and the parietes of the cranium, have been defcribed in their proper places. The foramina of the cribriform plate, through which the branches of the olfactory nerves pafs, appear to be numerous in proportion to the perfection of the fenfe of fmelling. They are lefs numerous in the *monkey* than the human fubject.

In quadrupeds thefe foramina are of different fizes, and collected into groups. In fome fpecies of different tribes, as the *fheep*, *hog*, *ant-eater*, &c. there is a row of larger holes on each fide of the crifta galli of the ethmoid bone. The *faltigrade quadrupeds* have the feweft foramina in the cribriform lamella, and the *digitigrade* the greateft number of them.

The *cells* of the *ethmoid bone*, as they are generally found in mammalia, are well defcribed by Cuvier. He fays, it is neceffary to imagine a great number of hollow pedicles, all connected to the cribriform bone. They extend forwards and outwards; and, in proportion as they advance, thofe which are neareft unite. Vefícles arife from them, which increafe in fize in proportion as they become lefs numerous: they are all hollow, and there are an infinite number of conduits or ways between them, all of which communicate with each other. The ethmoidal cells are moft numerous in the *carnivorous* quadrupeds, which have the fineft fenfe of fmell. In the *faltigrade* order there are very few of thefe cells. Some genera of this tribe, as for inftance the *hare*, and the *quadrumanous* mammalia, have irregular cells like thofe of the human fubject.

The ethmoidal cells are diftinct from the fuperior turbinated bone in many mammalia. They are fometimes feparated from the reft of the nafal cavity by a particular feptum. This is efpecially to be obferved in the *hog*, where it is produced by a plate of the palatine bones inferiorly, and anteriorly by a procefs of the maxillary bones. It extends to the feptum nafi, and leaves only a narrow paffage above it. In the *carnivorous* tribe and the *horfe* the projection of the maxillary bones is lefs confiderable; but it is fufficient to feparate the ethmoidal cells, which are contained in a depreffion behind it. In the *faltigrade* and *cloven-hoofed* quadrupeds this depreffion is little marked.

The *fuperior turbinated* bone is formed by one of the ethmoidal cells in the *hoofed* quadrupeds. This cell is larger and much longer than the reft, and extends as far as the inferior turbinated bone which it covers.

The *inferior turbinated bones* are much more complicated in mammalia than in man.

Cuvier fays, in the *monkies* of the old continent, they are formed as in the human fubject, but in the *American monkies* thefe bones are made nearly as in the *many-hoofed* and *cloven-footed* quadrupeds.

In thefe two orders the fuperior turbinated bones commence each as a fingle lamina, which foon forms two.

 Thefe

Thefe are coiled upon themfelves in a fpiral manner, and make either two or two and a half turns, according to the fpecies, fo as to produce a fort of horn or concha, clofed pofteriorly in a point. This horn contains two canals; the one above, the other below the principal lamina. The fuperior canal leads to the maxillary finus in the *cloven-hoofed* quadrupeds, and in the *hog* it is continued pofteriorly in a long groove, which ends in a canal that goes into the malar finus. The inferior canal of the concha conducts into the back of the nafal cavity, as in the human fubject.

The turbinated bones are compreffed horizontally in the *hippopotamus,* owing to the fhape of the animal's head.

The laminæ of the turbinated bones are generally in the *hoofed* quadrupeds porous or filled with foramina, which are of various fizes in different fpecies; in fome inftances the holes are fo large and numerous, that the bones form merely an offeous net-work. The *pig*, however, has no foramina in thefe bones.

In the internal part of the turbinated bone there are feveral partitions, which are alfo perforated with vacancies.

In the *folid-hoofed* tribe, according to Cuvier, the horizontal lamina of the inferior turbinated bones does not divide into two, but at firft folds downwards, then bends upwards, and is attached behind to the maxillary bone. It afcends pofteriorly, to cover the opening into the inferior maxillary finus, and even to pafs into it. Laftly, it produces, towards its middle, two or three oblique laminæ, which are attached to the anterior edge of this hole.

The inferior turbinated bones of the *edentata* and *three-toed floth*, very nearly refemble thofe defcribed in the *cloven-footed* quadrupeds. In the *two-toed ant-eater*, however, Cuvier fays, they are like two prifmatic boxes clofed on all parts, and divided internally by fome vertical laminæ. The *lemur* has fimilar bones, but without any divifion anteriorly.

In the *porcupine* and *marmot* thefe bones confift of a double lamina, attached longitudinally; the two parts of which feparate from each other, and afcend by a fpiral convolution, giving the appearance of the periwinkle fhell (*turbo*). The *rat* has the turbinated bones fimilar to thofe of the *cloven-hoofed* quadrupeds. The other *faltigrada* almoft all have thefe bones complicated, as in the *carnivorous* tribes.

In thefe laft the lamina, by which the inferior turbinated bone is affixed, divides into two branches, each of which is again divided. The laft laminæ form a number of canals covered by the pituitary membrane. The air paffes through thefe canals on its way from the noftrils to the lungs, and back again. The *feal* and *otter* have the inferior turbinated bone more fubdivided than any other animals of this clafs. Profeffor Harwood has calculated that the internal furface is equal to 120 fquare inches in each nafal cavity of the *feal*. The laminæ are moft numerous in the *beaver* amongft the *faltigrada*. When there are few laminæ in the *carnivorous* and *faltigrade* orders, the laft laminæ are fpirally twifted in the fame manner as where there are but two in other animals. The *lion* has the lamina divided into two, each of which has a double roll. It is perforated by many foramina. The *civet* and the *viverra genetta* have only the lamina convoluted and without foramina.

The intention of the divifions and convolutions of the inferior turbinated bones, is evidently to extend the furface of the pituitary membrane which is fpread upon them, and as we find this furface, almoft without exception, great in proportion to the acutenefs of the fenfe of fmell, we cannot but fuppofe the olfactory nerve is diftributed to it, although its branches have not yet been clearly traced beyond the fuperior turbinated bone.

The *olfactory* nerve has been already defcribed until its entrance into the nafal cavity. Upon arriving there, its diftribution appears to be exactly the fame both in man and mammalia. Cuvier mentions two branches, which are longer and plainer than the reft, upon the feptum, but thefe appear to us to be branches of the fifth pair of nerves, diftributed to the pituitary membrane for common fenfation.

The *finufes* of the different bones in the neighbourhood of the nafal cavity, more particularly the *frontal* finufes, have been confidered by Blumenbach and others as being fubfervient to the organs of fmelling. We muft confefs, however, that the ufe of thefe parts does not appear to us to be quite determined. The membrane which lines the finufes is not organized for receiving the impreffion of odorous effluvia, and the retention of the latter in the cavities of the finufes does not feem likely to produce much effect upon the pituitary membrane. We may obferve, that when animals wifh to fmell any fubftance particularly, they make fhort infpirations, which is called *fnuffing*. The chief ufe of the finufes, as connected with the organs of fmelling, appears to be to fupply a clear watery fluid for keeping thofe parts moift which are really the feat of this fenfe, for we find, when the fecretion of the finufes becomes infpiffated or fuppreffed by catarrhal inflammation, the fenfe of fmelling is very much impaired.

The *frontal finufes* vary very much in fize and figure, even in the genera of the fame tribe. They are fmall in the *monkey* kind generally, and are even abfent in fome fpecies. Thofe with *prehenfile tails,* on the contrary, have them large. The *bats* want thefe finufes.

In the *digitigrada* they are large, and particularly fo in the *dog* kind, in which they not only occupy the anterior part of the os frontis, but the poft-orbitar proceffes, and each fide of the pofterior parietes of the orbit.

Thefe finufes are very extenfive alfo in moft of the *plantigrada*. The *badger*, and the greater number of the *weafel kind*, want them altogether, but have the poft-orbitar proceffes hollow, and communicating freely with the nafal cavity.

Moft of the *faltigrade* quadrupeds want the frontal finufes; yet in the *porcupine* they are fo large as to pafs into the fubftance of the nafal bones.

In the *edentata* thefe finufes do not exift, in the *ant-eater* and *pangolin*, but the *armadillo* has them of fome fize.

In the *floth* they are very extenfive, reaching nearly to the occiput.

The *cloven-footed* quadrupeds have the frontal finufes in general very large, and in the *ox*, *goat*, and *fheep*, they extend into the interior of the offeous procefs, which fuftains the horn. Cuvier thinks the *ftag* has no frontal finufes. Harwood fays the *deer* want thefe finufes, but have membranous cells between the nofe and internal angle of the eye.

The *elephant* has the finufes correfponding to the frontal of prodigious extent. They give the remarkable prominence of the forehead which this animal poffeffes, and render feveral of the bones of the head hollow. They are divided into a great number of fmaller cells, fo that the texture of the cranium in the elephant has, when laid open, the appearance of a honey-comb, or rather of a fponge that has large cells.

In the *hog* thefe finufes are larger than in any other animal, except the *elephant*. They extend in both thefe quadrupeds as far as the occiput. In the *common hog* and *babirouffa* they are divided by fome laminæ of bone, but do not form that intricate cellular ftructure found in the *elephant*. The *hippopotamus* and *rhinoceros* have no frontal finufes.

Thefe finufes are of tolerable extent in the *horfe*, but are confined

confined to the frontal bone, and in place of opening, as ufual, into the fuperior part of the nafal cavity, communicate on ea h fide, by a large opening, with the pofterior maxillary finus.

The *feal* wants the frontal finufes.

It will be feen, from the above account, that the magnitude of the frontal finufes keeps pace in general, though not conftantly, with the degree of excellence in which the animal poffeffes the fenfe of fmelling, from whence the opinion arofe, which we have already noticed, of thefe finufes being particularly connected with the organ of fmelling.

The *maxillary finufes* are very fmall in many orders of mammalia, as the *digitigrada*, *plantigrada*, the greater number of the *faltigrada*, and *edentata*, and ufually in all the quadrupeds in whom the maxillary bone does not form a floor to the noftrils. They are lefs in the *monkey* and *lemur* than in man in proportion. Generally in the *digitated* quadrupeds, when there is a cavity in the maxillary bone, it is in common with that of the nofe.

Hogs want the maxillary finus, but they have finufes in the malar bone. The *hippopotamus* has likewife a fmall finus in the fame fituation. The maxillary finufes of the *elephant* are cellular, like the others of this animal. The cells communicate, and one of them opens into the nafal cavity.

The *cloven-hoofed* quadrupeds have the maxillary finufes, as well as the frontal, very large. Each finus opens into the nafal cavity, behind the inferior turbinated bone, by a narrow flit.

In the *horfe* there are two maxillary finufes, an anterior and pofterior. The latter is the larger, and forms a projection into the nafal cavity.

The *fphenoidal finufes*, although, from the pofition of the head of quadrupeds, they muft perform the fame offices as the frontal finufes, do not correfpond with thefe laft in regard to fize.

In the *quadrumana*, they are lefs than in man in proportion.

The *carnivorous* tribes have fmall fphenoidal finufes, and fome of them, as the *otter*, *pole-cat*, and *feal*, want them.

They appear to be abfent alfo in moft of the other genera of mammalia. They are found in the *hog* and *hippopotamus*, but of a fmall fize. The *elephant* has them of a very great magnitude. They extend into the pterygoid proceffes of the fphenoid bone. Their interior is not cellular, as the other finufes of the *elephant* are.

The fphenoidal finufes exift in the *horfe*; they open into the pofterior maxillary finufes.

The entrance into the organ of fmelling, is in general compofed of the fame cartilages in man and many mammalia, only differing in form and fize in the latter.

In thofe with *fnouts*, the cartilages make in general a perfect tube. Cuvier thus defcribes the fnout of the *bear*. The cartilaginous feptum is reflected inferiorly as well as fuperiorly; the fuperior alæ bend downwards; they meet on the fides, where they are united by cellular fubftances, and complete the external parietes of each noftril. The edge of each ala continues afterwards to bend inward, and forms a kind of concha, which makes an addition to the inferior turbinated bone, and which is covered, like it, by a prolongation of the pituitary membrane.

In the *horfe*, a great part of the external nares is membranous. The edge of the noftrils contains a femi-lunar cartilage, which correfponds to the inferior cartilage of the human fubject. It has two branches, one is long and narrow, and is nearly parallel to the feptum; the other is fhort, almoft fquare, and fituated in the external ala of the nofe. The reft of the ala is formed by the integuments, which are at firft inflected to produce a foffa, which is known by the name of the *falfe noftril*. The paffage into the real nares is a long flit.

The probofcis of the *elephant* and *tapir* is the moft remarkable prolongation of the external parts of the organs of fmelling. The two external nares are extended into two membranous tubes, which in the *elephant* are of great length. Thefe tubes are inclofed by the complicated mufcular ftructure already defcribed, and the integuments.

The mufcles which move the different parts of the external nares are defcribed along with thofe of the reft of the body.

We have before obferved, that the *cetacea* do not poffefs any olfactory nerves, or apparently any organ calculated for receiving impreffions from odorous fubftances. Yet Mr. Hunter afcribed the fenfe of fmelling to the *fpermaceti whales*, and Cuvier feems to think, that it may exift, in a degree, in a certain cavity and cells which communicate with the Euftachian tube. Thefe are fituated on the lateral parts of the bafe of the fkull, and are partly formed by projections of the bone, and partly by proceffes of ligament. They are very irregular interiorly, and are lined with a thin mucous membrane. Thefe cells communicate with the frontal finufes, by a canal which afcends before the orbit. There is a tolerably large opening from the principal cavity into the Euftachian tube. This laft terminates in the nares. The cellular cavity, therefore, has no direct communication with the nares. There are feveral branches of the fifth pair of nerves difperfed through thefe membranous cells, but there is no reafon for fuppofing that thefe have any fenfibility for odorous fubftances, even if they were fairly applied to them.

The two canals correfponding to the nares, are ufed in *cetacea* for the tranfmiffion of the air to and from the lungs, as thefe animals do not refpire by the mouth; for the larynx, inftead of opening at the back of the mouth, afcends in the form of a pyramid, and is received into a flefhy tube, which is common to the two nares. *Whales*, therefore, can keep the mouth in the water, and fwallow their food, without interrupting their refpiration, and it is to enable them to do fo frequently, that the external opening of the nares is upon the top of the head. The flefhy tube which receives the fuperior part of the larynx foon divides into two canals, which pafs on each fide of the vomer, and are analogous to the pofterior paffages, into the nafal cavity of other mammalia. They are, however, lined by a thin, dry integument, very unlike the pituitary membrane. They afcend in two canals that are formed in the bones of the cranium, feparated by a thin feptum. Where the two canals terminate, they are provided with a flefhy valve in the fhape of two femicircles. This valve is attached to the anterior edge of their orifice, and clofes it by means of a very ftrong mufcle, that is attached to the intermaxillary bones. On the outfide of this valvular opening, there are placed two large, oval, membranous bags. Thefe are lined by a black mucous integument, which appears to be the continuation of the fkin; it is very deeply wrinkled in a relaxed ftate.

A ftrong layer of flefhy fibres arifes in a radiated manner from the circumference of the cranium, and unites upon thefe two bags. The fkin of the head covers them, and there appears externally only a fmall flit of a femi-lunar figure, which is a common opening to the two bags.

It is the ftructure juft defcribed which enables the *cetacea* to expel any water which may get into the pharynx or nafal paffages. This is done with fo much force, that the jet is feen in the larger fpecies at a confiderable diftance at fea. Some *whales* are reported to fpout the water from their blow

blow holes as high as 40 feet. When these animals wish to expel the water from these spiracles, they close the pharynx and larynx by their proper muscles; the larynx retreats from the fleshy tube which embraces it during inspiration, and leaves the passage into the nares free, through which the water is urged to ascend, until it arrives in the oval bags situated on the forehead, which is the upper part of the head in these animals. The valve that guards the opening of the nares into the oval bags is shut, to prevent the retreat of the water; the muscles of the bags contract, and the water is thrown out through the semi-lunar fissure of the skin with extraordinary force.

Fig. 4. *Plate* XIII. of the *Anatomy of Mammalia*, is a section of the anterior part of the skull and upper jaw of the *hog*, in which most of the circumstances in the structure of the organ of smelling are brought into view: *a*, the frontal sinuses, which are very large in this animal; *b*, the sphenoidal sinuses of a small size; *c*, the ethmoidal cells; *d*, the superior turbinated bone; *e*, the inferior turbinated bone; *f*, the passage to the malar sinus; *g*, the septum dividing the ethmoidal cells from the superior turbinated bone.

Organs of Hearing.—The *concha* and *cartilaginous meatus auditorius*, which constitute the *external projecting ear*, are generally much larger in mammalia than in man. Some, however, that burrow in the ground, are deprived of concha, as the *mole* and some *shrews*, the *zemni* and some *mole-rats*. It is also wanting in the *pangolins*, the *ornithorhynchus*, some *seals*, and the *morse*. In the *cetacea*, there are no external parts to the ear. The cartilaginous meatus commences by a very small orifice in the skin, and leads to the membrana tympani.

The concha is large in those mammalia that have occasion to collect distant sounds in the air, as the *bat*, several *cloven-footed* quadrupeds, the *ass*, the *hare*, the *rabbit*, &c. In the fugitive quadrupeds, the concavity of the concha is usually turned backwards; and in those that hunt for their food, it is generally directed forwards. In the *bat* kind, the hollow of the ear is turned forwards, probably for feeling the approach of other bodies in the same manner, as the wings of these animals do. The ears of the *vespertilio spasma* are immoveably fixed in the forward direction, as they are united to each other by their internal edges. The superior part of the external ear being pendulous, Cuvier remarks, is an effect of domestication. The ear of the *elephant* is also pendulous, but not in the same way as in domestic animals; it being only the posterior and inferior part of the *elephant's* ear which hangs down.

In proportion as the ear is found larger than in man, it usually becomes also more elongated in its figure: it is also thinner. It is nearly membranous in the *opossum*.

The *eminences* of the external ear are various in mammalia. The most singular peculiarities are seen in the *bat* kind. That remarkable projection which appears like one concha, contained within another in the *great eared bat*, is the eminence called the *tragus* prodigiously enlarged. This part is also unusually formed in the other species of *bat*. It is forked in the *vespertilio spasma;* notched in the *vespertilio leporinus*, and *v. crenatus*.

The *antitragus* is extended forwards in the *vespertilio molossus*. to the angle of the mouth. It forms an operculum to the ear in some *shrews*, particularly in the *aquatic shrew*, which has the opening into the ear perfectly covered by this means.

Quadrupeds often have the cartilaginous meatus auditórius composed of two pieces; one is joined with the concha; the other is a tube which is connected to the bony meatus by ligament: both pieces have a longitudinal fissure. The design of this structure is to permit the contraction and elongation of the cartilaginous tube of the ear.

In the long-eared quadrupeds also, there is a third cartilage, to which nothing similar exists in the ear of the human subject. It is situated above the cartilaginous meatus; it is flat, and forms no part of the concavity, but merely serves for the attachment of certain muscles. It varies in shape; it is triangular in the *horse;* lunated in the *sheep;* pointed posteriorly, and bilobed posteriorly in the *rabbit*. and rhomboidal in the *dog*. Cuvier, from whom we borrow this account, calls this cartilage the *scutum*.

The external meatus auditorius is long and curiously twisted in the *ornithorhynchus*.

The *muscles* which move the external ear in most quadrupeds are very numerous and complicated; they have received a distinct description along with the other muscles of the body.

The *osseous portion* of the *meatus auditorius* is subject to a good deal of variety with respect to its length and direction. The latter seems to be influenced by the course in which the sounds approach the animal that it is the most concerned to hear. The osseous meatus is singularly formed in the *mole;* it is flattened superiorly and extended on the sides. The membrana tympani, which is very large, constitutes its superior parietes; by this means the *mole* is enabled to collect more perfectly the sounds that arise from the earth.

The *whale* tribe have no osseous meatus auditorius, but the auditory passage is long and serpentine; it is made of cartilages and membranes that allow its being lengthened and shortened.

The *membrana tympani* is extensive in general for the acuteness of the sense of hearing. It is also situated more or less obliquely in those that hear well. In the *mole* it is nearly flat, and forms the bottom of the cavity of the tympanum. It is nearly as oblique, according to Cuvier, in the *otter*, *weasel*, and *badger*. In the *pangolin*, also, it is very oblique. Its position is nearly vertical in many other *carnivorous* quadrupeds. It is nearly vertical, and turned towards the side, in the *hare*, *cavy*, *marmot*, and most of the *cloven-footed* order.

The form of the membrana tympani depends upon the frame of bone in which it is placed. It is generally in mammalia an oval, with the great axis descending obliquely forwards, and the anterior arch less convex than the posterior. In some of the *saltigrada*, the membrana tympani approaches the figure it possesses in man; and in the *mole* it is perfectly round. It has the figure of a trefoil leaf in the *cetacea*.

The osseous frame of the *membrana tympani* is only perfect, according to Cuvier, in the *guinea-pig*, the *paca*, the *seal*, and the *ant-eater*. There is in other instances a greater or less deficiency in the upper part of it. This is often about one quarter of its circumference. In the *elephant* the half of the upper part of the osseous frame is wanting.

In the *cetacea* there is no proper process of bone for a frame.

The membrana tympani has something of the infundibular figure in all mammalia, except in the *mole*, where it exhibits no concavity on the outer surface.

The structure of this membrane appears to be the same in all the class of mammiferous animals. In the larger quadrupeds there is no difficulty in exposing its three layers, and in the *elephant* the muscularity of the middle layer is said to be clearly demonstrable.

The cavity of the tympanum in most mammalia is dilated at the lower part, usually into a semi-oval or semi-spherical cell. Those of each side produce two eminences that are visible upon the lower part of the skull.

They

They are feen even in the *prehenfile-tailed monkies* ; but are moft remarkable in the *carnivorous* mammalia ; they are very large in the *cat* kind, and the *feal*. Thefe protuberances are more or lefs angular in the *floth*, the *cavy*, the *cloven-hoofed*, and feveral of the *many-hoofed* quadrupeds. They are flat in the *mole*, and fo broad as to touch each other. In the *bear* there are no projections vifible. In the *hog* they are elongated, and end in bulbous heads.

The *maftoid procefs* can hardly be faid to exift in mammalia. Its place feems to be fupplied by the dilatation we have juft defcribed. In the *cloven* and *folid-hoofed* quadrupeds, the *hog*, *cavy*, and *guinea-pig*, there is a ftyle-fhaped procefs from the occipital bone, which has been confidered as analogous to the maftoid procefs by fome anatomifts.

The interior of the cavity of the tympanum is, in many genera, more or lefs fubdivided into different parts. A number of the *carnivorous* tribes have a tranfverfe offeous ridge from the frame of the membrana tympani, to which it appears to ferve as a fupport. In addition to this, there is, in the *cat* and *civet* genera, an offeous procefs, that extends from the pofterior inferior edge of the frame of the membrana tympani, to the promontory, and which, being prolonged obliquely, divides the cavity of the tympanum into two unequal parts, that only communicate with each other by a hole. The anterior of thefe two cavities contains the bones of the ear and the foramen ovale. The pofterior cavity is much larger, and holds the foramen rotundum. It feems to correfpond with the large cells of birds.

Cuvier ftates that *prehenfile-tailed monkies* and *ant-eaters* have an additional cell, fituated before the cavity of the tympanum, and that the *floth* has a cell at the root of the zygomatic procefs.

The interior of the tympanum is intercepted in the *elephant* by a number of bony proceffes, which crofs in every direction, and produce a multitude of cells. A fimilar ftructure exifts in a degree in the *guinea-pig*, *marmot*, *cavy*, and *porcupine*, according to Cuvier. The two tympani of the *elephant* communicate by the cellular ftructure of the fkull.

The tympanum has offeous fepta in the *pig* and horned *bifulca*, which divide its cavity into cells like thofe of a ripe fruit.

In the *hippopotamus* the proper cavity of the tympanum opens by a hole into a cellular cavity.

The *feal* and *morfe* have the tympanum very wide, but without fepta.

The offeous part of the *Euftachian tube* in the *cat* and *civet*, is rather a narrow fiffure than a canal ; in the *otter*, *badger*, and *weafel*, &c. it is a hole ; in the *cavy* it is a half formed canal at firft, which is completed in paffing through the petrous part of the temporal bone. In the *elephant* it is a long wide canal.

There is a large membranous fac in the back of the mouth of the *horfe*, in which the Euftachian trumpet ends.

In the *cetacea*, the cavity of the tympanum, as well as the petrous portion of the temporal bone, is diftinct from the reft of the fkull, to which thefe parts are only bound by ligament and periofteum. The tympanum refembles in figure the fea fhell called *bulla*. The part which correfponds to that containing the fpiral cavity in the bulla is, however, folid in the tympanum. This part is more than two inches thick in the *cachalot* (*phyfeter*). This tympanum adheres to the petrous bone by its pofterior extremity, and by a procefs of the anterior part of its thin edge. Cuvier ftates that in the *dolphin*, the anterior procefs of the tympanum alfo afcends to the petrous bone, but in the *cachalots* (*phyfeter*) it does not reach that part. The tympanum of the *cetacea* is rough upon the furface. It is very ponderous, from poffeffing a great quantity of earthy matter, and is lined with a ftrong membrane, which Hunter thought had a cuticle. There is a thick plexus of veffels in the cavity of the tympanum, one part of which is attached, and the other floats at liberty, like the plexus choroides in the ventricles of the brain. The Euftachian tube in *cetacea* is wideft at its commencement from the tympanum, the anterior extremity of which is entirely open. The tube afcends along the pterygoid procefs, penetrates the maxillary bone, and terminates by a valvular opening in the nafal paffage. Both the tube and the cavity of the tympanum communicate with feveral ligamentous cells, which Hunter confidered analogous to the maftoid in fome refpects.

The two foramina which connect the cavity of the tympanum are fo various in their form, that the ufual names of *foramen rotundum*, and *foramen ovale*, would be improper. Cuvier, therefore, has called the firft the *feneftra cochlearis*, and the fecond the *feneftra veftibularis*.

In the *bat*, the foramen of the cochlea is larger than the other.

In the *mole*, they have both an oval figure. There is a hollow offeous bar which gives paffage to fome blood-veffels extended acrofs the feneftra veftibularis in this animal ; it paffes between the branches of the ftapes. A fimilar bar is found in other inftances.

In the *cat* and *civet*, the foramen of the cochlea is almoft twice as large as the veftibular feneftra.

In the *opoffum*, the foramen called oval in the human fubject is round, and the one called round is fmall and irregular. The latter is triangular in the *beaver* and *marmot*, and in the *hare* it is a fmall fiffure. The veftibular foramen in this laft animal is round and large.

The cochlear feneftra is about double the fize of the other in the *calf* and *pig*, and three times larger in the *hippopotamus*. But in the *elephant* it is very fmall and irregularly fhaped. It is larger than the veftibular foramen in the *horfe*.

The two foramina are farther afunder in the *cetacea* than in quadrupeds. The one of the cochlea is the larger. It has an opening for blood-veffels. The lining of the tympanum projects into the cochlear feneftra.

The fame number of *officula auditus* are found in mammalia as in man, with hardly any exceptions. The *ornithorhynchus paradoxus* has only two officula ; the firft correfponds to the *malleus* of other mammalia ; the fecond refembles very much the fingle officulum of birds. Perhaps a mechanifm fimilar, or approaching to this, would be found in fome of the other *edentata*. There have been difcovered in fome of the *cloven-hoofed* quadrupeds one or two fmall bones in addition to the ufual number. Thefe do not appear to be a natural ftructure. We fhall not enter into a minute defcription of the varieties in the form of the bones of the ear, as many of them do not appear to influence the functions of the organ. We fhall only notice the more remarkable peculiarities obferved in the officula auditus, and refer the reader to Cuvier's "Comparative Anatomy," vol. ii. and Mr. Carlile's paper upon the ftapes in the Philofophical Tranfactions for 1805, &c. for a more particular defcription of thefe parts.

The *proceffus gracilis* of the *malleus* is formed into a thin lamina at its extremity in fome *monkies*, and in the *dog* and *cat*. In the two latter, the *fhort procefs* of the malleus is very prominent, and there is another procefs at the inner part of the neck of the officulum, which fupplies the place of the fmall fpine of the human fubject.

In the *mole*, the proceffus gracilis is fo broad as to make the malleus appear nearly fquare.

In the *faltigrada*, the handle of the malleus is very thin. It

It is likewise so in the *sloth*, *ant-eater*, and *pangolin*, and in all these the short posterior process is almost effaced.

In the *seal*, the handle of the malleus is also compressed, and there is hardly any processus gracilis.

In the *cetacea*, the handle of the malleus is different, but its place is in some degree supplied by a tendinous elongation of membrana tympani, which has more of the funnel shape than in the other mammalia, especially on the inner side. This prolongation of the point of the infundibular membrana tympani is inserted into the base of the neck of the malleus. The neck is truncated obliquely, and there is a processus gracilis which is conical and arched in its form.

There is less variation in the forms of the *incus* of mammalia, than in the preceding officulum. The *mole* has the most remarkably shaped incus. Its inferior or stapedian process is very short and small; while the other is very large, oblong, and hollowed posteriorly like a spoon. Cuvier imagines this may be for holding a muscle.

The stapedian process is very long, and the other hardly apparent in the *rat* and *hare*.

The existence of the *orbiculare* as a distinct officulum has been doubted by some anatomists. Blumenbach considers it only as an epiphysis of the incus. He says it is often wanting even in negroes and North American Indians, whose organs of hearing are very perfect: that it is consolidated with the incus in the adult, and that when it is found as a distinct bone it is not a natural structure. It has appeared, however, to us to be too easily separated, and too regular in its figure, for a mere epiphysis of the incus. It is wanting altogether in the *cetacea*. The *bottle-nosed whale*, according to Hunter, has a small bone in the tendon of the stapideus muscle.

There are several varieties in the figure of the *stapes*, which are pointed out by Mr. Carlile, as above-mentioned.

The form of this officulum is most peculiar in the *mole*, and in the *aquatic* mammalia. The former has the branches of the stapes very much arched and far asunder. The base of the officulum is an elongated oval shape. In the *cetacea* the parts corresponding to the branches are so thick and close to each other, that the stapes appears as a solid bone, with a very minute foramen in the middle. The base is small in proportion to the rest of the officulum. In those species we have examined, the foramen was only large enough to admit the point of a pin. Cuvier describes the stapes of the *lamantin* as resembling a twisted cylinder: on one side there is an oblique groove, and the foramen has the appearance of the puncture of a pin. The surface of the base applied to the fenestra vestibularis is very convex. Some approaches to this structure of the stapes has been observed in the *seal*, from whence it has been supposed, that a solid state of this officulum was favourable to hearing sounds communicated through water.

The *muscles* of the bones in the tympanum have not received as much investigation as they merit, either in man or animals. The same number appear to exist in mammalia as in man, with the exception of the *cetacea*, which seem to want all the muscles inserted into the malleus. They have, however, the *stapideus* muscle. Cuvier says, it is inserted very far up, and not in the middle of the branch of the officulum, as in man.

The *labyrinth* consists of the same parts in mammalia as in man. The *semi-circular canals* were at one time not supposed to exist in the *cetacea*. They are so extremely small that they even escaped the notice, for a long time, of so accurate an anatomist as Camper. In the *porpoise* we have found them just large enough to admit a bristle to pass in them. The extreme hardness and brittleness of the petrous bone in *cetacea*, are additional reasons for these canals remaining undiscovered, and stand in the way of investigating all the parts of the organ of hearing in these animals. This bone, and indeed the tympanum also, in *cetacea*, are as dense and weighty as common stone, and when dried are very easily broken in all directions. The petrous bone is not united, even by suture, with any of the other bones of the cranium, but is retained by ligament and periosteum in a vacancy formed principally in the occipital bone.

The *mole*, whose organ of hearing, in many respects, is formed upon an opposite plan to that of the *cetacea*, is distinguished by the extent of the semi-circular canals, and these are plainly seen on the inside of the cranium, from not being imbedded in a bone harder than the rest of the cranium, as usual in other cases.

Some mammalia are remarkable for the great size of their *cochlea*, in proportion to their parts of the ear. The *bats* have it of the greatest relative size. Cuvier states, that the *horse-shoe bat* has the diameter of the cochlea ten times greater than that of one of the semi-circular canals. The cochlea is visible in this genus on the lower part of the cranium, generally where its form is distinctly exhibited without any dissection of the temporal bone. It bears a perfect likeness to the snail-shell. The semi-circular canals are visible on the internal part of the cranium. There is no petrous portion, properly so called, either in the *bat* or the *mole*, except what constitutes the labyrinth itself. In the *hare-lipped bat*, according to Cuvier, the cochlea projects on the inside of the cranium.

In most of the *carnivorous tribes* of mammalia, the cochlea is larger in relation to the semi-circular canals than it is in the human subject. It is, likewise, so in the *hog*, *elephant*, and *horse*. On the contrary, the relative size of the cochlea to the canals, is less in the *mole* and *hare* than in man.

In general, the cochlea forms two turns and a half in mammalia, as in man. But the *guinea-pig*, *cavy*, and *porcupine*, have three turns and a half. Their cochlea has a pyramidal figure, and makes a projection into the cavity of the tympanum.

The cochlea of *cetacea* is very peculiar. It is large, but only forms one turn and a half, which is nearly in the plane of its axis. The osseous *lamina spiralis* is divided throughout its length by a very narrow fissure into two parts. That which touches the axis is three times larger than the other. The fissure is only completed in the recent state by a membrane.

The osseous part of this septum also, which touches the axis, has under its base, and in the scala of the tympanum, a small canal, which follows the same curvature from one extremity of the cochlea to the other. This canal appears like a third *scala* to the cochlea, but it differs in the circumstance of its capacity increasing as it proceeds in the cochlea; it is widest at the apex. Cuvier observes, that there is a similar canal, though much smaller, in the *cloven-hoofed* quadrupeds. In the other mammalia, only the part of the lamina spiralis which touches the axis is osseous, as in man.

According to Cuvier, the *dog*, *sloth*, *elephant*, *horse*, *dolphin*, &c. resemble man in having the scala of the cochlea that goes to the tympanum rather larger than the other. It is much greater in the *bat*. The scala that leads to the vestibulum, is the larger in the *calf*, *goat*, *sheep*, *hare*, *cat*, *guinea-pig*, *rat*, &c.

The *aqueducts*, as they are called, appear to exist in all mammalia. They have been observed to be very large in the *dolphin*.

The figures which illuſtrate the organ of hearing, are found in *Plate* XIII. of the *Anatomy of Mammalia*.

Fig. 5. repreſents the under ſurface of the ſkull in the *mole*, the lower jaw being removed : *a* is the flat dilatation of the cavity of the tympanum, analogous to the maſtoid cells, ſeen externally on the left hand ſide : *b* is the round, level, membrana tympani, expoſed on the other ſide by the bone being cut away : *c*, the oſſeous meatus auditorius. *Fig.* 6. ſhews an undiſſected view of the bone, containing the organ of hearing in the *grampus*, removed from its connections with the ſkull : *a*, the bone which forms the tympanum : *b b*, the extenſive ſlit-ſhaped opening into the cavity of the tympanum, and which has been compared to the aperture of the *bulla* ſhell : *c*, the irregular trilobed ſpace left for the attachment of the membrana tympani : *d*, the part of the petrous bone containing the labyrinth. *Fig.* 7. is a view of the malleus of the *mole*. *Fig.* 8. ſhews the ſame bone in the *hare*. *Fig.* 9. is the ſhort, thick malleus of the *grampus*, with the membrana tympani attached to it : *a*, the oſſiculum : *b*, the infundibular membrana tympani, with its elongated point inſerted into the neck of the malleus. *Fig.* 10. gives the ſhape of the incus in the *mole* : *a* is the hollow proceſs of the bone. *Fig.* 11. is the incus of the *grampus*. *Fig.* 12. exhibits the ſtapes of the *mole* in ſitu : *a*, the oſſiculum : *b*, the oſſeous bar that croſſes the feneſtra veſtibularis between the branches of the ſtapes : *c*, *c*, are the ſurrounding parts of the temporal bone left in the diſſection. *Fig.* 13. gives a ſide view of the ſtapes in the *grampus*, in which is ſhewn the ſmall aperture that correſponds to the ſpace left between the limbs of that bone in other mammalia. *Fig.* 14. is a view of the lower part of the interior of the cranium in the *mole* : *a* indicates the labyrinth as it appears, without any diſſection of the bones of the cranium : *b*, the ſemi-circular canals and cochlea expoſed, by cutting away ſome part of the cranium, which is very looſe and cellular in its texture, adjoining the oſſeous labyrinth in this animal. *Fig.* 15. is a repreſentation of the oſſeous labyrinth of the *bat*, removed from the ſkull, and a little magnified : *a*, the ſemi-circular canal : *b*, the very large cochlea : *c*, the foramen cochlea feneſtra : *d*, the veſtibular feneſtra. *Fig.* 16. exhibits the turriculated cochlea of the *guinea-pig*, laid open on one ſide, to expoſe the three turns and a half made by it in this animal. *Fig.* 17. ſhews the cochlea and part of the ſemi-circular canals of the *grampus*, excavated from the petrous bone : *a*, *b*, the two tubes which form the cochlea : *c*, *d*, parts of the ſemi-circular canals expoſed and laid open in making the ſections of the bone in which they are incloſed : *e* is the portion of the petrous bone left in the diſſection. *Fig.* 18. ſhews the entire cochlea of the *whale*, abſtracted from all ſurrounding bone ; at the extremity are ſeen the openings into the two tubes of the organ. *Fig.* 19. is a lateral view of the ſame cochlea : *a*, *b*, are the two ſmall openings of the cochlea ; *c* is the beginning of a ridge which divides the entrance of the cochlea : *d*, the tube, which appeared to Camper to contain a nerve.

Organs of Viſion.—The eye is compoſed of the ſame coats and humours in mammalia as in the human ſubject. The comparative anatomy of the organs of viſion in this claſs, relates to varieties in the ſtructure of particular parts, with a deſcription of a few appendages to the eye, that do not exiſt in man.

There is ſome diverſity in the external figure of the eye-ball in different mammalia. Agreeable to a general principle already laid down, it is more globular, or the anterior part is more gibbous, in proportion to the tenuity of the medium, through which the animal beholds objects. We therefore find that eyes of the *aquatic* mammalia are moſt flat upon the anterior ſide, in which circumſtance they approach in form the eyes of fiſhes.

The departure from the ſpherical form of the eye is indicated by a table publiſhed in Cuvier's "Comparative Anatomy," in which the length of the axis is compared with that of the tranſverſe diameter of the eye. We ſhall extract the following examples.

	Axis.		Tranſverſe Diameter.
Man - - -	1	to	1
or, to be more accurate	137	:	136
Monkey - - -		the ſame	
Dog - - -	24	to	25
Ox - - -	20	:	21
Horſe - - -	24	:	25
Porpoiſe, meaſured externally	2	:	3
Whale, meaſured internally	6	:	11

Both the permanent and changeable forms of the eye-ball depend neceſſarily upon its external parietes, which are the ſclerotic coat and cornea.

The *ſclerotic coat* has the ſame texture, and proportionate thickneſs of its different parts, in mammalia generally as in man. There are, nevertheleſs, ſome ſtriking exceptions to this obſervation in the *aquatic* tribes. The ſclerotic of the *ſeals* is thick and firm at the anterior, and ſtill more ſo at the poſterior parts of the eye ; but around the middle this coat is very thin and pliant. This change of the ſtrength of the coat is not, however, abrupt. Blumenbach attributes to this ſtructure the power of accommodating the form of the organ to the different media in which theſe animals reſide. The cornea of the *ſeal* tribe is alſo thin and yielding, and the muſcles which act upon the eye-ball are ſtrong. The reſult of all theſe circumſtances is, that the creature can elongate and ſhorten the axis of the eye according to the occaſion, and thereby adapt it to viſion in the two media of air and water.

D'Albus has diſcovered a ſimilar conformation of the ſclerotic in the *walrus*, in which it is alſo obviouſly intended to anſwer the ſame purpoſes.

The ſclerotic coat of the eye in *cetaceous* mammalia is very peculiar. It is prodigiouſly thick at the poſterior part ; in the larger ſpecies about an inch and a half ; in the *grampus* about $\frac{3}{4}$ths of an inch ; and in the *porpoiſe* two or three lines thick.

It gradually declines until it arrives at the cornea, where it poſſeſſes the ordinary thickneſs of the ſclerotic, in proportion to the ſize of the animal. The compoſition of this coat is equally curious with its form. Upon dividing it, we find a multitude of ligamentous fibres paſſing through it in all directions, and forming an inextricable plexus, which contains in its meſhes a brown fungous elaſtic ſubſtance. A ſection of the ſclerotic has very much the appearance of that of tanned leather, only that it is paler. The coat is looſer in its texture, and ſofter quite at the back part, than on the ſides of the eye-ball. The meſhes there contain an oily ſubſtance. The ſheath of the dura mater, which contains the optic nerve, is neceſſarily very long, and is very eaſily demonſtrated in the *cetacea*. The fibres which enter into the compoſition of the ſclerotic are ſeen to depart from the external part of the ſheath, which fact has been taken as the proof of the ſclerotic coat being, in all caſes, a production of the dura mater, as ſuppoſed by the ancient anatomiſts. The ſclerotic of the *whale* kind, by its great firmneſs, defends the internal parts of the eye from preſſure, to which they would otherwiſe be ſubject, from the ſhallowneſs of the orbits. The form of the internal part of the organ is alſo altered to nearly an oval, although the external figure is ſpherical.

The *tranſparent cornea* generally reſembles that of the human ſubject in the claſs of mammalia. The *porcupine* and *opoſſum* have this part large, and forming the ſame ſphere with the ſclerotic. Blumenbach ſays the cornea of the *porcupine* extends over half the globe of the eye.

The diſtinction between the cornea and the ſclerotic, which is generally but an apparent change of ſtructure, is very clearly to be traced in ſome of the large animals, in which theſe two coats can be ſeparated. In the *whales* and the *rhinoceros*, the attachment of the ſclerotica to the cornea is by the fibres of the former paſſing into the latter. In the *ox*, &c. the line of ſeparation can be ſeen to be oblique, the cornea paſſing a little under the edge of the ſclerotic. In the *hare* and others, the edge of the ſclerotica is double, and embraces on both ſides the margin of the cornea.

The *tunica conjunctiva* is, eſpecially in the large quadrupeds, leſs adherent to the eye-ball than in man. Mr. Pierce Smith has profeſſed to trace not only the conjunctiva, but the expanſion of the ſtraight muſcles over the cornea. The plaineſt evidence of the continuation of the conjunctiva over the front of the cornea is found in the *zemni rat* (*mus typhlus*), which has the conjunctiva retaining the ſtructure of the true ſkin, and even covered with hair, ſo that the eye is altogether uſeleſs, or at moſt can faintly diſcern the difference between light and darkneſs. The eye of this animal is ſaid to be not larger than a poppy ſeed. In the *mole*, alſo, the eye is extremely minute, and ſo much ſhut in by the hair on the eyelids, that it does not appear to be capable of ſeeing any object diſtinctly: indeed the eyes of the *mole* are ſo much concealed, that they are ſuppoſed by common people to be wanting altogether.

In the *whale* and the large quadrupeds, the diſtinction of the two layers of the *choroid coat* is very perceptible. The internal layer, or *membrana Ruyſchiana*, is particularly plain in the *whale*.

Mr. Thomas has diſcovered a moſt curious apparatus connected with the choroides in the *Eaſt Indian rhinoceros*. Four tendinous proceſſes ariſe from the back part of the ſclerotic coat, expand anteriorly, and form a ſpecies of muſcular membrane, which is loſt in the choroides at the broadeſt diameter of the eye-ball. It is eaſy to conceive that this ſtructure can produce material alterations in the figure of the eye, and in the diſtance of the cryſtalline lens from the retina, but we cannot conceive why ſo great a power of adjuſtment in the eye to different diſtances ſhould belong excluſively to this animal.

The *pigment* of the internal ſurface of the membrana Ruyſchiana is of various colours in mammalia, particularly on the back of the eye. The *monkey* has it dark coloured. The *hare*, *rabbit*, and *hog*, have it a brown: but in many other mammalia the pigment upon the back of the eye has light and vivid colours. It is called, in theſe caſes, the *tapetum lucidum*. The *ox* has the back of the eye a green, which is loſt in an azure blue. In the *ſheep* it is a pale yellow-green, or ſometimes blueiſh. Some anatomiſts, who ſeem to have confined theſe obſervations to thoſe two caſes, have conjectured that the uſe of the tapetum is to reflect the natural colour of the animal's food. But the abſurdity of this opinion is ſhewn by the varieties of the colour of the back of the eye in other animals.

The tapetum is a ſilvery blue, changing to violet in the *horſe*, *goat*, *buffalo*, and *ſtag*. It is a pale golden yellow in the *lion*, *cat*, *bear*, and *dolphin*. It is a pure white, terminating in blue, in the *dog*, *wolf*, and *badger*.

The ſhape of the coloured portion of the Ruyſchian coat is irregular, and is ſituated chiefly upon the temporal ſide of the entrance of the optic nerve: but in the *whales* the whole of the Ruyſchiana is a ſilver colour; the ciliary proceſſes and back of the iris alone being dark. The uſe of the tapetum is not very obvious. The moſt probable opinion reſpecting it is, that it enables animals to ſee better in the dark.

The *ciliary proceſſes* do not appear to differ in their ſtructure in this claſs and in the human ſubject. It is true they are very prominent in the large ſpecies, and the denticulation of their edges is ſo much increaſed, as to form a rich fringed appearance, particularly in the *rhinoceros* and *whale*. The laminæ of theſe proceſſes are long and narrow in the *cat* kind, more eſpecially in the *lion*.

Mammalia have the *iris* uſually of a more uniform colour than in man. In *domeſtic* quadrupeds, however, there is conſiderable variety in this reſpect. The colour of the iris correſponds ſo much with that of the hair, that in *ſpotted dogs*, &c. the iris is often of a mixed colour.

In the large mammalia the iris is of conſiderable thickneſs, but no difference of ſtructure has been perceived.

The *uvea* is found much more plain in the *ox*, *rhinoceros*, and *whale*, &c. than in man, and the ſtriæ that are continued upon the uvea from the ciliary proceſſes, are very diſtinct in theſe ſpecies. They extend in the *rhinoceros* nearly to the edge of the pupil.

The *pupil* of the eye has various forms in ſome mammalia.

It is in the *cat* kind a vertical ſlit, over which theſe animals have great command, ſometimes contracting it to a mere line, and at others dilating it to nearly a round figure. In the *cloven-hoofed* order, the pupil is a tranſverſe ſlit, with the ends of the ſlit wider than the middle. In the *horſe* it is alſo tranſverſe, but the ſuperior edge projects a little way. This has been compared to the curtain that hangs over the pupil in the *ſkate* by Swammerdam, although there is but little reſemblance between the two parts.

It is a tranſverſe oblong aperture in the true *whales*, and in the genus *delphinus* it is a heart ſhape.

The *retina* is formed uſually in the ſame manner in mammalia as in man. It ſometimes happens that the *optic nerve*, immediately on entering the cavity of the eye, forms a ſlight projection. In the *hare* and *rabbit*, this projection is deſcribed as producing a kind of oval cupola, which is ſlightly concave in the middle. The retina ariſes from the edge of it. The fibres of the nerve are condenſed on each ſide into two ſtreaks or pencils, which are a more opaque white than the other parts of the retina. In almoſt all mammalia the retina has at its origin the appearance of its ſubſtance being collected into folds, or fibres, which ariſe in a radiated manner.

Comparetti ſtates, that the optic nerve of the *bat* perforates the ſclerotic coat by a number of foramina. The filaments, thus formed, unite to produce the retina.

The *foramen* of the retina, which uſually takes the name of Sömmerring, has not been found in any of this claſs, except the *monkey* tribe. Cuvier ſtates, that he found it in the *cynocephalus* conſiderably larger than in man, and of an oval ſhape.

It is ſingular, that although this foramen does not exiſt in the *lemur*, yet the fold which contains it in man and the *monkey* is found. The uſes of the foramen of Sömmerring are not yet determined. Mr. Home imagined that it gave exit to an abſorbent veſſel; but it is much more probable that its exiſtence is connected with the poſition of the eyes, as it is only met with in thoſe that have the eyes placed ſo that their axes are parallel. Blumenbach obferves, upon this fubject, that when the two eyes are fituated, as in man and the *monkey*, they are liable to be both dazzled at the fame time, by an expofure to a ftrong light, as the rays fall upon the correfponding principal focufes of both eyes at once. He concludes, that the foramen of Sömmerring being in the principal focus, the rays pafs through it, and are fuffocated in the pigment of the choroid coat. But to produce fuch an effect, without weakening vifion at all times, would require a mufcular power to open and fhut the foramen according to circumftances, nothing of which kind appears to be provided.

The *aqueous humour* of the eye would appear to be in lefs quantity, according to the bulk of the organ in mammalia, than in man.

The *cryftalline*, on the contrary, occupies lefs fpace in proportion to the other parts in man than any of the mammalia. It is alfo more of a fpherical figure in all this clafs than it is in the human fubject. Blumenbach ftates, that he found the cryftalline to be largeft in relation to the vitreous humour in the *Virginian opoffum*. We felect the following inftances from a table founded on the obfervations of Petit and Cuvier, to fhew that there is a fcale, from man to the *cetacea*, with refpect to the form of the cryftalline, by which it will be found, that the lens is leaft fpherical in the human fubject, and moft fo in the aquatic mammalia.

The axis of the cryftalline is to the tranfverfe diameter,

In *Man*, as	-	-	1 to 2 generally.
Monkey	-	-	the fame.
Ox -	-	-	5 to 8
Horfe -	-	-	2 : 3
Dog -	-		7 : 9
Hare -			4 : 5
Otter -	-	-	4 : 5
Porpoife	-	-	9 : 10
Whale -	-	-	13 : 15

In the *cetacea*, therefore, the lens is nearly a perfect fphere, as in fifhes.

The *vitreous humour* of man is more abundant, in proportion, than that of mammalia. Thus, the human vitreous humour is twenty times larger than the aqueous, while, in the *ox*, it is only ten times as large, and in the *fheep* but nine times the fize of the aqueous humour.

The *oblique mufcles* of the eye-ball do not differ from thofe of the human fubject; but the *ftraight mufcles* are more numerous, except in the *monkey* kind. In many there is but one additional mufcle, which enclofes the back of the eye and the optic nerve, as if in a funnel. It arifes, like the other recti mufcles, from around the optic foramen, and is inferted into the fclerotic behind them. This mufcle is called the *fufpenfory*, *choanoid*, or *retractor* of the eye.

The fufpenfory mufcle is divided into four flips, or, as fome might ftate it, there are four additional ftraight mufcles in moft of the carnivorous mammalia, and the *cetacea*.

In the *rhinoceros* there are only two portions correfponding to the fufpenfory mufcles.

In all mammalia, we find the four recti mufcles as in man, independently of the fufpenfory above-mentioned.

The *third eye-lid* is confiderably developed in many quadrupeds. It is ufually femi-lunar in its figure. In the *hare*, *rats*, *agouti*, &c. its free edge is convex. In many cafes, it contains a thin cartilage, which, from a fuppofed refemblance to a nail, is called *unguis*. This cartilaginous plate is broad and triangular in the third eye-lid of the *hare*. There is almoft always a row of pores upon this eye-lid, which difcharge an unctuous fluid. The third eye-lid is large in the *cat* genus, the *opoffum*, the *feal*, and particularly fo in the *elephant*.

There is no trace of the third eye-lid in the *cetacea*, and the two ufual eye-lids are fo much thickened by the adipofe fubftance, that they have fcarcely any motion. They feem half clofed, but, we believe, are never completely fhut, the conftant refidence of thefe animals in water not making it neceffary.

The *lacrymal gland* exifts in mammalia, except the *cetacea*.

In the *hare* and *rabbit* it is extremely large. It nearly encompaffes the eye, and even paffes out of the orbit on the fide of the nofe. Cuvier thinks it has but one excretory duct.

The lacrymal gland in the *cloven-hoofed* quadrupeds is divided into two or three maffes. Some feparate grains have each a very fhort excretory duct.

The *puncta lacrymalia*, and the *nafal duct*, for carrying off the tears, have been obferved in the *bifulca*, *hog*, *floth*, and *ant-eaters*, &c. and probably are to be found generally. Camper, however, denies the *puncta lacrymalia*, *lacrymal fac*, and even the *os unguis* to the *elephant*. Some anatomifts have confidered cells below the internal angle of the eye in the *deer* and *antilope* genera as receptacles for the tears; but thefe foffæ, as already mentioned, in defcribing the excretory glands, have no connection with the lacrymal paffages and contain an unctuous matter.

In the *hare* and *rabbit*, the puncta lacrymalia are fupplied by a femi-lunar fiffure, which is placed under the inferior edge of the third eye. The border of this flit is provided with cartilages to keep it open. There is a fingle lacrymal duct, and a fmall valve in the canal, to prevent the tears returning upon the eye. There is no apparatus for the fecretion of tears in the *cetacea*. Thus, conftant refidence in the water is fufficient to keep their eyes moift.

In many mammalia there is an additional gland to the eye, which, from an anatomift that defcribed it, has been called *glandula Harderi*. It is placed near the inner angle of the eye-lids, and difcharges its fecretion, which is a thick unctuous fluid, through an opening under the third eye-lid. The glandula Harderi confifts of fmall lobes, and refembles very much the true lacrymal gland in its ftructure. There would feem to be two glands of this defcription in the *hare*, one is a white colour, the other red; but both apparently have the fame ftructure. They are connected by cellular fubftance. This gland is large and double in the *water rat*. It is fingle, oblong, and hard in its texture in the *cloven-hoofed* quadrupeds. It has been found oval in many others. There are fome fetaceous follicles under the upper eye-lid of *cetaceous* mammalia, which probably fulfil the fame purpofes as the glandula Harderi.

In *Plate* XIV. of the *Anatomy of Mammalia*, *fig.* 1. exhibits a fection of the eye of the *feal*, in the direction of the optic nerve: *a* is the anterior part of the fclerotic coat, which is thick; *b*, the pofterior part, ftill thicker; *c*, the middle portion, which is thin; *d*, the cornea; *e*, the optic nerve; *f*, the vitreous humour; *g* is the cryftalline lens, which is feen to approach the figure of a true fphere. *Fig.* 2. reprefents a fimilar fection of the eye in the *grampus*: *a* is the optic nerve paffing in the canal formed in the fclerotic coat at *b b*. That coat is alfo fhewn to derive its white fibres from the fheath of the optic nerve; *c*, the cornea; *d*, the ciliary proceffes; *e*, the membrana Ruyfchiana; *f*, the choroides. Its two layers are a little feparated, to fhew them more diftinctly. *Fig.* 3. is a view of the interior of the front of the eye in the *ox*, produced by the vertical fection of the organ: *a*, the divided coats; *b*, *b*, the fringed ciliary proceffes; *c*, *c*, the ftriæ of the uvea; *d*, the tranf-

verfe

verſe pupil. *Fig.* 4. is the front of the eye in the *cat*, with the cornea removed, to ſhew the vertical ſlit produced by the pupil in this genus. *Fig.* 5. is a ſimilar preparation of the eye of the *porpoiſe*, to ſhew the figure of its pupil. *Fig.* 6. is a view of the eye-lids in the *hare*, with the aperture into the lacrymal duct: *a*, *b*, the upper and lower eye-lids; *c*, the third eye-lid; *d*, the fiſſure correſponding to the puncta lacrymalia. *Fig.* 7. exhibits the glands of the eye in the *hare*: *a* is the lacrymal gland; *b*, the white glandula Harderi; *c*, is the red-coloured one.

Weapons and Organs of Defence.—There is no animal ſo unprovided with the natural means of protection or defence as man. His ſtrength and his ſecurity depend upon the ſocial inſtitutions eſtabliſhed by his ſpecies. It is true many of the mammalia are not furniſhed with natural arms, but in place of them, they are endowed with great ſwiftneſs of foot, and an acute ſenſe of hearing, as may be obſerved in almoſt all the *ſaltigrade* quadrupeds, and others which are purſued by the beaſts of prey. Some fugitive animals ſeek ſecurity in concealment, as the *digging* and *diving* quadrupeds, for example the *mole*, the *duck-billed* animal, &c.

The various coverings of mammalia, ſuch as *hair*, *hoofs*, *ſcales*, *ſpines*, &c. not only ſerve to ſhelter quadrupeds from the inclemency of the weather, but from the attacks of hoſtile animals. The ſtrong tough hair of the *ant-eaters* and *ſloth*, the ſcales of the *pangolin*, the ſpines of the *hedgehog* and *porcupine*, and, moſt of all, the bands of the *armadillo*, are well calculated for this purpoſe.

Thoſe quadrupeds that have defenſive integuments, have generally the power of rolling themſelves up, ſo as to conceal the head, feet, and under parts of the body, which are commonly unarmed. The muſcles that are deſigned for the contraction of the body, are deſcribed with the other organs of motion.

The moſt powerful weapons of mammalia are their horns, their teeth, and the hard ſubſtances with which their toes are armed. The ſtructure and growth of each of theſe parts are deſcribed in their proper place.

The horns are generally employed as the means of *defence*, and chiefly belong to quadrupeds that are gregarious and inoffenſive, unleſs much irritated, or during thoſe periods in which they are under the excitation of the ſexual or parental inſtincts.

The teeth are the weapons moſt commonly employed by animals; almoſt every quadruped may be provoked to make uſe of them; even man himſelf, in thoſe ſtates of ſociety where rules of combat are not acknowledged, always reſorts to his teeth, when preſſed by an adverſary. As the teeth are the moſt general weapons of animals, they are alſo the moſt deſtructive in the operation; when any animal kills another, it is moſt commonly by means of its teeth. The large teeth called *tuſks*, although generally incapable of being employed in any other way than as weapons, are leſs dangerous than the ſmall front teeth of many animals. Some tuſks, although ſo formidable in their appearance, are very harmleſs in fact. The tuſks of the *babirouſſa* are ſo much turned backward, that they cannot inflict a wound, and thoſe of the *elephant* and *mammoth* ſeem incapable of injuring a ſmall animal. The tuſks of the *narwhal* are ſaid to be terrible weapons, which their direction, length, and pointed figure render very probable; there being alſo ſo frequently one of them wanting, it is likely that it may have been loſt in combat.

The feet of quadrupeds are amongſt their moſt effectual weapons when they are furniſhed with claws, as in moſt of the beaſts of prey. The ſtrength of the limbs in all predaceous quadrupeds has already been remarked. The mechaniſm of their feet, by which the claws are inverted by the very act of graſping any object, is ſingularly uſeful to thoſe animals.

Some of the mammalia poſſeſs a great ſecurity from the aſſaults of others, in certain excretions produced by peculiar glands, ſituated commonly in the neighbourhood of the anus. Theſe excretions have a diſagreeable ſmell, which is probably particularly offenſive to thoſe animals they are intended to repel. Some of the American ſpecies of *viverra* are ſaid to occaſion ſo ſtrong a fœtor by the expulſion of the contents of their anal glands, that it is diſcerned at the diſtance of two miles, and cannot be immediately approached by any perſon without the greateſt danger. The organs which furniſh theſe fœtid matters are deſcribed along with other *excretory* glands.

Organs of Voice.—The *monkey* tribe, which have in moſt parts of their anatomy ſo ſtrong a likeneſs to the human body, have many ſtriking and important peculiarities in the organs of voice, ſome of which are even poſſeſſed by the *ourang-outang*.

This animal has the *arytenoid cartilages* ſmaller, and the *cuneiform* ones larger than in man. The *cordæ vocales* are looſe and ſharp upon the edge. The ventricles of the glottis are large oval cavities, and partially divided by a partition. The ſuperior part of each ventricle leads into a hole, which is ſituated between the thyroid cartilage and the os hyoides, and is the opening of a large membranous ſac. Theſe two ſacs lie under the ſkin of the throat, and are in contact with each other, and deſcend towards the cheſt. Theſe ſacs, in ſome individuals, are of different ſizes according to Camper's obſervations. Blumenbach found the right ſac three inches long and two inches round, and the left only the bulk of a nutmeg in the *pigmy ape* (*ſimia ſylvanus.*)

In many other *monkies* there is one large pouch or membranous ſac, which communicates with the glottis. This ſac has been deſcribed by Camper in the *Barbary ape* (*ſimia inuus*), and the *common baboon* (*ſimia ſphinx*). The opening from the glottis in theſe caſes is in the middle, at the root of the epiglottis, immediately above the thyroid cartilage. Vic d'Azir alſo diſcovered the ſame kind of ſac in the *ribbed-noſe ape* (*ſimia maimon*), in which it is very large, and has a round opening under the epiglottis. Cuvier found a ſimilar laryngeal ſac in the *hare-lipped ape* (*ſimia cynomolgus*), and a very large one in the *ſimia veter*. It has been deſcribed in the *varied ape* (*ſimia mona*); but Cuvier denies there being any appearance of it in this ſpecies, and even of the hole or depreſſion at the baſe of the epiglottis, which exiſts in ſome *monkies* that do not poſſeſs a laryngeal ſac, as in the *great baboon* (*ſimia hamadryas*), the *red ape* (*ſimia rubra*), and the *Chineſe ape* (*ſimia ſinica*).

In the *ſilky monkey* (*ſimia marikina*), the laryngeal ſac has its opening between the cricoid and thyroid cartilages.

The *howling baboon* (*ſimia beelzebul*), and the *ſimia ſeniculus*, have the laryngeal ſacs incloſed in a bony caſe, which is hollowed out in the os hyoides. Camper deſcribed but one ſac, which he ſtated to communicate with the larynx by an aperture between the os hyoides and the thyroid cartilage. Vic d'Azir alſo found but one ſac, which he deſcribed as being of an irregular pyramidal figure, ſituated under the tongue between the two branches of the lower jaw, with its pointed part forwards, and divided interiorly by ſeveral thin projections of bone. It had a wide opening poſteriorly, above which was placed a bony plate, with two projections at its two extremities. The opening of of the fac communicated with a large, firm, membranous tube, which proceeding horizontally backwards, terminated in the larynx between the alæ of the thyroid cartilage, fo as to form a communication with both the ventricles of the glottis. The thyroid cartilage was remarkably large, and projected downwards: from its cornu on each fide there paffed a ligament to the two projections of the bony fac. The thyroid cartilage had a projection where it terminated, which feemed to divide the canal leading from the bony fac into two channels: fuch is the defcription given by Vic d'Azir of the organ of voice in the *howling baboon*. Cuvier, however, ftates, that in the *fimia feniculus* each ventricle leads into a membranous fac, which glides between the epiglottis and contiguous ala of the thyroid cartilage, and proceeds towards the os hyoides. In the individual which he diffected, the right fac alone occupied almoft the whole of the cavity in the os hyoides; the left terminated at the moment when it was to enter that bone: but he conceives, that in other individuals, the facs were of equal fize, or that the left might even be the larger of the two.

The effect of all thefe cavities connected with the larynx is to increafe the refonance of the voice. The cartilaginous frame of the larynx and trachea in all animals has the fame operation in a greater or lefs degree; for if the cordæ vocales could only occafion the parts immediately adjoining them to vibrate, the found which they would produce would fcarcely be audible. The power of hollow parts in multiplying found, or rendering it loud by a fecondary vibration, is ftrikingly exemplified in the difference obferved between the *common* and the *mute fiddle*. The body of the latter is a narrow folid piece of wood, and although the tones are the fame as thofe of the common fiddle, they are fo faint as fcarcely to be heard. The influence of the laryngeal cavities upon the voice is clearly fhewn in thofe animals which poffefs them. The *howling baboons*, that have the beft contrived apparatus for increafing the voice, are faid to utter a cry which is really terrific.

One fpecies of *monkey*, the *fimia panifcus*, has a different kind of dilatation than is found in the reft of this tribe. It is a very confiderable enlargement of the membranous part of the trachea immediately behind the cricoid cartilage. The mufcles which go from the larynx to the pharynx comprefs this fac, and urge the air it contains in a ftronger current through the parts that immediately produce the voice.

Cuvier defcribes in this monkey, and in all thofe of the continent of America, a peculiarity in the ftructure of their larynx, by which their voice is rendered foft, like the tone of a flute, and they are therefore called *whiftling monkies*. This peculiarity confifts in the fmallnefs of the arytenoid cartilages, and the great bulk of the cuneiform cartilages, which, increafed by fome fat cellular fubftance, form before the fuperior extremity of the ventricle of the glottis a large cufhion, having the figure of a fegment of a fphere on each fide. It follows from this ftructure, that the air which has vibrated in the ventricles has to go through a narrow canal, curved in the figure of an S, which is formed by the oppofition of thefe cufhions and the concavity of the epiglottis.

In the *fimia jacchus*, and the *fimia midas*, the cuneiform cartilages are fo large, that their fuperior projection even divides the upper part of the glottis into two, fo as to give it apparently a refemblance to the larynx of birds.

The os hyoides is large and round on the front, even in thofe *monkies* which do not poffefs laryngeal facs, as in the *fimia apella* and the *fimia capucina*.

In the *lemur*, the fuperior ligaments of the glottis are very prominent, and there are between them and the epiglottis depreffions, which might be confidered perhaps as fuperior cordæ vocales and ventricles.

The epiglottis of the *bats* is foft and hardly perceptible. Its exiftence has been denied by Vic d'Azir. The cordæ vocales alfo are very indiftinct. In the *vampyre bat*, there is a flight membranous projection in place of epiglottis.

In the *dog* genus the cordæ vocales are prominent, thin, and free; the ventricles are deep; and the membrane which lines them is wider than they are. The cuneiform cartilages have the fhape of an italic *S*. The loofenefs of the cordæ vocales and the membrane of the ventricles, no doubt tends to produce the *barking* voice of thefe quadrupeds.

In the *cat* genus, the anterior ligaments of the glottis are, as in the *dog*, contiguous to the internal parietes of the epiglottis, but are feparated by a wide deep groove on each fide. The pofterior ligaments, or *cordæ vocales*, are not loofe or fharp. There are two fmall thin membranes near them, which, when they vibrate, produce the *purring* found of the *cat's* voice. Cuvier thinks, that the anterior ligaments of the epiglottis conftitute the cordæ vocales of the *cat*, the ventricles being fo very fhallow.

The *ichneumon* and *civet* have the organs of voice fimilar to thofe of the *cat* genus.

In the *badger*, the ventricle is open, and leads into two pouches, one of which extends forwards under the root of the tongue, where it is only feparated from that of the oppofite fide by the hyo-epiglottidei mufcles; the other goes backwards between the thyroid and cricoid cartilages. The found of the voice in this animal appears to be occafioned by the vibration of the breath againft the pofterior edge of the anterior ligament, when it is driven with force into thefe two pouches. There are fimilar pouches in the *weafel*, but the anterior has lefs extent.

The *marfupial* animals have the larynx peculiarly formed.

In the *kanguroo* the arytenoid cartilages are very large, Their fuperior edge forms the two-thirds of that of the glottis. The cuneiform cartilages, the anterior ligaments, and the ventricles of the glottis, do not exift in this animal, and it can fcarcely be faid that there is even any pofterior ligament or cordæ vocales. Cuvier is difpofed to think that the *kanguroo* is very nearly mute.

The *American opoffum* has alfo the arytenoid cartilages of great fize, and the thyroid cartilage concave. The fuperior ligament of the glottis is wanting, as in the *kanguroo*. The cordæ vocales are very fmall, and fcarcely to be diftinguifhed from the furrounding membrane. There is an oval epiglottis, with two little folds of membrane at its root, which are fufceptible of vibration.

The *long-tailed phalangers of Cook* have a membrane, which ferves at once for a vocal ligament and the edge of the glottis; between which, and the cricoid cartilage, there is a groove which might be confidered as a ventricle in an unufual fituation. This ventricle has alfo been obferved in the glottis of the *ornithorhynchus*, in which animal it is very deep. Both the *ornithorhynchus* and *echidna* have the edge of the glottis formed by the arytenoid cartilage, and a fingle vocal ligament. There is no ventricle in the glottis of the *echidna*.

In the *didelphis orientalis* there is no diftinct ligament, and the epiglottis is deeply notched.

In the *faltigrade* mammalia, Cuvier has defcribed two different kinds of ftructure in the organs of voice. In the one, of which he gives the *porcupine* as an inftance, the cordæ vocales and ventricles are not found, or fcarcely difcernible: in the other, which feems to belong to the great majority of the

the order, the vocal ligaments are diſtinct, and the ventricles often deep. The glottis in the *hare* and *rabbit* is peculiar. It wants the ſuperior ligament, and the cuneiform cartilages: nevertheleſs, the arytenoid cartilages are pyramidal, and afford attachment to two cordæ vocales, which are very free and thin edged, and are ſeparated from the baſe of the epiglottis by a deep narrow groove. Between their commiſſure, at the baſe of the epiglottis, there are two little cartilaginous tubercles projecting inwards. They do not give any attachment to the anterior extremities of the vocal ligaments, which are fixed externally to them.

Amongſt the *edentata*, Cuvier deſcribes the organs of voice as differing in each genus. In the *Cape ant-eater* (*oryctleropus*), the cordæ vocales form the edge of the glottis; there is but a ſlight groove in place of the ventricle. In the *armadillo* the larynx is ſmooth internally, and the epiglottis is in two lobes.

The *tardigrade* quadrupeds have a ſingularly formed larynx. The free edges of the cordæ vocales are the inferior ones; they hang down againſt the inner ſide of the cricoid cartilage, like triangular valves. There are no ventricles or anterior ligaments.

Amongſt the *many-hoofed tribe* of quadrupeds, the *elephant* has a ſimply formed larynx. The inferior ligaments of the glottis or cordæ vocales are prominent, and ſharp edged. They aſcend in proceeding to their anterior attachment much more than is uſual. The ventricles are mere grooves.

In the *pig*, the direction of the cordæ vocales is peculiar: they deſcend anteriorly. They are long and ſharp edged, and capable of being rendered extremely tenſe by the actions of the larynx, which enable this animal to utter the ſhrill cry it is ſo remarkable for. The ventricle opens poſteriorly into an oblong ſinus, that aſcends between the internal membrane and the thyroid cartilage. The magnitude of this ſinus has been over-rated by ſome anatomiſts. Its real ſize, according to Cuvier's obſervations and our own, is about ſufficient to admit the end of the little finger. It is this cavity which enables the *pig* to produce the *grunting* ſound, the cordæ vocales being at the ſame time in the relaxed ſtate.

In the *cloven-hoofed* quadrupeds, a ſuperior angle of the arytenoid cartilages bends backwards, and makes the two-thirds of the end of the glottis; and an inferior angle of the arytenoid bends forwards, and gives attachment to the cordæ vocales. This laſt has the anterior part more or leſs free, ſharp, and thin, according to the ſpecies, but its poſterior edge is blunt, and continued into the membrane lining the reſt of the glottis. The anterior ligaments are not found, and the place of the ventricle is ſupplied by the furrow ariſing from the projection of the cordæ vocales. There are no cuneiform cartilages in this tribe. The thyroid cartilage ſwells out anteriorly, where the cordæ vocales are attached in the *fallow deer*, and ſtill more in the *cervine antilope*, in which the projection is nearly pyramidal. The ſwelling under the throat in the *antilope gutturoſa*, is occaſioned by this enlargement of the thyroid cartilage.

There is a membranous ſac in the front of the thyroid cartilage in ſeveral of the *antilope* genus and the *rein deer*. The opening into it is at the root of the epiglottis. The ſac of the *rein deer* is very large, extending under the neck, as in the *mandril* (*ſimia maimon*.)

Cuvier has given a full deſcription of the organs of voice in the *ſolid-hoofed* quadrupeds, in which he has corrected many errors in the account of the larynx of the *horſe* and *aſs* by Heriſſant. The chief peculiarities of the vocal organs of theſe animals, conſiſt in the ſacs connected with the larynx. There are three of theſe: one is ſituated anteriorly, under the vault formed by the anterior boundary of the thyroid cartilage: the opening into it is under the root of the epiglottis. The two others are oblong ſinuſes contained between the lateral parietes of the glottis and the thyroid cartilage, and covered, in a great meaſure, by the thyro-arytenoidei muſcles, by which they are compreſſed. There is no anterior ligament of the glottis, nor any ventricle, properly ſpeaking; but above the cordæ vocales, on each ſide, there is a foramen which leads into the lateral ſac.

In the *horſe* the apertures of the lateral ſacs are long and wide, and bear ſome reſemblance to the uſual ventricles of the glottis. The opening into the anterior cavity is very wide in the *horſe*, in which alſo this cavity is a ſhallow depreſſion. On the contrary, in the *aſs*, the opening into each of the three ſacs is a ſmall and round hole, and the anterior ſac is a real bag of conſiderable ſize.

Cuvier ſtates that the *mule*, which is generated by the *male aſs* and the *mare*, has the openings into the laryngeal ſacs wide, and the ſtructure of the organs of voice altogether approaching that found in the *horſe*, and he concludes that the account publiſhed by Heriſſant was taken from the diſſection of the offspring of the *ſtallion* and the *female aſs*. Blumenbach has, however, followed many other anatomiſts in attributing ſimilar organs of voice to the *common mule* and the *aſs*. We are not enabled to decide the point, not having diſſected theſe organs in the *mule*.

Cuvier further adds, that in the *horſe* and the *mule* there is at the commiſſure of the two cordæ vocales a ſlight fold of the membrane, which is not viſible in the *aſs*. The ſize of this fold has been greatly exaggerated by Heriſſant; he has alſo attributed to it important offices which it does not ſeem to perform.

The peculiar ſound called a *bray*, is uttered by the *aſs* in conſequence of the extent of the laryngeal ſacs, and their being ſo much ſeparated from the cavity of the larynx, by thus having ſmall apertures. The *bray* ſeems to be a compound diſcordant ſound, produced from the reſonance of different ſized cavities.

Cuvier found in the *couagga* the larynx organized as in the *horſe*, except that the membrane extending from one corda vocalis to the other did not exiſt.

The larynx is very peculiarly formed in the *cetacea*. The arytenoid cartilages and the epiglottis have the figure of very elongated triangles. Theſe three cartilages are united to each other by the membrane of the glottis, and have a degree and kind of motion ſomewhat ſimilar to that of the parts about the mouth of a fiſh. The top of the larynx, which is compoſed of theſe three cartilages, has a pyramidal figure, and is inſerted into the common origin of the poſterior nares. It is retained in that ſituation by the circular muſcles of the fleſhy tube which forms the common paſſage to the nares. The uſual office of the epiglottis is, therefore, loſt in *cetacea*, and inſtead of making an operculum to the rima of the glottis, it enters into the compoſition of that aperture, which is thence rendered wideſt in the tranſverſe direction, and reſembles very much, in appearance, the mouth of a fiſh. The advantage of having the air-tube immediately connected with the naſal paſſages in the *whale* kind, muſt be obvious. Theſe animals catch their prey by ſwimming with their mouths open, and below the ſurface of the ſea, at which times, the water and ſmall fiſh are carried through the fauces on each ſide of the pyramid formed by the larynx. When, however, the latter is withdrawn from the poſterior nares, in order to eject the water through the ſpiracles, the rima glottidis is ſhut; but rather by the edges being cloſely applied to each other, than by being covered by the epiglottis.

The

The interior part of the larynx in *cetacea*, exhibits no true cordæ vocales or ventricles. The membrane, at the anterior part of the cavity, forms ſome very irregular folds, or rather a corded appearance, reſembling, in a degree, the internal ſurfaces of the heart. Cuvier ſays, he only perceived ſome longitudinal rugæ. The inequalities on the interior part of the larynx, in theſe animals, do not, however, appear capable of vibrating ſufficiently to produce any voice; or if the *whale tribe* do utter any ſound, it muſt, we conceive, be a kind of *hiſs*, occaſioned by the forcible emiſſion of the air through the aperture of the glottis.

In *Plates* XIV. and XV. of the *Anatomy of Mammalia*, the figures are found which illuſtrate the ſtructure of the organs of voice.

In *Plate* XIV. *fig.* 8 repreſents the entire larynx and ſac of the *mandril* (*ſimia maimon*), as it appears when diſſected out: *a*, the root of the tongue left with the larynx; *b*, the os hyoides; *c* is the laryngeal ſac diſtended with air; *d*, the trachea ſeen beyond it. *Fig.* 9, of the ſame plate, ſhews the larynx opened from behind; and the hole which leads into the laryngeal ſac, as it uſually appears in thoſe monkies that have theſe dilatations connected with the organ of voice: *a*, the epiglottis; *b*, the foramen at its baſe, opening into the laryngeal ſac, which has been cut off in this preparation; *c*, *c*, the cordæ vocales; *d*, *d*, the two ventricles.

In *Plate* XV. *fig.* 1 is a view of the larynx, and bony ſac attached to it, divided longitudinally to ſhew their internal formation in the *howling baboon*. This figure is copied from one of Vic d'Azir's, and of courſe agrees with his deſcription of the organs of voice in this animal: *a* is the tongue, divided lengthwiſe through its middle; *b*, *e*, pharynx and œſophagus laid open; *c*, the ligament between the bony ſac and the thyroid cartilage; *q*, *s*, *o*, *p*, *t*, larynx and trachea laid open; *d*, epiglottis; *f g h*, bony ſac laid open; *i k l*, the courſe of the tube leading from the ſac to the larynx; *m*, a projection of the thyroid cartilage dividing the tube into two; *p*, the corda vocalis of that ſide; *o*, the ventricle of the glottis. *Fig.* 2 exhibits a view of the larynx, ſimilar to the laſt, in the *ſimia paniſcus*: *a*, the tongue; *b*, the epiglottis; *c*, the thyroid cartilage; *d*, the arytenoid cartilage; *f*, the ventricle of the glottis; *g g*, cricoid cartilage; *h*, the ſac, which in this animal is placed at the membranous part of the beginning of the trachea: it is laid open. *Fig.* 3 repreſents the interior of the larynx in the *cat*: *a*, the epiglottis; *b*, *b*, the cordæ vocales; *c*, *c*, the two membranes, which are thought to produce, by their vibration, the *purring* ſound made by this animal. *Fig.* 4 ſhews the internal parts in the larynx of the *pig*: *a*, *a*, the ligaments of the glottis ſeen deſcending towards the thyroid cartilage; *b*, *b*, the ventricles; *c*, *c*, their opening into the ſinuſes connected with them. *Fig.* 5 is the larynx of the *porpoiſe* laid open behind: *a*, the epiglottis; *b*, *b*, the arytenoid cartilages; *c*, the wrinkled or corded appearance, which ſeems to correſpond with the cordæ vocales and ventricles of other mammalia. *Fig.* 6 gives a view of the interior of the larynx in the *horſe*, to ſhew the opening into the three laryngeal ſacs: *a*, the aperture of the anterior ſac; *b*, *b*, the openings of the lateral cavities; *c*, the tranſverſe membrane found in the *horſe* at the commiſſure of the cordæ vocales. *Fig.* 7 is a lateral view of the larynx and ſacs in the *aſs*, with the parts laid open: *a*, the anterior ſac, which has a conſiderable capacity, although ſo ſmall an opening into the larynx; *b*, the aperture of the lateral ſac on one ſide; *c*, part of the ſac of the other ſide, which is not removed in the diſſection.

MAMMARIA, in *Natural Hiſtory*, a genus of the claſs Vermes, and order Molluſca. The generic character is, body ſmooth; without cirri or rays; aperture ſingle. There are three

Species.

MAMMILLA. In this the body is conic, ventricoſe, white: it is found in the North ſeas.

VARIA. Body ovate, varied with white and purple: inhabits the northern ocean.

GLOBULUS. Body globular, cinereous, and not fixed. Found on the Greenland ſhores, among the roots of fuci. The body is very ſimple, ſoft, ſmooth, gelatinous, with a thin ſkin about the eighth of an inch in diameter.

MAMMARY, in *Anatomy*, an epithet applied to various parts belonging to, or connected with, the breaſt. The internal mammary artery is a branch of the ſubclavian ſituated within the cheſt. (See ARTERY.) There is a vein correſponding to it. The mammary gland is the organ ſecreting the milk. See BREAST.

MAMMEA, in *Botany*, one of Plumier's genera, ſo called from its vernacular appellation in the Weſt Indies, *Mamei*. Linnæus admitted the name, becauſe of its affinity to *mamma*, a breaſt, alluding to the ſhape of the fruit. Schreber and Jacquin place this genus in the claſs *Polygamia*, but we refer it, after Linnæus and Willdenow, to *Polyandria*. Plum. Nov. Gen. 44. t. 4. Linn. Gen. 265. Schreb. 729. Willd. Sp. Pl. v. 2. 1157. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 3. 297. Jacq. Amer. 268. Juſſ. 257. Lamarck. Illuſtr. t. 458.—Claſs and order, *Polyandria Monogynia*. Nat. Ord. *Guttiferæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, cloven into two, roundiſh, concave, leathery, coloured, widely ſpreading, deciduous ſegments. *Cor.* Petals four, roundiſh, concave, widely ſpreading, ſomewhat leathery, longer than the calyx. *Stam.* Filaments numerous, briſtle-ſhaped, erect, very ſhort, inſerted into the receptacle; anthers oblong, obtuſe, erect. *Piſt.* Germen roundiſh, depreſſed; ſtyle cylindrical, erect, longer than the ſtamens, permanent; ſtigma capitate, convex. *Peric.* Fruit ſpherical, fleſhy, of one cell, very large, pointed with a part of the ſtyle, its rind leathery. *Seeds* four, nearly ovate, rough, ſeparated from each other by the pulp.

Eſſ. Ch. Corolla of four petals. Calyx of two leaves. Fruit very large, inferior, with four ſeeds.

Obſ. The flowers of this genus, inſtead of being always perfect, are occaſionally found to be only male ones on the ſame or on a different plant. This was obſerved by Jacquin, and Browne in his hiſtory of Jamaica takes occaſion from this circumſtance to make different ſpecies of ſuch as have perfect, and ſuch as have only male flowers; Swartz alſo obſerves that the former trees are larger and loftier than the latter.

1. M. *americana*. American Mammeé apple. Linn. Sp. Pl. 731. Plum. Ic. t. 170.—A native of Jamaica, Hiſpaniola, and the Caribbee Iſlands. A tall, handſome *tree*, with a thick ſpreading, elegant head. *Branches* quadrangular when young. *Leaves* oppoſite, on ſhort footſtalks, oval, or obovate, entire, blunt, very ſmooth and ſhining, leathery, firm, from five to eight inches in length. *Flower-ſtalks* ſhort, ſcattered over the ſtouter branches, bearing a ſolitary, fragrant, white *flower* an inch and half in diameter. The *calyx* is occaſionally trifid, and the *corolla* five or ſix-petalled. *Fruit* ſlightly angular, generally having one or two abortive ſeeds, from three to ſeven inches in diameter; its rind double, the outer leathery, tough, browniſh; the inner thin, yellow, adhering cloſely to the *pulp* which is firm, bright yellow, of a pleaſant, though ſingular flavour, and a ſweet aromatic ſmell. The *ſkin* and *ſeeds* are bitter

bitter and refinous. Jacquin tells us that the Mammee fruit is eaten raw and alone, or cut into flices with wine and fugar, or preferved in fyrup. In Martinico, the flowers are diftilled with fpirits, making a liquor which is called *Eau Creole*. The French term this plant *Abricot-fauvage*, the yellownefs of its pulp refembling that of an Apricot. Browne informs us that this is one of the largeft trees in Jamaica, that it abounds with a refinous gum, and is efteemed one of the beft timber-trees. From Miller we learn that it rifes to the height of fixty or feventy feet, and that its fruit, which is of a yellowifh-green colour, and highly efteemed, is commonly to be purchafed in the markets of the Spanifh Weft Indies.

This tree having a long downright tap-root, is of courfe very difficult to tranfplant, fo that the beft mode of propagating it is by fetting the ftones or feeds, as frefh as poffible, in pots filled with light earth, and then to plunge them into a hot-bed of bark.

M. *afiatica* of Linnæus Sp. Pl. 731, is now called Barringtonia; fee that article in this work, and in Mart. Mill. Dict. v. 1.

Willdenow defcribes another fpecies which he calls *humilis*, the fruit of which contains only three feeds; but he fays that Vahl takes it to be nothing elfe than *Rheedia lateriflora* of Linnæus.

Mammea, in *Gardening*, contains plants of the evergreen exotic tree kind, of which the fpecies moftly cultivated is, the American mammee, (M. americana.)

Method of Culture.—This tree may be increafed from feeds procured from America, which fhould be fown in the early fpring, in pots filled with light frefh mould, plunging them in a bark hot-bed, keeping the mould moift by occafional watering, when they will foon come up. The young plants fhould be often watered in dry weather. When they have attained fome growth, they fhould be removed, with earth about them, into other pots a little larger, being replaced in the hot-bed, till frefh rooted, filling up the pots with frefh mould; due fhade, air, and water being given. In the autumn they fhould be removed into the ftove, where they muft be kept, being fhifted into other pots in the following fpring; having regard not to over-pot them.

And they may alfo be raifed by placing the ftones of the fruit under the pots upon the tan, more expeditioufly than when planted in the mould of the pots.

Thefe plants afford a fine variety among others of the ftove kind.

MAMMEE Bay, in *Geography*, a bay on the north coaft of the ifland of Jamaica. N. lat. 18° 58′. W. long. 77°.

MAMMILLARIS Processus, in *Anatomy*, the fame as the maftoid procefs. This term, mammillary, has been fometimes applied to the uriniferous fubftance of the kidney. See Kidney.

MAMMOTH'S Teeth, or *Mammout Bones* and *Mammon's Horns*, in *Natural Hiftory*, names given by travellers and other writers to certain foffil teeth, and other bones, found in Ruffia and fome other parts of the world, and that ufually at great depth in the earth. The Ruffians and other people give them this name, fuppofing them to have belonged to an animal, which they defcribe as being of a monftrous fize, and living in caverns under ground. But the true account of them is, that they are in reality the teeth and other bones of an animal now unknown, there being no fuch beaft as thefe people defcribe. The mammoth of America, whofe enormous bones are found particularly near the falt fprings upon the Ohio, though armed with tufks of ivory, has been fuppofed to be even five or fix times larger than the elephant; but the bones are probably the fame with thofe of the fuppofed elephant found in Siberia. In Siberia the bones of the mammoth are thrown afhore from the Frozen ocean; and it is probable that thefe and other fimilar remains may have been driven by currents from very diftant parts of the globe, and depofited on the banks of rivers by the tide, when a great part of the north of Siberia was covered by the fea. The tufks of the mammoth are equal to elephants' teeth in whitenefs and beauty, but very different in their fhape, being all bent fpirally, forming about one round and a half; and eight feet form their greateft length. See Elephant's *Bones*, Ivory, &c.

MAMOOJOO, in *Geography*, a town on the weft coaft of the ifland of Celebes. S. lat. 2° 19′. E. long. 119° 12′.

MAMORA. See Mahmora.

MAMOS, a town of South America, in the audience of Quito; 110 miles E.N.E. of Archidona.

MAMOSA, La, a town of Naples, in Bafilicata; 19 miles S.W. of Turfi.

MAMOUTKAN, a town of Afiatic Turkey, in the province of Caramania; 12 miles S.E. of Erekli.

MAMPATA, in *Botany*, according to Juffieu, is the Senegal name of a tree, gathered there by Adanfon, which the former conceives to be of the fame genus with Aublet's *Parinari*, Aubl. Guian. t. 204—206, the *Petrocarya* of Schreber, though its nut is lefs deeply furrowed, and the ftamens appear to be fifteen inftead of fourteen. The germen, moreover, is laterally attached to the calyx. See Petrocarya and Neou.

MAMTRASNA, in *Geography*, a mountain of Ireland, in the county of Galway; 15 miles S. of Caftlebar.

MAMUD, an ifland in the Sooloo Archipelago. N. lat. 6° 4′. E. long. 121° 42′.

MAMUL, a town of Walachia; 31 miles N.E. of Krajova.

MAMUN, a town of Africa, in the country of Sugulmeffa; 25 miles S.E. of Sugulmeffa.

MAN. To write a complete hiftory of man, it is neceffary that we fhould defcribe both the individual and the fpecies: that we fhould, with reference to the former, relate the phenomena of his firft production, examine his anatomical ftructure, his bodily and intellectual functions, and his difeafes, and purfue his progrefs from the time of birth to the grave: in refpect to the latter, it would be neceffary to point out the circumftances that diftinguifh him from other animals, to delineate the phyfical and moral characters of the people inhabiting the different portions of the globe, and trace their progrefs from the firft rudiments of civil fociety to the ftate at which they are now arrived (See on the latter fubject, Condorcet Tableau du Progrés de l'Efprit humain; Ifelin, Gefchichte der menfchheit; Fergufon's Hiftory of Civil Society; Adelung verfuch einer Gefchichte der Cultur des menfchlichen Gefchlechts, &c.) To treat the fubject in this way would demand a familiar acquaintance with almoft the whole circle of human knowledge, and a combination of the moft oppofite purfuits and talents; of the knowledge of nature poffeffed by a Buffon, a Cuvier, or a Blumenbach; the infight into the operations of the human mind and paffions of a Hume, a Rouffeau, and a Condorcet; and a knowledge of hiftory and antiquities in their moft extenfive fenfe: a cyclopædia would be neceffary, rather than a fingle article. This extenfive labour, which could not be properly executed by any individual, is divided into feveral fubordinate branches. The anatomift and phyfiologift unfold the ftructure and functions of the body; the furgeon and phyfician defcribe its difeafes; and the metaphyfician and moralift employ themfelves with the functions that

that conftitute the mind, and with the moral fentiments. We refer, therefore, to the different articles of the Cyclopædia on thefe fubjects; giving only, what could not be entirely omitted in a view of the hiftory of man, a fhort general fketch of his paffage through the various periods of his exiftence. Man in fociety, his progrefs in the various countries and ages of the world, his multiplication, &c. &c. are the province of the hiftorian and political economift. Our object, in the following article, is the defcription of the fpecies. We fhall fpeak, in the firft place, of the fituations which man occupies on the globe, of his food, intoxicating drinks, dwellings, and drefs: we fhall endeavour to explain the diftinctions, more particularly in bodily ftructure, between man and animals; to defcribe the principal differences between the various races of mankind, and to confider the caufes by which thefe have been accounted for. This, indeed, is rather what our limits and the confined knowledge of an individual reftrain us to, than a difcuffion of all the points which the hiftory of man fhould involve. We think it fhould contain, moreover, a confideration of the original abode and diftribution of the fpecies, of the varieties of intellectual power, and moral difpofitions. The remarkable manners and cuftoms, the employments and pleafures, the notions of decency and elegance, honour and fhame, the religious opinions, forms of government and laws, particularly among uncivilized nations, are very interefting fubjects, when confidered in general, but are not included in the labours of the hiftorian or moralift. The education of children, and treatment of women, in all parts of the world; the various degrees of cultivation; the opinions of favage people concerning the moft important works and phenomena of nature; the origin of the moft neceffary fciences, as arithmetic, meafure of time, and medicine, are not lefs interefting than important topics, which are not confidered at all, as the hiftorian, the geographer, the moralift, and the man of fcience, occupied with other purfuits, confider them, each, as not belonging to his department. Thefe, together with the fubjects of the prefent article, would conftitute a peculiar fcience, or branch of fcience, under the name of the hiftory of man, which, in point of inftruction or entertainment, would not be inferior to the narratives of intrigue and treachery, of war, conqueft, and defolation, that compofe general hiftory.

The natural hiftory of man is yet in its infancy; infomuch, that we cannot pretend to give any thing like a complete view of the fubject. The defcription and arrangement of the various productions of the globe have occupied numerous obfervers in all ages of the world. Every plant and every infect has had its hiftorian, and has been defcribed with minute accuracy, while the human fubject has been comparatively neglected. In a very voluminous work on the hiftory of the animal kingdom, now publifhing in this country, ("General Zoology, or Syftematic Natural Hiftory,") man is entirely omitted. Does the learned author deem him more or lefs than an animal? Whether we invefligate the phyfical or the moral nature of man, we recognife, at every ftep, the limited extent of our knowledge, and are obliged to confefs that ignorance, which a Rouffeau and a Buffon have not been afhamed to avow. "The moft ufeful and the leaft fuccefsfully cultivated of all human knowledge, is that of man; and the infcription on the temple of Delphi contained a more important and difficult precept, than all the books of the moralifts." (Difcours fur l'Inegalité; preface.) The immortal hiftorian of nature gives his teftimony to the fame effect. "Quelque interet que nous ayons a nous connoitre nousmêmes, je ne fais fi nous ne connaiffons pas mieux tout ce qui n'eft pas nous." (De la Nature de l'Homme.) It is only of late, and principally through the excellent writings of Blumenbach, that the natural hiftory of man has begun to receive its due fhare of attention; and we fhall venture to affert, that, whether we regard the intrinfic importance of the queftions that arife, and their relation to the affinities, migrations, and hiftory of nations, or advert merely to the pleafure of the refearch, no fubject will be found more worthy of minute inveftigation.

I. *Hiftory of the Individual.*

The fources from which the hiftory of man muft be derived, are human and comparative anatomy; the natural hiftory of organifed beings in general, and of the animal kingdom in particular. Thefe branches of knowledge are of the greateft importance: comparative anatomy, and the analogies afforded by the natural hiftory of animals, will often afford us more afiiftance than the moft learned labours of the hiftorian. We muft not be content with noting the more ftriking varieties of the human fpecies, but muft inveftigate all the intermediate gradations. The beft fources of information in books, particularly of travels, muft not be employed too indifcriminately: a difpofition to doubt, and a critical eftimation and balancing of authorities, are effentially neceffary to prevent us from being led into error by the ignorance or credulity, the inaccuracy or the pre-conceived notions of the writers. Certain parts of phyfical fcience are connected with the fubject; as an acquaintance with the face of the globe, climates, &c. Hiftory, in the common acceptation of the word; that of the human race in its early periods; of particular people and their changes of fituation, when they have emerged from the thick cloud that covers the firft ages of the world, fo as to admit of being diftinctly traced, will very confiderably aid our inveftigations. The fubject ftill labours under difficulties, from our imperfect knowledge of the habits and anatomy of thofe fimiæ which moft nearly refemble man; from the impenetrable darknefs that involves the infancy of the fpecies; the uncertainty of the ancient geography in general, and of the modern geography of many remote regions; and our defective acquaintance with the wild races.

Progrefs of Man through the various Stages of his Exiftence.—The differences in ftructure and functions between the male and female are explained in the article GENERATION, under the head of *fexual diftinctions;* the mode in which reproduction is effected in the human fubject, as well as the different theories concerning this highly interefting and important, but obfcure function, are confidered in the fame article. Under EMBRYO, we have defcribed the formation and developement of the new being, and the circumftances in which its organization and mode of exiftence differ from thofe of the individual after birth.

Fetal Exiftence.—The precife period at which the future man begins to exift, and the form under which his rudiment appears, are not yet known. For many days after conception, the cavity of the uterus contains nothing in which we can conceive organization to refide: the lord of the creation is loft in a drop of mucus. A foft fubftance, not refifting the flighteft touch, and unfolding to our obfervation no arrangement of different parts, affumes a roundifh fhape about the fecond week after a fruitful coition, and may be regarded as the firft appearance of the ovum: a fœtus cannot be feen in this till towards the end of the third week. Poffeffing at this time the moft fimple kind of vitality, very fimilar indeed to that of the vegetable, it has true blood about the fourth week. Now the motion of the heart is vifible; in fome very rare inftances (Blumenbach, Inftit. Phyfiol.

Phyfiol. § 641.) it has been feen in the human embryo, but it was obferved even by Ariftotle in the incubated chick: its motion could not fail to be noticed from the contraft it afforded to the quiefcence of the other parts, and hence the expreffion of *punctum faliens*. The formation of bone commences at the feventh or eighth week: bony nuclei are firft vifible in the clavicles, ribs, vertebræ, the larger cylindrical bones of the extremities, the lower jaw, and fome other bones of the face: a moft delicate bony network is developed at the fame time in the flat bones of the cranium, as the frontal and occipital, later in the parietal, &c.

The nearer the embryo, and indeed the animal both before and after birth, is to the epocha of its firft production, the more rapid is its growth. That the firft germ, when hidden in the ovum, muft be exceedingly fmall, is clear, becaufe it efcapes our clofeft obfervation, even when affifted by the microfcope: from this minutenefs it increafes in nine months to the weight of fix or eight pounds. It grows in the firft month to 300,000 times its firft fize; in the fecond month to 48 times; and in each of the remaining months of utero-geftation, one with the other, to 15 times. At the end of three years the child has grown from 105 to 281 ounces, or nearly in the ratio of five to fourteen; and in the 22 following, from 281 to 2250 ounces, which is an increafe of about eight times.

About the middle of pregnancy, motions of the child are firft perceived by the mother; in common language it is faid to *quicken*, and the popular notion is that it receives life at this time. The judicial queftions concerning abortion, and the execution of pregnant criminals, render it important that right views fhould be entertained on this point. By the Roman law the punifhment of death was inflicted, when a formed and animated fœtus perifhed by abortion intentionally produced; and it was held that the fœtus poffeffed animation on the fortieth day. In this country a condemned criminal is refpited, if fhe is found to be *quick* with child. It feems to be implied in both cafes, and fuch we believe to be the general opinion, that the child is not alive until a certain period of geftation. This is moft erroneous, phyfiologically: vital proceffes, as an exceedingly rapid growth and developement of parts, are carried on with great activity from the earlieft time, at which the germ can be difcerned, and the heart actually beats at the fourth week. Hence, if abortion be procured at the end of a month, or a woman be executed at the fame time, a child is deftroyed in either cafe, juft as much as if thefe things happen after the ordinary period of quickening. Our phyfiological views of fetal exiftence lead us to fuppofe that the creature in utero has no fenfations, and is unconfcious of its own life: its deftruction, therefore, cannot be charged with the infliction of cruelty on a fentient being.

Divines are much interefted in a point allied to this; namely, at what time the new being has a foul. Very nice queftions have been raifed in the Romifh church concerning the propriety of baptifing, adminiftering the facrament of extreme unction, and performing the burial fervice at particular ages; and thefe muft be equally interefting topics to all, as fuch ceremonies are ordained for the benefit of thofe animals only which have fouls. Phyfiologifts, in general, have not acted very fairly in refufing their affiftance towards elucidating fo important a fubject. "De his myfteriis," fays Haller, "et de animæ humanæ origine, perinde cum Galeno abftineo pronuntiare." He adds, however, immediately after, that he fuppofes the fœtus to have a foul, when it performs fpontaneous motion. (Lib. 29, fect. 3, § 21.) To afcertain the meaning of the word foul, is a very important preliminary in fettling our notions on this fubject. We are fully convinced that the fœtus has no fenfations, and confequently can have no will, nor any intellectual functions (fee EMBRYO): this is equivalent to faying that it has no foul. For an account of the different opinions concerning the nature and faculties of the foul, fee SOUL.

Fat and bile are formed about the middle of utero-geftation. In the remaining part of the time, the hair of the head and the nails appear; the external ear becomes firm and elaftic; and the teftes defcend in the male.

The fœtus is lodged in the uterus, until its organization is arrived at fuch a degree of developement, as will enable it to affume independent exiftence. During its refidence in this organ, it may be regarded as a part of the body of the mother: although it has brain, organs of fenfe and voice, thefe are yet inactive, and do not give rife to any relations between it and furrounding objects: its organs of digeftion, fecretion, and locomotion, are equally inert, and calculated, like the former, for the fucceeding ftage of exiftence. It has all the organs that enable it to exift by itfelf, although their functions are not neceffary while it continues in the womb of the mother. (See MONSTER.) The chief peculiarities of the fetal ftate are, the fimplicity of its life, confifting of little more than the function of nutrition, and the inactivity of almoft all the important organs: its confinement, furrounded by the fluid of the amnios, in the uterus, where no external impreffions can reach it, and the exercife of the moving powers is impracticable, even if volition could take place: the connection with the mother through the umbilical chord and placenta (fee EMBRYO): the uniform colour of the blood in all the veffels, and the communications between the two fides of the heart. (See HEART and CIRCULATION.) As refpiration has never taken place, the lungs fink in water. (See LUNGS.) The cæcum is very different from that of the adult, and the large inteftine, in general, is diftended with a peculiar dark green femi-fluid fubftance, called meconium. (See INTESTINE.) The urachus, the membrana pupillaris, and the defcent of the teftes, are important peculiarities in the fetal ftate, as nothing like a rational conjecture concerning their ufe or purpofe can be formed. (See the defcription of the bladder, in the article KIDNEY; of the iris, in EYE; and of the teftis, in GENERATION.) Three organs, of a tiffue approaching more nearly to that of glands than to any other, appear by their fuperior fize in the unborn child to belong particularly to its economy, although here, as in the parts juft noticed, we are entirely ignorant of the ufes to which they are fubfervient. The two former are not only much larger in the fœtus than in the adult, but they alfo contain a confiderable quantity of fluid in their texture; the thymus, although as large as the heart in the fœtus, is entirely loft in the adult: the two other organs are much fmaller comparatively after birth. See THYMUS, LARYNX, and KIDNEY.

Birth.—Towards the end of the tenth lunar month, when the child has arrived at a weight varying from four to eleven pounds, though generally between five and eight, and is from eighteen to twenty-one inches long, parturition takes place; feveral very important changes occur in the animal economy, and a ftate of being, altogether new, commences. "Nothing," fays Buffon, "exhibits fuch a ftriking picture of weaknefs, of pain, and of mifery, as the condition of an infant immediately after birth. Incapable of employing its organs or its fenfes, the infant requires every kind of affiftance; it is more helplefs than the young of any other animal; its uncertain life feems every moment to vibrate on the borders of death. It can neither move nor

 fupport

ſupport its body; it has hardly ſtrength enough to exiſt, and to announce, by groans, the pain which it ſuffers; as if nature intended to appriſe the little innocent, that it is born to miſery, and that it is to be ranked among human creatures only to partake of their infirmities and afflictions." Hiſtory of Man, ſect. ii.

The navel-ſtring being tied and divided, the connection between the mother and child is ſeparated. In animals, this cord is ſevered by the teeth; if it were not tied in the human ſubject, fatal hæmorrhage would enſue. The child, from the warm medium of the amniotic fluid, is introduced into a new and more ſtimulating element, the air, and draws it into his lungs: thus reſpiration begins, and produces changes in the blood, which ſeem to make up for the loſs of the placental circulation. A healthy and ſtrong child generally cries as ſoon as it comes out of the vagina, and inſpiration is neceſſary to this action. We uſually waſh the body with warm water and ſoap, in order to remove the greaſy ſubſtance that covers the ſkin, and are very careful to keep the child warm; but there are whole nations, inhabiting climates colder than our's, where the infants are plunged into cold water as ſoon as they are born, without receiving the ſlighteſt injury. The deſire for food ſeems to be coeval with the commencement of the new exiſtence: ſucking is performed at once in a perfect manner, as ſoon as the mouth is brought to the nipple.

Within a few hours after birth, meconium and urine are diſcharged. The infant ſleeps much, and ſeems to awake only for the purpoſe of taking food: the gratification of the latter want, and ſleep, are the great employments of the firſt months.

Infancy.—As we remember nothing of what paſſes at this early period of our exiſtence, we cannot diſcover the feelings produced by the firſt impreſſions of the air; but the cries uttered immediately after birth ſeem to indicate that the action of the atmoſphere cauſes painful impreſſions. The ſenſes at firſt act very imperfectly; the newly born creatures have a ſtupid appearance, and give hardly any proof that their organs of ſenſe act. The eyes are fixed and dull, and have not the motions which accompany diſtinct viſion; yet they feel the impreſſion of light, and the pupil contracts or dilates in proportion to its quantity. When any thing is ſuddenly brought near to the eye, neither the lids nor the head are moved. The other ſenſes are in an equally imperfect ſtate. All the other parts of the body are extremely feeble, and their motions awkward and ill directed. The thighs and legs are bent, from the habit contracted while in the womb of the mother; there is not ſtrength enough to ſeize any thing with the hands; if abandoned in this condition, the child would remain on its back, without being able to turn to one ſide or the other. See LIFE.

The pulſation of the brain is felt at the fontanells.

Beſides the commencement of the functions that connect us to the external world, as well as thoſe of the digeſtive apparatus, and the modifications of the circulating organs conſequent on the ligature of the chord, and the beginning of reſpiration, various alterations in the external habit of the body are diſcernible after parturition. The downy covering of the ſkin gradually diſappears, the wrinkles are obliterated, the nates are developed, and hide the opening of the anus.

A newly born infant diſcovers pain by its cries; but it has no expreſſion indicating pleaſure. It ſmiles about the ſixth or ſeventh week, and it begins to weep about the ſame time; for its former cries were not accompanied with tears.

Newly born children ſleep much, but only for ſhort periods; they require very frequent nouriſhment, and expreſs this want by crying, which generally terminates their ſleep. This indication ſhould always be carefully attended to. Nothing is required in addition to what nature has provided in the mother's milk; no ſubſtitute is equal to this, though the milk of other animals may be employed in caſes of neceſſity: the teat of the animal may be ſubſtituted for that of the mother. Buffon ſays that he has known ſeveral peaſants, who had no other nurſes than ewes; and yet they were equally vigorous as thoſe who had been nurſed by their mothers.

As ſoon as the infant had eſcaped from the uterus, and enjoyed the liberty of ſtretching its limbs, it was again condemned, while the uſe of ſwaddling clothes prevailed, to a more cruel and unnatural bondage. The head and limbs were fixed, and the whole body ſo laced and fettered, that hardly a joint could be moved. People now begin to find out that the developement of the body will be accompliſhed without this artificial aſſiſtance. Perhaps they are hardly yet aware, that the efforts of the little priſoners to diſentangle themſelves have a more direct tendency to diſtort their members, than any poſitions they could aſſume, if left in the full poſſeſſion of liberty. Swaddling bands may be compared to the ſtays worn by young girls, which occaſion many more deformities and diſeaſes than they are intended to prevent. The practices of ſavage nations have been much more rational than thoſe of the civilized; they lay their infants naked in hanging beds of cotton, or cradles lined with fur, in which they are at perfect liberty to move themſelves as they are inclined, and provide at the ſame time very carefully for abſorbing the moiſture of their diſcharges. No improvement can be ſuggeſted on this plan.

As the child becomes accuſtomed to external objects, it gradually learns the uſe of its ſenſes, and loſes the apparent ſtupidity that characterizes it for the firſt months of exiſtence. It is fond of light, and directs its eyes always to the lighteſt part of a room; hence the propriety of placing it ſo that both eyes may receive the light at the ſame time, and conſequently acquire by exerciſe an equal degree of ſtrength. It is attracted by any ſhining objects, and endeavours to ſeize them; when pleaſed, it ſmiles; and cries and attempts to reſiſt, when it is hurt or vexed: it recogniſes individuals, and is frightened by ſtrangers. The organs of the external ſenſes are more perfectly finiſhed, as the external ear, the noſtrils, the ſuperciliary arches and eye-brows, &c. At the ſame time, the mental functions, dependent on the operation of theſe organs, as attention, perception, memory, the will, &c. are gradually developed: hence dreams are obſerved in a few months after birth. The bones of the cranium become more firmly united, and the fontanells are gradually cloſed. Dentition, which begins about the ſixth or ſeventh month, is a moſt important era in the life of the infant. The proceſs is always painful, and not unfrequently fatal. For the deſcription of the teeth and the hiſtory of their developement, ſee CRANIUM: the dangers with which it is accompanied are deſcribed under INFANTS, *Diſeaſes of.* This change points out the natural time for weaning: the newly acquired inſtruments, which injure the nipple of the mother, enable the infant to uſe firmer food, and thus make it independent of the breaſt. As conception does not uſually take place again, while ſuckling is continued, mothers, who wiſh not to have a numerous family, often keep the child at the breaſt long after this time, although there is no advantage to be derived to the child from the practice.

Oſſification goes on with great activity, and confers on all parts of the ſkeleton that firmneſs which is eſſential to the execution of their functions. Bony nuclei are ſeen in the cartilages, which are afterwards to form the bones of the carpus

carpus and tarfus. The urine contains little or no phofphat of lime, as that fubftance is all employed in the completion of the bones. Towards the beginning or middle of the fecond year, they have become ftrong enough to fupport the weight of the body, hence the infant at this time begins to learn the ufe of his feet, and to affume the erect attitude, one of the moft remarkable prerogatives of the human fpecies. The fmallnefs of the lower limbs and pelvis, in comparifon to the head and upper part of the trunk; the foft ftate of the bones, as well as the want of power in the mufcles, which, like the organs of fenfe, require the flow education of frequent exercife; and the very complicated exertion neceffary to maintain the body erect (fee MUSCLE, towards the end), poftpone the power of going alone to this late period after birth, and render all the motions and pofitions connected with it very unfteady and unfafe for a ftill longer time; although animals in general can maintain themfelves in their natural attitudes tolerably well from the day of birth. Attempts to make the child affume the erect attitude before the epocha we have mentioned, are dangerous, as the flexible bones, unequal to the burden, give way under it, and thus deformity is produced.

Removal from the mother's breaft, and the power of going alone, are two very important fteps, and the progrefs towards independent exiftence is greatly affifted by another remarkable privilege of the human fpecies, the ufe of fpeech, which begins in children of lively minds foon after the firft year. The founds uttered in the careffes of the mother are attended to, and eagerly imitated; and every faculty is ftrained to the utmoft, for the purpofe of acquiring the ufe of an inftrument fo important towards attaining the gratification of its daily increafing defires, and eftablifhing its communications with furrounding beings. The power of fpeech, however, like the ufe of the fenfes, and of the moving organs, is not poffeffed perfectly at once; it is the offspring of laborious and repeated efforts. The vowel A (broad) is the moft eafily pronounced, as it requires only the opening of the mouth, and forcing out the air: the confonants, B, P, and M require the leaft motion of the organs, and are moft eafily articulated. The other founds are formed in proportion as the organs learn their offices. (See ARTICULATION.) Some can articulate diftinctly, and repeat whatever is faid to them, at two years of age, but a longer time is generally neceffary.

While the infant is thus flowly advancing in the developement of its powers, it is expofed to numerous and deftructive difeafes, which render its life very precarious for the three firft years. (See INFANTS, *Difeafes of.*) Half of the children produced die in the firft few years of life, and the work of deftruction proceeds ftill more rapidly, when they are crowded together in confiderable numbers. Camper informs us, that of 5989 admitted into the eftablifhments for foundlings at Paris, in one year, 4095 died in the firft month, and 673 more in the remaining eleven months: only 884 were alive at the end of five years. Ludwig Grundrifs der Naturgefchichte der Menfchenfpecies, p. 293. See MORTALITY.

About the feventh year, the deciduous or milk teeth begin to fall out, and a fecond dentition enfues. Of the thirty-two permanent teeth, which are defigned to remain through life, the greateft number have come into the vacancies left by the fucceffive difcharge of the temporary ones, by the twelfth year; but the whole fet is not complete till the 18th or 20th year.

Childhood, or Adolefcence.—In the age of infancy, memory feems to excel the other faculties of the mind, and affords a moft commodious inftrument for retaining the figns of furrounding objects. It hardly continues in its original ftrength beyond the fifteenth year. The imagination is developed after it, and begins to predominate when the memory is weakened; its exercife is affifted by the happy memory of this age, which fupplies it with materials. The judgment is developed at a later age: children pafs rapidly from one object to another, without beftowing the time for accurate comparifon and enquiry, which judgment requires.

The nervous fyftem is eafily affected in childhood, and grief and joy are excited by flight caufes. Much time is paffed in fleep.

A confiderable ftratum of fat covers the body under the integuments, hides the mufcles and bones, and beftows a roundnefs and foftnefs of outline on the whole frame. See MEMBRANE, *Cellular*, and MUSCLE, under the head of *developement* of thofe tiffues.

The fluids undergo a confiderable change: in the fœtus, or in a young child, the urine, fæces, and perfpiration are not fetid; the bile is not bitter; all the fecretions indeed are mild. But the urine foon acquires its diftinguifhing fmell; the kidnies, which form an agreeable food in the calf, are rejected on account of their ftrong tafte in the bullock; the fæces become more confiftent, and have a powerful odour. The food and mode of life are not the caufes of thefe alterations; for the fæces, perfpiration, &c. have their ftrong fenfible properties in the adult, even when the diet confifts of milk or vegetables.

Puberty.—The great developement of the imagination is about the age of puberty, when man is prepared, by various and important changes of his organization, for the exercife of the generative functions. Nature hitherto feems to have had nothing further in view than the growth and prefervation of her work. The child enjoys an exiftence confined to itfelf, which it cannot communicate; but the principles of life foon multiply beyond what is fufficient for our own being, and enable us to beftow exiftence on others.

When the mammæ enlarge in the female, the beard fhews itfelf in the male, and the other phenomena of approaching puberty are exhibited in both fexes, as the developement of hair on the external organs, &c. the former begins to have the menftrual difcharge, which is accompanied, amongft other appearances, with increafed luftre of the eyes, rednefs of the lips, and more fenfible properties in the perfpiration; the latter fecretes true femen, having at the fame time a more copious growth of the beard, and a memorable change of the voice into a deeper tone. The latter, for a confiderable time, is rough and unequal; after which it becomes more full, articulate, and ftrong. This change is very confpicuous in boys; but it is lefs diftinguifhable in girls, whofe voices are naturally more fharp. A very remarkable enlargement of the vocal organ, coeval with puberty, is the fource of the alteration juft mentioned. There is hardly a fenfible difference of fize in the larynx, between a child of three, and another of twelve years: there is at leaft nothing correfponding to the diverfity of ftature. But at puberty, in the fpace of a year, the opening of the male glottis is doubled, both in length and breadth. This increafe in the female is only in the proportion of feven to five. (Richerand, Elem. de Phyfiol. ed. 3. § 226.) Thefe marks are not always uniform. The beard, for example, does not always appear precifely at the age of puberty: there are even whole nations, who have hardly any beard. On the contrary, there is no country where the age of puberty in women is not diftinguifhed by the enlargement of the breafts. At the fame time the fexual inftinct is awakened by what we may call the fpontaneous internal voice of nature, and both fexes, in this fpring of their exiftence, become capable of exercifing that important function of all animated beings, the propagation of the fpecies. For the detailed confideration of this fubject, fee GENERATION. In that article the reader will find a view of the changes occurring in the generative organs at this age, and of the effects, which they exert in the body in general, of menftruation, and of the phenomena obferved where unufual organizations exift, conftituting what have been often called hermaphrodites.

Virginity, impotence, circumcifion, caftration, infibulation, &c. are articles fo important in the hiftory of man, either on account of the intereft attached to fome of the fubjects, or of the general prevalence of fome of the practices, that we fhould confider it a facrifice of what is effential to falfe notions of delicacy, if we paffed them over entirely unnoticed. On the fubject of virginity, fee the account of the hymen, in the defcription of the vagina, in the article GENERATION, and Buffon's Hiftory of Man, fect. 3: refpecting *Circumcifion* and *Impotence*, fee thofe articles; and concerning the latter, Mr. Hunter's Treatife on the Venereal Difeafe, pt. iii. ch. 11 and 12. Boys are infibulated by drawing the prepuce forwards, piercing it, and putting through the holes a fmall cord, which remains until the cicatrix is formed; the cord is then removed, and a ring fubftituted in its place, which is made of fufficient ftrength to laft as long as the perfon, who ordered the operation, pleafes; and it fometimes remains for life. The Eaftern monks, who took the vow of chaftity, ufed to employ a large ring, which rendered a breach of their oath impoffible. On this fubject hardly any thing can be imagined fo ridiculous that it has not been practifed by fome men, either from motives of paffion or of fuperftition. A fimilar mode of fecuring the chaftity of the women, which could only be fuggefted by the rudenefs of their manners, has been practifed in many barbarous nations. In Ethiopia, and other parts of Africa, in Arabia, Pegu, and other nations of Afia, the inhabitants, immediately after the birth of females, few up thofe parts which nature has feparated, leaving only a fpace fufficient for the natural evacuations. As the child grows, the parts gradually adhere, and when the time of marriage arrives, they are again difunited by incifion. Inftead of thread, the fibres of the afbeftos are faid to be employed, which is a fubftance not liable to fudden corruption. Some tribes content themfelves with putting a ring through the parts. To this precaution wives as well as girls are fubjected, with this difference, that the ring allotted to the latter cannot be removed, but in that of the former there is a lock, of which the hufband keeps the key.

The practice of caftration is of great antiquity, and has prevailed very extenfively. It is employed in Afia, to procure guards for the chaftity of the women; in Italy, this infamous, this cruel operation, has for its object only the improvement of the voice. Befides deftroying the faculty of propagation, it prevents, or very fignally modifies, the changes that ufually occur at the time of puberty, and remarkably influences the voice. (See GENERATION and EUNUCHS.) The fpecies of caftration varies according to the object in view; the tefticles only are removed, when the improvement of the voice is intended. But men, whofe minds are poffeffed with jealoufy, would not believe their females fafe in the cuftody of fuch eunuchs; they employ none but thofe who have been deprived of all the external organs of generation. Sometimes the texture of the organs has been deftroyed by preffing and rubbing them for a long time; but the effect of this procefs cannot be fo fecurely depended on as that of removal. Infancy is always preferable for thefe operations. The amputation of the tefticles is not very dangerous: but the more complete removal is often fatal, efpecially if performed after the age of fifteen; even in the moft favourable time, from feven to ten years, there is always great danger. The difficulty of preferving fuch eunuchs renders them exceedingly precious. Tavernier informs us, that in Turkey and Perfia, they bring five or fix times the price of the other kind. Chardin obferves, that the total amputation is performed pretty fafely upon young children, and is exceedingly dangerous after the age of fifteen; that hardly a fourth part efcape with life, and that the wound is never cured in lefs than fix weeks. On the other hand, Pietro della Valle afferts, that thofe who fuffer this punifhment in Perfia for rapes, and other crimes of that nature, recover eafily, though advanced in years; and that they apply nothing but afhes to the wound. According to Thevenot, vaft numbers of negroes, who are forced by the Turks to fubmit to this operation, perifh, even when it is performed on individuals eight or ten years old.

The arrival of puberty differs according to climate, temperament, way of life, &c. fo that no particular age can be fet down for its general occurrence. It is earlier in women than in men; the former, in our climate, fhew the phenomena of puberty at about the age of fifteen, the latter at that of eighteen. Inftances are not very uncommon, of confiderable developement of the body, with the changes that ufually occur at puberty, fuch as the appearance of the beard, enlargement of the generative organs, fecretion of femen, expanfion of the breafts, flow of the menfes, and formation of hair on the pubes, at a much earlier age than we have mentioned. Befides the inftances related in the article GENERATION, a confiderable number may be found in Haller's Elementa Phyfiologiæ, lib. xxx. fect. i. § 15. Puer triennis pubefcens, virili in pudendis robore, altus 37 uncias. Journ. de Medecine, 1757. Puella quatuor annorum mammis confpicua et pube, ut etiam menfes pateretur. Valifneri Op. t. iii. p. 309. Puer quatuor annorum nubilis, feminarum cupidus, voce gravi, tanto robore, ut libras 50 elevaret. Journ. de Medecine, 1759. Many other examples are mentioned of children younger than thefe, who exhibited figns of puberty, fuch as the growth of the beard, and of the hair on the pubes; and there are numerous inftances of others from four years upwards, who have been able to perform all the fexual functions. The termination of the growth of the body in length is fixed a little after this time; the epiphyfes of the bones, hitherto diftinct from the bodies, now coalefce, and are completely confolidated to them.

Stature of Man.—There is no fixed law, determining invariably the human ftature, although there is a ftandard, as in other fpecies of animals, from which the deviations, independently of difeafe or accident, are not very confiderable in either direction. In the temperate climates of Europe, the height of the human race may be ftated at five feet two inches to five feet ten. Schreber gives to the human fpecies a height of from two feet four inches, to five feet eight inches. (Mammalia, t. i. p. 27.) Individuals of fix feet, and even as high as fix feet three and four, are not uncommon in this and other European countries. Occafional inftances have been known in various parts of the world, of men reaching the height of feven and eight feet; and ancient as well as modern authors fpeak of the human ftature reaching nine, ten, and even eighteen feet. The latter reprefentations are generally grounded on bones dug out of the earth; thefe, together with the common propenfity to believe and report what is marvellous, and the notion that mankind have undergone

undergone a degeneracy fince their firft formation, have led to a very common belief that the human ftature in general, is at this period lefs than it was in remote ages. We are warranted in fufpecting the accounts of fuch great elevation above the ordinary ftature, in the human fpecies, by obferving that nature, within the time of which we have any authentic records, exhibits no fuch difproportions in other fpecies. We find, too, that the height of thefe giants is reduced, as we approach to modern times, to what we have opportunities of obferving now; fo that we may probably affirm, that no fufficiently authenticated example can be adduced of a man higher than eight or nine feet. The large bones on which the notions about giants have been, in many inftances, founded, have been difcovered, by the accurate examinations of modern fcience, to belong to extinct fpecies of animals of the elephant and other allied kinds. Of the loofe and unphilofophical mode in which thefe matters have generally been inquired into, we have a fpecimen in the fuppofed bones of a barbarian king. Habicot, an anatomift, in a work entitled "Gigantofteologie," defcribes fome huge bones, found near the ruins of the caftle of Chaumont in Dauphiny, in a fepulchre, over which was a grey ftone, infcribed TEUTOBOCCHUS REX. This fkeleton, he fays, was 25½ feet long, and 10 broad at the fhoulders. Riolan, in his "Gigantomachie," difputes the meafurements, and affirms that the bones belong to the elephant. In the long controverfy which enfued, it is remarkable that no exact defcription or reprefentations of the bones fhould have been given. It is very furprifing that fuch a philofopher as Buffon fhould have figured and defcribed the foffil bones of large animals as remains of human giants, in the 5th vol. of the fupplement of his claffical work. Among others he has thofe dug up at Lucerne, in the 16th century, and ftill preferved there. Blumenbach found thefe, on the firft view, to be elephants' bones. Felix Plater, an excellent phyfician and anatomift of his time, after carefully examining and meafuring thefe bones, declared that they belonged to a human giant of feventeen feet, and had a drawing made of this fkeleton, according to his opinion of its dimenfions, which is ftill preferved in the Jefuits' college at Lucerne. (Blumenbach de Gen. Human. Variet. Nat. p. 251, note.) That men in general were taller in the early ages of the world than at prefent, or that examples of very tall men were then more frequent than now, has been afferted without any proof. The remains of human bones, and particularly the teeth, which are unchanged in the moft ancient urns and burial places, the mummies, and the farcophagus of the great pyramid of Egypt (Norden's Travels), demonftrate this point clearly; and every fact which we can collect from ancient works of art, from armour, as helmets and breaft plates, or from buildings defigned for the accommodation of men, concurs in ftrengthening the proof. Blumenbach has the fkull and bones of an old perfon, taken out of a burial place of the moft remote antiquity in Denmark (in antiquiffimo tumulo Cimbrico), and correfponding in fize to the modern ftandard. (Ibid, p. 252, note.) That we cannot have degenerated in confequence of the habits of civilized fociety is clear, becaufe the individuals of nations living in a way fo different from us as the Americans, Africans, Southern iflanders, &c. do not exceed us in ftature. Indeed it has been generally obferved that the Americans are fhorter than the Europeans.

We frequently meet with examples of individuals below, as well as above the ordinary ftature; but when the deviation is confiderable, they are rarely well made.

Giants and Dwarfs.—In mentioning individuals who have exceeded the ordinary height, it is neceffary to confine ourfelves, in order to avoid what may be fabulous or exaggerated, to inftances in our own times. One of the king of Pruffia's gigantic guards, a Swede, was 8½ feet, and a yeoman of the duke John Frederic, at Brunfwick-Hanover, was of the fame meafure. Gilly, who was fhewn, meafured 8 feet (Swedifh). I. H. Hartmann Reichardt of Friedberg, near Frankfort, was 8ft. 3in.: his father was a giant, and his fifter a giantefs. A female of Stargard, named La Pierre, was 7 ft. (Danifh). Ludwig, Grundrifs der Naturgefchichte, &c. p. 150. See alfo Haller, Elem. Phyfiol. lib. xxx. fect. 1. § 17. Martin Salmeron, the Mexican giant, is the fon of a Meftizo by an Indian woman, and meafures 7 ft. 3½ in. (Englifh.) He is very well proportioned. Humboldt's Political Effay, b. ii. ch. 6. Several Irifhmen, of from 7 to 8 feet, have been exhibited in this country. Bebe, the dwarf of Staniflaus king of Poland, was 33 in. (French), and well proportioned. His fpine became curved as he approached manhood; he grew weak, and died at 23. Buffon, Hift. Naturelle, xv. p. 176.

The Polifh nobleman Borwlafki meafured 28 Paris inches; was well made, clever, and fkilled in languages. He had a brother of 34 in. and a fifter of 21. Memoirs of the celebrated dwarf Jof. Borwlafki, &c. Lond. 1788.

A Friefland peafant at 26 years of age had reached 29 Amfterdam inches. C. H. Stöberin of Nürnberg was nearly 3 feet high at 20, well proportioned, and poffeffed of talents. Her parents, brothers, and fifters, were dwarfs. Lavater Phyfiognomifche Fragmente iv. p. 72.

Of numerous other inftances on record, moft feem to have been difeafed, and particularly rickety, individuals; fo that they may rather be claffed among pathological phenomena. The men who have confiderably exceeded the ordinary ftandard, have neither poffeffed thofe proportions in their form, which we account elegant; nor has their ftrength by any means correfponded to their fize. The head, in thefe cafes, is below the ratio which it fhould bear to the body, according to what we deduce from men of ordinary ftature; hence the brain muft be comparatively fmaller. It is a general obfervation that very large men are feldom diftinguifhed by extent or force of mental power. The dwarfs, again, are generally ill made; the head, in particular, is too large. There are very few inftances of what we could deem healthy well made men, with all the proper attributes of the race, much below the general ftandard.

Manhood.—The age of manhood extends from the twenty-firft or fifth year to the forty-fifth or fiftieth in the male; it begins and ends rather fooner in the female. At its beginning the growth of the body in length has ended; but it ftill increafes in the other dimenfions. All the organs acquire a fuperior firmnefs in their texture; the fat and cellular fubftances are diminifhed, and the mufcles confpicuoufly enlarged; hence the fharp and hard lines of mufcular protuberances are fubftituted in the place of the rounded and foft outlines of youth. Great mufcular ftrength, vigour, and celerity in the actions of the nervous fyftem, perfect execution of all the bodily functions, in fhort the higheft ftate of vitality, are the attributes of this age. It is not lefs characterized by a perfect developement of the mental faculties. The judgment in particular is matured, and fucceeds to the empire of imagination. Man is now capable of fulfilling all the duties of active life as a citizen and parent. During this long interval, he enjoys the plenitude of his exiftence. It has been fuppofed that the body remains in the fame condition in this part of life, and hence it has been called by Latin writers, *ftatus hominis*. The function of nutrition fupplies whatever is loft in the other proceffes of the economy, and thus a perpetual change is kept up, although the body appears the fame; in this circulation, it has been conceived that

that the whole is changed in the courfe of a few years. There are no accurate data for calculating the time in which all the particles are renewed; probably, however, this is different in the different tiffues. The hair and nails are rapidly renewed; the fat is often increafed or removed within a very fhort time; on the contrary, the marks in the fkin produced by punćturing it, and rubbing in various coloured fubftances, continue through life.

Towards the latter half of the age of manhood, there is a difpofition to the depofition of fat over the whole body; indeed fuch depofitions take place at any part of this period, when tranquillity of mind and inactivity of body are joined with copious food. Fat is particularly formed about the abdomen. (See Corpulence.) As the growth of the frame is finifhed, and all the functions are carried on with vigour, there is a redundance of nutrient particles, by which we can account for this occurrence.

Temperaments.—We avail ourfelves of this age, in which the characters of the human fpecies, roughly fketched in infancy and youth, are fixed and drawn in indelible colours, in order to delineate the diftinctive traits of individuals. We defignate by the word temperament the phyfical and moral differences of men, depending on the various proportions and relations of the part entering into their organization, as well as on the various degrees of energy in certain organs. Thus, the collection of circumftances in the organization or functions of the body, that characterife a number of individuals, conftitutes their temperament. Again, each perfon has a mode of being peculiar to himfelf, diftinguifhing his temperament from that of all others, to fome of whom he may, however, bear in general a confiderable refemblance. Thefe individual temperaments, of which the knowledge is highly important in the practice of medicine, are called idiofyncrafies.

The predominance of a particular fyftem of organs modifies the whole economy, impreffes ftriking differences on the refults of organization, and exerts no lefs influence on the moral and intellectual than on the phyfical powers. This predominance eftablifhes temperament, of which it is the caufe and effence.

Since the conftruction of the body follows the fame model in all, it feems ftrange, at firft fight, that each individual fhould be different from all others, and fhould poffefs a character peculiar to himfelf. Let the number of tiffues, or elementary ingredients of the body, be confidered; let the number of organs compofed by thefe be taken into the view; let us remember the various vital properties which thefe poffefs, and the very numerous functions which they exercife. The original component ftructure may differ, the organs, which they build up, may vary: the vital forces exift in every poffible degree from the higheft pitch to the loweft ftate: the functions are modified by innumerable caufes, as climate, food, clothing, way of life, exercife, labour of mind and body, &c. &c. By the various combinations produced by all thefe differences, individual temperaments or idiofyncrafies are fufficiently accounted for. It feems probable, however, that thefe diverfities are in a great meafure factitious: all wild animals are alike; the differences between individuals are not confiderable in the domefticated races: and there is much greater general refemblance between individual men in favage than in civilized life.

When we afcribe temperaments to differences of organization, we are aware that the truth of the propofition cannot be eafily proved, that the anatomift cannot trace in the material fabric the caufes of thefe phenomena, which at prefent muft be regarded rather as characters of the vital functions than of the organization. The operation of moral caufes, too, muft greatly obfcure this intricate queftion. Education, acquired habits, fituation, and fortune in life, and a long lift of caufes, have fo great an influence on the character and many of the bodily functions, that we are at a great lofs in pointing out what ought to be afcribed to original conformation or difpofition, and what flows from fubfequent agency. We wifh, therefore, the following fketch of temperaments which we have borrowed from a French writer (Richerand, Elemens de Phyfiologie, chap. 11.) not to be received in a very rigorous fenfe, as founded on the bafis of anatomy, but rather to be regarded as a ftatement of the views generally entertained on the fubject, to the truth of which, anatomically, we would not be confidered as pledged.

When the agents of circulation, the heart and bloodveffels, enjoy a predominant activity, the pulfe will be ftrong, frequent, and regular, the fkin highly coloured, the phyfiognomy animated, the forms foft but well expreffed, the flefh tolerably firm, the embonpoint moderate, the hair light coloured; the nervous fufceptibility lively and rapid, united with quick conception, good memory, and fportive imagination. Such individuals facrifice freely to Bacchus and Venus, and have their health rarely interrupted by difeafe. The latter is generally fituated in the circulating fyftem, (inflammatory fever, inflammations, active hæmorrhages,) and requires the ufe of antiphlogiftic remedies, particularly of blood-letting. The ancients gave the name of *fanguine* temperament to this difpofition of body: they had very correctly obferved that it was to be noticed generally in young perfons of both fexes, and that its characters are moft clearly developed in fpring.

The phyfical traits of this temperament may be feen in the beautiful ftatues of Antinous, and the Apollo of Belvedere: its moral phyfiognomy is delineated in the lives of Marc Antony and Alcibiades. Inconftancy is a characteriftic attribute of this temperament; great variety is neceffary as well as agreeable to the individuals whom it marks. Generous, fenfible, and paffionate, but inconftant, they are too foon tired after poffeffion, and free themfelves from the dominion of Beauty at the very inftant when fhe fancies fhe has fecured them by a durable chain. He, on whom nature has beftowed a fanguine temperament, vainly endeavours to renounce fenfual enjoyments, and arrive, by deep meditation, at abftract truth: overpowered by his phyfical difpofitions, he is conftantly forced back to the pleafures which he avoids: his mind is better calculated for the brilliant productions of wit, than the fublime conceptions of genius.

When a man of this temperament is forced, by his condition, to undergo labours, which exercife confiderably his organs of motion, the mufcles acquire a developement proportioned to that of the circulating organs, and increafe in fize; the mufcular or athletic temperament, characterifed by all the external figns of vigour, is the refult. The head is fmall, the neck powerful, particularly behind, the fhoulders broad, the cheft wide, the hips firm, and the mufcular forms ftrongly marked. The hands, the feet, the knees, and all the joints not much covered by mufcles, appear fmall; the tendons difplay themfelves under the fkin. The fufceptibility is not confiderable, but when the calm is once difturbed, the greateft refiftances are overcome. The Farnefe Hercules affords a model of the phyfical attributes of this conftitution, and the exploits of this demi-god, as recorded in fabulous antiquity, give us a tolerably juft notion of the concomitant moral difpofitions. We fee him performing his twelve labours without calculation, without reflection, and, as it were by inftinct, courageous becaufe he is ftrong, feeking obftacles that he may overcome them, certain of overwhelming

overwhelming all refiftance, but uniting with this vaft ftrength fo little addrefs, that he is cheated by all the kings whom he ferves, and by all the women whom he loves. It would be difficult to find inftances of men who have joined to the phyfical force of this temperament a confiderable degree of intellectual power. To attain excellence in the fciences or fine arts, acute fenfibility is neceffary, a condition almoft incompatible with any marked developement of the mufcles.

If to an eafily excited fenfibility we join the power of purfuing one object for a long time; if the pulfe is ftrong, hard, and frequent, the fubcutaneous veins prominent, the fkin of a brownifh tint, inclining towards yellow, the hair black, the flefh firm with the mufcles ftrongly expreffed; the paffions will be violent, the movements of the foul fudden and impetuous, the character firm and inflexible. Bold in conception, firm and invincible in execution, fuch men at different epochas have directed the deftinies of the world: courageous and active, they have fignalized themfelves by great exploits, and have commanded the dread or admiration, at all events the homage, of an univerfe. Such have been Alexander, Julius Cæfar, Brutus, Mahomet, Charles XII, Cromwell, cardinal Richelieu: fuch is Napoleon the Firft.

As love in the fanguine, ambition may be regarded the ruling paffion of the bilious. Obferve that man, who born in an obfcure family, vegetates for a long time in the lower ranks of life: great commotions agitate and overturn empires; he is at firft a fubordinate agent, but, concealing his defigns in his own breaft, he gradually rifes to the fovereign power, and employs, in retaining it, the fame addrefs which has aided his elevation. Such is the hiftory of Cromwell, and of all the extraordinary men, whofe talents have met with a favourable field for their developement. Profound diffimulation and invincible conftancy are equally neceffary for executing fuch defigns; and thefe qualities are eminently difplayed by men of the bilious temperament, as we may fee in the lives of pope Sixtus V. and cardinal Richelieu.

Premature developement of the moral faculties is another character of this temperament. When their youth had hardly ended, the men whom we have named conceived and executed defigns fufficient to render them illuftrious. The ancients called this the *bilious* temperament, as a remarkable developement of the liver, and fuper-abundance of its fecretions are united in it to energy of the fanguiferous fyftem. Derangements of the hepatic organs appear in the perfons of this temperament as a principal or acceffory circumftance of their difeafes.

When to the bilious temperament are added a difeafe of fome organ in the abdomen, a derangement in the functions of the nervous fyftem, or a feeble and irregular execution of the vital functions, the fkin affumes a deeper colour, the countenance is dark and reftlefs, the abdominal vifcera inactive, and the pulfe hard. The general uneafinefs gives a character to the thoughts; the imagination becomes melancholy, and the character fufpicious. The exceedingly numerous varieties of this temperament, which the ancients called *atrabilious* or *melancholic*, and the diverfity of circumftances which may produce it, fuch as hereditary difeafe, long continued anxiety, excefs of ftudy, &c. lead us to the opinion that the melancholic temperament is lefs to be regarded as a natural and primitive conftitution, than as a morbid affection, either hereditary or acquired. The characters of Louis XI. and Tiberius exhibit moft faithfully its moral traits, of which diftruft and timidity are the moft ftriking. The hiftory of men, who have attained celebrity in the fciences, arts, and literature, makes us acquainted with melancholic individuals of a different character: endued with an exquifite fenfibility, enthufiaftically fond of the beautiful, and capable of realizing it in their conceptions, living in fociety in a ftate of referve bordering on diftruft, analyfing moft carefully the actions of men, perceiving in matters of fentiment even the moft delicate fhades, but difpofed to unfavourable interpretations, and feeing all objects through the diftorting medium of melancholy. It would be extremely difficult to defcribe this temperament in a general or abftract manner. Although the ground of the picture is the fame, the finifhing is fufceptible of infinite variations: it is better therefore to refort to the hiftory of the illuftrious characters in whom it is exhibited. Of thefe, Taffo, Pafcal, Rouffeau, Gilbert, and Zimmermann, furnifh remarkable illuftrations. In the philofopher of Geneva particularly, the melancholic temperament exifted in a high degree of energy: numerous paffages of his well-known writings, and efpecially the two laft parts of the Confeffions and the Reveries du Promeneur folitaire, give us an inftructive picture of its workings.

When the liquids are abundant, they diftend and develope the cellular tiffue, and give to the whole body a confiderable volume. The flefh is foft, the countenance dull, the hair of fome light tint, the pulfe feeble, the forms rounded and inexpreffive, all the vital actions more or lefs languid, the memory treacherous, and the power of attention weak. The individuals of this temperament, called, by the ancients, pituitous, and which we term *phlegmatic*, have, generally, a ftrong difpofition to idlenefs, and an invincible repugnance to exercife of the mind as well as of the body: hence, we are not to be furprifed that no examples occur among the illuftrious men of Plutarch: little fuited for bufinefs, they have not exercifed dominion over their fpecies, nor altered the furface of the globe by negociation or conqueft. Atticus, the friend of Cicero, who lived on good terms with all the parties who fucceffively haraffed the Roman republic in the civil wars of Cæfar and Pompey, is an example of this temperament. The circulation is tranquil, the imagination cool, and the paffions moderate. From this moderation of the defires arife often the virtues of temperament, as they are called; virtues, by the bye, of which the poffeffors ought to be the lefs proud.

The property, by virtue of which we are more or lefs fenfible to impreffions on our organs, which is weak in the phlegmatic, very inconfiderable in the mufcular, moderate in the fanguine temperament, and tolerably lively in the bilious, conftitutes, when it is exceffive, the *nervous* temperament. This is feldom original, but more commonly acquired, and arifing from a fedentary life, habits of pleafure, and an unnatural ftate of mind, kept up by reading works of imagination, &c. Soft and fmall mufcles, and confequently inconfiderable fize of body, lively fenfations, promptitude and variability of decifion, are marks of this temperament: it is often exhibited in vapourifh women, in whom, however, it frequently exifts with tolerable embonpoint, the predominance of the nervous fyftem being connected with a moderate developement of the lymphatic fyftem. Convulfions are not unfrequent in fuch individuals. Antifpafmodics fucceed beft in the treatment of their difeafes, which always borrow their hue, more or lefs, from the temperament. This, like the melancholic, is not fo much a natural conftitution of the body, as the firft ftage of a difeafe. It exifts only, as the nervous affections, to which it difpofes, in focieties arrived at a high pitch of civilization, when man is as remote as poffible from the ftate of nature. The Roman women were not fubject to nervous

diforders

diſorders until the commencement of thoſe depraved manners, which ſignalized the downfal of the empire. Vapours were extremely common in France during the 18th century, in the times that preceded the ruin of the monarchy, and numerous works appeared on the ſubject within a ſhort time. Tronchin of Geneva acquired very extenſive reputation and a large fortune by his ſkill in treating theſe diſorders: he made idle women exerciſe themſelves habitually, till they were fatigued, and reſtricted them to ſimple and wholeſome food.

We cannot doubt, that the peculiar bodily diſpoſitions, on which the differences of temperament are grounded, are coeval with our birth; but they appear to be modified, or even entirely changed by education, mode of life, climate, and contracted habits. The prevalence of particular temperaments in certain countries ſhews us the influence of climate. The bilious characterizes the inhabitants of ſouthern climates; the ſanguine thoſe of the north; the phlegmatic conſtitution prevails in cold and wet countries, as Holland, &c. We rarely meet with individuals, who preſent the characters aſſigned to the various temperaments in all their purity, conſequently the ſketches here given of them are abſtractions, which it is difficult to realize. The ſanguine conſtitution is directly oppoſite to the melancholic, and never unites with it: we may make the ſame obſervation of the bilious and phlegmatic: yet a perſon, who is ſanguine in his youth, may become melancholic at a ſubſequent period of life; for man never remains as he came from the hand of nature: modified by every thing that ſurrounds him, his phyſical properties, as well as his character, preſent numerous differences at the different periods of his life.

Proportions.—The proportions which the parts of the body bear to each other, when its growth is completed, muſt alſo be conſidered in this diviſion of our ſubject. We have very little exact knowledge concerning theſe; they are hardly the ſame in any two individuals. Repeated obſervations alone can aſcertain a ſtandard, by which we may be enabled to form a perfect idea of the natural and beſt proportions of the human figure. The ancients made ſtatues ſo exquiſitely beautiful, that they have uniformly been regarded as exact repreſentations of the moſt perfect human forms. Theſe, which were only copies, are now conſidered as originals, becauſe they were not imitated from an individual, but from the whole ſpecies, ſo attentively compared, and diligently obſerved, that it is impoſſible to find an equal degree of ſymmetry and proportion in any one man that ever exiſted. We ſhall, therefore, relate the dimenſions of the different parts which theſe artiſts have fixed as ſtandards of perfection. The height of the body is ten times the length of the face; and each face, or tenth of the body, is divided into three equal parts; the firſt commences at the ſpringing of the hair on the forehead, and terminates at the root of the noſe; the noſe is the ſecond diviſion; and the third extends from the noſe to the end of the chin. The term noſe, or length of a noſe, is uſed to denote the third of a face, or the thirtieth part of the body. The firſt face begins at the root of the hair, above the forehead, and extends to the end of the chin; but, from the top of the forehead to the crown, there is ſtill a third of a face or a noſe in height. Thus, from the top of the head to the end of the chin, there is a face and a third; from the chin to the juncture of the clavicles, two-thirds of a face; and, therefore, from the top of the head to the breaſt is twice the length of the face, or the fifth of the body. From the joining of the clavicles to the under part of the breaſts, they reckon one face; from this to the navel is a fourth face; and the fifth extends from the navel to the diviſion of the inferior extremities, which ſhould complete half the length of the body. Two faces are exhauſted between the thigh and knee, to the laſt of which they allow half a face, being the firſt half of the eighth face; two faces are aſſigned between the knee and the top of the foot, and from that to the ſole half a face, which completes the ten faces, or the length of the body. This diviſion has been eſtabliſhed from men of ordinary ſize; but in thoſe of higher ſtature, they allow half a face additional between the breaſts and the commencement of the thighs, which, in tall men, is not the middle of the body.

When the arms are fully extended in a horizontal line, the ſpace between the tops of the middle fingers is equal to the length of the body. The ſpace between the two great toes, when the feet are ſeparated as widely as poſſible, is the ſame length. From the pubes to the heel is one-half of this length.

From the joining of the collar bones, to the articulation of the ſhoulder bone with that of the arm, is one face. When the arm hangs down, or is bent forwards, it is four faces in length; two between the ſhoulder and elbow, and two between the elbow and the root of the little finger; five faces, therefore, from the joining of the collar bones, and the ſame number for the other arm, make up the length of the body; about half a face remains for the length of the fingers; but it muſt be remarked, that this is loſt in the elbows and ſhoulders, when the arms are extended. The hand is about a face in length, the thumb a third of a face, or a noſe, and the longeſt toe is of the ſame length with the thumb. The under part of the foot is equal in length to the ſixth part of the length of the body; of this the tarſus compoſes three, the metatarſus five, and the toes four.

It is very difficult to fix the proportional thickneſs of the different parts of the body. The changes are ſo great when the ſame man is thin or fat, and the action of the muſcles, in different poſitions, creates ſo much variety in the dimenſions of the parts, that it is almoſt impoſſible to ſet down any fixed rules on the ſubject. The circumference of the trunk, about the cheſt or abdomen, equals half the length of the body.

Strength of the Body.—It is difficult to form any ſatisfactory compariſon between the ſtrength of men and of animals. The habit of exertion, the kind and quantity of food, the ſtate of health, and many other cauſes, have ſuch effect on the vital powers of the muſcles, that it is hardly poſſible to perform experiments under circumſtances in all reſpects ſimilar. Deſaguliers tells us, that by means of a certain harneſs, by which every part of a man's body was proportionally loaded, the perſon employed in the experiment could ſupport, in the erect poſture, a weight not leſs than 2000 pounds. A horſe, which is about ſix times the ſize of an ordinary man, ought, therefore, when managed in the ſame manner, to bear 12 or 14,000 pounds, a much greater weight than that animal can ſupport, even when it is diſtributed with every poſſible advantage.

The ſtrength of animals may likewiſe be eſtimated by agility, and perſeverance in labour. Men, when accuſtomed to running, are able to outſtrip horſes in the long run: a man will accompliſh a long journey ſooner, and be leſs fatigued, than the beſt road horſes. The royal meſſengers of Iſpahan, who are trained to running, go thirty-ſix leagues in fourteen or fifteen hours; we are aſſured by travellers, that the Hottentots outrun lions in the chace; and that thoſe ſavages, who live by hunting, purſue and even catch deer, and other animals of equal ſwiftneſs. Many

other

other ſtories are told of the amazing nimbleneſs of ſavages, of the long journies they accompliſh on foot over the moſt craggy mountains, where there is no path to direct, but every obſtacle to obſtruct their progreſs. Theſe people are ſaid to travel 1000 leagues in ſix weeks, or at moſt in two months. If we except birds, whoſe muſcles are proportionally ſtronger than thoſe of any other animals, no creature could ſupport ſuch long continued fatigue. Civilized man is ignorant of his own ſtrength; nor is he ſenſible how much he is weakened by effeminacy, nor to what extent he might recover his native force by an habitual and vigorous exerciſe of his powers.

Age of Decline.—Every object in nature muſt change and decay; the bodies of men, when arrived at full maturity, begin to decline. The waſte is at firſt inſenſible, and ſeveral years frequently revolve before we perceive any conſiderable alteration. The depoſition of fat may perhaps be regarded as the firſt ſtep towards decay; it is an addition of ſuperfluous matter, loading the body with an uſeleſs weight. As the quantity of it augments, the body loſes its former lightneſs and freedom of motion, the members become unwieldy, and extenſion is acquired at the expence of ſtrength and activity. But the moſt unequivocal ſigns of approaching old age are the ceſſation of the catamenia in women, often attended with a developement of the beard, diminiſhed ſexual appetite in men, the approach in both of what has been called the dryneſs of old age, (ſiccitas ſenilis,) and a ſenſible diminution of the vital forces. The epocha of theſe changes is from forty to forty-five in women; from forty-five to fifty in men: peculiar cauſes may either accelerate or retard the period. The individuals of both ſexes are now no longer capable of exerciſing that moſt important function, the propagation of the ſpecies; their ſexual life is at an end. Diminiſhed activity of the ſenſes and brain, impaired vigour in the moving organs, and leſſened energy of all the internal functions, gradually come on after this great revolution in the animal economy. Conſiderable organic changes are gradually developed; the motion of decompoſition begins to predominate in the internal functions, and the volume of the whole body is reduced. The cellular ſubſtance, ſoft and flexible in the youth, is converted into long and hard threads; it undergoes, over the whole body, a change that cannot but impair the mobility of the organs. The yielding ſkin of the infant, which has the ſoftneſs of velvet in the young woman, grows rough and harſh; a tawny and diſagreeable hue takes place of its freſh redneſs; its contractility is deſtroyed, the abſorption of the fat leaves it unſupported, and hence wrinkles are produced. They are firſt ſeen in the eye-lids, and extend over the whole body; but we notice them more particularly in the face, on the wrinkled front of which approaching decrepitude is marked in moſt legible characters. So hard does the texture of the ſkin become in very old individuals, that conſiderable force muſt ſometimes be uſed to penetrate it with a knife. The hair partakes of the ſame changes with the ſkin; it turns grey, becomes much thinner, then aſſumes a white colour, and is at laſt entirely loſt.

The cornea of the eye is rendered flatter, ſo that its power of refracting the rays of light, that come from near objects, is diminiſhed. The viſion of diſtant objects, however, is ſtill perfect; and the uſe of convex glaſſes ſupplies the imperfection in the ſight of what is near. A white circle is often developed in the cornea, near its attachment to the ſclerotica, and has been called arcus ſenilis.

The arteries are not exempt from the general decay; the larger trunks are dilated, their coats are more or leſs converted into a ſubſtance of cartilaginous or bony hardneſs, and aſſume a brittle texture. The proceſs of oſſification in the ſmaller tubes reduces their calibre. The capillaries are greatly diminiſhed in number. Hence injections, particularly minute ones, ſucceed very imperfectly in old bodies. This change affects organs of every deſcription; the ſame parts which exhibited innumerable blood-veſſels in the growing body, poſſeſs now but few and ſcattered ramifications. The veins are enlarged and varicous.

The muſcles become tough, and are rendered unfit in animals for the purpoſes of the table; fat is depoſited among their fibres, and the tendinous parts increaſe in their proportion. They feel, however, at this time actually ſoft and flabby.

The bones receive an undue depoſition of earthy matter, loſe their coheſion, break very eaſily, and unite after fractures very ſlowly and imperfectly. The cartilages become brittle, and in many inſtances are oſſified, the ligaments are rendered harder, but are leſs capable of reſiſting extenſion. The teeth fall out.

Analogous changes take place in all parts of the body, but are not equally obvious in all. Yet all the organs have ſomething peculiar in their characters at this time, by which we can eaſily diſtinguiſh them from thoſe of young individuals.

But the moſt important alterations are thoſe which affect the vital properties, and conſequently, the functions of the body. Theſe changes are often ſeen when the above-mentioned alterations of ſtructure are not viſible to any very great degree. The external ſenſes decay; viſion becomes dim, and hearing dull; the operations of the intellect are affected in the ſame manner, attention and perception are weakened, the memory becomes confuſed. Thus, the relations of the old man to the external world are gradually deſtroyed; he ſinks into ſecond infancy, becomes incapable of judging and willing, and has his intellectual world confined to a few confuſed recollections, which ſoon diſappear. When he is thus ſhut out from new impreſſions, he ſleeps moſt of his time, awakening only for the purpoſe of taking food; thus he is reduced to a kind of vegetative exiſtence.

The organs of motion loſe their vitality in an equal degree with thoſe of ſenſation and volition. The movements are ſlow, tremulous, and uncertain. The erector muſcles of the trunk can no longer ſupport it in the upright poſture, hence the body is bent forwards, and the legs become unable to ſuſtain and move the body. The intervertebral fibro-cartilages are compreſſed and reduced in ſize, and the ſtature, conſequently, experiences a real diminution.

Digeſtion, and the other parts of the aſſimilating proceſs, are executed ſlowly and imperfectly: the loſs of the teeth is diſadvantageous to the former. Food is taken at longer intervals; the bowels become torpid; and the fæces and urine are longer retained.

The vigour of the circulation is impaired; the pulſe becomes ſlower; the extremities of the body are ſoon rendered cold, and their vitality is ſo weak, that they eaſily ſlough. For a ſtatement of the number of the pulſe at different ages, ſee the article CIRCULATION.

Decrepitude.—From the end of manhood to death, there is a gradual progreſs, in which no ſtages can be very diſtinctly marked. Yet the firſt years of decay are ſometimes included under the term of green old age; in which all the functions are ſtill performed, but with leſſened energy. This may reach, with conſiderable latitude, however, to the ſixtieth year. In this time the memory grows dull: former events are remembered, but the more recent ſoon eſcape. This is ſucceeded by decrepitude. The nervous ſyſtem is now rendered nearly uſeleſs: the old impreſſions are effaced, and no new ones received. No deſire remains but that of food,

 which

which is the laſt to leave us: in the end food is not taken, unleſs it is offered. The irritation of the fæces in the large inteſtine is not perceived before death; and ſleep is almoſt conſtant. A. de Moivre, who died at the age of eighty-eight, ſlept twenty hours in the twenty-four during the laſt year of his life. Complete deafneſs and blindneſs come on. The muſcles are firſt exceedingly weak, and then loſe their power entirely, ſo that old people are obliged to lie conſtantly in bed. Exceſſive emaciation takes place. The heart at laſt fails; its pulſations are reduced to fifty, forty, thirty; and become intermittent; and the heat of the frame is no longer kept up.

Death.—For a more particular account of the changes preceding death, and of death itſelf, we refer to that article. We have only to add here a few obſervations concerning the apprehenſions generally entertained of this event. We have ſhewn, in the preceding ſketch, that life both commences and terminates by imperceptible degrees. Why then ſhould we be afraid of death, if we have no reaſonable apprehenſions of its conſequences? why dread this ſingle moment, which has been preceded by ſo many others of the ſame order? ſince death is fully as natural as life, and both arrive in the ſame manner, without our being able to perceive their approach. If we inquire of thoſe who are accuſtomed to obſerve the actions and ſentiments of the dying, we ſhall find that, except in a few acute diſeaſes, attended with agitations and convulſions, which exhibit only the appearances of pain, moſt men expire quietly, and without the ſmalleſt indication of uneaſineſs. Even when perſons ſeem to be afflicted with the moſt dreadful agonies, theſe have no exiſtence but in the imagination of the ſpectator: the truth of this has been repeatedly atteſted by many perſons who have recovered after the moſt violent commotions and convulſions, yet were unable to recollect any thing they had felt during this ſeemingly diſtreſsful ſituation. The greateſt part of mankind die, therefore, without being ſenſible of the fatal ſtroke; and of thoſe who preſerve their ſenſes to the laſt groan, there are very few who do not entertain ſome hope of recovery. Death is a ſpectre which terrifies us at a diſtance, but diſappears when we approach it more cloſely. That the ſucceſſion of ideas may be ſo rapid as to give to a moment the appearance of an age, and thus to ſubject our departure from exiſtence to excruciating torture, has been ſuppoſed without a ſingle proof in its favour, and againſt all probability and analogy. Exceſſive pain extinguiſhes all reflection; yet ſymptoms of the latter have ſometimes appeared in the very moment of violent death. When Charles XII. received the blow, which terminated, in an inſtant, both his enterpriſes and his exiſtence, he clapped his hand upon his ſword. This mortal pang, ſince it excluded not reflection, could not be exceſſive. He found himſelf attacked, and determined to defend himſelf; it is evident, therefore, that he felt no greater pain than he would have ſuffered from an ordinary ſtroke.

If it were as eaſy to diſſipate the terrors cauſed by the anticipation of what is to happen after death, and to quiet the minds of men concerning the undiſcovered country beyond the grave, the Tartarus, with its judges and furies, its lakes of liquid fire, and the other helliſh apparatus, as it is to prove that the termination of exiſtence is not phyſically painful, the human race would be moſt ſignally benefited, and would no longer have to envy brutes their peaceful death.

Rigidity of the body, joined with coldneſs, flaccidity of the cornea, open ſtate of the anus, lividity of the back, and a cadaverous odour, where they exiſt together, prove very ſatisfactorily that death has taken place.

It is hardly poſſible to ſet down any age as the natural period of life, as the moſt common and regular limit of advanced old age. Blumenbach obſerves, however, that a careful inſpection of ſeveral bills of mortality has ſhewn him, that a comparatively conſiderable number of Europeans reach their eighty-fourth year, while very few ſurvive it.

On the whole, although the human race is deſtroyed in ſuch numbers, among other cauſes, from the weakneſs of the thread of life in the early years, by the intemperance of manhood, by diſeaſe and accident, that not more than ſeventy-eight out of a thouſand die a natural death; yet, where human longevity is compared to the period of life of the other mammalia under ſimilar circumſtances, it will be ſoon diſcovered, that of all the complaints concerning the miſery of human life, none is more unfair than that of its ſhortneſs.

On the very intereſting ſubjects of the probabilities of life at different ages, the annual mortality in different countries and ſituations, the number of marriages, deaths, and births, the rate of increaſe of population, and the proportions deſtroyed in the different ways by which exiſtence is terminated, ſee Expectation *of Life*, Life-Annuities, and an excellent table by M. Dupré de St. Maur, drawn up from the liſts of twelve country pariſhes in France, and three in Paris, and publiſhed by Buffon, in his Hiſtory of Man, ſect. 5. Mortality, Marriage, and Population. For an account of individuals who have reached an unuſual age, and of the circumſtances, under which this has happened, ſee Haller's Elementa Phyſiologiæ, lib. xxx. ſection 3; the article Longevity in this Cyclopædia; and ſir John Sinclair on Health and Longevity, 4 vols. 8vo.

II. *Hiſtory of the Species.*

In the diverſity of the regions which he is capable of inhabiting, the lord of the creation naturally holds the firſt place among animals. His frame and nature are ſtronger and more flexible than thoſe of any other creature; and he dwells, without injury, in all ſituations on the ſurface of the globe. The neighbourhood of the pole and the equator, the higheſt mountains and the deepeſt rivers are occupied by him: his ſtrong but pliant body bears cold, heat, moiſture, light or heavy air; he can thrive any where, and runs into leſs remarkable varieties than any other animals which occupy ſo great a diverſity of abodes;—a prerogative ſo ſingular, that it is not to be overlooked.

What climates, what degrees of heat and cold can man bear? where does he live? and how is he able to endure ſuch various abodes? Is he indebted for this privilege to the ſtrength and flexibility of his organization, or, as Buffon aſſerts, merely to his reaſon? Does he conſtitute a diſtinct ſpecies; or is he allied in kind to the ourang-outang? How do climate, food, and ſimilar cauſes operate on him? Are theſe ſufficient to account for all the diverſities hitherto obſerved; or muſt we ſuppoſe that ſeveral individuals were originally created, each for its own climate? What country did he firſt inhabit, and what was the appearance of the original man? Did he go erect, or on all fours? was he a Patagonian, or an Eſkimau, Negro, or Georgian? Such are the important queſtions which we have to conſider in the preſent diviſion of the article;—queſtions, of which a full diſcuſſion would require a much greater extent and variety of knowledge than the writer can lay the leaſt claim to, as well as a much larger portion of ſpace than the limits of this work will allow. We muſt, therefore, be contented with exhibiting a few hints, rather than a complete view of the matter.

Abode of the human Species.—The ſituations occupied by man in the preſent times, extend as far as the known ſurface of the earth. The Greenlander and Eſkimau live in the eightieth, and even, perhaps, in ſtill higher degrees of north latitude.

latitude. Noogfack, a Danifh fettlement, lies in 72° north latitude; and the Greenlanders themfelves go much higher. Three Ruffians lived between fix and feven years on Spitzbergen, in latitude between 77° and 78°. See Dr. Aikin in the Manchefter Society's Memoirs, vol. i. p. 96. The Negro lives under the equator, and all America is inhabited even to Terra del Fuego. Cook difcovered land about the 58th and 60th degrees of fouth latitude, which he called Sandwich land; and a clufter of iflands as far as the 66th degree, on which he faw no men. Very probably there are no human inhabitants here: but it is fufficiently proved that places at leaft as cold are habitable. Perhaps we are not quite warranted in afferting that there are men in the interior of Africa; yet the accounts received from thofe on the coafts induce us to believe that thefe regions are in fome degree peopled. Hence we find that man is capable of exifting and propagating his fpecies in the hotteft and coldeft countries of the earth.

The greateft natural cold which has been afcertained by thermometrical meafurement, was that experienced by the elder Gmelin in the year 1735 at Jenifeik in 58 north latitude, and 110 eaft longitude (from Ferro). The mercury fell to 126 below 0. (Flora Sibirica, pref.) The fparrows and jays were killed. When Pallas was at Krafnaiarfk 56° north latitude, and 110° eaft longitude, the thermometer fell to 80° below 0; and the quickfilver froze in the bulb. A mafs of pure mercury, expofed in the open air, was frozen. (Travels in Ruffia, pt. 3.) Our own countrymen experienced apparently as fevere a degree of cold on the Churchill river in Hudfon's Bay. Brandy was frozen in the rooms where they had fires. (Phil. Tranf. N° 465.) Yet the Canadian favages and the Efkimau go to the chace in this temperature; and the inhabitants of the countries vifited by Gmelin and Pallas cannot remain conftantly in their houfes during their winters. Even Europeans, accuftomed to warmer climates, can undergo fuch cold as we have juft mentioned, and efcape unhurt, if they take exercife enough. The Danes have lived in Greenland in the 72° north latitude; and the Dutch, under Heemfkerk, wintered at Nova Zembla in 1597, in 76° north latitude. Some of them perifhed; but thofe who moved enough, and were in found health at firft, withftood the dreadful cold, which the polar bear (urfus maritimus), apparently born for thefe climes, feems to have been incapable of fupporting; for the journal ftates that, as foon as the fun finks below the horizon, the cold is fo intenfe, that the bears are no longer feen, and the white fox (canis lagopus), alone braves the weather. (Voy. de la Comp. des Indes, part i.) For an account of other examples, and particularly of one, in which three men remained for between fix and feven years in 78° north latitude, fee Dr. Aikin's Memoir, already quoted, concerning the attempts to winter in high northern latitudes.

The power of the human body to withftand fevere degrees of cold will appear in a more remarkable light, when we obferve what heat it is capable of bearing. Boerhaave afferted, that a heat of from 96° to 100° would be fatal to man. Adanfon faw the thermometer in the fhade at 108½ at Senegal in 17° north latitude; and Buffon cites an inftance of its being feen at 117½. Probably the country to the weft of the great defert is ftill hotter from the effect of the winds which have blown over the whole tract of its burning fands. When the firocco blows in Sicily, the thermometer rifes to 112°, according to Brydone. Dr. Chalmers obferved a heat of 115 in South Carolina, in the fhade: (On the Weather and Difeafes of South Carolina;) and Humboldt experienced a temperature from 110° to 115° in the Llanos or deferts near the Orinoco, in South America. (Tableau Phyfique des Regions Equatoriales.) Much greater degrees of artificial heat have been fupported. See HEAT, *Animal.*

Thus we fee that man can fuftain all poffible degrees of atmofpherical heat and cold. He has an equal power of fupporting varieties of preffure. We may reckon the ordinary preffure of the air, at the level of the fea, at 32,235 lbs. for the whole furface of the body; fuppofing the barometer to ftand at 30 inches. If we afcend to a height of 12,000 feet, (extenfive tracts in South America, inhabited by thoufands, have this height,) the barometer ftands at 20¼ inches, and the preffure is 21,750. Condamine and Bouguer, with their attendants, lived three weeks at a height where the barometer ftood at 15 inches 9 lines, and the preffure muft confequently have been 16,920. (Mem. de l'Acad. des Sciences, 1744.) In the Peruvian territory, extenfive plains occur at an altitude of 9000 feet; and three-fifths of the viceroyalty of Mexico, comprehending the interior provinces, prefent a furface of half a million of fquare miles, which runs nearly level at an elevation of from 6000 to 8000 feet. Mexico is 7475, and Quito 9550 feet above the fea. The hamlet of Antifana, 13,500 feet above the level of the fea, is the higheft inhabited fpot on the furface of our globe; but Humboldt afcended to 19,300 feet. (Tableau Phyfique des Regions Equatoriales; et Tableaux de la Nature.) There are no inftances of men living under a preffure much greater than we have juft mentioned: the depths to which the earth has been penetrated, in the operations of mining, are trifling in this point of view. In diving, however, the body is fubject to, and can bear feveral atmofpheres; as, on the contrary, in balloons, men have afcended beyond any point of elevation on the furface of the earth, and have confequently been expofed to a much more confiderable diminution of the ordinary preffure than what we have ftated above.

Food.—The great variety of fubftances, which man is not only capable of digefting, but from which his organs can extract wholefome nourifhment, contribute very effentially to his wide extenfion over the furface of the earth. We have already explained, under the article DIGESTION, that almoft the whole animal and vegetable kingdom afford food to man. Under particular circumftances, he can not only derive his nutriment exclufively from the animal kingdom, as in New South Wales, and in the Archipelago between Afia and America, from fifh; in the iflands to the fouth of Iceland, from fifh and puffins (fee fir G. Mackenzie's Travels in Iceland); but can confume what appears to us the moft filthy and difgufting objects. The Greenlander and the inhabitants of Alafka eat the whale, and can digeft this hard and revolting food without the affiftance of cookery. The former bury a feal, when they catch one, under the grafs in fummer, and the fnow in winter, and eat the half-frozen half-putrid flefh with as keen a relifh as the European finds in his greateft dainties. (Cranz Hift. of Greenland.) They drink the blood of the feal while warm, and eat dried herrings moiftened with whale oil. They mix frefh, putrid, and half-incubated eggs, whortle berries, and angelica, in a bag of feal-fkin, pour whale-blubber on it, and referve the infernal mixture as a delicacy for the winter. The people of admiral Monk, and fome Ruffians, caft away on one of the Aleutian iflands, greedily confumed the putrid remains of a whale; and the Greenlanders always difpofe of the whales ftranded on their coafts in this way, not defifting, however far putrefaction may have proceeded, till the whole is gone.

Even the earth, impregnated with the reliquiæ of animal and vegetable matter, affords food to fome favages. The Ottomaques, on the banks of the Meta and the Orinoco, feed

feed on a fat unctuous earth, or a species of pipe-clay tinged with a little oxyd of iron. They collect this clay very carefully, distinguishing it by the taste: they knead it into balls of four or six inches in diameter, which they bake slightly before a slow fire. Whole stacks of such provisions are seen piled up in their huts. Those clods are soaked in water, when about to be used; and each individual eats nearly a pound of the material every day. The only addition which they occasionally make to this unnatural fare, consists in small fish, lizards, and fern roots. The quantity of clay that the Ottomaques consume, and the greediness with which they devour it, seem to prove that it does more than merely distend their hungry stomachs, and that the organs of digestion have the power of extracting from it something convertible into animal substance. Humboldt Tableau Physique des Regions Equatoriales.

The researches of Meiners respecting food seem to have exhausted every accessible authority on the subject: his deductions, supported by an almost infinite number of quotations, exhibit so complete a view of the matter, that we present them to the reader in his own words. "The common positions concerning the earlier use of vegetables, and the effects of vegetable and animal food on the dispositions of people, have been brought forwards by men not acquainted with all the facts which history presents. There were formerly, and still are, many people, particularly among the dark coloured nations, who eat nothing, or almost nothing but flesh; and that with little or no preparation. Examples of this are afforded in Asia, by the Huns, Calmucks, and people of Thibet; by the Burates, Tungooses, Kamtschatkans, and eastern islanders; by the Ostiaks and Samoiedes, whom the Russians were obliged to imitate in Nova Zembla, and the Eastern ocean; by the Woguls, Circassians, Mingrelians, and Abcassas; and lastly, by some tribes in Babylon: in Europe, by the Alani, all the Celtic people, the Tartars of the Crimea, and even the inhabitants of St. Kilda: in America, by the Esquimaux, the Greenlanders, the North American savages, the Peruvians, and the inhabitants of Terra del Fuego: in Africa, by the Ethiopians and Gallas: in the southern countries, and the islands of the South Sea, by the New Hollanders, New Zealanders, and the inhabitants of the Friendly and Society islands.

"On the contrary, there have been, and still are, many people who live almost exclusively, or wholly on vegetables. Such are the Cretans, Spartans, and Romans, in certain periods; most of the Slavonic tribes; the Turks, Arabians, and Persians; the Mahometans, and still more the Brahmins in Hindoostan; the Chinese, Japanese, and certain of the Javanese; most of the Otaheitans, and inhabitants of the Marian islands; lastly, the Egyptians, Moors, Negroes, Hottentots, and inhabitants of Sennaar.

"The most common animal food is fish, which, in the warm climates of Asia and Africa, is seldom eaten except in a stinking or putrid state. After fish come pigs and dogs; then camels, mules, horses, and locusts. The southern people prefer smoked and salted, the northern fresh meat. The modes of preparation are very various: very few boil; most either dry or roast their flesh, and this in very different ways.

"Of vegetable foods, maize deserves the first place; then bananas, potatoes, yams, and other roots; rice, and millet. The history of our European corn is very obscure. Originally the corn was eaten either raw or roasted; or else it was pounded or bruised, and the meal taken, either raw, or roasted or boiled. Examples of these methods are still found. The vine, as well as some of our kinds of corn, are produced in much more southern countries than is commonly supposed.

"Of trees that produce fruits, those of the palm kind should be first mentioned; the sago and bread-fruit trees are much less widely extended. Many people eat acorns or chesnuts, or the rind or exuded juices of well known trees; or the pith, fruit, or roots of trees that we know little of. In other situations, moss or berries, or the roots and bulbs of known plants, have been employed. The fruit trees of our climates grow neither in the torrid nor in the frigid zones. The use of hot spices generally increases with the heat of the climate. The perfectly irregular meals of savages are less remarkable than the quick eating of the orientals.

"The orientals are the most moderate; all of Mongolian or mixed origin, in all climates, and even in the torrid zone, are the most voracious. Respectable writers bear testimony to this voracity in the Nogays, Tungooses, Baschkirs, and Kirgises; in the Greenlanders, Laplanders, and Fins; in the Hindoos, Tunquinese, and the inhabitants of Laos; in the Negroes and Hottentots; in the North and South Americans. There are situations, in which the appetite of new comers is much increased, or a greater quantity of food is required to support the bodily powers.

"These voracious people swallow with brutal avidity the most disgusting and difficultly digestible substances. The Calmucks devour putrid and stinking matters, the after-birth of animals, marmots, mice, otters, birds of prey, foxes, and wolves; but not dogs nor weasels. The Jakuts eat carnivorous animals; and the after-birth of their women is a delicious morsel, to which they invite their friends: they will not, however, touch frogs or pigs. The Tungooses and Ostiaks swallow slimy mud: the former also eat lice and the snot of their children. The Samoiedes eat putrid relics of horses, cats, dogs, whales, &c.; and the Kamtschatkans indigestible fungi. The women of the former used to eat the after-birth, that they might conceive again sooner. The Tschutskis and their guests drink the urine of the women; and the inhabitants of the Fox islands, besides lice, eat raw whale-blubber: they also lick themselves dry, after washing with urine. The Laplanders chew tobacco; stick it behind their ears, and then chew it again. The Tunquinese eat tigers, lions, snakes, bats, elephants, stinking and uncleaned fish; the Chinese, dead dogs, horses, and rats; the Arracanese, Siamese, and Formosans, besides such things, devour entrails, with all their contents. The inhabitants of the Bashee islands in the Indian ocean, who are in other respects cleanly, consider the contents of a goat's stomach as a great luxury. Crocodiles, eagles, ostriches, hippopotami, serpents, raw and putrid buffaloes and elephants, uncleaned entrails, toads, rats, and worms, the most stinking carcases, chalk, and earth, are eaten by the Negroes. The Bosjesmen make themselves fat with ants, and maggots of wood; and, like the Negroes, are fond of elephants' flesh, which they cut in pieces, and dry in the sun. The women of the Americans free each other from vermin, and eat them; and the contents of a rein-deer's stomach, mixed up with whale-oil or bears'-grease, is deemed a bonne bouche by the Greenlanders. They also cook fish with blubber, chewing them, and spitting them into the vessels, that nothing may be wasted: they stroke off the sweat with their fingers, and swallow it. The Californians not only consume lice, uncleaned entrails, serpents, lizards, insects of all kinds, maggots from rotten wood, spoiled corn full of worms, but also dry leather and clay; undigested grains of the pitochaias, which they get from human excrement; and lastly, rats and mice, which they put on the fire

for

for a ſhort time, and then ſwallow quite bloody. Beſides other matters, the Braſilians and Chileſe eat the bleeding hearts of their enemies; and the former alſo the bodies and broken bones of their children and leaders. The Caribs, and other people on the Orinoco, like the Negroes, eat chalk and clay; and make with them, and ſpoiled maize, balls which they moiſten with turtle fat, and ſwallow with great delight.

"Almoſt all people, even the wildeſt and moſt ſtupid, have deviſed methods for intoxicating or ſtupifying themſelves. For this purpoſe they either ſmoked or chewed leaves or herbs, in ſome inſtances. The orientals, who poſſeſſed the weſtern half of ſouthern Aſia, and the north-weſt ſide of Africa, have from early times preferred the uſe of opium; and the ſouth-eaſt nations, and their colonies, that of betel. The orientals and the Eaſt Indians drink wine to exceſs; but they prefer the ſpirit extracted from ſugar or rice, or ſtill ſtronger liquors. The Ruſſians in Siberia, and the European coloniſts in the torrid zone, drink brandy in great quantities. Palm and honey wine are very common in hot countries. There is ſcarcely any herb or vegetable production, and much leſs any article of vegetable food, from which intoxicating drinks have not been extracted. Bread, malt, meal, fruit, ſago, caſſava (juca dulce et amarga), potatoes, the aloe (agave americana), millet, and mares' milk, have been uſed for this purpoſe. The chica of the Americans, of which maize is the baſis, is the moſt diſguſting liquor. Very few people have been entirely unacquainted with boiling liquors: the love of theſe, however, ſeems particularly ſtrong in the ugly races of Aſia and America." Meiners' Grundriſs, p. 140—162.

On the ſubject of eating human fleſh, ſee the articles Cannibal and Anthropophagi.

In almoſt all ages there have been diſputes concerning the food beſt ſuited to the nature of man; whether a mixed diet, or one purely animal or vegetable, is moſt favourable to the developement of the bodily and mental powers. "The Pythagorean diet," ſays Buffon, "though extolled by ancient and modern philoſophers, and even recommended by certain phyſicians, was never indicated by nature. If man were obliged to abſtain totally from fleſh, he could not, at leaſt in our climates, either exiſt or multiply. An entire abſtinence from fleſh can have no effect but to enfeeble nature. To preſerve himſelf in proper plight, man requires not only the uſe of this ſolid nouriſhment, but even to vary it. To obtain complete vigour, he muſt chooſe that ſpecies of food which is the moſt agreeable to his conſtitution; and as he cannot preſerve himſelf in a ſtate of activity but by procuring new ſenſations, he muſt give his ſenſes their full ſtretch, and eat a variety of meats, to prevent the diſguſt ariſing from an uniformity of nouriſhment." We are told, on the other ſide, that, in the golden age, man was as innocent as the dove; his food was acorns, and his beverage pure water from the fountain: finding every where abundant ſubſiſtence he felt no anxieties, but lived independent, and always in peace both with himſelf and the other animals. But he no ſooner forgot his native dignity, and ſacrificed his liberty to the bonds of ſociety, than war and the iron age ſucceeded that of gold and of peace. Cruelty and an inſatiable appetite for fleſh and blood were the firſt fruits of a depraved nature, the corruption of which was completed by the invention of manners and arts. Either immediately, or remotely, all the phyſical and moral evil, by which individuals are afflicted and ſociety laid waſte, aroſe from theſe carnivorous practices.

We cannot give our approbation to either of theſe repreſentations, both of which are contradicted by the only criterion in ſuch queſtions, an appeal to experience. That men can be perfectly nouriſhed, and that their phyſical and intellectual capabilities can be fully developed in any climate, by a diet purely vegetable, has been proved by ſuch abundant experience, that it will not be neceſſary to adduce any formal arguments on the ſubject. The repreſentations of the Pythagoreans are the mere offſpring of imagination. We have not the ſhadow of a proof that this ſtate of ideal innocence, of exalted temperance, of entire abſtinence from fleſh, of perfect tranquillity, of profound peace, ever exiſted, or that it is more than a fable deſigned to convey to us moral inſtruction. If the experience of every individual were not ſufficient to convince him, that the uſe of animal food is quite conſiſtent with the greateſt ſtrength of body and of mind, the truth of this point is proclaimed by the voice of all hiſtory. A few hundreds of Europeans hold in bondage the vegetable eating millions of the Eaſt. We ſee the carnivorous Romans winning their way, from a beginning ſo inconſiderable, that it is loſt in the obſcurity of fable, to the empire of the world; we ſee them, by the power of intellect, eſtabliſhing that dominion which they had acquired by the ſword, and furniſhing ſuch compoſitions in poetry, oratory, philoſophy, and hiſtory, as are at once the admiration and deſpair of ſucceeding ages: we ſee our own countrymen rivalling them in arts and in arms, exhibiting no leſs ſignal bravery in the field and on the ocean, and diſplaying in a Milton and Shakſpeare, in a Newton, Bacon, and Locke, in a Chatham, Erſkine, and Fox, no leſs mental energy: yet, with theſe proofs before their eyes, men are actually found, who would have us believe, on the faith of ſome inſulated, exaggerated, and miſrepreſented facts, and ſtill more miſerable hypotheſes, that the developement, form, and powers of the body are impaired and leſſened, and the intellectual and moral faculties injured and perverted by animal diet.

The preſent ſeems a very proper place for conſidering a queſtion, that is frequently agitated on this ſubject; whether man approaches moſt nearly to the carnivorous or herbivorous animals in his ſtructure? We naturally expect to find, in the figure and conſtruction of the teeth, a relation to the kind of food which an animal ſubſiſts on. The carnivorous have very long and pointed cuſpidati or canine teeth, which are employed as weapons of offence and defence, and are very ſerviceable in ſeizing and lacerating their prey: theſe are three or four times as long as the other teeth in ſome animals, as the lion, tiger, &c. and conſtitute very formidable weapons. The grinding teeth have their baſes elevated into pointed prominences; and thoſe of the lower ſhut within thoſe of the upper jaw. In the herbivorous animals, theſe terrible canine teeth are not found, and the grinders have broad ſurfaces, oppoſed in a vertical line to each other in the two jaws: enamel is generally intermixed with the bone of the tooth in the latter, and thus produces ridges on the grinding ſurface, by which their operation on the food is increaſed: in the former, it is confined altogether to the ſurface. For further details on this ſubject, ſee Mammalia. The articulation of the lower jaw differs very remarkably in the two kinds of animals: in the carnivorous, it can only move forwards and backwards; in the herbivorous it has, moreover, motion from ſide to ſide. Thus we obſerve, in the fleſh eaters, teeth calculated only for tearing, and ſubſervient, in part at leaſt, to the procuring of food, as well as to purpoſes of defence, and an articulation of the lower jaw that precludes all lateral motion: in thoſe which live on vegetables, the form of the teeth, and the nature of the joint, are calculated for the lateral

ral or grinding motion: the former ſwallow the food in maſſes, while in the latter it undergoes conſiderable comminution before it is ſwallowed. The teeth of man have not the ſlighteſt reſemblance to thoſe of the carnivorous animals, except that their enamel is confined to the external ſurface: he poſſeſſes, indeed, teeth called canine, but they do not exceed the level of the others, and are obviouſly unſuited to the purpoſes which the correſponding teeth execute in carnivorous animals. Theſe organs, in ſhort, very cloſely reſemble the teeth of monkies, except that the canine are much longer and ſtronger in the latter animals. In the freedom of lateral motion, the lower jaw of the human ſubject reſembles that of herbivorous animals. In the form of the ſtomach again, and, indeed, in the ſtructure of the whole alimentary canal, man comes much nearer to the monkey than to any other animal. The length and diviſions of the inteſtinal tube are very different according to the kind of food employed. In the proper carnivorous animals the canal is very ſhort, and the large inteſtine is cylindrical; in the herbivora, the former is very long, and there is either a complicated ſtomach, or a very large cæcum and a ſacculated colon. In comparing the length of the inteſtines to that of the body in man, and in other animals, a difficulty ariſes on account of the legs, which are included in the former, and left out in the latter: hence the comparative length of the inteſtinal tube is ſtated at leſs than it ought to be in man. If allowance be made for this circumſtance, man will be placed on nearly the ſame line with the monkey race, and will be removed to a conſiderable diſtance from the proper carnivora. Soemmerring ſtates that the inteſtinal canal of man varies from three to eight times the length of the body. (De Corp. Hum. Fab. t. 6. p. 200.) In Tyſon's chimpanſee of 26 inches, the canal meaſured 159 inches, which is about ſix times the length of the body: in two ſapajous and two monkies, the inteſtines were reſpectively 62 and 96 inches, which muſt be conſiderably ſhorter in proportion, although the length of the body is not mentioned. P. 32.

The following are the comparative lengths of the canal and body in ſeveral ſimiæ, according to Cuvier, t. 3 p. 448. As the hind limbs are not included in the length of the body, it will be immediately apparent that the alimentary canal of theſe herbivorous animals is generally ſhorter than that of man.

	Body.	Inteſtinal Canal.

Man poſſeſſes a tolerably large cæcum, and a cellular colon, which we believe is found in no carnivorous animal. In general, then, the human teeth and joint of the jaw reſemble moſt thoſe of herbivorous animals: and man approaches moſt nearly in theſe, as well as in other points, to the monkey race, which are, in their natural ſtate, completely herbivorous.

In ſtating theſe circumſtances, we do not wiſh our readers to draw the inference, that man is deſigned by nature to feed on vegetables. The differences between him and other animals, render it difficult to apply to him reaſonings drawn from them. The hands of man, and particularly his arts, procure for him the food which carnivorous animals earn by their teeth. The proceſſes of cookery bring what he eats into a different ſtate from that in which it is employed by either carnivorous or herbivorous animals. Hence the analogy is too looſe for us to place much confidence on the reſults of theſe comparative views. We muſt truſt to experience alone for elucidating the great problem of diet: but the experimental mode of inveſtigation is ſo difficult; mankind are ſo averſe to relinquiſh long habits, and there are ſo many other cauſes affecting human health, that we are by no means ſanguine in our expectations of important reſults. Before we can venture to draw any inferences on a ſubject, beſet with ſo many obſtacles, we want to know the effects of a purely animal diet on ſeveral individuals of different habits. We muſt have accurate reports of their ſtate, both bodily and mental, and muſt learn the condition of two or three ſucceeding generations fed in the ſame way. A ſimilar ſtatement will be neceſſary on the operation of a ſtrictly vegetable diet. The drink, too, is an important conſideration. For further remarks on this ſubject, ſee Corpulency and Diet.

Abodes and Dreſs of various Nations.—We ſhall employ on this ſubject the obſervations of Meiners, who has collected his materials from every acceſſible ſource of information, both ancient and modern, and ſubjoined the numerous authorities from which they are derived.

Abodes.—There have been more people than is commonly ſuppoſed, without any, or at leaſt without any ſecure and protecting dwelling; and theſe were, without exception, dark coloured or ugly nations; ſuch were the Fenni of Tacitus, the ſavages about Hudſon's Bay, northwards from the river St. Laurence, and in North America in general, the Californians, Peruvians, the Indians near Garcias de Dios, the Braſilians, thoſe on the Oronoco and Maranon, the New Hollanders, ſome of the New Zealanders, ſome ſavages near Abyſſinia, and in Natal.

The firſt ſtep was made by thoſe who built huts incloſed on all ſides, but ſuch as were eaſily covered with leaves or branches, bark of trees or ſkins, and therefore admitted of being ſeparated and conveyed from place to place. Almoſt all the inhabitants of northern Aſia, Europe, and America; the Burates, and Tungooſes; the Samoiedes, Jakuts, and Oſtiaks; the Greenlanders, Laplanders, and people about Hudſon's Bay; the Chileſe, and ſome ſavages in Louiſiana; and the loweſt inhabitants of Sumatra, Arabia, and Hindooſtan, have ſuch huts.

More ſolid and perfect edifices were conſtructed with beams, or ſtones, or woodwork; the walls covered with earth. In this way the Greeks, Germans, and Slavons of ancient times built; the ſame method is adopted ſtill by the Morlachians, the inhabitants of ſeveral German and Turkiſh provinces; the Finnic and mixed races in Europe and Aſia; the Ruſſians and Icelanders; ſeveral ſavages in America; moſt of the Negroes; the Cabyles and Moors in Africa, ſeveral of the Arabians, and Perſians, Hindoos, Ceyloneſe, Chineſe, and Japaneſe.

The mode of building is modified by various cauſes. Conſtant danger taught the nations of the middle ages, the Greeks of the iſlands, the Mingrelians, the inhabitants of Sumatra, the Baſhee iſlands, New Zealand, &c. to provide themſelves with the means of ſafety. Thoſe who are expoſed to earthquakes, inundations, vermin, rapacious animals, will build differently from ſuch as know nothing of theſe evils. Extreme heat and cold of the climate require different methods; paſtoral and agricultural people will lodge themſelves very differently. There are many reaſons

why

why this part of the world has produced chef-d'œuvres of architecture, and why the subjects of the despots of Europe, Asia, and Africa, are worse off in their houses than the free subjects of the more happy states. In comparing the descriptions of the dwellings and cities of the Turks, Moors, Persians, Arabians, Hindoos, Siamese, Tunquinese, Chinese, inhabitants of Thibet, Formosans, and Japanese, we cannot help wondering at the remarkable uniformity of architecture in such different nations. The most uncultivated people in Africa and America had public buildings." Meiners Grundriss, chap. 5.

Dress and Ornament.—"As there have been people, without any secure habitation, so there have been many without any dress, or at least such as covered the greatest part of the body. The Celtic nations were formerly naked or nearly so; and this is the case at present with the Mingrelians, the inhabitants of Terra del Fuego and their neighbours, and the New Hollanders. The savages of California, Louisiana, the isthmus of Darien, Guiana, Brazil, and Paraguay, several islands of the South Sea, and several negroes, go also naked.

The place of clothing is supplied in the naked people by smearing the body with oil or grease, generally mixed with coloured earths or plants. Painting of the whole body, or of parts, and particularly of the face, has been a chief object and employment of vanity with nearly all the savage people of the world. One or the other was practised by the Celts, Persians, and Medes: the custom still prevails in Asia among the Brahmins, Hindoos, and their women; among the females of the Arabians, Persians, Turks, Armenians, Egyptians, and Mingrelians, to whom we may add those of the Greeks, Walachians, and Russians; also the Chinese, Peguans and Siamese, the New Hollanders, New Zealanders, inhabitants of several South sea islands, and the Kamtschatkans; the Negroes and Hottentots, and all the wild Americans, both north and south. The practice of puncturing and tattooing the skin, performed with very various objects, and on very different parts, has not been less universal; we find, at least, that it has existed among the Celts, the Egyptians, Syrians, Brahmins, and Arracanese, the Turks, Arabians, Moors, and the Formosans, the Tungooses, Ostiaks, Greenlanders, and eastern islanders, the North and South Americans, and the South sea islanders. Instead of punctures and lines incisions with a knife were made in some instances.

Great attention has generally been paid to decorating the hair, to changing its colour by powders and grease, to curling it in various ways, or adorning it with feathers and other articles. The women of the Greeks and Romans, even in their times of simplicity, were distinguished in this way, also the Turks and Moors and their women, the southern islanders, most of the negroes, and nearly all the American savages. Several people, from their notions of beauty, have employed themselves in staining, filing, and otherwise decorating their teeth: also in colouring and encouraging the growth of their nails. Still more extraordinary attempts at personal decoration have been made by the Giaga women, several negroes of both sexes, the Carib women, the Gallas, and the natives of Natal.

With the view of beautifying the person, the ears and nose have been perforated, and the lips and cheeks either slit up, or perforated. The latter practice has been observed chiefly in the inhabitants of the eastern islands, and the savages of Paraguay and Brazil; but it was much more common to make holes in the ears or nose, to hold rings or other ornaments. This was carried no where so far as in south America, the eastern islands, and those of the south sea. The taste for rings, not only in the ears and nose, but also about the neck, arms, legs, body, &c. prevails still chiefly in Africa and Asia, where it has existed from the earliest times. The Europeans also, in the dark ages, took pleasure in sounding and heavy ornaments. The decoration of the female head was formerly, and still continues, the most complex and heavy, in the oriental nations of Asia, and the mixed people of Siberia. The astonishing ornaments made of feathers are among the peculiarities of the Americans.

The inhabitants of cold climates resemble each other in their dress more nearly than those of warm ones. The latter wear either an apron or shirt, with or without breeches, mantle, and pelisse or covering of fur. The southern people distinguish themselves by having the head either covered or naked. Women have generally been clothed like the men. Leather and felt, and the most simple kind of weaving, appear to be all of nearly equal antiquity. Barbarous people generally like the most lively colours, but here, as in most other remarks on man in general, there are many exceptions. Ibid. ch. 6.

Does Man constitute a distinct Species?—The differences between man and animals constitute a very important subject in his natural history. We feel here, what we have often occasion to observe in the study of natural history, and particularly of zoology, that it is much easier to perceive, as it were intuitively, the distinctive characters of two neighbouring species of animals, than to express them in words. Thus we readily discern the difference between the rat and the mouse, the hare and the rabbit, though it would be much more difficult to describe clearly the characteristic marks on which that difference rests. That this kind of difficulty exists in the present subject has been candidly confessed by some great men. Linnæus, whose sagacity in perceiving the characteristic marks of the various objects of natural history, and in expressing them in appropriate language, has never been exceeded, observes in the preface of his Fauna Suecica "rem perquam arduæ indaginis esse propriam tradere hominis differentiam specificam; et nullum se hactenus characterem eruere potuisse, unde homo a simia internoscatur." In the Systema Naturæ he again says, "mirum adeo parum differre stultissimam simiam a sapientissimo homine, ut iste geodætes naturæ etiamnum quærendus, qui hos limitet;" accordingly he gives neither the generic nor specific character of man in that work, but puts him on a level with the long-armed ape, (under the name of homo lar.)

Other authors have distinctly asserted the opinion that man and the monkey, or ourang-outang, belong to the same species, and are no otherwise distinguished from each other, than by circumstances, which can be accounted for by the different physical and moral agencies to which they have been exposed. (Monboddo on the Origin and Progress of Language, vol. i. and Ancient Metaphysics, vol. iii. Rousseau sur l'Inegalité des Conditions, note 10.) The former of these writers even supposes that the human race once possessed tails; and he says "the ourang-outangs are proved to be of our species by marks of humanity that I think are incontestible." The latter conceives that the observations of travellers, concerning various animals of the monkey kind, prove the existence of wild men. "Toutes ces observations sur les variétés que mille causes peuvent produire et ont produit en effet dans l'éspece humaine, me font douter si divers animaux semblables aux hommes, pris par les voyageurs pour des bêtes sans beaucoup d'examen, ou a cause de quelques différences qu'ils remarquoient dans la conformation exterieure, ou seulement parceque ces animaux ne parloient pas, ne seroient point en effet de veritables hommes sauvages, dont la race

race difperfée anciennement dans les bois n'avoit eu occafion de développer aucune de fes facultés virtuelles, n'avoit acquis aucun degré de perfection, et fe trouvoit encore dans l'état primitif de nature."

Other writers, who have pleafed themfelves with defcribing what they call a regular gradation or chain of beings, reprefent man only as a fuperior kind of monkey; and place the unfortunate African as the connecting link between the fuperior races of mankind and the ourang-outang. (White's account of the regular gradation in man and animals, &c. 4to. London 1779.) The precife meaning of the word gradation, in this mode of employing it, we do not underftand, nor do thofe who ufe it favour us with any definition of a term fo very important in fettling the queftion: we conceive the meaning to be that man is not a race originally diftinct from monkies. That the flave merchant, who traffics in human blood, and the negro-driver, who ufes his fellow creatures worfe than brutes, fhould endeavour to juftify their conduct by depreffing the African to a level with the brute, is what we might reafonably expect, as well as to hear the flave traffic commended becaufe it imparts to the negroes the bleffings of Chriftianity: but we fhould not have expected to find fuch opinions defended by the natural hiftorian: and we fhall not hefitate to affert that they are as falfe philofophically, as the moral and political confequences, to which they would lead, are fhocking and deteftable. We fet out with this pofition, that man has numerous diftinctive marks, by which, under every circumftance of roughnefs and uncivilization, and every variety of country and race, he is feparated by a broad and moft clearly defined interval from every other animal, even of thofe fpecies which, from their general refemblance to the human fubject, have been called anthropo-morphous. We cannot, indeed, by any means coincide with thofe moderns who have indulged their imaginations in painting a certain continuity or gradation of created beings; and who fancy they have difcovered great wifdom of the creator, and great wifdom of the creation in this refpect; that nature makes no leaps, but has connected the various objects of the three kingdoms with each other like the fteps of a ftair-cafe, or the links of a chain. The candid and unprejudiced obferver muft allow, that in the animal kingdom there are whole claffes, as birds, and particular genera, as the cuttlefifh, which cannot find a place in fuch a fcheme of arrangement without a very forced and unnatural introduction: and again, that there are certain genera, as the coccus, where the two fexes are fo different from each other, that the male and female muft be feparated, and occupy different parts of the fcale in this artificial plan of gradation.

The completely unfupported affertions of Monboddo and Rouffeau only fhew that they are equally ignorant of the ftructure and characters of men and monkies, and that they know nothing of the laws, according to which the deviations of an animal from the original ftock take place. We fhould not wafte a moment in refuting what is not defended by a fingle proof. But the fubject is important and very interefting and we fhall therefore confider at fome length what are the fpecific characters of man.

In this part of our fubject we fhall have frequent occafion to mention the ourang-outang, and therefore think it neceffary to obferve, that two diftinct fpecies have been confounded under this common appellation. Linnæus, Buffon, and Erxleben, have not rectified this miftake, although Blumenbach had long ago pointed it out. The latter author, in his manual of natural hiftory, defcribes, under the name of fimia troglodytes, the animal of which Tyfon, in his anatomy of the pigmy, has given fo excellent an anatomical defcription. It is found in Angola, Congo, and the interior of Africa, and, as well as the following, reaches about the fize of a boy eight years old. It is called chimpanfee, and has been defcribed by the names pongo, jocko, and barris. It is diftinguifhed by its black hair and very large ears; and has a nail on the thumb of the hind hand. The fimia fatyrus is the proper ourang-outang (which word, in the Malay language, means man of the woods), is found in the ifland of Borneo, and is the animal diffected by Camper. It has reddifh-brown hair, and no nail on the thumbs of the hind hands.

Diftinctions between Man and Animals.—The circumftances which diftinguifh man from other animals, may be confidered under the divifions of 1, external conformation; 2, internal ftructure; 3, functions of the animal economy; 4, faculties of the mind; 5, difeafes; 6, alleged, but not well-grounded differences.

1. *External Conformation; erect Stature.*—Under the firft head we remark, as the moft diftinguifhing peculiarity of man, his erect ftature: that majeftic attitude which announces his fuperiority over all the other inhabitants of the globe. He is the only being adapted by his natural formation to the upright pofition. Enflaved to their fenfes, and partaking merely of phyfical enjoyments, other animals have the head directed towards the earth: "quæ natura prona atque ventri obedientia finxit." Man, whofe more elevated nature is connected to furrounding objects by moral relations, who can embrace in his mind the fyftem of the univerfe, and follow the connections of caufes and effects, boldly regards the heavens, and can direct his fight even into the ftarry regions.

> "Pronaque cum fpectent animalia cetera terram,
> Os homini fublime dedit; cœlumque tueri
> Juffit; et erectos ad fidera tollere vultus."

In confidering this diftinction, it will be neceffary for us to prove two points: 1, that the erect ftature is fuited to the organization of the human fubject; 2, that it is peculiar to man.

Erect Attitude fuited to the human Organization.—The former is clear from what we fhall obferve afterwards, concerning the arrangement of certain parts of the human frame; it is not lefs evinced by the invariable practice of all nations in all ages of the world. The individuals of no nation, even in the wildeft ftate, have ever gone on all fours; and no animal has ever altered its gait. The chief fupport of this notion concerning the human fubject being defigned to fupport the body on four limbs, has been derived from the examples of children loft in woods and growing up in a wild ftate. Can we conceive any thing more widely removed from the natural condition of man than thefe wretched individuals? and might we not as well adopt any monftrous birth for a model of the human form, as draw our notions of attitude and way of life from thefe fpecimens? Moreover, if we look attentively into the moft authentic accounts of thefe wild men, we fhall find, that in the leaft fufpicious inftances they were erect; as for inftance, Peter the wild boy (Blumenbach in Voigt's Magazin fur Phyfik, &c. v. iv. pt. 3. p. 91. Monboddo Ancient Metaphyfics, v. iii. p. 57 and 367.), the girl defcribed by Condamine (Hiftoire d'une jeune fille Sauvage, Paris, 1761, 12mo.), a man found in the Pyrenées (Leroy fur l'Exploitation de la Nature dans les Pyrenées, London, 1776, 4to. p. 8.); and the young favage of Aveyron (Hiftorical Account of the young Savage of Aveyron, London, 12mo.) On the other hand, where they have been defcribed as going on all-fours, many circumftances of a very fufpicious kind will be detected in the narrative, as in the account of the juvenis ovinus Hibernus of Linnæus: we cannot therefore help fufpecting that Linnæus's homo fapiens ferus has no more claim to the epithet *tetrapus* than to that of hirfutus.

That the ftructure of the human body is adapted to the erect attitude, may be deemed fo clear as to need no proof: but two refpectable authors have defended the contrary paradox (Mofcati von der körperlichen wefentlichen unterfchiede zwifchen der Structur der Thiere und der Menfchen; Göttingen, 1771, 8vo. and Schrage in a Dutch Journal.)

Structure of the lower Limbs.—The fupport of the trunk upon the two lower limbs, and its being moved by the mufcles of thofe limbs, lead us to expect great peculiarities in their ftructure. We find accordingly, that man is diftinguifhed by the great length of the legs in comparifon to the trunk and to the arms. Daubenton's affertion, that no animal but man has lower extremities equalling the trunk and head together in length, is nearly correct: (the kanguroo, jerboa, &c. form exceptions, but do not invalidate the affertion fo far as regards our prefent purpofe.) The hind limbs of the ourang-outang fall very far fhort of this proportion. This length of the legs, which is fo convenient in our erect attitude, makes us altogether unfit for going on all-fours, as any perfon will immediately difcern by making or obferving a trial: the limbs in fuch an experiment muft be thrown obliquely backwards, or the articulations held in a bent and very infecure pofition. Even children, before they can walk, in whom the lower limbs are comparatively fhorter than in adults, crawl upon their knees, or elfe drag the lower extremities after them on the ground. The feet of man are much broader than thofe of any animal, and admit of being feparated more widely from each other. The fources of the latter prerogative refide in the fuperior breadth of the human pelvis, and in the length and obliquity of the neck of the femur, which, by throwing the body of the bone outwards, difengages it from the hip-joint. The whole tarfus, metatarfus, and toes, reft on the ground in the human fubject, and afford an ample bafe of fupport for the body. The fimiæ and the bear have the end of the os calcis raifed from the furface; while, on the contrary, it projects in man, and its prominent portion has a moft important fhare in fupporting the back of the foot: it is larger and more prominent in man than in any animal. The thigh-bone is ftraight, and its two condyles of equal length in the ourang-outang. The thigh is placed in the fame line with the trunk in man; it always forms an angle with the fpine in animals; and this is often even an acute one: the unfteadinefs of the erect attitude, and the difficulty of maintaining the equilibrium under fuch an arrangement, are too obvious to need any particular explanation.

Not only the length, but alfo the remarkable ftrength of the legs, when contrafted with the flender arms, clearly fhew that the former are defigned for fupporting and moving the body. And here we may adduce a further argument drawn from the progrefs of offification. The bones of the tarfus, and particularly the os calcis, offify at an earlier period, and advance more rapidly in their developement than thofe of the carpus. Very little ftrength of hand is required in the firft years of life, while the feet, at the end of twelve months, begin to be employed in fuftaining the body, and advancing it by progreffive motion.

The Mufcles.—The extenfor mufcles of the ankle joint, and chiefly thofe which form the calf of the leg, are very fmall in the mammalia, even in the genus fimia. The peculiar mode of progreffion of the human fubject accounts fufficiently for their vaftly fuperior magnitude in man. By elevating the os calcis, they raife the whole body in the act of progreffion; and, by extending the leg on the foot, they counteract that tendency, which the weight of the body has to bend the leg in ftanding. Hence Ariftotle, and others after him, very juftly obferved, that true calves of the legs can be afcribed to man only. See GASTROCNEMIUS and MUSCLE, under the head of *Standing and walking*.

The extenfors of the knee are much ftronger in the human fubject than in other mammalia; as their double effect of extending the leg on the thigh, and of bringing the thigh forwards on the leg, forms a very effential part in the human mode of progreffion. The flexors of the knee are, on the contrary, ftronger in animals; and are inferted fo much lower down in the tibia (even in the fimia) than in the human fubject, that the fupport of the body on the hind legs muft be very infecure, fince the thigh and leg form an angle, inftead of being continued in a ftraight line.

Upper Limbs.—A very curfory infpection of the upper limbs will convince us, that, whether we regard the fituation and mode of their connection to the trunk, or the direction and arrangement of the articulations throughout, they are entirely unfuited to the office of fupporting the body, and as well calculated for the ufes to which we put them, of feizing and holding objects, and thereby executing, befides all the proceffes of the arts, a thoufand minute but moft ferviceable actions of conftant recurrence. The arms, inftead of falling perpendicularly under the anterior part of the trunk, are thruft outwards by the clavicles; the glenoid cavities of the fcapulæ, inftead of being directed downwards, as in quadrupeds, look outwards: the elbows bend outwards, inftead of forwards, &c.

Thorax.—The whole arrangement of the thorax fhews man to be a biped. Thofe quadrupeds which have long legs, have a thorax compreffed at the fides, narrow and keel-fhaped in front, confequently deep from the fpine to the fternum, but confined in the tranfverfe dimenfion, and they are deftitute of clavicles, fo that the front legs come together, and fupport with greater firmnefs and facility the front of the trunk. They poffefs moreover a longer fternum, or a greater number of ribs (18 in the horfe), which advance nearer to the crifta of the os innominatum, for the purpofe of fupporting the abdominal vifcera in the horizontal pofition of the trunk. Even in the ourang-outang, the meafurement of the thorax from fpine to fternum exceeds that from fide to fide. (Œuvres de P. Camper. i. p. 115.) All thefe particulars are different in man. His thorax is flattened in front, very broad, but fhallow from before backwards: the humeri are thrown to the fides of the trunk, and thus acquire a more extenfive range in their motions: the fternum is fhort, and the abdomen unprovided with bony fupports in a very great fhare of its furface. Thefe, with other points which cannot efcape obfervation, when the fkeleton of any rather long-legged quadruped is compared to that of man, fhew how unfit he is for the attitude on all fours, which in his cafe can never be otherwife than unfteady, irkfome, and fatiguing in the higheft degree.

Pelvis.—The peculiarities of the human pelvis afford a ftrong confirmation of what we have already ftated. The form of this part is very characteriftic in man, and enables us to diftinguifh him from the anthropo-morphous fimiæ, and indeed from all the other mammalia. Although it might found paradoxical and affected, yet we could defend the affertion that the human fkeleton alone has a proper *pelvis;* that is, fuch a connection of the facrum and coccyx with the offa innominata, as forms a cavity refembling a bafon; from which the elongated offa innominata of other mammalia differ toto cœlo. In the ourang-outang and elephant we find the nearest approach to the human formation: in the former, however, the upper part of the ileum is narrow and elongated, stretching upwards in the direction of the spine, and its length exceeds its breadth, so that the relations of these two dimensions are very different in man and this animal. The height of the whole pelvis, from the tuber ischii to the anterior spine of the ileum, is 7 in. 3 li. in man, and 6 in. in the ourang-outang; its breadth between the two anterior spines in the former 10 in. 6 li.; in the latter 6 in. 6 li.: in the latter the symphysis pubis is very deep: and in both, there is neither that incurvation of the sacrum from its promontory dowawards, nor that direction of the coccyx towards the front, which, with the broad, horizontal expansion of the ilia, and the slenderness of the symphysis pubis are peculiar to the human frame, and constitute a broad and firm basis for the trunk, on which the weight of the abdominal contents is supported. The sacrum of the ourang-outang is flat and contracted, and continued in a straight line with the vertebral column.

Further Proofs.—Such then are the supports by which the trunk of the human body is firmly maintained in the erect position, and such are the properties of the trunk contributing to the same end. The breadth of the human pelvis affords a firm basis, on which all the superior parts rest securely; the same part is so narrow in other animals, that the trunk represents an inverted pyramid: there must consequently be great difficulty in maintaining it in a state of equilibrium, if it were possible for the animal to assume the erect position. In those instances where the pelvis is broader, the other conditions of the upright stature are absent: the bear, however, forms an exception to this observation, and consequently may be taught to stand and walk erect, although the posture is manifestly inconvenient and irksome to the animal. When quadrupeds endeavour to support themselves on the hind extremities, as, for instance, for the purpose of seizing any objects with the fore-feet, they rather sit down than assume the erect position. For they rest on the thighs as well as on the feet, and this can only be done where the fore-part of the body is small, as in the simiæ, the squirrel, &c.: in other cases the animal is obliged to support itself by the fore-feet also, as in the dog, cat, &c.

The perpendicular position of the vertebral column under the centre of the basis cranii, and the direction of the eyes and mouth forwards, would be as inconvenient to man, if he went on all fours, as they are well adapted to his erect stature. In the former case he would not be able to look before him; and the great weight of the head, with the comparative weakness of the extensor muscles, and the want of ligamentum nuchæ, would render the elevation of that organ almost impossible. See CRANIUM, under the head of "comparison of the human skull with that of animals," and HEAD.

Every part of the skeleton would lead to the same inference on this subject: but we forbear to enter into further detail, as being unnecessary. The reader will meet with some observations on this subject in the articles EXTREMITIES and MUSCLE.

The relation of the neighbouring soft parts to the pelvis deserves our consideration. Its posterior surface gives origin to the glutei muscles, of which the exterior (glutei magni), exceeding in size all others in the body, and covered by a remarkable stratum of fat, form the buttocks, which, by their ample, fleshy, and convex protuberances, conceal the anus, and are accounted, both by the classical authors in natural history, as Aristotle and Buffon, and by the greatest physiologists, as Galen and Haller, as the chief character by which man is distinguished from the buttockless simiæ. "Les fesses," says the great historian of nature, "n'appartiennent qu'a l'espèce humaine." The final cause of this prerogative has been assigned by an anatomist: "Solus homo ex omnibus animalibus commode sedet, cui carnosæ et magnæ nates contigere, et pro substernaculo pulvinarique, tomento repleto, inserviunt, ut citra molestiam sedendo, cogitationibus rerum divinarum animum recte applicare possit." Spigel. de Hum. Corp. Fab. p. 9.

The use of the glutei, however, is not confined solely to what the pious Spigelius has imagined, *viz.* the forming a cushion on which the body may be softly supported for the purposes of divine cogitation; but they are very important agents in extending the pelvis on the thighs, and maintaining it in that state in the erect position of the trunk. (See GLUTEUS.) Thus the muscles are particularly connected with the attitude of man; and hence the gluteus maximus, which is the largest muscle of the human body, is so small and insignificant in animals, that it may be almost said not to exist. F. Cuvier says of the ourang-outang "les fesses etoient presque nulles, ainsi que les mollets." Annales du Museum, t. 16. p. 47.

Direction of the Vagina.—The peculiar curvature of the human sacrum and os coccygis gives rise to the particular direction of the organs of generation, and especially of the vagina. That canal, which in the other female mammalia nearly follows the axis of the pelvis, is placed almost at right angles to that axis in the woman: hence parturition is more difficult; but many inconveniences, to which she would have been otherwise exposed, particularly during pregnancy, are obviated.

From this direction of the vagina we explain why the human female is not, like that of brutes, retromingent: and there is this further difference, that the orifice of the urethra in brutes, instead of being placed as in woman, within the labia pudendi, opens into the vagina itself: such at least is the case, according to Blumenbach, in the papio maimon, and simia cynomolgus.

The same circumstance concerning the direction of the vagina will enable us to determine the question agitated from the time of Lucretius, about the most natural posture for the act of copulation, "et quibus ipsa modis tractetur blanda voluptas."—"Quanquam enim," says Blumenbach, "non uno tantum modo sacra hæc celebrare possit homo, eademque cultus varietas a Latinobarbaris ad ea relata sit, quibus ipse a brutis differat, imo et physicæ causæ quandoque intercedere possint, quæ eundem 'more ferarum, quadrupedumque magis ritu' concumbere suadeant; in universum tamen vaginæ ad virilem hastam relatio obversæ veneri magis adaptata videtur." The opinion referred to in this passage by Blumenbach is in the commentaries of Berenger of Carpi, on the anatomy of Mundinus, p. 13. "Homo inter cætera animalia coit per diversos situs, dando amplexus et oscula, et detestandus est in hoc, quia est magis vitiosum ac voluptuosum et diabolicum, quam rationale."

"Monkies always copulate backwards: this is performed sometimes when the female is standing on all fours; and at other times the male brings her between his thighs when he is sitting, holding her with his fore-paws." Hunter on the Animal Economy, p. 136.

That we may finish at once what we have to observe concerning these organs of the female, we add a few remarks on the hymen, &c. It has been generally asserted that this membrane is found nowhere but in the human subject: but there are doubts on this point. (See GENERATION.) Blumenbach examined many animals of the genus simia, and a female elephant, without finding either hymen, or any thing like carunculæ myrtiformes. It is a very singular part of the

the female frame, and one for which no rational ufe has been hitherto affigned. See GENERATION.

The nymphæ and clitoris, which have been fuppofed, like the hymen, to be peculiar to the human fubject, are certainly found in many animals.

Man is a two-handed Animal.—From the erect attitude of man arifes another very diftinguifhing prerogative ; *viz.* the moft free ufe of his two very perfect hands. So greatly does he excel other animals in the conformation of thefe parts, that Anaxagoras was hence induced to make an obfervation, which Helvetius has again brought forwards in our time, " that man is the wifeft of animals, becaufe he poffeffes hands." This indeed is too much, yet Ariftotle is well juftified in obferving that man alone poffeffes hands really deferving that name. Several genera of the mammalia poffefs hands ; but they are much lefs complete, and confequently lefs ufeful than that of the human fubject, which well deferves the name given to it by the Stagyrite, of the organ of all organs. The great fuperiority of that moft perfect inftrument, the human hand, arifes from the fize and ftrength of the thumb, which can be brought into a ftate of oppofition to the fingers, and is hence of the greateft ufe in enabling us to grafp fpherical bodies, and take up any object in the hand, in giving a firm hold on whatever we feize, in executing all the mechanical proceffes of the arts, in fhort, in a thoufand offices, which occur every moment of our lives, and which either could not be accomplifhed at all, if the thumb were abfent, or would require the concurrence of both hands, inftead of being done by one only. All the fimiæ poffefs hands : but the moft diftinguifhing part, namely the thumb, is flender, fhort, and weak, even in the moft anthropo-morphous : regarded as an imitation of the human ftructure, it would almoft warrant the term employed by Euftachius, ridiculous : and the other fingers are elongated and flender. The thumb reached to the firft articulation of the index in the ourang-outang defcribed by F. Cuvier, Annales du Mufeum. t. 16. p. 47.

Monkies are four-handed.—The monkies, apes, and other anthropo-morphous animals can, in fact, be called neither bipeds nor quadrupeds ; but they are quadrumanous, or four-handed. Their pofterior limbs are furnifhed with a thumb, inftead of a great toe ; which latter part belongs only to man, and arifes from the manner in which his body is fupported in the erect pofition.

By a thumb we mean a member, not placed in a parallel direction to the other fingers, but ftanding off from them laterally, enjoying a free power of feparate motion, and, therefore, capable of being brought into oppofition to the other fingers, fo as to give to the member the power of grafping or prehenfion. A great toe, in its direction, articulations, and extent of motion, correfponds entirely to the other toes ; whereas, the joints and mufcles muft be altogether different in the thumb. It is hardly neceffary to point out how entirely unfit the human feet are for all purpofes of prehenfion : but the hind limbs of the fimiæ really deferve the name of hands more than the front ; and are more advantageoufly conftructed for holding. There is, too, a kind of monkey (fimia panifcus, Linn. Coaita, Buff.) without any thumb to the fore limb ; but no fpecies has been difcovered without the thumbs on the hind-limbs.

Hence the difpute concerning the mode of progreffion of the ourang-outang and other fimiæ ; *viz.* whether they go on all-fours, or are fupported by the pofterior limbs only, will be eafily fettled. Neither of thefe reprefentations is correct. Since the hands of thefe animals are not formed for walking, but for feizing and holding objects, it is clear that nature has defigned them to live chiefly in trees. They climb thefe, and feek their food in them ; and one pair of hands is employed in fixing and fupporting the body, while the other gathers their food, or ferves for other offices. Hence fome, who have lefs perfect hands, are furnifhed with prehenfile tails, by which they can be more fecurely fupported in trees.

It is hardly neceffary to add, that when we fee monkies walking erect, it is to be afcribed to inftruction and difcipline. The delineations of the ourang-outang, taken accurately from the life, fhew how inconvenient and unnatural the erect pofture is to thefe animals : they are drawn with the front hands leaning on a ftick, while the pofterior ones are gathered up into the appearance of a fift. No inftance has ever been produced of a monkey, nor of any other animal, except man, which could preferve his body in a ftate of equilibrium, when ftanding on one foot only. All thefe confiderations render it very clear, that the erect ftature not only arifes out of the ftructure and conformation of the human body, but alfo that it is peculiar to man : and that the differences in the form and arrangements of parts, derived from this fource only, are abundantly fufficient to diftinguifh man by a wide interval from other animals.

Monkies not conftructed for the erect Attitude.—The circumftances in the ftructure of the monkey kind, which render them unfuited for the erect attitude, have been already in part explained : *viz.* the narrownefs of the pelvis, fhort and weak lower limbs, fmall fize of the mufcles compofing the buttocks and calves, and flight prominence of the os calcis, which does not come to the ground. We may add, that the exterior margin of the foot chiefly refts on the ground in the fimiæ, which circumftance, while it leaves them a freer ufe of their thumb and long toes in feizing the branches of trees, &c. renders the organ fo much the lefs adapted to fupport the body on level ground. The plantaris mufcle, inftead of terminating in the os calcis, expands into the plantar fafcia, in animals of the monkey kind ; and in other quadrupeds it holds the place of the flexor perforatus digitorum pedis, paffing over the os calcis in fuch a direction, that its tendon would be compreffed, and its action impeded if the heel refted on the ground.

It is rather fingular, fince perfons have been found to contend that man ought to go on all-fours, that there fhould have been others, who undertake to prove, that the ourang-outang, and the monkey tribe in general, have an organization fuited to biped progreffion. Buffon even ftates, that one which he faw always went on two feet, and he afcribes the erect attitude to him without any hefitation. We do not doubt that he can fuftain this pofture for fome time, and when in the unnatural condition of confinement, he may frequently fit : hence, perhaps, we may account for the numerous obfervations in which he is faid to go erect. But the circumftances of ftructure already explained, fhew moft clearly that he is not calculated, like man, for that attitude ; and we find, in fome of the moft authentic accounts, that he is faid to go on all-fours. Allamand, who faw one (fimia fatyrus) in Holland, gives us the following account of its motions and attitudes. " Its ufual attitude was fitting, with its thighs and knees raifed ; it walked nearly in the fame pofture, its rump being very near the ground. I never faw it perfectly upright, except when it wifhed to reach fomething ; and even then its knees were always a little on the bend, and it tottered." (Buffon, by Wood, vol. x. p. 79.) Vofmaer, who has defcribed the fame individual, fays, " This animal generally walked on all-fours, like the other monkies, but it could, likewife, walk erect on its hind feet, and, provided with a ftick, it would often fupport

port itself for a considerable time. However, it never rested its feet flat on the ground, as a man would do, but bent backwards in such a manner, that it supported itself on the external edge of its hind feet, with the toes drawn inwards, which denotes a posture for climbing trees." (Ibid. p. 84.) The testimony of Camper, concerning one which lived for some time at the menagerie of the stadtholder at Petit Loo, is to the same effect: "L'orang vivant couroit a quatre pattes, et lorsqu'il se tenoit debout (ce qu'il fit le plus, dans les premeirs tems de son arriveé et lorsqu'il jouissoit encore de toute sa vigueur) il tenoit les genoux ployés." (Œuvres, tom. i. p. 60.) The bent knees, and general attitude of the figure represented by Tyson, shew clearly that the animal was not designed for a biped: "Being weak," says the author, "the better to support him, I have given him a stick in his right hand." (P. 16.) Several passages shew that this animal often went on all-fours, and thus concur with the representation given in the report of the directors of the Sierra Leone company, p. 164: in describing a young one, they say, "at first he crawled on all-fours, always walking on the outside of his hands; but when grown larger, he endeavoured to go erect, supporting himself by a stick, which he carried in his hand." The description of the individual observed by F. Cuvier, corroborates these observations: he climbed excellently, but walked as imperfectly. In the latter operation, he rested his closed hands on the ground, and dragged forward his hind parts. If one hand was held, he could walk on his feet; but then he supported himself partly by resting the other hand on the ground. The outer edge of the foot alone touched the ground, and the toes were bent. Annales du Museum, vol. xvi. p. 49.

That the gibbon (simia longimana), another of the anthropo-morphous simiæ, is not suited for the erect attitude, appears from the testimony of Daubenton. It could carry itself almost erect on its feet, but the legs and thighs were rather bent, and sometimes the hand touched the ground to support the reeling body; it was unsteady whenever it stopped while in an upright posture; it rested on the heel only, and raised the sole of the foot; it remained but a short time in this attitude, which appeared unnatural. (Buffon, by Wood, vol. x. p. 80.) We must, therefore, set down as incorrect the following assertion of Linnæus: "Dari simias erecto corpore binis æque ac homo pedibus incedentes, et pedum et manuum ministerio humanam referentes speciem."

The relative size of the cranium and face, the nearly vertical direction of a line drawn in front of the forehead and face, and the position and direction of the great occipital foramen and condyles, are points in which man differs from all animals. See CRANIUM.

Teeth.—The teeth of man are distinguished by the circumstance of their being arranged in an uniform, unbroken series: there are intervals, and some teeth project beyond the others in all animals. The canine teeth are longer than the others in monkies; in some genera very considerably so; and there are intervals in each jaw to receive the teeth of the other. The lower incisors are placed perpendicularly, which is a principal characteristic of the human frame: the cuspidati neither project beyond the neighbouring teeth, nor are separated from them by any interval. The molares are clearly distinguished by their obtuse prominences from those of all the simiæ. The lower jaw is remarkable for three circumstances; *viz* its shortness, the prominence of the chin, which corresponds to the perpendicularity of the incisor teeth, and the form, direction, and articulation of the condyles. The lower incisors of man and the front of his jaw are placed in the same vertical line: in animals the former slant very considerably backwards, the jaw slopes backwards directly from the alveoli, and there is consequently no chin.

Smoothness of the Skin.—Passing over some circumstances of less consequence, ordinarily enumerated among the distinctive characters of man, as the lobules of the ear, the tumid lips, particularly the inferior one, &c. we have a few remarks to make on the smoothness of the human integuments. "Dantur," says Linnæus, "alicubi terrarum simiæ minus quam homo pilosæ:" but he does not tell us in what part of the world they are to be found. The unanimous reports of all travellers, as well as the specimens of such animals exhibited in Europe, prove incontestibly that the man-like simiæ, called ourang-outangs, whether the species from Angola, or that from Borneo, as well as the long-armed monkey or gibbon, are naturally much more hairy than the human subject. Although the individuals brought into these countries have been under the adult age, and generally very sickly, their body has been in all cases universally hairy. We have, indeed, some accounts of people, particularly in the islands of the South sea, remarkable for their hairiness: but they are not completely satisfactory. Spangberg relates, that he found such a race in one of the Southern Kurile islands (lat. 43 50'), on his return from Japan to Kamtschatka. (Müller Sammlung Russischer Geschichte, tom. iii. p. 174.) And J. R. Forster observed individual instances in the islands of Tanna, Mallicollo, and New Caledonia. (Observations on a Voyage round the World.) Such a race is said to be found in the interior of Sumatra. Marsden, History of Sumatra, p. 35, note.

While man is remarkable for the smoothness of his skin on the whole, some parts of his body are even more hairy than they are in animals, as, for example, the pubes and axilla, which the ancients consequently regarded as peculiar characters of man.

Comparative Proportions of the Body in Man and the Ourang-outangs.—To this division we shall subjoin a short statement of the comparative size of parts in the human subject and in the ourang-outangs: it is an important point in illustrating the specific differences of the two animals, and cannot be so conveniently introduced in any other part.

The difference of stature is remarkable: none of those hitherto brought into Europe has been more than three feet high, and most have been under that size. Of eight seen by Camper, none exceeded $2\frac{1}{2}$ feet (Rhynland measure): (Œuvres, vol. i. p. 51.) From observing the state of the teeth, and progress of ossification, and estimating, according to the human subject, the additions which the stature might be expected to receive, he thinks that their adult height may be set down at 4 feet (Rhynland measure); and F. Cuvier makes it considerably less. (Annales du Museum, vol. xvi. p. 51.) Yet travellers speak of them as 5 and 6 feet high, and even more: what they say of their erect gait, of their violating women, &c. &c. is probably of equal accuracy.

Tyson's chimpansee (simia troglodytes) was 26 inches from the top of the head to the heel: the arm, from the shoulder to the end of the fingers, 17 inches: the hand, $5\frac{1}{2}$ inches: the middle finger $2\frac{1}{2}$ inches. From the head of the thigh-bone to the heel, 12 inches: from the heel to the end of the middle toe, which was the longest, $5\frac{3}{4}$ inches. femur, 7: Tyson's Anatomy of a Pigmy, p. 15.

In the true ourang-outang (S. satyrus), according to Camper, the whole length was less than 32 inches: the arm, $8\frac{1}{2}$: the fore-arm, 9: the hand, 7: the fingers, 3: the femur, 7: the tibia, 7: the foot, $7\frac{1}{2}$: the toes, $2\frac{3}{4}$.

In the ourang-outang described by F. Cuvier, the height was

was between 26 and 30 inches: the arm, from the axilla to the end of the fingers, meafured 18: and the lower extremity, from the top of the thigh to the tarfus, 8 or 9. Annales du Mufeum, vol. xvi. p. 46.

The important differences will be perceived by comparing thefe meafures with the proportions of the human frame, as given in a former part of this article: we juft place, in parallel lines, two or three of the moft ftriking.

	In Man.	Ourang-outang.
Length of the whole body -	8 heads.	6 heads.
Length, from the end of one middle finger to that of other, when the arms are extended -	8 ——	8 ——
Length of the hand -	$\frac{4}{5}$ ——	$1\frac{1}{5}$ ——
Length of the foot -	$1\frac{1}{3}$ ——	$1\frac{1}{5}$ ——

In the following table we have placed together the dimenfions of fome parts of a male fkeleton; of the fimia fatyrus (ourang-outang, Camper); and of the fimia troglodytes, (chimpanfee, Tyfon.)

	Man.	S. Satyrus. (Camper.)	S. Troglodytes. (Tyfon.)
	Inches.	Inches.	Inches.
The whole body	71	uncertain, but lefs than } 30	26
Upper extremity	32	*$24\frac{1}{2}$	17
Lower extremity	39	16	12
Hand - -	$8\frac{1}{4}$	7	$5\frac{1}{2}$
Thumb - -	$4\frac{1}{4}$	$1\frac{1}{4}$	$1\frac{1}{4}$
Middle finger -	$4\frac{1}{4}$	3	$2\frac{1}{2}$
Femur - -	20	7	
Tibia - -	$16\frac{3}{4}$	7	
Foot - -	$10\frac{1}{2}$	$7\frac{1}{2}$	$5\frac{3}{4}$
Middle toe -	$2\frac{1}{4}$	$2\frac{3}{4}$	$1\frac{1}{2}$

* This length feems exceffive: Camper's meafures are, arm $8\frac{1}{2}$, fore-arm 9, hand 7. In another, rather fmaller individual, the fame parts meafured refpectively, $6\frac{1}{2}$, 6, and $5\frac{1}{2}$ inches. Œuvres, vol. i. p. 49.

The comparative lengths of the upper arm and fore-arm, exhibit alfo a ftriking difference in man and the monkey kind. In a male fkeleton meafuring 5 feet 8 inches, the os humeri was 13, and the ulna $9\frac{7}{8}$; in a living man of 5 feet $9\frac{1}{2}$ inches, thefe bones were refpectively 14 and 11. In Tyfon's chimpanfee of 26 inches, the humerus was little more than 5, the ulna 5, and the radius $5\frac{1}{2}$: in a monkey of 2 feet 2 inches, the humerus was $4\frac{1}{4}$, the ulna 5.

Other Diftinctions.—We may obferve further, with refpect to the comparifon of man and the ourang-outangs, that one fpecies of the latter (fatyrus) has no nail on the thumb of the hind hand; and the other (troglodytes), according to Tyfon, has 13 ribs. Both of them have a facrum compofed of three pieces only, inftead of five, as in the human fubject; and one at leaft (fatyrus) has a large membranous pouch communicating with the larynx. The ourang-outang has no ligamentum teres (Camper, l. c. p. 132.); it has a membranous canal running along the fpermatic chord from the abdomen to the tunica vaginalis, as other monkies and quadrupeds have (ibid. p. 109.); but this does not exift in the chimpanfee. (Tyfon, p. 82.) We venture to affert that thefe differences only, without any others, would be fufficient to eftablifh the diftinction of fpecies: that no example can be adduced of animal ftructure deviating from its original model in this way; and confequently that the difference can be accounted for only by referring the animals to fpecies originally diftinct.

II. *Diftinctions of Internal Structure.*

1. Parts that man alone, or with a few other mammalia does not poffefs. Moft of thefe, which are found chiefly in the domefticated kinds, were formerly attributed to man, when human diffections were rare, from the want of opportunity, or greater attachment to zootomy.

The *Panniculus carnofus*, or fubcutaneous ftratum of fibres, defcribed by Galen and his followers, even by Vefalius, the great reftorer of anatomy, and expofer of Galen's errors, as a part of the human body, does not exift in man, nor, according to Tyfon, in the chimpanfee. It is found in the monkies.

The *rete mirabile* of the head, the feventh or fufpenforius mufcle of the eye, the membrana allantois, and ligamentum nuchæ, are parts not found in the human fubject.

The foramen incifivum is common to man with animals; but it is fmall and fingle: moft other mammalia have it double and large.

On the fubject of the intermaxillary bone, fee the comparifon of the human head with that of animals, in the article CRANIUM; and the article MAMMALIA, in *Comparative Anatomy*.

2. *Differences between Man and Animals, in certain internal Parts: the Brain.*—Paffing over in filence fome lefs important points, as, for inftance, that the human cryftalline is proportionally fmaller than that of any animals, excepting the cetacea, and lefs convex in the adult, that the foramen occipitale is placed further forwards in the head (fee CRANIUM), &c. we find in the brain a very ftriking difference between man and other animals. He has the largeft brain, not, according to the opinion which has been generally received fince the time of Ariftotle, in proportion to the reft of the body, but to the fize of the nerves, which proceed from it. Hence, if we divide the nervous fyftem into two parts, one confifting of the nerves, and that part of the brain, from which they arife, which is to be confidered as appropriated to the functions of a merely animal life; the other, comprehending the remainder of the brain, and connecting the functions of the nerves with the faculties of the mind, man will poffefs the greateft proportion of the latter more important part. See Soemmerring Diff. de Bafi Encephali, p. 17. I. G. Ebel Obf. Neurologicæ ex Anatome comparata Franc. of. ad Viadr. 1788. Soemmerring von der körperlichen Verfchiedenheit des Mohren vom Europäer, 1785.

From the latter work of Soemmerring, to whom we owe the difcovery of this very interefting circumftance, we extract his own account of the matter. "The careful and accurate comparifon of the brains of animals of various orders, for which my opportunities have been very confiderable, conducted me at laft to the following pofition, firft difcovered by myfelf: 'that man poffeffes with the largeft brain the fmalleft nerves;' or, that the affertion that man has the largeft brain will hold good only in comparing that organ to its nerves. That acute phyfiologift Monro feems to be the firft who adopted and confirmed this opinion. (On the Nervous Syftem, Edinb. fol. chap. 8.) It was formerly conjectured, indeed affumed, that man has the largeft brain; but how was this proved? by weighing the brain and the body in man, and in the moft common domeftic animals: thus far obfervation confirmed it. But thofe phyfiologifts who carried their inveftigations further, were confiderably perplexed at finding that birds exceed man in the proportion which their brain bears to the reft of the body, and that the dolphin, feals, and the fmaller mammalia, as the moufe, fquirrel, &c. have, in proportion to their fmall bodies, (but

certainly

certainly not in proportion to their head and organs of ſenſe, or to that part which the face forms, compared with the cranium) a very large brain.

"It is a very looſe mode of proceeding to compare the body, of which the weight varies ſo conſiderably according to fatigue, illneſs, emaciation, or embonpoint, with the brain, which is affected by none of theſe circumſtances, and ſeems to remain conſtantly the ſame ; an eaſier and much leſs deceptive compariſon is that of the brain to its own nerves.

"I do not conceive that the nerves are related to this organ, as excretory ducts are to a gland ; but I think it probable that a very ſmall proportion of its maſs is ſufficient for their connection, ſo far as mere animal exiſtence is concerned. Conſequently, the being which poſſeſſes the greateſt quantity of brain over and above this portion, will probably poſſeſs the greateſt intellectual capacity. Man, who holds only a middle rank in reſpect to his bodily properties, is raiſed in this point of view far above other animals ; he is the firſt of beings. All the ſimiæ (for I have been fortunate enough to procure ſpecimens of the four principal diviſions) come after him ; for, although the proportion of their brain to the body, particularly in the ſmall ſpecies with prehenſile tails, is equal to that of man, their very large eyes, ears, tongue, and jaws, require a much larger maſs of brain than the corresponding parts in the human ſubject ; and if you remove this, the ratio of the brain to the body is much diminiſhed.

"Animals of various kinds ſeem to me to poſſeſs a larger or ſmaller quantity of this ſuperabundant portion of brain, according to the degree of their ſagacity and docility.

"The largeſt brain of a horſe, which I poſſeſs, weighs one pound ſeven ounces ; the ſmalleſt human brain that I have met with in an adult, two pounds five ounces and a quarter. But the nerves on the baſis of the horſe's brain are ten times larger than in the other inſtance, although it weighs leſs by fourteen ounces and a quarter.

"But we are not haſtily to conclude that the human ſpecies have ſmaller nerves than any other animal. In order that my ideas may be better underſtood, I ſhall ſtate the following imaginary caſe. Suppoſe the ball of the eye to require 600 nervous fibrils in one inſtance, and 300 in another, though only half the ſize of the former ; further, that the animal with 600 fibrils poſſeſſes a brain of ſeven, and that with 300 a brain of only five drams ; to the latter we ought to aſcribe the larger brain, and a more ample capacity of regiſtering the impreſſions made on the organ of viſion ; for, allowing one dram of encephalon to 100 fibrils, the brain which is abſolutely the leaſt will have a ſuperfluous quantity of two drams, while the larger has only one. That the eye, which is ſupplied with a double quantity of fibrils, may be a more complete organ of ſenſe, will be readily admitted ; but the remark is inapplicable to the ſubject in diſpute." P. 59—67.

The brain of the monkey is eaſily diſtinguiſhed from that of man, independently of its ſize and weight ; Soemmerring found no leſs than fifteen viſible material anatomical differences between the human brain and that of the common ape. Ibid. p. 77.

Soemmerring has alſo ſhewn that the earthy matter of the pineal gland does not exiſt in any animal beſides man. He found it once in the brain of a deer, and Caldani informed Blumenbach that it did not exiſt in an old man, whom he diſſected. De Gen. Hum. Variet. p. 44.

Other Parts.—The ſituation of the heart, which reſts, not on the ſternum, as in quadrupeds, but, according to the erect attitude of man, on the diaphragm, is peculiar. Its baſis does not look towards the head, as in the former, but towards the dorſal vertebræ ; while the apex is turned to the left breaſt. There are very few mammalia, beſides man, which have the pericardium fixed to the diaphragm.

The appendix vermiformis cæci belongs to the chimpanſee and ourang-outang, the gibbon according to Daubenton, the phaſcoloma of New Holland, and man.

In addition to what we have ſaid about female organs, the parenchyma of the uterus is unlike that of any animal ; the texture of the placenta, the length of the chord, and the ſingle umbilical vein are peculiar to man. The veſicula umbilicalis, found in all human conceptions before the fourth month, has been obſerved in no other animal.

3. *Functions of the animal Economy. Pliancy of the human Frame.*—The moſt important prerogative under this head, according to Blumenbach, is the ſoftneſs and pliancy (teneritudo et obſequioſa mollities) of the cellular ſubſtance. Zinn obſerved that this tiſſue is more fine and tender in man than in any animal. To this circumſtance Blumenbach aſcribes the ſingular power of adaptation to every climate on the globe. "Uti ergo natura hominem reſpectu victus omnivorum fecit ; ita reſpectu habitationis eum omnis ſoli et climatis (παντοδαπον) eſſe voluit ; ideoque corpus ejus ex maxime obſequioſo contextu mucoſo fabricatum eſt, ut eo facilius ad multifarios diverſorum climatum impulſus ſe aptare et accommodare poſſit." De Gen. Hum. Variet. Nat. p. 48.

If we adopt this view, it will afford an anſwer to a queſtion ſtated in the outſet, whether the exiſtence of men in ſuch various climates can be aſcribed to phyſical conſtruction or reaſon ? In what way do the Greenlander, the Eſkimau, and the Canadian employ remarkable talents or invention to protect themſelves againſt the cold ? they brave the winter with open breaſt and uncovered limbs, and devour their whales and ſeals dreſt, raw, or putrid. The negro is healthy and ſtrong under a vertical ſun, with the ſoles of his feet bare on the burning ſands. The fox, the beaver, the marmot, and the hamſter, dig dwellings for themſelves : where then is the prerogative of man ? The mind indeed employs the excellent ſtructure of the body, lifts man above the reſt of the creation, accommodates him to all places, gives him iron, fire, and arms, furs, and ſcreens from the ſun, &c. but with all this could never make him what he now is, the inhabitant of all climates, if he did not poſſeſs the moſt enduring and flexible body. The lower animals have no defence againſt the evils of a new climate, but the force of nature. The arts of human ingenuity furniſh a defence to man againſt the dangers that ſurround him in every region. Accordingly we ſee the ſame nation paſs into all the climates of the earth ; reſide whole winters at the pole ; plant colonies beneath the equator ; purſue their commerce, and eſtabliſh their factories in Africa, Aſia, and America. They can equally live under a burning and a frozen ſky, and inhabit regions, where the hardieſt animals cannot exiſt. Such great changes indeed ought not to be hazarded ſuddenly, and without precaution. The greateſt evils that have ariſen from change of climate, have been occaſioned by the preſumption of health that refuſes to uſe the neceſſary precautions, or the neglect of ignorance that knows not what precautions to uſe. But when changes are gradually and prudently effected, habit ſoon accommodates the conſtitution to a new ſituation, and human ingenuity diſcovers the means of guarding againſt the dangers of every ſeaſon, and of every climate. The ſuperiority of man appears more ſtriking, when we compare him to the animals which moſt reſemble him in form and properties. The moſt anthropo-morphous ſimiæ inhabit only a few ſmall ſouthern diſtricts and iſlands of the old world ; are ſubject to numerous diſeaſes, loſe all their vivacity, ſtrength, and natural character, and periſh after

lingering

lingering in a miserable way, when removed from their native abodes. An ourang-outang brought to Paris, never recovered the expofure to cold in croffing the Pyrenées, and died at the age of fifteen months, with moft of the vifcera "déforganifé et remplis d'obftructions." (Annales du Mufeum, t. xvi. p. 53.) The monkies in general are confined within very narrow limits; they exift with difficulty in temperate countries, and can propagate only in warm climates. One which was impregnated in this country, and attended with all poffible care, brought forth a young one, which died immediately. (Hunter on the Animal Economy, p. 137.) Probably the fpecies could not be continued here, with all the aid of art; and it certainly could not be effected, if the animals were wild. When they are introduced into the north (indeed into the greater part) of Europe, and very carefully managed in their food, temperature, &c. they die very quickly, and, in almoft all cafes of difeafed vifcera, particularly the lungs.

Slow Developement.—Other circumftances in the economy correfpond with this power of adaptation; fuch are, the flow growth, long infancy, and late puberty of man. In no animal but man do the futures of the cranium clofe, or the teeth come out at fo late a period; none is fo long before it can fupport the body on the legs, before it arrives at the complete adult ftature, and capacity for exercifing the fexual functions. If we add to thefe circumftances, that man is not provided by nature with means of defence, and, confequently, requires affiftance; and that his great diftinctions, reafon, and fpeech, are only germs, which are not developed of themfelves, but are brought to maturity by extraneous affiftance, cultivation, and education, we fhall infer that he is defigned, by nature, for focial union. Such a condition appears more confonant to the ftructure, properties, and functions of our frame, even if it were not fupported by the concurring voice of actual experience in all ages and nations, than the imaginary and moft abfurdly named "ftate of nature," of fome philofophers. Rouffeau, the great apoftle of this doctrine, informs us, in direct words, that the ftate of nature never has exifted; and he fets afide all facts as foreign to the queftion. With thefe admiffions before us, we are required to believe that we have degenerated from our natural ftate; that fpeech, fociety, arts, inventions, fciences, agriculture, commerce, property, civil government, and inequality of conditions, have introduced all poffible mifery, and have debilitated our phyfical being; that we fhould live in the woods fcattered and folitary to get food enough, protect life by flight and force, fatisfy our defires and fleep. Buffon has reafoned fo well on this fubject, that we employ his words. "In this condition of nature, the firft education requires an equal time as in the civilized ftate; for, in both, the infant is equally feeble, and equally flow in its growth; and, confequently, demands the care of its parents during an equal period. In a word, if abandoned before the age of three years, it would infallibly perifh. Now, this neceffary and long-continued intercourfe between mother and child is fufficient to communicate to it all that fhe poffeffes: and though we fhould falfely fuppofe that a mother, in a ftate of nature, poffeffes nothing, not even the faculty of fpeech, would not this long intercourfe with her infant produce a language? Hence a ftate of pure nature, in which man is fuppofed neither to think nor fpeak, is imaginary, and never had an exiftence. This neceffity of a long intercourfe between parents and children produces fociety in the midft of a defart. The family underftand each other both by figns and founds; and this firft ray of intelligence, when cherifhed, cultivated, and communicated, unfolds, in procefs of time, all the germs of cogitation. As this habitual intercourfe could not fubfift fo long, without producing mutual figns and founds, thefe, always repeated and gradually engraven on the memory of the child, would become permanent expreffions. The catalogue of words, though fhort, forms a language, which will foon extend as the family augments, and will always follow, in its improvement, the progrefs of fociety. As foon as fociety begins to be formed, the education of the infant is no longer individual, fince the parents communicate to it, not only what they derive from nature, but likewife what they have received from their progenitors, and from the fociety to which they belong. It is no longer a communication between detached individuals, which, as in the animals, would be limited to the tranfmiffion of fimple faculties, but are inftitutions of which the whole fpecies participates, and whofe produce conftitutes the bafis and bond of fociety." Buffon, by Wood, vol. x. p. 30.

Some other Characters.—No other of the clafs mammalia enjoys fo long a life as man in proportion to his fize. As the duration of life is in proportion to the time fpent in arriving at the full growth, there is every reafon to fuppofe that the monkies will fall very far fhort of man in this refpect: in this climate they are cut off fo quickly, that we cannot form a judgment.

The celebration of the rites of Venus is not confined to any particular feafon of the year; although the author of a work "de Amore," dedicated to Joanna of Arragon, fo highly celebrated for her perfonal charms, enquires why "æftate puellæ fint libidinofiores & amantiores; viri autem contra hyeme."

Nocturnal difcharges of the feminal fluid are peculiar to man. See Generation, in the phyfiology of the male organs.

Menfes.—The menftrual difcharge is peculiar to women, and belongs to the whole fex in all countries: fo that Pliny is right in regarding woman as the only "animal menftruale." "I know indeed," fays Blumenbach, "that the fame difcharge has been afcribed to other animals, particularly of the order quadrumana. I have carefully enquired about all the female monkies, which I have feen for thefe twenty years, either in menageries or carried about for public exhibition, and have found fome of them liable to uterine hæmorrhage, which obferved no period, and was regarded by the more intelligent keepers as a circumftance arifing from difeafe, although they acknowledged, that in order to excite the admiration of the fpectators, they often reprefented it as true menftruation." De Gen. Hum. Var. note, p. 51.

4. *Faculties of the Mind: Reafon.*—All philofophers refer with one accord to the enjoyment of reafon, as the chief and moft important prerogative of the human fpecies. If we enquire, however, more particularly into the meaning of this word, we fhall be furprized to find what various fenfes different individuals affix to the fame expreffion, or, as Blumenbach obferves, "quam longe diverfiffimas de rationis notione reddunt rationes philofophi maxime rationales." According to fome, reafon is a peculiar faculty of the mind, belonging exclufively to man: others confider it as a more enlarged and complete developement of a power, which exifts, in a lefs degree, in other animals: fome defcribe it as a combination of all the higher faculties of the mind; while others affert that it is only a peculiar direction of the powers of the human mind, &c. "Non noftrum inter hos tantas componere lites."

The fubject may perhaps be more fhortly and fafely difpatched by confidering it a pofteriori. In the enumeration of natural exiftences we are obliged to rank man in the clafs

clafs of animals: but the analogies on which we do this are external, and authorize us not to pronounce that the nature of man is fimilar to that of the brute. In order to acquire a diftinct idea concerning the nature of each, it is neceffary that we fhould have as complete a knowledge of the internal qualities of animals, as we have of our own. But, as it is impoffible to know what paffes within them, or how to rank and eftimate their fenfations, in relation to thofe of man, we can only judge by comparing the effects which refult from the natural operations of both.

Let us, therefore, confider thefe effects; and, while we acknowledge all the particular refemblances, we fhall only examine fome of the moft general diftinctions. The moft ftupid man is able to manage the moft alert and fagacious animal: he governs it, and makes it fubfervient to his purpofes. This he effects not fo much by ftrength or addrefs, as by the fuperiority of his nature. He compels the animal to obey him, by his being poffeffed of reafon, which enables him to project and to act in a fyftematic manner. "Quifquis es, iniquus æftimator fortis humanæ, cogita quanta nobis tribuerit parens nofter, quanto valentiora animalia fub jugum miferrimus, quanto velociora affequamur, quam nihil fit mortale non fub ictu noftro pofitum." Seneca. The ftrongeft and moft fagacious animals have not the capacity of commanding the inferior tribes, or of reducing them to a ftate of fervitude. The ftronger, indeed, devour the weaker: but this action implies an urgent neceffity only, and a voracious appetite, qualities very different from that which produces a train of actions all directed to one common defign. If animals be endowed with this faculty, why do not fome of them affume the reins of government over others, and force them to furnifh their food, to watch over them, and to relieve the fick or wounded? But, among animals there is no mark of fubordination, nor the leaft trace of any of them being able to recognize or feel a fuperiority in his nature above that of other fpecies. We fhould therefore conclude, that all animals are of the fame nature, and that the nature of man is not only far fuperior, but likewife of a very different kind from that of the brute.

Man ufes all kinds of food, and inhabits every climate of the globe. The unlimited power, which he poffeffes in thefe refpects, gives rife to various wants, from the infinite variety of climate, soil, and other circumftances.

Pater ipfe colendi
Haud facilem effe viam voluit, primufque per artem
Movit agros, curis acuens mortalia corda.

Man receives, therefore, from his creator the power of invention and reafon, which fupply his wants. Hence, in the moft ancient times, and by the wifeft nations, the genius of invention has been honoured with divine worfhip: it forms the Thoth of the Egyptians, the Hermes of the Greeks. Thus, to give a few inftances, man has made tools for affifting his labour; and hence Franklin fagacioufly defined him a "tool-making animal:" he has formed arms and weapons; he has devifed various means of procuring fire. Laftly, "the moft noble and profitable invention of all others was that of fpeech, whereby men declare their thoughts one to another for mutual utility and converfation; without which, there had been amongft men neither commonwealth, nor fociety, no more than amongft lions, bears, and wolves." (Hobbes' Leviathan.) This is a moft important characteriftic of man, fince it is not born with him, like the voices of animals, but has been framed and brought into ufe by himfelf, as the arbitrary variety of different languages inconteftibly proves; or, as fome conceive, with extraordinary affiftance. See LANGUAGE.

Man exhibits, by external figns, what paffes within him: he communicates his fentiments by words; and this fign is univerfal. The favage and the civilized man have the fame powers of utterance; both fpeak naturally, and are equally underftood. It is not owing, as fome have imagined, to any defect in their organs, that animals are denied the faculty of fpeech. The tongue of a monkey is as perfect as that of a man: Camper afferts that the laryngeal pouch renders it impoffible for the ourang-outang to fpeak; we do not underftand how this is afcertained; but, allowing its truth, there are other monkies who have no pouch, and yet cannot fpeak.

There are infinite fubtleties both in the ancient and modern fcholaftics concerning the fpeech of brutes. We cite, as an example, Albertus, furnamed the Great, who allows to a monkey the privilege of fpeech, but with a memorable reftriction: "Pygmæus loquitur quidem, cum tamen fit irrationabile animal, verum non difputat; nec loquitur de univerfalibus rerum, fed potius fuæ voces diriguntur ad res particulares de quibus loquitur."

Several animals may be taught to pronounce words, and even to repeat fentences; which proves clearly that the want of fpeech is not owing to any defect in their organs: but to make them conceive the ideas which thefe words exprefs, is beyond the power of art. They articulate and repeat like an echo or machine.

Language implies a train of thinking; and for this reafon brute animals are incapable of fpeech: for though we fhould allow them to poffefs fomething fimilar to our firft apprehenfions, and to our moft grofs and mechanical fenfations, it is certain that they are unable to form that affociation of ideas in which alone the effence of thought confifts. They can neither think nor fpeak, becaufe they can neither join nor feparate ideas; and, for the fame reafon, they neither invent nor bring any thing to perfection.

With the operations of animals, who always perform the fame work in the very fame manner, the execution of any individual being neither better nor worfe than that of any other, in whom the individual, at the end of fome months, is what he will remain through life, and the fpecies, after a thoufand years, juft what it was in the firft year; contraft the refults of human induftry and invention, and the fruits of that perfectibility, which characterifes both the fpecies and the individual: by the intelligence of man the animals have been fubdued, tamed, and reduced to perpetual flavery. By his labours marfhes have been drained, rivers confined, their cataracts effaced, forefts cleared, and the earth cultivated. By his reflexion, time has been computed, fpace meafured, the celeftial motions recognized and reprefented, the heavens and the earth compared, and the Creator worthily adored. By his art, which is an emanation of fcience, the feas have been traverfed, and mountains overcome; nations have been united; a new world has been difcovered; a thoufand other detached lands have been reduced under his dominion; laftly, the whole face of the earth at prefent exhibits the works of his power, which, though fubordinate to that of nature, often exceeds, at leaft, fo wonderfully feconds her operations, that, by the aid of his hands, her whole extent is unfolded, and fhe has gradually arrived at that point of perfection and magnificence in which we now behold her.

In the point of view which we have juft confidered, man ftands alone; his reafon, and what he has effected by it, place him at a wide interval from all animals; at an interval, which no animal hitherto known to us can fill up. The man-like monkey, the almoft reafonable elephant, the docile dog, the fagacious beaver, the bee have no reafon. In

 none

none of these instances is there any progress either in the individuals or the species. See the article INSTINCT.

Laughter and Weeping.—Whether these are peculiar to man may admit of some doubt; they were not, like speech, invented by him, but seem rather born with him, and are more connected with the passions than with reason. Many animals secrete tears; but the question is, do they weep from grief? The fact has been asserted by some respectable witnesses, as by Steller of the seal, and Pallas of the camel. It is more doubtful whether they manifest mirth by laughter, though this has been asserted. Le Cat says, that he saw the chimpansee both laugh and weep.

5. *Diseases.*—There are many diseases peculiar to man, which may be thought a more fit subject for pathology than natural history; but as these unnatural phenomena arise out of the natural organization and habit of the body, and dispositions of the animal economy, they undoubtedly deserve a place in the discussion.

While the causes of disease in general are so obscure, it is hazardous to set down any particular affections as exclusively belonging to man; they might affect other animals also, if they were exposed to the same causes. Wild animals, we believe, have no diseases; domesticated ones have several; and they are more numerous in proportion as the subjugation is more complete, and the way of life differs more widely from the natural one. The diseases of our more valuable domestic animals, are sufficiently numerous to employ a particular order of men; and the horse alone has a set of surgeons or physicians to his own share. The miserable canary birds seem to be equally in want of professional assistance: among the disorders to which they are exposed, Buffon enumerates inflammation of the bowels, asthma, epilepsy, abscess, shankers on the bill, and scabs. (Vol. xiv. p. 87.) In man, the most artificial of all animals, the most exposed to all the circumstances that can act unfavourably on his frame, diseases are the most numerous, and so abundant and diversified, as to exercise the ingenuity of the nosologist, and fatigue the memory of the physician. Perhaps nosological catalogues afford the most convincing proof, that man has departed from his natural habits, or has deserted that way of life to which nature had destined him; unless, indeed, it should be contended that these afflictions are a part of his nature, a distinction from animals of which he will not be very likely to boast. This, however, we apprehend, will be too much even for the sons of Galen to defend, and it would certainly bring the theologians on their backs, as leading to inferences not very favourable to the benevolence of the Deity. The following sentiments of a most eloquent writer, and great philosopher, deserve attention, although he was no physician. "Have we any solid reason to suppose, that in countries where medicine is most neglected, the life of man is shorter than where this art is the most carefully cultivated? And how should it be so, if the evils we bring on ourselves are more numerous than the remedies which medicine furnishes. The extreme inequality in the mode of living, the excessive labours which consume the bodies and break down the spirits of the poor, the still more dangerous softness, which enfeebles the rich, destroying the one by their wants, and the others by their excess; the ease with which sensuality can be excited and gratified, the too luxurious food of the rich, the monstrous mixtures, the pernicious seasonings which stimulate and overwhelm them with indigestion; the bad and often insufficient nourishment of the poor; the spoiled provisions, the sophisticated drugs; the knavery of those who sell, the errors of those who administer them; the want of rest, the violent passions which agitate and exhaust us, the chagrins and vexations incidental to all conditions; are so many fatal proofs that most of our ills are our own work, and might have been avoided by adhering to the simple, uniform, and solitary life prescribed by nature. If she designed that we should be healthy, I would almost affirm that reflection is a state contrary to nature, and that the man, who meditates, is already a depraved animal. Consider the epidemic diseases engendered among multitudes collected together, the disorders caused by the delicacy in our mode of living, by passing from our heated rooms into the open air, by increasing or lessening our clothing without sufficient precaution, and all the cares converted by our excessive sensuality into necessary habits, and the neglect or privation of which then very frequently costs us our life or health; add to the account the fires and earthquakes, which consume and overturn whole cities, and sweep off the inhabitants by thousands; in short, bring together the dangers, which all these causes constantly suspend over our heads, and you will feel how dearly nature makes us pay for despising her lessons. When we reflect on the healthy constitutions of savages, at least of those whom we have not corrupted by our spirituous liquors, and remember that they know no other ailments than wounds and old age, we are led to suppose, that the history of disease would be easily written by following that of civil societies." Discours sur l'Inegalite, p. 69, and note 8.

The history of the young savage of Aveyron strikingly illustrates several of the foregoing remarks. In his wild state, he bore the cold of the severest winter without any clothing, and could remain, when he was first taken, for several hours together, in the winter, exposed half naked to wind and rain on the wet turf. He refused high-seasoned dishes and strong liquors, even when very hungry, and ate at first only potatoes, acorns, and raw chesnuts. His civilization went on so rapidly and successfully, that in a few months he had had three severe colds, and soon after became subject to epileptic fits. An observation of Humboldt tends to confirm the position, that the individuals, whose bodies are strengthened by healthy habits in respect to food, exercise, &c. are enabled to resist those causes which produce diseases in other men. Humboldt paints to us the Indians of New Spain as a set of peaceful cultivators, accustomed to uniform nourishment, of an almost entirely vegetable nature, that of their maize and cereal gramina: they are subject to no deformity: he never saw a hunch-backed Indian, and it is extremely rare to see any who squint, or are lame in the arm or leg. "In the countries where the inhabitants suffer from the goitre, this affection of the thyroid gland is never observed among the Indians, and seldom among the Mestizos." (Political Essay on the Kingdom of New Spain, book ii. ch. 6.) Similar observations on the freedom from deformity occur in the descriptions of most savages.

This comparison of diseases is difficult, since the nosology of brutes must by its very nature be cultivated under the most serious obstacles. The diseases in the following list, derived from Blumenbach, may be considered, in all probability, as peculiar to man.

Nearly all the exanthemata, at least

*Variolæ**,
Morbilli,
Scarlatina,
Miliares,
Petechiæ,
Pestis.

* A monkey at Amsterdam, contracted a local ulcer from the contagion of small-pox, but had no fever.

 Of

Of the Hæmorrhagies.
Epistaxis,
Hæmorrhoides,
Menorrhagia.
Of nervous affections.
Hypochondriasis,
Hysteria,
Mental affections, properly so called, as *melancholia*, *nostalgia*, &c. probably also *satyriasis* and *nymphomania*,
Cretinismus.
Of the cachexiæ,
Rhachitis,
Scrofula,
Lues Venerea,
Pellagra,
Lepra and *Elephantiasis.*
Of the Locales.
Amenorrhæa,
Cancer,
Clavus,
Hernia congenita?
The various kinds of *prolapsus*, particularly that congenital one of the urinary bladder.
Herpes,
Tinea capitis.

6. In the preceding remarks, we have adverted to some of the points, in which man has been erroneously supposed to differ from animals: a few only remain. The approximation of the two eyes is not peculiar; they are much nearer to each other in the simiæ.

Many other mammalia, particularly among the quadrumana, have eye-lashes in both eye-lids: this is the case in the elephant.

The long-nosed monkey (simia rostrata or nasalis) exceeds man in the length of the nose.

The external ears are not immoveable in all men, nor moveable in all other mammalia, as in the ant-eaters for example.

Many quadrumana have an organ of touch, and an uvula, as well as man.

Varieties of the human Species.—Our next point is the consideration of the varieties of the human species, and their causes.

The differences which exist between inhabitants of different regions of the globe, both in bodily conformation and in the faculties of the mind, are so striking, that they must have attracted the notice even of superficial observers. There are two ways of explaining these: first, by referring the different races of men to different original families, according to which supposition they will form in the language of naturalists, different species; or we may suppose them all to have descended from one family, and account for the diversity, which is observable in them, by the influence of physical and moral causes; in which case they will only form different varieties of the same species.

This disquisition will perhaps appear superfluous to the devout believer, whose philosophy on this point will be derived from the writings composed with the assistance of divine inspiration, and therefore commanding our implicit assent. The account of the creation of the human race, and of its dispersion over the face of the globe, contained in the book of Genesis, will supersede in his mind the necessity of having recourse to any argument on the subject. We shall venture to submit, that the Mosaic account does not make it quite clear that the inhabitants of all the world descended from Adam and Eve: we are told indeed, that "Adam called his wife's name Eve, because she was the mother of all living." But in the first chapter of Genesis we learn, that God created man, male and female; and this seems to have been previously to the formation of Eve, which did not take place until after the garden of Eden had been made. Again, we are informed in the fifth chapter of Genesis, that "in the day that God created man, in the likeness of God made he him; male and female created he them; and blessed them, and called their name Adam, in the day when they were created." We find also that Cain, after slaying his brother, was married, although it does not appear that Eve had produced any daughters before this time. "Cain went out from the presence of the lord, and dwelt in the land of Nod, on the east of Eden. And Cain knew his wife, and she conceived and bare Enoch." Indeed it is said (ch. 5, v. 4.), that "the days of Adam, after he had begotten Seth, were eight hundred years, and he begat sons and daughters." This it should seem took place after the birth of Seth, and consequently, long after Cain had his wife; for Seth was not born till after the death of Abel. If Cain had sisters prior to that period, from amongst whom he might have taken a wife, it is singular, as some persons may allege, that Moses should not have noticed them. But we refer the solution of these difficulties to the biblical critic and commentary, in whose judgment they will not materially affect the general credibility of the Scripture history.

It appears, therefore, that the field is open for discussion on this subject; and at all events, if the descent of mankind from one stock can be proved independently of the holy writings, the conclusion will establish the authority of these inspired annals.

If we fail in tracing the succession of the human race from above downwards, much less are we able to trace back any particular tribe to their first origin from the present stock. To use the words of an elegant modern historian; "neither the annals nor traditions of nations reach back to those remote ages, in which the different descendants of the first pair took possession of the different countries where they are now settled. We cannot trace the branches of this first family, nor point out with certainty, the time and manner in which they divided and spread over the face of the globe. Even among the most enlightened people, the period of authentic history is extremely short, and every thing prior to that period is fabulous and obscure." In considering the present question, we must, therefore, be contented to proceed in the slow and humble, but sure method of observation; to ascertain carefully all the differences that actually exist between the various races of men; to compare these with the diversities observed among animals; and to draw our inferences concerning the causes from the analogies which these considerations may unfold. Above all things, we must enter our protest against arguments à priori on this subject. One philosopher tells us, that nature does nothing in vain; that she would not give herself the trouble to create several different stocks, when one family would be sufficient to colonise the world in a short space of time. Another, with equal speciousness, dilates on the absurdity of supposing, that immense regions should remain for ages an unoccupied and dreary waste, while the offspring of a single pair was slowly extending over the face of the earth; or that such an admirable variety of islands should display their charms in vain, till a shipwreck or some other casual occurrence may supply them with inhabitants. He shews how much more consonant to the wisdom and benevolence of the Deity it would be, for the earth to have teemed, from the first moment of its production, with trees and fruits, and to have been occupied by all kinds of animals

mals fuited to each foil and fky. We cannot too ftrongly exprefs our reprobation of fuch idle declamation, which, by withdrawing our attention from the right method of inveftigation, inevitably tends to perpetuate our ignorance of nature. Dr. Prichard, the author of an excellent inaugural difcourfe on this fubject, has fo well expofed the futility of fuch arguments, that we prefent our readers with his own words. "Hæc quanquam fatis fpeciofa videantur, omnia ut fit plerumque in hujufmodi argumentationibus fluxa et incerta funt. Qui magna loquuntur tanquam ipfi ex Dei concilio defcendiffent, neque ut humiles miniftros, et naturæ interpretes oportet, raro lumine quantulocunque ejus abdita illuftrant. Illi quidem dixerunt quomodo mundum conftituiffent, fi hoc eorum curationi fuiffet commiffum; fed qua ratione re ipfa conftitutus fit, talibus aufpiciis, et latet, et femper latebit." P. 5.

What is Species?—Before we proceed to the chief object of this divifion of our article, it is neceffary to confider what conftitutes a fpecies in zoology; and how varieties arife out of fpecies. We fhould anfwer, in the abftract, to the firft queftion; that all animals, which differ in fuch points only as might arife in the natural courfe of degeneration, belong to the fame fpecies; while thofe differences, which could not be accounted for on this fuppofition, would lead us to clafs the animals, which exhibit them, in different fpecies. But the chief difficulty, is to point out the characters, by which, in actual practice, we can diftinguifh mere varieties from genuine fpecific differences.

Of Breeding as a Criterion of Species.—In the fixteenth century, and confequently long before the time of Buffon, Ray referred to one and the fame fpecies thofe animals which copulated together, and produce a fertile offspring, afcribing the differences which may exift between them to adventitious caufes. The high authority of the great French naturalift, who adopted the fame opinion, has occafioned this criterion to be very generally relied on; Mr. Hunter, on the faith of it, included the dog, the wolf, and the jackal in one fpecies, and excluded the fox. If we adopt this, our prefent queftion would be immediately folved; for all the races breed together, and their progeny is prolific, either with each other, or with any of the original races. Indeed we know no difference in productivenefs between fuch unions and thofe of the fame race.

We apprehend that this rule involves a petitio principii; has it been proved, that animals of diftinct fpecies never produce together a fertile offspring? on the contrary, there are inftances, both among the mammalia and birds, of individuals belonging to fpecies univerfally held to be diftinct, uniting and producing young, which were prolific. That the mule can engender with the mare, and that the fhe-mule can conceive, was known to Ariftotle. The circumftance is faid to occur moft frequently in warm countries, but it has happened in Scotland. (Buffon, vol. iv. p. 200. 205.) The offspring of the he-goat and ewe feem to poffefs perfect powers of reproduction. The cock and hen canary birds produce with the hen and cock fifkin and goldfinch (ibid. v. xiv. p. 63, et feq.): the hen canary produces with the cock chaffinch, bullfinch, yellow-hammer, and fparrow. The progeny in all thefe cafes is prolific, and breeds not only with both the fpecies, from which they fpring, but likewife with each other. (Ibid. p. 70.) It appears alfo that the common cock and the hen partridge, as well as the cock and the guinea-hen, can produce together. (Ibid. v. xii. 61.) It is true, that all thefe unnatural unions take place in animals under the power of man, and that they generally require an attention to feveral preliminary circumftances: it is alfo found that unions of different fpecies may take place without fecundation, as of the bull and mare (Buffon, v. iv. p. 221.): but they prove fufficiently, that this affair of generation will not afford the criterion we are in fearch of.

It was foon found that this rule of reproduction could not be applied to domefticated animals, on account of their unnatural way of life, and hence Frifch, towards the beginning of the laft century, confined it entirely to the wild ones. And here it is of little fervice; for how can we expect ever to bring together thofe wild fpecies, particularly where they inhabit different countries, as for inftance the chimpanfee of Angola and the ourang-outang of Borneo? Nor are there fo many doubts about thefe, as about the domefticated animals, which are thus excluded.

The different breeds of dogs, for example, are referred by fome to different fpecies: others confider, that they have all defcended from the fhepherd's dog; others derive them from the jackal; and all the dogs with the latter animal, owe their origin, according to others, to the wolf.

Of other Marks.—Nor is the conftancy of any particular character to be deemed a mark of difference in fpecies. The white hair and red pupils of the white variety of the rabbit are as conftant as any fpecific characters; and we fee breeds of animals, produced under our own eyes, diftinguifhed by marks tranfmitted regularly to the offspring.

The Criterion of Analogy.—We muft therefore refort at laft to the criterion adopted by Blumenbach, and draw our notions of fpecies in zoology from analogy and probability. (De Gen. Hum. Variet. Nat. p. 70.) If we fee two races of animals refembling each other in general, and differing only in certain refpects, according to laws, which we have found to hold good in other inftances, we refer them to the fame fpecies without hefitation. "I fee" fays this moft acute and judicious naturalift, "a remarkable difference between the Afiatic and African elephants in the ftructure of the molar teeth. Whether thefe inhabitants of fuch diftant regions will ever be brought to copulate together, and whether this formation be univerfal is uncertain; but it exifts in all the fpecimens I have feen or heard of, and I know no example of molar teeth changed in fuch a manner by degeneration (or the action of adventitious caufes): therefore, I conjecture from analogy, that thefe elephants are not mere varieties but truly different fpecies. On the other hand, I hold the ferret (muftela furo) to be only a variety of the pole-cat (m. putorius), not fo much becaufe they produce together, but becaufe it has red pupils, and the analogy of numerous other inftances induces me to regard all the mammalia, which are deftitute of the colouring pigment of the eye, as varieties degenerated from their original ftocks."

It is very clear that this analogical method is the only one that we can adopt for folving the queftion concerning the varieties of the human fpecies; we muft explain the bodily diverfities of man upon the fame principles, as thefe of all other domeftic animals; and if we find thefe caufes adequate to the folution of the phenomena, it will be unneceffary to refort to the fuppofition of originally different fpecies.

A very fuperficial confideration will fhew, that there is no point of difference between the feveral races of mankind, which has not been found to arife, in at leaft an equal degree, among other animals as a mere variety, from the ufual caufes of degeneration. The inftances of this kind are derived chiefly from domefticated animals, as they are expofed to all thofe caufes which can produce fuch effects; by living with man they lead an artificial and unnatural kind of life, and are taken with him into climates and fituations, and expofed to various other circumftances altogether different

from

from their original deſtination; hence they run into numerous varieties of colour, form, ſize, &c. which, when they are eſtabliſhed as permanent breeds, would be conſidered by a perſon uninformed on theſe ſubjects, to be originally different ſpecies. Wild animals, on the contrary, remaining conſtantly in the ſtate for which they were originally framed, retain permanently their firſt character. Man, the inhabitant of every climate and ſoil, partaking of every kind of food, and of every variety in mode of life, muſt be expoſed ſtill more than any animal to the cauſes of degeneration.

Differences of Colour.—The various colours of the ſkin form very conſtant hereditary characters, moſt clearly influenced by that of both parents in the hybrid offspring of different varieties, having a cloſe and nearly uniform relation to that of the hair and iris, and indeed to the whole temperament of the individual; and for all theſe reaſons attracting moſt immediately the attention of a curſory obſerver.

The ſeat of this colour is in a thin mucous ſtratum, interpoſed between the cuticle, or dead ſurface of the body, and the true ſkin, and called rete mucoſum or Malpighii. The native reddiſh white of the real ſkin appears through this, which is very thin and almoſt colourleſs, in the white races of mankind. But in the darker varieties the rete mucoſum is much thicker, and contains throughout its ſubſtance a black pigment; while the cuticle and cutis deviate but little from the colour which they have in fair perſons. See INTEGUMENTS.

The different varieties of mankind exhibit every poſſible ſhade between the ſnowy whiteneſs of the Albino or of the moſt delicate European female and the jet black of the Negro. Although none of theſe gradations obtain ſo univerſally, as to be found in all the individuals of any particular nation, nor are ſo peculiar to one race, as not to occur occaſionally in other widely different ones, the national varieties of colour may be referred on the whole, with ſufficient accuracy, to the five following principal claſſes:

1. White, to which redneſs of the cheeks is almoſt wholly confined, being obſerved at leaſt very rarely, if at all, in the other varieties. This obtains in moſt of the European nations, in the weſtern Aſiatics, as the Turks, Georgians, Circaſſians, Mingrelians, Armenians, Perſians, &c. and in the inhabitants of the north of Africa.

Conſiderable variety, however, will be found to exiſt in the colour known by the general epithet white. That ſingular race of men, the Albinos, poſſeſs a milk-white or red ſkin and yellowiſh-white hair, with red eyes. In the natural hiſtory of our ſpecies they have not met with much better treatment than the poor Negroes; for ſome have doubted whether they, as well as the latter, belonged to the ſame ſpecies with us. The Negroes were thought to be too black, the Albinos too white. Their ſkin has an unnatural whiteneſs, often ſeeming to approach to a ſlight degree of lepra, and the hair of all parts of the body has the ſame character. The latter has not the ſnowy whiteneſs of old age, nor the elegant light yellow or flaxen appearance of the fair-haired in our climates (blondins, Fr.) but is rather to be compared to the appearance of cream; neither is the colour of the ſkin like that of the European, but it approaches to that of milk, or of a white horſe. The eye is deprived of its colouring matter; and hence the iris is of a pale roſe colour, and the pupil intenſely red, in conſequence of the blood contained in the numerous veſſels, which almoſt entirely make up the ſubſtance of thoſe parts. Thus, the colouring matter of the body, as well that of the ſkin (rete mucoſum), and hair, as that of the eye, (pigmentum nigrum, or more properly fuſcum) is deficient. Theſe affections of the ſkin and eye are always concomitant. This peculiarity always exiſts from the time of birth; it never changes afterwards, and it is ſometimes hereditary. The notion, that Albinos are incapable of propagation, is completely unfounded. They are in truth not numerous enough for them to breed together, and thus produce a permanent variety; but there are ſcattered inſtances to ſhew, that they can beget and conceive. A white negreſs bore a perfect negro to a negro father; and another produced with an European father three true Mulattoes, but with light hair. Blumenbach Beyträge zur Naturgeſchichte, p. 125. See ALBINOS, EYE, under the deſcription of the *Iris*, and INTEGUMENTS.

This variety was firſt obſerved in the African, as the great difference of colour would render the variation more ſtriking: and hence the individuals were termed Leucæthiopes or white negroes; their peculiar conſtitution, for the deviation is by no means confined to the ſurface of the body, may be conveniently termed, after ſome modern authors, Leucæthiopia. From their avoiding the light, the Dutch gave them (in the iſland of Java) the contemptuous appellation of Kakkerlakken (inſects ſhunning the light); the Spaniards called them Albinos, and the French Blafards. So far is this variety from being peculiar to the Negro, or even to the torrid zone, that there is no race of men, nor any part of the globe, in which it may not occur. Blumenbach has ſeen fixteen examples of it in various parts of Germany, and he refers to authors who have ſeen it in Denmark, England, Ireland, France, Switzerland, Italy, the Grecian Archipelago, and Hungary; in Arabia, on the coaſt of Malabar, in Madagaſcar, among the Caffres and Negroes, (as well thoſe born in Africa, as the deſcendants of the individuals conveyed to America); in the iſthmus of Darien and Brazil; in the iſlands of the Indian ocean and of the Pacific. De Gen. Hum. Variet. ſect. iii. § 78.

There is another deſcription of men with a very white ſkin, and often a roſy tint, particularly in the face, with yellow (flaxen) or red hair, and generally blue or whitiſh eyes (iris). The Germans, and nations deſcended from them, are of this kind.

Laſtly. There is a moſt extenſive race, including nearly all the nations enumerated in the firſt diviſion, with the ſkin, although white, poſſeſſing more or leſs of a brown tint, with black hair and dark eyes.

2. Yellow or olive (gilvus ſeu buxeus, a middle tint between that of wheat and the boiled quince or dried lemon peel), which characteriſes the Mongolian tribes, uſually called, together with the inhabitants of great part of Aſia, Tartars (Tatars.)

3. Red or copper colour (bronzé, Fr. an obſcure orange, or ruſty iron colour, not unlike the bark of the cinnamon tree) almoſt confined to the Americans.

4. Tawny or brown (badius, baſané, Fr. a middle tint between that of freſh mahogany and cloves or cheſnuts), which belongs to the Malays, and the inhabitants of the South ſea iſlands.

5. Black, in various ſhades from the ſooty colour or tawny black, to that of pitch, or jet black. This is well known to prevail very extenſively on the continent of Africa: it is found alſo in other very different and diſtant varieties of the human race, mingled with the national colour, as in the natives of Brazil, California, India, and ſome South ſea iſlands, as New Holland and New Guinea. The New Caledonians conſtitute an inſenſible tranſition, with the cheſnut coloured iſlanders of Tongataboo, from the tawny or brown Otaheitans to the black New Hollanders.

Intermediate Shades.—In deſcribing theſe varieties, we fix on the moſt ſtrongly marked tints, between which there is every conceivable intermediate ſhade of colour. The oppoſite extremes run into each other by the niceſt and moſt delicate gradations, in every other particular in which the human ſpecies differs. This forms no ſlight objection to the hypotheſis of different ſpecies: for, on that ſuppoſition, we cannot define the number of ſpecies, nor can we point out the boundaries that divide them; whereas, in animals moſt reſembling each other, the different ſpecies are preſerved pure and unmixed. Neither does the colour, which we deſcribe in general terms as belonging to any particular race, prevail ſo univerſally in all the individuals of that race as to conſtitute an invariable character, as we ſhould expect, if it aroſe from ſuch an uniform cauſe as an original ſpecific difference: its varieties, on the contrary, point out the action of other circumſtances. Thus, although the red colour is very prevalent on the American continent, travellers have obſerved fair tribes in ſeveral parts: as Bouguer, in Peru; Cook, at Nootka Sound; Humboldt, near the ſources of the Orinoco; and Weld, near the United States. The natives of New Zealand vary from a deepiſh black to an olive or yellowiſh tinge. In the Friendly Iſlands, they are of a complexion deeper than the copper-brown; but ſeveral of both ſexes are of the olive colour, and ſome of the women are much fairer.

Various Colours of Animals.—The domeſtic animals exhibit varieties entirely analogous to thoſe which we have juſt enumerated; a fact ſo familiarly known, with reſpect to the ſheep, pig, horſe, and cow, that it cannot be neceſſary to ſupport the aſſertion by any details. The leucæthiopic conſtitution, too, occurs in them as well as in the human ſubject: it has been obſerved (not to mention the well-known examples of the rabbit, ferret, mouſe, and horſe) in the monkey, ſquirrel, rat, hamſter, guinea-pig, mole, opoſſum, martin, weaſel, and roe. The crow, black-bird, canary bird, partridge, common fowl, and peacock, are ſometimes the ſubjects of it; but it has never been ſeen in any cold-blooded animal. Blumenbach, l. c.

Colour and Denominations of the mixed Breeds.—When two varieties copulate together, the offspring reſembles neither parent wholly, but partakes of the form and other peculiarities of both. This cannot with propriety be termed hybrid generation; as authors apply that expreſſion to the produce of the copulation of different ſpecies, as of the horſe and aſs, the canary bird and gold-finch, &c. In this ſenſe, hybrids are never produced in the human ſpecies. We read, indeed, various inſtances of this unnatural commerce, either where men, from depraved paſſions, ſolitary life, or miſtaken notions of ſanctity, have been connected with animals: ſee J. Warton, in a note on Theocr. Idyll. i. 88. p. 19. "Audivi ex docto quodam amico, qui per Siciliam inſulam iter faciens, ibidem cum vetera monumenta, tum populi mores accuratius inveſtigaverat, inter confeſſionis articulos a Siculis caprariis apud montes vitam ſolitariam degentibus, etiamnum per ſacerdotes proprios rite ſoleri exigi an rem cum hircis ſuis habuerint:" and M. Baumgarten, Peregrinatio in Ægyptum, Arabiam, &c. p. 73. "Ibi vidimus ſanctum unum Saracenicum, inter arenarum cumulos ita ut ex utero matris prodiit, nudum ſedentem. Audivimus ſanctum illum, quem eo loco vidimus, publicitus apprime commendari; eum eſſe hominem ſanctum, divinum, ac integritate præcipuum, eo quod nec feminarum unquam eſſet nec puerorum, ſed tantummodo aſellarum concubitor atque mularum:" or with the view of deriving benefit when ill, as Pallas ſtates; "Perſas iſchiade laborantes onagras inire," Neuen Nordiſchen Beyträgen, P. 2. p. 38: or, where women, from luſt or religious motives, have ſolicited the embraces of male animals, Steller of the Kamtſchatkan Women, in Beſchreibung von Kamtſchatka, p. 289; and the Mendeſian women with the ſacred goat, D'Hancarville Recherches ſur l'Origine des Arts de la Grece, tom. i. p. 320. The laws of various countries, too, have directed that the fruit of ſuch intercourſe ſhould be burned, or otherwiſe deſtroyed. Yet there is no inſtance, related by witneſſes worthy of credit, or with circumſtances ſufficient to authenticate it, of any offspring being produced. We only ſpeak of ſuch hybrids as reſult from the union of different varieties, as of the green and white canary birds; which unions have a moſt remarkable effect on the progeny, and are employed with wonderful advantage in improving the breeds of the domeſtic animals, particularly the horſe and ſheep.

Children, produced from the copulation of different races, exhibit in their colour the middle between the two tints of their parents. From a refinement of vanity, the inhabitants of the Spaniſh colonies in America have enriched their language with terms for the fineſt ſhades, which reſult from the degeneration of the primitive colour.

In the firſt generation, the offspring of Europeans and Negroes are called Mulattos. The word Creole (Criollo) has been frequently confounded with this, even by good writers; but that name (originally applied by the firſt Negroes, conveyed to America in the ſixteenth century, to their children born in that country, and borrowed by the Spaniards from them to denote their own offspring in the New World; Garcilaſſo del Origen de los Incas) belongs properly to the children of European parents born in the Eaſt or Weſt Indies. The offspring of Europeans and Indians are called Meſtizos; of Europeans and Americans, Meſtizos, alſo Meſtindi, Metiſi, and Mamelucki; of Negroes and Americans, Zambos or Sambos, alſo Mulattos, Lobos, Curibocas, and Kabuglos.

"The deſcendants of Negroes and Indian women bear at Mexico, Lima, and even at the Havannah, the ſtrange name of Chino, Chineſe. On the coaſt of Caraccas, and, as appears from the laws, even in New Spain, they are called Zambos. This laſt denomination is now principally limited to the deſcendants of a Negro and a female Mulatto, or a Negro and a Chineſe female." Humboldt's political Eſſay on New Spain, vol. i. p. 244.

All the above enumerated deſcriptions of perſons have the middle countenance and colour, formed by the union of thoſe of both parents; the latter is more or leſs brown or tawny, with hardly any viſible redneſs of the cheek. The hair of the Mulattos is curled; in the other inſtances ſtraight, and almoſt invariably black: the iris is dark. "A Meſtizo," ſays Humboldt, "is in colour almoſt a pure white; and his ſkin is of a particular tranſparency. The ſmall beard, and ſmall hands and feet, and a certain obliquity of the eyes, are more frequent indications of the mixture of Indian blood, than the nature of the hair." Ibid.

In the ſecond generation, two Mulattos produce Caſquos; Europeans and Mulattos, Tercerons, called by ſome authors Quarterons, Moriſcos, and even Meſtizos. The hair and countenance of theſe reſemble the European: the ſkin has a very ſlight brown tint, and the cheeks are red. The ſcrotum is blackiſh in the male, and the labia pudendi rather purple in the female.

Negroes with Mulattos produce Griffos (Zambos de Mulata, or Cabros); an European and Indian Meſtize, Caſtiſſos. "If a Meſtiza marry a white man, the ſecond generation differs hardly in any thing from the European race." (Humboldt, ibid.) From an European and American

rican Meſtizo come Quarterons (Quatralvi or Caſtiſſi); from an American and a Meſtizo, Tresalvos; from an American and Mulatto, Meſtizos; from an European and Zambo, Mulattos; from an American and Zambo, Zambaigos. The offspring of the Zambos are ſtyled in deriſion by the Spaniards Cholos; that of a Negro and Zamba is called Zambo prieto (black Zambo).

In the third generation, Europeans and Tercerons produce Quaterons or Quarterons (Ochavons, Octavons, or Alvinos), which, according to the moſt acute obſervers, retain no traces of their African original; a Mulatto and Terceron produce a Saltatra; an European and Caſtiſſo, a Polliſſo; an European and American Quarteron of the ſecond generation, an Octavon; a Quarteron and American Meſtizo of the firſt generation, a Coyota; a Griffo and a Zambo of the firſt generation, a Givero; a Zanbaigo and Mulatto, a Cambujo.

Some carry the genealogy of theſe hybrid races into the fifth generation, and call the children of Europeans and Quarterons, Quinterons (or Puchuelas); which name is alſo given to thoſe born of Europeans and American Octavons: but it is not credible that any trace of mixed origin can remain in this caſe, according to the obſervation of the moſt reſpectable eye-witneſſes concerning the third generation; that in colour and habit of body they cannot be diſtinguiſhed from their European progenitors.

In countries with a mixed population, governed by whites, the families reputed to have the leaſt mixture of black blood are naturally the moſt honoured. In America, the greater or leſs whiteneſs of the ſkin decides the rank which an individual occupies in ſociety. When a common man diſputes with one of his ſuperiors, he is frequently heard to ſay, "Do you think me not ſo white as yourſelf?" It becomes, conſequently, a very intereſting buſineſs for the public vanity to eſtimate accurately the fractions of European blood which belong to the different caſts. The proportions are repreſented below, according to the principles ſanctioned by uſage.

Parents.	Offspring.	Degree of Mixture.
White and Black,	Mulatto,	$\frac{1}{2}$ white $\frac{1}{2}$ black.
White and Mulatto,	Terceron,	$\frac{3}{4}$ white $\frac{1}{4}$ black.
Black and Mulatto,	Griffo or Zambo,	$\frac{3}{4}$ black $\frac{1}{4}$ white.
White and Terceron,	Quarteron,	$\frac{7}{8}$ white $\frac{1}{8}$ black.
Black and Terceron,	Quarteron,	$\frac{7}{8}$ black $\frac{1}{8}$ white.
White and Quarteron,	Quinteron,	$\frac{15}{16}$ white $\frac{1}{16}$ black.
Black and Quarteron,	Quinteron,	$\frac{15}{16}$ black $\frac{1}{16}$ white.

The two latter are reſpectively reputed white and black; the former are white by law, and conſequently free in our Weſt India iſlands. They are not diſtinguiſhable from pure whites in complexion, features, or hair.

Thus, in obedience to that principle, by which the properties of the offspring depend on thoſe of the parents, we have the power of changing one ſpecies into another by repeated intermixture. If the offspring of a white woman and a black be matched with a black man, and this proceſs be repeated two or three times, the form of the original mother is entirely loſt, and that of the father ſubſtituted; or, *vice verſâ:* and the ſame may be done with plants.

Exceptions to the Law concerning the Colour of the mixed Breeds.—Although the children generally partake of the character of both parents, they ſometimes reſemble one only; and in ſuch a caſe, the influence of the other is often obſerved in the ſecond or third generation. We ſee children like their grandſires, and unlike the father and mother.

> "Fit quoque, ut interdum ſimiles exiſtere avorum
> Poſſint, et referant proavorum ſæpe figuras.
> * * * * * * * *
> Inde Venus varias producit ſorte figuras,
> Majorumque refert voltus, voceſque, comaſque."
> Lucretius, lib. ii.

Thus, a white Negreſs (Albineſs) married an Engliſhman, and brought forth three true Mulattos, but with light hair. (Blumenbach, Beyträge, p. 125.) The offspring of a black and white may be either black or white, inſtead of being mixed; and in ſome rare caſes it has been ſpotted.

A black man married a white woman in York, who in due courſe of time had a child that was entirely black, and very much like the father both in colour and features, without the leaſt participation of the features or colour of the mother. A black man married a white woman in London, who afterwards had a daughter as fair as any one born of white parents, and like the mother in features; but her right buttock and thigh were as black as the ſkin of the father. A Negro woman had a white daughter by a man of her own race: white children had been frequently born in his family, and his own father was one of theſe; but his grandfather and grandmother were black. Parſons in Phil. Tranſ. vol. lv.

A Negreſs had twins by an Engliſhman: the one was perfectly black, with ſhort, woolly, curled hair; the other was white, with long hair. White on the regular Gradation, p. 122.

Production of Varieties.—It is a general law, that animals produce their like; and thus ſpecies and races preſerve uniformity of character. But this reſemblance between children and their parents is not conſtant: the former, under certain circumſtances, differ from the latter; and thus we have perſons in each race, with characters approaching to thoſe of the other races. In European countries, ſcattered inſtances of individuals, with ſkins nearly as dark as thoſe of the Mongols or South ſea iſlanders, are not unfrequent. Forſter, in his voyage round the world, ſaw a man with fair ſkin and red hair in an iſland, where the inhabitants in general are nearly black. Among the Otaheiteans, who are deſcended from the Malay race, light complexions and flaxen hair are not very uncommon; and red-haired individuals have been obſerved in moſt of the dark coloured nations, as the Wotiaks, Eſquimaux, iſlanders of New Guinea and New Zealand, and the Negroes. (Blumenbach, p. 169.) Again, the origin of Albinos, particularly in the black nations, is a remarkable example of native variety of colour.

Inſtances analogous to theſe are of daily occurrence among animals, as in the production of black ſheep, cats, horſes, foxes, &c. White ſheep produce black lambs; and grey rabbits may bring forth either white (leucæthiopic) or black ones. Two common peacocks produced fourteen young: two of them were white, and the reſt reſembled their parents. (Buffon, vol. xii. p. 286, note.) Leucæthiopic animals are conſtantly produced from thoſe of the ordinary characters.

The native varieties, thus produced, are propagated by generation,

generation, and become eſtabliſhed as permanent breeds, if individuals with theſe new characters conſtantly intermix. Thus, the leucæthiopic conſtitution has become fixed in the white rabbit and ferret; and thus, before our eyes, as great a deviation from the common ſtock has been formed, as any in the human race. Black rams are always rejected in breeding, becauſe they would transfer this colour to their progeny. In many parts of England, all the cattle are of one colour: this ariſes from the long-eſtabliſhed cuſtom of ſlaughtering all the calves which have not the deſired tint. (Prichard de Hom. Variet. p. 32.) We have no reaſon to doubt, that if the ſame plan were adopted with the human ſubject, that is, if perſons marked by certain native peculiarities were united, their offspring again matched with ſimilar individuals, and this conſtantly repeated, that any native variety might be fixed as a permanent breed. Human Albinos are ſo few, that this cannot be effected; and hence we have no race like the ferret or white rabbit. Travellers indeed report, that tribes of Albinos are found in Java, where they are called Kakkerlakken (Chacrelas); in Ceylon, (Bedas); and in the iſthmus of Darien. (See Buffon, vol. iii. p. 328. 344. 419.) The ſtatement concerning the latter is the moſt circumſtantial, and poſſeſſes the ſtrongeſt appearance of authenticity: but none of thoſe, who ſpeak of theſe white Indians, ſaw more than one or two of them; and we believe that ſubſequent reports have by no means corroborated the notion that whole nations of ſuch people exiſt. Hence we are to regard leucæthiopia as having occurred only in ſcattered inſtances in the human ſubject, and as having been very rarely tranſmitted by generation, becauſe the individuals are not numerous enough for them to breed together.

The diſpoſition to change is exhauſted in one generation, and the characters of the original ſtock return, unleſs the variety is kept up in the manner above mentioned; that is, when Albinos intermix with the common race, the offſpring reſembles the latter. A white Negreſs brought forth to a Negro a perfectly black ſon. (Blumenbach, Beyträge, p. 125.) And the ſame circumſtance is ſeen in vegetables: the variegated holly can only be preſerved as a variety by grafting; when we attempt to propagate it by ſeed, it returns to the common green holly.

In conſidering this as an explanation of the varieties of colour, an objection will probably occur; that we do not, in point of fact, ſee Negroes or Americans produced among the white races, nor Europeans among the former. If it were neceſſary to our theory to prove that ſuch varieties do occur, we ſhould deem it untenable: but the Negro and the European are the two extremes of a very long gradation; between them are almoſt innumerable intermediate ſtages, which differ from each other no more than the individuals, occaſionally produced in every race, differ from the generality of the race.

Spotted Individuals. — Examples occur of individuals ſpotted with different colours; but they are by no means ſo common as thoſe of ſpotted animals. See, on this ſubject, the *variations in the formation of the ſkin*, in the article Monster.

Other Properties of the Skin.—The ſkin differs in ſome other properties beſides its colour. Travellers have deſcribed it as remarkably ſoft and ſmooth, and as it were ſilky, in the Carib, Negro, Otaheitean, and Turk. It ſecretes a matter of peculiar odour in ſome races. "The Peruvian Indians," ſays Humboldt, "who, in the middle of the night, diſtinguiſh the different races by their quick ſenſe of ſmell, have formed three words to expreſs the odour of the European, the Indian American, and the Negro: they call the firſt pezuña, the ſecond poſco, and the third graio." Humboldt, p. 245.

The hair, as it grows and is nouriſhed from the common integuments, is connected with them in many points by a cloſe kind of ſympathy. Hence the ſpotted Africans have white hairs growing out of a white patch on the head. The four laſt of the varieties mentioned in the deſcription of the colours of men, have black hair; and in the firſt, or the white, every gradation from the fair to the dark, is accompanied by correſpondent alterations in the hair. This is true, not only of nations, but alſo of individuals in the white races. A light complexion and thin ſkin are accompanied with red or fair hair; a dark one, and thick ſkin, with black hair, almoſt invariably, even in individuals of the ſame family; a difference, which, according to the philoſophy of ſome writers, would be a ſufficient ground for claſſing them in different ſpecies. The other properties of the hair vary, as well as its colour; and theſe changes may be brought under the four following varieties:

1. Browniſh, deviating into red on one ſide and black on the other; this is copious, ſoft, and long, and ſlightly undulated. It obtains in moſt of the temperate climates of Europe, and formerly attracted particular notice in the ancient Germans. The thin and white ſkinned Albino has the ſofteſt and fineſt hair, of a white colour: in the Germanic race it is alſo very ſoft; and red hair is uſually found in conjunction with a thin and ſoft ſkin. The Celtic and Slavonic races, which make up the chief population of Europe, and the eaſtern Aſiatics and northern Africans have generally, with a rather thicker and darker ſkin, ſtronger, black, or darkiſh brown, and often more or leſs curling hair.

2. Black, ſtrong, ſtraight, and thin; occurring in the Mongolian and American races.

3. Black, ſofter, denſe, copious and curled; obſervable in moſt of the South Sea iſlanders.

4. Black, and criſp, ſo as generally to be called woolly; common to all the Ethiopians.

The analogy, on which the covering of the Africans has thus been called wool, is quite a looſe one, and goes no further than a ſlight reſemblance in appearance. The filament in wool is rough on its ſurface, in the hair it is ſmooth: the latter is of uniform thickneſs throughout, or rather ſlenderer towards the point, while the former is unequal in ſize, and rather larger towards its end. The wool is detached altogether, while the hairs fall off ſeparately. In none of theſe characters does the hair of the African agree with wool.

The above diviſion, although ſufficient for general purpoſes, is not uniformly true. For the woolly hair is not confined entirely to the Ethiopians, nor is the black colour invariably found in all the three laſt varieties. Some tribes of Africans have long hair, (Bruce of the Gallas) and other red coloured people, as thoſe of the Duke of York's iſland, have it ſtrongly curled. The New Hollanders form ſo complete a medium between the woolly haired African, and the copious curling hair of the other South Sea iſlanders, that we are completely puzzled how to claſs them. Individual inſtances of red hair occur in all the three laſt varieties.

The ſoft white hair of the Albino may be produced in any race of mankind; and is moſt widely different from the black hair of the dark varieties.

The animal kingdom furniſhes us with numerous parallel inſtances of varieties in the colour and texture of the hair; as, for example, in the black ſheep, black and white horſes, &c. The ſheep exhibit every kind of covering, from the delicate

delicate fleeces of Thibet or Spain, to the coarſe and rough hair which takes the place of wool in many warm countries.

The briſtles of the pig are ſo ſoft in ſome kinds, as in Normandy, that they are not applicable to the manufacture of the ordinary inſtruments. The wild pig has a ſoft curling hair interpoſed between its briſtles, which is entirely loſt in the domeſticated animal.

Sheep, rabbits and cats in Angora, a ſmall diſtrict of Aſia Minor, are remarkable for the length and ſoftneſs, as well as ſnowy whiteneſs of their coverings.

The ſheep of ſome of the Tatar tribes have hairs mixed with the wool: ſuch a mixture is obſerved even in this country, where the breed is neglected; and it occurs in the Argali, the ſuppoſed wild origin of our flocks. In theſe caſes, if the animals with the beſt fleeces are ſelected to breed from, and this rule be obſerved conſtantly, the wool would be gradually improved, and the hairs diſappear; or *vice verſa*, the ſheep would become entirely hairy.

A child born in Yorkſhire of European parents, had the woolly hair; and this is not the only example. Prichard de Generis Hum. Variet. p. 26.

It muſt appear very clearly, from theſe analogies, that the differences of the hair will not warrant us in eſtabliſhing diſtinct ſpecies of men.

Together with the differences of the hair we may mention thoſe of the beard. This growth is ſmall in quantity, and thin in many tribes of the Mongolian, African and American races. "One of the moſt general characters of the ugly nations," ſays Meiners, "is either an entire want of beard, or a very thin one, developed at a later period than uſual: on the contrary, a copious beard has always been the pride of the handſome races. Dark coloured nations, with ſtrong beards, are not much more numerous than individuals of handſome people with a weak growth." Grundriſs, p. 98.

Unfounded reports have been generally received of its entire abſence in the Americans, and this circumſtance has been repreſented as a characteriſtic peculiarity of the race. The concurring teſtimonies of all accurate modern travellers prove clearly that the Americans have naturally beards; that it is a very general cuſtom with them, as it has been with ſeveral Mongolian and Malay tribes, carefully to eradicate this excreſcence; but that various hordes in different parts of the continent preſerve it as other men do. Gmelin found this practice in Aſia. "It is not eaſy to find a Tunguſe, nor any man of the neighbouring tribes, with a beard. For they extract the hairs as ſoon as they appear, and repeat this proceſs until at laſt no more are formed." (Reiſe durch Sibirien, t. 2. p. 125.) The ſame circumſtance is reported of the Sumatrans by Marſden; of the Mindanao iſlanders by Forreſt; of the Pelew iſlanders by Wilſon; the inhabitants of New Guinea by Carteret; and thoſe of Navigators iſles, by Bougainville. From a cloud of unanimous teſtimonies concerning the Americans, we extract the following ſtatement of Cook reſpecting the inhabitants of Nootka Sound: "Some have no beards at all, and others only a thin one on the point of the chin. This does not ariſe from an original deficiency of hair in thoſe parts, but from their plucking it out by the roots: for thoſe, who do not deſtroy it, have not only conſiderable beards on every part of the chin, but alſo whiſkers, or muſtachios, running from the upper lip to the lower jaw obliquely downwards." (Laſt Voyage, v. 2. p. 240.) The teſtimony of Humboldt concerning the South Americans is to the ſame effect: "The Mexicans, particularly thoſe of the Aztec and Otomite races, have more beard than I ever ſaw in any other Indians of South America. Almoſt all the Indians in the neighbourhood of the capital wear ſmall muſtachios."—"I can affirm that the Indians, who inhabit the torrid zone of South America, have generally ſome beard; and that this beard increaſes when they ſhave themſelves."—"Mr. de Galeano, in the account of the laſt Spaniſh expedition to the Straits of Magellan, informs us that there are many old men among the Patagonians with beards, though they are ſhort, and by no means buſhy." (Political Eſſay on the Kingdom of New Spain, v. 1. p. 147.) The exiſtence of a beard, and the habit of extirpating it, are mentioned of the Greenlanders, by Cranz, Geſchichte von Grönland; by Charlevoix of the Eſkimaux, Nouvelle France, iii. p. 179: by Oldendorp of the Caribs, Geſchichte der Miſſion auf den Karaibiſchen Inſeln; p. 22: By Wafer of the Americans at Panama, Iſthmus of America, p. 106; by Bougainville of the Patagonians, Voyage autour du Monde; and by Parkinſon, of the inhabitants of Terra del Fuego, voyage v. 1. Commerſon ſpeaks of the whiſkers of the Patagonians, Journal Encyclop. 1772.

Colour of the Iris.—We have juſt explained how the hair is connected with the ſkin: that a ſimilar connexion in point of colour exiſts between the latter organ and the eyes, was noticed by Ariſtotle, who obſerved that white perſons have blue eyes, and black ones black. Thus, in Germany, Blumenbach ſays that newly-born children have generally blue eyes and light hair, and that both grow gradually dark together in individuals who become dark. Again, the pigmentum of the eye loſes much of its colour in proportion as the hair grows grey in the old ſubject. With their peculiar hair and ſkin, the Albinos have an entire deficiency of the pigment, and conſequently a pale red iris. Thoſe animals only which vary in the colour of the ſkin and hair, have differently coloured irides; and this is true, not only of men and horſes, according to the opinion of the ancients, but of other animals, particularly in the domeſticated ſtate. Moreover, the iris is often variegated in animals which have a ſpotted ſkin. This has been noticed in dogs (Comment. Inſtit. Bonon. t. iii. p. 281.). Blumenbach has obſerved ſomething of it in horſes and ſheep, but more particularly in rabbits: the grey, or thoſe which have the native colour of their wild ſtate, have dark irides; the ſpotted have them marked with different colours; and the white, like other Leucæthiopic animals, have them of a pale roſe colour.

The three principal colours of the human eye were well laid down by Ariſtotle; *viz.* 1, blue, paſſing, in its lighter tints, to what we call grey; 2, an obſcure orange, which he calls the colour of the eye in the goat (Gall. Yeux de Chevre:) it is a kind of middle tint, between blue and orange, and ſometimes remarkably green in men with red hair and freckled ſkin; and 3, blackiſh brown.

Theſe may all occur in different individuals of the ſame race; and again, they are ſometimes confined to the different tribes of the ſame country, within the boundaries of a few degrees. Thus Linnæus deſcribes in Sweden the Gothlander with light hair and greyiſh-blue eyes; the Fin with yellow hair and brown iris; and the Laplander with black hair and iris. Blue eyes, as well as yellow hair (rutilæ lat. denoting the reſemblance to gold, whence auricomi Batavi, Silius; ξανθος, Gr.) were formerly ſet down among the characters of the Germans (cærulei oculi, rutilæ comæ, Tacitus); and the ſame combination is met with in ſcattered inſtances, in the moſt remote nations. The iris of the negro is the moſt intenſely black, ſo that very cloſe inſpection is neceſſary, in living individuals, to diſtinguiſh it from the pupil.

Differences of Form.—The exiſtence of great variations in the

the conformation and proportions of the body in all animals, and particularly of the features of the human countenance, fubject, however, to certain fixed rules as to the general model, accords entirely with what we obferve throughout all nature.

" Præterea genus humanum, mutæque natantes
Squammigerum pecudes, et læta armenta, feræque,
Et variæ volucres ; lætantia quæ loca aquarum
Concelebrant, circum ripas, fontefque, lacufque ;
Et quæ pervolgant nemora avia pervolitantes ;
Horum unum quodvis generatim fumere perge :
Invenies tamen inter fe diftare figuris.
Nec ratione alia proles cognofcere matrem,
Nec mater poffit prolem ; quod poffe videmus,
Nec minus atque homines inter fe nota cluere."

National Features.—Although it is a common and very juft obfervation, that two individuals are hardly to be met with poffeffing exactly the fame features, yet there is generally a certain caft of countenance common to the particular races of men, and often to the inhabitants of particular countries. The five following varieties are eftablifhed by Blumenbach, after a careful comparifon of numerous drawings, and of the various races themfelves, in fituations, where commerce attracts them from all parts of the globe, as at London and Amfterdam.

1. An oval and ftraight face, with the different parts moderately diftinct from each other : forehead rather flattened, nofe narrow, and flightly aquiline, or at leaft with the dorfum fomewhat convex ; no prominence of the cheek-bones ; fmall mouth, with lips flightly turned out, particularly the lower one ; a full and rounded chin.

This is the kind of countenance which accords moft with our ideas of beauty : it may be confidered as a middle, departing into two extremes, exactly oppofed to each other ; of which one confifts in a lateral expanfion of the face, and the other in its being extended downwards. Each of thefe includes two varieties, which are moft readily diftinguifhed by a profile view ; one, in which the nofe and other parts run together, and the other, in which they are more prominent and feparate.

2. Broad and flattened face, with the parts flightly diftinguifhed, and as it were running together : the fpace between the eyes flat and very broad ; flat nofe, rounded projecting cheeks ; narrow and linear aperture of the eye-lids extending towards the temples (Yeux bridés, Fr.) chin flightly prominent.

This is the face of the Mongolian tribes; commonly called in Englifh the Tartar face, from the confufion of the Tartars (Tatars) with the Monguls.

3. Face broad, but not flat and depreffed, with prominent cheek-bones, and the parts, when viewed in profile, as it were, more deeply and diftinctly carved out. Short forehead ; eyes deeply feated ; nofe flattifh, but prominent. Such is the countenance of moft of the Americans.

4. Narrow face, projecting towards its lower part ; arched forehead ; eyes prominent (à fleur de tête) ; a thick nofe, confufed on either fide with the projecting cheeks (nez épaté) ; the lips, particularly the upper one, very thick ; the jaws prominent ; and the chin retracted. This is the countenance of the Negro—the Guinea face.

5. The face not fo narrow as in the preceding, rather projecting downwards, with the different parts in a fide-view, rifing more freely and diftinctly. The nofe rather full and broad, and thicker towards its apex (bottle-nofed). The mouth large. This is the face of the Malays, particularly of the South Sea iflanders. Excellent reprefentations of celebrated individuals of thefe five varieties may be feen in Blumenbach's Abbildungen Naturhiftorifcher Gegenftände, part i. ; alfo, in his Beyträge zur Naturgefchichte.

Intermediate Gradations and Varieties in the different Races.—In this refpect, as in colour, the different characters run into each other by the moft gentle gradations ; fo that, although any two extremes, when contrafted, appear ftrikingly different, they are connected by numerous intermediate and very flightly differing fhades ; and no formation is exhibited fo conftantly in all the individuals of one race, as not to admit of numerous exceptions.

In the Africans.—We fee, indeed, an aftonifhing difference, when we place an ugly Negro (for there are fuch as well as ugly Europeans), againft a fpecimen of the Grecian ideal model ; but, when we trace the intermediate gradations, this ftriking diverfity vanifhes. " Of the Negroes of both fexes," fays Blumenbach, " whom I have attentively examined, in very confiderable number, as well as in the portraits and profiles of others, and in the numerous Negro crania, which I poffefs, or have feen, there are not two completely refembling each other in their formation : they pafs, by infenfible gradations, into the forms of the other races, and approach to the other varieties even in their moft pleafing modifications. A Creole, whom I faw at Yverdun, born of parents from Congo, and brought from St. Domingo by the chevalier Treytorrens, had a countenance, of which no part, not even the nofe, and rather ftrongly marked lips, were very ftriking, much lefs difpleafing : the fame features, with an European complexion, would certainly have been generally agreeable." (Beyträge zur. Naturgefchichte, p. 89.) The teftimony of Le Maire, in his journey to Senegal and Gambia, is to the fame effect ; that there are Negreffes, except in colour, as handfome as European women. Vaillant fays of the Caffre women, that, fetting afide the prejudice which operates againft their colour, many might be accounted handfome, even in an European country. The accurate Adanfon confirms this ftatement, in his defcription of the Senegambians. " Les femmes font a peu prés de la taille des hommes, également bien faites. Leur form eft d'une fineffe et d'une douceur extrême. Elles ont les yeux noirs, bien fendus, la bouche et les levres petites, et les traits du vifage, bien proportionnés. Il s'en trouve plufieurs d'une beauté parfaite. Elles ont beaucoup de vivacité, et fur tout un air aifé de liberté qui fait plaifir." (Hift. Nat. du Senegal, p. 22.) The Jaloffs, according to Mungo Park, have not the protuberant lip, nor flat nofe of the African countenance. We have alfo the teftimony of another traveller, concerning this tribe, to the fame effect : the Jaloffs, according to Moore, have handfome features, and neither broad nofes nor thick lips. (Zimmermann Geographifche Gefchichte, &c. vol. i. p. 99.) Pigafetta ftates, that the Congo Negroes have not the thick lips of the Nubians, and that, except in colour, they are very like the Portuguefe. (Relazione del Reame di Congo, Roma, p. 12.) Dampier, in his account of Natâl, defcribes the natives as having curled hair, but a long face, well-proportioned nofe, and agreeable countenance. The fix Negro crania engraved in the two firft decades of Blumenbach, exhibit very clearly this diverfity of character in the African race ; and prove, moft unequivocally, that the variety among individuals is certainly not lefs, but greater than the difference between fome of them and many Europeans. See Decas Craniorum, p. 22, and Decas Altera, p. 13.

In the Americans.—The fame obfervations hold good of the American race. The moft accurate obfervers treat with contempt the hyperbolical affertion of fome, that all the inhabitants of the New World have one and the fame countenance, fo that he who has feen one may fay that he has feen all,

all. "Rido fra me stesso," says Molina, "quando leggo in certi scrittori moderni riputati diligenti osservatori, che tutti gli Americani hanno un medesimo aspetto, e che quando se ne abbia veduto uno, si posse dire di avergli veduti tutti. Codesti autori si lasciarono troppo sedurre da certe vaghe apparenze di somiglianza procedenti per lo piu dal colorito, le quali svaniscono tosto che si confrontano gl' individui di una nazione con quelli dell' altra. Un Chilese non si differenzia meno nell' aspetto da un Peruviano, che un Italiano da un Tedesco. Io ho veduto pur dei Paraguaii, de'Cujani, e dei Magellanici, i quali tutti hanno dei lineamenti peculiari, che li distinguono notabilmente gli uni dagli altri." (Storia Naturale del Chili, p. 336. We have further unexceptionable testimony to prove that the same variety of countenance is found in the Americans as in other races; although generally the countenance follows the model above described. In South America only we have the Caaiguas with flat noses, observed by Nic. del Techo; the neighbouring Abipons, of whom many individuals have aquiline noses, by Martin Dobrizhoffer; the Peruvians with narrow and aquiline nose by Ulloa; the Chilese with rather a broad nose by Molina; and the islanders of Terra del Fuego with a very depressed one by G. Forster. The truth of this representation is most fully attested by Humboldt, whose accuracy and extensive opportunities entitle his observations to the most implicit deference. "In the faithful portrait, which an excellent observer, Mr. Volney, has drawn of the Canada Indians, we undoubtedly recognise the tribes scattered in the meadows of the Rio Apure and the Carony. The same stile of feature exists, no doubt, in both Americas; but those Europeans who have sailed on the great rivers Orinoco and Amazons, and have had occasion to see a great number of tribes assembled under the monastical hierarchy in the missions, must have observed that the American race contains nations, whose features differ as essentially from one another, as the numerous varieties of the race of Caucasus, the Circassians, Moors, and Persians, differ from one another. The tall form of the Patagonians is again found by us, as it were, among the Caribs, who dwell in the plains from the delta of the Orinoco, to the sources of the Rio Blanco. What a difference between the figure, physiognomy and physical constitution of these Caribs, who ought to be accounted one of the most robust nations on the face of the earth, and are not to be confounded with the degenerate Zambos, formerly called Caribs of the island St. Vincent, and the squat bodies of the Chayma Indians of the province of Cumana! What a difference of form between the Indians of Tlascala and the Lipans and the Chichimeos of the northern part of Mexico." Political Essay on the Kingdom of New Spain, v. i. p. 142.

In the South Sea Islanders.—An analogous variety has been noticed in the features of the Friendly islanders: "their features are very various; insomuch, that it is scarcely possible to fix on any general likeness by which to characterize them, unless it be a fulness at the point of the nose, which is very common. But, on the other hand, we met with hundreds of truly European faces, and many genuine Roman noses amongst them." Cook's Last Voyage, v. i. p. 380.

In Europeans.—Again, particular individuals in Europe often have the countenance exactly resembling the Negro, or Mongol face.

Differences in the Skull.—The form of the cranium in the different varieties of man has been described in the article Cranium; in which the causes of the diversities of its figure are also considered. We have one or two additional remarks to make, particularly concerning the Negro. "The bony apparatus," says Soemmerring, "concerned in mastication, as well as the part of the face containing the organs of sense, are, whether considered generally or particularly, stronger, thicker, and more advantageously disposed for this strength in the Negro, than in the race where more extensive use of experience and reason, and greater cultivation supply the place of what is deficient in animal strength. Should we take the bones of the face in the Negro, as a basis, and add to them a cranium, according to the proportions observed in European heads, the space allotted for the reception of the organ of thinking would exceed the size that it has in us. Von der korperl. Verschiedenheit, § 12. The ridge that bounds the origin of the temporal muscle is more prominent, and rises much higher on the side of the head in the Negro, than in the European; consequently, the muscle is considerably larger, and the bony arch surrounding it (the zygoma), is larger, stronger, and more capacious. (Ibid. § 16 and 17.) Both openings of the nose are more ample, and the cavity itself considerably more capacious than in the European. The thin convoluted plates of the ethmoid bone are larger, and consequently increase the extent of the pituitary membrane: the cribriform plate is remarkably large. These circumstances of anatomical structure are not, however, peculiar to the Negro: Soemmerring finds the nasal cavity in the cranium of a North American savage still more ample than in most Negroes. (Ibid. § 21 and 22.) The instances related of the fineness of smell in these people, such as their being able to distinguish Europeans from Negroes and Americans, &c. correspond to what we observe in their organs.

"The nerves," says this anatomist, "connected with the basis of the brain, appear to me, in comparison with an European brain of the same size, to be, in proportion, rather larger; at least the olfactory, the fifth, and the facial nerves, are remarkably large, as we might have expected, from the greater size of the nose and face." § 56.

The relation between the cranium and face is best seen in a vertical section carried from before backwards: the area of the face, independently of the lower jaw, is about one-fourth of the cranium in the European: in the Negro, the cranium remaining the same, the face increases by about one-fifth. The proportion still increases in the ourang-outang: in the sapajous, the mandrils, and most of the carnivora, the face and cranium are about equal.

The ossa nasi of the Negro, instead of forming the bridge-like convexity which we see in the European, are nearly flat, and run together into an acute angle above, which makes them very much resemble the single triangular nasal bone of the ape. But in one cranium they exactly resemble the European. Ibid. § 19.

The varieties in the form of the teeth are also considered in the article Cranium.

Supposed Causes of Difference of Features: Climate.—That the national differences of features owe their origin to climate, has been the opinion of many philosophers; and some have even attempted to shew how the effect is produced. "En effet," says Volney, "j'observe que la figure des Negres représente precisément cet état de contraction que prend notre visage, lorsqu'il est frappé par la lumière et une forte réverbération de chaleur. Alors le sourcil se ferme; la pomme des joues s'élève; la paupière se serre; la bouche fait la moue. Cette contraction, qui a lieu perpétuellement dans le pays nud et chaud des Nègres, n'a-t-elle pas dû devenir le caractère propre de leur figure?" Volney, Voy. en Syrie et en Egypte, t. i. p. 74. It is unfortunate for these speculations that the most opposite kinds of features occur under similar climates in different parts of the world; and that there are races with flattened countenances, as well as with prominent ones in hot countries. Thefe caufes, too, could only affect the foft parts: a negro might "faire la moue" to eternity, without altering the whole bony compages of his head. Indeed, the whole account is fo fanciful, that it hardly deferves ferious attention. If there were any foundation for the fuppofition, we might expect Mr. Volney's countrymen, from their well-known habit of fhrugging the fhoulders, to have become long ago the higheft fhouldered race in the world.

Artificial Preffure.—The cuftom of carrying the children on the back has been referred to by others, in order to explain the flat nofe of the Negro: in the violent motions required for their hard labour, as in beating or pounding the millet, &c. the face of the young one is faid to be conftantly beating againft the back of the mother. The teftimonies concerning the employment of preffure, with a view to flatten the nofe, are fo numerous and refpectable, that we cannot refufe to believe that it is attempted. (See Blumenbach, de Varietate, p. 193.) But two reafons prevent us from afcribing any efficacy to thefe practices in producing the national varieties of the cranium. The diverfities extend fo generally through the whole bony fabric of the head, and are obfervable in fo many parts, where external preffure could have no influence, not to mention that they confift, in many inftances, of formations juft the reverfe of what preffure would effect, that we muft afcribe them to native variety. This determination is confirmed by the difcovery, that all the peculiarities of the Negro cranium exift in the fœtus. The refearches of Blumenbach, Camper, Soemmerring, Ludwig, and Loder, have proved this fact concerning Negro fœtufes of various ages, in whom they find the fame prominence of the jaws, flat nofe, &c. as in the adult. (Soemmerring von der körperl. Verfchiedenheit, § 4. Ludwig Grundrifs der Naturgefchichte der Menfchen Species, p. 121.) The children of Negro parents in Europe, America, and other fituations, where there are opportunities of knowing that no means are ufed to flatten the nofe, refemble, in all refpects, thofe born in Africa. Thefe arguments receive a further confirmation from three of the crania engraved by Blumenbach, of a Jewifh girl, five years old, a Mongolian child, a year and a half, and a newly born Negro, in which the characters of the Caucafian, Mongolian, and Ethiopian varieties are as ftrongly reprefented as in the heads of adults. Decas tertia, tab. 28—30. p. 14.

In the form and proportions of other parts, there are not fewer differences than in the compofition of the features.

Differences in the Form and Proportions of other Parts.—Connection of the Head and Trunk.—In confequence of the foramen magnum being placed further back in the head in the Negro than in the European (fee CRANIUM), and of the head of the former being confequently placed further forwards on the vertebral column, the occiput projects lefs behind the fpine. Hence, a line drawn from the occiput along the nape of the neck, is nearly ftraight in the Negro, but it dips in confiderably under the head in the European; as if a part of the cranium had been fliced off in the former. The fame circumftance may be obferved in a much more ftriking degree in the Simiæ.

Body and Limbs.—The body is large, fquare, and robuft; the extremities thick, fhort, and nervous; and the fhoulders high in the Monguls. They are well defcribed in a letter inferted in the Hiftoria Major of Matthew Paris, London, 1686, p. 530, under the name of Tartars (Tatars). "Habent autem Tartari pectora dura et robufta, facies macras et pallidas, fcapulas rigidas et erectas, nafos diftortos et breves, menta proeminentia et acuta, fuperiorem mandibulam humilem et profundam, dentes longos et raros, palpebras a crinibus ufque ad nafum pretenfas, oculos inconftantes et nigros, afpectus obliquos et torvos, extremitates offofas et nervofas, crura quoque groffa, fed tibias breviores, ftatura tamen nobis æquales; quod enim in tibiis deficit, in fuperiori corpore compenfatur."

In the negro the body is more flender, particularly about the loins and pelvis. The dimenfions of the latter cavity are actually fmaller than in the European: in the fkeleton of a negro, twenty years old,

	Inches.	Lines.
The great diameter of the pelvis is -	3	$11\frac{1}{2}$
The fmall ——————— -	3	$7\frac{1}{2}$
In a negro boy of 14, the great diameter is	3	2
——————— fmall ———	2	9
In an European of 16, the great ———	4	3
——————— fmall ———	3	9
In an old European, inferior in ftature to the negro of 20 years, the great -	4	6
——————— the fmall -	3	11

Camper found that the great diameter (from one os innominatum to the other) was to the fmaller (from the facrum to the fymphyfis pubis)

In the negro as -	39	to	$27\frac{1}{2}$
In the European as -	41		27

yet the ftature of the negro exceeded confiderably that of the European. In another European the proportions were as 44 to 28. (See Soemmering über die körperliche Verfchiedenheit, p. 33.) Not only is the cavity fmaller, but the bones compofing it are flenderer: and the circumftance has been noticed by travellers and others.

The fame flendernefs of the trunk may be obferved in fome of the Indians: it is at leaft apparent in the Lafcars, who come to this country with the Eaft India fhips. Their legs are long.

Proportionate Length of the Arm and Fore-arm.—The limbs are fmaller in the negro, and fome differences are obfervable in particular parts. "I meafured," fays Mr. White, "the arms of about fifty negroes, men, women, and children, born in very different climates, and found the lower arm longer than in Europeans, in proportion to the upper arm, and to the height of the body. The firft negro on the lift is one in the Lunatic hofpital at Liverpool; his fore-arm meafures $12\frac{3}{4}$ inches, and his ftature is only 5 feet $10\frac{1}{2}$ inches. I have meafured a great number of white people, from that fize up to 6 feet $4\frac{1}{2}$ inches, and among them one who was faid to have the longeft arms of any man in England, but none had a fore-arm equal to that of the black lunatic.

"I have meafured the arms of a great number of European fkeletons, and have found that the os humeri, or upper arm, exceeds in length the ulna, which is the longer bone of the fore-arm by two or three inches; in none by lefs than two, and in one by not lefs than $3\frac{1}{8}$ inches. In my negro fkeleton, the os humeri is only one inch and one-eighth longer than the ulna. In Dr. Tyfon's Pigmy (fimia fatyrus), the os humeri and ulna were of the fame length; and in my fkeleton of a common monkey, the ulna is $\frac{3}{4}$ of an inch longer than the os humeri." White, on the Regular Gradation, p. 52, et feq.

As the comparifon juft mentioned leads to fome interefting

ing refults, we fubjoin a tabular view of the chief particulars.

	Stature.		Length of os humeri.	Length of ulna.
	Feet.	Inch.	Inches.	Inches.
A female European fkeleton	5	$8\frac{1}{2}$	$12\frac{1}{2}$	10
A male ——— ———	5	8	13	$9\frac{7}{8}$
——— negro fkeleton	4	11	11	$9\frac{7}{8}$
A negro at the Lunatic hofpital, Liverpool	5	$10\frac{1}{2}$	15	$12\frac{3}{4}$
Another from Virginia	5	$5\frac{1}{2}$	$13\frac{1}{2}$	$11\frac{3}{4}$
——— ——— Barbadoes	5	$1\frac{3}{4}$	13	11
Male European -	5	$11\frac{1}{2}$	15	11
——— ——— -	5	8	$13\frac{1}{2}$	$10\frac{1}{2}$
——— ——— -	5	$5\frac{1}{2}$	$13\frac{5}{8}$	$10\frac{1}{4}$
——— ——— -	6	$3\frac{1}{2}$	$15\frac{1}{4}$	$11\frac{3}{4}$
——— ——— -	6	$4\frac{1}{2}$	16	$12\frac{1}{4}$
European woman -	5	4	13	$9\frac{3}{4}$

A Lafcar - -	5	4	$12\frac{3}{4}$	$10\frac{1}{2}$
Venus de Medicis -	5		$13\frac{1}{2}$	$9\frac{3}{4}$
Tyfon's chimpanfée -	2	2	$5\frac{1}{2}$	$5\frac{1}{2}$
Monkey - -	2	2	$4\frac{1}{4}$	5

Legs of the Negro, and other Races.—The ancients noticed, what they regarded as defects in the form of the lower limbs in the Egyptians, Ethiopians, and Negro flaves. Soemmering obferves, that the bones of the leg are directed outwards from the knee, fo that the knees appear farther apart, and the feet rather bent outwards: he found the fame circumftance in numerous living negroes. The femur and tibia are flated, both by him and White (who has given a comparative view of the bones of the negro and European leg and foot, pl. 1.), to be more convex in front than in the European. The calves of the leg are very high, fo as to encroach upon the hams. The feet and hands, but particularly the former, are flat; the os calcis, inftead of forming an arch, is continued in nearly a ftraight line with the other bones of the foot, which is remarkably broad. They both terminate in beautiful, but remarkably long fingers and toes, which in that refpect approach to thofe of the monkey; and they all poffeffed, what is not common among Europeans, fefamoid bones. (Von der körperlichen Verfchiedenheit, p. 39.) Unfeemly thicknefs of the legs is not uncommon among the negroes; and the feet are marked with numerous chinks and fiffures, which, as they occur principally in the foles, muft probably be referred to the operation of the burning fands on the epidermis. In the fole of a perfectly healthy negro leg, Blumenbach found this covering "mirum in modum craffa, rimofa, et in multifidas lamellas dehifcens." De Gen. Hum. Var. Nat. p. 246, note *b*.

It has been obferved, that the Indians of the peninfula and the New Hollanders have long and flender limbs; that the Hottentots have meagre bodies and fmall limbs, &c. The crooked legs fo common among the Calmucks, have been affigned to their mode of treating the children, and the practice of riding, to which they are accuftomed from their tendereft years. Pallas uber die Mongolifchen Völkerfchaften, p. 98, tom. i.

The lower limbs are very ill formed in the inhabitants of Terra del Fuego, according to Forfter: he fays that they bear no proportion to the body; that the thighs are meagre and thin, the legs bowed, the knees prominent, the toes turned inwards. Obf. on a Journey round the World.

Ears.—It is well known that the ears ftand off farther from the head, and are moveable in favages, and that the appendix is enlarged and monftroufly elongated by various artificial means in many tribes, particularly in the Eaft Indies and the Pacific. Thefe practices have given rife to the fables of fome older writers concerning the enormous ears of certain people.

Mammæ.—Many travellers have fpoken of the prolix and pendulous mammæ of the females of certain barbarous tribes, particularly in Africa, and in the South fea iflands. We cannot help fufpecting that many of thefe narratives are exaggerated; as, for example, in Hakluyt's Collection, vol. ii. p. 26, where it is faid, that "divers of the women have fuch exceeding long breafts, that fome of them will lay the fame upon the ground, and lie down by them;" in Bruce's Travels, where he fays, that they hang down to the knees in fome of the Shangallas; or in Mentzelius, Befchreibung des Vorgebürges der guten Hoffnung, tom. ii. p. 564, who fays, that purfes are made in great numbers from the breafts of the Hottentot females, and fold at the Cape of Good Hope. It is alfo certain that this conformation is not univerfal in the tribes alluded to, and that many negreffes, who may be feen in the great European emporia, as well as numerous females in the ifles of the Great Pacific (Forfter's Obfervations, &c.), have very beautifully fhaped breafts, and that it exifts alfo in feveral European countries. "I faw," fays Lithgow, "in Ireland's North parts women travayling the way, or toyling at home, carry their infants about their neckes, and laying the dugges over their fhoulders, would give fucke to the babes behinde ther backes, without taking them in their armes: fuch kind of breafts, me thinketh, were very fit to be made money-bags for Eaft or Weft Indian merchants, being more than halfe a yard long, and as well wrought, as any tanner, in the like charge, could ever mollifie fuch leather." (Rare Adventures and Painefulle Peregrinations, p. 433.) An unufually large fize of thefe parts has been obferved in the Morlachian women, by Fortis, (Viaggio in Dalmazia, vol. i. p. 81;) and the Greenland women are faid to fuckle their children at their back.

Long continued fuckling, and the habit of fuckling the children on the back of the mother, feem to be the principal caufes of this ftate of the mammæ. In fome inftances artificial means of elongation have been employed from peculiar notions of beauty.

A large and fwoln ftate of the breaft, is mentioned by Juvenal of the Egyptians, as a well-known fact. "In Meroe craffo majorem infante papillam." The Portuguefe women, of modern days, are faid to be remarkable in the fame way; while the breafts are fmall in the Spaniards, as in the laft century at leaft they took pains to comprefs them in order to prevent too great a luxuriance.

To the difgrace of London, even in this truly pious age of focieties for fuppreffing vice and diftributing bibles, a philofophic foreigner has found in her ftreets a proof of the effects of too early venereal excitement in enlarging the breaft; and has commemorated the fact in a claffical work, which muft convey the fcandal over the whole learned world. "Contraria cura ambitum mammarum augeri poffe nullum dubium eft; quantum vero præterea Venus quoque præmatura eo conferre poffit memorabili fane exemplo impuberes et nondum adultæ puellæ mercenariæ docent quæ Londinum, præfertim ex vicinis maxime fuburbiis, confluunt, et quæftum quæſtum corpore facientes ingenti numero plateas noctu pervagantur." De Gen. Hum. Variet. p. 239.

Organs of Generation.—Negroes are particularly famous for their organs of generation: and ſpecimens preſerved in anatomical cabinets ſeem to juſtify their celebrity for the ſize of theſe parts; but it is doubtful whether this be a general character. The frænum preputii does not exiſt in many of them. White, p. 62.

In the Hottentot women, and in ſome others, the nymphæ are ſaid to form growths of conſiderable ſize (in dactyliformes appendiculas abire); but the former are more celebrated for what has been deſcribed as a natural covering of ſkin, hanging from the abdomen, and hiding the parts of generation. This, with other arguments of equal force, is brought forward by Voltaire, to prove that the Hottentots are not of the ſame ſpecies with Europeans. (Lettres d'Amabed.) Blumenbach, who received from ſir Joſeph Banks, ſeveral views of theſe parts, drawn from the life, informs us that the peculiarity is an artificial elongation of the labia pudendi; in one repreſentation they are 6½ inches long. Le Vaillant's teſtimony is to the ſame effect. Voyage dans l'Inter. de l'Afrique, p. 371. See GENERATION.

Hands and Feet.—Smallneſs of the hands and feet has been mentioned as a character of ſome races, as the Indians, Chineſe, Kamtſchatkans, Eſkimaux, Peruvians, New Hollanders, and Hottentots. "It has been obſerved," ſays Hodges, "of the arms of the Hindoos frequently brought to England, that the gripe of the ſabre is too ſmall for moſt European hands." Travels in India, p. 3.

What art can produce in this way, is ſhewn by the feet of the Chineſe women.

Tranſmiſſion of native Characters to the Children.—Peculiarities of form, like thoſe of colour, are tranſmitted to the offspring; and this principle prevails ſo generally, that even thoſe minute, and to our ſenſes entirely imperceptible differences of organization or vital properties, which render men diſpoſed to particular diſeaſes, are conveyed from father to ſon for age after age. Hence we ſee a general reſemblance in perſons of the ſame blood, and may frequently obſerve a peculiar feature running through a whole family. The thick lip introduced into the imperial houſe of Auſtria by the marriage of Maximilian to Mary of Burgundy, is viſible in their deſcendants to this day. In ſmall and ſecluded communities, where marriages take place within what we may regard only as a more extenſive family, hereditary varieties are blended, and produce one form, which prevails through the whole circle. The operation of this principle may be clearly perceived in ſeveral ſmall diſtricts: it will act with more efficacy, and conſequently be more diſcernible, in larger collections of men, where differences of manners, religion, and language, and mutual animoſities, forbid all intermarriages with ſurrounding people. In the courſe of time the individual peculiarities are loſt, and a natural characteriſtic countenance or form is eſtabliſhed, which, if the reſtrictions of intercourſe are rigidly adhered to, is conſtantly more and more ſtrengthened. The ancient Germans, according to the deſcription of Tacitus, were ſuch a people, and his ſhort, but expreſſive ſketch of their character, moſt aptly confirms the preceding view: "Ipſe eorum opinionibus accedo, qui Germaniæ populos nullis aliis aliarum nationum connubiis infectos, propriam & ſinceram, et tantum ſui ſimilem gentem exſtitiſſe arbitrantur. Unde habitus quoque corporum, quanquam in tanto hominum numero, idem omnibus; truces & cærulei oculi, rutilæ comæ, magna corpora." De Morib. Germ. 4. The gipſies afford another example of a people ſpread over all Europe for the laſt four centuries, and nearly confined in marriages to their own race, by their peculiar way of life. In Tranſylvania, where there is a great number of them, and the race remains perfectly pure, their features can conſequently be more accurately obſerved: in every country and climate, however, which they have inhabited, they preſerve their diſtinctive character ſo perfectly that they are recognized at a glance, and cannot be confounded with the natives: ſee the deſcription and figure of the cranium of a Tranſylvanian Gipſey, in Blumenbach, Decas Altera, p. 3. But, above all, the Jews exhibit the moſt ſtriking inſtance of a peculiar national countenance, ſo ſtrongly marked in almoſt every individual, that perſons the leaſt uſed to phyſiognomical obſervations detect it inſtantly, yet not eaſily underſtood or deſcribed. Religion has, in this caſe, moſt ſucceſsfully exerted its power in preventing communion with other races; and this excluſion of intercourſe with all others has preſerved the Jewiſh countenance ſo completely in every ſoil and climate of the globe, that a miracle has been thought neceſſary to account for the appearance.

In what other way can we explain the difference between the Engliſh and Scotch? Would it be more reaſonable to ſuppoſe that they deſcended from different ſtocks; or to aſcribe the high cheek bones of the latter to ſoil or climate?

Alteration of Form by Breeding.—As, on the one hand, a particular form may be perpetuated by confining the intercourſe of the ſexes to individuals in whom it exiſts; ſo, again, it may be changed by introducing into the breed thoſe remarkable for any other quality. Connections in marriage will generally be formed on the idea of human beauty in any country; an influence this, which will gradually approximate the countenance towards one common ſtandard. If men, in the affair of marriage, were as much under management as ſome other animals, an abſolute ruler might accompliſh, in his dominions, almoſt any idea of the human form. The great and noble have generally had it more in their power than others to ſelect the beauty of nations in marriage; and thus, while, without ſyſtem or deſign, they gratified merely their own taſte, they have generally diſtinguiſhed their order, as much by elegant proportions of perſon, and beautiful features, as by its prerogatives in ſociety. "The ſame ſuperiority," ſays Cook, "which is obſervable in the Erees or nobles in all the other iſlands, is found alſo here (Owhyhee.) Thoſe, whom we ſaw, were, without exception, perfectly well formed; whereas, the lower ſort, beſides their general inferiority, are ſubject to all the variety of make and figure that is ſeen in the populace of other countries." (Third Voyage, book iii. chap. 6.) In no inſtance, perhaps, has the perſonal beauty of a people been more improved, by introducing handſome individuals to breed from, than in the Perſians, of whom the nobility have, by this means, completely ſucceeded in waſhing out the ſtain of their Mongolian origin. "That the blood of the Perſians," ſays Chardin, "is naturally groſs, appears from the Guebres, who are a remnant of the ancient Perſians, and are an ugly, ill-made, rough-ſkinned people. This is alſo apparent from the inhabitants of the provinces in the neighbourhood of India, who are nearly as clumſy and deformed as the Guebres, becauſe they never formed alliances with any other tribes. But, in the other parts of the kingdom, the Perſian blood is now highly refined by frequent intermixtures with the Georgians and Circaſſians, two nations which ſurpaſs all the world in perſonal beauty. There is hardly a man of rank in Perſia, who is not born of a Georgian or Circaſſian mother; and even the king himſelf is commonly ſprung, on the female ſide, from one or other of theſe countries: as it is long

ſince

ſince this mixture commenced, the Perſian women have become very handſome and beautiful, though they do not rival the ladies of Georgia. The men are generally tall and erect: their complexion is ruddy and vigorous, and they have a graceful air, and an engaging deportment. The mildneſs of the climate, joined to their temperance in living, has a great influence in improving their perſonal beauty. This quality they inherit not from their fathers; for, without the mixture mentioned above, the men of rank in Perſia, who are deſcendants of the Tartars, would be extremely ugly and deformed." Voyage en Perſe, &c. tom. ii. p. 34.

The tranſmiſſion of natural peculiarities, by generation, is remarkably illuſtrated by ſome inſtances of unuſual formation: ſuch is the family of the porcupine men, and of the ſix-fingered and ſix-toed perſons, both produced from individuals of the common form. (See, for the former, the article MONSTER, and for the latter, GENERATION.) There is no reaſon to doubt, that if the individuals, with theſe peculiarities, had been carefully matched together, that a permanent variety might have been eſtabliſhed.

Let us ſuppoſe that the porcupine family had been exiled from human ſociety, and obliged to take up their abode in ſome ſolitary ſpot, or deſert iſland; by matching with each other a race would have been produced, more widely removed from us in external appearance than the negro. If they had been diſcovered at ſome remote period, our philoſophers would have explained to us how the ſoil, air, or climate, had produced ſo ſtrange an organization; or would have demonſtrated that they muſt have ſprung from an originally different race: for who would acknowledge ſuch briſtly beings for brothers?

We learn that the giants, collected with ſuch pains by Frederic William I. for his regiment of guards, produced, in a town of Germany, where they were quartered, a very tall race of men: in the language of Dr. Johnſon, they "propagated procerity."

Correſponding Varieties in Animals.—There is none of the varieties above enumerated, which does not not exiſt in a ſtill greater degree in animals confeſſedly of the ſame ſpecies. What differences in the figure and proportion of parts in the various breeds of horſes; in the Arabian, the Barb, and the German! How ſtriking the contraſt between the long-legged cattle of the Cape of Good Hope, and the ſhort-legged of England! The ſame difference is obſerved in ſwine. The cattle have no horns in ſome breeds of England and Ireland; in Sicily, on the contrary, they have very large ones. A breed of ſheep, with an extraordinary number of horns, as three, four, or five, occurs in ſome northern countries, and is accounted a mere variety (ovis polycerata); the Cretan breed of the ſame animal, has long, large, and twiſted horns. We may alſo point out the ſolidungular ſwine, with undivided hoof, as well as others, with three diviſions of that part; the five-toed fowl (gallus pentadactylus); the broad-tailed ſheep of Tatary, Thibet, &c. in which the tail grows ſo large that it is placed on a board, ſupported by wheels, for the convenience of the animal; and the rumpleſs fowl (gallus ecaudatus), of America, and particularly Virginia, which has undoubtedly deſcended from the Engliſh breed.

The common fowl, in different ſituations, runs into almoſt every conceivable variety. "E volucribus altilibus varietatum numero et inſigni diſcrepantia certe eminent gallinæ. Habentur magnæ, minutæ, proceræ, pumiliones, criſtarum parvitate vel multiplicitate, aut thiaris plumaceis inſignes, uropygio carentes, flavipedes, plumipedes; habentur toto corpore reverſis plumis hirſutæ; immo in India naſcitur varietas, plumis lanuginoſis albis veſtita, et cute per totum corpus nigra. Et hæ omnes, exceptis Indicis, innumera colorum diverſitate ludunt." Pallas, Spicileg. Zool. faſc. 4.

The formation of new varieties by breeding from individuals, in whom the deſirable properties exiſt in the greateſt degree, is ſeen much more diſtinctly in our domeſtic animals, than in our own ſpecies, ſince the former are entirely in our power. The great object is to preſerve the race pure, by ſelecting for propagation the animals moſt conſpicuous for the ſize, colour, form, proportion, or any other property we may fix on, and excluding moſt carefully all others. In this way we may gain ſheep valuable for their fleece, or for their carcaſe; large or ſmall; with thick or thin legs; juſt ſuch, in ſhort, as we chuſe, within certain limits. (See BREEDING and CATTLE.) The importance of this principle is fully underſtood in rearing horſes and cocks. The Arabian preſerves the pedigree of his horſe more carefully than his own, and never allows any ignoble blood to be mixed with that of his valued breeds: he atteſts their unſullied nobility by formal depoſitions and numerous witneſſes. (See Buffon on the Horſe.) The Engliſh breeder knows equally well that he muſt vary his ſtallions and mares according as he wiſhes for a cart horſe, a riding horſe, or a racer; and that a miſtake in this point would immediately fruſtrate his views. Blood is equally important in the cock; and the introduction of an inferior individual would inevitably deteriorate the properties of the offspring.

Stature.—No part of our ſubject has been more diſgraced by fables and hyperbolical exaggeration than the preſent diviſion. Not to mention the pigmies and giants of antiquity; the bones of different large animals, aſcribed to human ſubjects of immoderate ſtature, even by ſuch men as Buffon, ſufficiently prove our aſſertion. The accuracy of modern inveſtigation has, however, ſo completely expoſed the extravagance of ſuch ſuppoſitions, that we are relieved from the neceſſity of a detailed conſideration. All the remains of antiquity, which afford us any inferences on the ſubject of ſtature, ſuch as mummies, human bones, and particularly teeth taken from the oldeſt burial places and urns, armour, &c. concur in proving that the ancients did not exceed the moderns in this reſpect. Yet amongſt the latter there are obvious national differences. Of European nations ſome parts of Sweden and Switzerland are diſtinguiſhed for tallneſs, as Lapland is in the contrary reſpect. The Abipons in the new world are of large ſize, and the Eſquimaux ſmall; but neither are very remarkable: and there is no difference between any two modern nations, but what admits of eaſy explanation from the common cauſes of degeneration, and the analogous phenomena furniſhed by the natural hiſtory of other animals.

The Patagonians (ſo called from its being ſuppoſed that they were allied to a neighbouring people, the Chonos, and from their reſembling hairy-footed animals, called in Spaniſh Patas, through their practice of wearing the rough ſkin of the guanaco) or, according to their own indigenous name, the Tehuels, which occupy the ſouth-eaſt part of the extremity of South America, ſeem to be the talleſt of the human race; but their height has been much exaggerated. Pigafetta, who accompanied Magalhaens on his voyage round the world, aſſerted that they were twice as tall as Europeans, (Viaggio atorno il Mondo, in the collection of Ramuſio, vol. i.) From that time for two centuries and a half, the narratives of European voyages into that part of the world, are ſo ſtrangely contradictory and inconſiſtent with each other, on the ſubject of theſe Patagonians, that they afford a leſſon inculcating moſt ſtrongly the neceſſity of caution and diffidence in employing such reports. Blumenbach cites ten authors in illustration of this point (De Varietate p. 255). It is sufficient, for our present purpose, to represent what appears the most probable state of the case, after weighing and critically considering the most unexceptionable testimonies. They seem in truth to be a tall, though not gigantic race, and to possess a remarkably muscular frame. Thus at least they are represented by the most respectable observers. The only Patagonians ever seen in Europe, were brought to Spain towards the end of the 16th century, and seen at Seville by the truly classical traveller Van Linschoten, who says that they were "well formed and large in the body," (wel gestatueert ende grof van leden) The variety in the statements makes it difficult to assign any particular height; but they probably do not exceed six feet six inches English. Bougainville says that none were under five feet six inches, and none over five feet eleven inches, (Paris measure, of which the foot is to that of England as 144 to 135.) (Voy. autour du Monde, 4to. p. 126.) Commerson, however, makes some of the highest six feet four inches (French). Journal Encyclopedique, 1772.) Byron represents them as seven feet high; but he did not measure them: (Hawkesworth's Collection, vol. i. p. 28.) Wallis, who measured them carefully, found the general stature to be six feet, (Ibid. p. 374;) and the statement of Carteret coincides with this; Phil. Transact. vol. lx. The stature we have assigned to these people is not so very remarkable, since other native tribes of the same continent have been noticed for their height: for example, the Caribs of Cumana, seen by Humboldt. As they are a wandering race, we cannot be surprised at finding that Europeans visiting the coast have not always been able to see them. The accounts of travellers prove, that the height of the Patagonians is not a peculiar circumstance. Bartram represents the Muscogulges and Cherokees of North America, inhabiting between 31° and 35′ of North latitude, as taller than Europeans; many being above six feet, and few under five feet eight or ten inches. (Travels, p. 482.) The Caffres, according to Barrow, are "tall, robust, and muscular, and distinguished by a peculiar firmness of carriage; some of them were six feet ten inches, and so elegantly proportioned that they would not have disgraced the pedestal of the Farnese Hercules. We may perhaps regard the Patagonians, like the antient Germans, as a peculiar and genuine race, not modified or disturbed by intermixture with others. Large body and limbs, as well as undaunted courage, were the attributes of this people, according to Pomponius Mela; "immanes animis & corporibus," lib. iii. cap. 3. Cæsar and Tacitus corroborate this statement. By collecting and comparing all the notices concerning them in the writers of antiquity, we should be warranted in assigning to them a height of six feet three inches and a half (French), which at least equals the stature of the Tehuels. The Laplanders and Nova Zemblians in Europe, the Samoieds, Ostiacs, Yakuts, and Tungooses in Asia, and the Greenlanders and Esquimaux of America, all, in short who inhabit high northern latitudes, are short in stature, measuring from four to five feet; and they agree remarkably in other characters, although occupying such distant countries. It seems rather doubtful whether the miserable Pescherais, who wander naked over the rocks of Terra del Fuego, are also diminutive; but Barrow informs us that the Boshmen who adjoin the Cape, scarcely ever exceed four feet nine inches.

The nation of dwarfs in the interior of Madagascar, called Quimos or Kimos, seems to be only an exaggeration founded on the observation of a morbid individual. Commerson mentions that he measured one who was only three feet eight inches. (Journal Encyclopedique 1772.) It appears that the captain of the ship purchased a poor pallid dwarf, whose hands reached to her knees. That she had a head disproportionately large, uttered only indistinct sounds, and was quite stupid. From these circumstances Blumenbach conjectures that it was a case of Cretinism, and similar to the instances in Salzburg, the Valais, and particularly in Piedmont. De Variet. p. 261. Handbuch der Naturgeschichte, p. 65.

Every one will immediately perceive that the differences of stature in the human race are not equal to those occurring in different breeds of animals. The pigs taken from Europe into the island of Cuba have grown to twice their original size; and the cattle in Paraguay have experienced a great increase in this respect. Clavigero, Storia antica del Messico, t. iv. p. 142.

It is hardly necessary for us to mention the contrast between the small Welch and the huge cart horses, or the Flanders breed of these animals; and between the Welch and Holstein cattle. The Paduan fowl is twice the size of the common breed. Buffon, vol. xii. p. 112.

Fabulous Varieties.—Nations with bodies of variously monstrous configuration, as the Arimaspi with one eye, the Monosceli with one leg, the Cynomolgi with dogs' heads, &c. have been enumerated by cosmographers from the time of Herodotus, from various authorities, particularly Aristeus, Ctesias and Megasthenes. See J. A. Fabricius de Hominibus nostri Orbis Incolis, Hamb. 1721, 4to. It is not necessary to dwell on these fables, although we should probably find, as in other instances in natural history, that they consist of some truth, either hyperbolically exaggerated, or changed by absurd misrepresentation. We shall only speak of one out of this mass of prodigies, *viz.* the men with tails who have been again and again noticed by many authors of very different ages. Their last patron was lord Monboddo, in his Origin and Progress of Language, v. i. p. 234, and Antient Metaphysics, v. iii. p. 250.

Pliny in the first instance, and after him Ptolemy and Pausanias, speak of a nation in India with tails: we meet with them again in the middle ages in the Nubian Geographer; in Marco Polo the Venetian, and others: in more recent times such men are mentioned in the islands of the Indian archipelago, in some provinces of Russia, and in other places. Most of these accounts are derived from others, and not from ocular testimony; most of the reporters obviously deserve very little credit (the work of the Swede, for instance, who speaks of the tails of the Nicobar people, and is mentioned as a narrative "summæ fidei" in a letter of Linnæus to lord Monboddo, is characterised by Blumenbach as "ineptarum fabellarum plenissima"); and they differ most marvellously from each other (three eyewitnesses, who speak of the tails of the Formosans give quite different descriptions, see Blumenbach de Variet. p. 269, note *m.*) On the other hand the most intelligent and accurate travellers either make no mention of the prodigy, or else characterize it as a pure fiction. Some indeed have shewn what has given rise to the statement, as a pendulous portion of the dress in the Nicobar isles, see Fontana in the Asiatic Researches, v. iii. p. 151; or the mistake of a figure of a tailed and anthropomorphous simia. Blumenbach traced the engraving of such an animal through various authors, each of whom made it a little more human, until it was metamorphosed into the representation of a homo caudatus. Martini in his version of Buffon took a plate from the Amœnitates of Linnæus, who took it from Aldrovandus, who took it from Gesner, who took it from a German description of the Holy Land, (Reyss in das gelobte land. Mentz, 1486,) in which it represents a quadrumanous

manous monkey, which, with other exotic animals, was feen in the journey. (De Variet. p. 271, note p.) Thus, inftead of having any race of men with tails authenticated by credible witneffes, there is no example even of a fingle family difplaying fuch an anomaly, although there are many well-known inftances of families with fix fingers.

Monftrous Varieties.—Thefe occur only in individual inftances, and are probably to be regarded as pathological phænomena: their defcription is referred altogether to the article MONSTER.

Faculties of the Mind; and moral Feelings.—The different progrefs of various nations in general civilization, and in the culture of the arts and fciences, the different characters and degrees of excellence in their literary productions, their varied forms of government, and many other confiderations, muft convince us beyond the poffibility of doubt, that the races of mankind are no lefs characterized by diverfity of mental endowments, than by thofe differences of organization, which we have already enumerated and confidered. Such however has been the effect of education, of laws, of peculiar habits and cuftoms, and of the different forms of government in modifying the mind and character of men, that we can hardly now difcern what fhould be afcribed to original difference, and what fhould be referred to the operation of thefe external caufes. That climate will exert a powerful influence on the mind may be very reafonably expected; and it has an analogous influence on the animal creation. We are informed, that the dog in Kamtfchatka, inftead of being faithful and attached to his mafter, is malignant, treacherous, and full of deceit. He does not bark in the hot parts of Africa nor in Greenland; and in the latter country lofes his docility fo as not to be fit for hunting.

Yet, without denying that there are differences both in the extent and kind of mental power, we are decidedly of opinion that thefe differences are not fufficient in any inftance to warrant us in referring a particular race to an originally different fpecies; and we proteft efpecially againft the fentiments of thofe, who would either entirely deny to the Africans the enjoyment of reafon; or who afcribe to them fuch vicious, malignant, and treacherous propenfities as would degrade them, even below the level of the brute. It can be proved moft clearly, and the preceding obfervations will fuffice for this purpofe, that there is no circumftance of bodily ftructure fo peculiar to the Negro, as not to be found alfo in other far diftant nations; no character which does not run into thofe of other races, by the fame infenfible gradations as thofe which connect together all the varieties of mankind. We cannot but admire the reafoning and humanity of thofe, who, after tearing the African from his native foil, carrying him to the Weft Indies, and dooming him there to perpetual labour, complain that his underftanding fhews no figns of improvement, and that his temper and difpofition are incorrigibly perverfe, faithlefs, and treacherous. Let us however obferve him in a fomewhat more favourable ftate than in thofe dreadful receptacles of human mifery, the crowded decks of the flave-fhip, or in the lefs openly fhocking, but conftrained and extorted, and therefore painful, labours of the fugar plantation. That the negroes are much like Europeans, and behave to others according to the treatment which they receive, may be eafily gathered from the beft fources of information. They have not indeed reached that fublime height, the "beau idéal" of morality, the returning good for evil, probably becaufe their mafters have not yet found leifure enough from the purfuit of riches to inftil into them the true fpirit of Chriftianity. "The feelings of the Negroes are extremely acute. According to the manner in which they are treated, they are gay or melancholy, laborious or flothful, friends or enemies. When well fed, and not mal-treated, they are contented, joyous, ready for every enjoyment; and the fatisfaction of their mind is painted in their countenance. But, when oppreffed and abufed, they grow peevifh, and often die of melancholy. Of benefits and abufe they are extremely fenfible, and againft thofe who injure them they bear a mortal hatred. On the other hand, when they contract an affection to a mafter, there is no office, however hazardous, which they will not boldly execute, to demonftrate their zeal and attachment. They are naturally affectionate, and have an ardent love for their children, friends, and countrymen. The little they poffefs they freely diftribute among the neceffitous, without any other motive than that of pure compaffion for the indigent." Hift. des Antilles, p. 483.

The travels of Barrow, le Vaillant and Mungo Park, abound with anecdotes honourable to the moral character of the Africans, and proving that they betray no deficiency in the amiable qualities of the heart. One of thefe gives us an interefting portrait of the chief of a tribe: "His countenance was ftrongly marked with the habit of reflection; vigorous in his mental, and amiable in his perfonal qualities, Gaika was at once the friend and ruler of a happy people, who univerfally pronounced his name with tranfport, and bleffed his abode as the feat of felicity." Many highly polifhed European kings would appear to little advantage by the fide of this favage. We fee no reafon to doubt that the negroes, taken altogether, are not inferior to any variety of the human race in natural goodnefs of heart. It is confonant to our experience of mankind in general, that the latter quality fhould be deadened or completely extinguifhed in the flave fhip or the plantation: indeed it is as little creditable to the head as to the heart of their white tormentors to expect affection and fidelity from flaves after fuch treatment.

The acute and accurate Barbot, in his large work on Africa, fays, "The blacks have fufficient fenfe and underftanding, their conceptions are quick and accurate, and their memory poffeffes extraordinary ftrength. For, although they can neither read nor write, they never fall into confufion or error in the greateft hurry of bufinefs and traffic. Their experience of the knavery of Europeans has put them completely on their guard in tranfactions of exchange; they carefully examined all our goods, piece by piece, to afcertain if their quality and meafure are correctly ftated; and fhew as much fagacity and clearnefs in all thefe tranfactions, as any European tradefman could do." Of thofe imitative arts, in which perfection can be attained only in an improved ftate of fociety, it is natural to fuppofe that the Negroes can have but little knowledge; but the fabric and colours of the Guinea cloths are proofs of their native ingenuity; and, that they are capable of learning all kinds of the more delicate manual labours, is proved by the fact, that nine-tenths of the artificers in the Weft Indies are Negroes: many are expert carpenters, and fome watch-makers. The drawings and bufts executed by the wild Bofhman in the neighbourhood of the Cape are praifed by Barrow for their accuracy of outline, and correctnefs of proportion.

Inftances are by no means rare, of negroes, who have diftinguifhed themfelves in literature and the arts, when favoured by fortune with opportunities of education and improvement. In proof of their mufical talents, it may be mentioned that they have been known to earn fo much in America, as to purchafe their freedom with large fums. The younger Freidig in Vienna was an excellent performer both on the violin and violoncello; he was alfo acapital draftfman, and had made a very fuccefsful painting of himfelf.

The

The capacity of the negroes for the mathematical and phyfical fciences, is proved by Hannibal, a colonel in the Ruffian artillery, and Liflet of the ifle of France, who was named a correfponding member of the French academy of Sciences, on account of his excellent meteorological obfervations. Fuller of Maryland was an extraordinary example of quicknefs in reckoning. Being afked in a company, for the purpofe of trying his powers, how many feconds a perfon had lived who was 70 years and fome months old, he gave the anfwer in a minute and a half. On reckoning it up after him, a different refult was obtained ; have not you forgotten the leap years ? fays the negro. This omiffion was fupplied, and the number then agreed with his anfwer.

Boerhaave and De Haen have given the ftrongeft teftimony that our black brethren poffefs no mean infight into practical medicine ; and feveral have been known as very dextrous furgeons. A negrefs at Yverdun is mentioned by Blumenbach as a celebrated midwife of real knowledge and a fine experienced hand.

Omitting Madocks a methodift preacher, and not attempting to enumerate all the negroes who have written poems, we may mention that Blumenbach poffeffes Englifh, Dutch, and Latin poetry by different negroes. In 1734, A. W. Amo, an African, from the coaft of Guinea, took the degree of doctor in philofophy at the univerfity of Wittemberg. Two of his differtations, according to Blumenbach, exhibit much well digefted knowledge of the beft phyfiological works of the time. In an account of his life, publifhed at the time, by the academic council, his integrity, talents, induftry, and erudition, are very highly commended.

Jac. Eliza Joh. Capitein, who was bought by a flave dealer, when eight years old, ftudied theology at Leyden, and publifhed feveral fermons and poems ; his "Differtatio de Servitute Libertati Chriftianæ non contraria," went through four editions very quickly. He was ordained in Amfterdam, and went to Elmina on the Gold coaft, where he was either murdered, or exchanged for the life and faith of his countrymen thofe he had learned in Europe.

Ignatius Sancho, and Guftavus Vafa, the former born in a flave fhip on its paffage from Guinea to the Weft Indies, and the latter in the kingdom of Benin, have diftinguifhed themfelves as literary characters in this country in modern times ; their works and lives are fo well known, and fo eafily acceffible, that it is only neceffary for us to mention them.

Blumenbach, from whofe "Beyträge zur Naturgefchichte," the preceding inftances are taken, farcaftically obferves, that entire and large provinces of Europe might be named, in which it would be difficult to meet with fuch good writers, poets, philofophers, and correfpondents of the French academy ; and, on the other hand, that there is no favage people, which have diftinguifhed themfelves by fuch examples of perfectibility and even capacity for fcientific cultivation ; and confequently that none can approach more nearly to the polifhed nations of the globe, than the negro, p. 118.

The opportunities of obfervation, that fall to the lot of any individual, are fo limited, and the remarks of travellers and hiftorians fo likely, from various caufes, to be perverted by ignorance or mifreprefentation, that it muft be very difficult to produce any thing fatisfactory on the fubject of the general characters of the various races in intellect, difpofition, &c. We prefent therefore to the reader the conclufions which are drawn by Meiners, from an immenfe collection of authorities.

"Providence beftowed on the white and handfome races, not only confiderable prerogatives of bodily ftructure, but alfo of mental power ; connecting however neither of them with the fineft climates. The ancients obferved that the moft fruitful countries weakened the powers of the mind and the manly virtues. The favourable influence of climate on the intellect cannot be denied ; and it is equally true that the nobleft natures would be unavoidably corrupted and degraded in certain fituations. The moft dangerous are certain fpots on the coaft of Africa, Egypt, Hindooftan, the fouthern Afiatic kingdoms, particularly Siam, China, and feveral iflands, the Weft Indies, and various fpots in South America. An almoft incredible acutenefs of the external fenfes, which feems a gift of nature, is found in the dark and ugly nations. Among favages, as well as among the civilized, remarkable examples occur of men, who are not moved by the moft violent impreffions, and yet cannot bear the mildeft perfume. In the ugly nations, an almoft entire infenfibility to beauty of form, order, and harmony, is united to the greateft acutenefs of the fenfes. It feems that their imagination has a peculiar turn, which does not exift in the handfome nations.

The whole divifion of the ugly and dark coloured people is far below the white and handfome ones in the faculties of the mind ; yet there are confiderable differences between the various races in both. In Afia the Burates are the moft ftupid ; the Calmucks are more docile ; and fome fouthern people, as thofe of Pegu, the Malays, Chinefe, and Japanefe are much more fo. This want of talents affects alfo the lower cafts of the Hindoos. The original inhabitants of America poffefs ftill lefs intellect than the Mongolian tribes of Afia, and this is an incontrovertible proof that climate may rob the human race of genius and virtue. The ftupidity of the Americans was fo ftriking, and fo generally known, that there was fome trouble to convince the Spaniards that they were men, and capable of becoming chriftians ; yet thefe very Americans difplay, in certain points, a capability of learning, by which they exceed the moft ingenious Europeans. The negroes indeed come above the Americans ; but they are nearer to them than to the Europeans. Of the white people, the Celtic race has been much more richly endowed by nature, than the Slavonic or Oriental.

The dark people are again diftinguifhed from the fair by a deplorable abfence of virtues, and by feveral frightful exceffes. With an irritability arifing from weaknefs, and an incredible fenfibility to the flighteft affronts, the black nations combine an aftonifhing infenfibility of the pains and joys of others, even their neareft relations, inflexible cruelty, felfifhnefs and difpofition to cheat, and a want of all fympathetic impulfes and feelings. With more than female cowardice, and fear of open approaching danger and death, they join inconceivable calmnefs and indifference under the moft horrible tortures, difeafes, and actual death ; with want of affection towards their own children, an extraordinary degree of tendernefs to animals, even the moft difgufting vermin ; with brutal obfcenity, voracity, and fhamelefsnefs, either an immoderate attachment to fenfual love, or the greateft coldnefs, and confequent contempt of the female fex. Exceffive irritability is found in all the Finnic races of Afia and America. The Burates are the worft of all thefe favages, and are confiderably excelled by the Tungoofes, the Calmucks and Monguls, the Coriacks, the Tfchutfki, the Kuriles, and particularly the Japanefe. The Kamtfchatkans are more contemptible, but lefs cruel than the Laplanders. The Chinefe are one of the moft worthlefs people in Afia, and are exceeded in integrity at leaft, if in no other refpect, by the Tunquinefe, Siamefe and Hindoos. The Malays, and moft of the people who defcend from them, are feared, not only by the Afiatics, but even by the Europeans. The fouls of the blacks in New Guinea, New

 Holland,

Holland, &c. are not lefs ugly than their bodies; on the contrary, the difpofition alone of the inhabitants of the Nicobar and Bally iflands would prove that they are of more noble origin than their neighbours. The worthlefsnefs or corruption of human nature is no where more univerfal, or has been more accurately obferved, than in the Americans, the portraits of whom, fill the friend of humanity, by turns, with pity, horror, and indignation. The difpofitions of the negroes are as different as their defcent; hence the contradictory defcriptions of their manners. Even the flave dealers fix their prices, not merely according to the bodily powers, but in proportion to the docility and good difpofitions of their commodity. The worft negroes of Malabaric origin are the Jiagas, the Anzicos, thofe of Dahomey, and the Gallas, which, as well as all their black brethren, bear a remarkable refemblance in difpofition to the Americans.

"The white and handfome nations may degenerate and be reduced to a ftate of barbarifm by phyfical and moral caufes, as we learn from the examples of the Greeks and Romans, of the modern inhabitants of Caucafus and almoft all the European colonies in the torrid zone. But they have diftinguifhing prerogatives in their wildeft ftate, as a comparifon of the ancient Germans, Spaniards, Scandinavians, and Scythians, and of the modern Highland Scotch, and other Celtic people, with the African and American favages, will moft abundantly prove. The Celtic people alone have poffeffed true bravery, love of liberty, and other paffions and virtues of great fouls. They alone have been as generous and mild towards the weak and the vanquifhed, as terrible to their enemies; and have conftantly treated conquered nations and the female fex very differently from the Mongolians. Moft of the virtues, which adorn and ennoble man, have exifted from early times in a higher degree among the Celtic than among the Slavonic and Oriental people. The white people are neither fo debauched, nor fo cold, nor fo much addicted to unnatural enjoyments as the dark coloured. On the other hand, the Slavonics and Orientals have a much ftronger attachment to fenfual love than the Celts; and of the latter, the fouthern are more fenfual than the northern. Some favages indeed have conceived themfelves fuperior to Europeans; but, in general, they have acknowledged the excellence of thefe more noble races, and this confeffion is moft plainly implied in the practice of offering their wives and daughters to better men, and in the attachment and fidelity, which the women of the ugly nations difplay towards the more powerful Europeans, in preference to the men of their own race." Meiners, Grundrifs, p. 111. 128.

Caufes of the Varieties of the Human Species.—The caufes which operate on the bodies of living animals, either modify the individual, or alter the offspring. The former are of great importance in the hiftory of animals, and produce very aftonifhing alterations in their nature; but the latter are the moft powerful, affect the fpecies, and create the diverfities of race or breed

Climate.—That climate will exert a very powerful influence on all organized bodies, and particularly on warm blooded animals, muft naturally be expected, when we confider how conftantly and completely thefe animals are expofed to the action of the atmofphere in which they live; how wonderfully the compofition of this air, formerly fuppofed to be a fimple element, varies, not only in its gafeous ingredients, but alfo in the acceffory ones of light, heat, electricity, &c.; and what a variety of other circumftances is to be taken into confideration, as the geographical pofition of different countries, their elevation, mountains, rivers, vicinity to the fea, prevailing winds, &c. Let it be further remembered, that the blood expofed to this air in the cheft muft be varioufly changed according to its compofition and nature, and thus that the fecretions, as well as the function of nutrition, of which the materials are derived from this fluid, muft be greatly influenced.

Although this confiderable and conftant operation of climate on the animal economy, and the habit and form of the body has been noticed by attentive obfervers in all ages, it is rather difficult to define precifely what ought to be attributed to this caufe only, and what arifes from the other fources of degeneration, or from their concourfe. We fhall ftate one or two changes, which feem to depend unequivocally on this caufe.

The whitening (blanching or etiolation) of vegetables, when the fun's rays are excluded, demonftrates the agency of thofe rays on vegetable colours. In the fame way, men who are much expofed to the air acquire a deeper tint in their fkin than thofe who are more covered; and the tanning of the fkin by the fummer fun in parts of the body expofed to it, as the face and hands, is a phenomenon completely analogous. The ruddy and tawny hues of thofe who live in the country, and the pale fallow countenances of the inhabitants of towns owe their origin to this caufe. Men of the fame race are lighter or darker coloured according to the climate which they inhabit; the Moors, in their native colour, are not darker than the Spaniards, French, nor moft of the Englifh; but their acquired tint is fo much deeper, that we diftinguifh them inftantly. How fwarthy do the Europeans become, who feek their fortunes under the tropics and equator, and have their fkins parched by the burning funs of "Afric and of either Ind."

The white colour, in the northern regions, of many animals which poffefs other colours in more temperate climates, as the fox, the hare, beafts of burden, the falcon, crow, jackdaw, chaffinch, &c. feems to arife entirely from climate. This opinion is ftrengthened by the analogy of thofe animals, which change their colour, in the fame country at the winter feafon, to white or grey, as the ermine and weafel, hare, fquirrel, rein deer, white game (tetrao lagopus), fnow bunting (emberiza nivalis), &c. Linnæus Flora Lapponica; edit. of Smith, p. 55. 352. The common bear is differently coloured in different countries.

That the coverings of animals, as well as their colour, are much influenced by climate, is evinced in many inftances. The fheep in Africa has a coarfe hair fubftituted in the place of its wool; and the dog lofes its coat entirely, and has a fmooth and foft fkin. The wool of the fheep is thicker and longer in the winter, and in hilly northern fituations, than in the fummer, and on warm plains. Much benefit is derived, in the cultivation of this animal, by changing its paftures according to the feafons of the year, and protecting it from the feverity of the climate. The influence of various caufes, which may be comprehended under the general term of cultivation, is very ftriking in the fheep and goat; the great difference in the wool produced from the former, under various circumftances, is well known; and a perfon, who was acquainted with the covering of the goat in European climates, would hardly believe it poffible that the material from which the precious fhawls of Cafhmere are manufactured, could be produced from the fame animal.

Whether the long and filky coat of the goat, cat, fheep, and rabbits of Angora can be afcribed to the climate, we do not know; it is at leaft worthy of notice that this quality of the hair fhould exift in fo many animals. It continues when they are removed into other countries, and is tranfmitted to the offspring; fo that we may probably regard thefe animals as permanent breeds.

Muft

Muſt we not refer to climate the conſtant and remarkable degeneracy of the horſe in France. "In France," according to Buffon, "Spaniſh or Barbary horſes, when the breed is not croſſed, become French horſes, ſometimes in the ſecond generation, and always in the third." V. iv. p. 106.

Food.—We naturally expect that food will produce conſiderable changes in the living body; its effect ſeems to be proved by the well known fact that ſeveral ſinging birds, chiefly of the lark and finch kinds, become gradually black, if they are fed on hempſeed only. (Blumenbach, de Variet. p. 94.) The texture of the hair has been changed, in an African ſheep brought into England, from the coarſe nature of that of the camel, to conſiderable fineneſs and ſoftneſs, by one year's feeding in the paſtures of this country. The influence of the ſame cauſe on the ſtature and proportion of the body is ſhewn in the horſe, which grows to a large ſize in the marſhy grounds of Frieſland, while on ſtony ſoils, or dry heaths, they remain dwarfiſh. Oxen become very large and fat in rich ſoils, but are diſtinguiſhed by ſhortneſs of the legs; while in drier ſituations, their whole bulk is leſs, and the limbs are ſtronger and more fleſhy. We ſay nothing of the well-known differences of flavour and weight produced by different kinds of food.

Changes cauſed by Climate are temporary.—Two very different opinions have been maintained concerning theſe changes, produced by the action of external cauſes on the bodies of animals. Some, as Buffon, Blumenbach, Zimmermann, (Geographiſche geſchichte der Menſchen, &c.) contend that they are tranſmitted to the offspring, and thus cauſe varieties: others argue that the effect terminates in the individual; that the young animal is not in the ſlighteſt degree modified by it, but is born with the original properties, and conſtitution of the parents, and a ſuſceptibility only of the ſame changes when expoſed to the ſame cauſes. The latter opinion has been moſt ably defended in the inaugural diſputation of Dr. Prichard, Edinburgh, 1808, and ſeems to us to reſt upon the moſt incontrovertible grounds.

The change in the colour of the human ſkin, from expoſure to ſun and air, is obviouſly temporary; for it is diminiſhed and even removed when the cauſes no longer act. The diſcolouration, which we term tanning or being ſun-burnt, as well as the ſpots called freckles, are moſt incidental to fair ſkins, and diſappear when the parts are covered, or no longer expoſed to the ſun. The children of the huſbandman or of the ſailor, whoſe countenance bears the marks of other climes, are juſt as fair as thoſe of the moſt delicate and pale inhabitant of a city: nay, the Moors, who have lived for ages under a burning ſun, ſtill have white children; and the offspring of Europeans in the Indies have the original tint of their progenitors. Blumenbach has been led into a miſtake on this point by an Engliſh author (Hawkeſworth, in Collection of Voyages, v. iii. p. 374), who aſſerts that Creoles are born with a different complexion and caſt of countenance, from the children of the ſame parents brought forth in their native country. In oppoſition to this ſtatement, from one who was not an eye-witneſs, we ſhall place the authority of Long, who, in his hiſtory of Jamaica, affirms "that the children born in England have not, in general, lovelier or more tranſparent ſkins, than the offspring of white parents in Jamaica." The "auſtrum ſpirans vultus & color," which this acute and learned naturaliſt aſcribes to the Creole, is merely the acquired effect of the climate, and not a character exiſting at birth.

"Nothing," ſays Dr. Prichard, "ſeems to hold true more univerſally, than that all acquired conditions of body, whether produced by art or accident, end with the life of the individual in whom they are produced. Many nations mould their bodies into unnatural forms: the Indians flatten their foreheads (See CRANIUM); the Chineſe women reduce their feet to one-third of their natural dimenſions; ſavages elongate their ears; many races cut away the prepuce. We conſtantly mutilate our domeſtic animals by removing the tail or ears, and our own ſpecies are often obliged by diſeaſe to ſubmit to the loſs of limbs. That no deformity or mutilation of this kind is hereditary, is ſo plainly proved by every thing around us, that we wonder how the contrary opinion ſhould have gained any advocates. After the operation of circumciſion has prevailed for more than three thouſand years, the Jews are ſtill born with prepuces, and ſtill obliged to ſubmit to the painful rite. Docked horſes and cropped dogs bring forth young with entire ears and tails. But for this ſalutary law, what a frightful ſpectacle would every race of animals exhibit! The miſchances of all preceding times would overwhelm us with their united weight, and the catalogue would be continually increaſing, until the univerſe, inſtead of diſplaying a ſpectacle of beauty and pleaſure, would be filled with maimed, imperfect, and monſtrous ſhapes."

The changes produced in the coverings of animals by external cauſes, and thoſe brought about by food, are equally confined to the preſent race. If a breed with different qualities be required, other individuals, poſſeſſing thoſe qualities, muſt be employed.

Permanent Varieties of Animals are only produced by Generation.—That the foregoing cauſes are not adequate to account for thoſe more ſignal diverſities, which conſtitute differences of race in animals, will be readily admitted. Theſe can be explained only by native or congenital variety, as we have ſhewn in enumerating thoſe points, in which men and animals differ. In the preſent ſtate of phyſiological knowledge, we cannot attempt to ſhew how it happens that an offspring is produced, differing from the parents in ſome characters, which are conveyed by hereditary ſucceſſion; how a grey rabbit or cat ſhall bring forth at one birth, and from one father, yellow, black, white, and ſpotted young; how a white ſheep ſhall have a black lamb; or the ſame parents, Leucæthiopic and ordinary children at different times. In ſhort, in conſidering all the circumſtances under which animal bodies are influenced by external agents, we muſt be contented with ſtating the facts that prove the influence of ſuch cauſes, without attempting to explain how they produce their effects. As there is ſo little of a ſatisfactory nature aſcertained on this head, we ſhould be afraid of diſguſting the ſenſible reader, by ſubſtituting ſpeculation in the place of more ſolid information.

Influence of Mode of Life in producing Varieties.—The ſtate of domeſtication, or the artificial mode of life, which they lead under the dominion of man, is the moſt powerful cauſe in favouring the production of varieties in the animal kingdom. Wild animals, uſing always the ſame kind of food, being expoſed to the action of the climate without fire or artificial covering, chuſe, each of them according to its nature, their zone, and country: inſtead of diſperſing themſelves, like man, they continue in thoſe places, which are the moſt friendly to their conſtitutions. Hence their nature undergoes no change; their figure, colour, ſize, proportion, &c. are unaltered; and there is conſequently no difficulty in determining their ſpecies. But, ſays Buffon, when forced by man, or by any revolution on the globe, to abandon their native ſoil, their nature undergoes changes ſo great, that, to recognize them, recourſe muſt be had to accurate examination, and even to experiment and analogy. If to theſe natural cauſes of alteration in free animals, we add that of the empire of man over thoſe which he has reduced to ſlavery, we ſhall

ſhall be aſtoniſhed at the degree to which tyranny can degrade and disfigure nature; we ſhall perceive the marks of ſlavery, and the prints of her chains; we ſhall find that thoſe wounds are deeper and more incurable in proportion to their antiquity: and that, in the preſent condition of domeſtic animals, it is, perhaps, impoſſible to reſtore their primitive form, and thoſe attributes of nature, which we have taken from them." vol. iv. p. 6. To trace back our domeſtic animals to their wild originals, is in all caſes difficult, in ſome impoſſible: long ſlavery has ſo degraded their nature, that the primitive animal may be ſaid to be loſt, and a degenerated being, running into endleſs varieties, is ſubſtituted in its place. The wild original of the ſheep was for a long time unknown: Buffon conceived that he diſcovered it in the mouflon or argali (ovis ammon); and Pallas, who had an opportunity of ſtudying this animal, adds the weight of his highly reſpectable authority to the opinion of the French naturaliſt. Yet, Blumenbach regards the argali as a diſtinct ſpecies. Should we allow the latter to be the parent of our ſheep, and conſequently admit that the differences are explicable by degeneration, no difficulty can any longer exiſt about the unity of the human ſpecies. An incomplete horn of the argali, in the academical muſeum at Gottingen, weighs nine pounds. Blumenbach, handbuch der Naturgeſchichte. p. 111, note.

"Let us compare," ſays Buffon, "our pitiful ſheep with the mouflon, from which they derived their origin. The mouflon is a large animal. He is fleet as a ſtag, armed with horns and thick hoofs, covered with coarſe hair, and dreads neither the inclemency of the ſky, nor the voracity of the wolf. He not only eſcapes from his enemies by the ſwiftneſs of his courſe, and ſcaling, with truly wonderful leaps, the moſt frightful precipices; but he reſiſts them by the ſtrength of his body, and the ſolidity of the arms with which his head and feet are fortified. How different from our ſheep, which ſubſiſt with difficulty in flocks, who are unable to defend themſelves by their numbers, who cannot endure the cold of our winters without ſhelter, and who would all periſh, if man withdrew his protection. So completely are the frame and capabilities of this animal degraded by his aſſociation with us, that it is no longer able to ſubſiſt in a wild ſtate, if turned looſe, as the goat, pig, and cattle are. In the warmeſt climates of Aſia and Africa, the mouflon, who is the common parent of all the races of this ſpecies, appears to be leſs degenerated than in any other region. Though reduced to a domeſtic ſtate, he has preſerved his ſtature and his hair, but the ſize of his horns is diminiſhed. Of all domeſtic ſheep, thoſe of Senegal and India are the largeſt, and their nature has ſuffered leaſt degradation. The ſheep of Barbary, Egypt, Arabia, Perſia, Tartary, &c. have undergone greater changes. In relation to man, they are improved in ſome articles, and vitiated in others; but, with regard to nature, improvement, and degeneration are the ſame thing; for they both imply an alteration of original conſtitution. Their coarſe hair is changed into fine wool. Their tail, loaded with a maſs of fat, (and ſometimes reaching the weight of 40 pounds), has acquired a magnitude ſo incommodious, that the animals trail it with pain. While ſwollen with ſuperfluous matter, and adorned with a beautiful fleece, their ſtrength, agility, magnitude, and arms are diminiſhed: theſe long-tailed ſheep are half the ſize only of the mouflon. They can neither fly from danger, nor reſiſt the enemy. To preſerve and multiply the ſpecies, they require the conſtant care and ſupport of man. The degeneration of the original ſpecies is ſtill greater in our climates. Of all the qualities of the mouflon, our ewes and rams have retained nothing but a ſmall portion of vivacity, which yield to the crook of the ſhepherd. Timidity, weakneſs, reſignation, and ſtupidity, are the only melancholy remains of their degraded nature." Vol. iv. p. 7.

It will naturally be expected that degeneration has operated moſt deeply and variouſly on thoſe domeſtic animals which man has ſubjected for many ages, and ſo completely, that they propagate in their enſlaved condition; not on thoſe, of whom each individual is brought into captivity from his wild ſtate, as the elephant; nor on ſuch as have not been taken into foreign climates, as the rein-deer, which is confined to a very limited portion of the globe. The pig is a good example, becauſe his deſcent is more clearly made out than that of many others. The dog indeed degenerates before our eyes, but it will hardly ever, perhaps, be aſcertained whether there is one or more ſpecies. The extent of degeneration can be obſerved in the domeſtic pig, becauſe, we believe, no naturaliſt has hitherto been ſceptical enough to doubt whether he deſcended from the wild boar, and he was certainly firſt introduced by the Spaniards into the New World. The pigs conveyed, in 1509, from Spain to the Weſt India iſland Cubagua, then celebrated for the pearl fiſhery, degenerated into a monſtrous race with toes half a ſpan long. Herrera, hechos de los Caſtellanos en las Iſlas, &c. (vol. i. p. 239.) Thoſe of Cuba became more than twice as large as their European progenitors: Clavigero, ſtoria antica del Meſſico. (vol. iv. p. 145.) How remarkably again have the domeſtic ſwine degenerated from the wild ones in the old world; in the loſs of the ſoft downy hair from between the briſtles, in the vaſt accumulation of fat under the ſkin, in the form of the cranium, in the figure and growth of the whole body. The varieties of the domeſtic animal too are very numerous: in Piedmont they are almoſt invariably black; in Bavaria reddiſh-brown, in Normandy white, &c. The breed in England with ſtraight back and large pendulous belly is juſt the reverſe of that in the North of France, with high convex ſpine, and hanging head; and both are different from the German breed; to ſay nothing of the ſolid-ungular race found in herds in Hungary and Sweden, and already known by Ariſtotle, and many other varieties.

The aſs, in its wild ſtate, is remarkably ſwift and lively, and ſtill continues ſo in his native countries in the Eaſt; the biſon, or wild ox, has a long flowing mane, hanging almoſt to the ground.

The original ſtock of our poultry cannot be determined, nor can the varieties into which they have run be enumerated. No wild bird in our climates reſembles the domeſtic cock: the pheaſant, grous, and wood-hen, are the only analogous kinds; and it is uncertain whether theſe would intermix, and have prolific progeny. They have conſtituted diſtinct and ſeparate ſpecies from the earlieſt times; and they want the combs, ſpurs, and pendulous membranes of the gallinaceous tribes. Buffon, vol. xii. p. 112.

There are twenty-nine varieties of canary birds known by name, all produced from the grey bird. Buffon, vol. xiv. p. 61.

Moſt of the mammalia, which have been tamed by man, betray their ſubjugated ſtate by having the ears and tail pendulous; a condition of the former parts which, we believe, belongs to no wild animal. In many, the very functions of the body, as the ſecretions, generation, &c. are greatly changed. The domeſtic ſow produces young twice a year; the wild animal only once: it frequently brings forth monſtrous fœtuſes, and is invaded by a new ſpecies of hydatids, forming what is called the meaſles in pork.

A good hen, well ſupplied with food, lays 100 eggs between

tween ſpring and autumn; in the wild ſtate ſhe only produces eighteen or twenty. Buffon, vol. ii. p. 30.

The application of theſe facts to the queſtion concerning the human ſpecies is very obvious. If domeſticated animals vary, becauſe they have been taken from their primitive condition, and expoſed to the operation of many, to them unnatural, cauſes; if the pig is remarkable among theſe for its varieties, becauſe it has been the moſt expoſed to cauſes of degeneration; we ſhall be at no loſs to account for the diverſities in man, who is, in the true, though not ordinary ſenſe of the word, more of a domeſticated animal than any other. We know the wild ſtate of moſt of them; but we are ignorant of the natural wild condition to which man was deſtined. Probably there is no ſuch ſtate; becauſe nature, having limited him in no reſpect, having fitted him for every kind of life, every climate, and every variety of food, has given him the whole earth for his abode, and both the organized kingdoms for his nouriſhment.

The numerous varieties of domeſtic animals, which are inconteſtibly the offspring of domeſtication, may be regarded as a refutation of the general poſition, which we lately laid down, that no acquired condition is tranſmitted by generation. Theſe diverſities are undoubtedly the ſtrongeſt argument in favour of the changes produced by the way of life being hereditary; and we are not hitherto warranted in poſitively denying this. They admit of explanation, however, on another principle; *viz.* that the domeſtic ſtate cauſes a diſpoſition to the production of native varieties, which, as we well know, are hereditary. We know no direct obſervations, by which it can be decided that modifications of colour, form, &c. produced by external cauſes, are in no inſtance tranſmitted to the offspring, and that they are all firſt produced as native varieties in the courſe of generation. Analogy, however, very much favours this notion.

Such, then, are the cauſes by which the varieties of man may be accounted for. Although we have acknowledged our entire ignorance of the manner in which theſe operate, we have proved that they exiſt, and have ſhewn, by copious analogies, that they are ſufficient to explain the phenomena. The tendency, under certain circumſtances, to alterations of the original colour, form, and other properties of the body, and the law of tranſmiſſion to the offspring, are the ſources of varieties in man and animals, and thereby modify the ſpecies: climate, food, way of life, in a word, all the phyſical and moral cauſes that ſurround us, act indeed powerfully on the individual, but do not change the offſpring, except in the indirect manner alluded to in the preceding paragraph. We ſhould, therefore, openly violate the rules of philoſophiſing, which direct us to aſſign the ſame cauſes for natural effects of the ſame kind, and not to admit more cauſes than are ſufficient for explaining the phenomena, if we recurred, for the purpoſe of explaining the varieties of man, to the perfectly gratuitous aſſumption of originally different ſpecies, or called to our aid the operation of climate, &c.

Yet, if it be allowed that all men are of the ſame ſpecies, it does not follow that they all deſcend from the ſame family. Some contend that all parts of the globe were furniſhed at firſt with men and animals, and lay great ſtreſs on the difficulty which the race would experience in extending over wide tracts, and gaining acceſs to remote regions and iſlands. A reference to facts will ſhew us that theſe difficulties have been overcome. The numerous iſlands of the Pacific, in many inſtances very diſtant from each other, and from the continent, are inhabited by men of the ſame race; and we meet in Madagaſcar and Eaſter iſland, ſeparated by nearly half the globe, with men of the ſame origin, employing the ſame language. This view is confirmed by the very intereſting facts firſt noticed by Buffon, that no animals are found in both continents, but ſuch as are able to bear the cold of theſe regions where they probably join; and that not a ſingle animal of the torrid zone is common to the old world and the new.

Conſideration of the Opinion, which explains the Varieties of Mankind by the Operation of Climate. Statement of the Argument.—By the moſt intelligent and learned writers on the varieties of mankind, they have been explained altogether by the operation of adventitious cauſes, as climate, particularly the light and heat of the ſun, food, and way of life. It has been conſidered that theſe, acting on men originally alike, produce various bodily diverſities, and affect the colour of the ſkin eſpecially; and that ſuch alterations, tranſmitted to the offspring, and gradually increaſed through a long courſe of ages, account very ſufficiently for all the differences obſerved at preſent in the inhabitants of the different regions of the globe. If we were inclined to ſubmit in this queſtion to authority, the number and celebrity of the philoſophers, who have contended for the influence of climate, and other phyſical and moral cauſes, would certainly compel our aſſent to their opinions. Buffon, Blumenbach, Smith (Eſſay on the Cauſes of the Variety of Complexion and Figure in the human Species, Philadelphia), Zimmerman (Geographiſche Geſchichte des Menſchen, &c.) Ludwig (Grundriſs der Naturgeſchichte des Menſchen-ſpecies, &c.), are only a few of thoſe who have adopted and defended this view of the ſubject.

Opinion of Buffon.—"The heat of the climate," ſays Buffon, "is the chief cauſe of blackneſs among the human ſpecies. When this heat is exceſſive, as in Senegal and Guinea, the men are perfectly black; when it is a little leſs violent, the blackneſs is not ſo deep; when it becomes ſomewhat temperate, as in Barbary, Mongolia, Arabia, &c. mankind are only brown; and laſtly, when it is altogether temperate, as in Europe and Aſia, men are white. Some varieties, indeed, are produced by the mode of living. All the Tartars (Monguls), for example, are tawny; while the Europeans, who live under the ſame latitude, are white. This difference may ſafely be aſcribed to the Tartars being always expoſed to the air, to their having no cities or fixed habitations, to their ſleeping conſtantly on the ground, and to their rough and ſavage manner of living. Theſe circumſtances are ſufficient to render the Tartars more ſwarthy than the Europeans, who want nothing to make life eaſy and comfortable. Why are the Chineſe fairer than the Tartars, though they reſemble them in every feature? Becauſe they are more poliſhed; becauſe they live in towns, and practiſe every art to guard themſelves againſt the injuries of the weather: while the Tartars are perpetually expoſed to the action of the ſun and air.

"Climate may be regarded as the chief cauſe of the different colours of men: but food, though it has leſs influence than colour, greatly affects the form of our bodies. Coarſe, unwholeſome, and ill-prepared food makes the human ſpecies degenerate. All thoſe people, who live miſerably, are ugly and ill made. Even in France, the country people are not ſo beautiful as thoſe who live in towns: and I have often remarked, that in thoſe villages, where the people are richer and better fed than in others, the men are likewiſe more handſome, and have better countenances. The air and the ſoil have great influence on the figures of men, beaſts, and plants.

"Upon the whole, every circumſtance concurs in proving that mankind are not compoſed of ſpecies eſſentially different

ferent from each other; that, on the contrary, there was originally but one fpecies, which, after multiplying and fpreading over the whole furface of the earth, have undergone various changes by the influence of climate, food, mode of living, epidemic difeafes, and mixture of diffimilar individuals; that, at firft, thefe changes were not fo confpicuous, and produced only individual varieties; that thefe varieties became afterwards more fpecific, becaufe they were rendered more general, more ftrongly marked, and more permanent, by the continual action of the fame caufes; that they are tranfmitted from generation to generation, as deformities or difeafes pafs from parents to children; and that, laftly, as they were originally produced by a train of external and accidental caufes, and have only been perpetuated by time, and the conftant operation of thefe caufes, it is probable that they will gradually difappear, or, at leaft, that they will differ from what they are at prefent, if the caufes which produced them fhould ceafe, or if their operation fhould be varied by other circumftances and combinations." Natural Hiftory, by Wood, vol. iii. p. 443—446.

Opinion of Smith.—"In tracing the globe," fays Smith, "from the pole to the equator, we obferve a gradation in the complexion, nearly in proportion to the latitude of the country. Immediately below the arctic circle, a high and fanguine colour prevails: from this you defcend to the mixture of red and white: afterwards fucceed the brown, the olive, the tawny, and, at length, the black, as you proceed to the line. The fame diftance from the fun, however, does not, in every region, indicate the fame temperature of climate. Some fecondary caufes muft be taken into confideration, as correcting and limiting its influence. The elevation of the land, its vicinity to the fea, the nature of the foil, the ftate of cultivation, the courfe of winds, and many other circumftances, enter into this view. Elevated and mountainous countries are cool, in proportion to their altitude above the level of the fea, &c. &c." Effay, p. 8—10.

Opinion of Blumenbach.—Blumenbach informs us how climate operates in modifying the colour of the fkin, but does not attempt to explain its effects on the ftature, proportions, &c. He ftates that the proximate caufe of the dark colour of the integuments is an abundance of carbone, fecreted by the fkin with hydrogen, precipitated and fixed in the rete mucofum by the contact of the atmofpheric oxygen. (De Variet. p. 124.) He obferves further, that this abundance of carbone is moft diftinctly noticeable in perfons of an atrabilarious temperament; which fact, together with many others, proves the intimate connection between the biliary and the cutaneous organs; that hot climates exert a very fignal influence on the liver; and thus, that an unnatural ftate of the biliary fecretion, produced by heat, and increafed through many generations, caufes the veffels of the fkin to fecrete that abundance of carbone, which produces the black colour of the Negro. Ibid. p. 126—137.

Certain fuperficial Views favourable to this Opinion.—It cannot be fuppofed that men of undoubted talents and learning would take up thefe opinions without any foundation at all; and accordingly we find that there is a flender mixture of truth in thefe ftatements: but it is fo enveloped in a thick cloud of error, and fo concealed by mifreprefentation and exaggeration, that we do not recognzie it without difficulty. The colour of Europeans nearly follows the geographical pofitions of countries: this part of the world is occupied almoft entirely by a white race, of which the individuals are fairer in cold latitudes, and more fwarthy or fun-burnt in warm ones: thus, the French may be darker than the Englifh, the Spaniards than the French, and the Moors than the Spaniards. In the fame way, where different parts of a country differ much in latitude and in temperature, the inhabitants may be browner in the fouth than in the north: thus, the women of Granada are faid to be more fwarthy than thofe of Bifcay, and the fouthern than the northern Chinefe, &c. Thefe diverfities are produced by the climate, as we have already explained. The effect goes off if the caufe be removed: it terminates in the individual, and is never tranfmitted to the offspring, as we fhall prove moft incontrovertibly prefently.

On a fuperficial view again, we obferve that temperate Europe is occupied by a white race, and that the blacks, of whom we fee and hear moft, dwell chiefly under the burning funs and on the parched fands of Africa and Afia: the numerous whites who live in hot, and the greater number of dark coloured people who are found in cold countries, are not taken into the account in thefe imperfect and partial comparifons.

We are particularly furprifed that the acutenefs and good fenfe of Blumenbach fhould have allowed him to refort to an explanation grounded on fuch remote analogies, and fo obvioufly weak and inadequate, as that by which he attempts to account for the black colour of the Negro. To require us to believe that all the dark coloured races labour under hepatic difeafe, when our fenfes inform us that they are in perfect health, is really too much: the ftatement is too abfurd to require ferious refutation.

Arguments againft it.—We proceed to fhew that climate does not caufe the diverfities of mankind; and in this confideration, our remarks are chiefly directed to the colour of the fkin, as that is the part in which its operation has been regarded, by all the defenders of its influence, as the moft unequivocal: the reafoning, however, will apply in general to the other points of difference, as well as to this.

The uniform colour of all parts of the body is a ftrong argument againft thofe who afcribe the blacknefs of the Negro to the effect of the fun's rays. The glans penis, the cavity of the axilla, the infide of the thigh are juft as black as any other parts; indeed, the organs of generation, which are always covered, are among the blackeft parts of the body. Neither is the peculiar colour of the Negro confined to the fkin; a fmall circle of the conjunctiva, round the cornea, is blackifh, and the reft of the membrane has a yellowifh-brown tinge. The fat has a deep yellow colour, at leaft in many of them, which could be diftinguifhed by a very fuperficial infpection, from that of an European. On thefe points the teftimony of Soemmering coincides with our own obfervation. (Ueber die körperl. Verfch. § 7 and 46.) The fpecies of domeftic fowls in the Eaft Indies, with black periofteum, affords a further proof that the operation of the fun's rays is not the caufe of colour in animal bodies.

On the other hand, a black ftate of the fkin is fometimes partially produced in individuals of the white races. In the faireft women, towards the end of pregnancy, fpots of a more or lefs deep black colour have been often obferved; they gradually difappear after parturition. "The dark colour of the fkin," fays White, "in fome particular parts of the body, is not confined to either the torrid or frigid zones: for in England the nipple, the areola round the nipple, the pudenda, and the verge of the anus, are of a dark brown, and fometimes as black as in the Samoiede women. It is to be remarked that the colour of thefe parts grows darker in women at the full period of geftation. One morning I examined the breafts of twenty women in the lying-in hofpital in Manchefter, and found that nineteen of them had dark-coloured nipples; fome of them might be faid to be black, and the areola round the nipple, from one inch to

two

two inches and a half in diameter, was of the fame colour. (On the regular Gradation, p. 114. Camper, Kleinere Schriften, vol. i. part i. p. 47.) Le Cat mentions a woman near Paris, in whom the abdomen became black at each pregnancy, and afterwards recovered its colour; in another the fame change occurred in the leg. See Blumenbach de Variet. page 156, note z.

If we take the trouble of examining the races in any particular divifion of the world, we fhall quickly find that the opinion, which afcribes their diftinguifhing characters to climate, muft be given up; that the fame race inhabits the moft different regions, preferving in all an uniformity of character; that different races are found in the fame countries, and that thofe, who have changed their native abodes for fituations, in which, according to the hypothefis, they ought to have undergone a complete metamorphofis, ftill retain their original diftinctions.

Arguments from the Races that occupy Europe.—In the north of Europe, as alfo in the north of Afia and America, that is, in countries neareft to the pole, in which, according to the opinion above ftated, the whiteft races ought to be found, we have very brown and black people: they are much darker coloured than any other Europeans. The Moors in Africa, and the Arabs of the defert are born with a white fkin, and continue fair unlefs adventitious caufes are applied. But the Laplanders and Greenlanders, who hardly ever feel a moderate heat from the rays of the fun, are all very dark. "The Laplanders," fays Buffon, "the inhabitants of Nova Zembla, the Borandians, the Samoieds, the northern Tartars, the Oftiacs of the old continent, and the Greenlanders and the favages to the north of the Efkimaux Indians in the new continent, appear to be all the fame race, who have extended and multiplied along the coafts of the North fea, in deferts, and under climates which could not be inhabited by other nations. All thefe people have broad large faces, and flat nofes. Their eyes are of a yellowifh-brown colour, inclining to black; their eye-lids extend towards the temples: their cheek-bones are very prominent; their mouths are large, and their lips thick and reflected; the under part of their face is narrow; they have a fqueaking voice; the head is large, the hair black and fmooth, and the fkin is of a tawny or fwarthy hue. Their fize is diminutive, but, though meagre, their form is fquat. Moft of them are only four feet high, and their talleft men exceed not four feet and a half" Vol. iii. p. 302.

It is curious to obferve how eafily the afferters of the power of climate in changing the human body get over an inftance fo fatal to their opinions: they tell us roundly that great cold has the fame effect as great heat: "When the cold becomes extreme, it produces effects fimilar to thofe of violent heat. The Samoiedes, Laplanders and natives of Greenland are very tawny; we are even affured that fome of the Greenlanders are as black as the Africans; thus the two extremes approach each other: great cold and great heat produce the fame effect upon the fkin, becaufe each of thefe caufes acts by a quality common to both; and this quality is the drynefs of the air, which, perhaps is equally great in extreme cold and extreme heat. Both cold and heat dry the fkin, and give it that tawny hue which we find among the Laplanders. Cold contracts all the productions of nature. The Laplanders, accordingly, who are perpetually expofed to all the rigours of froft, are the fmalleft of the human fpecies." Buffon, vol. iii. p. 443. See alfo Smith's Effay.

If this reafoning fhould not convince us, there are other arguments in referve. The ftate of fociety is faid to have great effect on the conformation and colour of the body. The nakednefs of the favage, the filthy greafe and paint with which he fmears his body, his fmoky hut, fcanty diet, want of cleanlinefs, and the undrained and uncleared country which he inhabits, not only, according to Smith, darken his fkin, but render it impoffible that it ever fhould be fair. p. 48—52.) On the other hand, the conveniencies of clothing and lodging—the plenty and healthful quality of food—a country drained, cultivated, and freed from noxious effluvia—improved ideas of beauty—the conftant ftudy of elegance, and the infinite arts for attaining it, even in perfonal figure and appearance, give cultivated an immenfe advantage over favage fociety in its attempts to counteract the influence of climate, and to beautify the human form (p. 53.) What falfe notions muft mankind have hitherto entertained on this fubject! We can no longer believe travellers, who tell us that the fineft forms, and the greateft ftrength are to be feen in favage tribes, and that no ill-formed individuals can be met with amongft them: and as little can we truft the teftimony of our own fenfes, concerning the frequency of deformity and difeafe in civilized fociety; fince there are fo many reafons why the former fhould be deformed, black, and ugly, and the latter well proportioned, fair, and handfome. Unluckily, however, this fine-fpun theory does not correfpond with a few plain facts. Moft of the modern European nations exifted in a more or lefs complete ftate of barbarifm within times of which we have the moft authentic records: fome of thefe were feen and defcribed by philofophers; yet the permanence of their characters is fo remarkable after a greater progreffive civilization than has happened in any other inftance, that thofe defcriptions are applicable with the greateft exactnefs to the fame races of the prefent day. Inftead therefore of accounting for the dark colour, peculiar features, and ftature of the Greenlander, Laplander, and Samoiede, from their fmoke, their dirt, their food, or the coldnefs of the climate, we can have no hefitation in afcribing them to the fame caufe that makes the Briton and the German of this day refemble the portraits of their anceftors, drawn by Cæfar and Tacitus, *viz.* their defcent from a race marked by the fame characters as diftinguifh themfelves. Thefe tribes owe their origin to the Monguls, and retain in the north thofe marks of their defcent, which we find as ftrongly expreffed in the Chinefe, under the widely different latitudes of the fouth. At the fame time, the parent tribes live in the middle of Afia, equally removed from the former and the latter.

With flight exceptions, fays Dr. Prichard, the different countries of Europe are now occupied by the fame nations that have occupied them fince the date of our earlieft authentic accounts. Conquefts have been made by fmall numbers, fo that the races have been little changed by this caufe. Thus when Clovis and his 30,000 Franks reduced the large and populous province of Gaul under their dominion, the bodily characters, and the language of the conquerors were loft in thofe of the conquered. The nations which have inhabited Europe for the laft 2,500 years, confift of three great races, diftinguifhed from each other by their bodily formation, character, and language.

1. The Celtic race, with black hair and eyes, and a white fkin verging to brown, occupies the weft of Europe: to this belong the ancient and modern inhabitants of France, Spain, Portugal, and the greateft part of Italy: the ancient Britons, Welfh, Bretons, Irifh, Scotch, and Manks. The refemblance of the Silures to the Iberi was noticed by Tacitus; it is obvious to every obferver in the prefent time; nor is the obfervation peculiar to the Welfh; it holds good of

of all other Celtic nations. "Silurum colorati vultus, et torti plerumque crines, et posita contra Hispania, Iberos veteres trajecisse, easque sedes occupasse, fidem faciunt." That black hair and a browner complexion belonged to all the Celts, is not only proved by many direct observations, but also because the marks of the sanguine constitution were universally considered as the distinction of the German race.

2. The great German race, characterized by its blue eyes, yellow or reddish hair, fair and red skin, occupies the middle of Europe, and includes the Swedes, Norwegians, Icelanders, Danes, ancient and modern Germans, Saxons and English, Caledonians or Pictæ, and the Lowland Scotch, who have sprung from them, the inhabitants of the Low Countries, the Vandals and Goths, &c. Historical records, and the similarity of language and character both of body and mind, prove that all these people belong to the same race.

3. The east of Europe contains the Sarmatian and Slavonic tribes, characterized by dark hair and eyes, and a darker skin than the German, with perhaps larger limbs than the Celts. To this division belong the Russians, Poles, Croats, Slavons, Bohemians, Bulgarians, Cossacks, and others who speak the Slavonic language. (Diss. Inaug. de Variet. p. 102—109.) He proceeds to shew from Diodorus Siculus, that the Sarmatians descended from the Medes, and were found on the banks of the Tanais, 700 years before the Christian era: by the authority of Herodotus, that they occupied the country between the Tanais and the Borysthenes, when Darius Hystaspes invaded Syria; and from Cluverius, that the coasts of the Baltic, the banks of the Vistula, Prussia, and the country as far as the situation of the Finni and Venedi, were the ancient seats of the Sarmatians. Since then a people of very different race have existed in the neighbourhood of the Germans from the most remote times, how can we explain the differences of the European nations, by the operation of climate, by heat and cold? How does the same sky cause the whiteness of the German and Swede, and the comparatively dark complexion of the Pole and Russian?

But these European races are found also in Asia and Africa. All that part of the former region, which lies to the west of the river Ob, the Caspian sea, and the Ganges; all the north of Africa, Abyssinia, and perhaps other parts still farther south, on the east, are occupied by a race agreeing nearly in character with the Sarmatians and Celts.

Thus it appears, that, excepting the Germans, and the Laplanders and Samoiedes, whom we deem of Mongolian origin, the same native or congenital constitution prevails over the whole of Europe, the western parts of Asia, and the north of Africa. Black hair, dark eyes, and a white skin, tending rather to a brownish tint, than to the peculiar whiteness of the German tribes, belong to the French, Spaniards, Portuguese, Italians, and all the Celts; to the Russians, Poles, and others of Slavonic origin; to the Tatars, commonly confounded with the Mongols, the Circassians and Georgians, the Turks, Greeks, Arabians, Abyssinians, Syrians, Jews, and the inhabitants of Tripoli, Tunis, Algiers and Morocco. That climate cannot be the cause of the identity of character in nations spread over fifty degrees of latitude, and that food, dress, state of civilization, peculiar customs, &c. are equally inefficacious in accounting for this sameness, when we consider how numerous and diversified the nations are in whom it occurs, will be allowed by every unprejudiced observer.

Asiatic Races.—Two races are to be found in Asia, on the east of the Ob and the Caspian. "The vast tracts of mountains that stretch from the Caspian to the remotest borders of the east, have been occupied from time immemorial by the Mongolian tribes, distinct in their conformation from all other races, and more different from the Europeans than any negroes. Their skin varies from yellow-white to olive colour. Their hair is perfectly black from the time of birth. In stature they are short; they have round heads, large ears, oblique eyes, flat noses. To this nation the name of Tartars (Tatars) has been very improperly applied, as they have nothing in common with the true Tatars, who altogether resemble the Europeans. All the east of Asia, except a few spots occupied by Tatars and Ostiaks, the Tschutski, probably derived from the aborigines of America, and the Indians, contains several nations very closely resembling the Monguls, and arising in all probability from the same root. Among these we enumerate the Calmucks and Buriates, a part of the Mongolian nation itself, the Samoiedes, the Tungooses, the Mantchoos, who border on the Chinese, the Chinese themselves, the Jakuts, the Japanese, and the Kamtschatkans. "Calmucæ proprii," says Pallas, "Mongoli, Buriates, Kirguses, Solones Orientales, Tungusi Dauriæ, et Sinenses septentrionales sibi invicem simillimi sunt." (Voy. en Siberie.) "Les Samoyèdes de l'Ob ressemblent beaucoup aux Tungooses. Ils ont le visage plat, rond et large. Ils ont peu de barbe, et les cheveux noirs et rudes." "On trouve les restes de cette nation dans la partie orientale de la Sibérie près de l'Enisséi. Les Koibals, les Kamaches, les Abotors, les Soiots, les Karagasses ont la meme figure que les Samoiedes, et parlent tous leur langue." (Ibid.) "The Kamtschadales and Mungals (Mongols) are swarthy, have black hair, little beard, broad faces, nose short and flat, eyes small and sunk, the belly protuberant, and the legs small. The language of the Kamtschadales resembles the Mungal Chinese." Steller's Voyage to Kamtschatka.

"The Japanese in general, particularly the common people of Nipon, are ugly, short, strong, thick-legged, tawny, with flattish noses and thick eye-lids, though the eye stands not so deep in the forehead as in the Chinese. The noble families are more majestic in shape and countenance, and more like Europeans." Kæmpfer.

"The Mantchoo Tatars are scarcely distinguishable from the Chinese by external appearances: the Chinese are somewhat taller, but their features almost exactly resemble. The natural colour, both of Chinese and Tatars, seems to be that tint between a fair and a dark complexion, which we distinguish by the word brunet or brunette; and the shades of this complexion are deeper or lighter, according as they have been more or less exposed to the influence of climate. The women of the lower class, who labour in the fields, or who dwell in vessels, are almost invariably coarse, ill-featured, and of a deep brown complexion, like that of the Hottentots. We saw women in China, though very few, who might pass for beauties even in Europe. A small black or dark brown eye, a short rounded nose, generally a little flattened, lips considerably thicker than in Europeans, and black hair, are universal." (Barrow's China.) "Besides the general similarity of the tribes occupying such vast and distant regions, it is curious to observe that the Samoiedes, Kamtschatkans, and others towards the north, have a much darker skin than the Calmucks, Mantchoos, and Chinese in warmer countries." Prichard's Disputatio, p. 93—99.

"India is inhabited by a mixed race, made up of the aborigines, and of others whom the pursuits of war and conquest have at various times brought there. The religion of Brahma seems to have been conveyed there from the north;

north; and at later periods vaſt numbers of the Mongols have entered and conquered the country. Theſe mixtures have effaced the peculiar characters of the original inhabitants, which we muſt, therefore, ſeek for in the iſlands, protected by their ſituation from ſuch viſits. The iſlands of the Indian ſea, as well as thoſe of the Pacific, contain two races of men, differing in many reſpects. One of theſe approaches, and in ſome inſtances equals, the blackneſs of the Negro: the hair is curled and woolly, the body ſlender, the ſtature ſhort, the diſpoſition barbarous and cruel. The other is more like the Indians of the continent, has a fairer ſkin, larger limbs and ſtature, better proportions, and exhibits ſome marks of humanity and civilization. According to Forſter, the former, who are aborigines, have occupied the middle and mountainous parts of many iſlands, leaving the coaſts and plains to the more recent coloniſts. They occupy the higheſt parts of the Moluccas, the Philippines, Formoſa, and Borneo; all New Guinea, New Britain, Hibernia and Caledonia, Tanna, Mallicollo, New Holland, and Van Diemen's land. The more recent nation occupies Sumatra, and the other iſlands of the Indian ſea, Otaheite, and the Society iſlands, the Friendly iſlands, Marqueſas, Ladrones, Marian and Caroline iſlands, New Zealand, Sandwich and Eaſter iſlands. The language of all the latter reſembles the Malay, and there can be no doubt that they ariſe from that race, and have ſpread by their ſhips over theſe diſtant ſpots. The black people are every where barbarous, and, according to Forſter, have languages not agreeing with each other. In neither can we perceive any traces of the influence of climate. The latter race, ſcattered in various parts of the vaſt iſland of New Holland, which has ſuch variety of temperature, every where retains its black colour, although the climate at the Engliſh ſettlement is not much like unlike that of England; and in Van Diemen's land, extending to 45° S. lat. (it is well underſtood that the cold is much more ſevere in the ſouthern hemiſphere, at an equal diſtance from the equator, than in the northern) they are of a deep black, and have curled hair like the negroes.

"We may make the ſame remarks concerning the Malay race. The Sumatrans under a vertical ſun are the faireſt people of the Indian iſlands: and Marſden relates, that they ſometimes approach the whiteneſs of Europeans. The inhabitants of Otaheite are very fair: yellow hair is not unfrequently ſeen amongſt them; while thoſe of New Zealand, twice as diſtant from the equator, are much darker." (Ibid. 85—89.) It is ſufficiently obvious that in Aſia, where we have countries with every variety of ſituation and temperature, at every diſtance from the equator, with every diverſity of elevation, hills, vallies, plains, iſlands and continents, we can trace no effect of climate on the colour, or on any other character of the human race.

African Races.—On the hypotheſis, which aſſigns the varieties of mankind to the operation of climate as their cauſe, we ſhould expect to find in Africa all tribes under the equator of the moſt intenſely black colour; the tinge ſhould become lighter and lighter as we proceed thence towards the ſouth, and the complexion ought to be white when we arrive at regions which enjoy an European climate. This, however, is by no means the caſe. The Abyſſinians, on the eaſt, with dark olive colour and long hair, are placed near the equator, and ſurrounded by negroes. In the ſame part alſo, the Gallas, a great and barbarous nation, having, according to Bruce, long black hair, and white ſkin verging to brown, occupy extenſive regions under the equator itſelf. On the other hand, as we proceed from the equator towards the ſouth, through tribes of negroes, we find the black colour continued with undiminiſhed intenſity. It is known in the Weſt Indies, that the Congo negroes in the blackneſs of their ſkin and woolly hair equal any race of Africans. Paterſon aſſures us that the Caffres, within a few degrees of the Cape of Good Hope, where the climate is ſo far from being intolerably hot, that the corn is often hurt by the winter froſt, are of the deepeſt colour; and the ſame fact is familiarly known of the ſurrounding tribes.

The iſland of Madagaſcar, which is cooled by the mild breezes of the Indian ocean, and ought, therefore, to contain a white race, has two kinds of natives: one of olive colour with dark hair; the other true negroes.

The Hottentots, at one or two degrees from the deep black Caffres, are of a browniſh-yellow colour: this diſtance can hardly account for the difference. The obſervations of Barrow on the countenance and form of this race, render it probable that they owe their origin in part to the Chineſe, which circumſtance will enable us to explain their colour very eaſily. He ſays that the eye-lids are joined towards the noſe, by a rounded ſweep without any angle: that the limbs and joints are ſmall both in the Hottentots and the Chineſe: that the voice and mode of ſpeaking are nearly the ſame in both: that a broad noſe, ſlanting eyes depreſſed towards the noſe, and other features, are common to both. The hair has a middle character between that of the Negro and Chineſe; it is ſuch, in ſhort, as the intermixture of the two races may be expected to produce.

When we conſider how large an extent of Africa is occupied by the black woolly-haired negroes, and that theſe regions vary in their latitude, their elevation, and every other point; that they include ſandy deſerts, coaſts, rivers, hills, vallies, and very great varieties of climate, the concluſion that theſe adventitious circumſtances do not influence the colour or other properties of the race is irreſiſtible.

American Races.—It only remains for us to examine the continent of America, which, as it ſtretches uninterruptedly from the neighbourhood of the north pole to 55° S. lat. and includes regions diverſified in every poſſible way, affords the moſt ample opportunity for the developement of all the changes that ſuch cauſes can produce; and to examine whether the facts aſcertained concerning its inhabitants are more favourable to the hypotheſis of climate than what we have obſerved in the other three diviſions of the world.

The reports of travellers are unanimous concerning the identity of character in the whole American race: copper-coloured ſkin, long and ſtraight black hair, and a certain caſt of features, are ſaid to belong to all the inhabitants of this extenſive continent. How remarkable this agreement is may be collected from the ſtatement ſometimes made, that a perſon who has ſeen one may conſider that he has ſeen all; which, however, in its full extent, muſt be conceived as an exaggerated or partial view. The Eſquimaux are not included in this account: their colour is more of the olive caſt; in which, as well as in other points, they betray their Aſiatic origin.

Herrara, Ulloa, and others who have viſited the American continent, affirm, that all the native tribes, both of the northern and ſouthern diviſions, are of the ſame colour. We may cite the teſtimonies of Stedman, Hearn and Mackenzie, Wallis and Cook, who aſcribe the copper colour reſpectively to the natives near Surinam, thoſe in the regions fartheſt north, and to the Patagonians and inhabitants of Terra del Fuego. Humboldt, whoſe extenſive opportunities of obſervation and philoſophic ſpirit give great weight to his ſtatements, confirms this repreſentation in the moſt ample manner.

"The Indians of New Spain bear a general reſemblance

to

to those who inhabit Canada, Florida, Peru, and Brazil. They have the same swarthy and copper colour, flat and smooth hair, small beard, squat body, long eye, with the corner directed upwards towards the temples, prominent cheek-bones, thick lips, and an expression of gentleness in the mouth, strongly contrasted with a gloomy and severe look. The American race, after the Hyperborean race, is the least numerous; but it occupies the greatest space in the globe. Over a million and a half of square leagues, from the Terra del Fuego islands to the river St. Lawrence and Beering's straits, we are struck at the first glance with the general resemblance in the features of the inhabitants. We think we perceive that they all descend from the same stock, notwithstanding the enormous diversity of language that separates them from each other. However, when we reflect more seriously on this family likeness, after living longer among the indigenous Americans, we discover that celebrated travellers, who could only observe a few individuals on the coasts, have singularly exaggerated the analogy of form among the Americans."—"The uniformity of the red coppery complexion, and dark, coarse, and glossy hair, conceals for a long time the diversity of individual features." "The Indians of New Spain have a more swarthy complexion than the inhabitants of the warmest climates of South America. This fact is so much the more remarkable, as in the race of Caucasus, which may also be called the European Arab race, the people of the south have not so fair a skin as those of the north. Though many of the Asiatic nations, who inundated Europe in the sixth century, had a very dark complexion, it appears that the shades of colour observable among the white race, are less owing to their origin or mixture than to the local influence of the climate. This influence appears to have almost no effect on the Americans and Negroes. These races, in which there is abundant deposition of carburetted hydrogen in the corpus mucosum or reticulatum of Malpighi, resist in a singular manner the impressions of the ambient air. The Negroes of the mountains of Upper Guinea are not less black than those who live upon the coast. There are, no doubt, tribes of a colour by no means deep among the Indians of the new continent, whose complexion approaches to that of the Arabs or Moors. We found the people of the Rio Negro swarthier than those of the lower Orinoco, and yet the banks of the first of these rivers enjoy a much cooler climate than the more northern regions. In the forests of Guinea, especially near the sources of the Orinoco, are several tribes of a whitish complexion, the Guaicas, Gunjaribs, and Arigues, of whom several robust individuals, exhibiting no symptom of the asthenical malady which characterizes Albinos, have the appearance of true Mestizos. Yet these tribes have never mingled with Europeans, and are surrounded by other tribes of a dark brown hue. The Indians in the torrid zone, who inhabit the most elevated plains of the Cordillera of the Andes, and those who, under the 45° of S. lat. live by fishing among the islands of the Archipelago of Chonos, have as coppery a complexion as those who under a burning climate cultivate bananas in the narrowest and deepest vallies of the equinoctial region. We must add, that the Indians of the mountains are clothed, and were so long before the conquest, while the aborigines, who wander over the plains, go quite naked, and are consequently always exposed to the perpendicular rays of the sun. I could never observe that in the same individual those parts of the body which were covered were less dark than those in contact with a warm and humid air. We every where perceive that the colour of the American depends very little on the local position in which we see him." Political Essay on the Kingdom of New Spain, vol. i. p. 140—145.

How does it happen, that the same sun, which makes the African black, tinges the American of a copper colour? and that the dark hue, which might possibly be produced by heat in the equatorial regions, should be found also in the cold and inhospitable tracts of Terra del Fuego, and the most northern part of the continent? The absence of white races can surely not be ascribed to the want of sufficiently cold climates. Bougainville found the thermometer, in the middle of summer, $54\frac{1}{2}°$ in lat. 52°; and Messrs. Banks and Solander, and their attendants, had nearly perished all together from the cold, in an excursion in Terra del Fuego, in the middle of the summer. Two of the servants were actually lost.

Differences in the same Regions.—A very cursory survey of the globe will shew us that the same regions have been occupied by men of different races, without any interchange of characters, in many instances, for several centuries The Moors and Negroes are found together in Africa; Europeans, Negroes, and Americans in North and South America; Celts, Germans, and Slavons in Europe, and even in the same kingdoms of Europe, &c. &c. The distinctions of these different races, except where they have been confused by intermarriages, is just as easy now as it has been in any time, of which we have authentic records.

Permanence of the original Character, when the Climate is changed.—The permanency of the characters of any race when it has changed its original situation for a very different one, when it has passed into other climes, adopted new manners, and been exposed to the action of these causes for several generations, affords the most indisputable proof that these characteristics are not the offspring of such adventitious circumstances. From the numerous examples, in every race, which a slight knowledge of history will furnish, we shall select a few of the most striking.

The establishments of the Europeans in Asia and America have now subsisted about three centuries. Vasquez de Gama landed at Calicut in 1498; and the Portuguese empire in India was founded in the beginning of the following century. Brazil was discovered and taken possession of by the same nation, under Alvarès Cabral in 1500. Towards the end of the fifteenth, and the beginning of the sixteenth century, Columbus, Cortez, and Pizarro subjugated for the Spaniards the West Indian islands, with the empires of Mexico and Peru. Sir Walter Raleigh planted an English colony in Virginia in 1584; and the French settlement of Canada has a rather later date. The colonists have, in no instance, approached to the natives of these countries; and their descendants, where the blood has been kept pure, have, at this time, the same characters as native Europeans. In the hotter situations indeed, as in the warmer countries of Europe, the skin is swarthy; but the children, at the time of birth, and women who are never exposed much to the sun's rays, have all their native whiteness. This observation admits of no exception: in the tint of the skin, the colour and other qualities of the hair, the features, the form of the cranium, the proportions and figure of the body, the European colonists retain all their original characters. The sanguine constitution, with its blue eyes, yellow hair, and fair skin, which is so remarkably different from that of the natives, is nevertheless transmitted without the least alteration from generation to generation.

Negroes have been introduced into the new world for nearly an equal length of time: in the West Indian islands, in the United States, in the various parts of Spanish America, they live under new climates, and have adopted new

new habits. Yet they have ftill woolly hair, black fkins, flat nofe, thick lips, and all the other characters of their race.

The Vandals paffed from Spain into Africa about the middle of the fifth century: their defcendants may be ftill traced, according to Shaw, in the mountains of Atlas, by their white and ruddy complexion, and yellow hair. The change, produced by climate, muft be infinitely fmall, fince it is not yet perceptible after a lapfe of thirteen centuries.

The inhabitants of Perfia, of Turkey, of Arabia, of Egypt, and of all Barbary, may be regarded as the fame race of people, who, in the time of Mahomet and his fucceffors, extended their dominions by invading immenfe territories. In all thefe fituations the fkin retains its native fairnefs, unlefs the tint be changed by expofure to the fun: and the children are invariably fair. "Il n'y a femme de laboureur ou de payfan en Afie (Afia Minor) qui n'a le teint frais comme une rofe, la peau delicate et blanche, fi polie et fi bien tendue, qu'il femble toucher du velours." (Obf. de Pierre Belon, p. 199.) The Arabians are fcorched by the heat of the fun, for moft of them are either covered with a tattered fhirt, or go entirely naked: La Boullaye informs us, that the Arabian women of the defert are born fair, but that their complexions are fpoiled by being continually expofed to the fun. (Voyages de la Boullaye le Gouz, p. 318.) Another traveller remarks that the Arabian princeffes and ladies, whom he was permitted to fee, were extremely handfome, beautiful, and fair, becaufe they are always covered from the rays of the fun; but that the common women are very much blackened by the fun. Voyage fait par Ordre du Roi dans la Paleftine, p. 260.

The Moors, who have lived in Africa fince the feventh century, have not degenerated in their phyfical conftitution from their Arabian progenitors: the fun exerts its full influence on their fkin, but their children are juft as white as thofe born in Europe. They are by no means confined to the northern coaft, but have penetrated, as the prevalence of the Mahometan religion attefts, deeply into the interior: here they dwell in countries, of which the woolly Negro is the native, but have not acquired, in fix centuries of expofure to the fame caufes, any of his characters. The intelligent and accurate Shaw informs us that moft of the Moorifh women would be reckoned handfome even in Europe; that the fkin of their children is exceedingly fair and delicate, and though the boys, by being expofed to the fun, foon grow fwarthy, yet the girls, who keep more within doors, preferve their beauty till the age of thirty, when they commonly give over childbearing. "Les Maures," fays Poiret, "ne font pas naturellement noirs, malgré le proverbe, et comme le penfent plufieurs ecrivains; mais ils naiffent blancs, et reftent blancs toute leur vie, quand leurs travaux ne les expofent pas aux ardeurs du foleil. Dans les villes les femmes ont une blancheur fi éclatante, qu'elles eclipferoient la plupart de nos Européennes; mais les Maurefques montagnardes, fans ceffe brulées par le foleil et prefque toujours à moitié nues, deviennent, méme dès l'enfance, d'une couleur brune qui approche beaucoup de celle de la fuie." (Voy. en Barbarie, tom. i. p. 31.) The teftimony of Bruce is to the fame effect.

That the fwarthinefs of the Southern Europeans is merely the effect of the fun's action on the individual, whofe children are born perfectly white, and continue fo unlefs expofed to the operation of the climate, might be eafily proved of the Spaniards and Portuguefe, the Greeks, Turks, &c. but the fact is too well known to render this neceffary.

The Jews exhibit one of the moft ftriking inftances of peculiar national formation, unaltered by the moft various changes. They have been fcattered, for ages, over the face of the whole earth; but their peculiar religious opinions and practices have kept the race uncommonly pure; accordingly their colour and their characteriftic features are ftill the fame under every diverfity of climate and fituation.

We confider it as fufficiently proved that native differences in general, and particularly that of colour, do not depend on extraneous caufes: we have an obfervation or two to make on fome other points. That the curled hair of the African is not produced by heat appears from its being found, in many fituations, not remarkable for high temperature, as the Moluccas, New Guinea, Mallicollo, Borneo, New Holland, and even in the cold region of Van Diemen's land; as well as from the hot regions of Afia and America being inhabited by a long-haired race. The differences in ftature, again, have been very confidently afcribed to adventitious caufes. Temperate climate, pure air, copious food, &c. have been thought favourable to the full developement of the human frame; while extreme cold, bad and unwholefome food, noxious air, and fimilar caufes, have been thought capable of reducing the dimenfions of the body below the ordinary ftandard. That thefe caufes may have fome effect on individuals we do not deny, although we believe that it is very flight: but the numerous examples of large people in cold countries, and diminutive men in warm climes, induce us to deny altogether its operation on the race. The tall and large-limbed Patagonians, the Tfchutfki, and the North Americans inhabit cold fituations; the Monguls, who are fmall in ftature, live in warm countries.

The foregoing facts and arguments warrant us, as we conceive, in drawing (with Dr. Prichard, Diff. p. 119.), the following conclufions.

1. That climate, manners, and other phyfical and moral caufes, have fome power in modifying the natural conftitution of man, as well as of animals.

2. That the influence of fuch caufes is confined to one generation; and that no alteration produced in this way, or brought about by art or chance, is tranfmitted to the offspring.

3. That all the diverfities of mankind are examples of a propenfity to the formation of natural varieties, common to all animals under certain circumftances, follow the fame laws, and are to be afcribed to the fame caufe.

4. Therefore, that the hypothefis of different fpecies having been originally formed, is unneceffary for the explanation of the phenomenon.

Divifions of Mankind. Arrangement of Man as an Object of Natural Hiftory.—Order, Bimanus. *Genus*, Homo. Erectus, bimanus, inermis, rationalis, loquens: mento prominulo: dentes incifores fupra & infra quatuor: dentes omnes æqualiter approximati; laniarii reliquis longitudine æquales; incifores inferiores erecti. See Blumenbach, Handbuch der Naturgefchichte. *Species*, H fapiens.

Varieties.—As we have fhewn, on the one hand, that there is no circumftance of difference between the varieties of the human race, which does not appear in a ftill greater degree among animals chiefly of the domefticated kinds, arifing from the ordinary fources of degeneration: fo there is no point, whether of colour, countenance, or ftature, which does not pafs by imperceivable gradations into the oppofite character, rendering all thefe diftinctions merely relative, and reducing them to differences in degree. Hence it is obvious, that any divifion of the varieties of the human race muft be in a great meafure arbitrary.

The fingle fpecies then, which the genus Homo contains, is divided by Blumenbach into the five following varieties;

rieties; 1. Caucafian; 2. Mongolian; 3. Æthiopian; 4. American; 5. Malay. The Caucafian, for reafons which will afterwards be mentioned, is regarded as the primitive ftock. This deviates into two extremes moft remote and different from each other; *viz.* the Mongolian on one fide, and the Æthiopian on the other. The two remaining varieties hold the middle places between the Caucafian and the two extremes: that is, the American comes in between the Caucafian and Mongolian; and the Malay between the Caucafian and Æthiopian.

Thefe five varieties may, on the whole, be defined by the following marks and defcriptions. But it is neceffary to obferve, in the firft place, that on account of the multifarious diverfity and gradations of characters, one or two are not fufficient for determining the race, confequently that an union of feveral is required; and, fecondly, that even this combination of characters is fubject to numerous exceptions in each variety. The union of the different races by intermarriages, and the changes of fituation for the purpofes of war and conqueft, that lead to thefe, account for a great deal of this uncertainty. On the whole, however, the following will be found a tolerably clear and correct view of the matter.

1. *Caucafian Variety.*—White fkin, inclining to brown, red cheeks, hair black and of the various lighter colours, head of a fomewhat globular form; oval and ftraight face, with features moderately feparate from each other, expanded forehead, narrow and rather aquiline nofe, and fmall mouth: front teeth of both jaws perpendicular; lips, particularly the lower, gently turned out; chin full and rounded. In fhort, that kind of countenance which accords with our notions of beauty.

It includes all the Europeans, except the Laplanders and the reft of the Finnifh race; the Weftern Afiatics, as far as the river Ob, the Cafpian fea, and the Ganges; that is, the proper Tatars, the Georgians, Circaffians, Mingrelians, &c. the Perfians, Arabians, Syrians, the Turks; the Northern Africans, as the people of the Barbary ftates; the Egyptians and Abyffinians.

The name of this variety is derived from mount Caucafus, becaufe in its neighbourhood, and particularly towards the fouth, we meet with the moft beautiful race of men in the world, *viz.* the Georgians. From the accounts of numerous travellers, who all agree on this fubject, we felect the remark of Chardin: "The blood of Georgia is the fineft in the eaft, and I may fay in the world. I have not obferved a fingle ugly countenance in that country in either fex; but have feen numerous angelic ones. Nature has beftowed on the women graces and charms, which we fee in no other place. It is impoffible to look at them without loving them. More beautiful countenances, and finer figures, than thofe of the Georgian women, cannot even be imagined." Voyage en Perfe, t. i. p. 171.

Many reafons induce us to believe, that the primitive form of the human race, was that which we have defcribed as belonging to the Caucafian variety; and of which the Georgians, Turks, Greeks, and fome Europeans, exhibit now the fineft fpecimens. This race has the moft beautifully formed cranium, (fee Cranium, and *Anatomy of the Cranium, Pl.* 1. *fig.* 1.) from which, as from a middle and primitive configuration, the other forms defcend by a moft eafy and fimple gradation, on the one hand to the Mongolian, and on the other to the Æthiopian variety. The proportions of the body in general are the moft beautiful in this race, and their minds are the moft acute, fo that nearly all the arts and fciences have been difcovered by them. They occupy the middle regions of the globe, while the extremities are filled by others. The moft ancient, and moft early civilized nations have belonged to this variety. To this form alfo, according to the obfervation of Blumenbach, there is a difpofition to return in the other races; as may be obferved in the South fea iflands, and fome parts of Africa; while this does not eafily deviate into the dark coloured varieties.

If we admit the Caucafian to have been the primitive form of man, are we to fuppofe, that the eyes were blue, and the hair yellow or red, or that both were black? we can have little hefitation in adopting the latter opinion, fince that formation belongs to all of this race except the Germans, which have occupied only the more diftant regions. It forms, too, the middle colour of the human race, and appears often in fcattered inftances among the other varieties. Moreover, yellow or tawny breeds occur among animals, as in the rabbit and cat, by degeneration from the native colour.

In this Caucafian variety, Blumenbach and moft others include the German race; but Dr. Prichard affigns it a feparate place under the name of "conftitutio Germanica aut fanguinea." The form and proportions of the cranium, face, and body in general, are the fame as in the preceding; the features perhaps are rather lefs acute, and more rounded, and the eyes fmaller. The whole ftature and the limbs are rather larger. But the moft prominent diftinctions are in the very white fkin, approaching to rednefs; in the yellow or red hair, and the blue eyes.

2. *Mongolian Variety.*—Olive colour; black, ftraight, ftrong, and thin hair, fcarcely ever curled; head of a fquare form; broad and flattened face, with the features running together; the glabella (interval between the eye-brows) flat and very broad; nofe fmall and flat; rounded cheeks projecting externally; narrow and linear aperture of the eyelids; eyes placed very obliquely; flight projection of the chin; large ears, thick lips. The ftature, particularly in the countries near the North pole, is below that of the Europeans.

This includes the reft of the Afiatics (excepting the Malays); the Finnifh races of the colder parts of Europe, as the Laplanders, &c.; and the tribes of Efquimaux, extending over the northern parts of America, from Beering's ftrait to the extremity of Greenland.

The Mongolians, widely fcattered over the continent of Afia, have generally, but erroneoufly, been included with fome of very different origin and formation, under the name of Tartars; whereas the laft-mentioned tribes, properly fo called, belong to the firft divifion of the human race. The Calmucks, and other Mongolian nations, which overran the Saracen empire, under Zenghis Khan, about the middle of the thirteenth century, and had entered Europe, are defcribed in the "Hiftoria Major" of Matthew Paris under the name of Tartars, whereas that name (or, as it fhould be fpelled, Tatars) properly belongs to the weftern Afiatics, who had been vanquifhed by the Monguls. The error, however, arifing from this fource, has been propagated down to the prefent day, fo that in the works of the moft approved naturalifts, as Buffon and Erxleben, we find the characters of the Mongolian race afcribed to what they call the Tartars.

The Tatars indeed are connected by the Kirgufes, and neighbouring tribes, to the Monguls, in the fame way as the latter are joined by the inhabitants of Thibet to the Indians; by the Efquimaux, to the Americans; and by the Philippine iflanders, with the Malays.

3. *Ethiopian Variety.*—Black fkin and eyes; black and woolly hair; head narrow, and compreffed laterally; arched forehead; cheek-bones ftanding forwards; prominent eyes; thick

thick nose, confused with the extended jaw; alveolar arch narrow, and elongated anteriorly; the upper front teeth projecting obliquely; the lips, and particularly the upper one, thick; the chin receding; knees turned in in many instances. The remaining Africans, besides those classed in the first variety, belong to this.

The striking peculiarities of this variety, and particularly the very great difference between its colour and our own, have led many persons to adopt the opinion of Voltaire, who had not a sufficient knowledge of physiology and natural history to determine the question, that the Africans belong to a distinct species. We have shewn, in the preceding divisions of this article, that there is no one character so peculiar and common to the Africans, but that it is found frequently in the other varieties, and that negroes often want it; also, that the characters of this variety run by insensible gradations into those of the neighbouring races, as will be immediately perceived by comparing together different tribes of this race, as the Foulahs, Wulufs, and Mandingoes, and carefully noting how in these gradational differences they approach to the Moors, New Hollanders, &c.

Again, great stress has been laid on the fact, that the negroes resemble more nearly than the Europeans, the monkey tribe; the fear of being drawn into the family, even as distant relations, has we believe induced many to place our black brethren in a distinct species; while others have brought forwards this approximation to the simiæ, with the view of degrading the African below the standard of the human species, and thereby palliating the cruel hardships under which he groans in the islands and continent of the new world.

It is undoubtedly true, that in many of the points, wherein the Æthiopian differs from the Caucasian variety, it comes nearer to the monkies; *viz.* in the greater size of the bones of the face, compared to those of the cranium; in the protuberance of the alveoli and teeth, recession of the chin, form of the ossa nasi, position of the foramen magnum occipitale, outline of the union of the head and trunk, relative length of the humerus and ulna, &c. This resemblance is most unequivocally admitted by Soemmerring; über die körperl. verschied. pref. p. 19, and § 69. It appears to us, that this fact is not very important; if there are varieties of bodily formation among mankind, some one of these must approach nearer to the organization of the monkey than the others; but does this prove, that the variety in which the conformity occurs, is less man than the others? The solidungular variety of the common pig is more like the horse than other swine; do we hence infer, that the nature of this animal in general is less porcine, or more like that of the horse, than that of other pigs? The points in which the Negro differs from the European, are trivial and few, and do not touch upon those important characters which separate man in general from the animal world; the erect attitude, the two hands, the slow developement of the body, the use of reason, and consequently perfectibility, are attributes common to both.

That very little importance can be attached to the general observation of the resemblance of the negro and monkey, founded on external appearance, may be clearly inferred from this fact, that the same remark has been made, even by intelligent travellers, of particular people in the other varieties. Regnard concludes his description of the Laplanders with these words: "voilà la description de ce petit animal qu'on appelle Lapon, et l'on peut dire qu'il n'y en a point, après le singe, qui approche plus de l'homme. (Œuvres, t. i. p. 71.) An Esquimau, who was brought to London by Cartwright, when he first saw a monkey, asked "Is that an Esquimau?" His companion adds, "I must confess, that both the colour and contour of the countenance had considerable resemblance to the people of their nation." Nic. del Techo calls the Caaiguas of South America, "tam simiis similes, quam hominibus," Relat. de Caaig. gente, p. 34; and J. R. Forster, in the observations on his journey round the world, asserts "that the inhabitants of the island Mallicollo, of all the people whom I have seen, have the nearest relationship to the monkies."

4. *American Variety.*—Red colour; black, straight, strong, and thin hair; short forehead; deep eyes; nose somewhat flattened, but prominent; a broad, but not flattened face, with the cheeks standing out, and the different features projecting distinctly and separately; the forehead and vertex often deformed by art. This variety includes all the Americans, with the exception of the Esquimaux.

Several idle tales have been propagated, concerning the distinguishing characters of this race. Some have denied the existence of a beard in the male, and that of the menstrual discharge in the female; and others have ascribed an uniform colour and countenance to all the inhabitants of this vast continent. The concurring testimonies of all accurate modern travellers, prove clearly that the Americans have naturally beards; and that the report of their deficiency has arisen from their practice of eradicating it. See the general observations in this article on the beard.

The fabulous report of the American women not being subject to the menstrual discharge, seems to have arisen from the European travellers, who saw numerous females almost naked, having observed nothing of it. Two circumstances will account for this, according to Blumenbach: "partim nempe quod apud istas Americæ gentes feminæ quamdiu menstruatæ sint, felici prejudicio pro venenatis quasi habeantur, inque remotioribus tuguriolis e hominum conspectu remotæ tamdiu benefico ipsis otio fruantur; partim vero etiam laudatam ipsarum corporis munditiem et modestam crurum commissuram eo conferre ut nulla catameniorum vestigia in oculos incurrant, annotatum est." De Variet. p. 313.

The redness of the skin is not so constant, but that it varies in many instances towards a brown, and approaches likewise in some temperate situations to the white colour. Cook states, that the natives about Nootka Sound are little inferior in fairness to Europeans; and Bouguer makes the same observation of the Peruvians on the Andes. It is also fully ascertained at present, that the Americans possess the same varieties of feature which are observed in the other races.

5. *Malay Variety.*—Brown colour; hair black, soft, curled, and abundant; head moderately narrow, and forehead slightly arched; nose full and broad towards the apex; large mouth; upper jaw rather prominent; the features, when viewed in profile, projecting and distinct. The inhabitants of the peninsula of Malacca, of the South sea, Ladrone, Philippine, Molucca, and Sunda islands, are arranged under this division.

As the Americans in their national characters, hold the middle place between that middle variety of the human race, which we have called the Caucasian, and one of the extremes, *viz.* the Mongolian; so the Malay forms the connecting link between the Caucasian and the Ethiopian. The name of Malay is given to it, because most of the tribes which it includes, as those which inhabit the Indian islands near Malacca, the Sandwich, Society, and Friendly islands, also those of Madagascar, and thence to Easter island, use the Malay language. See Hawkesworth's collection. v. iii. p. 373;

p. 373; Cook's Voyage to the northern Hemiſphere, v. iii. p. 520; Marſden, in Archæologia, v. vi. p. 154.

Arrangements of other Naturaliſts.—The great number and diverſity of the objects, the contradictory, imperfect, and confuſed accounts which we poſſeſs of many of them, render all claſſifications very arbitrary; hence very different diviſions have been adopted by different ſyſtematic writers.

Of Linnæus.—This naturaliſt places the genus Homo in his order Primates, and gives him the company of the monkies, lemurs, and bats; the characters of the order are, "dentes primores inciſores, ſuperiores quatuor, paralleli: mammæ pectorales binæ." He admits three ſpecies:

I. Homo Sapiens; Diurnus, varians cultura, loco. Corpus erectum nudum, pilis raris remotiſſimis aſperſum, ſubſexpedale.

Varieties. *Ferus*; Tetrapus, mutus, hirſutus.

Americanus; Rufus, cholericus, rectus.
Pilis nigris, rectis, craſſis; naribus patulis; facie ephelitica; mento ſubimberbi.
Pertinax, contentus, liber.
Pingit ſe lineis dædaleis rubris.
Regitur conſuetudine.

Europæus; Albus, ſanguineus, toroſus.
Pilis flaveſcentibus prolixis. Oculis cæruleis.
Levis, argutus, inventor.
Tegitur veſtimentis arctis.
Regitur ritibus.

Aſiaticus; Luridus, melancholicus, rigidus.
Pilis nigricantibus. Oculis fuſcis.
Severus, faſtuoſus, avarus.
Tegitur indumentis laxis.
Regitur opinionibus.

Afer; Niger, phlegmaticus, laxus.
Pilis atris, contortuplicatis. Cute holoſericea, naſo ſimo. Labiis tumidis. Feminis ſinus pudoris; mammæ lactantes prolixæ.
Vafer, ſegnis, negligens.
Ungit ſe pingui.
Regitur arbitrio.

Monſtroſus; Solo et arte variat:
Alpini parvi, agiles, timidi.
Patagonici, magni, ſegnes.
Monorchides, ut minus fertiles; Hottentotti.
Junceæ puellæ abdomine attenutoa; Europeæ.
Macrocephali capite conico: Chinenſes.
Plagio-cephali capite antice compreſſo: Canadenſes.

II. H. Troglodytes; Nocturnus: habitat in Æthiopiæ conterminis, in Javæ, Amboinæ, Ternateæ ſpeluncis, in monte Ophir Malaccæ.

This ſeems to be a medley, compoſed of the characters of the leucæthiopes, and ourang-outangs.

III. Homo lar; brachiis longitudine corporis.

This is the gibbon, or long-armed monkey.

Of Buffon.—1. Lapponic or polar: 2. Tataric (Mongolian): 3. Southern Aſiatic: 4. European: 5. Æthiopian: 6. American.

Of Erxleben (Syſt. Regn. Anim. Mammalia).

Homo; Dentes primores inciſores, ſupra et infra quatuor: laniarii conici, longitudine æquales approximati. Manus in palmis, non in plantis. Mammæ pectorales binæ. Cauda nulla.

Var. 1. *Lappo*; Parvus, toroſus, albus, macrocephalus, facie plana lata, maxilla inferiore prominula acuminata vix barbata, oculis parvis profundis nigro fuſcis, naſo parvo obtuſo, buccis inflatis, ore magno, labiis craſſis, auriculis magnis, pilis rectis nigris craſſis, brachiis longioribus, manibus plantiſque minoribus.

Habitat in borealibus Europæ, Aſiæ, Americæ.

2. *Tatarus* (Mongolian): Mediocris olivaceus, facie plana lataque, fronte rugoſa, oculis parvis profundis nigris, ſuperciliis largis, naſo brevi craſſo, labiis tumidis, mento prominente acuminato, barba rariore, dentibus longioribus interſtitiis majoribus, pilis nigris craſſioribus, femoribus craſſis, cruribus brevioribus.

Ab Imao verſus circulum arcticum in Aſia.

3. *Aſiaticus*; Mediocris, luridus, rigidus, pilis nigricantibus, oculis parvis nigris, naſo depreſſo, labiis craſſis, dentibus antrorſum verſis.

Trans Gangem.

4. *Europæus*; Mediocris albus toroſus, pilis flaveſcentibus prolixis, oculis cæruleis vel fuſcis, labiis tenuioribus.

5. *Afer*; Magnus niger, cute holoſericea ex reticulo mucoſo Malpighiano craſſiore nigroque, pilis atris, contortuplicatis, oculis nigris viridibuſve, naſo ſimo, labiis tumidis, ventre inflato, mammis lactantibus prolixis.

Præcipue in Africa occidentali.

6. *Americanus*: Mediocris rufus, pilis nigris rectis craſſis, facie ephelitica, fronte parvo, oculis nigris, naſo aquilino, naribus patulis, mento ſubimberbi.

Meiners adopts two chief diviſions (haupt-ſtämme), the handſome and the ugly (ſchöne and häſsliche); of which the former is white, the latter dark-coloured (dunkel färbige). The handſome diviſion includes the Celtic, Slavonic, and Oriental people: the latter are the Armenians, Syrians, Arabians, Ægyptians, and others in the north-weſt of Africa, the Georgians, Circaſſians, Perſians, the inhabitants of Hindooſtan, Bucharia, and the neighbouring parts, and a large part of Siberia; under the ugly diviſion come all the reſt of mankind. Grundriſs, chap. ii.

Of J. R. Forſter.—1. Europeans, Aſiatics on the weſt of the Ob, the Caſpian, and the Ganges, Africans of Egypt, Nubia, Ethiopia, Cyrene, Tripoli, Tunis, Algiers, Fez, Morocco, and all the country as far as the river Sanhaga (Senegal?), in ſhort the Caucaſian of Blumenbach.

White, yellowiſh-brown, or even blackiſh colour; long face with well-formed noſe and lips; yellowiſh-white, reddiſh-brown, or black hair, which is long and particularly curled in locks.

2. All the Aſiatics beyond the Ob, the Caſpian and the Ganges; all the Americans from Unalaſchka and Cook's river northwards to the northern icy ocean, and particularly Labrador and Greenland; all the inhabitants of the coaſts in the Molucca, Philippine, weſtern South ſea iſlands, and New Zealand.

Yellowiſh-brown colour nearly univerſal; broad flattened faces with high cheek bones. Narrow opening of the eyelids, and internal angle of the eyes depreſſed towards the noſe (that is ſituated lower down than the external). Hair univerſally black, long, and generally ſmooth and ſtiff.

3. Africans or Negroes, and the inhabitants of the internal parts of various Indian and South ſea iſlands; and all New Holland.

Black with the under part of the face projecting: thick lips, broad flat noſes, and woolly curled hair.

4. Americans, except thoſe in the ſecond variety.

Copper red colour; noſe thin, long and pointed; hair black, ſmooth, and ſtiff.

Of Dumeril.—The firſt family of his claſs of mammalia are the Bimanes, which have theſe characters: Mammiferes

a membres

à membres separés onguiculès; aux trois fortes de dents, et à pouces oppofables aux mains feulement. He adopts the five varieties of Blumenbach, calling the firft Caucafian or European-Arab; and adds a fixth, under the name of Hyperboréenne, which includes the men dwelling near the north pole in Europe, Afia, and America. Zoologie Analytique, p. 7.

The arrangements of fome other authors may be found in Blumenbach de Varietate, fect. iv. § 83; and in Ludwig's Grundrifs, chap. vii.

It would be defirable to inveftigate the original abode of mankind, to afcertain the fituations of the different races from the earlieft authentic accounts, and to follow their migrations until we could trace them to the fituations which they now occupy. To accomplifh any thing fatisfactory on this head, a very exact knowledge of the bodily characters of the races fhould be combined with exact hiftorical information, and an acquaintance with languages, thofe living and unexceptionable teftimonies of the affinities of people. On the former of thefe points, although it might at firft appear that the facts are eafily acceffible, our data are ftill extremely imperfect; and hiftory furnifhes too feeble a light to guide us through the thick darknefs that involves the origins of nations. We feel ourfelves unable to bring forward any thing fufficiently clear and well-grounded to bear with much force on the principal points, which we have endeavoured to illuftrate in this article. A fhort fketch of the fubject is given in Dr. Prichard's Differtation.

Principal Works on the Natural Hiftory of Man.—Buffon's natural hiftory of man; his obfervations on mules, on the degeneration of animals, on wild and domeftic animals, and indeed his natural hiftory in general, contain a fund of moft valuable information.

White, account of the regular gradation in man and animals, &c. London, 4to. 1799.

Man *of the Wood.* See Ourang-outang.

Man, in *Geography*, an ifland fituated in the Irifh fea, at the diftance of 30 nautical miles from St. Bees-head in Cumberland, and 27 from Strangford in Ireland. The latitude of the middle of this ifle is 54° 7′ north, and its whole extent is about thirty miles in length, and ten in breadth. The whole is divided into two diftricts, which are fubdivided into feventeen parifhes. Concerning the etymology and derivation of its name, different opinions have been offered. Bifhop Wilfon fuppofes it to be derived from the Saxon word *mang*, fignifying *among*, in allufion to its pofition, as furrounded by other territories, and this is juftly regarded as a very probable conjecture, its prefent Manks appellation, Manning, ftill retaining the fame meaning. Some other authors affert, that it plainly comes from Mona, a word which they imagine, but without fufficient authority, to have been ufed by Cæfar to denote this ifland. Ptolemy ftyles it Monaeda, or the more remote Mona, to diftinguifh it from Anglefea, the Mona of Tacitus. Pliny calls it Menania, Nennius Eubonia, and Orofius Mevania.

Hiftory.—According to tradition, the original inhabitants of Man were a colony from Britain. The primitive form of government eftablifhed by them was, no doubt, that of the Druids, whofe authority, in thefe diftant times, was acknowledged by almoft all the kingdoms of northern Europe. The inftitutions flowing from the Druidical fyftem, feem to have been preferved here, even fo late as the clofe of the fourth century, when the light of Chriftianity, under the direction of St. Patrick, penetrated the gloom of their umbrageous oaks, and by inducing new opinions, gave birth to new regulations in civil as well as in religious polity. At this period Boetius and other writers affert that the Ifle of Man was celebrated as the "fountain of all pure learning, and the acknowledged refidence of the mufes." Nennius fays that it was held by Buile, a Scot, in the reign of Arcadius and Honorius; but Sacheverel refers his government to a later era. St. Patrick appointed Germanus bifhop and ruler of it, and after his death two other bifhops fucceeded him. St. Maughold, who had been captain of a band of robbers in Ireland, fucceeded them, and from his period the bifhops retained the government, till the coming of a king, called Orry, who continued for fome years lord of Man. In the year 580 Brennus, defcended from the blood-royal of Scotland, obtained the fupreme authority. This prince having led an army to the affiftance of his uncle, loft his life in an action with the enemy, on which event this ifland appears to have been annexed to the Scottifh dominions. About 614 it was conquered by Edwin, king of Northumberland, from whofe reign a blank occurs, even in tradition, till the arrival of a fecond Orry, in the tenth century. This monarch was ſon of a king of Denmark and Norway, who, after reducing the Orcades and Hebrides, fixed his ſeat of government in the Iſle of Man, where he reigned long and proſperouſly, as an independent king. In his reign, the houſe of Keys, which will be more particularly noticed hereafter, was eſtabliſhed, as the conſtitutional parliament of the iſland. Guttred, the ſon of Orry, was diſtinguiſhed as the Numa of his ſmall kingdom, having devoted his whole attention to the civilization and welfare of his ſubjects. Reginald, who ſucceeded, was not leſs noted for his vices, which ultimately occaſioned his aſſaſſination by the brothers of a lady whom he had diſhonoured. Olave, the next prince of Man, unjuſtly ſuffered as a traitor, at the court of the king of Denmark, for having aſſumed the crown without his approbation. Olain, his brother, became his ſucceſſor, and after an equitable reign, left his diadem to his ſon Allen, a tyrannical prince, who was poiſoned. Maccon next took poſſeſſion of the ſovereignty, but having refuſed to pay homage to the Engliſh crown, he was depoſed by Edgar, but was afterwards reinſtated in his former dignity with additional power. The Engliſh monarch is likewiſe ſaid to have appointed him admiral of an immenſe fleet, (amounting, according to Matthew of Weſtminſter, to 4800 ſail, but this number is certainly incredible.) with which he ſailed, twice a year, round the whole Britiſh iſlands, in order to protect their coaſts from the piracies of the Danes and Normans. How long this great man continued to reign is uncertain, but towards the middle of the eleventh century we find Goddard, the ſon of Syrach, upon the throne, whoſe barbarous conduct rendered him extremely abhorrent to his ſubjects. Fingal, his ſon, ſucceeded, who, on the other hand, was greatly beloved for his mildneſs and generoſity. In his reign, Godred Crovan, a Norwegian chief, arrived with a numerous fleet, and though twice defeated, at laſt obtained a deciſive victory, the king and his principal officers being ſlain in the battle. This event occurred in the ſame year in which the conqueſt of England was effected by William of Normandy, and in conſequence the whole iſland ſubmitted to the ſuperior fortune of Godred. During his government the monks greatly diſtinguiſhed themſelves in war. He firſt made a ſucceſsful predatory incurſion into Ireland, and afterwards ſubdued the Hebrides, and ſo effectually kept the Scots in awe by the power of his navy, that, to uſe the metaphorical language of the Ruſhen monks, "they durſt not, when building a ſhip or boat, drive more than three nails into it." Godred had three ſons, the eldeſt of whom, named Lagman, ſucceeded to the throne. Harold, the ſecond ſon, was long in rebellion againſt his brother, but being at laſt taken priſoner, had his eyes put out, and was otherwiſe mutilated.

Lagman afterwards repenting of this cruel conduct, was overwhelmed with ſorrow, renounced his kingdom, and as an expiation of his guilt, made a pilgrimage to Jeruſalem, where he died in 1089. Olave, his youngeſt brother, being yet a minor, the inhabitants of Man ſent a deputation to Murchand O'Brien, king of Ireland, requeſting him to ſend over ſome perſon of royal extraction to govern them till he ſhould come of age. Accordingly this monarch nominated Donald Tade, who governed with ſuch barbarity and extortion, that the indignant natives expelled him from the iſland within three years. The chiefs then elected Macmarus, but that event, notwithſtanding the clemency of his rule, gave birth to a conſpiracy againſt him, and in the battle which it occaſioned, both he, and earl Oughter, the leader of the conſpirators, fell. According to the Manks tradition, the northern men had nearly accompliſhed the victory, when the women of the ſouth ſide flew with ſuch reſolution to the aſſiſtance of their huſbands, as to turn the tide of fortune in their favour. The Chronicon-Manniae, however, aſcribes the victory to the inhabitants of the northern diſtrict. About this time, Magnus, king of Norway, having reſigned his own throne on account of an abſurd ſuperſtition, fitted out an army, with which he made himſelf maſter of the Orcades and Hebrides, as well as of the Iſle of Man, where he landed the day ſucceeding the battle, and received the ſubmiſſion of the Manks without a conteſt. Here he eſtabliſhed his ſeat of government, and after reigning ſix years, made a deſcent upon Ireland, where, having unwarily left his ſhip, he was ſurrounded and ſlain, in the year 1102. During theſe tranſactions, Olave, the ſon of Godred, reſided in great favour at the court of Henry I. of England. Upon the death of Magnus, however, the chiefs of Man immediately diſpatched meſſengers to offer him the crown, which he readily accepted. Aſcending the throne, to the great ſatisfaction of the people, he concluded treaties with all the neighbouring monarchs, and enjoyed profound peace for forty years of his reign. In 1142, however, during the abſence of his ſon Godred, whom he had ſent to Norway to do homage for the crown of Man, the three ſons of his brother Harold landed on the iſland, and demanded one half of his kingdom. Olave, willing to pacify them, promiſed to ſubmit the matter to his council, and appointed a place of meeting for that purpoſe, near Ramſey haven. The king, with his retinue, placed himſelf on one ſide, while his nephews, with their followers, ſeated themſelves on the other. At this moment, Reginald, one of the princes, pretending to ſalute the king, ſuddenly raiſed his ſhining battle axe, and cut off the head of his aged and venerable uncle at one blow. A general ſlaughter of the nobility enſued, and the ſubjugation of the whole iſland, which the three brothers divided among themſelves. In the ſame year they collected a fleet, and landed in Galloway, but were defeated with great ſlaughter. Juſt at this time Godred returned from Norway, and the inhabitants crowding to his ſtandard, the uſurpers deemed it adviſable to ſubmit to his authority, without hazarding a battle. whereupon Reginald was condemned to death, and the other two had their eyes put out. Godred, when he aſcended the throne, was in the bloom of youth and manly intelligence, majeſtic in ſtature, magnanimous in his ſentiments, and heroic in his actions. Theſe qualities uniting with the recollection of his father's virtues, obtained him, not only the love of his own ſubjects, but the eſteem of all the neighbouring nations. In the third year of his reign the fame of his merit induced the chief nobility of the province of Leinſter to elect him their ſovereign. Murchand, king of Ireland, oppoſed his acceſſion, but being defeated, Godred ſeated himſelf on the throne to which the ſuffrages of the people had called him. His abſence, however, excited conſiderable diſcontent in Man, which probably induced him, upon his return, to act ſomewhat in a deſpotic manner towards ſeveral of his nobility. One of them, named Thorfinus, a powerful and ferocious chief, fled to Summerled, thane of Argyle, in Scotland, who had married one of the daughters of Olave, and prevailed upon him to invade the weſtern iſles, then part of the dominions of Godred. Theſe being reduced, he ſailed with a large fleet to attempt the conqueſt of Man, but being met at ſea by his brother in law, alſo at the head of a powerful armament, a dreadful battle enſued, which terminated in a peace, by which Godred retained Man, but ceded the other iſlands to Summerled. This event happened in 1156, but two years ſubſequent, the latter broke the treaty, and invaded Man with a fleet of 53 ſail, defeated Godred, who ſought refuge in Norway, and compelled the whole iſle to ſubmit to his ſovereignty. This ſucceſs ſo puffed up the ambition of Summerled, that he projected

jected the conquest of Scotland, and accordingly made a descent upon Renfrew with that intention, but was defeated in the first engagement, himself and his son being among the number of the slain. About the same time, Reginald, one of the illegitimate sons of Olave, having raised a party, invaded Man, and though opposed with great bravery by the Manks people, succeeded in defeating them by the treachery of one of their generals. His power, however, was but of short duration, for only four days after the commencement of his reign, Godred arrived from Norway with a large army, attacked and took prisoner the usurper, and was hailed by his subjects with the most cordial expressions of attachment. In the residue of this monarch's reign, mention is first made of the pope's influence in Man, his apostolic majesty having sent over from Ireland his legate, Vivian, who compelled the king to re-marry his queen, Phingola, according to the forms of the Romish church. Godred died in 1187, the latter years of his life being spent in perfect tranquillity, and left Olave, his only legitimate son, heir to his kingdom. Reginald, one of his natural sons, however, was appointed king during Olave's minority. This monarch, in 1192, fought a severe battle in the isles with Engus, the son of Sommerled, in which he was defeated with considerable loss. In 1203, he invaded Ireland, but was here unsuccessful also. In 1210, the Isle of Man was plundered by an English earl, named Fulco, during his absence on a visit to his more northern dominions. But notwithstanding these unfavourable circumstances, Reginald was enabled to retain the government, even after Olave, the rightful owner, had attained the years of maturity. But battles ensued, and the latter ultimately ascended the throne, and reigned till his death, which happened in 1237, when his son Harold was fourteen years of age. Having refused to appear at the court of the king of Norway, his territories were invaded by a Norwegian army, under Gospatrick and Gillchrist, who converted the tributes of the country to the service of their own sovereign; but Harold, being at length induced to submit, sailed over to Norway, and, performing the usual homage, was confirmed in the possession of all the islands which his predecessors had enjoyed. On his return home, he entered into treaties with the kings of England and Scotland. To the former he paid a visit, and received from him the honour of knighthood, and other distinguished marks of his royal favour. Soon after he sailed from Norway to espouse the daughter of that monarch, offered to him in marriage by her father, but both he and his princess perished by shipwreck, when on their way back. His brother, Reginald, succeeded, who was slain only a few days after his accession to the throne by Yvar, a knight. Harold, the son of Godred Don, now assumed the title of king, but was soon obliged to surrender his usurped authority to Magnus, the son of Olave, who, as rightful heir, had obtained the sanction of the Norwegian monarch. This prince was the last sovereign of the Norwegian race in Mona. His death happened in 1268. At this period, the king of Norway finding himself unable to afford protection to his distant dominions, agreed to surrender the western islands to Alexander III., king of Scotland, from the dominions of whose ancestors they had been originally wrested by the Norwegian arms. This enterprising monarch soon after extended his authority over the island of Man also, and vested the government in thanes, or lieutenants. These behaving with great oppression towards the inhabitants, so exasperated the Manks, that they formed the resolution of exterminating the Scots, or perishing in the attempt. From this bloody purpose, however, they were restrained by the influence of their bishop, who proposed, in imitation of the warriors of Rome and Alba, that the future fate of their country should be decided by a contest between select combatants. This proposal being eagerly embraced by both parties, thirty heroes were chosen on each side, and a vale was appointed as the scene of the conflict. The two nations covered the opposite mountains in anxious expectation, the one of confirming their conquests, and the other of regaining their former independence. The battle was long and heroically fought, but at length the Scots prevailed, though their thane, and five and twenty of their combatants, paid the forfeit of their lives for the glory of their country. After this period, no attempt seems to have been made by the Manks to regain their liberty, but their island now became the theatre of contests between Scotland and England. William de Montacuto, a descendant of one of the Manks monarchs, having landed here with a body of English troops, forced the Scots to retire to their own country. In the reign of king Edward II. this island was bestowed on Gaveston, who was created earl of Cornwall. In 1340, it was recovered to the Scots by their heroic king, Robert Bruce, and continued in their possession till the earl of Salisbury, under the sanction of Edward III., wrested it again from their authority, and sold it to William Scroop, who was chamberlain to the king. On Henry's gaining possession of the throne, he granted the Isle of Man to the earl of Percy, who afterwards rebelling against his sovereign, had his estates forfeited by an act of attainder, but they were all afterwards restored, with exception of this island, which was bestowed on sir John Stanley and his successors for ever. In his reign, the laws of Man, which had hitherto been concealed in the bosoms of the deemsters, or judges, were first publicly promulgated, and committed to writing. For this purpose, the sovereign convened the entire body of the people at the Fynwald, where he himself attended, invested in all the insignia of royalty. All things being in readiness, the venerable deemsters rose, and, with an audible voice, alternately published to the assembly several laws, which, though more favourable to the monarch than to his subjects, were received with reiterated applause. From this period, the royalties and revenues of Man descended regularly, and without molestation, from ancestor to heir, till the time of William VI., earl of Derby, against whose title some objections were started and legally removed. To put the question beyond doubt, however, a new grant was obtained from James I., which afterwards received the sanction of parliament. It should be observed, that the fifth descendant of this line resigned the title of king, and assumed that of lord of the island, conceiving it to be more honourable to be esteemed a great baron than a petty and dependent monarch. In the time of the civil wars, Man held out for the king till near the close of that unhappy contest, when it was surrendered to the parliamentary forces. It was now granted to lord Fairfax, but upon the accession of Charles II. it was restored to the earl of Derby, son of him who had been beheaded at Bolton. In the same family it continued till the year 1735, when it became the inheritance of James, the second duke of Athol, as grandson of Sophia, youngest sister of that earl.

Before this period, the vast extent of the contraband trade carried on between this island and Great Britain, attracted the serious attention of the government, and an act was passed in 1726, authorising the lord of Man to resign his royalties for a pecuniary compensation; but no sale was effected till the 7th of March, 1765, when John, duke of Athol, resigned all his regal privileges and immunities for the sum of 70,000*l*. An annuity has since been granted by parliament, for the joint lives of himself and his duchess, as an additional

 compensation

compenſation for the loſs he was ſuppoſed to have ſuſtained by this tranſaction, which has, in no ſmall degree, ſecured the revenues of the Britiſh iſlands.

The *conſtitution* and *government* may be partly inferred from the preceding narrative. About the fifth century the government became a deſpotic and feudal monarchy. In the tenth, the foundation was laid for a new dynaſty called the Houſe of Keys, whereby the inhabitants were allowed to chooſe ſixteen repreſentatives, who, with eight from the Iſles, were to form the legiſlature. Theſe repreſentatives were called Taxiaxes, but neither the period of their election, nor the preciſe power with which they were inveſted, can now be aſcertained. It is probable, however, that their privileges were very limited, and that, in reality, they were mere nominal adviſers, all ſubſtantial power being veſted in the perſon of the monarch. Indeed, no mention is made of any interference on the part of this aſſembly in public affairs till the thirteenth century, when the iſland was taken by Alexander, king of Scotland. At this period, however, they appear to have exerciſed the right of enquiring into the exiſting laws and petitioning for new ones, but they poſſeſſed no power of enactment. After the acceſſion of the Stanley family the liberties of the people began to extend, and, in 1430, they obtained the excluſive privilege of electing the members of this aſſembly, who were increaſed to twenty-four in number for the Iſle of Man alone. This dawn of liberty, however, was only of ſhort duration, being deſtroyed by the Houſe of Keys itſelf, which, upon the death of any of its members, proceeded to elect another in his ſtead, in direct oppoſition to the democratic principle upon which the inſtitution was founded. Conſtituted notwithſtanding as it was, this aſſembly proved no inconſiderable check upon the encroachments of the regal authority. In conjunction with the king, his council, and the deemſters, it poſſeſſed the entire legiſlative authority of the iſle. Theſe four eſtates were denominated the *Tynwald Court.* Since the purchaſe of the regalities by the Britiſh government, the power of this court has been conſiderably reſtricted, but it ſtill retains the right of making certain ordinances, provided they agree with the general tenor of the ancient cuſtoms, which form what may be termed the Manks common law. The power of the Keys is judicial as well as legiſlative. Appeals may be made to them from the inferior courts, and in all ſuch caſes, as well as in actions, their deciſion is final, unleſs the cauſe be carried before the king in council. They always determine by a majority, and in their legiſlative capacity they conduct their deliberations in private. Foreigners, as well as natives, are eligible to ſeats in this houſe, the only requiſite qualification being the poſſeſſion of land. A grand court, conſiſting of the whole four eſtates of the iſland, continues to be held every year at the Twynald-Mount, where all new acts are publicly read, and thenceforth become binding on the people, who are ſuppoſed to give them their concurrence. The governor is nominated by the king. He is chancellor *ex officio*, and by himſelf or deputy is empowered to hear appeals from the deciſion of minor tribunals in all civil queſtions, except ſuch as relate to the poſſeſſion of land, which can only be entertained in the Keys. All arreſts, both civil and criminal, are granted in his name, and he can, at pleaſure, convene the different branches of the legiſlature; but there are ſome doubts reſpecting his powers of prorogation. He likewiſe poſſeſſes the prerogative of coining, as the repreſentative of the ancient monarchs: but no money is legal till declared to be ſo by an act of Tynwald.

The council of the governor conſiſts of five perſons, who hold their ſeats *ex officio*. Theſe are the lord biſhop, the water-bailiff, the attorney-general, the clerk of the rolls, and the archdeacon. Several other officers, both of the church and ſtate, have likewiſe claimed this privilege, but their claims have not yet been recognized. The deemſters, of whom there is one for the northern, and another for the ſouthern diſtrict of the iſland, are judges both in common and criminal cauſes. They have each a diſtinct court, anſwering to thoſe diviſions where they preſide, and give judgment without the intervention of a jury. The ſituation of deemſters is of great dignity, and their influence over the people formerly reſembled, in ſome degree, the civil authority of the ancient Druids, whoſe inſtitutions were, in all probability, the original foundations of their authority. In the criminal courts, the uſage obſerved by the Saxons before the conqueſt is ſtill retained. The biſhop, or his deputy, ſits with the governor till ſentence is to be pronounced, when, inſtead of the uſual enquiry of guilty, or not guilty, the deemſters aſk, "Vod ſir charree ſire?" ſignifying, "May the man of the chancel, or he that miniſters at the altar, continue to ſit." If the queſtion is anſwered in the affirmative, the biſhop, or his ſubſtitute, continues ſitting, but if ſentence of death is to be pronounced he riſes and leaves the court.

The other chief civil officers of the iſland, beſides thoſe already noticed, are the lieutenant-governor, who has little power, except in the abſence of the governor; the high-bailiffs, one in each of the four towns, the coroners or ſheriffs, the lock-men or bailiffs, coroner's officers, and the conſtables. The coroner is chief keeper of the peace, and is authorized to arreſt any one who breaks it. He likewiſe ſees that the governor's arreſts are put in execution, has the impannelling of the juries, and the charge of enforcing the ſentences of the courts of law.

Laws.—To give a detailed view of the laws of this iſland, would occupy a greater ſpace than can with propriety be permitted in an article like the preſent. The more prominent features and characteriſtic peculiarities by which they are ſo diſtinguiſhed ſeem, however, to have a more than ordinary claim to a diſtinct and ample expoſition. At an early period, the Manks conſtitution and government being wholly arbitrary, the will of the ſovereign, or of his judges, was probably the only principle which regulated the deciſions of their courts of juſtice. This much at leaſt is certain, that no laws of any deſcription were ever promulgated till towards the middle of the fifteenth century, when the independence of the Houſe of Keys was fully eſtabliſhed. Since that time, juſtice has been adminiſtered, generally, with ſtrict impartiality, either according to the ſtatutory enactments of the Tynwald, or the common law of the country. The laws affecting the lower orders were, ſo late as the year 1777, oppreſſive and tyrannical. They even regulated the amount of the wages of workmen, and ordained that all children not brought up, or put apprentice to any trade, ſhould be ordered into ſervice, except in the event of the parents being old or decrepid. Servants refuſing to work on the legal terms were impriſoned till they gave their compliance, and no perſon who had done a day's work for any compenſation, could leave the iſland before he or ſhe had arrived at the age of twenty-five years. On the ſubject of marriage, the laws were nearly ſilent till the year 1757, ſo that perſons of any age or condition might marry without either licence or the publication of banns. Since that time, however, the marriage regulations have been, in ſome reſpects, ſimilar to thoſe of England, but, in others, they are yet eſſentially different. The ceremony is according to the forms preſcribed by the Proteſtant church, but no perſon without a ſpecial licence from the ordinary can enter the ſtate of wedlock till he has received the ſacrament. By the Manks law, the huſband and wife are not ſo completely united into one perſon as they are by the Engliſh. Marriage is, indeed, regarded as a ſpecies of partnerſhip, but it does not give an excluſive title to eſtates, either real or perſonal. In fact, the landed property of each always remains diſtinct, but the parties poſſeſs every thing elſe in common, with this difference, that the huſband may bequeath his poſſeſſions to whom he pleaſes; but ſince the act paſſed in 1777, the wife can only leave her's to the children of the exiſting union. In caſe of either being found guilty of treaſon or felony, only the criminal's ſhare is liable to forfeiture. Fathers are obliged to maintain their children till they reach the age of fourteen, when all legal obligation between them ceaſes. A child may then claim any legacy, and depart, if he is ſo inclined; but if he remains, his father is entitled to the intereſt or uſe of his money as a compenſation for his maintenance. Upon the death of the huſband without a will, the widow enters upon her ſhare of the property only, but in the event of the woman's demiſe inteſtate, the huſband enters upon the whole. Where there is only one child, and the father neglects to appoint a guardian, his kindred are entitled to the cuſtody of it; but if there are two children, the mother takes care of the eldeſt, and the ſecond is taken care of, as an only one would be. A child, though a baſtard at the time of its birth, becomes legitimate by the marriage of the parents within three years after that period. At the deceaſe of his father the eldeſt ſon ſucceeds to his heritable property, and if there are no ſons, the eldeſt daughter, even though the eſtates are entailed. The origin of this cuſtom, ſo different from the practice in other feudal countries, is attributed to the bravery of the ſouthern women in aſſiſting their huſbands in a great battle, and enabling them to gain the victory.

All the lands of this iſland at an early period belonged to the lord or ſovereign: even ſo lately as the ſixteenth century, real property could not be alienated on any pretence without his ſpecial conſent, or that of his three principal officers. The occupants were ſtyled the lord's tenants, and were ſubject to the payment of a fine or rental. Attempts were made about the middle of the ſeventeenth century to render all the tenures leaſehold, either for three lives, or for twenty-one years. This produced a warm diſpute between the ſovereign and the land-holders, which was not terminated till the year 1703, when it was agreed that the latter ſhould retain their poſſeſſion ſo long as they continued to pay the fines and rentals ſettled between them and the earls of Derby's commiſſioners after the year 1643. The period of a leaſe is reſtricted to twenty-five years, and a mortgage, not redeemed within five years, renders the parties liable to the fine of alienation.

The whole iſland was formerly divided into ſix hundred portions, called quarter-lands, but Feltham ſays, their number is now increaſed to ſeven hundred and fifty. All other eſtates are either allotments out of, or encroachments upon, theſe. The titles to property are, as may be ſuppoſed, various and ſimilar in their nature, though ſometimes different in their limitations, to thoſe acknowledged by the laws of England. Unmoleſted poſſeſſion for ten years, till very lately, conſtituted a ſufficient right to any ſpecies of property; but the term is now extended to twenty-one years. Every proprietor poſſeſſes the privilege of feeding a certain number of cattle upon the commons, which abound in various parts of the iſle, and every inhabitant has the privilege of quarrying ſtone and digging peat for his own uſe. All wrecks not claimed within a year and a day, and all mines, belong to the lord by his prerogative. Game, likewiſe, was anciently his property. Goods taken in diſtreſs, or execution, muſt remain one month as a pawn, redeemable by the tenant, or defendant, on paying of the rent, or of money recovered in an action at law.

But the moſt marked peculiarity in the Manks law is, that no arreſt can be granted againſt a landed proprietor or native, to impriſon or hold him to bail in a civil action, unleſs there appears ſome juſt cauſe to conclude that he intends leaving the iſland without making ſatisfaction to his creditors. Such perſons as are proſecuted for a foreign debt can only be obliged to find bail for his perſonal appearance, and for the forthcoming of all his property on the iſland, except his clothes and money, which remain his own. It is from the operation of this latter law that the unfortunate, and too often the fraudulent alſo, find an aſylum here from the proſecution of their creditors. By converting the reſidue of the property into money, they are enabled to reſide on this iſland in comfort, and without the danger of legal moleſtation. If, however, there is any thing clearly ſhewn to be ſo criminal in the conduct of any individual as to infer the pains of law, the governor generally grants a warrant for delivering him over to the juſtice of the country to which he belongs.

By the laws relative to public wrongs, here no offender can be convicted of any capital crime, except by a jury at the court of general gaol delivery. Formerly, indeed, a perſon who made an attack upon the lord, or his lieutenant, could be condemned immediately, without any form of trial, but the practice has been long obſolete. This offence was deemed treaſon; ſo likewiſe was the ſtriking of any of the lord's ſervants in his preſence, robbing him in court, conſtraining him to hold a Tynwald court, relieving or concealing a rebel, counterfeiting the current coin of the iſland, and bringing in any falſe money and making payment with it. Thus, even copper coinage is treaſon, contrary to the law of England, which confines it to the counterfeiting of gold and ſilver money.

For bigamy, or polygamy, there is no puniſhment by the Manks law, even at the preſent day; but the ſecond marriage, being illegal, is null and void, and the children are, conſequently, regarded as baſtards, and deprived of their rights to inherit the property of their parents. Suicide is puniſhed by forfeiture. In the event of a rape on a married woman, there is no alternative but death; but if the woman is unmarried, ſhe has her choice to hang, behead, or marry the offender. What is remarkable, there is no inſtance of a conviction for this crime upon record, and only one traditionary, and in that caſe the lady is ſaid to have adopted the laſt condition, juſt at the moment when her raviſher was about to be launched into eternity. Aſſault and battery are puniſhed by fine and impriſonment, according to the deciſion of the governor or deemſter, without the intervention of a jury. It is felonious to enter a houſe with burglarious intention, even though it ſhould be without a door, provided two ſticks are placed acroſs the entrance. Forging is not accounted criminal, at leaſt the offence is only regarded by the law as a civil debt. Theft, above the value of ſixpence-halfpenny, is capital. Below that value the crime is termed petty larceny, and ſubjects the offender to corporal puniſhment and impriſonment at the diſcretion of the court. To convict for felony one reſpectable witneſs is now ſufficient, if his evidence is ſupported by probable circumſtances.

Religion.—The eſtabliſhed religion of Man is the ſame with that of England. Toleration, however, having extended its beneficial influence here, as in other parts of the Britiſh empire, Diſſenters of almoſt every denomination are prevalent. Among theſe the moſt numerous ſect is undoubtedly the

the Methodifts, who form at leaft one-tenth of the whole population. The eftablifhment is placed under the direction of a bifhop, affifted by an archdeacon, two vicars-general, and an epifcopal regiftrar. The patronage of the fee ftill continues in the Athol family, but the nomination of the fuperior clergy muft be approved of by his majefty. The bifhop is confecrated by the archbifhop of York as metropolitan of the diocefe, and enjoys all the privileges and fpiritual rights of other bifhops; but his fee not being baronial, he is not entitled to vote in the houfe of lords. He has, however, a feat, as Mr. Wood fuppofes, by courtefy, above the bar. The firft bifhop of Man was St. Germain, to whom the cathedral church is dedicated. At that time the diocefe was limited to the boundaries of the ifland, nor did it extend beyond them till the conqueft of the weftern ifles by the Norwegians, about the commencement of the twelfth century. When the *infulæ Sodorenfes*, fo called from the bifhopric of Sodor, a fmall village in Iona, and once "the metropolis of learning and piety," were united to it; the whole formed one bifhopric, ftyled Sodor and Man. The metropolitan at that period was the archbifhop of Drontheim. After the annexation of the ifland to the crown of England, the conjoined bifhoprics were feparated.

Surface and Rivers.—The general afpect of this ifland prefents confiderable diverfity of hill and dale. A chain of mountains, moderately high, divides it nearly into two equal portions, in a direction from N.E. to S.W. This range is broken only at one place, between mount Kreevey and South Barrule. The moft confpicuous fummit of the whole is Snawfel, the height of which, as taken by the barometer, appeared to be 580 yards above the level of the fea. The two Barrules, which form its northern and fouthern extremities, are nearly of the fame elevation. Between North Barrule and mount Kreevey arife feveral rivers, which empty themfelves into the fea at Ramfey, at Laxey, and at Douglas. Of thefe rivers, that of Ramfey is by far the largeft, being fo much influenced by the tide, from the level nature of the diftrict through which it flows, that it is navigable for veffels of confiderable burthen at the diftance of more than two miles from its mouth. The other rivers in the ifland are very fhallow and inconfiderable ftreams. Here is a great deficiency of wood.

Soil and Climate.—The foil of this ifland is various. Towards the fouth parts the greater proportion is loam, but ftiff clays likewife abound, and in fome fpots the furface exhibits a fine light fand. The northern diftrict confifts principally of a fandy loam, with a bottom of clay or marle. Here is an immenfe tract of land called the *Curraugh*, extending nearly acrofs the whole ifland, from Ballaugh to Ramfey, which was formerly a bog, but is now drained and produces excellent grafs crops. In a few places of this tract is a remarkable layer of peat, which ftretches itfelf feveral miles under a ftratum of gravel, or earth. The thicknefs of the layer varies from two to three feet, and that of the gravel, &c. from two to four feet. In other parts of the fame tract the peat has been removed to the depth of ten feet. The climate is generally reckoned milder in winter than that either of England or Ireland in the fame latitude, as, from the proximity of every part of the ifle to the fea, froft and fnow are feldom of long continuance. The fummers, however, are lefs warm, and gales of wind and falls of rain, during this period, are extremely frequent, often occafioning very confiderable damage, not only to the fruit, but alfo to the grain-crops.

The mineralogy of the Ifle of Man offers very few objects of intereft or importance. More than two-thirds of the whole furface refts on ftrata of wacke-flate, or clay-flate. The hills, called North and South Barrule, are compofed of mica-flate, covered with clay-flate; Mount Kreevey confifts of the fame materials, traverfed by many large veins of quartz, two or three feet in thicknefs. On the north fide of South Barrule appear fome blocks of granite, containing a quantity of filvery mica, reddifh feldfpar, and grey quartz. In the neighbourhood of Caftletown is found a blueifh-grey lime-ftone, intermixed with impreffions of fhells and other marine exuviæ, and interfected by fmall veins of calcareous fpar. This lime-ftone lies above a ftratum of wacke flate, from which it is feparated at fome points by a thin layer of white clay, which does not in the flighteft degree effervefce with acids. Near Pool-vafh-bay this mineral becomes fo highly indurated, that it is quarried below high-water mark, as a tolerable good marble for tomb-ftones. Not far from Langefs a fmall quantity of compact brown iron-ftone is found, lying under a breccia compofed of pieces of quartz in a filiceous bafe, and bearing fome refemblance to horn porphyry. The Calf of Man, which is feparated about 100 yards from the main, confifts entirely of a gloffy blueifh-grey clay-flate, lying more inclined to the eaft, and more unequally ftratified than the flate-rock on the oppofite fhore. At Kirk Arbovy are fhafts of lead-mines now entirely deferted. Breda-head copper-mine is chiefly the fulphuret of that metal. The mines of Foxdale, celebrated for their fine lead-glance, are now entirely drowned by the tide; fo that the only mines at prefent wrought on the ifland are thofe of Laxey, which produce a very confiderable quantity of lead and copper, both of excellent quality. Cryftals of iron pyrites are occafionally found in different places.

From thefe few facts the geologift will perceive that this ifland confifts partly of primitive clay-flate and mica-flate, refting probably upon granite; of grey wacke-flate, and of lime-ftone which feems to belong to the rocks of tranfition of the Wernerian geognofy; of fand-ftone of the earlieft formation, and of fand refting upon clay.

The agriculture of this ifland, though much improved of late years, ftill continues at a very low ebb. More than a third of the whole furface lies in an uncultivated ftate, and entirely appropriated to the feeding either of fheep or cattle. The value of land in this condition varies from five to ten fhillings *per* acre; but arable land often rifes above two pounds. The enclofures are formed in general of embankments of earth, unaccountably crooked and irregular, and containing from four to ten acres. Barley conftitutes the chief grain raifed by the farmers, as the foil and climate are thought to agree better with its growth than with that of any other corn. Potatoes and turnips are likewife cultivated in great abundance. Crops of flax are very common in every part of the ifland; almoft every cottager growing a fmall quantity, both for home ufe and exportation. Hemp is fown in gardens, and on rich enclofures, but very rarely in the open fields. The plough in common ufe is of a light conftruction, and generally procured either from England or Scotland. Owing to the fmall fize of the horfes, four are requifite to turn a furrow four inches deep. The Manks harrow and roller are generally of a good make, though light; but with refpect to wheel-carriages, a total ignorance of their proper conftruction prevails. Cart-wheels are invariably very narrow and fmall. Drilling and hoeing machines are little ufed.

The native fheep of the ifland are fmall and hardy, bearing a refemblance to the South Down: when properly fed, their meat is of the moft delicious kind. This is ftill called the mountain breed, being reared entirely on the hills and uplands; but in the lowlands a larger fpecies has been introduced.

troduced. Besides these there is a third breed, called the Laughton, which affords very fine wool of a dark buff colour, much used by the inhabitants in making stockings. Many hundred head of cattle are fattened annually for exportation; and pigs and poultry are reared in great abundance, as are also geese and ducks; but turkies are rather scarce. The manure chiefly used by the farmers is farm-yard dung, or, if near the shore, sea-weed. A regular rotation of crops is little understood or practised, and summer fallowing scarcely ever occurs. The indolent disposition of the men, (for the women are lively and active,) joined to the attractions of the herring fisheries, and the operation of the tithe system, are radical obstacles here to agricultural improvement, which even the Cumberland Society, lately extended to this island, will find it difficult to remove. Intimately connected with this subject is the state of the

Roads and buildings, both of which have of late been greatly improved. Forty years ago, the former were dangerous for carriages even in summer, but at present they are very good during that period; though, owing to the clayey nature of their composition, they sometimes become impassable for several days in winter. Houses of the best sort, both in town and country, are constructed of hewn stone; and those of an inferior description of rough stone. Farm-houses and offices are usually small, irregular, and ill built: a few modern ones, however, are on a better plan. The meaner cottages consist principally of sods of earth, with a thatch of straw. The bridges are mostly in tolerable condition, being built and supported at the expence of the public, and requiring an act of Tynwald to authorise their erection.

Towns and Villages.—This island possesses a number of small towns and villages, situated principally on the coasts. The chief of these are Castleton, Douglas, Peel, and Ramsey. Castleton is considered as the capital, being the residence of the governor, and the seat of the superior courts; but Douglas is of more importance in a commercial point of view. In the centre of Castleton is Castle-Rushen, an irregular fortified building of stone, said to have been erected in the year 960, by the Danish prince Guthred, who was buried within its walls. The stone glacis, which surrounds it, is supposed to have been the work of cardinal Wolsey. This fabric was the ancient mansion of the kings of Man, where they lived in all the warlike pomp of feodal magnificence. Douglas, only a century ago, was merely a group of huts; but it is now the most opulent and best built town on the island. The duke of Athol's principal residence is situated in this vicinity. Ramsey is a neat town, where the deemster of the northern district resides, and holds his courts. Peel is likewise a pleasant village, and more distinguished, than any other spot in Man, for its remains of antiquity. Peel castle, placed on a small island, divided from the main by a narrow channel, deep during the flow of the tide, but easily fordable at its ebb, is a very noble remnant of ancient architecture. Near it are the ruins of two churches: one dedicated to St Patrick, of uncertain origin; and the other called St. Germain's, or the cathedral, which was constructed about the year 1245.

Commerce and Manufactures.—None of the mechanical arts having yet reached any degree of perfection in Man, its manufactures are few, and of little value. Indeed, the only ones worthy of observation are those of Douglas, where sheeting, towelling, sail-cloth, and sack-cloth are made. In commercial concerns, however, it is of more importance, great quantities of lead, cattle, sheep, fowls, butter, and eggs, being shipped from hence to England. Some strong linens and sail-cloth likewise form articles of export, but the chief source of opulence here, as in Shetland, is the herring fisheries; for the smuggling traffic, which proved so advantageous in former times, is now almost entirely cut up. About five hundred boats are regularly employed in the fisheries every season, beginning with July, and ending with September. A few years ago it was customary for the fishermen to offer up a prayer for success on leaving the harbour, but that practice has fallen into disuse. As yet, however, they make it a rule never to sail either on a Saturday or Sunday evening, lest the sabbath should be violated. The ordinary size of the boats is about eight tons, and their value, including the nets, &c. somewhat more than 80*l.* Every night's produce is divided into nine shares, of which two belong to the proprietors of the vessels, one to the owners of the nets, and the residue to the fishermen. Of the white herrings, the greater proportion are sold in England, but most of those termed red herrings are exported to the different ports of the Mediterranean. Previous to the commencement of the late war, a salmon-fishery was established here upon an extensive scale, but since that period it has much declined. The imports to the island consist of manufactured goods of almost every description, together with coal, wine, brandy, and other spirituous liquors: the balance of trade is greatly against the island. The deficiency, however, may probably be made up by remittances to the numerous strangers, who, in order to avoid the visits of a bailiff, or the extravagance of English living, resort hither either as a temporary or permanent retreat.

Antiquities.—The Isle of Man contains considerable vestiges of ancient times. The little Isle of St. Michael is joined to the Main, at Longness-point, by a high breast-work, about one hundred yards in length, and on the Isle itself are the ruins of a circular fort, built by one of the earls of Derby. On the road from Castle-town to Douglas, at the distance of two miles from the former, stand the venerable remains of Rushen-abbey, founded in the year 1098 by prince Macmarus. This establishment consisted of an abbot and twelve monks of the Cistercian order, who were so celebrated for their hospitality, as to acquire the title of almoners of the poor. The abbot, in later times, became a baron of the island, and was invested with the power of holding courts in his own name. Many of the kings of Man were interred in this monastery. Not far from Douglas appear the remains of another monastery for female votaries, said to owe its original foundation to St. Bridget, in the sixth century. The prioress of this institution was likewise a baroness of Man, and held courts in her own name. Immediately adjoining to Laxey, on an elevated scite by the road-side, is a small circular range of stones, some of them standing erect, and others leaning towards the centre, which has apparently formed a *kist-vaen*, but is now mutilated. This monument bears the name of the *Cloven-stones*. The parish of Kirk-Andreas, north of Ramsey, is particularly distinguished by a variety of ancient remains. The entrenchment at Ballachury, situated on a small natural eminence, is in more complete preservation than, perhaps, any other erection of the same kind in the British dominions. It is of a square form, and has a very noble bastion at each angle; the whole surrounded by a wet foss of ample dimensions. Many barrows are to be met with in this neighbourhood, some of which have been opened, and earthen urns discovered in them. In the parish church stands a square stone pillar, with a Runic inscription, thus translated by Mr. Beaufort. "The son of Ulf of the Swedri (or Swedes) erected this cross to the warrior Afterarin, the son of Cunnu." Many other Runic inscriptions and tumuli appear in various parts of the island; indeed, they are probably more numerous here than in any other diftrict of a fimilar extent in Europe. The Tynwald is the only object that now remains to be mentioned. It is fituated about three miles from Peel, near the fide of the high-road leading to Douglas. The name of this artificial mount is compounded of the Britifh words Tyng and Val, fignifying the juridical hill. This monument of ancient days is in the form of an obtruncated cone, divided into three ftages or circles, regularly advanced three feet above each other, but proportionally diminifhed, both in circuit and width, the nearer they approach the fummit. The whole was formerly furrounded by a ditch and rampart of earth, inclofing a fpace, on which ftood a fmall chapel dedicated to St. John, lately re-built. Concerning the firft erection of this mount nothing is known, either from hiftory or tradition; but judging from its name and appropriation, it would feem to have been conftructed by the aboriginal inhabitants of the ifland.

Population, and Means of Defence.—The number of inhabitants in this ifland has varied much at different periods. In the time of Bede, it is faid by that author to have contained only 300 families. Hollinfhed, who wrote about the year 1584, obferves, "there were formerly in this ifland 1300 families, but now fcarcely half that number." In 1726, the population was 14,511; in 1757, it had increafed to 19,144; and, in 1792, to 27,913. At prefent it is thought to exceed 30,000 perfons, an increafe partly owing to the improved ftate of agriculture, and partly to the greater number of ftrangers who now take up their abode in this land of freedom from taxes and arrefts. The military eftablifhment of the ifland confifts folely of a regiment of fencibles, who are enlifted voluntarily, and receive a bounty of three guineas. Their pay is the fame as that of Englifh regiments, and the fervice being eafy, moft of the individuals which compofe them are engaged in fome trade or bufinefs, for here military duty is not reckoned incompatible with the purfuits of civil life.

Language, Manners, and Cuftoms.—From the number of ftrangers continually flocking to this ifland from Great Britain and Ireland, and the commercial intercourfe that fubfifts between them, it may reafonably be fuppofed that the Englifh language is ufually fpoken in the towns on the fea-coaft. In the interior, however, the original Manks language ftill prevails. This laft is merely a dialect of the Gaelic, or that ufed in the Highlands of Scotland, with a commixture of Welfh, Saxon, and Danifh words. The radixes, indeed, are chiefly Welfh. The New Teftament, and feveral fcriptural publications, have been tranflated into the Manks tongue; and in the country parifhes it is cuftomary to preach in this language and in Englifh every alternate Sunday.

With refpect to the character of the people in this ifland, it is generally obferved that the men are habitually of a lazy and indolent difpofition. This is not improbably the confequence of the herring-fifheries, in which the greater part of them are engaged; for fuch purfuits, in certain conditions of fociety, are, beyond doubt, prejudicial to the more active concerns of agriculture and the arts. In fine, wherever fifheries are eftablifhed upon a fcale fufficiently extenfive to afford employment to the men, the affairs of the field are left to the women in a great meafure; and this is precifely the cafe in Man, the females being both the reapers and threfhers of all the corn in the ifland. Hence it happens, that the women are as remarkable for their activity and fprightlinefs, as the men are for their indolence. Unfortunately, however, an extreme laxity of opinion prevails among them in refpect to chaftity. A fervant girl, by becoming a mother, does not fuffer any degradation of character. The event is, therefore, of no unfrequent occurrence, and is probably the reafon why women of the town are fcarcely ever to be met with, even in Douglas. Like the Highlanders and Swifs, the Manks are much attached to their native vales and mountains, as well as to their ancient cuftoms and laws. They conceive themfelves to be independent of Great Britain, and were much affected by the fale of the ifland, becaufe they feared it would blend the countries. A great fondnefs for litigation, and an uncommon love of hofpitality, are ftriking, though fomewhat contradictory, features, in the Manks character. So much, indeed, are they naturally difpofed to charity, that poor's rates are wholly unknown, and there is no fuch inftitution as an hofpital, or workhoufe, in the whole ifland. Every parifh, however, has a charity-fchool, and generally a fmall library, both of them fupported by voluntary contributions, or funds arifing from legacies or donations. Neither fhoes nor ftockings are worn by the lower orders, excepting on particular occafions. A blue cloak is the common body-drefs of the women, and ftrangers are ufually habited in a failor's jacket, and trowfers of the fame colour. This drefs is termed the Manks livery. The belief of fairies, and fuch imaginary fpirits, ftill firmly maintains its influence over the inhabitants of this ifland; a circumftance afcribed by many to the natural gloom and folitude which pervades every portion of the country. Thefe airy fpirits are divided, by fuch as pretend to fkill in vifionary lore, into two claffes, the one comprehending the playful and benignant fprites, and the other the fullen and vindictive ones. The former, gay and beautiful, feek the margin of the brooks to fport among the bufhes, or dance on the tops of the adjacent mountains, while the latter find a habitation in the hideous precipices of the fea-fhore, and to their malignant influence the Manksman imputes every calamity which may affail him. A belief in the fecond fight, and in warnings and fore-knowledge of their own deaths, is no lefs common than this fairy fuperftition. Many, in their lonely wanderings, have met with a vifionary funeral, following them wherever they might turn, awfully portentous of the approaching diffolution of the devoted victim. Thefe opinions are not confined to the lower orders alone, but are credited by individuals even of high refpectability. In other refpects, however, the fuperior claffes differ completely from their fellow iflanders, and affimilate themfelves as much as poffible, both in drefs, habits, and fentiments, to the fame orders in England. An Account of the paft and prefent State of the Ifle of Man, by George Woods, 8vo. 1811. A Tour though the Ifland of Man in 1797 and 1798, by John Feltham, 8vo. 1798. A Journal kept in the Ifland of Man by Richard Townley, efq. 2 vols. 8vo. 1791.

Man is alfo an ifland in the Pacific ocean, in St. George's channel, between New Britain and New Ireland, about 50 miles in circumference; difcovered by captain Carteret in the year 1767. S. lat. 4°. E. long. 151° 25'.—Alfo, a town of Hindooftan, in the Carnatic; 11 miles W. of Tricolore.

Man *at Arms*, in *Ancient Military Language*, derived the appellation from being completely armed de cap-à-pied, or from head to foot. The men at arms formed a part of the cavalry of our ancient Englifh armies foon after the conqueft, which confifted of knights, or men at arms and hobilers; as the infantry was compofed of fpear and bill men, crofs-bow men, and archers. However, in garrifons the men at arms occafionally ferved on foot. Thefe men at arms were chiefly compofed of the tenants in capite, holding by military fervice, or their fubftitutes, fometimes called fervientes. The defenfive armour of a man at arms was a hauberk of double mail, compofed of ringlets of iron linked together

together like a net, which covered the body, and to it were joined a hood, breeches, ſtockings, and ſabatons or ſhoes of the ſame conſtruction: the hands and arms were alſo defended by gauntlets and ſleeves of mail; the hauberk was the proper armour of a knight; an eſquire might wear a ſhirt of mail over his gambeſon, but might not uſe the hood, breeches, hoſe, nor ſleeves of mail. Sometimes, but not commonly, men at arms wore habergeons made of plate mail, formed of ſmall round plates of iron, laid one over the other like ſcales of fiſh. Sometimes over the hauberk, but commonly under it, was worn a looſe garment called the *gambeſon* (which ſee), deſcending to the knees, ſtuffed with wool or cotton, and deſigned for deadening the ſtrokes of the ſword or lance, which, though they might not divide the mail, would ſeverely bruiſe the body without the interpoſition of the gambeſon. Under or between the hauberk and gambeſon, a breaſt-plate of forged iron, called a plaſtron, was occaſionally put on; over which all men of family wore ſurcoats of ſatin, velvet, or cloth of gold or ſilver, richly embroidered with their armorial bearings. By a ſtrap hung over the neck, the men at arms carried a ſhield made of wood, covered with leather, bound or ſtrengthened with iron or braſs, having handles on the inſide for *braſing* it, which was the term then in uſe for putting it over the left arm, Fr. *bras*. Theſe ſhields were for at leaſt a century after the conqueſt of a triangular form, pointed at the bottom, and a little convex in the direction of their breadth. The helmets worn by the men at arms were of different forms; ſome conical or pyramidical, with a ſmall projection, called a "naſal," to defend the face from a tranſverſe ſtroke; ſome cylindrical, covering the whole head down below the chin, with apertures for ſight and breath; and others in which the face was totally uncovered. Helmets with bevers and vizors do not ſeem to have been in uſe till the middle of the fourteenth century, about which time the hauberk was exchanged by many of our men at arms for plate-armour, ſo called from being formed of plates of iron. On the creſts of their helmets' kings frequently wore their crowns, earls and dukes their coronets, generals or other officers of rank either their armorial cogniſances, or any other device at pleaſure. This was done to give them a more terrific aſpect to their enemies, and to render them conſpicuous to their own officers and ſoldiers. To the above liſt of defenſive armour we may add the war-ſaddle, whoſe arcon of bows of ſteel covered the rider as high as the navel. The knights of the three or four reigns next ſucceeding the conqueſt, commonly wore the pryck ſpur, which had only a ſingle point, after which the rouelle, or wheel ſpur, came in faſhion, ſome of which rouelles were ſix inches in diameter. Thus enveloped and loaded with incumbrances, we need not wonder, that in the heat of ſummer, and duſt, and preſſure of an engagement, men at arms ſhould be ſuffocated in their armour.

The offenſive arms of a horſeman, or man at arms, were a ſword or ſwords, a lance, and a ſmall dagger, called a "Miſericorde" (which ſee), and alſo iron maces ſuſpended at their ſaddle-bow. The horſes of the men at arms were no leſs encumbered than their riders; their faces, heads, and ears, were covered over with a ſort of maſk, ſo contrived that they could not ſee right before them and be terrified. This maſk was called a "chafron," or ſhafront. Beſides other appendages, which it is needleſs to enumerate in detail, they were occaſionally covered all over with mail, or linen ſtuffed and quilted like the gambeſon, and adorned with rich embroidery. Horſes, thus covered, were called "barded," and corruptly barbed horſes. Theſe war-horſes, for preventing their being fatigued, were not mounted till the men at arms were certain of coming to action, and they had commonly hackneys for riding on a march. Barded horſes were in uſe in our armies at the time of king Edward VI. When plate-armour came into general uſe, about the middle of the fourteenth century, the accoutrements of the men at arms were a cloſe helmet, with a viſor, or viſor and beaver revolving on the ſame pivot, and capable of being lifted up or let down. The neck and throat were defended by a gorget, or hallercet, the body by a cuiraſs, the arms by braſſarts, the hands by gauntlets, the ſhoulders by poultrons, the thighs by cuiſſarts, and the legs by iron boots, called greaves, and ſometimes by boots of jacked leather. Under all theſe was worn a jacket of thick fuſtian, or buff leather. About the time of queen Mary the appellation of men at arms, ſignifying the heavy-armed cavalry, ſeems to have been changed to that of ſpears and lances, and afterwards to cuiraſſiers. The armour of a lancier was much the ſame as that we have deſcribed: their offenſive weapons were a *lance* (which ſee), of ſixteen or eighteen feet in length, a ſword, and petrenels, which laſt were ſomewhat longer than the piſtols then in uſe.

The hobilers (ſee Hobler) were a ſpecies of light horſemen, chiefly calculated for the purpoſes of reconnoitring, carrying intelligence, haraſſing troops on a march, intercepting convoys, and purſuing a routed army: their horſes were ſmall and unable to reſiſt the ſhock of a charge. Some derive the appellation from a Daniſh word, ſignifying a mare; but this is not likely, as the men at arms were chiefly mounted on ſtone-horſes, and in the days of chivalry it was conſidered a degradation for any knight or man at arms to be ſeen mounted on a mare. This name was more probably derived from the hobbies or ſmall horſes which they rode. The eſtabliſhment of hobilers has been commonly, but erroneouſly, referred to the reign of Edward III.; but they are mentioned as part of the Britiſh army that attended king Edward II. into Scotland, in the year 1322. The name ſeems to have been totally loſt about the latter end of the reign of Henry VIII. or queen Mary; theſe troops being then diſtinguiſhed by the appellation of demy-launces and light horſe. The arms and appointments of a hobiler, as directed by king Edward III., were a horſe, a hagueton or armour of plate, a bacinet, iron gauntlets, a ſword, knife and a lance. Sometimes archers were mounted on light horſes, whence they were ſtyled hobiler-archers. Groſe's Mil. Antiq. vol. i.

Man, in the *Materia Medica of the Ancients*, a name by which manna has been called by the oldeſt writers. There has been, however, ſome confuſion in the hiſtory of manna, owing to the too general uſe of this word, the ſame authors uſing it as the name of ſeveral other ſubſtances of very different kinds, which came to their hand in forms of ſmall granules, or flakes like the manna. The fragments of frankincenſe, in particular, were called by this name, with the addition of the word *thuris*, and ſometimes without man or men ſtanding ſingly for that drug.

Man, in *Mythology*, the name of a deity among the ancient Germans; whom they ſuppoſed to be the ſon of Tuiſton, and celebrated with ſongs, as the founder of their nation: and to him they conſecrated their groves and foreſts.

Man *the Capſtan*, on board a *Ship*. See Capstan.

Man *the Side*, or *Ladder*, is when an officer or any perſon of diſtinction is at the ſhip's ſide ready to come aboard, the men are commanded to wait, and help him up the ſide.

Man *the Top*, or *Yard*, a word of command for the men to go up to the top, or yard, for ſome particular ſervice.

Man *of War*, the ſame with a ſhip of war. See Ship and Rate.

MAN *of War Key* in *Geography*, a ſmall iſland among the Bahamas. N. lat. 26° 20'. W. long. 77° 15'.

MAN *of War Keys*, ſmall iſlands and rocks in the Spaniſh main, near the Moſquito ſhore. N. lat. 12° 55'. W. long. 88° 35'.— Alſo, ſmall iſlands at the entrance of Weſt harbour on the S. coaſt of the iſland of Jamaica.

MANA, a town of Peru, in the dioceſe of La Plata; 15 miles S. of Potoſi.

MANAA, in the *Jewiſh Cuſtoms*, a kind of offerings made in the temple, otherwiſe called Mincha. The word manaa is uſed in the Septuagint.

MANAAR, or MANARA, in *Geography*, a ſmall iſland, the name of which is derived from the Malabar words *man*, ſend, and *aar*, river, lying off the coaſt of Ceylon, about 60 miles S.W. of Jafnapatam. Manaar was formerly more flouriſhing than it is at preſent. The fort was ſmall, but ſtrong, ſquare, and regular. The city now conſiſts of only a few tiled houſes, government offices, and ſome low huts, inhabited by boatmen and fiſhermen. At low water the iſland of Manaar is ſeparated from Ceylon by a ſmall winding river; but when the tide flows, this river appears as an arm of the ſea, and is about three miles over. It is called the "gulf of Manaar." Manaar lies in N. lat. 9°, and is about 2½ German leagues in length, and one in breadth, including a ſalt river. The fort is ſituated near the channel or ſtrait which divides Manaar from Ceylon. There are beſides ſeven villages in the iſland. At the extreme end, where boat is taken for the coaſt of Coromandel, there are four or five churches for the natives and Malabar Chriſtians, beſides that of Carcal uſed by the Dutch. The iſland is barren and ſandy, with a few palmiras and cocoa-trees ſcattered here and there. The ſurrounding ſea ſupplies abundance of fiſh. The paſſage from this iſland to Ramiſeram, on the Coromandel coaſt, is not above 12 or 14 leagues, but the paſſage is interrupted by innumerable ſhallows and ſand-banks, many of which are high and completely dry, except during the monſoons. Adam's bridge, or Ramas bridge, is formed by a line of ſand-banks, which runs quite acroſs from Manaar to Ramiſeram. (See ADAM'S *Bridge*.) It is an univerſal opinion among the natives, that Ceylon was either the Paradiſe, in which the anceſtor of the human race reſided, or the ſpot on which he firſt touched on being expelled from the celeſtial paradiſe. Adam's bridge was, as they conceive, the way by which he paſſed over to the continent; and ſome of them imagine, that the gulf of Manaar, like the Red ſea in ſcripture hiſtory, cloſed after him to prevent his return. It is, however, univerſally believed, that Ceylon, at a diſtant period, formed a part of the continent, and was ſeparated from it by ſome great convulſion of nature. In addition to other circumſtances that favour this preſumption, we may obſerve, that the appearance of the ſoil and the ſurface of the country are very ſimilar on the W. coaſt of Ceylon and the oppoſite continent. The ſituation and appearance of the Maldive iſlands, on the other ſide of the peninſula of India, agree with thoſe on the W. coaſt of Ceylon, to ſupport the opinion that this continent muſt have been once much more extenſive, till the ocean, from ſome unknown cauſe or other, exceeded its former boundaries.

The gulf of Manaar, though too ſhallow to admit veſſels of large ſize, is not altogether uſeleſs for the purpoſes of commerce. Sloops, donies, and various ſmall veſſels, convey goods by this paſſage from Madras and other places on the Coromandel coaſt directly to Columbo, inſtead of rounding the iſlands by Trincomalee and Point de Galle. Notwithſtanding the obſtructions that occur in this paſſage, the Dutch have found means to carry on a conſtant traffic in this way between the weſtern coaſt of Ceylon and their factories of Tutucoran, Vipar, Manapar, Ponicail, and Kilkerre. Coarſe cloths and calicoes were the chief articles thus imported by the Dutch, and in return they carried back areca and cocoa-nuts, betel leaf, fruits, arrack, and coya, or cordage made from the cocoa-tree. All theſe places are now in poſſeſſion of the Engliſh, who may avail themſelves by the traffic which they afford.

The ſhort paſſage from Ramiſeram to Manaar forms a ſpeedy communication of intelligence to people of buſineſs; and government has boats ſtationed here for the purpoſe of conveying the "tapal," or letter-bags, between Ceylon and the continent. The "Peons," a caſt of people employed for this purpoſe, travel at the rate of five miles an hour, and they are relieved at certain ſtages by freſh runners. They uſually go from Columbo to Manaar, a diſtance of 160 miles, in three days. Here they take boat, and croſs over by Adam's bridge to Ramiſeram, and then proceed along the Coromandel coaſt to Madras. An expreſs will generally run from Columbo to Madras in eight days. See RAMISERAM.

The Dutch built a fort on the iſland of Manaar, with a view to command the paſſage and the communication with the continent by Adam's bridge. It was principally intended to prevent the ſubjects of the king of Candy from ſmuggling over any of the produce of the iſland, particularly ſpiceries; and alſo to cut off all intercourſe between that prince and thoſe of the continent, by which he might have formed alliances dangerous to their intereſts. The protection of the pearl-banks and pearl-fiſhery, which lie at no great diſtance from this iſland, was alſo another object for conſtructing a fort here. It alſo contributed conſiderably to the revenues of government, as a ſtation where certain duties are levied on the vaſt quantities of calicoes, coarſe muſlins, cottons, and other articles, brought through this paſſage to Columbo by the Moors, Malabars, and other inhabitants of the continent. Theſe circumſtances are ſufficiently important in order to keep in this place a conſtant garriſon, the expence of which is greatly overbalanced by its advantages. The garriſon ſtationed here conſiſts only of a company of Malays or Sepoys, under the command of an European officer; but during the pearl-fiſhery, an additional force is ſent from Columbo.

In proceeding along the coaſt of Ceylon from Manaar, the country is found to be ſandy, wild, and barren, equally deſtitute of accommodation and proviſions. The woods are ſo infeſted with wild animals, that it is very dangerous to travel along the roads here without a proper guard. The ſea is ſkirted by a tract of low flat ſand: but farther inland there are rice and paddy fields, with ſome ſcattered houſes. This appearance continues about 30 miles to the ſouthward of Manaar, when the wood and jungle again begin to approach to the ſhore, and to cover the whole ſurface of the country, till at Chilou the cinnamon woods ſhew the commencement of the diſtrict of Nigumbo. At Mantotte, near Manaar, there are ſome remains of antiquity. A Gentoo city is ſaid to have ſtood there, and to have been built by that harmleſs people, who took refuge here: the veſtiges of the embankment of a tank, and a number of brick ruins ſtill remain. About 12 miles from Manaar lies the village of Arippo, where the civil and military officers, who attend the pearl-fiſhery, reſide during the ſeaſon. This is the only place in their vicinity where good water can be procured. Here is a chapel for thoſe of the Roman Catholic perſuaſion, who conſiſt chiefly of the Parawas and Malabars, reſorting hither during the ſeaſon of the pearl-fiſhery. In the neighbourhood the woods are very full of deer and wild hogs.

hogs. At no great diſtance lies the bay of *Condatchy;* which fee. Percival's Ceylon.

MANABACCA, a ſmall iſland in the Eaſt Indian ſea. S. lat. 3° 59′. E. long. 131° 45′.

MANABEA, in *Botany*, (from the Caribean name of one of the ſpecies, *Manabo,*) Aubl. Guian. 61. t. 23—25, Juſſ. 107, Lamarck Illuſtr. t. 70, is referred by Schreber to *Ægiphila;* ſee that article. Willdenow in his Sp. Pl. v. 1. 615, defines eight ſpecies of *Ægiphila*, three of which are the above plants of Aublet; one is *Æ. martinicenſis* of Jacquin and Linnæus; another the *Nuxia* of Commerſon, Lamarck Illuſtr. t. 71; the three remaining ones being adopted from Swartz.

MANACA, a Braſilian bacciferous ſhrub, with an umbilicated fruit, like that of the juniper, containing three elliptical ſeeds, of the ſize of lentils; the part uſed in medicine is the root, which is great, ſolid, and whitiſh; its medullary ſubſtance, reduced to powder, has very conſiderable effects; but becauſe it works too violently, both upwards and downwards, in the ſame manner as ſcammony, or the eſula, it is uſually given only to very robuſt perſons, and then with correctives, in a juſt doſe; it has ſomewhat of a bitterneſs and acor. The root, macerated in water, makes a fomentation, or bath, for thoſe who are afflicted with wandering pains in the joints, eſpecially ſuch as are contracted by cold: the plant is uſed as a vulnerary by the Braſilians.

MANACHA, in *Geography*, a conſiderable town of Arabia, in the province of Yemen, the ſeat of the dola of Harras, and famous for its fairs.

MANACHOKE, a town of Hindooſtan, in Bahar; 26 miles N.W. of Durbungah.

MANACIZO, a town of Naples, in the province of Otranto; 12 miles S.E. of Tarento.

MANACOR, a town of the iſland of Majorca, ſituated in a fertile plain, where perſons of rank and of the moſt conſiderable property ſpend the ſummer ſeaſon. Its population conſiſts of about 7000 inhabitants. It contains a pariſh church, a monaſtery of Dominican friars, and an hoſpital for invalids. The productions of the ſoil in its vicinity are corn of all ſorts, wines, fruits, vegetables, and paſtures for flocks and herds. Proceeding along the coaſt from Manacor towards the eaſt, you paſs San Serveia, and on the north of the village diſcover "Arta," containing near 8000 perſons. This town, built in a mountainous ſituation, is one of the richeſt in the iſland: it contains a pariſh church, a convent, a public oratory, and two chapels of eaſe for the villagers. The land in the neighbourhood affords paſture for cattle of all kinds, and produces wine, olives, corn, and vegetables. The inhabitants cultivate the cotton tree very ſucceſsfully, and make a large quantity of oil.

MANACUS, Manakin, in *Ornithology*. See Pipra.

MANADO, in *Geography*, a ſmall iſland and town, near the north coaſt of the iſland of Celebes. N. lat. 1° 8′. E. long. 124° 32′.

MANAGE, or Manege, an academy, or place for learning to ride the great horſe; as well as for breaking horſes to the proper motions and actions.

The word is borrowed from the French *manege*, and that from the Italian *maneggio*, or ſome will have it, *à manu agendo*, from acting with the hand.

In every manege is a centre, or place deſtined for vaulting round a pillar; a courſe or career for running the ring; and, on the ſide, are pillars, between which are placed the horſes intended for high airs.

Manage, or *Manege*, is alſo uſed for the exerciſe itſelf, either of the horſe or the rider. See Horsemanship.

MANAGUERA, in *Geography*, a town ſituated on the weſt coaſt of Madagaſcar.

MANAKIN, in *Ornithology*. See Pipra.

MANAM, in *Geography*, a town of Africa, in Sugulmeſſa; 16 miles E. of Sugulmeſſa.

MANAMAG, a ſmall iſland in the ſea of Mindoro. N. lat. 11° 27′. E. long. 120° 45′.

MANAMANGALUM, a town of Hindooſtan, in Travancore, near the coaſt of Malabar; 40 miles S.S.E. of Cochin.

MANAMBE, a town on the eaſt coaſt of Madagaſcar. S. lat. 15° 20′. E. long. 50° 5′.

MANAMBOTCHE, a town on the eaſt coaſt of Madagaſcar. S. lat. 15° 50′. E. long 50° 5′.

MANAMBOUVE, a river of Madagaſcar, which runs into the ſea on the ſouth coaſt, S. lat. 25° 20.

MANAN, an iſland of the Atlantic ocean, near the coaſt of Main, in North America; 30 miles in circumference. N. lat. 44° 48′. W. long. 66° 45′.

MANANBATO, a town on the eaſt coaſt of Madagaſcar. S lat. 24° 5′. E. long. 47° 30′.

MANANCIALES, a town of South America, in the government of Buenos Ayres; 190 miles N.N.W. of Buenos Ayres.

MANANGHERA, a river of Madagaſcar, which runs into the ſea on the eaſt ſide of the iſland, S. lat. 22° 45. E. long. 52° 4′.

MANANGOUROU, a river of Madagaſcar, on the ſouth coaſt, which runs into the ſea, oppoſite to the iſland of St. Mary, S. lat. 17°.

MANANZARI, a town on the eaſt coaſt of Madagaſcar. S. lat. 21° 8′. E. long 48° 20′.

MANAPAR, a town of Hindooſtan, in the country of Tinevally, lying on a point of land projecting into the gulf of Manera; 33 miles S.E. of Palamcotta. N. lat. 8° 18′. E. long. 78° 12′.

MANARA. See Manaar.

MANARAN, a ſmall iſland in the ſea of Mindoro. N. lat. 11° 20′. E. long. 120° 51′.

MANARDI, John, in *Biography*, a learned phyſician, was born at Ferrara in the year 1462. He purſued his ſtudies in philoſophy and medicine under that able teacher, Nicholas Leonicens, who was then profeſſor of theſe ſciences at Ferrara, and who took much intereſt in foſtering his talents by private as well as public inſtruction. But Manardi has been accuſed of much ingratitude, in his ſubſequent conduct towards his maſter. In the year 1482 he was appointed medical profeſſor in his native univerſity, and occupied this poſt until 1495; when he quitted Ferrara, and reſided for ſome years with Gian-Franceſco Pico, of Mirandola, to whom he was both phyſician and preceptor, and whom he aſſiſted in publiſhing the work of the celebrated John Pico againſt judicial aſtrology. In 1513 he was invited to become phyſician to Ladiſlaus, king of Hungary: he accepted the appointment, and remained in that country two years after the death of that prince, which occurred in 1516. On his return to Ferrara, he reſumed his functions as a teacher in the beginning of 1519. At an advanced age he married a ſecond wife, young and of great beauty, by which he was ſuppoſed to have ſhortened his days. He died at Ferrara, on the 8th of March 1536, at the age of ſeventy-four; and a very honourable inſcription to his memory was placed on his tomb by his widow. After his return from Hungary, he publiſhed the following works, which are all that he produced: 1. "Medicinales Epiſtolæ Recentiorum Errata et Antiquorum Decreta peritiſſimè referentes," Ferrar. 1521. This work went through numerous editions, the latter of which were much augmented, to the

the number of twenty books, with alterations in the title, *viz.* "Epiſtolarum Medicinalium Libri xx." Baſil, 1540, folio; to which, and ſeveral ſubſequent editions, were added his "Annotationes et Cenſuræ in Joannis Meſuæ ſimplicia et compoſita;" and ultimately, "Curia Medica xx. Libris Epiſtolarum, et Conſultationum adumbrata," Hanov. 1611, folio. Theſe letters were written principally between the years 1500 and 1536. They contain a miſcellaneous collection of remarks, of very various merit, upon the writings and practice of the ancients, with corrections and refutations. Haller terms Manardi a ſemi-Arabiſt and ſemi-Galeniſt; which implies a bold and obſervant mind, attached to the ancient doctrines only when they were not repugnant to cautious obſervation. His cenſures on the practice of the Arabians are often expreſſed with great vivacity; but they are mingled with many uſeleſs and trivial diſcuſſions. He treats of the lues venerea, as a new diſeaſe imported from America, and recommends the cure by guaiacum in preference to mercury. 2. He alſo publiſhed "In primum Artis parvæ Galeni Librum Commentarius," Romæ, 1525, 4to. Gen. Biog. Eloy Dict. Hiſt. De la Med.

MANAS, in *Geography*, a river of Aſia, which runs into the Caſpian ſea, 15 miles N. of Derbend.

MANAS *Hotun*, a town of Thibet; 125 miles N.W. of Tourſan. N lat. 44 58'. E. long. 86 44'.

MANASQUAN, a river of America, in New Jerſey, which runs into the Atlantic, N. lat. 40°. W. long. 74 8'.

MANASSEH, *Half Tribe of*, that lay beyond Jordan, in *Scripture Geography*, was bounded by the tribe of Gad on the ſouth, the Jordan and Semachonite lake on the weſt, the hills of Baſhan and Hermon on the eaſt, and part of the Lebanon on the north. This territory extended from 32° 36' to 33° 36' of latitude, and was more properly called, afterwards, Upper Galilee, or Galilee of the Gentiles. (See GALILEE.) It had ſeveral large territories and conſiderable cities: thoſe of the former ſort were known by the names of Gilead, Batanea, Gaulonitis, Auranitis, Machonitis, Geſhur, Auran or Amram, and Argob; all of them deriving their names from their capitals. The cities of this half tribe were Boſra or Bozrah, Selſcha, Maachah or Maacati, Gerſhon, Aſhtaroth, Adrach or Hadrach-Kedar, or the tents of Kedar, Sueta, Gamala, Eſdrai, Gilead, Pella, Abel, Abel-Maachah or Abel-Beth-Maachah, Jabez-Gilead, Corazin or Corozaim, Julias, Bethſaida, near the deſert of its name, Giraſa or Girgeſha, Hippo, Gader, and Ephron, beſides a number of others of leſs note.

MANASSEH, *Half tribe of*, on this ſide of the Jordan, was ſituated ſouth of the tribe of Zebulun. The territory of this Manaſſeh was hemmed in, N. and S., by Iſſachar and Ephraim, and, on the E. and W., by the Jordan and Mediterranean. It exhibited a variety of plains, mountains, vallies, ſprings, and a good number of ſtately cities; among which were Beth-Shean or Scythopolis, Salem, Aner, Bezech, Abel-Meholah, Caſtrum Alexandrinum, Tirſhah or Terſa, Acrabata, Thebez, Thanac or Tanac, Gath-Rimmon, Maccoth, Ennon, Megiddo, Gilgal, Dor or Dora, Cæſarea Paleſtina, and Antipatris.

MANASWARY, in *Geography*, a ſmall iſland in the Pacific ocean, at the entrance into Dory harbour, near the N. coaſt of New Guinea. In 1775 captain Foreſt found the true nut-meg tree on this iſland.

MANATAWNY CREEK, a river of America, in Pennſylvania, which runs into the Schuylkill, N. lat. 40° 15'. W. long. 75° 40'.

MANATE, a river of Honduras, which runs into the bay, N. lat. 15° 45'. W. long. 88° 22'.

MANATE *Lagoon*, a bay on the coaſt of Yucatan. N. lat. 18° 22'. W. long. 89° 18'.

MANATEE BAY, a bay on the S. coaſt of Jamaica. N. lat. 17° 51'. W. long. 76° 45'.

MANATENGHA, a river of Madagaſcar, which runs into the ſea on the E. coaſt, S. lat. 23° 30'.

MANATI, a town of the iſland of Cuba, in a bay on the N. coaſt. N. lat. 24° 32'. W. long. 76° 20'.

MANATI, or *Sea-cow*, in *Zoology*. See TRICHECUS *Manatus*.

MANATI *Lapis*, a name given to a bone, of which there are two found in the head of the manati, or ſea-cow; they are roundiſh, and are uſually of the ſize of a hand-bell. They are ſaid to have great virtues againſt the ſtone and gravel, when burnt to aſhes, and given in white wine. The world need not, however, regret the ſcarcity of this remedy, for probably any animal bone, when burnt to aſhes, is poſſeſſed of all its virtues.

MANATIRSKA, in *Geography*, a town of Ruſſia, in the government of Irkutſk, on the Itchora; 84 miles N.N.E. of Kirenſk. N. lat. 58° 45'. E. long. 109 44'.

MANATOULIN, a chain of iſlands in lake Huron, extending 90 miles in length, and about ſix in breadth. The term, according to Carver, ſignifies in the Indian language the place of ſpirits, and the iſland is eſteemed ſacred by the Indians. N. lat. 45° 20' to 45° 49'. W. long. 81° 50' to 84°.

MANAZERUDAM, a diſtrict or province of Turkeſtan, N. of Fergana.

MANBAGE, a town on the S. coaſt of the iſland of Sibu. N. lat. 10 10'. E. long. 123° 38'.

MANBALLA, in *Zoology*, the Ceyloneſe name of a ſpecies of ſerpent, called alſo the *canine*, or *dog-ſerpent*, from its manner of flying at every thing that comes in its way, as our dogs do: it is of a deep brown colour, beautifully variegated with white.

MANBED, in *Geography*, a town of Perſia, in the province of Irak; 174 miles E.S.E. of Iſpahan.

MANBONA, the capital of the kingdom of Sabia, in Africa, ſituated on the ſea coaſt, at the entrance of the channel of Mozambique; 30 miles S. of Sofala. S. lat. 20° 45'.

MANBOOM, a town of Bengal; 54 miles N.W. of Midnapour. N. lat. 23 6'. E. long. 87 28'.

MANBOTE, in our *Old Writers*, a compenſation or recompence for homicide, particularly due to the lord for killing his man or vaſſal.

MANC, in *Geography*, a town of Grand Bucharia; 50 miles W. of Badakſhan.

MANCA, a town of America, in Weſt Florida, on the E. bank of the Miſſiſippi, at the mouth of Hona-chitto river.

MANCAENBLANCA, a town of the iſland of Borneo; 30 miles N. of Negara.

MANCANILLA, in *Botany*, a name given by Plumier to a genus of plants, ſince characteriſed by Linnæus in the name of *hippomane*; which ſee.

MANCENILLA, in *Geography*, a large bay on the N. ſide of the iſland of St. Domingo, about 4000 fathoms long from weſt to eaſt, and 2800 broad from north to ſouth. The S.E. part is very wide, and affords excellent anchorage even for veſſels of the largeſt ſize. In other parts it is too ſhallow. The river Maſſacre, which ſeparated the French and Spaniſh colonies on the N. ſide of the iſland, runs a N. courſe towards its mouth N.W. and enters the eaſtern part of the bay. The river ſwarms with fiſh, particularly with thoſe large mullets, which are highly prized at Cape François. Fiſhing in the bay is difficult on account of the drifted wood, but

but the negroes, being good divers, plunge to the bottom and disengage the feine, in doing which, the negroes, fifh, and alligators are engaged in an amufing kind of conteft. The negroes kill the alligators, knock out their teeth, and fell them for making corals, which ferve to mark the luxury and pride of thofe who fufpend them to the necks of their children. The plenty of fifh often attracts fhips of war to this bay. The mouth of Maffacre river lies in N. lat. 19° 44'. W. long. from Paris 74° 9'.

MANCHA, La, an extenfive province of Spain, north of New Caftile, by which it is bounded on one fide, on the W. by Eftramadura, on the S. by Cordova and Jaen, and on the E. by Murcia and Valencia. It is 43 leagues long and 33 broad; and divided into Upper and Lower. The capital of the former is Ciudad Real, and that of the latter Occana. The foil is in general dry and dufty; and the country abounds in plains of confiderable extent, but they are wafte and almoft wholly without trees. The rivers that water it are little more than rivulets. A great part of the province is furrounded by mountains, forming part of the chain beginning in Sierra d'Occa, called by the ancients "Montes Orofpadani." The moft confiderable of thefe mountains is the Sierra d'Alcarrez, extending from N. to S., towards the fouthern and eaftern parts of the kingdom of Jaen. In La Mancha alfo, near Alcarrez, and at the fide of the Sierra of that name, begins the famous Sierra Morena, or the "Montes Mariani" of the Romans. They continue to the kingdom of Cordova; a ridge fpreads into Jaen, and they extend as far as Eftramadura, and even to the banks of the Guadalquivir. The province of La Mancha contains 111 parifhes, 78 monafteries and convents, two cities, and 121 towns, of which ten belong to the crown, and 75 to the military orders, 46 villages, one intendency of a province, and one hofpital. The principal towns are Ciudad Real, Occana, Alcafar, and Almagro.

Ciudad Real, which is reckoned the capital of La Mancha, is fituated in a plain, which is rich, and productive of corn, wine, and fruits. This city has loft much of its ancient fplendour; its woollen manufactures and trade have much declined, and its population is of courfe reduced to the number of eight or nine thoufand perfons. The town is regularly laid out; the ftreets are ftraight and well paved; and it has a fquare 150 paces long, and 75 broad, furrounded with two rows of boxes for the accommodation of the fpectators at bull-fights and public fhows. This place is the refidence of the intendent of La Mancha, and the grand vicar and ordinary of the archbifhop of Toledo, and the principal place within the controul of a corregidor. In the parifh church of St. Mary is a fpacious and lofty chancel; the chief altar of which is compofed of four different orders of architecture, each of which is ornamented with pillars, upon the whole well executed. A great quantity of leather for fhoes was formerly prepared in this city, and a confiderable manufactory of them was eftablifhed. The cardinal of Lorenzana, the archbifhop of Toledo, erected at his own expence a hofpital, which coft about 12,500*l.* fterling; and he alfo fet on foot a manufactory of flannels and coarfe woollen cloths; and he lately propofed to eftablifh another of filks. For an account of the other towns, fee the refpective articles. The population is rather more than 200,000 inhabitants, or, according to the furvey of 1787 and 1788, 206,160; and the clergy not numerous. The Mefa d'Occana is the richeft and moft fertile plain in the whole country.

La Mancha is a flat level country, and the foil is parched with heat. The productions of fuch a foil muft neceffarily be limited; it produces corn, and efpecially oats, in fufficient quantity to fupply the neighbouring provinces. But the principal part of the country is fo deftitute of trees, that for feveral leagues in fucceffion you fcarcely fee one. The moft common trees are chefnuts of a dwarf fpecies, which grow fpontaneoufly; olive trees, however, are found in many parts, and alfo a number of vines, the beft of which are thofe of *Menzanares*, which fee. The other productions of La Mancha are faffron, honey, and fpar. No fruit is to be met with except in fome particular diftricts, and in fmall quantities. Almagro is famous for melons and potatoes. The meadows are not numerous, except for about four leagues between Ciudad Real, and Santa Cruz de Mudela, where they are fine and extenfive; immenfe herds are fed in thefe plains, and efpecially mules, which are of an excellent breed. The manufactures of La Mancha are now declined. They formerly fabricated ribbons, garters, worfted ftockings, tapeftry, and filks of different forts, and a great quantity of leather-gloves, both at Ciudad Real and Occana: at the former of thofe towns they made all forts of woollen ftuffs, but they have very much declined. A fabric of blond lace has been lately fet on foot at Almagro, which employs 2300 people. The other branches of labour are reduced to four; one of hard foap at Occana; another of flannels at the fame place and Campo de Criptance; a third at Alcazar de St. Juan, of gunpowder; and three refining-houfes of faltpetre at Pedronera, Zemblaque, and Alcazar de St. Juan, the laft of which furnifhes annually 200,000 quintals of faltpetre to the crown, on whofe account it is wrought. The wool fpinning is a confiderable fource of induftry throughout this province, and employs from 12 to 16,000 people of all ages and fexes. Commerce is in a very low ftate in this province: the only productions with which it furnifhes the neighbouring provinces are a little fpar, oats, and wine, together with a fmall quantity of blond lace and fhoe-leather. But thefe few articles do not counterbalance the imports from other provinces and countries, which fupply La Mancha with fhot, fpices, falt provifions, hardware, linen, muflins, broad cloth, fine woollen ftuffs, filks, and in a word all articles of luxury, and even many of neceffity with regard to clothing. The animal and vegetable kingdoms prefent nothing worthy of much attention in this province: but it has fome mines and mineral waters that may deferve notice: fuch are mines of iron, ochre, rock-cryftal, bole, calamine, antimony, cinnabar, &c. It has alfo mineral waters both for drinking and bathing. In the cultivation of the arts and fciences, La Mancha does not excel. The manners of this province differ little from thofe of Caftile. The people, fays La Borde, are more grave and folemn in their deportment, and more attached to ancient cuftoms and ceremonies, and their conftitutions more robuft and fit for labour: their temper in general is mild and peaceable, and they are truly good-humoured. Perfons in the higher ranks pafs their lives in eafe and apathy; on the other hand, the common people are laborious and frugal; and both orders, fays La Borde, take no part in any fort of diffipation, or even of diverfion. Every thing is grave and formal. Other travellers, however, report, that this is the moft cheerful country in Spain; that the inhabitants are very fond of mufic and dancing. A player on the guitar, and a finger of fequidillas, are perfons in great requeft in this part of the country. The girls, young men, and married women are faid to affemble at the firft found of the inftrument; the beft voices fing fequidillas, and the blind accompany them on their inftruments. A late traveller fays, "there is no labourer nor young female peafant who is not well acquainted with Don Quixote and Sancho." The traveller, fays another writer, can fcarcely enter

ter the province of La Mancha without having conftantly in his thoughts the fabulous hero, whofe name renders this country more celebrated than its fpacious and parched-up plains could ever have made it. Cervantes, in his endeavours to ridicule the tafte for romances, perhaps has left only a fofter recollection of the fpirit of chivalry, which his hero, notwithftanding his madnefs, always renders venerable. The names of Quintenar and Tobofo are impreffed on the memory of every one, and one looks round for the village of the famed and peerlefs Dulcinea, and the wood where the firft meeting took place between her and the doughty Don Quixote. The coftume of all ranks of the people, in the principal towns of this diftrict, is fimilar to that of New Caftile. The peafant wears a clofe camifole of cloth, or leather, faftened with a leathern girdle, and on his head a fquare cap rifing to a point. The fides, which are turned up, continually beat againft each other: it is made of cloth, or leather, and is called a "montera." A ftranger, who vifited fome of the affemblies of amufement in this province, would be aftonifhed at feeing a labourer in the drefs of Sancho, wearing a broad leathern girdle, become an agreeable dancer, and perform all his fteps with grace, precifion, and meafure. The fongs and fequidillas on thefe occafions are peculiar to this part of the kingdom, and it is to be remarked, that to finging and dancing the Manchegas add the merit of poetry. Moft of the fequidillas are voluptuous, and turn on the fubject of love or abfence; though fome are fatirical.

MANCHAC, a town or parifh on both fides of the Miffifippi, in Louifiana, extending 12 miles on the river. See LOUISIANA.

MANCHE, LA, the *Channel*, one of the nine departments of the N.W. region of France, compofed of Cotantin and Avranchin, and oppofite to Jerfey and Guernfey, in 49 N lat. The five circles into which it is divided are Valognes, containing 143,777 inhabitants, St. Lo, including 90,329, Mortain 69,565, Avranches, 94,711, and Coutances, 130,530. The foil, partly fandy and partly marfhy, is better adapted to pafture than cultivation: it produces, however, fome grain, flax, hemp, fruits, and roots. It has mines of copper, iron, and cinnabar, with mineral fprings. Salt, in confiderable quantities, is manufactured and exported. For a further account of this department, fee CHANNEL.

MANCHESTER, a market town in the hundred of Salford and county of Lancafter, England, is feated on the banks of the fmall rivers Irk, Medlock, and Irwell, at the diftance of 185 miles from London and 32 from Liverpool. In point of commercial and political importance, though not a corporation, it is undoubtedly the fecond town in the kingdom. The whole population, according to the parliamentary cenfus of 1800, amounted to 84,053 perfons, of whom 44,500 were engaged in different branches of trade: 44,900 were females, and 39,110 were males. The amazing increafe of population in this town is fhewn by returns obtained in the years 1773 and 1811. In the former year there were 29,951 perfons; and in the latter 98,573. The parifh of Manchefter comprehends feveral of the contiguous townfhips, the whole population of which is 136,370.

Manchefter appears, from the teftimony of Mr. Whitaker, to be a town of great antiquity. A ftation occupied by the ancient Britons is fuppofed to have been fettled here 500 years before the Chriftian era. It did not, however, deferve the name of a town till after the invafion of this ifland by the Romans, when it became one of the fortified retreats of the brave but undifciplined natives. At this period it was called Mancenion, that is, the "place of tents;" but Agricola, who conquered it A.D. 79, changed its name to Mancunium. It was afterwards called Manduefuedum, and Mancaftre, from which latter term its prefent appellation is evidently derived. The Romans, upon achieving the conqueft of this ftation, built an extenfive caftle upon the fpot now denominated Caftle-field, fituated near the conflux of the Medlock with the Irwell; but every veftige of this is removed to make room for modern buildings. After having retained it in continued poffeffion for fomewhat more than 400 years, the declining fortunes of Rome compelled the legionary foldiers to abandon it to the original poffeffors, who in their turn foon yielded it to their new conquerors and tyrants the Saxons. During the dynafties of that ferocious people, Manchefter was feveral times a place of military conflict, being feated on the immediate confines of the Northumbrian kingdom. Edward the Elder, king of the Mercians, is faid to have fortified and rebuilt a confiderable part of it, which time and violence had united to deftroy. At the period of the grand Domefday furvey, two churches appear to have exifted here, called St. Mary's and St. Michael's. Albert de Grefley obtained from the Conqueror the lordfhip of the manor. In 1301 his grandfon, Thomas, granted a charter to his burgeffes of Manchefter, conftituting their town a free borough. Lord de la Warr, the laft male heir of this family, laid the foundation of the collegiate church, which tended, in no fmall degree, to promote its increafe and improvement. This town in early times was a place of fanctuary, and one of the eight places to which that privilege was confirmed by Henry VIII. in 1540. The year following, however, it was removed to Chefter, which the ftatute declares "had a ftrong gaol and a mayor, and had not the wealth, credit, great occupings and good order which Manchefter had." In 1605, a peftilence raged here, and carried off upwards of 1000 perfons. Upon the breaking out of the civil war between Charles I. and the parliament, Manchefter decidedly efpoufed the republican caufe, and fuccefsfully refifted feveral fieges by the royal army, under the earl of Derby. Notwithftanding thefe circumftances, however, the inhabitants feem to have honoured the reftoration of Charles II. with particular marks of joy.

From this fhort fketch it will readily be perceived that, in an hiftorical point of view, Manchefter is only entitled to a very fmall fhare of general attention: though regarded as a manufacturing town, it is defervedly diftinguifhed above every other in England. When it firft began to be noted for its manufactures is uncertain; but in the time of Edward VI. Manchefter cottons, Manchefter rugs, and Manchefter friezes are frequently mentioned in various acts of parliament. In 1650, its trade is defcribed as "not inferior to that of many cities in the kingdom, chiefly confifting in woollen friezes, fuftians, fack-cloths, mingled ftuffs, caps, inkles, tapes, points, &c. whereby not only the better fort of men are employed, but alfo the very children by their own labour can maintain themfelves. There are, befides, all kinds of foreign merchandize brought and returned by the merchants of the town, amounting to the fum of many thoufand pounds." About this time great quantities of linen yarn feem to have been imported here from Ireland, which being wrought into cloth, was refhipped for the Irifh market. It was not, however, till after the middle of the laft century, that Manchefter rofe to a pre-eminent rank among our manufacturing towns; a rank for which it is chiefly indebted to the ingenuity and invention of Mr. Hargreave and fir Richard Arkwright. Previous to the year 1760, all the cotton yarn manufactured in the country was fpun by hand, upon that well known domeftic inftrument called

called a one-thread wheel. Shortly after this period, Mr. Hargreave conftructed a machine denominated a *jenny*, by which one perfon was enabled to fpin from twenty to forty threads at a time. Thefe machines foon came into general ufe, but were much limited in their employment till the year 1775, when fir Richard brought the improvements of his predeceffor to much greater perfection. This gentleman having eftablifhed his extenfive manufactories here, made Manchefter the principal feat of the fpinning trade, the rapid increafe of which produced a correfponding increafe in the buildings and population of the town. See the preceding articles of ARKWRIGHT, vol. ii. and COTTON, vol. x. for further particulars. In Brayley's "Beauties of England," vol. iii., Derbyfhire, is an interefting and ample memoir of fir Richard Arkwright, with accounts of the prefent ftate and proceffes of the cotton manufactures.

As Manchefter, notwithftanding its extent and political importance, is not a corporate town, the government is vefted in a headborough, called the boroughreeve, and two conftables. Thefe are chofen annually from the moft refpectable of the inhabitants by a jury impannelled by the fteward of the manor, at the courts leet, which are held by the lord of the manor twice every year at Eafter and Michaelmas. The boroughreeve is ufually one of the gentlemen who has ferved as conftable for the preceding year, and is treated perhaps with more refpect (the paraphernalia of a mace-bearer excepted), than any mayor in the kingdom. The chief duty of this officer is to prefide at public meetings, and to diftribute certain charities, denominated "boroughreeve charities," all the judicial functions connected with the police being executed by the conftables and their deputies. A court of requefts is held every month for the recovery of fmall debts; and every Wednefday and Saturday feveral refpectable magiftrates fit in the court-room of the New-Bayley for the adminiftration of juftice in pleas of almoft every defcription, whether civil or criminal. Quarter feffions alfo are held four times a-year; and, from prefs of bufinefs, the court is fometimes obliged to continue its fittings for nearly a fortnight.

This town is divided into two portions by the river Irwell, which receives the Irk at a fhort diftance from the collegiate church. The fituation of Salford is very fimilar to that of Southwark, the communication between the two towns being kept up, as in London, by three bridges thrown acrofs the river at different places. The moft ancient of thefe is called the "Hanging bridge," Old, or Salford bridge, and is fuppofed to have been originally founded in the time of the Romans. The prefent, built in the reign of Edward III., was formerly very dangerous for foot paffengers, but in 1778 it underwent a thorough repair and extenfion. Blackfriar's bridge, erected about fifty years ago, is conftructed entirely of wood, and flagged for foot paffengers only. But the fineft bridge over the Irwell is the New bridge, commonly called the New Bayley bridge, which was founded in 1785, and is conftructed wholly of ftone. It confifts of three large arches, and a fourth of fmaller dimenfions, left open in fupport of the duke of Bridgewater's right to a towing path to his quay, in Salford, agreeably to the tenor of the act, enabling His Grace to form his extenfive canals. Six bridges are here thrown acrofs the Irk, the chief of which are Huntfbank bridge, fituated near the college, and Scotland bridge: nine are thrown over the Medlock, which runs in a ferpentine courfe through the fouthern fuburbs of the town. Oxford-ftreet bridge forms a part of a ftreet of that name. A variety of other bridges lie acrofs the numerous canals which interfect the fuburbs at different places, and at Knotmill, in the vicinity of Caftle-field, is a very noble tunnel, through which the Rochdale canal paffes, not far from its junction with that of the late duke of Bridgewater's.

With refpect to the plan and buildings of this town, it may be remarked, that the portion of it called the Old Town confifts of a very motley affemblage of old and new houfes, clofely huddled together, and exhibiting little elegance in their exterior appearance. Even the new ftreets, though much fuperior to the old, are ufually narrow, except in a few inftances where they have been improved by the acts of 1775 and 1791. In thefe latter, however, there are a number of very excellent modern buildings. Mofley-ftreet and Portland place would do honour to the capital itfelf. Grofvenor-fquare, when finifhed, will probably rival the fineft in the kingdom. The fuburbs of Ardwick-green and Salford crefcent are peculiarly pleafant, and contain fome handfome houfes, which are moftly occupied by the wealthy manufacturers.

The churches and other public edifices of this town are numerous, but few of them are diftinguifhed for architectural beauty. The College, or parifh church, founded, as already mentioned, by lord de la Warr, bifhop of Durham and rector of Manchefter, is a venerable building in the rich ornamented ftye of the 15th century. In the interior its appearance is confufed and heterogeneous. The windows ftill retain many rich remains of the painted glafs with which they were formerly ornamented. The roof is of elegant wood-work, interfperfed with carved figures of angels playing upon different mufical inftruments. In front of the gallery, on each fide of the clock, are fufpended the colours of the 72d regiment, raifed in this town by fubfcription during the American war, whofe noble conduct at the fiege of Gibraltar is ftill remembered with exultation by every lover of his country, and particularly by the inhabitants of Manchefter. Adjoining to this church are a number of fmall chapels well worthy of the attention both of the architect and the antiquary. A view of this church, with a particular account of its hiftory and architectural peculiarities, written by J. H. Markland, F. S. A. are given in the third volume of "The Architectural Antiquities of Great Britain."

St. Ann's church, fituated at the end of the fquare to which it gives name, is diftinguifhed for its handfome appearance. It was founded by lady Ann Bland in 1709, in compliment to whom it was dedicated to the faint whofe name it bears. The church of St. Mary, fituated between Deanfgate and the river Irwell, is admired for the beauty and fine proportions of its fpire, which meafures 186 feet in height. The lanthorn which fupports it is peculiarly ftriking, being compofed of eight noble Ionic pillars, furmounted by a large globe, upon which is placed a maffy crofs. St. John's church is built in the ftyle which is called modern Gothic. In the veftry are feveral pictures, and a beautiful window of ftained glafs. Two of the windows in the body of the church are alfo decorated with fine painted glafs. The other churches in this town are St. Paul's in Turner-ftreet, St. James's in George-ftreet, St. Michael's in Angel-ftreet, St. Clement's in Lever-ftreet, St. Stephen's near Bolton-ftreet, St. George's in the neighbourhood of Newton-lane, and St. Peter's, which terminates the profpect down Dawfon-ftreet and Mofley-ftreet. The latter was defigned and executed by James Wyatt, efq. In Salford is Trinity chapel, a neat ftone edifice of the Doric order.

Befides thefe churches there are three others alfo belonging to the eftablifhment, fituated in the adjoining townfhips of Ardwick, Chorlton, and Pendleton, which, from their vicinity to Manchefter, may not improperly be confidered as belonging to it. Numerous chapels and meeting-houfes, appropriated for the public worfhip of diffenters of almoft every denomination

denomination, are likewife difperfed through various parts of the town. Catholics are numerous here, and the Methodifts are found to comprife a very confiderable proportion of the whole population.

The vaft number of excellent charitable inftitutions with which Manchefter abounds are highly creditable to the benevolence, liberality, and public fpirit of its inhabitants. Indeed, in this refpect, this town is not furpaffed by any in the Britifh empire, whether the fuitablenefs of the buildings for their refpective purpofes, or the liberal contributions by which they are fupported, are taken into view. Among thefe eftablifhments, Chetham's-Hofpital, commonly called the College, is firft deferving of notice, by priority of foundation. It owes its exiftence and entire fupport to the munificent bequeft of Humphrey Chetham, efq. of Clayton, whofe will is dated the 16th of December 1651. At firft, the number of boys clothed and educated here amounted only to forty; but from an increafe in the value of the eftates belonging to the foundation, the number was augmented more than thirty years ago to eighty. The building appropriated to this charity is fituated on a lofty rock, near the confluence of the rivers Irk and Irwell, immediately adjoining to the collegiate church already mentioned, to which indeed it formerly belonged. Upon this fpot Mr. Whitaker fuppofes the Romans had their prætorium, or fummer camp; and certainly the fituation was admirably adapted for that object. In a large gallery, in this edifice, is a public library, likewife founded by Mr. Chetham, which now contains upwards of 15,000 volumes in various languages, and in almoft every branch of fcience or literature, befides fome very valuable manufcripts. The Infirmary, Difpenfary, Lunatic Hofpital, and Afylum, are all included in one fpacious building, fituated in the front of Lever's Row, which is confidered as the higheft ground in the town. The foundation of the firft edifice was laid in 1753, for the reception of forty patients; but the number was foon afterwards doubled, and now there are 160 beds appropriated for the ufe of the fick. The Lunatic Hofpital was opened in 1766, and the Difpenfary in 1792. The annual fubfcriptions for the fupport of thefe inftitutions, amount to feveral thoufand pounds. Here are two poor-houfes, one of which was erected in 1792, on the fide of the Irk, nearly oppofite the College; and the other built the year following, at the upper end of Greengate in Salford. Both of them are handfome buildings, and admirably fitted up for the purpofe to which they are appropriated. The Lying-in-Hofpital was inftituted in 1790, and not only provides profeffional aid for in-door patients, but likewife for the affiftance of fuch poor married women as find it inconvenient to leave their own houfes. The Houfe of Recovery is intended chiefly for the reception of patients afflicted with contagious fevers. The other principal charities are the ftrangers-friend-fociety, inftituted in 1791, and the boroughreeve's charity: the former defigned for the relief of ftrangers, and the latter for the aid of the poor inhabitants in general. The Free-fchool is an excellent foundation, which owes its origin to Hugh Oldham, bifhop of Exeter. In this fchool the greater part of the clergy of the town and neighbourhood have been educated, as well as many noblemen. There are, befides, feveral inferior charity and Sunday fchools in various parts of Manchefter.

Though in every refpect a manufacturing town, Manchefter has not wholly neglected the promotion of literature and fcience. Societies, having this object in view, are numerous. The chief of them are the Literary and Philofophical, inftituted by Dr. Thomas Percival in 1781; and the Philological Society, which commenced its meetings in 1803. Here are alfo two very extenfive public circulating libraries; the former founded in 1757, and the latter in 1792. The Manchefter Agricultural Society was eftablifhed in 1767, and has for its object the encouragement of the ufeful arts in general, by the diftribution of premiums for fcientific difcoveries. A laudable practice is alfo adopted, of granting preminms to cottagers, who fupport their families without parochial aid; and in fome inftances likewife, honeft and good fervants are rewarded by honorary prefents. The repofitory, defigned to encourage and reward induftrious females, has proved highly ferviceable to many individuals, and is therefore juftly entitled to liberal and careful fupport.

Befides thofe already noticed, many other public buildings and inftitutions, intended either for ufeful purpofes or for amufement, may properly claim attention in this place. The Theatre, a commodious and extenfive building, was erected in 1807. It is open during feven months of the year, and can in general boaft of a very refpectable company of performers. The gentlemen's Concert-room is elegant and capacious, and will accommodate upwards of 1200 perfons. This is fupported by a voluntary fubfcription; and ftrangers are admitted with a fubfcriber's ticket. There are likewife very excellent new and commodious affembly-rooms for balls, card-affemblies, &c. The New-Bayley, or Penitentiary houfe, is well deferving attention, both on account of the extent of the edifice and arrangement of its parts, and alfo for the economy obferved in the interior. Immediately above the entrance is a large room, where the feffions are held; and adjoining to it are feveral commodious rooms for the magiftrates, jurors, &c. Beyond this, in the centre of a large area enclofed by lofty walls, ftands the prifon, an extenfive building in the fhape of a crofs, three ftories high. It is remarkable for the cleannefs with which it is kept, as well as for its regulations. Prifoners, not confined for capital crimes, are allowed the free exercife of their refpective trades. A workhoufe, on a large fcale, has alfo been lately built.

A new ftructure, called the Manchefter Commercial Building, or Exchange, was commenced in the year 1806, from defigns by Mr. Harrifon, architect. It was completed in January 1809, and is appropriated to the ufe of the merchants and manufacturers of the town, who fubfcribed certain fhares of 50*l*. each, to defray the expences of its erection. The building comprifes an exchange-room, dining-room, drawing-room, ware-rooms, fhops, and counting-houfes, a fuite of rooms for the poft-office, with extenfive cellars under the whole. It is built of ftone, and prefents a fimple, but claffical façade, with demi-columns of the Grecian Doric order. The exchange-room is very fpacious, containing an area of 4000 fuperficial feet, in the centre of which is a glazed dome, 40 feet in height, fupported by eight fluted columns of the Ionic order. Over a part of this room is a gallery, or femicircular fuite of rooms, appropriated to an extenfive library, belonging to Mr. Ford, a refpectable bookfeller of this town, whofe large catalogue contains a valuable affortment of fcarce, curious, and interefting works.

The Trade of Manchefter confifts chiefly, but not entirely, in the manufacture of cotton goods. Velverets, checks, a variety of fmall articles, fuch as filleting, tapes, laces, gartering, &c. are likewife made in great quantities. The filk manufacture has advanced rapidly here within the laft ten years; and a manufactory for making and finifhing hats is now carried on to a great extent. The profufion of goods made here is conveyed, by means of the Irwell and the numerous canals which interfect the town, to different ports both on the eaftern and weftern coaft. Liverpool, however, is the principal mart for the exportation of the cottons; and between

tween that town and Manchefter there is a conftant and rapid communication both by land and water-carriage.

Manchefter has two markets, called the old and the new, both of which are held twice a week on Tuefdays and Saturdays: the latter is the principal one for provifions; the former being moftly frequented for tranfacting the manufacturing bufinefs of the town with the country traders. Moft of the ftreets are paved and lighted, and are guarded at night by about 200 watchmen. For the regulation of parochial affairs, Manchefter is divided into fourteen diftricts. It gives title of duke to the noble family of Montague, fome of whom have been diftinguifhed characters. In the paths of literary fame, however, it can claim little diftinction; but Byrom and Falkner may be properly ranked with what Fuller calls "the worthies of the place."

The environs of this town abound with old manfions, refpectable villas, and a number of modern feats. Ancoats-hall, the manorial manfion-houfe, is a venerable building, the parts of which are difpofed in a moft curious and grotefque manner. Hulme-hall, or Holme, is an edifice of a fimilar kind, exhibiting a remarkable fpecimen of ancient domeftic architecture. It ftands on the edge of a fhelving bank of the Irwell, and exteriorly offers to the view a moft romantic and picturefque object. Heaton-houfe, the feat of the earl of Wilton, lies about four miles to the north-eaft of the town. The houfe, a handfome modern ftructure of ftone, ftands on a commanding fituation, in the midft of a very noble park, finely decorated with venerable trees and numerous thriving plantations. The other principal feats are Trafford-houfe, Alkington, and Smedley-hall; near which laft is Broughton-hall, formerly the property of the Stanleys, earls of Derby. Every part of the furrounding country difplays the higheft ftate of agricultural improvement, and in times of profperity prefents one vaft fcene of enterprize and induftry. Beauties of England and Wales, vol. ix. Aikin's Hiftory of Manchefter, and its Environs, 4to. by J. Afton. The Manchefter Guide, 12mo. 1804. Whitaker's Hiftory of Manchefter, 2 vols. 4to. 1771.

Manchester, a poft and fifhing town of America, on the fea-coaft between Cape Anne and Beverly, in the county of Effex and ftate of Maffachufetts. This townfhip was incorporated in 1645 and contains 1082 inhabitants.—Alfo, a poft-town of Vermont, in Bennington county, on Battenkill; 22 miles N.E. of Bennington and 59 N.E. of Albany in New York; the townfhip containing 1397 inhabitants.—Alfo, a townfhip in York county, Pennfylvania, including 1175 inhabitants. Weft Manchefter, in the fame county, contains 794 inhabitants.—Alfo, a fmall poft-town of Virginia, on the S. fide of James river, oppofite to Richmond, with which it is connected by a bridge.—Alfo, a town of Nova Scotia, 10 leagues N.W. of Cape Canfo, which in 1783 contained 250 families.

Manchester *Houfe*, a factory belonging to the Hudfon Bay Company, 100 miles W. of Hudfon's houfe and 75 S.E. of Buckingham houfe; fituated on the S.W. fide of Safkafhawan river, in the N.W. part of North America. N. lat. 53° 14′ 18″. W. long. 109° 20′.—Alfo, a poft-town in Adam's county, on the N. bank of the Ohio, about 10 miles above Maffiefburgh; incorporated in January 1802.

MANCHICOURT, Pierre, in *Biography*, a native of Bethune, in Artois, and director of the mufic in the cathedral of Dornick, who flourifhed in the middle of the fixteenth century, and whofe name frequently appears among the compofers of motets and fongs, in four and five parts, does not reward lovers of mufic of this period for the trouble of fcoring his productions fo much as many of his contemporaries; and, indeed, in three or four of them that we have examined, he feems not only a dry but a clumfy contrapuntift.

MANCHINEAL Harbour, in *Geography*, a bay on the E. coaft of Jamaica. N. lat. 18° 4′. W. long. 75° 58′.

Manchineal, in *Botany*. See Hippomane.

Dr. Peyffonnel, in his obfervations on the fruit of this tree, informs us that the favages ufe the juice of it to poifon their arms, the wounds of which are thereby rendered mortal; that the rain which wafhes off the leaves, and falls on the human body, caufes blifters to rife like boiling oil, and that even the fhade of the tree is fatal to thofe who fit under it. However, timely application by purges and emetics have prevented their ill effects. Phil. Tranf. vol. l. art. 105. p. 772.

MANCHULL, in *Geography*, a town of Hindooftan, in the circar of Joodpour; 19 miles S. of Joodpour.

MANCIAT, a town of France, in the department of the Gers; 16 miles S.W. of Condom. N. lat. 43° 59′. E. long. 0° 7′.

MANCINELLA, in *Botany*. See Hippomane.

MANCINI, Francesco, in *Biography*, compofed an oratorio which acquired him great reputation, intitled "L'Amor divino trionfante nella morte di Crifto;" and hymns for the Florentine brotherhood of the Pietà, during Lent, which were publifhed at Rome in 1700. Mancini was a Neapolitan, and, feemingly, the firft opera compofer of eminence in that country during the laft century. Between the years 1700 and 1731, he produced feveral operas and intermezzi that were much efteemed by the firft profeffors of his time, particularly Haffe and Geminiani, who always fpoke of him as a very able mafter. The celebrated opera of *Idafpe fidele*, or Hydafpes, brought on our ftage in 1711 by Nicolini, was fet by Francefco Mancini. In this opera it was, that Nicolini's battle with the lion gave birth to Addifon's humorous papers on the fubject, in the firft volume of the Spectator.

Mancini, Thomas, fon of the chapel-mafter of Groningen, and one of the 53 examiners of the organ erected in that city in 1596, recorded by Werckmeifter, in his "Org. Gruning. Rediv." See Organ, and Werckmeister.

Mancini, Giambatista, maeftro di canto della corte Imperiale, or finging-mafter to the Imperial court, and Accademico filarmonico, publifhed in 1774, at Vienna, a treatife on finging in 4to. intitled "Penfieri e Rifleffioni pratiche," or practical thoughts and reflexions on figurative fong; a work of merit, fuperior to any treatife on the fame fubject that has appeared fince the time of Tofi. The author was a fcholar of the famous Bernacchi, the celebrated difciple of Piftocchi, the founder of the Bologna fchool of finging, and mafter, not only of Mancini, but of Amadori, Guarducci and Raof, the celebrated tenor, all renowned opera fingers of the firft clafs during the laft century.

In the IId article, or fection of this book, the author gives a lift and character of all the moft celebrated opera fingers, male and female, from the time of Piftocchi down to Pacchiefatti and the Gabriele.

In the IIId fection he defcribes the vocal organ, its feveral parts, phyfical defects, and qualities neceffary to its perfection.

IV. Of the *voce di petto*, voice from the cheft; *voce di tefta*, *tesla*, or falset, and the art of uniting them, that is, the natural voice that comes from the chest, and the feigned voice that is merely formed in the throat, and the uniting them in such a manner, that the hearer cannot distinguish where nature ends and art begins.

V. Of intonation.

VI. Of the manner of opening the mouth, and emission of voice free from the teeth, nose, and throat.

VII. Of the portamento, and manner of forming, modulating, and conducting the voice.

VIII. Of the union of different registers of voice, of the apoggiatura and concealment of defects.

IX. Of the *messa di voce*, or swell, and description of the voice of Farinelli.

X. Of the shake and beat. The author calls the trill or shake the support, ornament, and life of song; "Oh trillo! sostegno, decoro, e vita del canto." Describes the shake *alla capro, alla cavallo*, or that resembles the goat's cough, or the neighing of a horse.

XI. Of the cadence or close.

XII. Of agility of voice or rapid execution.

XIII. Of the knowledge and accomplishments necessary to appearing on the stage as a public singer.

XIV. Of recitative and action.

XV. Of the sobriety and regularity of conduct necessary to a student in singing.

The author in conversation mentioned to us at Vienna, what he has since inserted in his book, a curious operation performed at Naples by signior Francisco Piccillo, an eminent surgeon, on the organ of voice, by cutting the glands of the throat, when so inflated or prominent as to obstruct the free passage of the voice. It is certain, says signior Mancini, that the glands of the throat may be safely removed, but it is likewise equally certain that the defect still remains. The operation was performed at Naples on three several persons in a most dextrous manner, with two cane-knives, without however meliorating the voice.

The ingenious author of this useful tract, who had himself been a capital vocal performer on the opera stage, and drew his rules from long practice and experience, died at Vienna about 1779. A third edition of the "Pensieri e Reflessione," and Mancini's "Treatise on Singing," appeared at Milan in 1778.

MANCIPIUM, or Manceps, in the language of ancient jurisprudence, was a name used to distinguish those spoils that were taken with the hand; and whenever they were sold or *emancipated*, the purchaser required some assurance that they had been the property of an enemy, and not of a fellow-citizen.

MANCIPLE, Manceps, in *Old Authors*, denotes a caterer. There was anciently an officer in the Temple called by this name, who is now called the steward; and both name and office are still retained in the colleges in both universities.

MANCO Capac, in *Biography*, legislator and first Inca among the Peruvians, was the twelfth in ascent from the Inca who reigned at the time of the Spanish invasion of Peru in 1532, which interval was computed by the natives at about 400 years. According to their tradition this personage, with his wife and sister Mama Ocollo, otherwise called Caya Mama, both of majestic form and clothed in decent garments, appeared in an island of the lake Titicaca, and declared themselves to be children of the sun, sent to civilize and instruct the savage people who then inhabited that country. Manco accordingly instructed the men in agriculture and other useful arts, while his wife taught the women to spin and weave. After this, Manco began to form them into a regular society, and to give them a system of laws and policy. Manco Capac, toward the close of a long and prosperous reign, assembled his numerous family and principal subjects in the city of Cuzco, and after a suitable exhortation he expired in their sight. His memory was held in the utmost veneration by his own people, and as far as we can rely upon the tradition annexed to his name, he seems justly entitled to rank among the benefactors of mankind. If what is supernatural be rejected from this tradition, it will appear that some stranger from a civilized land arrived in Peru, and, by calling in the aid of religion, obtained an ascendancy over the minds of the natives, which enabled him to form a regular government, and place himself at its head. Absolute power in the monarch was the necessary consequence of this sanctity of character, and the government took the form of a theocracy. Its civil institutions were directed to the preservation of order and tranquillity; its religious rites were for the most part innocent and humane; and gentleness and submission distinguished the Peruvians among the nations of South America. Robertson's Hist. of America.

MANCORA, in *Geography*, a town of Peru, in the diocese of Truxillo, on the road from Guayaquil to Truxillo, on the sea-coast; 70 miles N. of Payta.

MANCORON, a word used by the ancients to express what they call a sort of honey, which seems to have been evidently our modern *sugar*. They say that it was a sort of dry honey found concreted in canes or reeds, and was of the consistence of salt, and that it was found in India and Arabia Felix, and that when taken into the mouth, it broke under the teeth like salt.

MANCUNIUM, in *Ancient Geography*, a town of Britain mentioned in the 10th Iter or rout of Antonine's Itinerary, and supposed to be the same with *Manchester*; which see.

MANCUS, formed of *manu cusus*, in *Antiquity*, an Anglo-Saxon gold coin, equal in value to $2\frac{1}{2}$ solidi, or thirty pence; and in weight to fifty-five troy grains. The first account of this coin that occurs in the history of our country, is about the close of the eighth century, in an embassy of Cenwulf, king of Mercia, to Leo III. requesting the restoration of the jurisdiction of the see of Canterbury; this embassy was enforced by a present of 120 mancuses. Ethelwolf also sent yearly to Rome 300 mancuses: and these coins are said to have continued, in some form or other, till towards the conclusion of the Saxon government. The heriots of the nobility are chiefly estimated by this standard in Canute's laws. It came originally from Italy, where it was called ducat: and is supposed to have been the same with the drachma or miliarensis, current in the Byzantine empire. Clarke on Coins, p. 280, &c. See Mark.

MANDA, in *Geography*, an island in the straits of Malacca, near the coast of Sumatra, about 35 miles in circumference. N. lat. 0° 28′. E. long. 103 2′.

MANDACH, a village in the district of Wildenstein, in the Swiss canton of Aargau, on the left banks of the river Aar. The neighbourhood of this place is famous for the variety of petrifactions with which it abounds. The fields in its vicinity furnish numerous fragments of immense cornua ammonis, most of them several feet in diameter, likewise large quantities of petrified coralloids, such as milleporæ, porpytæ, trochitæ, terebratulitæ. Not far from Mandach, at Holwyl, elephants' tusks have been found, together with various species of cochlitæ, buccinitæ, turbinitæ, ostracitæ, echinitæ, &c. Still more of these fossil remains occur at Deutsch-

Deutsch-Beuren, among which is a vast stratum of gryphitæ, the prototypes of which do no longer exist; and, in a bed of sand, a thin stratum of the shell called concha hypocephaloides in its recent state, and hitherto not observed in any other place. Near Elfingen a stratum of small cochlitæ is seen, perfectly unmixed with other substances. In the neighbourhood of Veltheim we find belemnites, ammonites, tellinitæ, &c. in great profusion; and at Castelen and Schenkenberg, oolites, ostracitæ, chamitæ, &c.

All these petrifactions in the district of Wildenstein are deposited in the sand-stone formation, which overlays strata of lime-stone.

MANDADO, a small island in the East Indian sea, near the N. coast of Celebes. N. lat. 1° 18'. E. long. 124° 21'.

MANDAL, a sea-port town of Norway, in the province of Christiansand, at the mouth of a river of the same name; 19 miles W.S.W. of Christiansand. N. lat. 58° 2'. E. long. 7° 42'.

MANDALIG Islands, three or four small islands near the N. coast of Java. S. lat. 6° 27'. E. long. 110° 56'.

MANDAMUS, in *Law*, a writ issuing out of the court of king's bench, sent by the king, and directed to any person, corporation, or inferior court of judicature within the king's dominions; requiring them to do some particular thing therein specified, which pertains to their office and duty, and which the court of king's bench has previously determined, or, at least, supposes to be consonant to right and justice. This is a high prerogative writ, of a most extensive remedial nature; and may be issued in some cases, where the injured party has also a more tedious method of redress, as in the case of admission, or restitution to an office: but it issues in all cases where the party hath a right to have any thing done, and hath no other specific means of compelling its performance. A mandamus, therefore, lies to compel the admission or restoration of the party applying, to any office or franchise of a public nature, whether spiritual or temporal: to academical degrees; to the use of a meeting-house, &c. It lies for the production, inspection, or delivery of public books and papers; for the surrender of the regalia of a corporation; to oblige bodies corporate to affix their common seal; and to compel the holding of a court, &c. The writ of mandamus is made by statute (9 Ann. cap. 20.) a most full and effectual remedy for the refusal of admission, where a person is entitled to an office or place in any corporation, and also for wrongful removal, when a person is legally possessed. It may also be issued in pursuance of the statute, (11 Geo. I. cap. 4.) in case within the regular time no election shall be made of the mayor or other chief officer of any city, borough, or town corporate, or (being made) it shall afterwards become void; to require the electors to proceed to election, and proper courts to be held, for admitting and swearing in the magistrates so respectively chosen. This writ issues to the judges of any inferior court, commanding them to do justice according to the powers of their office, whenever the same is delayed. For it is the peculiar business of the court of king's bench to superintend all other inferior tribunals, and therein to inforce the due exercise of those judicial or ministerial powers, with which the crown or legislature has invested them; and this, not only by restraining their excesses, but by quickening their negligence, and obviating their denial of justice. A mandamus may, therefore, be had to the courts of the city of London, to enter up judgment (Raym. 214.); to the spiritual courts to grant an administration, to swear a churchwarden and the like. This writ is founded on a suggestion, by the oath of the party injured, of his own right, and the denial of justice below: whereupon, in order more fully to satisfy the court that there is a probable ground for such interposition, a rule is made (except in some general cases, where the probable ground is manifest), directing the party complained of to shew cause why a writ of mandamus should not issue; and if he shews no sufficient cause, the writ itself is issued, at first in the alternative, to do thus, or signify some reason to the contrary; to which a return or answer must be made, at a certain day. And if the inferior judge, or other person to whom the writ is directed, returns or signifies an insufficient reason, then there issues in the second place a peremptory mandamus, to do the thing absolutely; to which no other return will be admitted, but a certificate of perfect obedience and due execution of the writ. If the inferior judge or other person makes no return, or fails in his respect and obedience, he is punishable for his contempt by attachment. But if he, at the first, returns a sufficient cause, although it should be false in fact, the court of king's bench will not try the truth of the fact upon affidavits; but will for the present believe him, and proceed no farther on the mandamus. But then the party injured may have an action against him for his false return, and (if found false by the jury) shall recover damages equivalent to the injury sustained; together with a peremptory mandamus to the defendant to do his duty. Blackst. Com. book iii.

Mandamus was also a charge to the sheriff, to take into the king's hands all the lands and tenements of the king's widow, who, against her oath formerly given, married without the king's consent.

MANDANS, the name of those Indians who inhabit the vicinity of the Missouri in Louisiana. These Indians are brave, humane, and hospitable; and are, upon the whole, the most friendly and well-disposed in this part of the country. About thirty years ago they lived in six villages, about forty miles below their present villages, on both sides of the Missouri. Repeated visitations of the small-pox, together with frequent attacks of the Sioux, have reduced them to their present number. They claim no particular tract of country. They live in fortified villages, hunt in their own neighbourhood, and cultivate corn, beans, squashes, and tobacco, which form articles of traffic with their neighbours, the Assiniboins: they also barter horses with them for arms, ammunition, axes, kettles, and other articles of European manufacture, which the Assiniboins obtain from the British establishments on the Assiniboin river. The articles which they thus obtain from the Assiniboins, and the British traders who visit them, they again exchange for horses and leather tents with the Crow Indians, Chyennes, Watapahatoes, Kiawes, Kanenavich, Stactan, and Kataka, who visit them occasionally for the purpose of traffic. Their trade may be much increased. Their country is similar to that of the Ricaras: and their population is increasing. Jefferson.

MANDAR, a town of the island of Celebes; 125 miles N. of Macassar.

MANDARA, a town of Egypt, on the E. branch of the Nile; 38 miles N. of Cairo.

MANDAREE, a town of Bengal; 30 miles N.N.W. of Midnapour.

MANDARIN, a name given by the Portuguese to the nobility and magistracy of the eastern countries, especially to those of China.

The word mandarin is unknown in this sense among the Chinese, who, in lieu thereof, call their grandees and magiſtrates *quan*, or *quan fu*, q. d. ſervant or miniſter of a prince.

In China they have two claſſes of mandarins, thoſe of letters and thoſe of arms, who compoſe what is called the nobility. Theſe mandarins enjoy a very diſtinguiſhing privilege; in caſes of neceſſity, they may remonſtrate with the emperor, either individually, or as a body, upon any action or omiſſion on his part which may be contrary to the intereſts of the empire. Their remonſtrances are ſeldom ill-received by the ſovereign; but he reſerves to himſelf the right of paying to them that attention which he thinks they deſerve. Theſe mandarins are choſen from the *Literati* (which ſee), who are highly honoured in China. A mandarin of arms, however, is far from enjoying the ſame conſideration as a mandarin of letters; and hence it happens, that there is little emulation among the higher military ranks.

In order to obtain the degree of *mandarin of letters*, it is neceſſary to paſs through ſeveral other gradations: ſuch as that of bachelor (*ſie* or *tſai*), of licentiate (*kiu-gin*), and of doctor (*tſing ſsëe*). Sometimes by favour it is ſufficient to have attained to the two firſt degrees; but even thoſe on whom the third is conferred obtain at firſt only the government of a city of the ſecond or third claſs: and the manner of election is as follows: when ſeveral places happen to become vacant, the emperor invites to court a like number of literati, whoſe names are inſcribed in a liſt. The names of the vacant governments are put into a box, which is raiſed ſo high, that the candidates can only reach it with their hands. They then draw in their turns, and each is appointed governor of that city of which he has drawn the name.

There are eight orders of mandarins in China. The firſt is that of "Calao." Their number depends upon the will of the prince. Miniſters of ſtate, the preſidents of the ſupreme courts, and all the ſuperior officers of the militia, are choſen from this order, the chief of which is called "Cheou-ſiang." He is preſident of the emperor's council, and in him the emperor always repoſes great confidence. From the ſecond order of mandarins are ſelected the viceroys and preſidents of the ſupreme councils of the different provinces. Every mandarin of this rank is called "te-hioſe," *i. e.* a man of acknowledged ability. The title of "tchong-chueo," or ſchool of mandarins, is given to thoſe of the third order. One of their principal functions is that of ſecretary to the emperor. Certain employments are alſo aſſigned to each of the other claſſes. It is the buſineſs of mandarins of the fourth order, ſtyled "y-tchuen-tao," when no particular government is entruſted to them, or when they belong to no fixed tribunal, to keep in repair the harbours, royal lodging-houſes, and banks, of which the emperor is proprietor, in their diſtrict. The fifth order ("ping-pi-tao") have the inſpection of the troops. The ſixth ("tun-tien-pao") have the care of the highways. The ſeventh, or "ho-tao," have the ſuperintendance of the rivers; and the eighth, called "hai-tao," that of the ſea-coaſts. In a word, the whole adminiſtration of the Chineſe empire is entruſted to the mandarins of letters. From among them are choſen the governors of provinces, the governors of cities of the firſt, ſecond, and third claſs, and the preſidents and members of all the tribunals. Honours are laviſhed upon them, and every privilege and mark of diſtinction ſeem to be reſerved for them alone. The homage which the people pay to every mandarin in office is almoſt equal to that which is paid to the emperor himſelf. Among the Chineſe it is a received opinion, that their monarch is the father of the whole empire; that the governor of a province is the father of that province; and that the mandarin, who is governor of a city, is alſo the father of that city. The homage which the mandarins of letters receive is not diminiſhed by their great number. They amount to more than 14,000; and yet the veneration which the people entertain for them is always the ſame.

Public honours are more ſparingly beſtowed upon the *mandarins of arms*. They are never indulged with the ſmalleſt ſhare in the government of the ſtate; and yet, in order to be admitted to this rank, it is neceſſary, as well as for that of a mandarin of letters, to have paſſed through the three degrees of bachelor of arms, licentiate in arms, and doctor of arms. Strength of body, agility in performing the different military exerciſes, and a readineſs in comprehending and executing orders, are all the previous qualifications required in mandarins of arms; and in theſe conſiſt the various examinations which candidates are obliged to undergo before they can be admitted to that rank. Candidates for the two firſt degrees are always examined in the capital city of the province. The mandarins of arms have tribunals, the members of which are ſelected from among their chiefs. Among theſe they reckon princes, dukes, and counts, all which dignities, or other equivalent to them, are found in China. The principal of theſe tribunals is fixed at Peking, and it is compoſed of five different claſſes, *viz.* that of the mandarins of the rear-guard, named "Heou-fou," that of the mandarins of the left wing, called "Tſa-fou," that of the mandarins of the right wing, ſtyled "Yeou-feou," that compoſed of the mandarins of the advanced main-guard, known by the name of "Tchong-fou," and that conſiſting of the mandarins of the advanced guard, called "Tſien-fou." Theſe five tribunals are ſubordinate to a ſupreme tribunal of war, called "Iong-tching-fou," which is alſo eſtabliſhed at Peking. The preſident of this tribunal is one of the great lords of the empire, whoſe authority extends over all the officers and ſoldiers of the army. This preſident has for his aſſeſſor a mandarin of letters, who enjoys the title, and exerciſes the function of ſuperintendant of arms. He is required to take the advice of two inſpectors, who are named by the emperor; and when theſe four perſons have agreed upon any meaſure, their reſolution muſt ſtill be ſubmitted to the reviſion of a fourth ſupreme court, called "Ping-pou," which is entirely of a civil nature. The chief of the mandarins of arms is a general by birth; his power in the field is equivalent to that of our commander-in-chief. Under him there is a certain number of mandarins, who act as lieutenant-generals; other mandarins diſcharge the duty of colonels, captains, lieutenants, and enſigns. It is computed that there are in China between eighteen and twenty thouſand mandarins of war; in this reſpect they are ſuperior to the mandarins of letters; but the importance of the latter makes them to be conſidered the firſt and principal body in the empire. Thus, literature is encouraged, but military ardour is checked. The weakneſs of the mandarins of arms occaſioned the conqueſt of China by the Tartars; and they have made no alteration ſince in theſe two branches of the Chineſe conſtitution.

The viceroy of a province, diſtinguiſhed by the title of "Tſong-tou," is always a mandarin of the firſt claſs, and his power in his diſtrict is almoſt unlimited. He never quits his palace without a guard of 100 men. He is the receiver-general of all the taxes collected in his province, and by him they are tranſmitted to the capital. All law-ſuits are brought to his tribunal, and he has the power of condemning criminals to death; ſubject, however, in the exerciſe of it, to the approbation or confirmation of the emperor. The viceroy, every three years, tranſmits to court an account of the conduct of ſubordinate mandarins; and ſuch is his influence, that they are accordingly continued in office or difgraced. The conduct of the viceroy himfelf is watched by infpectors, whofe authority is formidable to him; and more efpecially to inferior mandarins, whom he has power to deprive of their employments for mifbehaviour. In order to prevent partiality among the mandarins, relations in the fourth degree cannot have a feat at the fame time in any of the provincial tribunals. Sick or fuperannuated mandarins are liberally provided for by government. All mandarins, whether Tartars or Chinefe, of arms or of letters, are obliged, every three years, to give in writing an exact account of the faults they have committed in difcharging the duties of their office; and this kind of confeffion is examined at court, if the mandarin belong to any of the four firft claffes: but if it be made by any mandarins of the lower claffes, it muft be laid before the provincial tribunal of the governor. Informations, as the refult of private inquiry, are addreffed to the tribunal of mandarins, and there carefully examined: and diftributive juftice is exercifed accordingly. Every mandarin who has difcharged his duty with ability, zeal, and fidelity, is rewarded; but if he has been guilty of oppreffion and malpractices, he is not only difmiffed, but impeached, and tried before the tribunal of crimes.

Since the time that the Tartars have rendered themfelves mafters of China, moft of the tribunals, or courts of juftice, &c. inftead of one mandarin for a prefident, have two, the one a Tartar, and the other a Chinefe.

The mandarinate is not hereditary. Duhalde. Grofier.

Mandarin is alfo a name which the Chinefe give to the learned language of the country

Befides the proper and peculiar language of each nation and province, they have one common to all the learned men in the empire. This they call the mandarin tongue, or the language of the court. Their public officers, as notaries, lawyers, judges, and chief magiftrates, write and fpeak the mandarin.

MANDATA, in *Geography*, a town on the S.W. coaft of Sumatra; 45 miles S.E. of Indrapour.

MANDATARY, Mandatarius, he to whom a command or charge is given: and he that comes to a benefice by a mandamus is called by this name.

MANDATE, Mandatum, in the *Canon Law*, denotes a refcript of the pope, by which he commands fome ordinary, collator, or prefenter, to put the perfon there nominated in poffeffion of the firft benefice vacant in his collation.

An apoftolical mandate for the provifion of benefices, is a monitorial and comminatory letter from the pope to a bifhop, by which he is enjoined to provide a fubfiftence for thofe who have been ordained by him, or his predeceffors, from the tonfure to facred orders inclufively; and to allow them their fubfiftence till they be provided with a benefice. This practice was occafioned by the bifhops formerly laying hands on great numbers, and afterwards abandoning them to mifery and want.

At firft the popes only gave monitory mandates, which were no more than fimple prayers and requefts, that did not bind the ordinary; afterwards they gave preceptory mandates, which did not annul the provifions of the ordinary; at laft they fet up executory mandates, by which the provifions made by the ordinary, in prejudice of the mandate, were declared null; and the executor of the mandate, in default of the ordinary, conferred the benefice on the mandatory: but the pope's power in iffuing thefe mandates is now very much reftrained, and almoft totally annulled.

Mandates, *Royal*, to judges for interfering in private caufes, conftituted a branch of the royal prerogative, which was given up by our Englifh Juftinian, Edward I.; and alfo by 2 Edw. III. c. 8, and 11 Ric. II. c. 10, it is enacted, that no commands or letters fhall be fent under the great feal, or the little feal, the fignet, or privy feal, in difturbance of the law; or to difturb or delay common right; and, though fuch commandments fhould come, the judges fhall not ceafe to do right; which is alfo made a part of their oath by ftatute 18 Edw. III. ft. 4; and by 1 W. & M. ft. 2. c. 2, it is declared, that the pretended power of fufpending, or difpenfing with laws, or the execution of laws, by regal authority, without confent of parliament, is illegal.

MANDATTA, in *Geography*, a town of Hindooftan, in Candeifh; 30 miles S.S.E. of Indore.

MANDAVEE, a town of Hindooftan, in Guzerat; 25 miles E. of Surat.—Alfo, a town of Hindooftan, in Baglana; 12 miles N.N.E. of Baffeen.

Mandawee *Iflands*, a clufter of fmall iflands in the Eaft Indian fea, near the S. coaft of Borneo. S. lat. 3° 20'. E. long. 113° 30'.

MANDAYA, a town on the W. coaft of the ifland of Celebes. S. lat. 2° 33'. E. long. 119° 9'.

MANDE', St., a fmall ifland in the Englifh channel, near the coaft of France. N. lat. 48° 51'. W. long. 2° 59'.

MANDEGELE, a town of the ifland of Ceylon, near the E. coaft; 88 miles E.S.E. of Candy.

MANDELGUR, a town of Hindooftan, in the circar of Meywar; 14 miles N. of Cheetore.

MANDELLI, a town of Abyffinia; 150 miles E. of Gondar.

MANDELSLO, John-Albert, in *Biography*, a native of Mecklenburg, was page to the duke of Holftein, and accompanied, as gentleman of the chamber, the embaffadors whom that duke fent to Mufcovy and Perfia in 1636. From the court of Perfia, he went to Ormuz, and embarked for the Indies. On his return he drew up a "Journal of his Voyages," which is printed in the fecond volume of the Travels of Olearius, who was fecretary to the embaffy, and is held in much efteem. Moreri.

MANDELSTEIN, in *Mineralogy*. See Trap.

MANDERA, in *Geography*, a town of Africa; 120 miles N.E. of Sennaar. N. lat. 14° 45'. E. long. 35° 10'.

MANDERSCHEID, a town of France, in the department of the Sarre, and chief place of a canton, in the diftrict of Prum; 21 miles N.N.E. of Treves. The place contains 323, and the canton 2595 inhabitants, in 24 communes.

MANDERY, a town of Hindooftan, in Dowlatabad; 10 miles W.N.W. of Ranapour.

MANDEVILLE, *Sir* John, in *Biography*, a celebrated early traveller, was born at St. Albans about the beginning of the fourteenth century. He was intended for the profeffion of phyfic, which he probably practifed, but an ardent defire of vifiting foreign countries induced him, in 1332, to fet out upon a courfe of travels, in which he fpent more than thirty years. During this period he extended his peregrinations through the greateft part of Afia, Egypt, and Lybia, making himfelf mafter of many languages, and collected a great mafs of information, which he committed to writing in Latin, Englifh, and French. He died at Liege in the year 1372. The only genuine edition of his travels is thus entitled, "The Voiage and Travaile of fir John Mandeville, knight:" it was printed from the original MS. in the Cottonian library, 1727. The character of fir John, for veracity, has been very differently regarded by different and competent judges; his narratives were highly efteemed in his own age, and they rendered him celebrated throughout Europe,

Europe. By fome of his remarks it fhould feem that he had a general acquaintance with the fcience of the period in which he flourifhed.

MANDEWAR, in *Geography*, a town of Hindooftan, in Bahar; 32 miles S.S.W. of Arrah.

MANDIBLE, the *Jaw*, in *Anatomy*. See MAXILLA and CRANIUM.

MANDIBULARES, or MANDUCATORII *Mufculi*. See MASSETER and DEGLUTITION.

MANDIL, or MANDRIL, the name of a kind of cap or turban worn by the Perfians.

The mandil is formed by firft wrapping round the head a piece of fine white linen five or fix ells long; over this they wrap, in the fame manner, a piece of filk of the fame length, and often times of great value. To make the mandil genteel, care muft be taken, that, in wrapping the filk, it be fo managed, as that the feveral colours found in the feveral folds make a kind of waves, fomewhat like what we fee on marbled paper.

The drefs is extremely majeftic, but at the fame time very heavy: it ferves either as a fhelter to the head from cold, or as a fcreen from the exceffive heat of the fun; it is faid, that a blow of a cutlafs will not penetrate it. In rainy weather they cover it with a kind of cafe or hood, made of red cloth.

The mode of the mandril has been for fome time altered: during the time of Schah-Abbas II. it was round at top; in the time of Schah-Soliman, they brought one end of the filk out of the middle of the mandril over the head; and, laftly, in the reign of Schah-Huffein, the end of the filk, in lieu of its being gathered as before, was plaited in manner of a rofe; and this the Perfians account extremely graceful, and ufe it to this day.

MANDING, or MANDINGA, in *Geography*, a country of Africa, fituated on both fides of the river Joliba or Niger, towards its fources, and fupplying thofe ftreams or rivers, called Bafing and Kokoro, that form the Senegal. This country comprehends a confiderable tract from between 11° and 13° N. lat. and between about 5° and 7° W. long. The inhabitants of this country, and thofe of other diftricts in the weftern part of Africa, who have probably migrated from hence, are called Mandingoes, and their language has a confiderable extent. The government of this country is faid to be republican, though that of the other African ftates is, in general, monarchical. In their complexions and perfons, the Mandingoes are eafily diftinguifhed from thofe Africans who are born nearer to the equator; and yet they confift of very diftinct tribes, fome of which are remarkably tall and black; and there is one tribe among them (called alfo the Phulies) that feemed to Mr. Edwards to conftitute the link between the Moors and Negroes, properly fo called. They are of a lefs gloffy black than the Gold Coaft negroes; and their hair, though bufhy and crifped, is not woolly, but foft and filky to the touch. Neither have the Mandingoes, in common, the thick lips and flat nofes of the more fouthern natives; and they are, in a great degree, exempt from that ftrong and fetid odour which exhales from the fkin of moft of the latter; but in general they are not well adapted for hard labour. After all, they differ lefs in their perfons, than in the qualities of the mind, from the natives of the Gold Coaft; who may be faid to conftitute the genuine and original unmixed negro, both in perfon and character. See KOROMANTYN *Negroes*.

The Mandingoes, in general, are of a mild, fociable, and obliging difpofition; the men are commonly above the middle fize; and the women are fprightly, good-humoured, and agreeable. The drefs of both fexes confifts of cotton cloth, of their own manufacture; that of the men is a loofe frock, not unlike a furplice, with drawers which reach half-way down the leg, and they wear fandals on their feet, and white cotton caps on their heads. The women's drefs confifts of two pieces of cloth, each of which is about fix feet long and three broad; one of which they wrap round the waift, which, hanging down to the ancles, ferves for a petticoat, and the other is thrown negligently over the bofom and fhoulders. In the conftruction of their houfes, the Mandingoes, like the other Africans, in this part of the continent, content themfelves with fmall hovels. A circular mud-wall, about four feet high, upon which is placed a conical roof compofed of the bamboo cane, and thatched with grafs, forms their common dwelling for people of all ranks. Their houfhold furniture is no lefs fimple; a hurdle of canes placed upon upright ftakes, about two feet from the ground, upon which is fpread a mat, or bullock's hide, anfwers the purpofe of a bed; a water jar, fome earthen pots for dreffing their food, a few wooden bowls and calabafhes, and one or two low ftools, are their other domeftic articles. As every man of free condition has a plurality of wives, it becomes neceffary, for the prevention of difputes, to accommodate each lady with a hut to herfelf; and all the huts belonging to the fame family are furrounded by a fence conftructed of bamboo canes, fplit and formed into a fort of wicker work. The whole inclofure is denominated a "firk," or "furk." A number of thefe inclofures, feparated by narrow paffages, conftitute what is called a town; in which the houfes are placed without any order, except that the door is fituated towards the fouth-weft, in order to admit the fea-breeze. Their religion is, as we may conceive, blended with many fuperftitious opinions and practices. Although they admit the exiftence of a deity, as the maker and preferver of all things, they confider him as too remote and too exalted in his nature to regard the fupplications of wretched mortals, or to alter for their fake any of his purpofes and decrees. The prayers which are offered up at the appearance of the new moon are performed merely in conformity to a cuftom which has been tranfmitted to them from their anceftors. Subordinate fpirits, as they imagine, are entrufted by the almighty with the fuperintendence and direction of all human concerns; and thefe fpirits are much under the influence of certain magical ceremonies. The rite of circumcifion prevails in this part of Africa even by thofe negroes, who have never received the religion of Mahomet. The Jaloffs confine it to the males; but the Mandingoes, both Soninkees and Bufhreens, extend the ceremony to both fexes, as the ancient Egyptians did before them; and the operation is performed at the commencement of puberty. Mr. Park, in his "Travels," informs us, that the negroes, in general, did not feem to confider this painful rite as an act of religious duty, and as fuch, effential to their future falvation; but rather as an operation of phyfical neceffity; without which the marriage ftate could not, in their opinion, be prolific. (See CIRCUMCISION.) We learn alfo from this obferving and intelligent traveller, that the negroes of this part of Africa firmly believe in a life beyond the grave, and a ftate of retribution after death, in which good men will be rewarded, and bad men punifhed. He converfed with the natives of all defcriptions on this important fubject, and pronounces, without the fmalleft hefitation, that a conviction of this great truth among the negroes is entire, hereditary, and univerfal.

Among the Mandingoes there are few or no inftances of longevity: at 40, moft of them become grey-haired and wrinkled; and few furvive the age of 50 or 60, counting their years by the number of rainy feafons, one of which only occurs in the year. Their difeafes, however, are few; the

the principal being the dyſentery, the yaws, the elephantiaſis, and a leproſy of the worſt kind. The Guinea worm is alſo in ſome places very common, eſpecially at the commencement of the rainy ſeaſon, and this they attribute to bad water; to which they likewiſe aſcribe the goitres, or ſwellings of the neck, which are very common in ſome parts of Bambarra.

The principal of their muſical inſtruments are the koonting, a ſort of guitar with three ſtrings; the korro, a large harp with eighteen ſtrings; the ſimbing, a ſmall harp with ſeven ſtrings; the balafon, compoſed of twenty pieces of hard wood of different lengths, with the ſhells of gourds hung under them, for increaſing the ſound; the tangtang, a drum open at the lower end; and the tabala, a large drum uſed for cauſing an alarm through the country. Beſides theſe, they make uſe of ſmall flutes, bow-ſtrings, elephants' teeth, and bells; and at all their dances and concerts, clapping of hands conſtitutes a neceſſary part of the chorus.

The beverage of the pagan Negroes is beer and mead, in the uſe of which they are apt to indulge to exceſs. The Mahometan converts drink nothing but water. The natives of all deſcriptions take ſnuff, and ſmoke tobacco; and their pipes are made of wood, with an earthen bowl of curious workmanſhip. But in the interior diſtricts, the greateſt of all luxuries is ſalt. The arts of weaving, dyeing, ſewing, &c. are univerſally practiſed; but the only artiſts, acknowledged as ſuch by the Negroes, are the manufacturers of leather and iron. They tan and dreſs leather very expeditiouſly, by firſt ſteeping the hide in a mixture of wood-aſhes and water, until it parts with the hair; and afterwards uſing the pounded leaves of a tree called goo, as an aſtringent. Moſt of the African blackſmiths are acquainted with the method of ſmelting gold; in which proceſs they uſe an alkaline ſalt, obtained from a ley of burnt corn-ſtalks, evaporated to dryneſs. They likewiſe draw gold into wire, and form it into a variety of ornaments, with great ingenuity and taſte. Gold is found in every part of Mandingo, in ſmall grains, nearly in a pure ſtate, from the ſize of a pin's head to that of a pea.

The Mandingoes, moſt of whom are proſelyted to Mahometaniſm, have frequent wars with each other, as well as with thoſe nations regarded by them as enemies of their faith. The advantage poſſeſſed by a few of theſe people, of being able to read and write, is a circumſtance on which the Mandingo Negroes in the Weſt Indies pride themſelves greatly among the reſt of the ſlaves, over whom they conſider themſelves as poſſeſſing a decided ſuperiority; and in truth, ſays Mr. B. Edwards, they diſplay ſuch gentleneſs of diſpoſition and demeanour, as would ſeem to be the reſult of early education and diſcipline, were it not that, generally ſpeaking, they are more prone to theft than any of the African tribes. It has been ſuppoſed that this propenſity, among other vices, is natural to a ſtate of ſlavery, which degrades and corrupts the human mind in a deplorable manner; but why the Mandingoes ſhould have become more vicious in this reſpect than the reſt of the natives of Africa, in the ſame condition of life, is a queſtion not eaſily reſolved. Edwards's Hiſt. of the Weſt Indies, vol. ii.

MANDIOLY, an iſland in the Eaſt Indian ſea, of a ſemicircular form, about 120 miles in circumference, ſeparated from the weſt coaſt of Gilolo by the ſtraits of Patientia, and belonging to the ſultan of Bachian. The iſland is centrally traverſed by the equator. E. long. 124°.

MANDOE, a ſmall iſland in the German ocean, near the coaſt of Sleſwick; 10 miles W.S.W. of Ripen. N. lat. 55° 10'. E. long. 8° 32'.

MANDOLA, a town of Italy, in the marquiſate of Ancona; 30 miles N.E. of Spoleto.

Mandola, and *Mandora*, Ital.; *Teſtudo minor*, Lat.; *Mandole*, and *Mandoline*, Fr.; a very ſmall inſtrument, in form of a violin, with four ſtrings, and a fretted neck, played with a quill in the right hand inſtead of a bow. About thirty years ago there was a Neapolitan here, of the name of Franceſe, who played admirably on this diminutive tinkling inſtrument, which had very little tone or variety of expreſſion; yet, by his taſte, fancy, and enthuſiaſm, Franceſe entertained lovers and nice judges of muſic during ſeveral hours, without tiring them with its monotony, or rather total want of tone.

MANDORE, a ſmall lute or guitar, with four ſtrings, tuned fourths and fifths, ſometimes thrummed with the finger, and ſometimes played with a quill, like the mandoline.

MANDRA, in *Geography*, a town of Ruſſia, in the government of Irkutſk; 76 miles N.E. of Kirenſk.

MANDRAGORA, in *Botany*. See Atropa and Dudaim.

Mandragora, *Chineſe*, is the plant *Ginſeng*; which ſee.

MANDRAKE. See Atropa and Dudaim.

The roots of mandrake vary both in form and colour, being either divided or entire, and externally brown or black: hence they have been diſtinguiſhed into male and female. The internal ſubſtance is white, and to the taſte ſomewhat viſcid, bitter, and nauſeous.

Mandrake, in the *Materia Medica*, has been recommended in caſe of barrenneſs, but without foundation. All the eminent writers on mandrake repreſent the root to be an anodyne and ſoporific; but in large doſes it is ſaid to excite maniacal fury. They employed it principally in continued watchings, and in thoſe more painful and obſtinate affections which were found to reſiſt leſs powerful medicines. It was alſo uſed in melancholia, convulſions, rheumatic pains, ſcrophulous tumours, &c.: and for theſe purpoſes, either the expreſſed juice of the cortical part of the root, inſpiſſated, or a vinous decoction or infuſion of the root, was directed. Pallas alſo mentions it as of frequent uſe for chronic diſeaſes in ſome parts of Ruſſia. (See Atropa *Mandragora*.) The experiments, recited under that article, ſhew that the mandrake acts as an opiate; which confirms the opinion entertained by the ancients: and hence it may be concluded, that if it be not adminiſtered with great care, it may prove a deleterious and mental narcotic. This caution is the more neceſſary, as the berries of mandrake are ſaid to have been eaten without producing any bad effect. Woodville.

Mandrake-*Wine*, *Mandragorites Vinum*, a ſort of medicinal impregnation of wine with the virtues of mandrake root. It is prepared by cutting into thin ſlices half a pound of the bark of mandrake roots, and ſtringing them on a thread, and letting them down into a veſſel containing nine gallons of white wine, ſo that they may hang looſely in it, and by that means fully impregnate it with their virtues. It was uſed in ſmall doſes as an anodyne and ſoporific. It had the ſame effects alſo, if only ſmelled to, and was ſometimes injected in clyſters to the ſame purpoſe. They ſay that half a pint of this liquor, mixed with twelve times its quantity of wine, brings on a carus; and that even a ſmaller doſe than this, leſs diluted, is mortal. See the preceding article, and Atropa *Mandragora*.

MANDREL, a kind of wooden pulley, making a member of the turner's lathe.

Of thefe there are feveral kinds; as,

Mandrels, *Flat*, which have three or more little pegs or points near the verge, and are ufeful for turning flat boards on.

Mandrels, *Pin*, which have a long wooden fhank to fit into a round hole made in the work to be turned.

Mandrels, *Hollow*, which are hollow of themfelves, and ufed for turning hollow work.

Mandrels, *Screw*, for turning fcrews, &c.

MANDRIL, in *Zoology*, a fpecies of baboon, or monkey. See Simia *Maimon*.

MANDSHURES, in *Geography*, people of Siberia who form two nations, the one called Mandfhu or Mandfhures, and the other Tungufes. Both thefe nations are related by defcent, as we may conclude from their traditions, their language, and their bodily ftructure. The whole fwarm together poffeffes extenfive countries and deferts in eaftern Siberia, and in the northern Mongolia. The Mandfhu are ftill very powerful; one of their princely families being in hereditary poffeffion of the throne of China. Before the Ruffians entered Siberia, the Mandfhures were in poffeffion of all Daouria, or the eaftern Siberia, from the Baikal quite to the Mongolian mountains, together with the regions adjacent to the Amoor, and its collateral rivers. They were at that time divided into feveral ftems, of which the Daourians inhabited the parts about the Selenga and the Upper Amoor; the Dutfchares dwelt between the Argoon and the Schilka; the Atfchares about the middle Amoor; and the Ghiliaks at the mouth of the Amoor, on the coafts of the Eaftern ocean.

The Daourian Mandfhu, not waiting for the arrival of the Ruffians in their territories, retreated to the Amoor, and into the empire of China. At the firft Ruffian expedition, about the middle of the feventeenth century, the Daourians and Dutfchares were fubjects of the Chinefe emperor, who, as a native Mandfhu, aided their flight, and afforded them protection. The Ghiliaks and Atfchares fubfifted then in a ftate of independence, and accepted the Ruffian patronage without oppofition. Their example was followed by confiderable multitudes of the other two ftems; but moft of them, by orders of the Chinefe government, were tranfported from the Amoor, of which the Ruffians had made themfelves mafters, farther towards China. Afterwards, at a peace concluded at Nertfchinfk, the whole of the Amoor, with all the Mandfhures belonging to Ruffia, was ceded to China; and at prefent, the mountain-ridge Stannovoi Khrebet, which ftretches from Daouria northeaftward between the rivers Lena and Amoor to the Eaftern ocean, forms the boundary betwixt the two empires. In the frontier mountains themfelves, however, are no Mandfhures, but Tungufes, who are partly tributary to the Chinefe, partly to Ruffia, or live in complete independence.

The Mandfhu, particularly the Daourian, while they inhabited the modern Ruffia, were by no means an uncivilized people. According to their written accounts and traditions, they had a conftitution compofed of nomadic and civil parts, and adapted to their fituation, their mode of life, &c. They lived peaceably among themfelves and with their neighbours, attending fedulonfly to agriculture, grazing, and even to mining. Traces are ftill feen about the Bargufin, and other rivers, of their gardens, orchards, and fields, artfully laid out, and watered with artificial water-courfes. The Daourian mine-works on the banks of the Argoon, ftill famous under the name of the Nertfchinkian mines, as well as all Daouria, afford numerous proofs of the mineral labours of the ancient Daourians. Tooke's Ruff. Emp. vol. i. See Tunguses.

The country of the Mandfhures is divided by the Chinefe into three great governments. 1. That of Chin-yang or *Chen-yang*; which fee. 2. The government of Kiren-Oula. (See Kirin.) 3. The government of *Tfitchicar*; which fee. See *Mantcheew* Tartars.

MANDSJADE, in *Botany*, is an Indian filiquous or pod-bearing tree, with a fpiked pentapetalous flower, and long pods containing nodous fcarlet-coloured beans; the tree is one of the talleft in the kingdom of Malabar, bears fruit the twentieth year after planting, and living near two hundred years.

The wood is of common ufe for various purpofes, on account of its folidity; the leaves, reduced to powder, are ufed in the pagan religious rites; the feeds, which are not ungrateful to the tafte, are eaten by the common people, either boiled whole or ground to a meal; and are, befides, of great ufe to goldfmiths and jewellers, who, on account of their exact equality, employ them inftead of grains in weighing their wares; for each maljelina, as they call them, weighs four grains, fuch as are in ufe among the goldfmiths; who, alfo of the bruifed feeds, moiftened with water and borax, prepare a glue for conglutinating the finer fort of veffels, when broken. Of the bruifed leaves the phyficians prepare a potion for mitigating pains in the loins.

MANDU, in *Geography*, a town of Hindooftan, in Myfore; 10 miles N.E. of Seringapatam.

MANDUCATION, the action of *chewing*, otherwife called *maftication*.

Manducation is a term feldom ufed but in fpeaking of the eucharift. The Catholics maintain a real manducation of the body of Chrift; the reformed, on the contrary, take this manducation to be only figurative, and by faith. St. Auguftine calls it *fpiritual manducation*.

MANDUN, in *Geography*, a town of Hindooftan, in Guzerat; 30 miles S.E. of Janegur.

MANDURIA, an ancient town of Naples, in Calabria Citra. After having funk into decay, it was rebuilt at a little diftance from its former feite, and called "Cafale Nuovo," which name it retained till the year 1790, when, at the requeft of the inhabitants, the original name was reftored. It contained about 4000 inhabitants. In 1783 it fuffered very much by an earthquake.

MANE', a fea-port on the W. coaft of Madagafcar, at the mouth of the river Manfiatre. S. lat. 33° 35'.

Mane *of a Horfe*, in the *Manege*. (See Horse.) The adjuftment of the manes of horfes was an object of particular attention among the Armenians, and others who valued themfelves on their breed of thefe animals. Some, as we learn from Vegetius, ufed to cut them clear off, a practice which he condemns, becaufe it rendered the horfe unfightly and deformed. Others clipped them, fo as to make them refemble an arch or bow, called by us an "hog's mane." Others again feparated the mane into notches, like the battlements of a tower; while fome cut it clofe, but only on one fide, leaving the hair long and flowing on the other, which was very graceful and becoming: the fide on which the mane was turned and repofed being always to the right. To this Virgil alludes, when he directs the mane to be laid on the right fhoulder.

"Denfa juba, et dextro jactata recumbit in armo."

This method was practifed by the Perfians as well as the Armenians; and appears, by the above citation, to have been

been in uſe with the Romans, as well as that of ſhearing the manes of their "manni" or nags; whence Propertius ſays, his miſtreſs Cynthia was carried in her litter by ſhorn horſes.

"Et mea detonſis advecta eſt Cynthia mannis."

Varro likewiſe directs the mane to be turned to the right ſide. They alſo tied it in knots, or plaited it, as the word "implicata" (lib. iv. c. 7.) aptly expreſſes. No particular reaſon is aſſigned for always turning the mane on the right ſide: it might be owing, perhaps, to the cuſtom of mounting on the right, which was frequently, but not always, the practice; and in that caſe, the mane hanging on the ſide, from which the horſeman got up, offered itſelf to his hand to aſſiſt him in the action; while we, without any meaning, always mount on the left, and always turn the mane to the right. The Armenians, as well as the Parthians, had another method of trimming their horſes, by which they made them as it were "double maned;" for the hair being cut away in the middle, the mane was divided, and falling down, clothed each ſide of the neck; a faſhion ſometimes uſed at preſent, but generally among coach horſes. Berenger's Hiſt. &c. of Horſemanſhip, vol. i.

Mane-*ſheet*, is a ſort of covering for the upper part of a horſe's head, and all round his neck, which at one end has two holes for the ears to paſs through, and then joins to the halter upon the fore-part of the head, and likewiſe to the ſurcingle, or long girth, upon the horſe's back.

MAN-EATER's Island, in *Geography*, a ſmall iſland in the Indian ſea, near the N. coaſt of the iſland of Java, between Batavia and Bantam.

MANEBELLO, a ſmall iſland in the Eaſt Indian ſea. S. lat. 4° 9'. E. long. 131° 58'.

MANEGE. A horſe is ſaid to manege when he works upon volts and airs, which ſuppoſes him broke and bred. See Manage.

Manege *for a Soldier's Horſe*, is a gallop of unequal ſwiftneſs, but ſo that the horſe changes hands readily.

Manege, *High*, is the high or raiſed airs, which are proper for leaping horſes. See Airs.

MANEGED. A horſe is ſaid to be thoroughly maneged, or a finiſhed horſe, that is well broken, bred, and confirmed in a particular air or manege, ſo as to bear well upon the hand, know the heels, and ſit well upon the hips.

MANELLI, Francesco, of Tivoli, in *Biography*, compoſer of the firſt Italian opera that was performed on a public ſtage in Venice, in 1635. The drama, intitled "Temiſtocle," was written by Ferrari, himſelf a compoſer; but the preference given to Manelli, either by the author of the words, or by the public, at ſuch an era, is an indiſputable proof of reſpect for his abilities; and a ſtill leſs ſuſpicious compliment to his talents, was his being retained by the ſame poet, and the ſame public, to compoſe a ſecond opera, "Andromeda," in 1637. In ſubſequent years he compoſed four more operas, which had great ſucceſs. See Opera and Venice.

MANEQUIN, among *Painters*. See Layman.

MANERBIO, in *Geography*, a town of Italy, in the department of the Mela; 12 miles S. of Breſcia.

MANES, or Mani, in *Biography*. See Manichees.

Manes, a poetical term, ſignifying the ſhades or ſouls of the deceaſed.

The heathens uſed a variety of ceremonies and ſacrifices to appeaſe the manes of thoſe who were deprived of burial. See Lemures and Lemuria.

Manes, *Dii*, were the ſame with *inferi*, or the infernal gods, who tormented men; and to theſe the heathens offered ſacrifices, to aſſuage their indignation.

The heathen theology is a little obſcure with regard to theſe gods, manes. Some hold, that they were the ſouls of the dead; others that they were the genii of men; which laſt opinion ſuits beſt with the etymology of the word, and ſuch is their origin according to Heſiod.

The heathens, it is pretty evident, uſed the word manes in ſeveral ſenſes; ſo that it ſometimes ſignified the ghoſts of the departed, and ſometimes the infernal or ſubterraneous deities, and in general all divinities that preſided over tombs, and the ghoſts that were thought to wander about theſe tombs. Accordingly, their true original may be referred to a prevailing opinion, that the world was full of genii, ſome of whom attended on the living, and others on the dead: that ſome were good and others bad, and that the former were called "familiar lares," and the latter lemures or larvæ. Thus, when Virgil ſays, "Quiſque ſuos patimur manes," it is, according to Servius, as if he had ſaid, "we have each of us our genius." Apuleius, in his explication of the *Lemures* and *Larvæ* (ſee both theſe articles), ſays that the lares and larvæ are denominated "Dii Manes," and that the deſignation of gods is added to them by way of honour. Agreeably to this opinion it is no wonder that the ancients ſhould confound the manes with the lares and the lemures.

The evocation of the manes of the dead ſeems to have been very frequent among the Theſſalians; but it was expreſsly prohibited by the Romans. See Lares.

MANESSON-MALLET, Alan, in *Biography*, a native of Paris, who flouriſhed in the 17th century, and who was diſtinguiſhed in the ſervice of the king of Portugal as a military engineer. He is known, however, chiefly by his works, which continue ſtill to be in requeſt: they are "Martial Studies, or the Art of War," 1691, in three vols: "A Deſcription of the Univerſe," &c. 1683, in five vols: "Practical Geometry," 1702, in four vols. 8vo. His works are all illuſtrated with plans, maps, and other engravings.

MANETHOS, an ancient Egyptian hiſtorian, called the Sebennite, from the place of his origin, was high-prieſt of Heliopolis in the reign of Ptolemy Philadelphus, about the year 304 B.C. He wrote in the Greek language a hiſtory of Egypt, the ſubject matter of which he aſſerts to have been extracted from certain pillars in the Siriadic land, on which inſcriptions had been made in the ſacred dialect of Thoth, the firſt Mercury, which after the flood were tranſlated into the Greek tongue, but were written in the ſacred character, and were laid up in books in the ſacred receſſes of Egypt by the ſecond Mercury. But this account, which certainly related to the earlier portions of the hiſtory, is ſo incredible, by its reference to the Greek language, at a period when it could not be known in Egypt, that the writers of the Univerſal Hiſtory ſuſpect ſome miſtake or corruption in the paſſage of Euſebius containing it. The work of Manethos was divided into three tomes, the firſt of which comprehended the hiſtory of the gods and demi-gods, who in his eſtimation were mortal men very eminent for virtue; the ſecond that of the eight dynaſties of kings, and the third of twelve. The hiſtory, which is, in a good meaſure, fabulous, is loſt, but his dynaſties have been preſerved in the chronicle of Euſebius. Some fragments of the hiſtory are to be found in Joſephus's work againſt Apion.

MANETTI, Gianozzo, was born at Florence in 1396: he was intended for trade, and received an education ſuitable to it, but being put into the houſe of a banker when he was only ten years of age, he became diſguſted with the employment,

employment, and was accordingly permitted to apply his mind to the various kinds of literature that were then cultivated. During nine years he devoted himfelf to thefe purfuits, after which he was appointed by the Florentines to give public lectures on the ethics of Ariftotle, which were attended by a vaft number of pupils. From the age of thirty-five, he was employed by the ftate in various honourable offices, and was feveral times deputed to prefide over the public ftudies, which always flourifhed under his fuperintendance. He was fent on embaffies to the republic of Genoa; to king Alphonfo; to Francis Sforza; to the popes Eugenius IV. and Nicholas V.; to feveral of the Italian ftates, and to the emperor Frederic III., and on all thefe occafions he gave proof of great prudence and dexterity in the management of affairs, and of an eloquence which was the object of univerfal admiration. Notwithftanding the high rank to which he had attained, he found caufe for diffatisfaction at his own court, and retired to that of Nicholas V., who received him with great honour; but as he was cited to appear at Florence, on pain of banifhment, the pope deputed him to go thither in the character of his embaffador. His conduct in this new fituation fo ingratiated him with his countrymen, that from a culprit he became a principal magiftrate. He afterwards returned to Rome, and was made fecretary to Nicholas V., in which poft he was continued by Calixtus III. Going to Naples on private bufinefs, Alphonfo kept him there with a penfion for three years, during which he compofed the greater part of his works. He died in 1459 with the character of one of the moft learned and excellent men of his age. He was deeply fkilled in the Hebrew language, and employed his great learning in this refpect to confute the Jews from their own fcriptures. He wrote a work againft their tenets in ten books, which is faid ftill to remain in MS. in the Laurentian library. Among his printed works are, "The Hiftory of Piftoia;" "The Lives of Nicholas V., Dante, Petrarch, and Boccaccio;" "The Funeral Oration of Leonardo Bruni;" "De Dignitate et Excellentia Hominis," and fome "Orations."

MANETTIA, in *Botany*, was named by Mutis and Linnæus, in honour of Xavier Manetti, curator of the Botanic Garden at Florence, who was born in the year 1723, and died in 1784. He publifhed, in 1747, a catalogue of fuch plants as grew in the garden at Florence, interfperfed with obfervations on the falutary and hurtful properties of vegetables. He alfo wrote a treatife upon the domeftic economy of making bread from different kinds of corn, but upon the whole prefers that which is made from *Triticum polonicum*. Linn. Mant. 553. Schreb. 75. Willd. Sp. Pl. v. 1. 624. Mart. Mill. Dict. v. 3. (Nacibea; Aubl. Guian. 95. t. 37. Juff. 199. Lamarck Illuftr. t. 64.)—Clafs and order, *Tetrandria Monogynia*. Nat. Ord. *Contortæ*, Linn. *Rubiaceæ*, Juff.

Gen. Ch. *Cal.* Perianth fuperior, of eight linear, concave, hairy, permanent leaves. *Cor.* of one petal, falver-fhaped; tube cylindrical, longer than the calyx, marked on the infide with four lines; limb divided into four fegments, which are fhorter than the tube, ovate, obtufe, bearded within. Nectary a rim furrounding the receptacle, quite entire, concave. *Stam.* Filaments four, thread-fhaped, very fmall, placed at the mouth; anthers linear, incumbent, two-celled. *Pift.* Germen inferior, turbinate, compreffed; ftyle thread-fhaped, bent down, the length of the tube; ftigma cloven, thickifh, obtufe. *Peric.* Capfule turbinate, compreffed, furrowed on both fides, of one cell and two valves, or feparable as it were into two capfules. *Seeds* few, flat, winged, orbiculate with a central embryo, imbricated on a pulpy oblong receptacle.

Eff. Ch. Calyx of eight leaves, fuperior. Corolla four-cleft. Capfule inferior, of two valves and one cell. Seeds imbricated, orbicular, with a central embryo.

1. M. *reclinata*. Linn. Mant. 558. Swartz. Prod. 37.—Leaves ovate, acute, downy. Stem reclined, herbaceous.—A native of Mexico.—*Root* annual. *Stem* weak and branching. *Leaves* oppofite, on footftalks, crowded, fomewhat fringed, an inch and half long. *Footftalks* very fhort, hairy. *Stipulas* oppofite, clofely faftened to the ftalks, femicircular, very fhort. *Flower-ftalks* axillary, folitary, fhorter than the leaves, many-flowered; partial ftalks oppofite, round, hairy, furnifhed with a fingle, fmall, acute *bractea*. *Flowers* white.

2. M. *Lygiftum*. Swartz. Prod. 37. Willd. n. 2. (Petefia Lygiftum; Linn. Sp. Pl. 160. Lygiftum; Brown. Jam. 142. t. 3. f. 2.)—Leaves ovate, acute, veiny. Stem twining, fomewhat fhrubby.—Native of Jamaica.—This weakly *fhrub* has a branched, twifted *ftem*, about feven feet in length. *Leaves* oppofite, on footftalks, large. *Flowers* in bunches, terminal, on long, branched footftalks, generally two together, or folitary. Swartz obferves that the calyx of this plant has eight leaves, and that the feeds are imbricated, which induced him to refer it to the prefent genus.

3. M. *coccinea*. Willd. n. 3. (Nacibea coccinea; Aubl. Guian. t. 37. f. 1.)—Leaves ovate, acuminate. Clufters many-flowered. Stem twining, fhrubby.—A native of Guiana, where it flowered and fruited in May.—*Root* perennial. *Stems* numerous, knotty, branched, fquare. *Leaves* at the knobs, in pairs, oppofite, on footftalks, fmooth. *Flowers* in clufters, the tube of the corolla white, marked with red dots; the limb of a fcarlet colour above, downy; the mouth of the tube clofed with yellow hairs.

4. M. *picta*. Willd. n. 4. (Nacibea alba; Aubl. Guian. t. 37. f. 2.)—Leaves ovate, acute. Calyx four-toothed. Stem twifting and climbing, fhrubby.—Found at the fame place with the laft, from which it differs in having the *calyx* four-toothed; the *corolla* fhorter and white; the *leaves* broader, and variegated with yellow.

5. M. *lanceolata*. Willd. n. 5. Vahl. Symb. p. 1. 12. (Ophiorrhiza lanceolata; Forfk. Defcr. 42.)—Leaves lanceolate. Calyx five-cleft, unequal. Flowers pentandrous. Stem erect.—A native of the lofty mountains of Hadie, in Arabia. *Stem* fhrubby. *Flower-ftalks* three together, terminal, the lateral ones thrice as long as that in the centre, cloven at the top. *Flowers* at firft heaped together, then racemofe, all directed one way.—Vahl obferves that this fpecies is nearly allied to *Cinchona*, and that it differs from the reft of this genus in the number of ftamens and fegments of the calyx.

MANFELOUT, or MAMFLOT, in *Geography*, a town of Egypt, on the left fide of the Nile, a mile from that river. Its name fignifies in Arabic "the place of Lot's exile;" and it is fo called, according to the Jefuit F. Vanfleb, who founds his opinion on a tradition of the Copts, becaufe a perfon of the name of Lot was banifhed thither by his brother, one of the ancient kings of Egypt. The town is tolerably large, being about a mile in circumference, and much handfomer than Miniet; its ftreets are wider and better paved. It is the capital of a diftrict, and agreeably fituated in a country that furnifhes abundance of productions of every kind; and its walls are fhaded by fruit-trees, overtopped by a number of lofty palms. It is governed by a kiafchef or cafhef, and is the fee of a bifhop, who prefides over about 200 Chriftians. Its commerce confifts of all forts ſorts of grain, and of linen cloths, which are manufactured here in great quantities. The Turks have different moſques, as well as a garriſon, in this place. Oppoſite to it is a Coptic convent, on the E. bank of the Nile, which is wholly incloſed with high walls, and into which the only mode of admiſſion, in order to be ſecure againſt the rapacious Arabs, is that of being hoiſted up in a baſket, by means of a pulley; whence it has obtained the name of the "Convent of the Pulley." Two leagues below Manfelout, on the eaſt bank of the Nile, is a chain of very high mountains, formed entirely of barren rock; the waters of the river have undermined them, ſo that their ſummit projects conſiderably beyond their baſe. This chain of rocks is called the mountain of "Aboufeda," from the name of a Muſſulman ſaint who is buried there, and in honour of whom a ſmall chapel has been erected. By the ſide of this monument of piety, or rather of the abſurd ſuperſtition of the Mahometans, ſome men of the ſame religion, who are devout worſhippers of ſaint Aboufeda, and, at the ſame time, determined robbers, live in retreats dug in the rock, and formerly, as it is ſaid, inhabited by Anchorites. But theſe excavations, as well as thoſe in Scheick Abadé, and in the two chains of mountains between which the Nile runs, in the upper part of Egypt, are probably burial places and ancient tombs. However this be, the perſons who now occupy them are the moſt formidable pirates that obſtruct the navigation of Egypt, and alſo the moſt difficult to be exterminated, as they take refuge in the inacceſſible cavities of theſe mountains. Manfelout is 13 miles N.N.W. of Siout. N. lat. 27° 42′. E. long. 31° 36′. Sonnini's Travels in Egypt.

MANFORT, a town of Africa, on the Gold Coaſt, in the country of Fantin.

MANFRED, or Mainfroy, in *Biography*, king of Naples and Sicily, was natural ſon of the emperor Frederic II.; on the death of his father in 1250, he became poſſeſſed of the principality of Tarento, and ſome adjacent counties. When his brother Conrad arrived from Germany, to take poſſeſſion of the Sicilian kingdoms, he became jealous of Manfred's power and abilities, and took from him a part of his inheritance, but upon the death of Conrad, he became poſſeſſed of the regency in behalf of his nephew, the infant Conradin. The pope, however, claimed the kingdom as fief to the holy ſee, and excommunicated Manfred, who being unable to make oppoſition, received his holineſs very ſubmiſſively in Naples. Soon after he raiſed a body of troops, and defeated the papal army, and after other ſucceſſes he recovered all the Neapolitan territory, and was received with great rejoicings into the city of Naples, where he behaved with much generoſity and clemency. He afterwards paſſed over to Sicily, and a report being ſpread of the death of Conradin, he was unanimouſly elected king by the Sicilian and Apulian barons, was accordingly crowned at Palermo in 1258, and by a mild and very equitable adminiſtration, ſecured the affections of the people. His peace was in a ſhort time diſturbed by intelligence, that Conradin was not only alive, but claimed the crown as his birth right; to which Manfred replied, that he had conquered the kingdom from two popes, and what he had won by his valour he could not think of reſigning, but would leave the kingdom to Conradin at his death. He founded a new city on the Adriatic, to which he gave the name of Manfredonia, and peopled it with the inhabitants of Siponto, which he deſtroyed on account of its unhealthy ſituation. His troops gained a ſignal victory over the Guelfs, in conſequence of which the city of Florence acknowledged his ſovereignty. In 1262, pope Urban IV. publiſhed a cruſade againſt him, and in the following year conferred the kingdoms of Naples and Sicily upon Charles of Anjou, brother of the French king Lewis IX. Charles prepared to invade the country, and Manfred was as zealous in his diſpoſitions to reſiſt him; but he was at length betrayed by his barons, who ſecretly negociated with his rival; and in February 1266, Manfred, engaging with the French army near Benevento, after fighting with great valour, was defeated and ſlain. As an excommunicated perſon, his body was thrown into a ditch, and buried under a heap of ſtones. The pope afterwards ordered it to be taken up, and carried out of the territories of the church. Manfred, though blackened by his enemies, diſplayed the talents and virtues of a great ſovereign; he was accompliſhed beyond moſt princes of his time, and if he were guilty of criminal ambition in gaining a crown, he wore it with honour. Mod. Univer. Hiſt.

MANFREDI, Eustachio, an Italian mathematician and aſtronomer, ſon of a notary, was born in the year 1674. He enjoyed the benefits of an excellent education, and made ſo great progreſs in his ſtudies, that at the age of eighteen, he obtained the degree of doctor of laws. He was, however, more attached to philoſophy and the mathematics than to mere legal diſcuſſions, and applied himſelf moſt diligently to the ſciences connected with or ſubſervient to the ſtudy of aſtronomy. In the midſt of his learned labours he found time to write poetry, and the pieces which he produced at this period, were, after the author's death, collected and publiſhed in an 8vo. volume, which has been many times reprinted. In 1698, Manfredi was nominated profeſſor of mathematics in the univerſity of Bologna. All the time that he was not employed in the duties of his profeſſorſhip, he devoted to the ſtudy of aſtronomy, and in company with Victor Stancari, he ſpent whole nights in contemplating the heavens, and obſerving the motions and paſſages of the ſtars and planets. An account was publiſhed of their obſervations made before the year 1703. In the ſame year Manfredi publiſhed a treatiſe "On the ſolar Spots," and in the following ſeaſon he was appointed by the ſenate of Bologna to the office of ſuperintendant-general of the rivers and waters of the Bologneſe. The duties of this office he conducted with a degree of ſkill and prudence, that proved highly beneficial to his country, and gave him a firſt rate reputation as a practical hydrauliſt. About the ſame time he was elected regent to the college of Monte-alto, founded by pope Sixtus V. at Bologna, for the education of young perſons of his province, who were intended for the church; in this ſituation, which was thought to be unworthy of his talents, he was enabled to do much for the eſtabliſhed religion, by ſending into its ſervice many celebrated divines, and others who ſuſtained a conſpicuous rank in the republic of letters. In the midſt of his various labours, Manfredi found leiſure to continue his aſtronomical ſtudies, and to attend to other mathematical ſubjects; at the ſame time he correſponded with men of ſcience in different parts of Europe, and began the compoſition of his famous "Ephemerides," which were afterwards publiſhed in ſeveral quarto volumes. In the year 1717, Manfredi was ſent to Rome, on the ſubject of a diſpute between the cities of Bologna and Ferrara, reſpecting the manner of conducting the inundations of the river Rheno into the Po. On his return home, he reſumed his aſtronomical labours, and in 1723 had the long wiſhed-for opportunity of obſerving a tranſit of Mercury over the ſun, of which he publiſhed an account in the following year, under the title of "Congreſſus Mercurii de ſolis in Aſtronomia Specula Bononienſis Scientiarum Inſtituti," &c. In 1726 he was admitted an aſſociate of the Royal Academy of Sciences at Paris, to whom he ſent a treatiſe "On the Method of determining the Figure of the Earth from the Parallax of the Moon," and another "On the Mode of defining the Solſtices, by the fixed Stars." In 1729, he was elected a foreign member of the Royal Society at London. In his latter years, he employed himſelf in completing his "Elements of Geometry and Trigonometry," which he had formerly drawn up for the uſe of a young nobleman, and his "Aſtronomical Inſtitutions." He died in the year 1739, when he was in the ſixty-fifth year of his age. He was author of a great number of works which have not been noticed above, but the titles of which may be found in "Fabroni Vit. Italor. Doct." He had a brother Gabriel, who firſt introduced into the univerſity of Bologna the ſtudy of algebra, and the new analyſis, and acquired much celebrity by his treatiſe "De Conſtructione Æquationum Differentialium primi Generis," publiſhed in 1707. He died in the year 1761, at the age of eighty. Moreri.

MANFREDONIA, in *Geography*, a ſea-port town of Naples, in Capitanata, ſeated on a bay of the Adriatic, called the "gulf of Manfredonia." King Manfred, who founded it in the year 1256, took great pains to give it permanent celebrity. Beſides ſeeking counſel as to the place and time of building it, from the moſt eminent aſtrologers, to whom he could have acceſs, he ſpared no labour or expence in the conſtruction of it. The port was ſecured from ſtorms by a pier, the ramparts were built of the moſt ſolid materials, and in the great tower was fixed a bell, of ſo large a ſize, that it might be heard over all the plains of Capitanata, to alarm the country in caſe of an invaſion. He alſo took care to have it erected into an archbiſhopric. Notwithſtanding all his precautions, it ſcarcely muſters 6000 inhabitants; though moſt of the corn exported from the province is ſhipped off here, and a direct trade carried on with Venice and Greece, with a view to which a lazaretto is eſtabliſhed. Vegetables of all ſorts are abundant in the vicinity of this town, and fiſh is plentiful and cheap; 93 miles N.E. of Naples. N. lat. 41 42′. E. long. 51° 56′.

MANFRO, a town of Africa, on the Gold Coaſt, near Cape Coaſt. The town is of an oval form, ſituated on the banks of a river, in a place almoſt inacceſſible, on account of rugged rocks that ſurround it. The inhabitants are inceſſantly employed in fiſhing, agriculture, and making ſalt, which is much wanted; and many of them act as factors to the merchants of the interior parts.

MANG, a river of the county of Kerry, which riſes in the mountains adjoining Cork and Limerick, and falls into Caſtlemain harbour, at the bottom of the great bay of Dingle, which can only admit veſſels of moderate burden. The Mang, which is navigable to Caſtlemain, was the northern boundary of the ancient county palatine of Deſmond. Beaufort.

Mang, in *Rural Economy*, a provincial word applied to ſignify a maſh of bran, malt, or other ſimilar ſubſtance.

MANGA, in *Gardening*. See Mangifera.

MANGABEY, in *Zoology*, the white eye-lid ape of Pennant. See Simia *Æthiops*.

MANGAGUABO, in *Geography*, a river of Braſil, which runs into the Atlantic, S. lat. 6° 56′.

MANGALA, in *Aſtronomy*, is the Sanſkrit name of the planet Mars, and he, as in Europe, preſides over Tueſday. In Indian paintings, he is repreſented of a deep red colour, with pink clothing, mounted ſometimes on a white ram, with red legs, ſometimes on a horſe, and holding a lotus and a ſtaff in his hands.

MANGALLO, in *Geography*, a town of Africa, in Querimba. S. lat. 10° 10′. E. long. 41° 20′.

MANGALLOON, a ſmall iſland near the N.W. coaſt of Borneo. N. lat. 6° 9′. E. long. 115 36′.

MANGALORE, a town of Hindooſtan, in the Canara country, on the coaſt of Malabar, with a good road for veſſels in the rainy ſeaſon. It was ceded to Britain in 1794; 124 miles W.N.W. of Seringapatam. N. lat. 12° 50′. E. long. 74° 44′.—Alſo, a town of Hindooſtan, in the Carnatic; 32 miles S. of Arcot.—Alſo, a town of Hindooſtan, in the circar of Rachore; 100 miles W.S.W. of Rachore.—Alſo, a town of Hindooſtan, in Guzerat, on the coaſt; 12 miles N of Puttan Sumnaut.—Alſo, a town of the Carnatic; 10 miles N. of Volconda.

MANGALUM, a town of Hindooſtan, in Coimbetore; 25 miles S.E. of Coimbetore.

MANGAN Islands, a cluſter of ſmall iſlands, in the gulf of St. Laurence, near the S. coaſt of Labrador. N. lat. 50° 15′. W. long. 63° 40.

MANGANADIA, a town of Hindooſtan, in Cochin; 20 miles N.E. of Cochin.

MANGANESE, in *Chemiſtry*, an elementary oxydable body, and a metal. It may be obtained in a ſtate of purity from any of its ores deſcribed in the next article. The native black oxyd, however, is the moſt convenient for affording this metallic ſubſtance. In order to obtain the oxyd free from the oxyds of other metals, the black oxyd muſt be diſſolved in muriatic acid. Sulphuric acid being gradually added, the lime and barytes, if it contain any, will be precipitated in the ſtate of ſulphats of thoſe earths. The ſolution may contain oxyds of iron and copper, beſides that of manganeſe. Carbonat of potaſh being added will diſſolve the manganeſe, but will precipitate the other oxyds. The oxyd of manganeſe may be afterwards precipitated by pure potaſh.

The above ſolution of the different metals may alſo be treated as follows. The copper may be precipitated by a clean piece of iron, and the iron be afterwards ſeparated by the ſuccinat of potaſh. The oxyd of manganeſe may at the laſt be ſeparated by pure potaſh. The oxyd of manganeſe, thus ſeparated, is in a ſtate of powder. Let this powder be made into a paſte with oil, and put into a crucible lined with charcoal, and filled up with powdered charcoal, the whole being cloſely covered. The crucible is now to be expoſed for an hour to the intenſe heat of a forge fire, or a blaſt-furnace, on the plan of Dr. Aikin's. At the bottom of the crucible will be found ſmall metallic grains, which are the manganeſe in its metallic form. For this proceſs we are indebted to Ghan, who firſt ſucceeded in the reduction of this metal.

This metal, when pure, is of a greyiſh-white colour, of tolerable metallic luſtre. Its ſpecific gravity is about 6.85. It is very brittle, and in hardneſs little inferior to iron. Hence it is not a malleable metal. It melts at 160° Wedgewood. It is not magnetic when perfectly free from iron.

It has no perceptible taſte or ſmell: when expoſed to the air it ſoon loſes its metallic luſtre, and changes into the ſtate of a brown powder, which ultimately becomes black. Theſe changes are produced by its combination with oxygen, for which it poſſeſſes a ſtronger affinity at the common temperature than any of the metals, with the exception of the baſis of the earth and alkalies. This property renders it of little or no uſe in the metallic ſtate.

It combines with three doſes of oxygen. The protoxyd, or firſt oxyd, is obtained by diſſolving the black oxyd of manganeſe in nitric acid, adding, at the ſame time, ſome ſugar or other inflammable matter, to take the exceſs of oxygen

oxygen from the black oxyd. The folution, by this treatment, becomes a nitrat of manganefe, with an oxyd at a minimum of oxydation. On pure potafh being added, the protoxyd is precipitated of a white colour. It is compofed, according to Bergman, of 80 of manganefe and 20 of oxygen in the 100.

This oxyd, expofed to the air, foon changes to a brown, and ultimately becomes of a black colour, by combining with more oxygen.

The fecond, or deuterotoxyd, is eafily obtained by diffolving black oxyd in fulphuric acid with heat. A portion of oxygen gas is feparated, fo as to conftitute this oxyd. If to the folution pure potafh be added, the oxyd is precipitated of a red colour. It is compofed of 74 of manganefe and 26 of oxygen, from the authority of Bergman. This oxyd, like the laft, attracts more oxygen from the atmofphere, and becomes black.

The black, or peroxyd of manganefe, may be obtained by expofing the other oxyds to the air for fome time. In a ftate of lefs purity it is found abundantly in nature, in which ftate it is ufed in bleaching linen and calico, to furnifh oxygen to the muriatic acid.

When expofed to a red heat it gives out one dofe of oxygen, and is converted into the fecond, or red oxyd. Hence its ufe in the chemical elaboratory for furnifhing oxygen gas.

It fometimes, however, contains carbonat of lime, in which cafe the gas obtained is liable to contain carbonic acid gas. The latter may be feparated from the oxygen by paffing the gas through lime water. The pure black oxyd is compofed of 60 of manganefe and 40 of oxygen.

The oxyds of manganefe have not been examined by many chemifts. We are indebted to Bergman for almoft the whole of our knowledge of thefe compounds. If bodies combine in limited dofes, according to the hypothefis of Dalton, the relative proportions of oxygen will be found incorrect. Agreeably to the proportion of the red oxyd, which is 26 *per cent.* Dalton fixes the atom of manganefe at 40, the oxygen being 7. Hence, for the protoxyd, we have $\frac{40 + 7}{7} = \frac{100}{15}$, or nearly 15 *per cent.* of oxygen. For the fecond oxygen we have $\frac{40 + 2 \quad 7}{2 \times 7} = \frac{\quad}{26}$, or 26 *per cent.* agreeably to the authority of Bergman.

The black, or peroxyd, from the fame data, will be $\frac{40 + 3 \times 7}{3 \times 7} = \frac{100}{34{\cdot}4}$, or 34·4 *per cent.* Hence it would appear that the protoxyd and the peroxyds are a little over-rated.

The black oxyd of manganefe is ufed in the manufacture of flint glafs, along with the oxyd of lead, to render the glafs colourlefs. The oxyd of manganefe alone would give to the glafs a purple colour, while the lead would render it of a yellow colour. In certain proportions, however, they produce no colour. May not this arife from the mixture of the three primitive colours conftituting whitenefs, namely, the purple, or blue and red, of the manganefe, with the yellow of the lead?

If this effect depended upon the oxygen of the manganefe, to which it has by fome been attributed, the glafs ought to be more coloured, from the oxyd of lead being more coloured in proportion to the oxygen it contains.

The black oxyd of manganefe, when mixed with drying oil to form paint, caufes fpontaneous inflammation.

Manganefe does not combine with hydrogen, nor, in all probability, with carbon.

The metal does not, according to Bergman, combine with fulphur. The fame chemift, however, fucceeded in combining its oxyd with fulphur, forming a fulphuretted oxyd. It is of a green colour, and affords fulphuretted hydrogen by treating with acids. There is ftrong reafon to believe that fulphuret of manganefe may be formed, fince a native fulphuret has been found.

Phofphorus combines with manganefe, forming a cryftalline, brittle, white fubftance, which is not decompofed at the common temperature.

It is more fufible than manganefe, but at this heat the phofphorus burns, and the manganefe combines with the oxygen of the atmofphere.

Manganefe combines with fome of the malats, forming alloys.

Mr. Hatchett fucceeded in alloying manganefe with gold by the following procefs. The black oxyd was frequently heated with oil, till the oil inflamed. By this means the oxyd was partly reduced. This fubftance was introduced, with fome gold, into a crucible lined with charcoal, and clofely covered; a ftrong heat was applied. The gold by this means combined with fome of the manganefe, forming an alloy of a yellowifh-grey colour. It was very hard, and fufceptible of a good polifh.

This alloy contained from $\frac{1}{9}$th to $\frac{1}{8}$th of manganefe. The gold could be feparated by cupellation.

Manganefe does not combine with mercury; it combines with copper, forming an alloy of a red colour, which is malleable.

It combines with iron with great facility, and is often a component part of iron, made from iron ores containing manganefe. It is faid to be effential to the formation of fteel, and that no iron can be ufed for making fteel but fuch as contains manganefe. This, however, is very doubtful. The alloys of manganefe with bifmuth and antimony are difficult to form, and of no importance.

Salts of Manganefe.—Although the oxyd of manganefe combines with the acids like the reft of the metallic oxyds, the properties of moft of thefe compounds have not been attended to by chemifts.

Sulphat of Manganefe.—When dilute fulphuric acid is applied to this metal the water is decompofed, hydrogen gas is evolved, and the acid combines with oxyd, forming a fulphat of manganefe. The folution of this falt is colourlefs; it affords cryftals by evaporation of a rhomboidal form. It has a bitter difagreeable tafte: when expofed to ftrong heat the acid efcapes.

This falt confifts of the protoxyd united with the acid; and agreeably to the hypothefis of Dalton, the atom of acid being 34, and the oxyd 40 + 7, the compofition of the falt ought to be $\frac{40 + 7 + 34}{34} = \frac{100}{42}$, which gives 100; 42 of acid and 58 of white oxyd.

Oxyfulphat of Manganefe.—This falt confifts of the red oxyd of manganefe combined with the acid.

It may be formed by diftilling a mixture of fulphuric acid with the black oxyd. A quantity of oxygen gas comes over, and a liquid of a purple colour, which is water, containing the oxyfulphat. When evaporated it affords a glutinous mafs, which gives fome cryftals with difficulty. When an alkali is added, the red oxyd is precipitated. This falt, from the above

above data, ſuppoſing it to be neutral, ſhould be compoſed as follows, $\frac{40 + 2 \times 7 + 34}{34}$, which gives 38.6 acid, and 61.4 red oxyd. The way in which this ſalt is prepared, renders it probable that it is ſuper-ſalt, a ſub-ſalt being left in the retort.

The ſuper-ſalt will be, therefore, $\frac{40 + 2 \times 7 + 34 \times 2}{34 \times 2} = \frac{100}{55.74}$, or 55.74 acid, and 44.26 of red oxyd. The ſub-ſalt would be $\frac{(40 + 2 \times 7) \times 2 + 34}{34} = \frac{100}{24}$, or 24 acid, and 76 red oxyd. The ſulphurous acid added to the black oxyd is converted into the ſulphuric acid, and diſſolves the remaining oxyd forming the ſulphat.

Nitrat of Manganeſe.—When the metal is added to dilute nitric acid, fumes of nitrous gas, mixed with nitrogen, and, perhaps, the nitrous oxyd, are diſengaged, ariſing from the decompoſition of part of the acid, while the remaining acid diſſolves the oxyd forming the ſalt in queſtion. It may alſo be formed by adding the black oxyd to the acid, at the ſame time adding ſome ſugar to take up the exceſs of oxygen, which the black oxyd contains above that of the white. Carbonic acid gas is, in conſequence, evolved, and the white oxyd is diſſolved.

The ſolution of this ſalt is colourleſs; it does not afford cryſtals by evaporation. If the heat be continued to dryneſs the ſalt is decompoſed, the acid being ſeparated.

Its component parts, ſuppoſing it a ſuper-ſalt, will be $\frac{40 + 7 + 19 \times 2}{19 \times 2} = \frac{100}{44.7}$, or 44.7 acid, and 55.3 white oxyd.

Muriat of Manganeſe.—The muriatic acid being added to the metal affords hydrogen from the decompoſition of the water, while the oxyd is diſſolved forming this ſalt. It conſiſts of the acid combined with the white oxyd.

When the black oxyd is digeſted in muriatic acid, one part of the acid combines with the exceſs of oxygen in this oxyd, forming the oxymuriatic acid, which eſcapes in the gaſeous form: the remainder of the acid unites with the white oxyd. Of this ſalt there is little known; it is difficult of cryſtallization, and is deliqueſcent.

When the muriatic acid is added to black oxyd in the cold, a red ſolution is formed, conſiſting of the red oxyd with the acid, and which is an oxymuriat of manganeſe. The muriat may, in all likelihood, conſiſt of $\frac{40 + 7 + 22}{22} = \frac{100}{32}$, or 32 and 67 baſe.

Phoſphat of Manganeſe.—This ſalt may be formed by adding phoſphat of ſoda to a ſoluble mangneſian ſalt. A white powder falls down, which is phoſphat of manganeſe. It is, therefore, inſoluble, or nearly ſo.

Fluats and borats of manganeſe may be formed by a ſimilar proceſs to the laſt: but theſe ſalts have not been examined.

Carbonat of Manganeſe.—This ſalt is more ſoluble than moſt of the metallic carbonats. In precipitating metallic oxyds from their ſolutions where manganeſe is contained by the alkaline carbonats, the latter oxyd is held in ſolution by the carbonic acid. This affords a ready method of ſeparating manganeſe from moſt other oxyds.

Oxalic acid combines with the oxyd of manganeſe, forming a ſalt in a ſtate of inſoluble white powder.

Tartarat of Manganeſe.—Tartaric acid added to the black oxyd of manganeſe, is partly decompoſed by heat. The carbon of the acid combines with exceſs of oxygen in the oxyd. The remaining acid afterwards diſſolves the reduced oxyd. On the citric acid it has a ſimilar effect.

Scheele informs us, that the arſenic acid diſſolves the white oxyd of manganeſe, forming a ſalt which affords cryſtals.

The ſuccinic acid forms a ſoluble ſalt with the white oxyd. The ſuccinat of potaſh has, in conſequence, been employed to ſeparate manganeſe from iron, the ſuccinat of the ſalts being inſoluble.

The reſt of the ſalts of this metal are not known.

MANGANESE. The ores of this metal may be divided into the following ſpecies: 1. Grey manganeſe; 2. Black manganeſe; 3. Red manganeſe; 4. Sulphuret of manganeſe; and 5. Phoſphat of manganeſe.

I. *The grey manganeſe ore* is ſubdivided into the *radiated*, *foliated*, *compact*, and *earthy*.

1. *Radiated grey manganeſe; Strahliges graubraunſtein-ertz*, Wern.; *Striated grey manganeſe ore*, Kirw.; *Manganèſe oxidé métalloïde gris*, Haüy.; *Manganèſe métalloïde chalybin*, Brongn.

Colour dark ſteel-grey, paſſing into iron black; ſometimes with variegated tarniſh. It occurs maſſive, diſſeminated, and cryſtallized.

The primitive form of the cryſtals is the four-ſided rhomboidal priſm, with edges of about 100° and 80°, according to Haüy; but of 115° and 65°, according to Hauſſmann's meaſurement. It is diviſible in the direction of its ſix planes; and, according to Haüy, alſo in that of the ſhort diagonal of the terminal planes; which latter is conſidered as erroneous by Hauſſmann; who, therefore, pronounces the form of the integrant molecule to be the ſame as that of the primitive cryſtal.

Its moſt remarkable ſecondary forms are:

A. The rectangular four-ſided priſm.

B. The oblique four-ſided priſm (being the primitive form).

a. Summits truncated; plane of truncation ſtraight.

b. Truncated obliquely at the ſummits: the plane of truncation either on one of the obtuſe, or on one of the acute lateral edges of the priſm. The truncation is ſometimes produced by two planes placed on two adjoining lateral planes.

c. Acuminated; the acuminating planes placed either on the obtuſe lateral edges (edge of acumination = 94° 7′ 6″), or on the acute lateral edges (edge of acumination 118° 40′ 36″.) The planes of acumination ſometimes again truncated.

d. Acuminated by four planes; the acuminating planes placed either on the lateral edges (with ſummit ſometimes truncated), or on the lateral planes. (Inclination of the acuminating on the lateral planes = 118 53′ 6.″)

C. The ſix-ſided priſm. (Two oppoſite, primitive, lateral edges = 65°, the four others = 147 30′.)

a. Summits truncated; plane of truncation ſtraight or flat.

b. Acuminated by two planes placed on the ſecondary lateral planes; at the other ſolid angles more or leſs truncated.

D. The eight-ſided priſm (with two lateral edges of 115°; two others of 124° 45′ 46″; and four of 150 7′ 7″.)

a. Summits truncated; plane of truncation ſtraight.

b. Obliquely

b. Obliquely truncated by two pentagonal planes.

c. Acuminated by four planes placed on the moſt obtuſe lateral edges.

d. Acuminated by ſix planes, four of which are placed on the obtuſe lateral edges, while the two others are placed either on the lateral edges of 124° 45′ 46″, or on thoſe of 115°.

e. Acuminated by eight planes placed on the lateral planes.

The cryſtals are generally aggregated and grown together in all directions; they ſometimes form globular aggregations. Their ſize varies, but they are ſeldom found exceeding one inch in length; and the generality of them are very ſmall. Upon the whole it may be ſaid, that their thickneſs is at leaſt four times exceeded by their length; while in the *foliated mangane/e* both dimenſions generally approach more to equality. The greateſt relative length we find in the ſix-ſided priſmatic cryſtals, which ſometimes are of a lanceolate ſhape, the breadth of the two ſecondary planes often increaſing to ſuch a degree, that but little remains of the four primitive planes.

By the union of ſeveral priſmatic cryſtals of equal length, a particular kind of priſmatic aggregations is frequently produced, having ſix, eight, or more lateral planes. They might be miſtaken for ſimple cryſtals, from which, however, they are eaſily diſtinguiſhable; 1. By their lateral planes ſeldom forming ſharp edges with one another, and being moreover always furniſhed with ſtriæ, and even deep furrows; and 2. By their acuminating facets never exhibiting continued planes, but only tranſverſal ſections intercepted by interſtices left by the aggregated priſms, which are in cloſe contact with each other.

The planes of the cryſtals are ſplendent, the primitive ones eminently ſo; the ſecondary planes are always longitudinally ſtriated. The ſurfaces of cleavage and fracture vary between ſhining and gliſtening: the luſtre is metallic. Yields a dull iron black ſtreak. It is opaque.

The texture of this ore is radiated, paſſing on one ſide into coarſe fibrous, on the other into foliated. The amorphous, maſſive, and diſſeminated radiated grey manganeſe ſometimes exhibits tranſverſal fiſſures in the radii, in the direction of the terminal planes of the nucleus.

Fracture uneven, frequently diſplaying ſmall granular maſſes, approaching to wedge-ſhaped. Fragments wedge-ſhaped, and long ſplintery; in the maſſive they are indeterminately angular and blunt-edged.

It is ſoft, brittle, and in large pieces pretty difficultly frangible. It ſoils ſtrongly when rubbed.

Specific gravity 3.530—4.325, Muſchenbroeck; 4.143, Hagen; 4.2491—4.7563, Briſſon; 4.181, Rinmann.

According to the analyſes given of the radiated grey manganeſe ore, by Klaproth, 100 parts afforded

	From Ihlefeld.	From Moravia.
Brown oxyd of manganeſe	90.50	89.
Water	7.	0.5
Oxygen gas	2.25	10.25
	99.75	99.75

Klapr. Beitr. ij.

This ore is found principally at Ihlefeld, on the Hartz; in Saxony, at Langeberg, Johangeorgenſtadt, Kamſdorf, Ilmenau, Salfeld in Thuringia; in Sileſia, at Konradſwaldau, Kupferberg, &c.; in Bohemia, at Mieſs, Platten; in the Bannat; in Carinthia, at Hüttenberg; on mount St. Gothard; in Piemont and Iſchia, in the Vicentine territory; in various parts of Great Britain, in Cornwall, Devonſhire, Somerſetſhire, Derbyſhire; and alſo near Aberdeen, in Scotland. Jameſon.

The radiated grey manganeſe ore of Ihlefeld occurs partly in veins, and partly as nodules, in clay-porphyry: it is accompanied with fleſh-red barytes, uſually cryſtallized in their ſexangular tables with fleſh-red or white rhomboidal calcareous ſpar, compact and foliated black manganeſe, and with friable lithomarge of a roſe-red colour. Hauſſmann in Mohr's Archiv. 1ſt b. p. 32.

2. *Foliated grey manganeſe ore; blättriges grau-braunſtein-ertz*, Wern. (var. of *Manganèſe oxidé métalloïde gris*, Haüy.)

Its colour is the ſame as that of the preceding ſub-ſpecies; it ſometimes in a ſtrong light appears iridescent.

It occurs maſſive, diſſeminated, and as covering of other ores. Alſo cryſtallized in four-ſided, rectangular, and rhomboidal priſms, whoſe planes are nearly equal to each other; and in low ſix-ſided priſms, with lateral planes either of the ſame breadth, or with ſecondary planes encroaching on the primitive, and thus producing rectangular tables, ſometimes bevilled at two oppoſite ſides, ſometimes rounded off: if rounded off in the whole of their circumference, the tabular paſſes into the lenticular form.

The cryſtals are generally globularly or botroïdally aggregated, and often form the uppermoſt covering in druſy cavities formed of black iron-ſtone, and lined by compact black, and amorphous foliated grey manganeſe ore. The oblique four-ſided priſms are ſometimes ſo intimately united, as to diſplay no more of their ſurface than a three-planed ſolid angle, formed by a terminating and two lateral planes. The cryſtals are always very ſmall; the magnifying glaſs diſcovers their lateral planes to be ſtriated; the terminating planes are ſmooth.

The luſtre of the ſurface of the cryſtals and of the cleavage is metallic ſplendent; that of the croſs fracture leſs ſo.

The texture of this ore is imperfect, and moſtly ſtraight foliated, often delicately ſtreaked, and paſſing over into radiated.

Fracture uneven, ſometimes exhibiting fine granular diſtinct concretions. Fragments indeterminately angular, blunt-edged.

It is ſoft, and brittle. It marks ſtrongly when rubbed. Yields a black dull ſtreak. Specific gravity 3.742, Hagen.

The foliated grey manganeſe ore is found in ſeveral places with the preceding ſub-ſpecies, to which it is, indeed, very nearly related. It formerly occurred plentifully in the mine St. Joachim, at Zellerfeld, on the Hartz, as coating of the druſy cavities in black and brown iron-ſtone, as alſo on quartz, &c. Hauſſmann, loc. cit.

3. *Compact grey manganeſe ore; Dichtes grau-braunſtein-ertz*, Wern.; *Indurated grey ore of manganeſe*, Kirw.

Its colour is bluiſh-black, paſſing into ſteel-grey; that of the ſtreak iron-black; in a ſtate of incipient decompoſition it takes a ruſt-brown hue. In a ſtrong light its ſurface is iridescent.

It is found maſſive, and in botroïdal maſſes, formed by the union of many globular diſtinct concretions. They are ſometimes confluent, when they form concentric, flat conchoidal diſtinct layers. The globules (at leaſt in the variety from Hertzberg, deſcribed by Hauſſmann) are divergingly radiated towards the centre; but towards the circumference, the radiated paſſes through fibrous and granular into perfectly compact. The flat conchoidal layers approach to the columnar, and here and there to the faſcicularly diverging radiated ſtructure, which again paſſes into compact.

Fracture even, very fine-grained, ſometimes inclining to flat

flat conchoidal. Fragments indeterminately angular, not very ſharp-edged.

It is hard, brittle, eaſily frangible. It ſoils leſs than the preceding ſub-ſpecies.

Internally it is either matt, *i.e.* dull, or gliſtening with a metallic luſtre; ſtreak generally ſhining.

Specific gravity 4.125, Hauſſmann.

According to an analyſis of Mr. Hauſſmann, it contains

Browniſh black oxyd of manganeſe	85
Silica	4
Oxygen	11
	100

The compact manganeſe of Romaneche, near Macon, in France, (which is remarkable for its conſiderable hardneſs, and in which barytes appears to be chemically combined with the metallic oxyd,) is, according to Vauquelin, compoſed of

Yellow oxyd of manganeſe	50
Barytes	14.7
Silex	1.2
Oxygen	33.7
Carbon	0.4
	100.0

It is found in Saxony, at Johangeorgenſtadt, in the Palatinate, where it occurs with lithomarge; at the Wurzelberg, in the Hertzberg foreſt, on the Hartz, where it is uſed as flux for the reduction of a rich, but very refractory red hematite. Hauſſmann, loc. cit.

In France it is found at Suquet, near Thiviez, department of Dordogne, in the neighbourhood of Perigueux. This is known by the name of *pierre de Périgueux.* Alſo at l'Aveline, near Saint-Diez, department of the Voſges; at Macon; at St. Micaud, department of the Saône and Loire. Brongn.

4. *Earthy grey manganeſe ore; Erdeges grau-braunſtein-ertz*, Wern; *Ochre of manganeſe*, Kirw.

Its colour varies between ſteel-grey and browniſh-black. Commonly maſſive or diſſeminated, ſometimes ſuperficial and dendritic.

Internally it is matt, or glimmering with metallic luſtre.

Fracture earthy, fine-grained; ſometimes fine ſcaly; fragments indeterminately angular, blunt-edged.

It ſoils ſtrongly, is very tender, and meagre to the touch.

It is found in Saxony, at Raſchau, Ilmenau, Ehrenſtock, &c. in Bohemia, in Cornwall and Somerſetſhire.

Brongniart refers to the earthy grey manganeſe that of Saint-Jean de Gardonenque in the Cevennes. It is very light and friable, and ſeparates, like baſalt, into irregular priſms. It occurs in granite.

Lenz, Wiedermann, and other authors, claſs with this ſub-ſpecies, the *black wad* of Derbyſhire and Devonſhire, which is alſo known under the name of *inflammable manganeſe*, on account of the property it poſſeſſes of inflaming ſpontaneouſly, when mixed with one-fourth of its weight of linſeed oil. It conſiſts, according to the analyſis of Wedgewood, of 0.43 manganeſe, 0.43 iron, and 0.04 lead. Werner firſt made a diſtinct ſub-ſpecies of it. According to other mineralogiſts, it is a variety of the black earthy manganeſe ore, (which ſee below.)

The *frothy manganeſe* (*Braunſtein-ſchaum* of Wiedenmann and others, *Manganeſe oxidé argentin*, Haüy,) appears likewiſe to be related to this ſub-ſpecies; but ſome dark coloured varieties have been referred to the black earthy manganeſe ore. They require to be ſubjected to cloſer examination.

II. *Black manganeſe ore; Schwartz braunſtein-ertz*, Wern. This is not ſubdivided by Werner; but Karſten, (in the new edition of his Mineralogiſche Tabellen,) and Reuſs (Mineralogie, v. p. 463.) diſtinguiſh the *indurated* and the *friable black manganeſe ores.* Hauſſmann, in his deſcription of the manganeſe ores from Ihlefeld, adds another, namely, the *foliated*, dividing the ſpecies, in the ſame manner as the grey manganeſe ore, into three ſub-ſpecies. Jameſon gives the following Wernerian deſcription of the black manganeſe ore.

Its colour is intermediate between browniſh-black and dark greyiſh-black.

Occurs maſſive, diſſeminated, and in octahedral cryſtals, which are ſmall, and very ſmall. The ſurface of the cryſtals is ſmooth and ſhining.

Fracture imperfect foliated, ſingle cleavage; ſometimes it inclines to uneven, and is alſo ſmall and ſcopiform, diverging radiated. Fragments indeterminately angular, blunt-edged.

Occurs in ſmall and fine granular diſtinct concretions. It is opaque. Gives a reddiſh-brown ſtreak. Is ſemi-hard, brittle, heavy.

It is found at Ehrenſtock, near Ilmenau, on grey antimony ore. Alſo at Rabenſtein, in Bavaria; at Zuhrbach, near Wagrain, in Salzburg; and at Miedzian, or Gora, in Weſt Gallicia.

The foliated black manganeſe ore of Hauſſmann was diſcovered at Ihlefeld by this diſtinguiſhed mineralogiſt, and firſt deſcribed by him in the ſeventh edition of Blumenbach's "Handbuch der Naturgeſchichte."

Its colour is coal black, approaching to a ſooty brown when paſſing into decompoſition. The powder is of an iron black colour.

It is found in curved lamellar layers of from ¼th to three lines in thickneſs, traverſing, in connection with compact black manganeſe ore, the clay-porphyry, which contains the veins of manganeſe ores in that diſtrict.

Its texture in one direction is imperfectly foliated; commonly ſtraight, ſeldom curved foliated.

Fracture uneven, of a fine grain. Fragments indeterminately angular, and not very ſharp-edged.

The ſurface of cleavage is ſemi-metallic, ſhining; that of the fracture is dull, or at beſt faintly glimmering, ſtreak ſhining. It is opaque. Semi-hard; rather brittle. Specific gravity from 3.7142—3.800.

The foliated black manganeſe ore is infuſible before the blowpipe; but with borax it melts into a purpliſh enamel. It ſtrongly effervefces with the mineral acids, and is precipitated by cauſtic alkalies, as brown, by carbonic acid, as white oxyd of manganeſe.

It has a near oryctognoſtic relationſhip to the manganeſe blende of Tranſylvania, from which, however, it is eaſily diſtinguiſhable, both by its chemical properties, and by colour and ſtreak. By decompoſition it paſſes into the compact black manganeſe ore.

It is accompanied with radiated grey manganeſe ore, compact black and red manganeſe ores, with calcareous ſpar, and lithomarge of a roſe red colour.

The compact black manganeſe ore of Hauſſmann is divided into *indurated* and *friable.*

The *indurated* variety is of a deep black colour; that of the powder is a ſooty or browniſh-black.

It

Strahan and Preſton,
New-Street Square, London.

It is found maſſive, and in thin curved lamellar layers. It is dull; ſtreak ſhining or glimmering.

Fracture fine earthy; fragments indeterminately angular, blunt-edged. It is ſoft; ſoils ſtrongly; feels meagre, and adheres to the tongue.

It has been found in St. Joachim mine, Zellerfeld (the maſſive), and at Ihlefeld, where it traverſes clay-porphyry in all its directions. It is accompanied by foliated black mangaueſe ore, which appears to paſs into it by decompoſition.

The *friable* variety is of a black and browniſh-black colour.

It is found maſſive, in globular maſſes, in thin curved lamellar diſtinct concretions on black hematite, often alſo as thin coating on black hematite, and dendritic.

Internally it is dull; the ſurfaces of the lamellar diſtinct concretions ſometimes glimmering; ſtreak ſhining.

Fracture fine earthy, fragments indeterminately angular, blunt-edged. It is perfectly friable; ſoils ſtrongly, feels meagre, and adheres ſtrongly to the tongue.

The variety from Hutthal, or the Hartz, was analyſed by Klaproth with the following reſult:

Brown oxyd of manganeſe	68
Oxyd of iron	6.50
Carbon	1
Barytes	1
Silica	8
Water	17.50
	102.0

It is found on the Hartz at the Iberg, at Zellerfeld, at the Galgenberg, near Clauſthal, and in the Hutthal, on the Hartz, where, according, to Klaproth, it was found iſſuing from the chinks of rocks as a moiſt, greaſy ſubſtance, which, on being expoſed to the air, was ſoon converted into a very fine black powder.

The fineſt dendritic varieties, from the Hartz, are thoſe of Grund, on a greyiſh-white marle-ſlate; and thoſe of Lerbach, on a green clay-ſlate.

Reuſs, who deſcribes the friable black manganeſe ore, refers to it the *wad*, mentioned above as a variety of the earthy grey manganeſe ore. It is, indeed, difficult to determine to which of the two the Engliſh black wad belongs, the different varieties of which require to be ſubjected to further examination.

Another ſubſtance nearly related to the wad is the *frothy manganeſe*, a metallic, reddiſh-brown, ſilmy ſubſtance, incruſting black hematite, and referred by ſome mineralogiſts to iron froth, by others to the earthy grey manganeſe.

III. *Red manganeſe ore; Rother braunſtein*, Werner; *Manganèſe ſilicifère blanc et roſe*, Haüy; *Manganèſe lithoïde blanc et rouge*, Brongn.

Its colour is roſe red of various intenſity; and ſometimes a very light yellowiſh-brown.

It occurs maſſive and diſſeminated.

Internally it is dull.

Fracture even, paſſing into large and flat conchoidal, and alſo ſometimes into ſplintery fragments: indeterminately angular, pretty ſharp-edged.

It is ſlightly tranſlucent, hard enough to ſcratch glaſs; brittle, and eaſily frangible.

Specific gravity 3.233, Kirwan, that of the Siberian 3.676, Lampadius.

Is infuſible before the blowpipe without addition, but aſſumes a browniſh colour; if the flame be urged by oxygen gas, ſmall particles will melt into a browniſh-black bead, attractable by the magnet. The Siberian red manganeſe ore, analyſed by Lampadius, is ſtated by this chemiſt to be fuſible by the heat of the blowpipe, when continued for a few minutes, into a ſhining black enamel; and much more eaſily with borax.

According to the analyſis given by Ruprecht, that from Tranſylvania conſiſts of

Oxyd of manganeſe	35.15
Oxyd of iron	7.04
Silica	55.06
Alumine	1.56
Water	0.78
	99.59

The analyſis of red manganeſe from Kapnik by Lampadius, appears to be that of a red variety of pearl-ſpar; (or perhaps of real carbonat of manganeſe.) The ſame chemiſt has, however, given an analyſis of the red manganeſian foſſil from Siberia, which certainly belongs to the ſubſtance under conſideration, although Mr. Lampadius himſelf appears to be of a different opinion. The reſults of his analyſis are

Oxyd of manganeſe	0.610
Oxyd of iron	0.050
Silica	0.300
Alumine	0.020
Loſs	0.020
	1000

The red manganeſe ore of Kapnik, which is placed by Mohs, near pearl-ſpar, under the name of Rothſtein, is found there as part of a vein formation, together with black ſilver ore, (Schwartz-giltig-ertz,) brown and yellow blende, galena, quartz, and now and then with ſome pearl-ſpar. The veins containing this formation are moſtly narrow, and often of a ſtratified ſtructure, in ſuch a manner that either maſſive quartz, or a mixture of quartz and red manganeſe, (Rothſtein), alternate with ſtrata of black ſilver ore, and blende, or galena, from the ſides towards the centre of the vein, where the druſes are generally incruſted with cryſtallized quartz, or alſo with pearl-ſpar. This, according to Mohs, is the general nature of thoſe veins, which however, alſo contain other foſſils beſides.

IV. *Sulphuret of manganeſe; Braunſtein blende; Manganglantz*, Karſt.; *Schwartz*, Klapr. Reuſs.

Its colour is between iron and pitch-black, here and there with a ruſt-coloured covering, often with variegated tarniſh. Colour of the powder dark braſs-yellow paſſing into greeniſh.

It is found maſſive, or coarſely diſſeminated in red manganeſe ore, which it alſo traverſes in foliated layers.

Texture in one direction imperfectly foliated; direction of the folia approaching to curved foliated. According to Haüy it is diviſible into a rhomboïdal priſm, which may be ſubdivided in the direction of the diagonals of its tranſverſal ſection.

It is opaque; its luſtre is ſemi-metallic ſhining; the ruſt-coloured decompoſing parts dull; ſtreak ſhining.

Fracture fine-grained uneven; fragments indeterminately angular, not particularly ſharp-edged.

It is ſoft, mild, and not difficultly frangible. Specific gravity 3.950. Klapr.

Infuſible before the blowpipe. When pulverized it gives out ſulphureted hydrogen as the addition of nitrous acid.

Strahan and Preſton,
New-Street Square, London.

According to Klaproth's analyfis, it confifts of

Oxyd of manganefe	82
Carbonic acid	5
Sulphur	11
	98

Klapr. Beitr. 3.

Vauquelin is of opinion, that the carbonic acid in the preceding analyfis belongs to the matrix of this ore. According to this chemift the conftituents are: manganefe at the minimum of oxydation 85, and fulphur 15.

It is found in Tranfylvania, in red manganefe ore accompanied with black tellurium, red and brown blende (fulphuret of zinc), copper pyrites, &c.

According to Delrio it has alfo been lately found in Mexico.

V. *Phofphat of manganefe; Phofphor-mangan,* Karft.; *Eifen-pech ertz,* Wern.; *Manganèfe phofphaté (ferrifère),* Haüy.

Its colour is reddifh and blackifh-brown, which paffes into black; colour of the ftreak greyifh, yellowifh, or reddifh-brown.

It occurs maffive. According to Haüy it is divifible in the direction of planes, which appear to indicate a rectangular parallelopipedon for the nucleus.

Internally it is fhining and gliftening, with a refinous luftre.

Fracture flat and imperfectly conchoidal, paffing into fine-grained uneven; fragments indeterminately angular.

It is faintly tranflucent at the edges.

It is femihard, paffing into foft; brittle.

Specific gravity 3.95.

It is readily fufible before the blowpipe into a black enamel; and is entirely foluble in nitric acid without effervefcence.

It is feldom found pure, generally containing iron, which, however, according to Darcet, appears to be accidental; the phofphoric acid being probably combined with the manganefe alone.

The light coloured varieties contain but a fmall quantity of iron.

Vauquelin, who analyfed this ore, obtained the following refult:

Oxyd of manganefe	42
Oxyd of iron	31
Phofphoric acid	27
	100

Journ. des Mines.

It has hitherto been found only near Limoges in France; it occurs in granite, in the fame veins that contain the well known opaque beryl.

MANGANUM, Μαγγάνον, among the Greeks, a general name for inftruments to throw large ftones with.

MANGATTI, in *Geography,* a town of Hindooftan, in Travancore; 18 miles N.E. of Anjenga.

MANGAVEIRAS, a town of Brafil, in the government of Para; 35 miles N.E. of Engenhoreal.

MANGEABOONG, a town on the N.W. coaft of Borneo. N. lat. 6° 3'. E. long. 116° 9'.

MANGEART, Thomas, in *Biography,* a learned monk, who obtained a very high reputation by his knowledge, and was appointed antiquary, librarian, and counfellor to duke Charles of Lorrain. He died in 1763, and is known in the republic of letters for a work entitled "Introduction à la Science des Medailles," fol. This work contains all the principles laid down in the elementary treatifes on the numifmatic fcience, and ferves as a fupplement to the "Antiquité expliquée" of Montfaucon.

MANGEE, in *Geography,* a town of Hindooftan, in Bahar; 13 miles W.N.W. of Chupra.

MANGEEA, or Mangya, an ifland in the South Pacific ocean, difcovered by captain Cook in the year 1777; but on which he could find neither a landing place nor anchorage. Such parts as fell under our navigator's obfervation were guarded by a reef of coral rock, on the outfide of which the fea is of an unfathomable depth. It is full five leagues in circuit, and of a moderate and pretty equal height; though, in clear weather, it may be feen at the diftance of ten leagues. In the middle it rifes into little hills, from which there is a gentle defcent to the fhore, which, at the S.W. part, is fteep, though not abuve 10 or 12 feet high, and has feveral excavations made by the beating of the waves againft a brownifh fand-ftone of which it is compofed. The defcent is covered with trees of a deep green colour, very thick, but not high, feeming to be of the fame fort, except near the fhore, where are many of that fpecies of dracæna found in the woods of New Zealand. On the N.W. part the fhore terminates in a fandy beach, beyond which the land is broken down into fmall chafms or gullies, and has a broad border of trees refembling tall willows. Farther on the afcent, the trees were of the deep green above-mentioned; and were fuppofed by fome to be the rima, intermixed with low cocoa-palms, and a few of fome other forts. On the little hills were trees of a taller fort, thinly fcattered; but the other parts were bare, and of a reddifh colour, or covered with fomething like fern. Upon the whole Cook obferves, that the ifland has a pretty afpect, and might be made a beautiful fpot by cultivation. When this ifland was firft difcovered, feveral of the natives were obferved to be armed with long fpears and clubs, which they brandifhed in the air either with figns of threatenings, or, as fome thought, with invitations to land. Moft of them appeared naked, except having a fort of girdle, which paffing between the thighs covered that part of the body. Some of them, however, had pieces of cloth of different colours, which they wore as a garment, thrown over their fhoulders: and almoft all of them had a white wrapper about their heads, not much unlike a turban, or like a high conical cap. Their colour was tawny, and they were in general of a middling ftature, but robuft and inclining to corpulence. They were at firft afraid of approaching the fhip in their canoe; but being addreffed by Omai in the Otaheitean language, their apprehenfions fubfided, and they came near enough to take fome beads and nails, which were thrown into their canoe. They were at firft afraid of touching thefe things, which probably arofe from fuperftition; for Omai underftood, that when prefents were offered them, they afked fomething for their "Eatooa," or god. When they were afked, if they ever ate human flefh; they anfwered in the negative, with a mixture of indignation and abhorrence. They wore a kind of fandals, made of a graffy fubftance interwoven, probably to defend their feet againft the rough coral rock on the fhore. Their beards were long; and the infide of their arms, from the fhoulder to the elbow, and fome other parts, were punctured or tattooed, like the inhabitants of almoft all the other iflands in the South fea. The lobes of their ears were pierced, or flit, to fuch a length, that one of them ftuck there a knife and fome beads which had been given him; and the fame perfon had two polifhed pearl-fhells and a bunch of human hair, loofely twifted, hanging about his neck,

neck, which was the only ornament that was obferved. The only canoe, that was feen, was not above 10 feet long, and very narrow, but both ftrong and neatly made. As the inhabitants feemed to be numerous and well fed, fuch articles of provifion as the ifland produces muft be very plentiful. One of the iflanders who came on board informed our navigators, that they had no animals, as hogs and dogs, both which they had heard of; but acknowledged that they had plantains, bread fruit, and taro. The only birds that were feen were fome white egg-birds, terns, and noddies; and one white heron on the fhore. The language of the inhabitants of Mangeea is a dialect of that fpoken at Otaheite; though their pronunciation, like that of the New Zealanders, be more guttural. The natives of Mangeea feem to refemble thofe of Otaheite and the Marquefas in the beauty of their perfons, more than thofe of any other nation feen by Capt. Cook in thofe feas; having a fmooth fkin and not being mufcular. Their general difpofition alfo correfponds with that which diftinguifhes the firft mentioned people; for they are not only cheerful, but are acquainted with all the lafcivious gefticulations which are practifed by the Otaheiteans in their dances. Their houfes alfo feem to refemble thofe of Otaheite. They falute ftrangers much after the manner of the New Zealanders, by joining nofes; adding, however, the ceremony of taking the hand of the perfon to whom they are paying civilities, and rubbing it with a degree of force upon their nofe and mouth. Cook's Third Voyage, vol. i.

MANGEL WURZEL, in *Agriculture*, a plant of the tap-rooted kind, which has been lately introduced into field culture. It is a variety of the common beet. The author of a late work on hufbandry remarks, that it grows to a large fize, both in the root and top, the former being of a reddifh caft, and the leaves in the latter of an oblong form, extremely thick, flefhy, and fucculent. Mr. Young, however, obferves, that it is but little in cultivation at prefent; though in Norfolk, fir Mordaunt Martin finds the root advantageous for his cow ftock. The leaves are afferted to be "equal in quality to fpinach, and from their frequently extending in length more than thirty inches, and in breadth above twenty, to greatly exceed that vegetable in point of produce."

Soil.—This, like all other tap-rooted plants that have been employed for the purpofes of hufbandry, thrives the beft in foils of the deep, friable, fandy, or light loamy defcriptions.

Preparation.—In preparing the ground for its reception, it is neceffary to render it as deep and fine as poffible in the mould. This may be beft effected in the heavier forts of land, by means of trench ploughing, in the manner of that for parfnips; and in thofe of the lighter kind, by repeated common deep ploughings. In both cafes, the frequent ufe of the harrows will be requifite. A proportion of good manure fhould alfo be turned in, fo as to render the ground fufficiently rich for the perfect growth of the plants. After this, at the time of putting in the feed, the land fhould be thrown into two-bout ridges, which leaves the tops about two feet in breadth, and the furrows one. In this way a confiderable increafe in the depth of mould is provided for the roots of the plants. And in foils that are in fome meafure retentive of moifture, the lands are kept much drier, and in a ftate more fit for the growth of the plants.

Seed and Method of fowing.—It is advifed, that the feed fhould be carefully felected from fuch plants as are the moft perfect of their kind, and that have been cultivated at a diftance from other varieties. It fhould have arrived at a full ftate of ripenefs, and be made ufe of while frefh. The moft proper feafon for putting the feed into the ground in the common method of fowing, is in the early part of the fpring as foon as the feafon will admit, as in the beginning or middle of April; but where the tranfplanting method is intended, it fhould be fown much earlier and very thinly, as the beginning of March, in order that the plants may be in a ftate to be fet out.

The moft common method, where the furface of the land is flat, is to fow the feed thinly over the ground, in the manner that is practifed for carrots, covering the feed in by means of very light harrowing. In this way, the plants are afterwards fet out by the hoe to proper diftances. But where the land is raifed into ridges in the manner juft defcribed, another mode is practifed: the feed is dropped fingly by the hand into little holes made by a dibble, to the depth of about half an inch, all along the middle of them, at the diftance of eight or nine inches from each other; the plants thus ftanding at the diftance of three feet, from row to row, and eight or nine inches apart in them. But as it is not neceffary that they fhould ftand nearer than 16 or 18 inches, every other plant may be removed, and ufed for filling up vacancies, where they occur, or if not wanted in that way, wholly removed by the hoe. In this mode the intervals can be kept perfectly clean by the plough or horfe-hoe, and the rows by hand-hoeing.

In the practice of tranfplanting, the plants fhould be removed, when not more than three or four inches in length, and be planted out in rows upon ridges prepared as above at the diftance of 18 inches each way. In performing the work, the holes fhould be made fufficiently deep to admit the roots without their being bent. The tops of the plants may be taken off before planting, but the roots fhould not be touched, nor fhould they be put in too deep. A rather moift feafon fhould be chofen, if poffible, for this bufinefs. But though the plants grow well in this method, the roots feldom become fo large as when they have remained in their original fituation.

All the culture that is afterwards neceffary in this fort of crop, is to fet out the plants to proper diftances, where put in, in the firft methods, and keep them clear from weeds by one or more hoeings, according to the manner of fowing that may have been practifed, and other circumftances.

It has been ftated that the application of this vegetable "has been chiefly in the feeding of neat cattle and hogs; in which both the tops and roots have been employed, but without that fuccefs which might have been expected from the manner in which it was brought to the notice of cultivators." It is probable, that upon the whole, the root has neither been found to be equal in quality as a cattle food, or to afford the quantity of produce that was fuppofed upon its firft introduction, but from its being of a hardy nature, and not liable to be injured, either by infects or the effects of drought, as well as from its leaves being capable of being repeatedly cut over, it may be occafionally cultivated in fituations where green food is much wanted in the latter end of the year, for milch cows or other forts of live ftock.

In fome trials detailed in the Annals of Agriculture, the plants feem, however, to have afforded a large produce in leaves, when gathered every two or three days, from July till late in September; others have not found the whole produce, in leaves and roots, equal to that of the large cabbage, on the fame kinds of foil, while the culture was confiderably more troublefome and expenfive, and the crop not fo ufeful for the purpofe of winter confumption.

In the trials of an ingenious cultivator, as stated in the Bath Papers, the tops were found to be eaten with much greediness by cows, calves, and hogs, when cut green, during the latter part of the summer and in autumn, but the roots were almost wholly rejected at these periods, though in winter, after they had been taken up, they were eaten very well.

The great objections to this vegetable, as a field plant, are, according to a late writer, ' the great expence of its culture, its being liable to degenerate, and the fibrous nature of the roots rendering their preparation as cattle food troublesome."

The roots frequently rise, it is said, to the weight of from five to eight or ten pounds, according to the goodness of the land; and they may be preserved in the winter, by being taken up and packed in the manner of carrots, or any other method.

MANGEN, in *Geography*, a town of the duchy of Courland; 10 miles S.W. of Piltyn.

MANGER, in *Ship Building*, a place parted off immediately within the hawse-holes. It prevents whatever water that comes in at the hawse-holes from running off, and is returned back again by the scuppers in the manger.

MANGER, in *Rural Economy*, an internal part of the stable in which the corn or cut provender of the horse is put. It is a sort of box or crib, and the usual method is to have them the whole breadth of the stall; but this is unnecessary, as when eighteen or twenty inches in length, and fourteen or sixteen in breadth, they will be sufficient for every useful purpose. In the fixing of them they should be so contrived as to admit of being removed for the purpose of being cleaned. This can, however, never be done in the old method of fixing them: but, by a little contrivance, may be easily effected. It is, in many cases, a convenient plan to have them in the corners or angles at the heads of the stalls. See STABLE and STALL.

MANGERA, in *Geography*, an island of Mexico, about four miles in circumference, in the gulf of Amapalla.

MANGERA *Strait*, a channel of the East Indian sea, between the islands of Cumbava and Flores, full of small islands. Flores is also called Mangeray.

MANGERBARY, a town of Hindoostan, in Visiapour; 15 miles S. of Merritch.

MANGERTON, a mountain of Ireland, in the county of Kerry, S. of the lake of Killarney, and forming a very interesting object in the scenery of that beautiful and romantic spot. It is one of the highest mountains in Ireland, being 2500 feet above the lake. From its summit, the two lakes, with the passage between them, and a large tract of country, may be seen to great advantage. To ascend Mangerton should therefore be a fixed object of every person who visits Killarney.

MANGET, JOHN JAMES, in *Biography*, a laborious medical writer, was born at Geneva in June, 1652. After going through his classical studies and the courses of philosophy, he commenced the study of theology, with the intention of entering the clerical profession, but after five years of labour, his inclination to medical pursuits prevailed, and by the aid of books alone, without any teacher, he made such a progress, that he was admitted to the degree of M.D. at Valence, in Dauphiny, in 1678. He then commenced the practice of physic, in which he obtained considerable reputation in his native city, which he refused to quit, though solicited by invitations from various quarters. In 1699, Frederick III. elector of Brandenburg, and afterwards the first king of Prussia, honoured him with the appointment of his first physician. In his literary labours, Manget was indefatigable, even to the end of his long life. He maintained a correspondence with many of the learned men of his time, some of whom, especially Daniel le Clerc, the author of the History of Medicine, are said to have assisted him in his works. He died at Geneva in August, 1742, in the ninety-first year of his age.

Among the numerous works of compilation, which Manget executed, originality is not to be expected; nor are they remarkable for judgment and accuracy. They are, however, still useful for reference. They are as follows: 1. "Messis Medico-spagyrica, &c." folio, Geneva, 1683; which contains a most abundant collection of pharmaceutical preparations, arranged in a very complex order. 2. In the same year he edited, "Pauli Barbette Opera omnia Medica & Chirurgica," with additional cases and illustrations. 3. "Bibliotheca Anatomica," 1685, two vols. folio; a work which was executed in conjunction with Daniel le Clerc. He afterwards edited; 4. The "Compendium Medicinæ Practicum," of J. And. Schmitz. 5. The "Pharmacopeia Schrodero-Hoffmanniana." 6. The "Tractatus de Febribus" of Franc. Picus; and 7. The "Sepulchretum" of Bonetus, to which he added several remarks and histories. 8. In 1695, he published his "Bibliotheca Medico-Practica," four vols. folio; a vast collection of practical matter relative to all the diseases of the human body, arranged in alphabetical order. Other compilations of a similar kind he afterwards published relative to surgery, chemistry, and pharmacy: *viz.* 9. "Bibliotheca Chemica curiosa," two vols. folio, 1702; 10. "Bibliotheca Pharmaceutico-Medica," two vols. folio, 1703; and 11. "Bibliotheca Chirurgica," four vols. in two, folio, 1721. But in the mean time, he had printed his (12.) "Theatrum Anatomicum, cum Eustachii Tabulis Anatomicis," two vols. folio, 1716. This is a description of all the parts of the body, abridged from various authors; the osteology is that of Bidloo; the myology that of Brown; and the splanchnology that of Ruysch; and his selections are not to be praised. It has been justly objected to him, that he omitted to notice the discoveries of the anatomists of the sixteenth century. There is scarcely any thing of his own in this work, except some morbid dissections. On the appearance of the plague at Marseilles, he published a collection of facts and opinions on that disease, under the title of "Traité de la Peste recueilli des meilleurs Auteurs," two vols. 12mo. 1721: and, in the following year, 14. "Nouvelles Reflexions sur l'Origine, la Cause, la Propagation, les Preservatifs, et la Cure de la Peste," 12mo. 15. His "Observations sur la Maladie qui a commencé depuis quelques années à attaquer le gros Betail," was a collection of the opinions of the Genevese physicians concerning the distemper of horned cattle. The last work of Manget was his "Bibliotheca Scriptorum Medicorum veterum et recentiorum," at which he laboured when at least eighty years of age, and published it in two vols. folio, in 1731. It is the most important of his productions, being an useful collection of medical lives, and catalogues of writings. Eloy Dict. Hist. Gen. Biog.

MANGEY, THOMAS, a learned English divine, was educated at St. John's college, Cambridge, where, in due time, he took his degree of D.D. He was distinguished in the church as prebendary of Durham, and published an edition of "Philo Judæus," in 2 vols. folio: "An Answer to Toland's Nazarenus;" and a volume of "Sermons on the Lord's Prayer." He died in the year 1755.

MANGIFERA, in *Botany*, is that celebrated fruit of the East Indies called *Mango*, whose different varieties are universally known and cultivated in that country, being as much esteemed, and nearly as various in quality, as the different

different kinds of apples produced in England. The vernacular name of this fruit, which may be confidered as a fort of plum, is *Manga*, or *Manghos*, and this appellation being coupled to the verb *fero*, to bear, fhews the derivation of its generic name. Linn. Gen. 110. Schreb. 153. Willd. Sp. Pl. v. 1. 1150. Ait. Hort. Kew. ed. 2. v. 2. 39. Juff. 369. Lamarck Illuftr. t. 138. Gærtn. t. 100. —Clafs and order, *Pentandria Monogynia*. Nat. Ord. *Terebintaceæ*, Juff.

Gen. Ch. *Cal.* Perianth inferior, deeply cloven into five, lanceolate fegments. *Cor.* Petals five, lanceolate, furrowed, longer than the calyx. *Stam.* Filaments five, awl-fhaped, fpreading, as long as the corolla; anthers inclining to heart-fhaped. *Pift.* Germen fuperior, roundifh; ftyle thread-fhaped, the length of the calyx; ftigma fimple. *Peric.* Drupa kidney-fhaped, oblong, keeled, compreffed. *Seed*, an oblong, compreffed, woolly nut.

Eff. Ch. Corolla of five lanceolate petals. Drupa fuperior, kidney-fhaped. Nut woolly.

1. M. *indica*. Mango Tree. Linn. Sp. Pl. 290. Jacq. Ic. Rar. v. 2. t. 337. Andr. Bot. Repof. t. 425. (Manga domeftica; Rumph. Amboin. v. 1. 93. t. 25.)—Leaves ftalked, lanceolate-oblong. Four of the ftamens abortive. —Native of the Eaft Indies. With us it is kept in the ftove, where it bloffoms in fpring and autumn, though rarely. In India it forms a tall and fpreading *tree*, not unlike an oak in its manner of growth, with thick and wide-extended branches, but the wood is far more brittle and lefs hard and firm. *Leaves* fcattered, ftalked, fimple, about a fpan long, and an inch or two wide, wavy, entire, tapering at each end, veiny, fmooth and fhining. *Panicles* terminal, compound, fpreading, downy, of innumerable fmall white *flowers*, moft of which are abortive. *Fruit* the fize of a large plum, of an orange or tawny colour with a tinge of red; its pulp extremely juicy, with a rich fweet perfumed flavour, accompanied by a grateful acidity. Rumphius fays it is the fineft Indian fruit except the Mangoftan; (fee GARCINIA.) In an unripe ftate it makes an excellent pickle, often brought to Europe.

2. M. *laxiflora*. Loofe-flowered Mango. Lamarck Dict. v. 3. 697. Willd. n. 2.—" Leaves ovato-lanceolate, nearly feffile. Stamens all perfect. Fruit roundifh." —Native of the ifland of Mauritius. We know this fpecies merely by Lamarck's account. It is faid to have the habit of the foregoing, but the *leaves* are nearly feffile, the *panicles* more elongated and lax, the *ftamens* all perfect, fegments of the *calyx* much more obtufe, and the *fruit* fmaller, more oval and rounded.

3. M. *axillaris*. Axillary-flowered Mango. Lamarck Dict. v. 3. 697. Willd. n. 3.—" Leaves ovate-oblong, bluntifh. Panicles axillary. Stamens ten."—Found by Sonnerat in the Eaft Indies. Lamarck, who received it from that intelligent traveller, defcribes this fpecies as clearly diftinguifhable from the two former by the above characters. The *leaves* are four or five inches long, and near two in breadth. *Fruit* the fize of a fmall cherry, but that author faw it only in a dry, and poffibly unripe ftate.

Another fpecies is defcribed in the *Supplementum* of Linnæus, p. 156, by the name of M. *pinnata*, but this is now referred by Willdenow to *Spondias*, and, as it feems, juftly. See SPONDIAS.

MANGIFERA, in *Gardening*, comprehends a plant of the tree exotic kind for the ftove, of which the fpecies cultivated is the Mango-tree (M. indica.)

There are feveral varieties, none of which are cultivated.

Method of Culture.—As the vegetative property of the feed or nuts of this fpecies of tree does not feem to be long preferved, the readieft method to obtain plants, is to have a quantity of the nuts fet in tubs of earth in the country where they grow naturally, and when the plants are grown a foot high, to have them fhipped, placing a covering over them to defend them from the water and fpray of the fea, being careful not to give them too much water in the paffage. When they arrive in a cold climate, they fhould be fcreened from cold. The plants fhould afterwards be fet in pots filled with light kitchen-garden earth, and be placed in a dry ftove, where, in warm weather, they fhould have frefh air daily, and in winter the air be kept up to temperate, as marked on the botanical thermometer; as they do not fucceed well in the tan-bed of the ftove.

And where the nuts are made ufe of, they fhould be fent over in wax to preferve their vegetative property.

They are alfo capable of being increafed from cuttings, in the manner of gardenia, in this climate.

MANGISCHLAK, in *Geography*, a town on the E. coaft of the Cafpian fea, which is a place of confiderable trade between the Tartars and Ruffians of Aftrachan; 180 miles S.E. of Aftrachan. N. lat. 44° 10'. E. long. 52 14'.

MANGIT, a town of European Turkey, in Beffarabia; 22 miles N.N.E. of Tobak.

MANGLARES, or CORN ISLAND, an ifland in the Spanifh Main, about 15 miles long and five broad; near which is another fmall ifland called "Little Manglares." N. lat. 11° 44'. W. long. 82° 20'.

MANGLE. See LAU[illegible]

MANGLE, or *Mangles*, in *Botany*. See RHIZOPHORA.

MANGLILLA, Juff. 151. A Peruvian fhrub, with the habit of a Cherry-laurel, but with fmall axillary pentandrous flowers, to which Dombey gave the name of *Dubamelia*. It is called *Caballeria* in the *Flora Peruviana*. See MYRSINE, to which genus this plant is referred by Mr. R. Brown.

MA[illegible]NOR, in *Geography*, a town of Norway, in the province of Aggerhuus; 15 miles S. of Konigfwinger.

MANGO, a town of Africa, in the kingdom of Agonna; which fee.—Alfo, a river of Sweden, which runs into the Wenner lake; 10 miles W. of Carlftadt, in the province of Warmeland.

MANGO-*Tree*, in *Botany*. See MANGIFERA.

There are various forts of this fruit, as there are of our apples and pears, which are very different, according to the countries where they grow: that fpecies, which is without a ftone, and is very grateful to the palate, feems to us only a variety or a degenerated fruit; the fruit is cut into flices, and eaten either without wine, or macerated in wine, it is alfo candied, in order to its prefervation; fometimes they open it with a knife, and fill up the middle with frefh ginger, garlick, muftard, and falt, with oil or vinegar, that they may eat it with rice, or after the manner of pickled olives.

As to its temperament, this fruit is cold and moift, though the Indian phyficians affirm the contrary. We make ufe of pickled mangoes which are imported to us, as we do of pickled cucumbers. The ftones roafted are faid to cure a loofenefs, which Garcias found to be true. The wood of the tree, with cinders, is ufed for burning the carcafes of the Pagans, as being confecrated to this rite; whence it ferves alfo for coffins, in which they depofit their dead; it is, however, of a foft fubftance, and of a fhort duration. The ftalks fupply the place of areca, or caunga, in the chewing of betel; the fame, calcined and reduced to powder, take away warts. Of the tender leaves, with the bark of the avanacoe, that is, the ricinus, the feed of cummin and parpaclagam, is made a decoction, which is faid to be highly beneficial in the cough, afthma, and other affections of the thorax. The bark of the tree pulverized, and taken in chicken broth, is an excellent diffolvent of extravafated and coagulated blood, occafioned by a fall, in any part of the body. The juice of the bark, with the white of an egg, and a very little opium, taken inwardly, is a prefent remedy againft the diarrhœa, dyfentery, and tenefmus. Of the gum of the tree, and the flowers of rice, with the addition of a fmall quantity of opium and pepper, are prepared pills, which alfo cure all forts of fluxes of the belly. Of the flour of the dried kernels the natives have the art of preparing various kinds of food. James.

MANGO, in *Ornithology*, a fpecies of *Trochilus*; which fee.

MANGONA, in *Military Language*, formed from a Greek word of the fame import, in the time of the lower empire, was ufed in general to denote all kinds of machines; and *Mangonel* was a diminution, applied to the fmaller machines.

MANGONEGRO, in *Geography*, a market and poft-town of Spain, in the kingdom of Seville, three leagues from Cordova.

MANGONNE, one of the fmaller Friendly iflands. S. lat. 19° 38'. E. long. 185 30'.

MANGOPUNGLY, a town of Hindooftan, in Meywar; 38 miles E. of Cheitore.

MANGOR, a town of Africa, in the kingdom of Kayor.

MANGOSTANA, in *Botany*. See GARCINIA.

MANGOUSTE, in *Zoology*, the *Viverra Mungo*. See VIVERRA and ICHNEUMON.

MANGRABA, in *Geography*, a town of Hindooftan; in Bahar; 55 miles N. of Hajypour.

MANGROLLA, a town of Hindooftan, in Guzerat; 25 miles N.E. of Surat.

MANGROVE, in *Botany*. See RHIZOPHORA.

MANGROVE *Grape*. See COCCOLOBA.

MANGROVE *Ifland*, in *Geography*, a fmall ifland among the Bahamas. N. lat. 26° 12'. W. long. 78° 45'.

MANGROVE *River*, a river of New Zealand, fo called by lieutenant Cook in 1769, on account of the number of mangrove trees about it, which runs into Mercury bay. The fafeft and beft way of failing into this river is to keep the fouth fhore all the way on the board. The country on the E. fide of the river and bay is very barren, its produce being only fern, and a few other plants that will grow in a poor foil. The land on the N.W. fide is covered with wood, and the foil, being much more fertile, will, doubtlefs, produce all the neceffaries of life with proper cultivation. The inhabitants have no plantations; their canoes are mean, and without ornament; they fleep in the open air, and fay, that Taratu, whofe fovereignty they do not acknowledge, if he was to come among them, would kill them. Hence it was inferred, that they were outlaws; though they faid that they had heppahs, or ftrong holds, to which they retired in time of danger. Hawkefworth's Voy. vol. ii.

MANGSCHATE, a town of Silefia, in the principality of Brieg; 8 miles N.E. of Brieg.

MANGULUM, a town of Hindooftan, in Coimbetore; 25 miles S.S.E. of Coimbetore.

MANGUT, a town of Hindooftan, in Baramaul; 28 miles S.S.E. of Darempoor.

MANGUTZKOI, a town of Ruffia, in the government of Irkutfk, on the borders of China; 88 miles W. of Doroninfk. N. lat. 49 40'. E. long. 111° 4'.

MANHEIM, a city of Germany, now belonging to the electorate of Baden, is fituated on a low plain, near the conflux of the Neckar and the Rhine. The old village and citadel of Manheim were converted into a town by the elector Frederic IV. in the year 1606, and adapted to the accommodation of fome Netherlanders, who had quitted their country for the fake of liberty of confcience: and though it was afterwards, *viz.* in 1622, befieged and taken by the Bavarians, and again, *viz.* in 1688, entirely demolifhed by the French, it was re-built by the electors John William and Charles Philip, and fortified in fuch a manner, that it became one of the ftrongeft places in Germany. Its prefent works were formed upon the fyftem of Coehorn. The number of inhabitants, exclufive of the garrifon, was, in 1784, 21,858. Some of the ftreets are planted with rows of trees, and it has five or fix open places, fuitable for promenades or markets. The cuftom-houfe, forming one fide of thefe, is a noble ftone-building, refembling a palace, having under the colonnades that furround it fhops for jewellery and other commodities. The elector's palace opens on one fide to the city, and on the other to the ramparts; it contains a gallery for paintings, and cabinets of antiquities and fubjects of natural hiftory, a library, treafury, and menage. Manheim was taken by the French in 1795, and, in 1802, it was ceded, together with its territory, to the margrave (elector) of Baden. N. lat. 49° 28' 59". E. long. 8° 27' 22".

MANHEIM *School of Mufic*. About the year 1759, the band of the elector palatine in this city, and at Schwetzingen, was regarded as the moft complete and beft difciplined in Europe. We found it to be, indeed, all that its fame had made us expect: power will naturally arife from a great number of hands; but the judicious ufe of that power, on all occafions, muft be the confequence of good difcipline; indeed, there were more folo players and good compofers in this than perhaps in any other orcheftra in Europe; it was an army of generals, equally fit to plan a battle as to fight it.

But it was not merely at the elector's great opera that inftrumental mufic had been fo highly cultivated and refined, but at his concerts, where this extraordinary band had full liberty to difplay all its powers, and to produce great effects without the impropriety of deftroying the greater and more delicate beauties peculiar to vocal mufic; it was here that Stamitz, ftimulated by the productions of Jomelli, firft furpaffed the bounds of common opera overtures, which had hitherto only ferved in the theatre as a kind of court-cryer, with an "O Yes!" in order to awaken attention and befpeak filence at the entrance of the fingers. Since the difcovery which the genius of Stamitz firft made, every effect has been tried which fuch an aggregate of found can produce; it was here that the crefcendo and diminuendo had birth; and the piano, which was before chiefly ufed as an echo, with which it was generally fynonimous, as well as the forte, were found to be mufical colours which had their fhades, as much as red or blue in painting.

In 1772, the band of his electoral highnefs confifted of near a hundred hands and voices. Among whom were Hotzbauer, Canabich, Charles and John Toefchi, Bapt. and Charles Wendling, and the late excellent performer on the violin and leader, Cramer. There were twenty-three vocal performers in this band, among whom Mad. Wendling, Mad. Danzi, afterwards married to Le Brun, a celebrated performer on the hautbois, Mad. Cramer, the mother of the prefent admirable performers now in England, and Alleganti; with the Italian vocal performers, Roncaglio, Pefarini, and Saporofi. His electoral highnefs of that period was himfelf a good performer on the German flute. And the operas

operas executed at Manheim in winter were reprefented in one of the largeft and moft fplendid theatres in Europe, capable of containing 5000 perfons. His electoral highnefs's fuite at Schwetzingen, during fummer, amounted to 1500 perfons, who were all lodged in this little village at his expence. To a ftranger walking through the ftreets of Schwetzingen at this time it muft feem to be inhabited only by a colony of muficians, who are conftantly exercifing their profeffion: at one houfe, a fine player on the violin is heard; at another, a German flute; here an excellent hautbois; there a baffoon, a clarinet, a violoncello, or a concert of feveral inftruments together. Mufic feems to be the chief and moft conftant of his electoral highnefs's amufements; and the operas and concerts, to which all his fubjects have admiffion, form the judgment, and eftablifh a tafte for mufic, throughout the electorate.

MANHEIM, in *Geography*, a town of America, in Pennfylvania, in the county of Lancafter, containing 60 houfes, and 1041 inhabitants, and a Dutch church; 11 miles N. by W. of Lancafter.—Alfo, a town in York county, Pennfylvania, having 1876 inhabitants.

MANI, in *Biography*. See MANICHEES.

MANI, in *Geography*, a town of Africa, in Benguela, on the coaft of the Atlantic; 16 miles S. S. E. of Old Benguela.

MANIA, in *Medicine*. See MENTAL *Derangement*.

MANIACI, in *Geography*, a town of Sicily, in the valley of Demona; 7 miles S.W. of Randazzo.

MANIANA, a country of Africa, fituated S.E. of Bambarra: the inhabitants of which are faid to be cannibals. N. lat. between 13° and 14°. W. long. 1°.

MANIARY, a town of Hindooftan, in Bahar; 22 miles N.E. of Maifey.

MANJAWICK, a town of Hindooftan, in the Carnatic; 30 miles S.E. of Tanjore.

MANJAWLY, a town of Hindooftan, in Oude; 40 miles S.E. of Goorapour. N. lat. 26° 17′. E. long. 84° 13′.

MANICA, a town of Africa, the capital of Chicanga, fituated on the river Sofala, S. lat. 20° 20′. E. long. 28°. —Alfo, a river which rifes in Chicanga, and runs into the Indian fea, S. lat. 25° 30′. E. long. 29° 30′; called alfo "Rio del Lagos," and "Rio del Spiritu Santo."

MANICA, properly a fleeve. See HIPPOCRATES's *fleeve*. Hildanus calls by this name a particular fort of purfe, open at both ends, which he defcribes in his Treatife "De Gangræna et Sphacelo," and gives a figure thereof. This he directs to be put about a limb, juft before the place of amputation, before the operation is performed.

MANICARIA, in *Botany*, fo named by Gærtner, from *manica*, a fleeve, in allufion to the fhape of the *fpatha*, which is like a pouch or bag; whence the older botanifts called the plant in queftion *Palma faccifera*, and Sachel Date. Gærtn. v. 2. 468. t. 176. Willd. v. 4. 493. Lamarck Illuftr. t. 774.—Clafs and order, *Monoecia Polyandria*. Nat. Ord. *Palmæ*, Linn. Juff.

Gen. Ch. *Cal.* Common Sheath pouch-like, pointed at the bafe, interwoven with innumerable fibres, not burfting, widely extenfible, permanent. Stalk bearing male and female flowers, enclofed within the fheath, wand-like, with numerous, fimple, ftraight, compreffed, crowded, notched, toothed, downy, rufty branches.—*Male flowers* very numerous, (above two thoufand,) covering the branches of the ftalk. *Cal.* Perianth of one leaf, fhort, angular, torn, membranous. *Cor.* obovate, triangular, of three equal coriaceous petals. *Stam.* Filaments twenty-four, capillary, diftinct; anthers oblong, furrowed.—*Female flowers* few, fcarcely more than twenty, feffile on the lower part of the branches of the ftalk. *Cal.* Perianth inferior, of one leaf, membranous, thin, obliquely ftriated, crenate and jagged. *Cor.* ovate, pointed, triangular, of three coriaceous petals, four times as large as thofe of the male. *Pift.* Germen fuperior, turbinate, triangular, of three cells; ftyle one, fhort, thick, conical; ftigma fimple. *Peric.* Drupa globofe, acutely tuberculated, dry, of three cells. *Seed.* Nuts folitary, very hard, roundifh, fmooth.

Eff. Ch. Common Sheath pouch-like, fibrous, not burfting.—Male, Calyx of one leaf, torn. Petals three. Stamens twenty-four.—Female, Calyx of one leaf, torn. Petals three. Style one. Drupa fuperior, dry, tuberculated. Nuts three.

1. M. *faccifera*. Sachel Palm. (Palma faccifera; Cluf. Exot 4. Bauh. Hift. v. 1. 383. Ger. em. 1554.)—Native of South America. Clufius fays it was found by fome Dutch failors on a defert ifland in the Atlantic ocean; Gærtner, that it grows in Curaçao and Dutch Guiana. Willdenow feems wrong in confidering it a native of the Eaft Indies. Of the *tree* itfelf, or its foliage, nothing is known. The *fpatha* is occafionally feen in the mufeums of the curious, and refembles a fort of netted fibrous bag, from two to four feet long, containing numerous, globular, three-celled *fruits*, the fize of a large cherry, or fmall walnut, whofe outfide is ftrongly muricated with fharp, prominent, unequal tubercles. Gærtner had not feen the fruit in an advanced ftate, or he would not have fufpected that it could be the fame as his *Coccos lapidea*, t. 6. f. 1.—We do not find the nuts fo very hard as Clufius defcribes them, and therefore conclude our fpecimen to be but about half ripe. The coat of the drupa is of a corky fubftance, but denfely fibrous, and is divided internally into three cells, each containing one nut, whofe fhell is fmooth and brittle. One of the cells is occafionally abortive. Of the kernel we can determine nothing, it being but half formed.

MANICHEES, or MANICHEANS, MANICHÆI, in *Ecclefiaftical Hiftory*, a fect of ancient heretics, who afferted two principles; fo called from their author *Manes*, *Mani*, or *Manichæus*, a Perfian by nation, and educated among the Magi, being himfelf one of that number before he embraced Chriftianity. See MAGI.

This herefy had its firft rife about the year 277, and fpread itfelf principally in Arabia, Egypt, and Africa. Dr. Lardner, after having examined many authorities, with regard to the rife of Manicheeifm, both in Perfia and in the Roman empire, concludes with expreffing his doubt whether it was known in the Roman empire before the very end of the third century, or the beginning of the fourth. St. Epiphanius, who treats of it at large, obferves, that the true name of this herefiarch was Cubricus; and that he changed it for *Manes*; which, in the Perfian or Babylonifh language, fignifies *veffel*. A rich widow, whofe fervant he had been, dying without iffue, left him ftore of wealth; after which he affumed the title of the apoftle or envoy of Jefus Chrift.

We fhall here fubjoin fome additional circumftances relating to this herefiarch. Mani, always fo called by the Perfians and Arabians, and ufually denominated Manes, or Manichee, by the Greeks and Romans, was a Perfian, or at leaft lived in the territories of the king of Perfia. This is allowed by all thofe authors who fpeak of him. Cave and Tollius derive his name from the Greek noun "mania," fignifying madnefs, intimating that his name was the fame as "Maneis," *i. e.* mad or furious; whereas the name is certainly Perfic or Chaldaic. Cyril of Jerufalem fays, that he changed his name from Cubricus to Manes, thinking by fo doing to gain honour among the Perfians, but

but divine providence fo ordered it, that he thereby affixed to himfelf among the Greeks the character of madnefs. Beaufobre obferves, that whatever was the meaning of the name, it certainly was very honourable; and if it fignified any thing, it denoted fome advantageous quality; for divers kings of Edeffa were named Manes, or Maanes; and Affemann fays, that it was a common name of the princes of Syria and Arabia. The Greek writers continually reprefent Mani as a flave, purchafed by a widow, and afterwards fet at liberty. This widow, it is faid, adopted him for her fon, gave him a good education, and at length made him her heir. It has been doubted, however, whether Mani was ever a flave, as no notice is taken of this circumftance by the eaftern writers: and even the Greek authors fpeak of him as rich, learned, educated among philofophers, and at the court of Perfia in his early age. Manes, among the Greeks, was a common name for flaves; and hence it has been conjectured originated the common opinion of the Greek writers concerning Mani's fervitude. The eaftern authors, cited by Hyde and Herbelot, fay that Mani was by profeffion a painter and engraver; that he had fo fine a hand as to draw lines and make circles without rule or compafs, and that he made a terreftrial globe with all its circles and divifions. It is alfo faid that he was fkilled in aftronomy, and that he wrote a book of aftrology. It is probable, according to Beaufobre, that Mani believed our earth to have two hemifpheres, an upper and a lower, both inhabited; and, confequently, that there are antipodes. He is reprefented as a learned man and a philofopher, and it is faid that he wrote a fyftem of philofophy, and invented a mufical inftrument, called by the Arabians "Oud." That he was learned appears from various circumftances already recited.

Mani was not contented with the quality of apoftle of Jefus Chrift, but he alfo affumed that of the Paraclete, whom Chrift had promifed to fend: which Auguftin explains, by faying, that Mani endeavoured to perfuade men, that the Holy Ghoft did perfonally dwell in him with full authority. He left feveral difciples, and, among others, Addas, Thomas, and Hermas. Thefe he fent, in his lifetime, into feveral provinces to preach his doctrine. Mani, having undertaken to cure the king of Perfia's fon, and not fucceeding, was put in prifon upon the young prince's death, whence he made his efcape; but he was apprehended foon after, and flayed alive. Beaufobre gives no credit to the ftory of his attempt to cure the king of Perfia's fon.

The oriental writers, cited by D'Herbelot and Hyde, tell us, that Mani, having gained fome efteem, began to gather together a number of people in the character of difciples, who oppofed the worfhip and ceremonies of the religion of Zoroafter, profeffed at that time by the Perfians. Sapor, on this account and the fubfequent difturbances, would have had him punifhed, but Mani, perceiving his danger, fled into Turkeftan, where he had full opportunity to propagate his opinions, and where he was regarded as a wonderful man, and even a god. Here it is faid he lodged for a year in a cave, where he framed an impofture that multiplied the number of his followers, who all went from Turkeftan into Perfia upon the death of Sapor. Mani was protected in a fingular manner by Hormizdas, who fucceeded Sapor in the Perfian throne, but he was unable to defend him, at length, againft the united hatred of the Chriftians, the Magi, the Jews, and the Pagans: he was fhut up in a ftrong caftle, to ferve him as a refuge againft thofe who perfecuted him on account of his doctrine. Thefe writers add, that, after the death of Hormizdas, Varanes I. his fucceffor, firft protected Mani, but afterwards gave him up to the fury of the Magi, whofe refentment againft him was due to his having adopted the Sadducean principles, as fome fay; while others attribute it to his having mingled the tenets of the Magi with the doctrines of Chriftianity. Varanes having at firft fuccoured him, afterwards brought him out of his caftle under a pretence of difputing with the doctors of the Zoroaftrian fect, flayed him alive, filled his fkin with chaff, and had it hung up in a confpicuous place to terrify thofe of his fect; upon which moft of his followers fled into India, and fome even to China. All who remained in Perfia loft their liberty, and were reduced to fervitude. It is generally reported, both by the Eaftern and Greek writers, that Mani was put to death by a king of Perfia; but they feem to have no knowledge of the death of the king of Perfia's fon; and it is certain that the Manicheans celebrated the day of their mafter's death, which is generally fuppofed to have happened in the year 278.

It has been a fubject of much controverfy, whether Mani was an impoftor who pretended to prophecy and infpiration. The learned Dr. Lardner has examined the arguments on both fides; and though he does not choofe to deny that he was an impoftor, he does not difcern evident proofs of it. He acknowledges that he was an arrogant philofopher, and a great fchemift; but whether he was an impoftor he cannot certainly fay. He was much too fond of philofophical notions, which he endeavoured to bring into religion, for which he is to be blamed: neverthelefs, he obferves, that every bold dogmatifer is not an impoftor. Lardner allows that Mani and his followers were Chriftians, and held many opinions in common with other Chriftians.

The doctrine of Mani, fays Mofheim, was a motley mixture of the tenets of Chriftianity with the ancient philofophy of the Perfians, in which he had been inftructed during his youth. He combined thefe two fyftems, and applied and accommodated to Jefus Chrift the characters and actions which the Perfians attributed to the god Mithras.

He eftablifhed two principles, *viz.* a good and an evil one: the firft a moft pure and fubtile matter, which he called *light*, did nothing but good; and the fecond, a grofs and corrupt fubftance, which he called *darknefs*, nothing but evil. This philofophy is very ancient; and Plutarch treats of it at large in his Ifis and Ofiris.

Our fouls, according to Mani, were made by the good principle, and our bodies by the evil one; thofe two principles being, according to him, co-eternal, and independent of each other. In this notion, according to St. Auguftin, his followers triumphed to a great degree, fuppofing that it afforded the beft account of the origin of evil. Each of thefe principles is fubject to the dominion of a fuperintending being, whofe exiftence is from all eternity. The being who prefides over the light is called God; he that rules the land of darknefs bears the title of hyle, or demon. The ruler of the light is fupremely happy, and, in confequence thereof, benevolent and good: the prince of darknefs is unhappy in himfelf, and defirous of rendering others partakers of his mifery, and is evil and malignant. Thefe two beings have produced an immenfe multitude of creatures, refembling themfelves, and diftributed them through their refpective provinces. After a conteft between the ruler of light and the prince of darknefs, in which the latter was defeated, this prince of darknefs produced the firft parents of the human race. The beings, engendered from this original ftock, confift of a body formed out of the corrupt matter of the kingdom of darknefs, and of two fouls, one of which is fenfitive and luftful, and owes its exiftence to the evil principle;

principle; the other rational and immortal, a particle of that divine light, which had been carried away in the conteft by the army of darknefs, and immerfed into the mafs of malignant matter. The earth was created by God, out of this corrupt mafs of matter, in order to be a dwelling for the human race, that their captive fouls might, by degrees, be delivered from their corporeal prifons, and their celeftial elements extracted from the grofs fubftance in which they were involved. With this view God produced two beings from his own fubftance, *viz.* Chrift, and the Holy Ghoft: for the Manicheans held a confubftantial Trinity. Chrift, or the glorious intelligence, called by the Perfians Mithras, fubfifting in and by himfelf, and refiding in the fun, appeared in due time among the Jews, clothed with the fhadowy form of a human body, to difengage the rational foul from the corrupt body, and to conquer the violence of malignant matter, and he demonftrated his divine miffion by ftupendous miracles. The Jews, incited by the prince of darknefs, put him to an ignominious death, which he fuffered not in reality, but only in appearance, and according to the opinion of men. When the purpofes of Chrift were accomplifhed, he returned to his throne in the fun, appointing apoftles to propagate his religion, and leaving his followers the promife of the Paraclete or Comforter, who is Mani, the Perfian. Thofe fouls who believe Jefus Chrift to be the fon of God, renounce the worfhip of the god of the Jews, who is the prince of darknefs, and obey the laws delivered by Chrift, and illuftrated by Mani, the comforter, are gradually purified from the contagion of matter; and their purification being completed, after having paffed through two ftates of trial, by water and fire, firft in the moon and then in the fun, their bodies return to their original mafs; for the Manicheans derided the refurrection of bodies; and their fouls afcend to the regions of light. But the fouls of thofe who have neglected the falutary work of purification, pafs, after death, into the bodies of other animals, or natures, where they remain till they have accomplifhed their probation. Some, however, more perverfe and obftinate, are configned to a feverer courfe of trial, being delivered over, for a time, to the power of malignant aerial fpirits, who torment them in various ways. After this, a fire fhall break forth and confume the frame of the world: and the prince and powers of darknefs fhall return to their primitive feats of anguifh and mifery, in which they fhall dwell for ever. Thefe manfions fhall be furrounded by an invincible guard, to prevent their ever renewing a war in the regions of light.

Mani borrowed many things from the ancient Gnoftics; on which account, many authors confider the Manicheans as a branch of the Gnoftics.

In truth, the Manichean doctrine was a fyftem of philofophy rather than of religion. They made ufe of amulets, in imitation of the Bafilidians; and are faid to have made profeffion of aftronomy and aftrology. They denied that Jefus Chrift, who was only God, affumed a true human body, and maintained it was only imaginary: and, therefore, they denied his incarnation, death, &c. They pretended that the law of Mofes did not come from God, or the good principle, but from the evil one; and that for this reafon it was abrogated. They rejected almoft all the facred books, in which Chriftians look for the fublime truths of their holy religion. They affirmed, that the Old Teftament was not the work of God, but of the prince of darknefs, who was fubftituted by the Jews in the place of the true God. They abftained entirely from eating the flefh of any animal; following herein the doctrine of the ancient Pythagoreans: they alfo condemned marriage. The reft of their errors may be feen in St. Epiphanius and St. Auguftin; which laft, having been of their fect, may be prefumed to have been thoroughly acquainted with them.

Though the Manichees profeffed to receive the books of the New Teftament, yet, in effect, they only took fo much of them as fuited with their own opinions. They firft formed to themfelves a certain idea or fcheme of Chriftianity, and to this adjufted the writings of the apoftles; pretending that whatever was inconfiftent with this, had been foifted into the New Teftament by later writers, who were half Jews. On the other hand, they made fables and apocryphal books pafs for apoftolical writings; and even are fufpected to have forged feveral others, the better to maintain their errors. St. Epiphanius gives a catalogue of feveral pieces publifhed by Mani, and adds extracts out of fome of them. Thefe are the Myfteries, Chapters, Gofpel, and Treafury.

The rule of life and manners which Mani prefcribed to his followers, was moft extravagantly rigorous and fevere. However, he divided his difciples into two claffes; one of which comprehended the perfect Chriftians, under the name of the *elect*; and the other, the imperfect and feeble, under the title of *auditors* or *hearers*. The *elect* were obliged to a rigorous and entire abftinence from flefh, eggs, milk, fifh, wine, all intoxicating drink, wedlock, and all amorous gratifications; and to live in a ftate of the fevereft penury, nourifhing their emaciated bodies with bread, herbs, pulfe, and melons, and depriving themfelves of all the comforts that arife from the moderate indulgence of natural paffions, and alfo from a variety of innocent and agreeable purfuits. The *auditors* were allowed to poffefs houfes, lands, and wealth, to feed on flefh, to enter into the bonds of conjugal tendernefs; but this liberty was granted them with many limitations, and under the tricteft conditions of moderation and temperance. The general affembly of the Manicheans was headed by a prefident, who reprefented Jefus Chrift. There was joined to him twelve rulers or mafters, who were defigned to reprefent the twelve apoftles, and thefe were followed by feventy-two bifhops, the images of the feventy-two difciples of our Lord. Thefe bifhops had prefbyters or deacons under them, and all the members of thefe religious orders were chofen out of the clafs of the elect. Their worfhip was fimple and plain; and confifted of prayers, reading the fcriptures, and hearing public difcourfes, at which both the auditors and elect were allowed to be prefent. They alfo obferved the Chriftian appointments of baptifm of infants and the eucharift, communicating frequently in both kinds. They kept the Lord's day, obferving it as a faft; and they likewife kept Eafter and Pentecoft.

Towards the fourth century, the Manicheans concealed themfelves under various names, which they fucceffively adopted, and changed in proportion as they were difcovered by them. Thus they affumed the names of Encratites, Apotactics, Saccophori, Hydroparaftates, Solitaries, and feveral others, under which they lay concealed for a certain time, but could not, however, long efcape the vigilance of their enemies. About the clofe of the fixth century, this fect gained a very confiderable influence, particularly among the Perfians.

Towards the middle of the twelfth century the fect of Manichees took a new face, on occafion of one Conftantine, an American, and an adherer to it; who took upon him to fupprefs the reading of all other books befides the Evangelifts, and the Epiftles of St. Paul, which he explained in fuch a manner as to make them contain a new fyftem of Manicheifm. He entirely difcarded all the writings of his predeceffors;

predeceffors; rejecting the chimæras of the Valentinians, and their thirty æons; the fable of Manes, with regard to the origin of rain, and other dreams; but ftill retained the impurities of Bafilides. In this manner he reformed Manicheifm, infomuch that his followers made no fcruple of anathematizing Scythian, Buddas, called alfo Addas and Terebinth, the contemporaries and difciples, as fome fay, and according to others, the predeceffors and mafters of Manes, and even Manes himfelf, Conftantine being now their great apoftle. After he had feduced an infinite number of people, he was at laft ftoned by order of the emperor.

This fect prevailed in Bofnia and the adjacent provinces, about the clofe of the fifteenth century; propagated their doctrines with confidence, and held their religious affemblies with impunity. See on the fubject of this article, Mofheim's Eccl. Hift. vol. i. p. 295, &c. 8vo. edit.; Lardner's Works, vol. iii.; and Bayle, art. *Manichees*.

MANICHORD, or Manichordion, a mufical keyed-inftrument, in the form of a fmall pianoforte. See Clavichord.

MANICKDURG, in *Geography*, a town of Hindooftan, in Berar; 5 miles S.E. of Chanda. N. lat. 19° 59'. E. long. 79 59.

MANICKPATAM, a town of Hindooftan, in the province of Cattack; 50 miles S. of Cattack.

MANICKPOUR, a circar of Oude, bounded N.E. by Oude proper, S.E. by Jionpour, S. by Allahabad S.W. by Currah and Corah, and N.W. by Lucknow; about 60 miles long, and 40 broad.—Alfo, the capital of the above circar; 30 miles N.W. of Allahabad. N. lat. 25 50'. E. long 81 40'.

MANICKRAJE, a town of Bengal; 42 miles S.S.E. of Dacca.

MANICOU, in *Zoology*. See Opossum.

MANICOUAGAN, or Black-river, in *Geography*, a river of Canada, which runs into the river St. Lawrence, near Manicouagan point, which is a cape on the north coaft of the river. N. lat. 49° 12'. W. long. 67° 50'.

Manicouagan, a lake of Canada; 300 miles N.E. from Quebec. N. lat. 56 20'. W. long. 66 45'.

MANICUM Strychnum, in *Botany*, a term ufed by the old Greek writers to exprefs a kind of nightfhade, which, when taken internally, caufed madnefs. Pliny, defcribing this fpecies, fays that it has leaves like the ocymum or bafil; and Theophraftus and Diofcorides fay it had leaves like the eruca or rocket. Where Pliny had his information is not eafy to guefs, for he commonly copies from thefe authors: they are, however, much more to be depended on; and as the leaves of the ocymum or bafil are not at all like thofe of the rocket, Pliny is certainly wrong in his account; and the moft probable reafon for his error is that he miftook the Greek name of the plant, to which thefe authors compared the leaves of the manicum ftrychnum, and tranflated *euzomon*, which is the name of the rocket, into ocymum, bafil; a name fomewhat like the Greek one in found, but wholly different in fignification; the two plants bafil and rocket not only having leaves very unlike one another, but being alfo of different genera. A yet greater error of Pliny, in regard to this plant, is his placing it among the efculent garden herbs, and faying that it was in ufe as a food, immediately after he had told us of its caufing madnefs in thofe who eat it. This is an evident confufion of the maniac folanum with the pomum amoris or love apple, the fruit of which is eaten in foups at this time.

MANJEAH, in *Geography*, a town of Hindooftan, in Bahar, on the Soane; 18 miles S. of Rotafgur. N. lat. 24° 20'. E. long. 83° 57'.

MANIEN, a fmall ifland in the Pacific ocean, near the coaft of Chili. S. lat. 45°.

MANIERA, *Ital.*, *Manner*, a mufical term to exprefs a good or bad ftyle of finging. In fpeaking of an individual performer, when it is faid, "à una bella maniera," it implies that fuch performer, male or female, fings in good tafte, in an elegant manner.

MANIFEST, in *Commerce*, a paper containing the particulars of a fhip and cargo; which paper muft be figned by the mafter of the veffel, before any of the goods can be landed.

MANIFESTO, an apology, or public declaration in writing, made by a prince, fhewing his intentions in any enterprize, the motives that induced him to it, and the reafons on which his right and pretenfions are founded.

MANIFOLD, Cape, in *Geography*, a point of land on the coaft of New Holland, or New South Wales, fo called by Cook in 1770, from the number of high hills which appeared over it; lying in S. lat. 22 43, and diftant about 17 leagues from cape Capricorn, in W. long. 208 58'. Between thefe two capes lies a large bay, called "Keppel bay;" which fee.

MANJHA, a town of Hindooftan, in Bundelcund; 60 miles S of Chatterpour.

MANIHOT, in *Botany*, an Indian name for the root of which Caffava bread is made. (See Jatropha *Manihot.*) The *Hibifcus Manihot* feems to have been fo named from the refemblance of its leaves to that plant, not from any fimilar ufe or quality.

MANILIA, in *Geography*, a town of South America, in the province of Tucuman; 30 miles E.S.E. of Rioja.

MANILIUS, Marcus, in *Biography*, a Latin poet, known only by his work, from which it fhould feem that he wrote in the reign of Auguftus, after the defeat of Varus, and that he was, if not a native of Rome, at leaft a Roman fubject. This poem is entitled "Aftronomicon," treating, in five books, upon the fixed ftars: a fixth appears to have related to the planets, but this is entirely loft. It unites the ancient fyftem of aftronomy with the philofophy of the Stoics: there are paffages in it which would not difgrace any poet of the Auguftan age. The work has been elucidated by fome very confiderable critics. Jofeph Scaliger publifhed an edition of it at Paris in 1579, and one at Leyden in 1600. The edition of our countryman Bentley, in 1739, is in high efteem. Thofe of Stoeber, cum notis variorum, and of Pingrè, with a French tranflation, are much valued. Creech gave a tranflation of Manilius in Englifh verfe. The poem was difcovered by the learned Poggius, in the fixteenth century.

MANILLA, in *Geography*, the capital city of Luçon, and alfo of the Spanifh fettlements in the Philippine iflands. In compafs it is about two miles; its length being about two-thirds of a mile; of an irregular form, narrow at both ends, and wide in the middle. It is well built; its ftreets are broad; its houfes, though conftructed of timber above the firft floor, are handfome, and rendered beautiful by their galleries; and its churches are magnificent. It is a fortified city, and fituated on the fouth-weft coaft, in a moft advantageous pofition, on the banks of a confiderable river, which wafhes its walls, and whofe divided branches completely traverfe the whole ifland. A third part of this city is occupied by convents; and the number of its Chriftian inhabitants is computed at 12,000. The fuburbs extend to a confiderable diftance beyond the walls. Within a mufket-fhot of the gate of Parian is the habitation of Chinefe merchants, called Sangleys, whose shops in several streets are furnished for sale with silk, porcelain, and other commodities. The number of persons, who availing themselves of the indolence of the Spaniards and Indians, profitably employ themselves in this way, is very considerable. These Sangleys are under the government of an alcaide, to whom, as well as to other officers, they allow handsome salaries. Beyond the bridge adjoining to Parian are fifteen suburbs or hamlets, inhabited by Japanese, Tagalis, and people of other nations, under the government of an alcaide. Their houses, constructed of wood, are situated near the river, and erected on pillars: the roofs are covered with palm-tree leaves, and the sides formed of canes; and they are ascended by ladders, as the ground is moist, or sometimes overflowed with water. The castle stands at the west end of the city, having the sea on one side, and the river on the other.

We shall here subjoin some additional particulars relating to Manilla and its suburbs, extracted from the first volume of the Travels of Pages, who resided some months in the island of Luçon or Luconia. The river, which flows under the city walls, is the harbour for merchant ships, and separates Manilla from the town of St. Croix. This latter town is in part equally well built with the capital, is populous in Indians and Spaniards, and is surrounded by three villages of the natives, which may be regarded as suburbs. At a short distance, on the opposite bank of the river, but on the same side with Manilla, are several considerable towns also belonging to the natives. Few merchants, and still fewer mechanics, reside within the walls of Manilla. The great seat of their manufactures, as well as the emporium of all kinds of merchandise, is the town named "Parian," on the other side of the river, which is pretty regularly built, and inhabited chiefly by Chinese. From a small colony, the population of these people has increased so as now to amount to more than 20,000, who, after engrossing the whole of the manufactures, and the principal part of the trade of Manilla, began to turn their attention to agriculture. Possessed of a considerable degree of art and address, they are sober, industrious, affable, and lively.

Among the inhabitants of Manilla are Armenian merchants, Malays, natives of the Malabar coast, and of the kingdom of Siam, and also a few Japanese.

Articles of beautiful workmanship in gold, and a species of metal named tombac, which is esteemed one-third more precious, are manufactured by the artists of Manilla; and the gold chains, made by their women, vie in beauty with the most elegant that are wrought in any part of the world.

In the year 1645, a great part of this city was destroyed by an earthquake, and 3000 persons perished in the ruins. The country surrounding this city is extremely fertile, and capable of any kind of cultivation; but the inhabitants have profited neither by the situation of the city, nor the fertility of its environs. The entrance of the river is obstructed by a bar, which is dangerous, with a rough sea; but no effectual labour has been undertaken for removing it. The soil is left uncultivated; and the law, by prohibiting exportation, discourages every attempt for increasing its produce. The consequence of this neglect has been occasional famine, when rains, or drought, or hurricanes, render the fecundity of the earth useless. The inhabitants, thus indolent in improving their natural means of wealth, direct their views and hopes towards the galleon, which sails every year for Acapulco. Formerly, a celebrated commerce was carried on between Manilla and this last-mentioned city, nearly in the same parallel on the west of Mexico, through a space of about 140°, or more than one-third of the circumference of the globe. The Manilla ships, called *galleons* (which see), were then of large size; but at a later period, smaller vessels have been employed in this trade. The return of the galleon, or other vessels, was valued every year at Manilla at three millions of piastres, which were soon expended in merchandise, generally purchased of an English vessel under American colours. But this kind of traffic, as Sonnerat states it, is a real loss to the inhabitants. On the one hand, they buy their merchandise at an exorbitant price; and on the other, they strip themselves of all the silver which enters their island. This writer adds, "the force of habit, the convenience of trafficking with gold instead of merchandise, which is necessarily accompanied with some trouble, makes them prefer trading in money with the English vessels to the commerce with ships from the isle of France, which would take in exchange the productions of their country, cordage, pitch, tar, cloth, sugar, oil, reeds, canes, indigo, cocoa, &c. which would be a commerce equally advantageous to both nations."

The bay of Manilla, says M. de la Perouse, is open to ships of every size, but can be defended only by men of war: any expedition, therefore, against this colony, presupposes a decided superiority of naval force. The fortifications of the place, though regular and perfectly well kept up, could only retard for a few days the surrender of a city, which cannot expect succours either from Europe, or from any other quarter. The garrison is composed of only one regiment of mulattoes. The corps of artillery, consisting of 200 men, as well as the 150 dragoons, are also Americans; and yet Perouse says, that he should not fear with 1500 men successfully to attack 3000 of them. "Upon the whole," he says, "the conquest of Manilla appears to me so easy, and so certain, with a superiority of naval force, and 5000 troops, I might answer for its success."

The city of Manilla was taken by the English in 1762; and the ransom of a million sterling remained unpaid. The Chinese, as we have already stated, were numerous in this city, till the beginning of the seventeenth century, when the Spaniards committed a dreadful massacre of these industrious people. In 1769, it is said that they were again expelled from all these isles by the bigotry of the governor: since which time there has been a great decline in industry and produce. N. lat. 14° 36′ 8″. E. long. 120° 51′ 15″. See Luçon and Philippines.

Manilla, a town of Hindoostan, in Mysore; 14 miles W. of Tademeri.

MANILLE, or Menille, in *Commerce*, one of the principal commodities carried by the Europeans to the coasts of Africa, to traffic with the Negroes in exchange for slaves. It is a large brass ring in form of a bracelet, either flat or round, plain or engraven; with which the natives used to deck themselves, putting them on the small of the leg, and the thick of the arm above the elbow.

The better sort among the Negroes wear silver and gold manilles; but these were of their own manufacture; most of the money they receive for their own merchandise being melted into manilles.

MANILLON, in *Geography*, a township of America, in Fayette county, Pennsylvania, containing 1207 inhabitants.

MANILVA, a town of Spain, not far from the route from Malaga to Gibraltar, situated across the mountains from Guayaro, and belonging to the house of Arcos. It is surrounded with vineyards, which produce an exquisite rich wine, known by the name of Manilva wine.

MANIMBODU, a town of Hindoostan, in the Carnatic; 15 miles S.W. of Pondicherry.

MANIMUNGALUM, a town of Hindooſtan, in the Carnatic; 16 miles S. W. of Madras.

MANINGEABO. See MENANGEABOW.

MANINGTREE, or MANNINGTREE, a ſmall irregular town in the hundred of Tendring, and county of Eſſex, England, is ſituated on the ſouthern banks of the river Stour, nine miles diſtant from Colcheſter, and 61 from London: though only a chapelry to the pariſh of Miſtley, it has the privilege of a market. Whence it derived its preſent name is uncertain: its ancient appellation was Sciddinchou, by which it is mentioned in Domeſday book, as being then held by Adeliza, counteſs of Albemarle, and half ſiſter to the Conqueror. It afterwards became the property of Maud de Clare, counteſs of Hereford and Glouceſter, who beſtowed the manor on the nunnery of the order of St. Auguſtine, at Canon-Lugh, in Devonſhire. After the diſſolution, Manningtree (called in the grant Many-tree, alias Scidinghoo) was given by Henry VIII. to ſir John Rainſworth. In the certificate of chantry lands it is called "a great towne, and alſo a haven towne, having in yt to the number of 700 howſeling people." In the year 1801, the population, as aſcertained under the act of parliament, was 1016, occupying 129 houſes, 953 of the inhabitants were returned as being employed in various trades and manufactures. The market is kept on Thurſdays; and an annual fair on the Thurſday in Whitſun week. The river Stour was made navigable from this town to Sudbury in Suffolk, by an act paſſed in the fifth year of queen Anne. The principal imports are deals, corn, coals, iron, and fiſh. Beauties of England and Wales, vol. iv.

MANIPA, one of the ſmaller Molucca iſlands, about 2500 toiſes in extent from N. to S. Although this iſland is very mountainous, it is populous, and contains about 1600 inhabitants; and many canoes ply along its ſhore: five or ſix leagues W. from Ceram. S. lat. 3° 21′. E. long. 127° 54′. —Alſo, a river on the W. coaſt of Celebes, which runs into the ſea, S. lat. 3° 12′.

MANIPULATION, a term uſed in the mines, to ſignify the manner of digging the ſilver, &c. out of the earth.

MANIPULUS, MANIPULE, among the Romans, was a little body of infantry, which, in the time of Romulus, conſiſted of a hundred men, and in the time of the conſuls and firſt Cæſars, of two hundred.

The word properly ſignifies a handful; and, according to ſome authors, was firſt given to the handful of hay which they bore at the end of a pole, to diſtinguiſh themſelves by, before the cuſtom was introduced of bearing an eagle for their enſign; and hence alſo the phraſe, a handful of men. But Vegetius, Modeſtus, and Varro, give other etymologies of the word: the laſt derives it from *manus*, a little body of men following the ſame ſtandard. According to the former, this corps was called *manipulus*, becauſe they fought hand in hand, or all together: "Contubernium autem manipulus vocabatur ab eo, quod conjunctis manibus pariter dimicabant."

Each manipule had two centurions, or captains, called *manipularii*, to command it; one whereof was lieutenant to the other. Each cohort was divided into three manipules, and each manipule into two centuries.

Aulus Gellius quotes an old author, one Cincius, who lived in the time of Hannibal (whoſe priſoner he was), and who, writing on the art of war, obſerves, that then each legion conſiſted of ſixty centuries, of thirty manipules, and of ten cohorts. And again, Varro and Vegetius mention it as the leaſt diviſion in the army, only conſiſting of the tenth part of a century; and Spartian adds, that it contained no more than ten men. This ſhews that the manipulus was not always the ſame thing. See LEGION.

MANIPULUS is alſo an eccleſiaſtical ornament, worn by the prieſts, deacons, and ſub-deacons, in the Romiſh church. It conſiſts of a little fillet in form of a ſtole, three or four inches broad, and made of the ſame ſtuff with the chaſuble; ſignifying and repreſenting an handkerchief, which the prieſts in the primitive church wore on the arm, to wipe off the tears they were continually ſhedding for the ſins of the people. There ſtill remains a mark of this uſage in a prayer rehearſed by thoſe who wear it; "Merear, Domine, portare manipulum fletus & doloris."

The Greeks and Maronites wear two manipules, one on each arm.

MANIPULUS, in *Phyſic*, denotes a meaſure, or fixed quantity, of herbs, or leaves, *viz.* a handful; or ſo much as the whole hand can graſp: it is generally marked in preſcription, with an *M.*

MANIQUE, in the *Materia Medica*, the name given by authors to an American root, commended greatly for curing tertian and quartan agues, and as an infallible remedy againſt venomous bites. Redi procured ſome of this famous root, and gave it many very fair trials, but could never diſcover any of theſe virtues in it.

MANIS, in *Natural Hiſtory*, a genus of quadrupeds the claſs Mammalia, and order Bruta, of which there are, according to Gmelin, two ſpecies, but Dr. Shaw mentions three. The generic character is, that it has no teeth; the tongue is round, and extenſile; the mouth is narrowed into a ſnout; the body is covered above with moveable bony ſcales.

This genus preſents an appearance as extraordinary as that of the Daſypus, being covered on every part, except the belly, with ſtrong and large ſcales, conſtituting a complete ſuit of armour, capable of defending the animals, when rolled up, from the aſſaults of the moſt ferocious enemies. This covering, together with the length of the body and tail, gives an aſpect ſo much reſembling that of a lizard, that the creatures of the genus are commonly known by the name of the ſcaly lizards, though they are in no other reſpects allied to the lizard tribe than in their covering. They are, however, admitted to form a ſort of link of approximation between the proper viviparous quadrupeds and the lizards. In their nature they are harmleſs, and feed in the ſame manner as the ant-eaters, by thruſting out their very long tongue into the neſts of ants and other inſects, and ſwallowing their prey, by ſuddenly drawing it back. They are found chiefly in India and the India iſlands.

Species.

PENTADACTYLA, five-toed or ſhort-tailed manis. The tail in this ſpecies is not ſo long as the body, it is very thick at the baſe, and from thence gradually tapering, but ending obtuſely. The head is ſmall, and the ears are likewiſe ſmall and rounded. The feet are furniſhed with five toes each, of which thoſe on the fore-feet are extremely ſtrong, except the exterior one, which is much ſmaller than the reſt. The whole animal is covered with thick, ſtrong, and large ſcales, which, when full grown, are perfectly ſmooth, but in thoſe which are ſmaller, they are ſtriated about half way from the baſe. They are channelled at the baſe, but at the edges they are ſharp, rounded, and imbricate. It inhabits Guinea, China, and India. The colour of the animal is of a pale yellow-brown, and the ſurface is gloſſy. It meaſures, including the tail, from ſix to eight feet in length. In Bengal, it has obtained the name of the "Thunderbult Reptile." from the hardneſs of its ſcales, which are ſaid to be capable of of ſtriking fire like a flint. It lives in woods and marſhy places, and feeds on ants, by laying its long tongue acroſs their paths. It walks ſlowly, and when purſued, rolls itſelf up, and is then ſo ſecurely armed, that even a leopard attacks it in vain. It is ſaid to be capable of deſtroying the elephant, by twiſting itſelf round the trunk, and thus compreſſing that tender and ſenſible organ with its hard ſcales.

Tetradactyla, four-toed or long-tailed manis. This animal is leſs than that already deſcribed; it is found in India; the ſcales are much channelled, each is armed with three points; the under parts are covered with hair, and the tail is three times as long as the body. The legs are very ſhort, and ſcaled like the body, and on each of the feet are four claws, of which thoſe on the fore-feet are ſtronger than thoſe on the hind. The colour is an uniform deep brown, with a yellowiſh caſt, and with a gloſſy or poliſhed ſurface. From the tip of the noſe to the extremity of the tail, its whole length is about five feet.

Latissima, or broad-tailed manis, is denominated, in the ſixtieth volume of the Philoſophical Tranſactions, in which there is a figure of the animal, the "New Manis." The creature here deſcribed was killed in the houſe of a merchant at Tranquebar, having been diſcovered in the cavity of a wall. When attacked it rolled itſelf up in ſuch a manner as to leave only the back and tail viſible, ſo that it was deſtroyed with much difficulty. It had five toes on the fore-feet, and four on the hind; the ſcales were of the ſhape of a muſcle; the belly quite ſmooth; the exterior ſcales ended in a ſharp point, ſomewhat incurvated; the tail was very broad, decreaſing to a point. It is doubtful, after all, whether this animal belongs to a diſtinct ſpecies, or whether it be a variety of one of thoſe already noticed. "In reality," ſays Dr. Shaw, "the differences do not ſeem ſufficient to conſtitute a ſpecific diſtinction, and are, probably, owing to the differences of age and ſex. In the Britiſh Muſeum there are ſpecimens of different ſizes, which ſhew theſe gradations. In one, the ſcales, all over the animal, are ſo regularly and completely truncated at the extremity, as to exhibit the appearance of ſo many hexagons. In another they are remarkably broad and rounded; and in a third, which is a very large ſpecimen, they are leſs obtuſe at the tips, and ſomewhat irregularly terminated, as if notched, or worn through age. The proportional breadth of the tail alſo varies ſomewhat in theſe ſpecimens, and ſeems greateſt in thoſe which are the leaſt advanced in age."

MANISSA, in *Geography*, a river of Africa, forming the ſouthern boundary of Inhambane, and running into the Indian ſea, S. lat. 25° 50′.

MANISTIE, a river of Canada, which runs into lake Michigan, N. lat. 45° 36′. W. long. 85° 40′.

MANISURIS, in *Botany*, a graſs moſt aptly ſo named by Linnæus, from *Manis*, the Scaly Lizard, and οὐρά, *a tail*, the ſingular appearance of its ſcaly ſpikes recalling very ſtrongly the idea of the no leſs extraordinary covering of that quadruped. Linn. Mant. 164. Schreb. 719. Mart. Mill. Dict. v. 3. Linn. fil. Nov. Gram. Gen. 21. t. 1. Juſſ. 34. Lamarck Illuſtr. t. 839. Gærtn. t. 175. Claſs and order, *Polygamia Monoecia*. Nat. Ord. *Gramina*.

Gen. Ch. *Perfect Flowers* imbricated, alternate, at the oppoſite ſides of a zigzag jointed ſpike, one to each joint, which is hollowed out to receive the baſe of the flower. *Cal.* Glume of two valves, ſingle-flowered; the *outermoſt valve* largeſt, coriaceous, rounded, rugged in the middle, either notched or entire at the top and ſides; *innermoſt* ſmaller, broadly lanceolate, membranous, cloſely preſſed to the former. *Cor.* Glume of two valves, membranous, thin and tranſparent, ſmaller than the calyx and concealed therein; the *outer valve* embracing with its edges the *inner*, which is ſmaller. Nectary a membranous ſcale. *Stam.* Filaments three, capillary, prominent; anthers oblong, incumbent. *Piſt.* Germen ovate, ſuperior; ſtyles two, ſhort, thread-ſhaped; ſtigmas oblong, bearded, ſpreading beyond the glumes at each ſide. *Peric.* none, the calyx incloſing the ſeed. *Seed* ſolitary, ovate.

Male Flowers marginal, alternate, at the back of the ſpike, projecting at each ſide, one to each joint. *Cal.* Glume of two valves, ſingle-flowered, nearly cylindrical; the *valves* equal, parallel, ovato-lanceolate, obtuſe, ſtriated, coriaceous, bordered with a membrane. *Cor.* Glume of two valves, membranous, thin, nearly as large as the calyx; the *outer valve* ovate, obtuſe, convoluted; *inner* lanceolate, plaited, ſcarcely longer than the outer. Nectary a membranous ſcale. *Stam.* Filaments three, very ſhort, ſometimes wanting; anthers as in the perfect flowers.

Eſſ. Ch. Perfect Flowers. Calyx a glume of two unequal, oppoſite valves, ſingle-flowered; the outer valve rounded and rugged. Corolla ſmaller than the calyx. Stamens three. Styles two.

Male Flowers. Calyx of two equal, parallel, oblong valves.

Obſ. This genus is one of the few that may properly be allowed to remain in the claſs *Polygamia*, as having a very different ſtructure in the two different kinds of flowers. Such is the caſe with the Britiſh genus *Atriplex*, but with few others admitted into this claſs by Linnæus. Theſe however, in our opinion, excuſe, if not juſtify, the preſervation of it in the Linnæan ſyſtem.

1. M. *myurus*. Mouſe-tail Scaly-graſs. Linn. Mant. 300. Linn. fil. Nov. Gram. Gen. t. 1. f. 1—3. Roxb. Corom. v. 2. 10. t. 117.—Outer glume of the perfect flowers elliptical, depreſſed, notched at the top and ſides. Sheaths of the leaves ſmooth.—Found by Koenig in dry elevated barren ground on the coaſt of Coromandel, not unfrequent. Dr. Roxburgh gathered it in the ſame country, and informs us that it is called by the Telingas *Nalla Panoocoo*. The *root* appears to be perennial, conſiſting of long, tough, downy fibres. *Stems* ſeveral, branched, jointed, leafy, ſmooth, compreſſed, ſolid, from 9 to 18 inches tall; decumbent and throwing out roots at their lower part. *Leaves* alternate, channelled, ſhort, narrow, acute, ſmooth, with long inflated ſheaths. *Spikes* about two inches long, linear, ſolitary at the ends of the principal, as well as the ſhort lateral, branches, compoſed of numerous, cloſely imbricated, *flowers*. The outer *glume* of ſuch as are furniſhed with both ſtamens and piſtil is ſhaped like a fiddle, its diſk marked with two tranſverſe elevations, and ſomewhat hairy, its membranous margin purpliſh. Dr. Roxburgh found two male florets in the oblong-leaved calyx, and his deſcription of the ſtructure and poſition of the calyx-glumes differs from that we have adopted, as well as from what we can diſcern in the dried ſpecimen, in which thoſe valves are certainly parallel, not oppoſite to each other, a very remarkable and diſtinguiſhing character between the male flowers and the perfect ones. The common ſtalk, or *rachis*, is zigzag, conſiſting of ſhort, turbinate, angular, ſlightly downy joints, each of which bears near its baſe, on one ſide, a ſingle perfect flower, and at its ſummit, on the oppoſite ſide, a male flower.

2. M. *granularis*. Granulated Scaly-graſs. Linn. fil. Nov. Gram. Gen. t. 1. f. 4—7. Swartz Prodr. 25. Ind. Occ. v. 1. 186. Roxb. Corom. v. 2. 11. t. 118. (Cenchrus granularis; Linn. Mant. 575. Gramen cyperoides polyſtachion, ſpicis ad nodos ex utriculis, ſeu foliorum alis, echinatis,

echinatis, prodeuntibus; Sloane Jam. v. 1. 120. t. 80.)—Outer glume of the perfect flowers orbicular, convex, entire, reticulated. Sheaths of the leaves hairy.—Native of the East and West Indies. Dr. Swartz gathered it in dry calcareous situations, in the south part of Jamaica; Roxburgh in bushy places, on the coast of Coromandel. The latter observes that both this and the foregoing are coarse grasses, not eaten by cattle. The *root* of the present is said by Swartz to be annual. It consists of numerous, nearly smooth, fibres. *Stem* a foot or two in height, branched from the bottom, leafy, round, smooth, slender. *Leaves* broad, taper-pointed, more or less hairy, with tumid, ribbed, very hairy, and minutely tuberculated, sheaths. *Spikes* solitary, at the ends of small, lateral, axillary, leafy branches. Each *spike* is about an inch long, composed of numerous imbricated *flowers*, on a zigzag stalk, the united ones conspicuous on one side, the males on the other. The outer *calyx-glume* of the former is orbicular, pale or purplish, the size of a small pin's head, strongly reticulated with elevated ribs, and intermediate depressions. Swartz says there are two inner glumes, which are ovate, nearly equal, pointed, white and pellucid. Roxburgh's figure does not accord with this. The former writer describes the *corolla* as of two minute, ovate, whitish glumes, half the size of the outer valve of the calyx, and the nectary of two extremely diminutive, fleshy, whitish scales, forming a cup at the base of the germen and stamens. The *male flowers* are rather larger, each consisting of two parallel, equal, ovate calyx-glumes, which are striated and hispid, with a small, white, bivalve *corolla*, and a similar nectary to the other. S.

MANITOU, or MANITOUALIN *Islands*, in *Geography*, a cluster of islands towards the N. shore of lake Huron, stretching from the vicinity of Cabots head, north-westerly across the lake to lake George, below the falls of St. Mary. These islands are held sacred by the Indians.

MANITOU *Kiamen*, a post of Chinese Tartary, in the country of the Kalkas. N. lat. 43° 22'. E. long. 106° 40'.

MANITOU *Oudour*, a town of Chinese Tartary, in the country of the Monguls. N. lat. 42°. E. long. 112° 14'.

MANITZKAIA, a town of Russia, in the country of the Cossacks; 40 miles E.N.E. of Azof.

MANIVAL, a town on the E. coast of Madagascar. S. lat. 17° 10' E. long 50°.

MANKAKO, a town of the island of Celebes, in Buggess bay, in which is a good market for gold and sago. S. lat 1° 45'.

MANKALIA, a sea-port town of Bulgaria, on the Black sea; 68 miles E.S.E. of Silistria. N. lat. 44°. E. long 28° 39'.

MANKANET, or ST. JOSEPH, a town of Africa, in Galam, in which is a French factory.

MANKAP, a small island in the East Indian sea, near the S. coast of Borneo. S. lat. 3° 2'. E. long. 109° 58'.

MANKETS. See NOGAYANS.

MANKOVA, a town of Russia, in the government of Irkutsk, on the Angara; 44 miles S.E. of Balaganskoi.

MANKOUH, a town of Persia, in the province of Khorasan; 66 miles N. of Meschid.

MANKOW. See *Ivory* COAST.

MANKUTOSKA, a town of Russia, in the government of Irkutsk; 28 miles N. of Stretensk.

MANLIUS, MARCUS, surnamed *Capitolinus*, in *Biography*, a distinguished Roman, was brought up to arms, and is said to have already served the office of consul, when he was one of the garrison of the Capitol at its siege by the Gauls in the year 390. On the attempt of the enemy to surprise it by night, Manlius was the first person awakened by the noise of the geese kept in the fortress. He ran to the ramparts, threw down two Gauls who had mounted to the top; and the alarm being caught by the centinels, the enterprize was defeated, and the Capitol saved. For this heroic act, Manlius received a house in the Capitol, with the title of Capitolinus. The high reputation which he now enjoyed, stimulated his ambition to become the first man in Rome. Camillus, the faviour of his country, was at the head of the patrician party, and Manlius, jealous of his power, threw himself into the opposite party, and began to court the Plebeians, by railing at the rich, and patronizing their insolvent and enslaved debtors, of whom there was always a great number in Rome. He liberated several of these at his own expence, and stood forth as the public advocate of the people in the division of the conquered lands. On account of some false charges which he exhibited against the nobles, he was thrown into prison; still, however, he was regarded as the hero of the party, and when he was liberated, he kept no measure in his hostility to the nobles, but proposed the abolition of consulates and dictatorships, and a perfect equality of rights. He offered himself as a leader to enforce these changes, and is said to have formed a plot to seize the Capitol, and usurp the sovereign power. The senate now passed a decree, enjoining the military tribunes "to take care that the republic should suffer no detriment," which was the form of investing them with absolute power. Manlius was charged with the crime of aiming at regal power; he appeared before his judges with mourning, unsupported by his nearest relations, who were of the opposite party. To excite the favour and compassion of the people, he produced four hundred persons whose debts he had paid; he displayed thirty suits of armour won from as many foes slain by him in single combat; a mural crown, and eight civic crowns; and he enumerated thirty-seven rewards received from his generals for acts of extraordinary valour. Lastly, he pointed to the Capitol itself, which he had saved, and which was full in view from the Campus Martius, the place of trial, and invoked its gods to his assistance. So long as this object was in their sight, the people refused to find him guilty, but when the place of assembly had been altered to a grove from which the Capitol could not be seen, sentence was obtained against him, and he was condemned to be thrown down from that very rock which he had defended from the attack of the Gauls. This execution took place in the year 384 B.C., and a decree was at the same time passed, that no patrician should from that time dwell in the Capitol. Plutarch. Livy.

MANLIUS, TITUS, surnamed *Torquatus*, a celebrated commander of the same family with the preceding, the son of Titus Manlius Imperiosus, who after he had served the office of dictator in 363, was cited before the people to answer for various acts of cruelty, and one of the charges against him was for keeping his son Titus, in the country, at work among his slaves, for no other reason than that he was of slow parts, and had an impediment in his speech. The young man being informed of this accusation, went to Rome by night, and proceeded directly to the house of the tribune Pomponius, his father's accuser, demanded a private interview; then drew a dagger and threatened him with instant death unless he took an oath to drop the prosecution against his father, with which he very readily complied. The people were so well pleased with this instance of filial piety, though in favour of a man whom they detested, that they raised the young Titus to the post of legionary tribune. Some time afterwards, when the Gauls, invading the Roman territory, had advanced within three miles of the

the city, and both armies lay on oppofite banks of the Anio, one of the enemy, of gigantic ftature, came to the bridge and challenged the braveft man among the Romans; Manlius begged to be allowed to accept the challenge, and armed with a fhort fword and buckler advanced to the encounter. Victory decided in his favour, and the Gauls, confidering the death of their champion as an omen of ill fuccefs, abandoned their camp in the night, and made a precipitate retreat. Manlius obtained the name of "Torquatus" from having torn a golden collar from the neck of his antagonift, and putting it on his own. In the year 355, he was nominated to the dictatorfhip, though he had not yet been conful, on account of his great merit. He was a fecond time dictator, and then fucceeded to the confulate. In the year 340, he marched with Decius Mus, to fupprefs a dangerous war with the Latins, and it was refolved, that no foldier nor commander fhould quit his ranks, or even fight, without exprefs permiffion, on pain of death. Soon after Manlius, the fon of Torquatus, who commanded a detachment of horfe, meeting with a fquadron of the enemy, was challenged to fingle combat by its leader; he in the height of his ardour accepted the offer, and flew his antagonift. Having ftripped him of his armour, he went triumphantly to his father's tent, and relating the deed, laid the fpoils at his feet. The conful immediately, and in the prefence of the Roman army, pronounced againft him fentence of death for difobedience of orders. In the enfuing battle, Decius was flain, and the event remained in doubt, till Manlius, by a fkilful movement, decided the day and gained a complete victory. On his return to Rome, he was received with honour by the feniors, but the younger part of the citizens abhorring his rigour towards his fon, refufed to go out to meet him. He was afterwards offered the confulfhip by general confent, but he declined it, telling the people, that as they could not bear his feverity, fo neither could he put up with their licentioufnefs. Livy. Univer. Hift.

Manlius, in *Geography*, a poft-town in Onondago county, New York, incorporated in 1794, and the feat of the county courts. It is well watered by feveral creeks, which unite at the N.E. corner of the town; and the ftream affuming the name Chittenengo, runs N. to Oneida lake, lying 10 miles N. of the centre of the town. It comprehends that part of the Onondago refervation, bounded S. by the Geneffee road, and W. by Onondago creek and the Salt lake. It contains 989 inhabitants.

MANNA, a diftrict, and alfo a river, on the fouth-weft coaft of the ifland of Sumatra. In this diftrict a progrefs in the art of cultivation is difcovered, fuperior to what appears in almoft any other part of the ifland; that occupied by the Battas excepted. Here the traveller may fee pieces of land, in fize from five to fifteen acres, regularly ploughed and harrowed. Mr. Marfden accounts for this difference by obferving that Manna is by much the moft populous diftrict to the fouthward, with the fmalleft extent of fea-coaft. Neceffity obliges them to cultivate the earth; or otherwife they would be obliged to abandon their native foil. In order to underftand the rate of produce, we muft firft explain the terms ufed in defcribing it. "Paddee" is rice whilft it is in the hufk; and paddee in Sumatra and the Malay iflands is diftinguifhed into two forts, *viz.* "laddang," or upland paddee, and "fawoor," or low-land; and thefe are always kept feparate, and will not grow reciprocally. From grounds tilled as they are, in the diftrict of Manna, the produce is reckoned at 30 for one; from the laddangs in common it is about 60 or 80. The fawoors are generally fuppofed to yield an increafe of 100 for one, but in fome of the northern parts 120. The excefs of this proportion of produce above that of our fields in Europe, which feldom exceeds 15, and is often under 10, is afcribed to various circumftances; *viz.* the difference of grain, rice being extremely prolific; the more genial influence of a warmer climate; and the earth's gradually lofing, by an exceffive cultivation, its fecundity; but principally, as Mr. Marfden conceives, to the different ftyle of cultivation. The Sumatrans, who do not grudge time or labour, make holes in the ground, and drop into each a few grains; or, by a procefs ftill more tedious, raife the feed in beds, and afterwards plant it out. The diftrict of Manna, as well as other parts of Sumatra, is fubject to very deftructive earthquakes. By a fevere calamity of this kind that occurred in 1770, a village was deftroyed by the houfes falling down and taking fire, and feveral lives were loft. The ground in one place was rent for a quarter of a mile to the width of two fathoms and depth of four or five. A bituminous matter is defcribed to have fwelled over the fides of the cavity, and the earth, for a long time after the fhock, was obferved to contract and dilate alternately. Many parts of the hills far inland, could be diftinguifhed to have given way, and as a confequence of this, Manna river was fo much impregnated with particles of clay that the natives could not bathe in it. At this time was formed, near to the mouth of Padang-goochie, a neighbouring river, fouth of the former, a large plain, feven miles long, and half a mile broad, where had before been only a narrow beach. A fmall but beautiful cafcade defcends perpendicularly from the fteep cliff, which, like an immenfe rampart, lines the fea-fhore near Manna. No country in the world is better watered than this. Springs are found wherever they are fought for. The rivers on the weftern coaft are innumerable, but too fmall and rapid for the purpofes of navigation. The vicinity of the mountains to that fide of the ifland occafions this profufion of rivulets, whilft it prevents their accumulating to any fize. At Manna the "Soompatan," that is, the fwearing apparatus, on which an oath is adminiftered, is a gun-barrel. When ufed for this purpofe, it is carried to the fpot in ftate, under an umbrella, and wrapt in filk. This parade has an advantageous effect, by influencing the mind of the party with an high idea of the importance and folemnity of an oath. In England it is to be regretted, that the familiarity of the object, and the fummary method of adminiftering oaths, are well known to diminifh their influence, and to render them too often nugatory. The Sumatrans fometimes fwear by the earth, laying their hands upon it, and wifhing that it may never produce aught for their nourifhment if they fpeak falfely. Marfden's Sumatra. The town of *Manna* is diftant 300 miles S.W. from Indrapour. S. lat. 4° 25′. E. long. 102° 40′.

Manna, a town of Africa, in Jallonkadoo, near the Senegal. N. lat. 12° 20′. W. long. 8° 50′.

Manna, in *Pharmacy*, a medicinal drug, of great ufe in the modern practice, as a gentle purgative, and cleanfer of the firft paffages.

Manna is a white fweet juice oozing from the trunk, branches, and leaves of a kind of afh-tree, being the Fraxinus *Ornus* (which fee), chiefly in Calabria, during the heats of fummer.

Manna has been erroneoufly held to be a kind of *mel aerium*, or honey-dew, which, falling in the night, gathers on certain trees, and even on rocks, and on the earth itfelf; where it hardens with the fun. But what refutes this opinion is, that fuch dews melt in the fun; whereas manna whitens and hardens in it. Add, that fuch dews are only found on the tops and extremes of the leaves, whereas manna is chiefly found to lodge on the trunks of the branches: and that the honey-

dew

dew falls only on trees open to the air; whereas manna is found on trees which are under cover; as was experienced by Dr. Cornelius, who gathered manna from branches covered on purpofe with cloth; and Lobel affures us, that manna had been gathered from branches of the afh, which had been thrown the day before into a cellar. It is much more rational to rank manna amongft the number of gums, which, exuding from the juice of the tree, is condenfed into thofe flakes in which we fee it.

Manna is far from being peculiar to the afh-tree of Calabria, on which it is ufually found. The Ornus is not the only fpecies of Afh or Fraxinus which produces it. It is afforded, though in lefs abundance, particularly in Sicily, by the *Fraxinus rotundifolia* and *excelfior*: thefe three fpecies are cultivated in Sicily, and planted on the declivity of a hill, with an eaftern afpect for the purpofe of procuring manna. After 10 years' growth, the trees begin to yield the manna, but they do not afford it in very confiderable quantity till they are much older; and as manna is no other than the matter of the fenfible tranfpiration of trees and plants in general, it is found on many different kinds, in different quantities.

At Briançon, in France, they collect manna from all forts of trees that grow there; and the inhabitants obferve, that fuch fummers as produce them the greateft quantities of manna, are very fatal to their trees. Their walnut-trees produce annually a confiderable quantity; but if there happen a year in which they produce more than ordinary, they ufually find many of them perifh in the following winter.

It feems very plain from the whole, that manna is only the extravafated juice of the tree, which cannot furvive fo great a lofs of it: and what not a little confirms this is, that the very hot fummers are always thofe which are the moft abundantly productive of manna. The ancients were fenfible of this fpontaneous production of manna, of feveral fpecies of trees, fo very different from one another, and from thence fell into the error of fuppofing it fomething wholly foreign to the tree; an error very natural to thofe who did not know that the nutritive juices of very many trees are nearly, if not wholly the fame. It was from this opinion of its origin, that they called it aerial honey.

Dr. Cullen very properly fuppofes manna to be a part of the fugar fo univerfally prefent in vegetables, and which exudes on the furface of a great number of them; and he thinks that the qualities of thefe exudations are very little, if at all different. The principal trees known to produce thefe mannas in different climates and feafons are, the larch, the fir, the orange, the walnut, the willow, the mulberry, oaks, the hagi Maurorum, or Hedyfarum alhagi of Linnæus. Of this latter Dr. Fothergill prefented a fpecimen to the Royal Society, which he confidered as the "Tereniabin" of the Arabians. (Phil. Tranf. vol. xliii. p. 87.) The Ciftus ladaniferus in fome parts of Spain produces a manna, which, in its recent ftate, has no purgative quality, and is eaten by the fhepherds, fo that fome fermentation feems to be neceffary, in order to give it a cathartic power.

The Italians gather three kinds of manna:—*Manna di corpo*, which oozes fpontaneoufly from the branches of the tree in the month of July. *Manna forfata*, or *forzatella*, which is not gathered till Auguft, after an incifion of the tree, when the flux of the firft has ceafed. *Manna di fronda*, which iffues of itfelf, in little drops, like a kind of fweat, from the nervous part of the leaves of the afh, and gathers into grains about the bignefs of thofe of wheat, which are hardened by the fun in Auguft. The leaves are frequently found fo laden with thefe grains, that they feem covered with fnow.

Although the manna exudes fpontaneoufly upon the afh-trees, yet for obtaining it more copioufly, incifions are made through the bark by means of a fharp crooked inftrument; and the feafon thought to be the moft favourable for inftituting this procefs is a little before the dog-days commence, when the weather is dry and ferene. The incifions are firft made in the lower part of the trunk, and repeated at the diftance of an inch from the former wound, ftill extending the incifions upwards as far as the branches, and confining them to one fide of the tree; the other fide being referved till the year following, when it undergoes the fame treatment. On making thefe incifions, which are of a longitudinal direction, about a fpan in length, and nearly two inches wide, a thick whitifh juice immediately begins to flow, which gradually hardens on the bark, and in the courfe of eight days acquires the confiftence and appearance in which the manna is imported into Britain, when it is collected in bafkets, and afterwards packed in large chefts. Sometimes the manna flows in fuch abundance from the incifions, that it runs upon the ground, by which it is mixed with various impurities, unlefs prevented, as is ufually the cafe, by interpofing large concave leaves, ftones, chips of wood, &c. The bufinefs of collecting manna ufually terminates at the end of September, when the rainy feafon fets in. Dr. Cirillo's account of the manner of collecting manna in the kingdom of Naples was communicated to the Royal Society, and was publifhed in Phil. Tranf. vol. lx. This ingenious writer begins with correcting a miftake, founded on an erroneous opinion of the ancients, which ftates the beft and pureft manna to be that which is obtained from the leaves of the tree. He never faw fuch a kind, and all thofe who are employed in the gathering of the manna, know of none that comes from the leaves. The manna is generally of two kinds, not differing in their intrinfic quality, but in the manner by which they are procured. In order to have the manna, fays our author, thofe who have the management of the woods of the Orni in the months of July and Auguft, when the weather is very dry and warm, make an oblong incifion, and take off from the bark of the tree about three inches in length and two in breadth; they leave the wound open, and by degrees the manna runs out, and is almoft fuddenly thickened to the proper confiftence, and is found adhering to the bark of the tree. This manna, which is collected in bafkets, and goes under the name of "manna groffa," is put in a dry place, becaufe moift and wet places will foon diffolve it again. This firft kind is often in large irregular pieces of a brownifh colour, and is frequently full of duft and other impurities. But when the people want to have a very fine manna, they apply to the incifion of the bark thin ftraw, or fmall bits of fhrubs, fo that the manna, in coming out, runs upon thofe bodies, and is collected in a fort of regular tubes, which gives it the name of "manna in cannoli," that is, manna in tubes: the fecond kind is more efteemed, and always preferred to the other, becaufe it is free and clear. There is indeed a third kind of manna, which is not commonly met with, and which our author fays he has feen fince he left Calabria: it is very white, like fugar; but as it is rather for curiofity than for ufe, he fays no more of it. The two forts of manna already mentioned undergo no kind of preparation whatfoever, before they are exported; fometimes they are finer, particularly the "manna groffa," and fometimes very dirty and full of impurities; but the Neapolitans have no intereft in adulterating the manna, becaufe they have always a great deal more than what they generally export; and if manna is kept in the magazines, it receives often very great hurt by the fouthern winds, fo common in our part of the world. The changes of the weather producees a fudden alteration in the time that the manna is to be gathered; and for

for this reafon, when the fummer is rainy, the manna is always very fcarce and very bad.

Manna is generally diftinguifhed into different kinds, *viz.* the manna in tears, the canulated and flaky manna, and the common brown or fat manna ; differences which depend upon their refpective purity, and the manner in which they are procured from the tree, and not upon the nature of the drug itfelf. When the juice tranfudes very flowly, the manna is more dry, tranfparent, and pure, and confequently of higher eftimation ; but when it flows more copioufly, it concretes into a coarfe brown unctuous mafs ; and hence we perceive that by applying ftraw, &c. to receive the flowing juice, the manna becomes much improved. Houel, who tafted the manna when flowing from the tree, found it much more bitter than in its concrete ftate ; and this bitternefs he afcribes to the aqueous part, which is then abundant : whence it appears that the manna is meliorated by all the circumftances which promote evaporation. Manna is a fubftance in many things very nearly related to fugar and to honey ; it is inflammable in the fame manner, and it melts in water as eafily as fugar, and liquifies even in a moift air, and by the affiftance of heat, in rectified fpirit alfo ; the impurities only being left by both menftrua. On infpiffating the watery folution, the manna is recovered of a much darker colour than at firft. From the faturated fpirituous folution great part of it feparates as the liquor cools, concreting into a flaky mafs, of a fnowy whitenefs, and a very grateful fweetnefs. When expofed on hot coals, it fwells, takes fire, and leaves a light bulky coal. When boiled with lime, clarified with white of egg, and concentrated by evaporation, it affords cryftals of fugar. By diftillation manna affords water, acid, oil, and ammonia ; and its coal affords alkali.

M. Lemery, in his analyfis, drew from manna a vinous liquor, of the fame kind with that obtained from honey. Mead may alfo be made of manna, in the fame way that it is made from honey ; but it is neither fo ftrong, nor fo agreeable to the tafte as that of honey. From as much mead as was made from two pounds of manna, M. Lemery drew off by diftillation eight ounces of a fort of brandy, and on rectifying this, procured an ounce and a half of a pure burning fpirit, like in all refpects to rectified fpirit of wine. This fpirit of manna is accounted by fome a fudorific, and is given from half a dram to a dram and a half. M. Lemery having left the remaining liquor, after the diftillation of the fpirituous part of the manna mead, in a warm place for two years, found that it depofited to the bottoms of the bottles feven drams of an effential falt of manna, which was white, hard, brittle, and formed into fine needles, and was of an acid tafte, with an admixture of fweet. This falt is purgative, and its dofe is a dram. All the remaining acid liquur being diftilled, there remained at the bottom of the retort a quantity of matter of the confiftence of honey, which weighed twenty ounces ; fo that out of two pounds of manna, there had been twelve ounces confumed, to make the fpirit. and to give the acidity to the remaining liquor. This honey-like refiduum, being finally diftilled with aftrong fire, there arofe a reddifh liquor of an acrid tafte, and with a ftrong empyreumatic fmell, and with this a few drops of blackifh oil ; after this operation, the remainder in the retort was four ounces of a very light black coal. The coal, it is to be obferved, is here only one-eighth of the weight of the manna, which is fomewhat fingular, fince in the pureft honey, treated in the fame manner, it always weighs one-fourth of the original whole quantity. It is plain from hence, that manna is a much purer fubftance than honey : it is alfo remarkable, that in farther treatment of this coal, there is a fmall quantity of iron always difcovered in it. Manna, honey, and all the other fweet fubftances, we fee, alfo lofe all their fweetnefs as foon as ever their acid is feparated from their oil. Hift. Acad. Par. 1708, p. 56.

The beft fort of manna is that in oblong pieces or flakes, moderately dry, friable, very light, of a whitifh or pale yellow colour, and, in fome degree, tranfparent : the inferior kinds are moift, unctuous, and brown. Manna of both forts is fometimes counterfeited by compofitions of fugar, honey, and purgative materials, which may be diftinguifhed in their folid form by their weight, compactnefs, and tranfparency ; and in the dry and moift ftate, by their tafte, and by their habitude to menftrua. Manna, in dofes of an ounce and upwards, proves a gentle laxative ; it operates in general with great mildnefs, fo as to be fafely given even to children and pregnant women, and in inflammatory or acute diftempers, where the ftimulating purgatives have no place It is particularly proper in ftomachic coughs ; in which intentions it is fometimes made up in a linctus or lohoch, with equal quantities of oil of almonds, and fyrup of violets. The gripes, flatulencies, and other inconveniences attending it in fome conftitutions, and when given to adults in large dofes, may be obviated by a fmall addition of fome grateful aromatic. Manna does not produce the full effect of a cathartic, unlefs taken in large dofes, as two ounces or more ; and, therefore, is feldom employed for this purpofe by itfelf : it may be commodioufly diffolved in the purging mineral waters, or fharpened with the cathartic falts, or other purgatives : its efficacy is faid to be much promoted by caffia fiftularis, a mixture of the two purging more than either of them feparately : it is therefore very properly an ingredient in the "electuarium e caffia."

Manna is alfo a fcripture term, fignifying a miraculous kind of food, which fell from heaven, for the fupport of the Ifraelites, in their paffage through the wildernefs ; being a fmall grain, white, like hoar-froft, round and of the fize of coriander feeds ; its colour like that of bdellium, and its tafte like honey.

They call it *manna*, either from the Hebrew word *manah*, *a gift*, to intimate its being a gift from heaven ; or from *minnah*, which fignifies *to prepare*, becaufe the manna came to them ready for eating, and needed no preparation but gathering ; or from the Egyptian word *man*, derived from the Hebrew *mah*, *what is it ?* which laft etymology feems the more probable, in regard the fcripture takes notice of the furprize they were under when they firft faw this new food defcend. Accordingly the Hebrews, on firft feeing this new food which God had provided for them, faid to one another *man-hu*, or *mah-hu*, *what is this ?* Others, among whom are Saumaife and many moderns, maintain, that the Hebrews well knew what manna was, and faid to one another, *man-hu*, *this is manna.*

Salmafius, however, prefers another etymology : according to him, the Arabs and Chaldeans ufed the word *man* to fignify a kind of dew or honey that fell on the trees, and was gathered in great abundance on mount Libanus. On which footing the Ifraelites did not ufe the term manna out of furprize, but becaufe they found this food fall with the dew, in the fame manner as the honey-dew, fo well known to them under the name of *man.* Salmafius adds, that the manna of the Ifraelities was in reality no other than that honey, or dew, condenfed ; and that the one and the other were the fame with the wild honey with which St. John was fed in the wildernefs ; fo that the miracle did not confift in the formation of any new fubftance in favour of the Ifraelites, but in the punctual manner in which it was difpenfed by Providence for the fuftenance of fo vaft a multitude.

On the contrary, the Hebrews and Orientals believe, that the fall of the manna was wholly miraculous. Whatever was the nature of this fubftance, which it is not eafy, or perhaps poffible, for us to afcertain, it was by the difpenfation of Providence a nutritive food, and ferved the children of Ifrael during their migration in the defarts of Arabia for forty years, from their eighth encampment in the wildernefs of Sin. Manna began to fall on Friday morning, the 16th day of the fecond month, which from thence was called Jiar; and, according to Ufher, this was Friday the 5th of June. (Exod. xvi. 14, 15.) It continued to fall daily in the morning, except on the fabbath, till after the paffage over Jordan, and to the paffover of the 40th year from the Exodus, *i. e.* from Friday the 5th of June, A.M. 2513, to the fecond day of the paffover, Wednefday the 5th of May, A.M. 2553, B.C. 1451. This manna, whatever it was, fell in fuch quantities, during forty years, as to be fufficient for the fuftenance of about a million of perfons. Every Friday it fell in a double portion (Exod. xvi. 5.): and though on other days it putrified, if it were kept from one day to another, yet on the fabbath it fuffered no fuch alteration. Thus, the Ifraelites were inftructed in their conftant and neceffary dependence on the providence of God.

MANNA *Alhagina*, a word ufed by fome authors to exprefs that kind of manna called by others *manna maftichina*, from its drops refembling maftich in fmall tears. It is called *alhagina* from the plant which produces it, it being collected from the *alhagi maurorum*, in the fame manner as the common manna from the Calabrian afh.

MANNA *Libanotis*, in the *Materia Medica*, a name given by the old Greek writers to the fmall flakes and fragments of the frankincenfe, which flew off the larger pieces in the gathering and putting them up. See LEPTOS *Libanotis*.

MANNA *Maftichina*, a name given by fome authors to a kind of manna which they defcribe as refembling maftich in its colour, and the fize of the lumps it is collected in. This is what we ufually know at this time under the name of *manna Perficum*, or *Perfian manna*, which is even now in ufe in medicine, in the Eaft, as a common purge.

MANNA *Perficum*, *Perfian Manna*. It does not appear in the writings of the ancient Greek phyficians, that they were acquainted with any fpecies of manna, though that medicine be now fo common in the fhops. They had the word indeed, but they applied it to a very different fenfe; what they called manna being what fome authors ftill called the manna of frankincenfe, that is fuch pieces of the common olibanum as broke off in the carriage from the larger pieces. Phil. Tranf. N° 472. p. 86. in vol. xlii.

The Arabians are by fome fuppofed to have firft brought what we call manna into ufe in medicine; but if they were not the abfolute inventors of this ufe of it, it is certain they were the firft who made it general and common as a purge. Their country afforded feveral diftinct fpecies of manna, all which feem to have been fo common among them, that they thought defcriptions of them needlefs; and for that reafon have not left us fufficient accounts of them, from which to determine what were their characters and differences. They diftinguifhed three kinds of this purging medicine, under three abfolute different names, which were *manna*, *tereniabin*, and *firacoft*; but it is not eafily proved whether thefe are all now known, or by what appellations they are at this time diftinguifhed.

Rawwolf, in his Itinerary publifhed by Mr. Ray, and Tournefort in his voyage to the Levant, have given the cleareft intimations, in regard to this fubject, of any of the known writers; and if to thefe we add Clufius, we have among the three all that is to be expected of any certainty upon the fubject; yet the defcriptions of thefe, though eyewitneffes of all they write, have not prevented fo eminent and late a writer as Geoffroy, from falling into an error concerning the manna of the Arabians. It is very evident, however, that we have ftill one fpecies of the manna Arabum, that is, the *tereniabin*, produced in fome parts of the world, there having been fpecimens of it fent over into England from Peterfburgh, near which place it is collected from a plant known among botanical writers under the name of *alhagi maurorum*.

This is ufually called *manna Perficum*; it appears at firft fight a mixed mafs of dirty reddifh-brown colour, but, upon a nearer view, it is feen to confift of feveral forts of particles. Firft, a great number of globular, cryftalline, and almoft tranfparent bodies of different fizes, and of a yellowifh-white colour; the biggeft of thefe do not much exceed a larger coriander-feed in fize, and they have fomewhat the appearance of fmall lumps of maftic, but are of a fomewhat reddifh caft. Secondly, there is among thefe a large quantity of fmall prickles, and other little woody bodies, which feem to have been the pedicles of leaves. Thirdly, there are a few fmall leaves which are of firm texture, and terminate in narrow points. Fourthly, there are a large number of fmall long reddifh coloured pods, of a fweetifh gelatinous tafte, containing from one to fix or feven hard, irregular, and kidney-fhaped feeds, which to the tafte are very four. And fifthly, there is ufually fome fand and earth among it. Four ounces of this manna diffolved in water ufually leave about one ounce of thefe fubftances in the filtre.

The globules firft defcribed are fomething hard, they break between the teeth like fugar-candy, and are of a pleafant fweet tafte, but have much lefs of the manna flavour than the Calabrian, but enough of it to difcover to what family the fubftance belongs: the feeds, fticks, leaves, and pods, feem to be all of them parts of the plant which produces the manna; and the feeds having been fown with us, have raifed plants of the alhagi. About the year 1537, when Rawwolf wrote his Itinerary, it appears that large quantities of this kind of manna were brought from Perfia to Aleppo, where it was then known by the name of *trunfchibil*, or *trunfchibin*, a corruption doubtlefs of the word *terenjabin*, or, as it ought to be written, according to Deufingius, *tereng jabin*.

Rawwolf alfo exprefsly informs us, that this fpecies of manna was gathered from a plant called *alhagi*. This plant is minutely defcribed by Tournefort, who confirms the account of the manna being gathered from it, which Rawwolf had given fo long before.

Tournefort fays, that it is chiefly gathered about Tauris, a city of Perfia, under the name of *trunjibin*, or *terenjabin*, mentioned by Avicenna and Serapion; he adds, that thofe authors thought it fell upon certain prickly fhrubs; whereas it is really the nutritious juice of the plant; and that, during the great heats in that part of the world, there are perceived fmall round drops, as it were, of honey ftanding upon the leaves of this plant; and that thefe harden into globules about the fize of coriander-feeds, and are then gathered by the inhabitants, together with leaves, ftalks, dirt, and the like foreign matter, which greatly take off from their virtue. M. Tournefort obferves, that this manna is greatly inferior to the Calabrian in virtue; and that twenty or thirty drams of it are given for a dofe. Philof. Tranf. N 472, p. 90. ubi fupra.

Clufius tells us, that the *terenjabin* of the Arabians is gathered from a prickly fhrub, fuch as the alhagi is defcribed

to

to be; and Avicenna declares, that it was found upon a thorny plant; though his translators have been misled from the near resemblance of two Arabic words, to make it stones, not a plant, that it was gathered from.

It appears very plainly from the whole, that this substance, now known in Russia, and some other parts of the world, under the name of *manna Persicum*, is truly the *terenjabin* of the Arabians and of Clusius, Rawwolf, and Tournefort; only that the word is differently spelt by the latter authors, and it is probably also that manna called by Bauhine, and some other writers, *manna mastichina orientalis*, from the round globules it is composed of resembling the drops of mastich.

Manna *Thuris*, the *manna of frankincense*, a term used by the ancient physicians to express such small pieces of frankincense, or olibanum, as broke off from the larger in the carriage. See Leptos *Libanotis*.

MANNACOTE, in *Geography*, a town of Kemaoon; 60 miles N.W. of Kerigar.

MANNEBACANI, a town of Congo; 40 miles S.W. of Congo.

MANNER, in *Painting*, is not only employed in its natural sense, as designatory of that peculiarity in each painter's mode of composition, drawing, and execution, which, like diversity in hand-writings, characterises the productions of different individuals; but it has also a technical meaning, in which it is commonly employed by artists and connoisseurs, *viz.* to mark certain kinds of deviation from nature in the works of artists, into which, either through conceit or weakness, they have fallen, by endeavouring to obtain that high portion of acknowledged excellence, known by the name of style; of which manner may be considered as the bathos.

The proper application of this word in the art is evident. No two painters have ever executed their works in a manner exactly similar, how nearly soever they may have imitated each other. In every case variety still appears, extending through every portion and principle of their compositions, as well as in their execution of them: just as men think and write differently upon the same subjects, and convey their ideas by dissimilar characters, though tracing the same letters.

It is by this diversity that connoisseurs are enabled to ascertain the authors of pictures, whose names as such would otherwise have been lost: by this the different schools of art are pointed out, and the works of the artists educated in them; although some of superior excellence have varied their manner, in the course of their practice, more than once. Thus, Titian is said to have had his first, second, and third manner; Raphael, his Perugino manner, his own, and that framed in imitation of Michael Angelo. By this, also, the gradual advance of the art may be traced, from its earliest periods, to its arrival at the highest perfection which it attained in the Italian and Flemish schools.

This is the natural and obvious sense of the word; the other is more easily felt th n defined. Every artist and amateur, conversant with the necessities and beauties of art, knows and feels that nature is not to be copied at all times, and under every situation. Her works must be selected and imitated only in her happiest moments, in her very best productions. When an artist understands, and can exhibit in his works those peculiarities which exemplify the purity of this select class of natural objects, in all their differing characters, and can avoid the trifling matters which are unnecessary in grand representations, adhering only to that which is truly characteristic, and giving to it all possible truth and force, he has obtained that dignified power which is denominated style. If, in the attempt, he misses his course, and stumbles upon a misconception of true character, and substitutes fanciful perfections of form and colour, which have not the foundation of genuine nature to support them, his style degenerates to manner: being false in its basis, it cannot be ennobled by that higher title, which of necessity implies truth.

Every application of style is indeed a manner; but the latter word is never used for the former, generally in opposition to it, and always derogatory to the artist and his works. For instance, Michael Angelo gave a fulness and grandeur to the form of man in his pictures, which is not to be found so complete in nature. But his perfect knowledge of the nature of the human frame, and the principles upon which it was set in motion, enabled him to apply his peculiar taste of line in a just and characteristic manner; so that though nature appears in his works to be almost extravagantly exerted, still it is not violated: hence the appropriate expression for his works is, that they are wrought in a grand style. His German imitators we speak of as mannerists; because, without comprehending his principles, they imitated his style, only to produce contortions and swellings without character or meaning; muscles in false motions, merely to produce something like what they saw and felt was grand and imposing; a fulness and wave of line, which they carried into parts that ought to have been tranquil, square, or straight: and thus falsifying the style, their art was mannered, drawn from other art, and not from nature.

Art has three stages, as natural to it as childhood, manhood, and age, to man; *viz. imitation*, *style*, and *manner*. The first is the sole object which can present itself to the wish of those who attempt to paint, without having any pictures before them; the imitation of a natural object being the proposed end of the attempt. When a man has obtained the power of representing bodies, he naturally seeks for the best and most agreeable subjects for the exercise of his acquired power, and also endeavours to give them as much beauty and interest as possible; this necessarily leads to *style*: and this, once acquired and exhibited to view, excites others to improve upon and indulge their minds in the ideal gratification which arises from it, and in weak hands produces *manner*, the bane of the art and artist. One striking difference between style and manner is this: the former may at first sight be unsatisfactory to an uninformed mind, but investigation will gradually increase its value, and heighten it in estimation; the latter, on the contrary, may charm at first sight, but never fails to disgust on a prolonged observation, when its folly and imperfection become apparent. It is an evil which those are always in great danger of being subjected to, who endeavour to make their pictures agreeable, rather than impressive; and forget that the highest praise due to an artist is given only, when he claims it by correctness of force and expression.

A simple imitation may be wrought in a bad or good style: it cannot be said to be mannered, unless some violation of the principles of nature appear introduced, in order to give an ideal improvement upon the natural effect. In drawing, all affectations of square or round, of straight or undulating lines; in colour, all introductions of florid or dull tints, which trench upon the true simplicity of nature; and in expression, all extravagant increase of actions in the features or limbs of a figure, which are not justified by the sentiment intended to be conveyed; all these come under the denomination of manner. These peculiarities are frequently to be found in the works of truly g eat men; but they are not the less objectionable in principle, and perhaps would not have been employed by them but to overcome ſome local diſadvantage: in that caſe, ſtyle becomes their proper name. But the want of this conſideration has often led ſtudents to the admiration of theſe very defects, and a blind imitation of them, which neceſſarily generates manner. Thus, Rubens's ſtyle of colour is in itſelf ſo violent, that, if not fully maintained in all its harmony, it deſerves no better title than manner, and becomes completely ſo in the hands of moſt of his imitators.

Titian's colour juſtly merits the moſt diſtinguiſhed appellation. It is true to nature, but it is in her ſimple garb, robbed of her minuter reflections and refractions, yet carefully followed in her general principles, and enriched and heightened by a favourable ſelection and arrangement of objects, their being placed in agreeable lights, and viewed in a choſen direction. The Venetians carried it to manner: even Tintoretto and P. Veroneſe, the beſt and grandeſt amongſt them after Titian and Giorgione. Having imbibed a taſte for the rich and luxurious colouring of their predeceſſors, they could not be content without endeavouring to extend its boundaries; and in ſo doing, loſt ſight of nature, and adopted their own fancies as improvements upon her ſyſtem, and thus ſunk in ſome meaſure to manneriſts.

It is when the practice of art has become matured by ſkilful men, that others build ſyſtems for their conduct upon the works of their predeceſſors; and though it is very proper that a ſyſtem be acted upon, as it greatly facilitates and improves the practice, yet too ready and ſtrict a reliance upon it is almoſt the certain guide to manner: to avoid which, a conſtant reference to nature is abſolutely neceſſary. Hence, after the period when M. Angelo, Raphael, Titian, and Corregio, lived and exerted their powerful talents in the perfection of the art of painting, ſucceeding artiſts, not endued with their vigour of perception, endeavoured to diſcover in their works ſome means of keeping up with them; to eſtabliſh ſome ſyſtem, on which they had or might have proceeded in their extraordinary and beautiful productions: it thence became as much an object to imitate the works of ſome favourite artiſt as thoſe of nature; and the true intention of the art, being thus but an acceſſory rather than a principal, was too often ſacrificed. Almoſt the whole number of the ingenious men who learned in the ſchool of the Caracci, and followed the principles inculcated there, may be properly termed manneriſts.

The manner, or the eaſe which a ſyſtem gives, of effecting ſomething attractive to the eye, and dazzling to the underſtanding, is too ſeductive to be frequently reſiſted by the inexperienced and vain. Thoſe who have been early taught by ſyſtem to impoſe upon themſelves, and led to imagine they exhibit great ingenuity in managing a pencil with dexterity, will moſt likely never believe that it is more difficult, and far more praiſe-worthy, to think juſtly, and to imitate attentively the preciſe terms of an expreſſion, though it be wrought with a heavier hand, and more laborious ſtudy. Manner, conſidered thus, is a kind of receipt for making a picture, a ready mode of combining the neceſſary ingredients; in which, however, though the hand of the artiſt may ſometimes by accident add a larger or ſmaller proportion of any one of them, the reſult is inevitably of nearly the ſame quality, and is in conſtant danger of being miſapplied: for it is equally as ridiculous to ſuppoſe that one kind of execution or mode of compoſition will ſuit the repreſentation of all kinds of ſubjects, as to believe that one compoſition of medical drugs is adequate to the cure of all kinds of diſeaſes.

Manners, in *Poetry*, denote the inclinations, genius, and humour, which the poet gives to his perſons, and whereby he diſtinguiſhes his characters.

Ariſtotle defines manners to be that which diſcovers the inclination of him who ſpeaks, and ſhews what he will reſolve upon, or what reject, before he was actually determined: whence he concludes, that manners have not place always, and in all kinds of diſcourſes.

One inſtance will make this definition clear. In the firſt book of Virgil, Æneas is repreſented extremely pious, determined to execute the will of the gods, at all adventures. In the fourth book he has a difficult choice propoſed; being engaged, on the one hand, out of a principle of love, gratitude, and honour, not to quit Dido; and having, on the other hand, an expreſs order from the gods to depart for Italy. Now, before it appears on which ſide he has determined, what he has before ſaid ſhould ſhew his will and inclinations, and which part he will take. And thoſe preceding diſcourſes, which diſcover his future reſolution, make what we call the poetical manners.

Thoſe make it paſt doubt he will abandon Dido to obey the gods; this he does in effect; and the manners, therefore, are good, and well conducted. Had he diſobeyed the orders of Jupiter, to ſtay with Dido, the manners had been ill; becauſe they would have foretold a reſolution contrary to what he was really to take. But had there been nothing to make us foreſee any reſolution of Æneas at all, neither that which he actually took, nor the contrary, in that caſe there had been no manners at all. It is the manners, as before obſerved, that diſtinguiſh the characters; and, unleſs the manners be well expreſſed, we ſhall never be acquainted with the perſons at all; nor, conſequently, ſhall we be either terrified with foreſeeing their dangers, nor melted into pity, by ſeeing their ſufferings.

The manners ſhould have four qualities; they ſhould be *good*, *like*, *ſuitable*, and *equal*.

The manners are *good*, when they are well marked or expreſſed; that is, when the diſcourſe of the perſons makes us clearly and diſtinctly ſee their inclinations, and what good or evil reſolutions they will take. *Likeneſs* of manners only relates to known and public perſons, whoſe characters are in hiſtory, with which the poetic characters muſt agree; that is, the poet muſt not give a perſon any quality contrary to any of thoſe which hiſtory has already given him. And here it may be obſerved, that the evil qualities given to princes, and great men, ought to be omitted by poets, if they be contrary to the character of a prince, &c. but the virtues oppoſite to thoſe known vices ought not to be impoſed; as by making him generous and liberal in the poem, who was avaricious in the hiſtory.

The manners muſt likewiſe be *ſuitable*; that is, they muſt be agreeable to the age, ſex, rank, climate, and condition of the perſon that has them. Horace obſerves, "Intererit multum Davuſne loquatur, an heros." Again, the manners muſt be *equal*; that is, they muſt be conſtant, or conſiſtent, through the whole character; or the variety or inequality of the manners, as in nature, ſo in the drama, muſt be equal. The fearful muſt never be brave, nor the brave timorous; the avaricious muſt never be liberal, nor *vice verſâ*. In this part Shakſpeare's manners are admirable.

Beſides theſe four qualities above mentioned, there is a fifth eſſential to their beauty; which is, that they be neceſſary; that is, that no vicious quality, or inclination, be given to any poetic perſon, unleſs it appear to be abſolutely neceſſary, or requiſite, to the carrying on of the action.

MANNERIST, in *Painting*, one who adopts a manner,

ner in his works, or a peculiar and affected mode of producing effect in them unauthorized by nature.

MANNERSDORFF, in *Geography*, a town of Auftria, on the Leytha, celebrated for its medicinal waters; 17 miles S.S.E. of Vienna.

MANNI, Genaro, in *Biography*, compofer of the archiepifcopal church, and a great and much refpected mafter at Naples, in 1770. His ftyle of church mufic much refembles that of Leo, with equal invention and learning. At the death of Jomelli, he formed a plan for a public funeral for that truly great mufician, and had intereft fufficient to have it executed with uncommon folemnity and fplendour. See Jomelli; alfo Genaro.

MANNIFERA Arbor, in the *Materia Medica*, the name by which the round-leaved afh, on which the manna is found, is often called.

MANNIN Bay, in *Geography*, a fmall harbour on the W. coaft of the county of Galway, Ireland, adjoining that of Ardbear, in which latter there is better anchorage and fhelter.

MANNING *a* Hawk, in *Falconry*, the making her tractable and tame.

Manning *the Fleet*, is the providing of it with a fufficient number of men for any expedition. One of the methods commonly recurred to for this purpofe is that of impreffing men, by warrants from the lord high admiral to the captains, which are by them affigned to their lieutenants; and to render this the more effectual, veffels, called *tenders*, are hired into the fervice, to proceed from place to place with thofe officers and prefs-gangs, not only to receive volunteers, but to imprefs any feamen whom they find. The power of impreffing men for the fea-fervice by the king's commiffion, fays judge Blackftone, has been a matter of fome difpute, and fubmitted to with great reluctance; though it hath very clearly and learnedly been fhewn by fir Michael Forfter, that the practice of impreffing, and granting powers, to the admiralty for that purpofe, is of very ancient date and hath been uniformly continued by a regular feries of precedents to the prefent time: whence he concludes it to be a part of the common law. The difficulty arifes from hence, that no ftatute has exprefsly declared this power to be in the crown, though many of them very ftrongly imply it. The ftat. 2 Ric. II. c. 4. fpeaks of mariners being arrefted and retained for the king's fervcie, as of a thing well known and practifed without difpute; and provides a remedy againft their running away. By ftat. 2 & 3 Ph. & M. c. 16. if any waterman, who ufes the river Thames, fhall hide himfelf during the execution of any commiffion of preffing for the king's fervice, he is liable to heavy penalties. By 5 Eliz. c. 5, no fifherman fhall be taken by the queen's commiffion to ferve as a mariner; but the commiffion fhall be firft brought to two juftices of the peace, inhabiting near the fea-coaft, where the mariners are to be taken, to the intent that the juftices may choofe out and return fuch a number of able-bodied men, as in the commiffion are contained, to ferve his majefty; and by 7 & 8 W. III. c. 21. 2 Ann. c. 6. 4 & 5 Ann. c. 19. 13 Geo. II. c. 17, &c. efpecial protections are allowed to feamen in particular circumftances, to prevent them from being impreffed. And ferrymen are alfo faid to be privileged from being impreffed, at common law; all which do moft evidently imply a power of impreffing to refide fomewhere; and, if any where, it muft, from the fpirit of our conftitution, as well as from the frequent mention of the king's commiffion, refide in the crown alone.

But, befide this method of impreffing, which is only defenfible from public neceffity, to which all private confiderations muft give way, there are other means tending to the increafe of feamen, and for manning the royal navy. Parifhes may bind out poor boys apprentices to mafters of merchantmen, who fhall be protected from being impreffed for the firft three years; and if they are impreffed afterwards, the mafters fhall be allowed their wages. (2 Ann. c. 6.) Great advantages in point of wages are given to volunteer feamen, in order to induce them to enter into his majefty's fervice. (1 Geo. II. ftat. 2. c. 14.) It is alfo ufual to promife, by proclamation, a bounty to all feamen and able-bodied landmen, who come into the fervice by a certain time; and every foreign feaman who, during a war, fhall ferve two years in any man of war, merchantman, or privateer, is naturalized *ipfo facto*. 13 Geo. II. c. 3.

About the middle of king William's reign, a fcheme was fet on foot (7 & 8 W. III. c. 21.) for a regifter of feamen, to the number of 30,000, for a conftant and regular fupply of the king's fleet, with great privileges to the regiftered feamen, and, on the other hand, heavy penalties in cafe of their non-appearance when called for; but this regiftry, being judged to be rather a badge of flavery, was abolifhed by 9 Ann. c. 21. Blackft. Com. vol. i. p. 419. &c.

MANNINGTON, a town of America, in Salem county, New Jerfey.

MANNOZZI, Giovanni, in *Biography*. See Giovanni da San Giovanni.

MANNUS, Man, in *Mythology*, the fon of the German god Tuifton; of whom, according to Tacitus De Moribus Germanum, thefe people were defcended.

MANO Armonica, Ital.; *Main Harmonique*, Fr.; *Harmonic Hand*. See Hand, *Harmonic*.

MANOD, in *Geography*, one of the fmaller Philippine iflands. N. lat. 12° 28′. E. long. 122° 24′.

MANŒUVRE, To, in *Military Language*, is fo to manage any body or armed force, as to derive fudden and unexpected advantages before the enemy from fuperior fkill in military movements. It confifts in diftributing equal motion to every part of a body of troops, that the whole may be enabled to form, or change its pofition, in the moft expeditious and beft method, fo as to anfwer the purpofes required of a battalion, brigade, or line of cavalry, infantry, or artillery.

Manœuvres confift chiefly in thofe various movements or evolutions, in which foldiers are exercifed, in order to fit them for defenfive or offenfive operations. See Battalion, Manual and Platoon *Exercifes*, and Review.

The platoon exercife has been altered as well as the manual. (See Platoon and Battalion.) The exercife is performed a little flower, three feconds being allowed between each motion. It is no longer done by fignal, from beat of drum, but all by word of command.

The infantry manœuvres, which were formerly fo numerous, are now reduced to 18; which are ordered to be practifed and performed in every regiment. The following are the movements, explanations of which, and directions for performing them, are given in the books of exercife. See Battalion.

1. Forming the battalion into clofe columns in the rear of the right company. 2. Clofe column in the front of the left company. 3. Clofe column in a central company, facing to the rear. 4. Changing pofition in open column. 5. Throwing back the wings. 6. Changing pofition by a countermarch. 7. Counter-marching by files in the centre of the battalion. 8. Marching in open column. 9. Echellon change of pofition. 10. Taking up a new line by the echellon movement. 11. Changing pofition to right or left. 12. Retreating in line. 13. Marching to a flank in echellon.

on. 14. Forming the hollow fquare. 15. Retiring in line and filing. 16. Advancing in line, filing, and charging to the front. 17. Retreating in line. 18. Advancing in line.

MANOK Manka, in *Geography*, an ifland in the Sooloo Archipelago. N. lat. 4° 54′. E. long. 119° 48′.

MANOMETER is the name of an inftrument in experimental philofophy; it is derived from μανος, *rare*, and μετρον, *meafure*, being intended to meafure the rarefaction and condenfation of elaftic fluids in confined circumftances, whether occafioned by variation of temperature, or by the actual deftruction or generation of portions of elaftic fluid. It is fometimes called *manofcope*.

Mr. Boyle's *ftatical barometer* was an inftrument of this kind; it confifted of a bubble of thin glafs, hermetically fealed, about the fize of an orange, which being counterpoifed when the air was in a mean ftate of denfity, by means of a nice pair of fcales, funk when the atmofphere became lighter, and rofe as it grew heavier. This inftrument would evidently indicate the changes of *denfity* of the atmofphere; but it leaves us uncertain as to the caufe, whether it is from a change of its *weight*, or of its *temperature*, or of both. See Barometer, *Statical*.

The manometer conftructed by Mr. Ramfden, and ufed by Captain Phipps, in his voyage to the North Pole, was compofed of a tube of a fmall bore, with a ball at the end; the barometer being at 29.7, a fmall quantity of quickfilver was put into the tube, to take off the communication between the external air, and that confined in the ball and the part of the tube below this quickfilver. A fcale is placed on the fide of the tube, which marks the degrees of dilatation arifing from the increafe of heat in this ftate of the weight of the air, and has the fame graduation as that of Fahrenheit's thermometer, the point of freezing being marked 32. In this ftate, therefore, it will fhew the degrees of heat in the fame manner as a thermometer. But if the air becomes lighter, the bubble inclofed in the ball, being lefs compreffed, will dilate itfelf, and take up a fpace as much larger as the compreffing force is lefs; therefore the changes arifing from the increafe of heat will be proportionably larger; and the inftrument will fhew the differences in the denfity of the air, arifing from the changes in its weight and heat. Mr. Ramfden found, that a heat equal to that of boiling water, increafed the magnitude of the air from what it was at the freezing point $\frac{404}{1000}$ of the whole. Hence it follows, that the ball and the part of the tube below the beginning of the fcale is of a magnitude equal to almoft 414 degrees of the fcale. If the height of both the manometer and thermometer be given, the height of the barometer may be thence deduced by this rule; as the height of the manometer increafed by 414 is to the height of the thermometer increafed by 414, fo is 29.7 to the height of the barometer.

In the 67th volume of the Philofophical Tranfactions for 1777, page 689, Col. William Roy has given a defcription of the manometers he ufed to afcertain the expanfion and contraction of dry and moift air by change of temperature. "They were of various lengths, from four to upwards of eight feet; they confifted of ftraight tubes, whofe bores were commonly from $\frac{1}{13}$th to $\frac{1}{23}$th of an inch in diameter. The capacity of the tube was carefully meafured, by making a column of quickfilver, about three or four inches in length, move along it from one end to the other. Thefe fpaces were feverally marked with a fine edged file on the tubes, and transferred from them to long flips of pafteboard, for the fubfequent conftruction of the fcales refpectively belonging to each. The bulb attached to one end of the manometer at the glafs-houfe, was of the form of a pear, whofe point being occafionally opened, dry or moift air could be readily admitted, and the bulb fealed again, without any fenfible alteration in its capacity.

"The air was confined by means of a column of quickfilver, long or fhort, and with the bulb downward or upwards, according to the nature of the propofed experiment. Here it muft be obferved, that from the adhefion of the quickfilver to the tube, the inftrument will not act truly, except it be in a vertical pofition; and even then it is neceffary to give it a fmall degree of motion, to bring the quickfilver into its true place, where it will remain in equilibrio, between the exterior preffure of the atmofphere on one fide, and the interior elaftic force of the confined air on the other.

"Pounded ice and water were ufed to fix a freezing point on the tube; and by means of falt and ice, the air was farther condenfed, generally four, and fometimes five or fix degrees below zero. The thermometer and manometer were then placed in the tin veffel, among water, which was brought into violent ebullition; where having remained a fufficient time, and motion being given to the manometer, a boiling point was marked thereon. After this the fire was removed, and the gradual defcents of the piece of quickfilver, correfponding to every 20 degrees of temperature in the thermometer, were fucceffively marked on a deal rod applied to the manometer. It is to be obferved that both inftruments, while in the water, were in circumftances perfectly fimilar; that is to fay, the ball and bulb were at the bottom of the veffel.

"In order to be certain that no air had efcaped by the fide of the quickfilver during the operation, the manometer was frequently placed a fecond time in melting ice. If the barometer had not altered between the beginning and end of the experiment, the quickfilver always became ftationary at or near the firft mark. If any fudden change had taken place in the weight of the atmofphere during that interval, the fame was noted, and allowance made for it in afterwards proportioning the fpaces.

"Long tubes, with bores truly cylindrical, or of any uniform figure, are fcarcely ever met with. Such, however, as were ufed in thefe experiments, generally tapered in a pretty regular manner from one end to the other. When the bulb was downwards, and the tube narrowed that way, the column of quickfilver confining the air lengthened in the lower half of the fcale, and augmented the preffure above the mean. In the upper half, the column being fhortened, the preffure was diminifhed below the mean. In this cafe the obferved fpaces, both ways from the centre, were diminifhed in the inverfe ratio of the heights of the barometers at each fpace, compared with its mean height. If the bore widened towards the bulb when downwards, the obferved fpaces each way from the centre were augmented in the fame inverfe ratio; but in the experiments on air lefs denfe than the atmofphere, the bulb being upwards, the fame equation was applied with contrary figns; and if any extraordinary irregularity took place in the tube, the correfponding fpaces were proportioned both ways from that point, whether high or low, that anfwered to the mean.

"The obferved and equated manometrical fpaces being thus laid down on the pafte-board containing the meafures of the tube; the 212° of the thermometer, in exact proportion to the fections of the bore, were conftructed along fide of them; hence the coincidences with each other were eafily feen; and the number of thermometrical degrees anfwering to each manometrical fpace readily transferred into a table prepared for the purpofe." For the important refults obtained by thefe inftruments, fee Barometer, *Meafurement of Altitudes*.

It

It may not be amifs to obferve that Colonel Roy's refults on the expanfion of dry air have been generally confirmed by the fubfequent experiments of Dalton and Gay Luffac; but thofe on moift air have been found lefs fatisfactory, unlefs in fuch cafes when water in a liquid ftate is prefent. Mr. Dalton has given a theorem, derived from his experience, to afcertain the expanfion of moift air (that is, when water is prefent in the liquid ftate) for any temperature. Suppofing the fpace occupied by the dry air at the given temperature to be 1, the atmofpheric preffure $= p$, and $f =$ the force of fteam at the temperature; then the fpace of the moift air will be $= \frac{p}{p-f}$.

The ftriking peculiarity of manometers of the above conftruction, and that on which their chief excellence depends, is that a mercurial column of about $\frac{1}{15}$th or $\frac{1}{20}$th of an inch in diameter, flides freely up and down a glafs tube, without fuffering any air to pafs either way. This character is, however, obtained only by preferving the tube and mercury very clear and dry. If any duft, moifture, or oxyd be found in the tube, the mercury becomes lefs free in its motion, and the air is apt to break the mercurial column, and gradually efcape. A bore of lefs diameter would occafion too much friction, and one of greater would fuffer the mercury to fall down.

When the expanfion or dilatation of the air in any experiment amounts to one-half of the original volume, or any other quantity exceeding that, a manometer of a ftill more fimple conftruction may be ufed, namely, a ftraight tube, or one without bulb, of the fame bore or capacity as Col. Roy's. It muft be divided into equal fpaces, by means of a fliding mercurial column, on account of the irregularity of the bore incident to fuch tubes; a fmall drop of mercury may then be let down by a clean iron wire to any part of the tube, fo as to conftitute a fliding column of about half an inch in length.

Another fpecies of manometer may be ufed when the object is to meafure the force of fteam or vapour, generated over certain liquids by heat. In this cafe a tube fimilar to the preceding may be bent into a fiphon with parallel legs, the fhorter leg of which muft be clofed, or hermetically fealed, and the longer open. A few drops of the liquid muft be conveyed to the extremity of the clofed leg; after which the greater part of the tube may be filled with mercury, fo as to leave no fpace with air between the mercury and the liquid; the manometer muft then be put into water, &c. of a known temperature, and held in a perpendicular pofture, with the bending loweft, and fo that the extremity of the tube containing the liquid may be wholly immerfed in the warm water, whilft the other extremity is without. The heat will expand part of the liquid into fteam, which will deprefs the mercury in the fame leg, and elevate it in the oppofite, till an equilibrium of preffure is eftablifhed. The elaftic force of the fteam will evidently be equal to the preffure of the atmofphere $\pm$ the difference of the heights of the two mercurial columns in the fiphon, according as the column in the open or clofed leg exceeds that of the other. If the difference of the heights is expected to be upwards of thirty inches, fome inconvenience arifes from the great length of tube requifite: in this cafe an ingenious contrivance has been invented to obviate it; the open end of the manometer muft be hermetically fealed, fo as to inclofe a column of atmofpheric air of due volume; when the fteam is formed in the liquid, and the mercury depreffed, it condenfes the air in the other leg, and the fpace occupied by the condenfed air, as is well known, is inverfely as the force; then the quantity of this force thus afcertained $\pm$ the difference of the two mercurial columns, will give the whole elaftic force of the fteam. Great care muft be taken that the air-column of the fiphon is clear of the liquid that generates the fteam. By this fort of inftrument Mr. Dalton finds the force of fteam from fulphuric ether at 212 Fahr. = 236 inches of mercury. See Manchefter Mem. vol. v. p. 567. Alfo, New Syftem of Chemiftry, part 1, p. 14.

The ftraight tube manometer is the moft elegant and fimple inftrument to prove the important property of elaftic fluids above alluded to, namely, that the fpace occupied by any permanent elaftic fluid is inverfely as the preffure. For this purpofe a fmall given portion of air is confined in the bottom of a long tube, of forty inches or more. A column of twenty-five inches, more or lefs, of mercury is admitted into the tube to confine the air; when the tube is held horizontally, the confined air is preffed by the atmofphere only: when the tube is held perpendicular, the air has the preffure of the atmofphere + that of the mercurial column; and when it is held downwards, the air has the preffure of the atmofphere — that of the mercurial column. By marking the fpaces occupied by the air in thefe circumftances, they are found to be inverfely as the preffures.

Sauffure, in his Effays on Hygrometry, defcribes his manometer: it was nothing but an ordinary barometer: a fimple ftraight tube was filled with boiled mercury, and its open end was immerfed in a cup of the fame liquid; the whole was then inclofed in a large glafs balloon, except a few inches of the upper extremity of the tube, to which a fcale of degrees or equal parts was attached, to fhew the variation of the altitude of the mercury. The tube paffed through a circular hole in a tin plate which covered the opening of the balloon, and which was very carefully luted, as was the paffage of the tube, fo as to be perfectly air-tight. In this cafe it was evident the inftrument was no longer a barometer, as it was cut off from the action of the air out of the balloon; but the mercury was fupported by the fpring or elafticity of the air within the balloon, and muft be fubject to fuch fluctuations as took place in it, independently of any change of weight in the atmofphere. By means of this apparatus, Sauffure found that atmofpheric air, in paffing from extreme drynefs to extreme moifture, in the temperature of 65 Fahr., increafed about $\frac{1}{54}$th in elafticity; and *vice verfâ*, in paffing from extreme moifture to extreme drynefs, it diminifhed $\frac{1}{54}$th in its elaftic force, the temperature being all the time uniform.

MANONOETOC, in *Natural Hiftory*, a name given by the people of the Philippine iflands to a fpecies of horned owl, common in thofe parts.

MANOOR, in *Geography*, a town of Hindooftan, in the province of Dindigul; 27 miles N.W. of Dindigul.

MANOORGUDY, a town of Hindooftan, in the circar of Mahur; 20 miles N. of Neermull.

MANOR, or MANNOR, an ancient lordfhip, or royalty; confifting of demefnes and fervices, and of a court-baron, as incident thereto.

The word is formed from the French *manoir*, a *manfion-houfe*; and that from the Latin *manere*, *to remain or dwell*; as being the lord's ufual place of refidence.

Manor is the fame with what was formerly called *baronia*, *barony*; as it is ftill called *lordfhip*; and lord or baron was empowered to hold a domeftic court, called the "court-baron," for redreffing mifdemefnors and nuifances within the manor, and for fettling difputes of property among the tenants. This court is an infeparable ingredient of every manor; and if the number of fuitors fhould fo fail as not to

leave

leave fufficient to make a jury or homage, that is, two tenants at the leaft, the manor itfelf is loft.

A manor is a kind of noble fee, granted out partly to tenants, for certain fervices to be performed, and partly referved to the ufe of the lord's family; with jurifdiction over his tenant, for the lands, or eftates, held of him. As to the original of manors, we are told there was anciently a certain compafs of ground, granted by the king to fome man of worth, for him and his heirs to dwell upon, and to exercife fome jurifdiction, more or lefs, within that circuit, fuch as he thought good to grant; but performing fuch fervices, and paying fuch yearly rent, as by this grant was required. Now the lord afterwards parcelling the fame to other meaner men, received rent and fervices from them, and by that means, as he became tenant to the king, the inferiors became tenants to him. The fuperior lord, under whom the fmaller manors continue to be held, is called, in fuch cafes, the lord paramount over all thefe manors; and his feignory is frequently termed an honor, not a manor, efpecially if it hath belonged to an ancient feudal baron, or hath been at any time in the hands of the crown. In procefs of time the inferior lords parcelled out and granted to others more minute eftates, to be held of themfelves, and fo downwards without limit; till at length their fuperior lords obferved, that by this method of fubinfeudation they loft all their feudal profits, of wardfhips, marriages, and efcheats, which fell into the hands of thefe mefne or middle lords, who were the immediate fuperior of the "terre-tenant," or occupier of the land; and alfo that the mefne lords themfelves were fo impoverifhed thereby, that they were difabled from performing their fervices to their own fuperiors. This occafioned, firft, that provifion in the 32d chapter of Magna Charta, 9 H. III. (which is not to be found in the firft charter granted by that prince, nor in the great charter of king John,) that no man fhould either give or fell his land, without referving fufficient to anfwer the demands of his lord; and afterwards the ftatute of Weftm. 3, or "quia emptores," 18 Edw. I. c. 1, which directs, that, upon all fales or feoffments of land, the feoffee fhall hold the fame, not of his immediate feoffor, but of the chief lord of the fee, of whom fuch feoffor himfelf held it. But thefe provifions, not extending to the king's own tenants *in capite*, the like law concerning them is declared by the ftatutes of "prerogativa Regis," 17 Edw. II. c. 6, and of 34 Edw. III. c. 15, by which laft all fubinfeudations, previous to the reign of king Edward I., were confirmed; but all fubfequent to that period were left open to the king's prerogative. And from hence it is clear, that all manors exifting at this day, muft have exifted as early as king Edward I.; for it is effential to a manor, that there be tenants who hold of the lord; and by the operation of thefe ftatutes, no tenant *in capite* fince the acceffion of that prince, and no tenant of a common lord fince the ftatute of "quia emptores," could create any new tenants to hold of himfelf.

At this time a manor rather fignifies a jurifdiction, and royalty incorporeal, than the land and fuit: for a man may now have a manor in grofs, *i. e.* the right and intereft of a court baron, with the perquifites, and another enjoy every foot of land belonging to it.

A manor may be compounded of divers things: as of an houfe, arable land, pafture, meadow, wood, rent, advowfon, court-baron, &c. And this ought to be, by long continuance of time, beyond man's memory.

It is held by fome, that a manor cannot now be made, fince a court-baron cannot be made; and without a court-baron, and at leaft two fuitors, there can be no manor. A manor may contain one or more villages or hamlets, or only a great part of a village; and there are capital manors or honors, which have other manors under them, the lords whereof perform cuftoms and fervices to the fuperior lords. There may be alfo cuftomary manors, granted by copy of court roll, and held of other manors. But it cannot be a manor in law, without freehold tenants; nor a cuftomary manor, without copyhold tenants. The cuftom remains, when tenements are divided from the reft of the manor, the tenants paying their fervices; and he who hath the freehold of them may keep a court of furvey, &c. See VILLEIN, COPYHOLD, and TENURE.

MANOR *Courts* are fuch as are held within the manor, for the purpofe of adjufting the various rights, claims, &c. It is obferved that the bufinefs of holding thefe, depends on whether they are held of right, or merely by cuftom. It is added, that "if the *copyhold tenure* is fo far worn out, in any manor, that there are not two ancient or feudal tenants remaining within it, the court has loft its legal power. It cannot by right take cognizance of crimes, nor enforce amerciaments." It is, however, allowed that manorial courts have their ufes, in regulating farm-roads, drift-ways, and water-courfes, and in preventing nuifances of different kinds within a manor, and it is generally right to preferve the cuftom of holding them for thefe purpofes. Where *copyhold courts* remain in force, and where legal forms are to be obferved, they are beft held by a law fteward.

MANOR, in *Geography*, a townfhip of America, in Lancafter county, Pennfylvania, containing 1804 inhabitants.

MANORCOTTA, a town of Hindooftan, in Madura; 15 miles N. of Coilpetta.

MANORE, a town of Hindooftan, in Baglana; 38 miles S. of Damaun.

MANOR-HAMILTON, a fmall poft-town of the county of Leitrim, Ireland, on the road to Sligo; being near 11 miles eaft of that town, and 94 miles N.W. from Dublin.

MANORIAL CLAIMS, the claims which the lords of manors have upon their tenants, and which are different in different cafes, according to the nature of the manor. In refpect to the appropriation of commonable lands, thefe claims fhould, according to a late writer, be regulated by the particular advantages which the lord of a given manor may enjoy, and which he may continue to enjoy, while they remain open and uninclofed, whether they may arife from mines, quarries, water, alien tenants, fuel, eftover, pannage, game, &c. The claims of lords, as guardians of the foil, which is productive of *pafturage* only, is, in moft inftances, merely honorary; and it is for the legiflature to apportion the fhare of lands, to which they are entitled, as an equivalent for fuch. But their claims, in the right of the foil on which *thriving timber* is ftanding, are more fubftantial; as out of thefe, they have in effect a real yearly income, equal to the annual increafing value of the timber; a fort of advantage which they of courfe will continue to enjoy, if the commons remain open and uninclofed, as long as the timber continues to increafe in value. Their claims in this refpect, confequently depend on the quantity of timber, and its ftate of growth, conjointly taken. It is fuppofed that, "young thriving timber, not only affords an annual increafe of value at prefent, but will continue its benefits for many years to come, if it be fuffered to remain undifturbed, or the foil which fupports it, during the eftimated period of its future increafe; whereas dotards and ftinted trees, which afford no increafe of value, do not entitle their owners to any fhare of the foil they ftand upon; the trees themfelves, or their intrinfic value, appear to be all that the lord has a right to claim."

It

It is conceived that the claims of the crown, or of hereditary rangers on foreſt lands, ſhould be ſatisfied on the ſame principle.

MANORPOUR, in *Geography*, a town of Hindooſtan, in Mewat; 25 miles S.W. of Cottilah.

MANOS, a town of the iſland of Cuba; 20 miles E.N.E. of Havannah.—Alſo, a cluſter of ſmall iſlands in the Spaniſh Main, near the coaſt of Darien. N. lat. 9° 17′. W. long. 78° 40′.

MANOSQUE, a town of France, in the department of the Lower Alps, and chief place of a canton, in the diſtrict of Forcalquier, which, before the revolution, was the reſidence of a governor, and contained ſeven churches and a commandery of Malta; near it is a medicinal ſpring; ſeven miles S. of Forcalquier. The place contains 5360, and the canton 11,527 inhabitants. N. lat. 44° 50′. E. long. 5° 51′.

MANOT, a town of Hindooſtan, in Aurungabad; 60 miles E.S.E. of Aurungabad.

MANOU, a kingdom of Africa, E. of Quoja.

MANOUARAN, a ſmall iſland in the North Pacific ocean, near the N. coaſt of Waygoo. N. lat. 0° 6′. E. long. 131° 10′.

MANPOUR, a town of Hindooſtan, in Benares; 12 miles N.W. of Bidzigur.—Alſo, a town of Hindooſtan, in Bahar; 35 miles S.W. of Bahar.—Alſo, a town of Hindooſtan, in Oude; 40 miles S.E. of Gorrackpour.

MANQUES Secas, a cluſter of ſmall iſlands in the Atlantic, near the coaſt of Brazil. S. lat. 2° 25′. W. long. 44° 50′.

Manques *Verdes*, a cluſter of ſmall iſlands in the Atlantic, near the coaſt of Brazil. S. lat. 2° 25′. W. long. 44° 46′.

MANRESA, Minorosa, or *Manxes*, a town of Spain, in Catalonia, which gives name to a viguier, *i. e.* governed by a viguier (*vicarius*) or juriſdiction, ſituated on a river, which ſoon after runs into the L'Obregat; it is defended by a caſtle, and contains ſeveral convents; 25 miles N.N.W. of Barcelona. N. lat. 41° 44′. E. long. 1° 44′.

MANRIQUE, D. Jorge, in *Biography*, a Spaniſh poet of the old ſchool, who has retained, to the preſent period of time, a large ſhare of popularity, and who flouriſhed in the fifteenth century. He is chiefly celebrated for the forty-two ſtanzas upon the death of his father, which are ſo natural, and which, being upon a ſubject that intereſts every breaſt, are read with pleaſure by all perſons from the throne to the friar's cell; they have been frequently reprinted with paraphraſes and commentaries. The other pieces of this poet are to be found in the "Cancionero." It was affirmed by Joam II. of Portugal, that it was as neceſſary for a man to know theſe ſtanzas by heart, as to know the pater-noſter. Gen. Biog.

MANS, Le, in *Geography*, a city of France, and capital of the department of the Sarthe, and chief place of a diſtrict, ſituated at the conflux of the Huiſne and Sarthe. Before the revolution it was the capital of Lower Maine, the ſee of a biſhop, the ſeat of a governor, an electorate, bailiwick, &c. and contained a cathedral, two collegiate, 13 pariſh churches, and 12 religious houſes. It is divided into two parts, one containing 9366, and the other 7855 inhabitants. The canton of the former contains 13,866, and that of the latter 11,534 inhabitants; on a territory of 140 kiliometres, in 16 communes. N. lat. 48°. E. long. 0° 17′.

MANSALA, a town of Sweden, in the province of Nyland; 21 miles N. of Borgo.

MANSAPE, a town of Lower Siam, near the coaſt. N. lat. 13° 15′. E. long. 102° 20′.

MANSARA, a town of Hindooſtan, in Bahar; 13 miles S. of Durbungah.

MANSAROAR, a lake of Thibet, about 115 miles in circumference, whence ſprings the ſouthern branch of the Ganges.

MANSART, Francis, in *Biography*, an eminent French architect, born at Paris in 1598, was ſon of the king's carpenter, and received thoſe inſtructions which led him to eminence, as an architect, from the celebrated Gautier; but for the high rank to which he attained in his profeſſion, he was indebted to the force of his own genius. His taſte and judgment, united with a fertile imagination and ſublime ideas, enabled him to equal the greateſt maſters in his plans; he was, however, too apt to alter his deſigns, and even, in aiming at perfection, to demoliſh what was already not only well done, but ſcarcely to be ſurpaſſed. This character was the means of preventing him the honour of finiſhing the fine abbey of Val-de-Grace, founded by Anne of Auſtria, which he had commenced in 1645, and which, when raiſed to the firſt ſtory, the queen put into other hands, to prevent its deſtruction by him who had reared it. He was employed by the preſident Longueil to build his great château de maiſons, near St. Germain's; and when a conſiderable part of it was erected, he pulled it down again without acquainting the maſter with his intentions. After this, it is to his credit, that he finiſhed it in a very noble ſtyle, and it is reckoned one of the fineſt architectural monuments of that age. A better idea cannot be given of his character than this; Colbert applied to him for a deſign of the principal front of the Louvre, and Manſart produced many ſketches of great beauty, but when told he muſt fix upon one to be invariably followed, if approved, he declined the buſineſs. His laſt great work was the portal of the Minims in the Place Royale; he died in 1666, at the age of ſixty-nine. He is known as the inventor of a particular kind of roof called the *manſarde*. He had a nephew Jules-Hardouin, who was alſo eminent in his profeſſion as an architect, and was educated by his uncle. He became a favourite of Lewis XIV. and was enabled, under his patronage, to realize a large fortune. Some of his principal works were the château de Clagny; the palace of Verſailles; the houſe of St. Cyr; the gallery of the Palais Royal; the palaces of Louis-le-Grand, and des Victoires, and the dome and finiſhing of the "Invalides." He died ſuddenly at Marly in the year 1708.

MANSBY, in *Geography*, a town of Sweden, in Weſt Bothnia, on the Calix; 25 miles W.N.W. of Tornea.

MANSCOE, a bailiwick in Georgia, S. of the Muſcle ſhoals, in the Teneſſee river, remarkable for the mammoth bones found here.

MANSDORF, a town of Pruſſia, in Pomerelia; ſeven miles N. of Marienburg.

MANSE, Mansus, *Manſa*, or *Manſum*, formed *a manendo*, *abiding*, as being the place of dwelling, or reſidence, in ancient *Law-Books*, denotes a houſe or habitation; either with or without land.

Manse, *Capital*, *manſum capitale*, denotes the manor-houſe or lord's court.

Manse, or *Manſus preſbyteri*, is a parſonage or vicarage-houſe, for the incumbent to reſide in.

This was originally, and ſtill remains, an eſſential part of the endowment of a pariſh-church, together with the glebe and tithes. It is ſometimes called *preſbyterium*.

MANSEL, in *Geography*, an iſland in the N.E. part of Hudſon's

Hudſon's bay, between Southampton iſland and the coaſt of Labrador. N. lat. 62 38′.

MANSERET, a town of Spain, in the Aſturia of Oviedo.

MANSFELD, Peter Ernest, *Count de*, in *Biography*, a German ſtateſman and commander: in 1552 he was made priſoner at Ivoy, which place he governed. He afterwards became governor of Luxemburg, where he maintained tranquillity, while the reſt of the Low Countries was in a ſtate of civil war. He had afterwards the entire command of Brabant. He died at the advanced age of 87, in the year 1604. Moreri.

Mansfeld, Ernest, *Count of*, a celebrated general, born in 1585, was the natural ſon of the foregoing Peter Erneſt, count of Mansfeld. He was brought up at the court of the archduke Erneſt, governor of the Low Countries, who ſent him at an early age into Hungary, to learn the art of war under his brother Charles. He ſerved the emperor and the king of Spain in Hungary and the Low Countries, and was legitimated by the former, on account of his bravery. He received ſome ſlights from the Spaniſh government, which cauſed him to quit its ſervice in diſguſt, and he entered into that of the duke of Savoy. He had been brought up in the Catholic religion, but did not ſcruple to enter into the league of the Proteſtant princes againſt the head of the empire, and henceforth he became one of the moſt formidable enemies of the houſe of Auſtria. He was ſent by Frederic, elector palatine, in 1618, into Bohemia, to ſupport the revolters from the authority of the emperor. The Bohemians appointed him grand-maſter of artillery and general of infantry; he took Pilſen, and gained other advantages. After Frederic, who had been elected king, had loſt the battle of Prague in 1620, Mansfeld kept on the war till he was compelled by the ſuperior forces of Tilly to retire into the palatinate. His heroiſm was now every where celebrated, and though lying under the ban of the empire, without eſtate or property of any kind, he had rendered his name ſo famous by his ſpirit of enterprize, and his ſingular faculty of recruiting after loſſes, and keeping the field though often defeated, that he found himſelf courted at the ſame time by the king of France, the French Proteſtants, the kings of Spain and England, and the republics of Holland and Venice. He determined, however, to join the duke of Bouillon, and the reformed party in France, and performed many feats of ſurpriſing valour. When he had diſbanded his troops he viſited France and England, and from the latter country he obtained troops, with which he aſſiſted the prince of Orange to raiſe the ſiege of Breda. In 1625 he returned to Germany, and after ravaging the archbiſhopric of Cologne, joined the king of Denmark in Lower Saxony; a train of ill ſucceſs now purſued him, and he was anxious to try his fortune at Venice; with this view he ſet out, accompanied by twelve officers, although at that time labouring under a ſlow fever. He, however, paſſed through Servia and Boſnia, and arrived in Dalmatia, but with ſuch an increaſe of his diſorder, that he was obliged to ſtop at a village near Zara. There, finding his end approaching, he exhorted his companions to remain true to the liberty of their country, and tranquilly expired in November 1626, at the age of forty-one. He had every quality of a great captain, and he always acted with fidelity and indefatigable zeal in the ſervice of the party whoſe cauſe he eſpouſed. The want of regular authority, and reſources, obliged him to connive at the diſorders committed by his ſoldiers; and his marches were ſometimes ſo deſtructive, that the houſe of Auſtria named him the "Attila of Chriſtendom." Moreri. Mod. Univer. Hiſt.

Mansfeld, in *Geography*, a town of Weſtphalia, in the county of Mansfeld, having a caſtle on a high rock, which was formerly a fortreſs, and the reſidence of the counts of Mansfeld, now in a conſiderably dilapidated ſtate; 36 miles N.N.E. of Erfurt. N. lat. 51 38′. E. long. 11 41′.

Mansfeld, *County of*, a principality of Weſtphalia, bounded by the electorate of Saxony and Querfurt, the dioceſe of Merſeburg and the duchy of Magdeburg, the principalities of Anholt and Halberſtadt, and the county of Stolberg. Its greateſt length is 28, and greateſt breadth 16 miles. Although it is generally mountainous, it affords good corn land and paſturage, with a conſiderable extent of woods, vineyards, chaces, and fiſheries; beſides a ſalt-work and mine, and a ſlate from which copper is extracted. This ſlate bears impreſſions of all kinds of animals, eſpecially of fiſhes. In this county are alſo two lakes, almoſt contiguous and communicating with each other; and yet the water of the one is ſalt, and that of the other freſh and ſweet. Theſe lakes abound with fiſh, which furniſh employment and ſubſiſtence for the adjoining inhabitants. They ſupply alſo a great number of wild-ducks, geeſe, ſnipes, and other water-fowl. The county contains ſeven towns. The prevalent religion is Lutheraniſm, introduced into the country by the activity and zeal of Albert VII., count of Mansfeld. This county is partly a fief of Saxony and Magdeburg. At the peace of Tilſit, the Pruſſian part of this county was annexed to Weſtphalia.

Mansfeld, a town of Pruſſia, in Natangen; 10 miles S.S.W. of Konigſberg.

MANSFIELD, Earl of, in *Biography*. See Murray.

Mansfield, in *Geography*, a market town and pariſh in the wapentake of Broxtow, Nottinghamſhire, England, is ſituated in the foreſt of Sherwood, at the diſtance of 14 miles from Nottingham, and 138 from London. It appears to have been a place of high antiquity; coins of ſeveral Roman emperors have been found in and near the town; and the recent diſcovery of ancient relics near Mansfield Woodhouſe is an indiſputable proof that the Romans had a ſtation or ſettlement in this vicinity. In the Domeſday ſurvey "Maunsfield," as it was anciently called, is mentioned as a royal manor; and ſucceſſive monarchs have granted ſeveral privileges to it. A market was eſtabliſhed by a charter of Henry III.; and a fair by a grant from Richard II. When Sherwood foreſt was a royal chace, here was a royal villa which the ſovereigns kept as a hunting ſeat; and, to uſe the words of an old inquiſition, "Henry Fauconberge held the mannor of Cuckney, in ſerjeantry by the ſervice of ſhoeing the king's palfrey when the king came to Mansfield." Leland's account of this place is not very favourable; he calls it "a little pore ſtreet, a thoroughfare at the end of the wood;" but at preſent it is a large and opulent town; the houſes, which are in general well built, were ſtated in the population return of the year 1800, to be, in number, 1245, and occupied by 5998 perſons. The market, which is held on Thurſdays, is generally well ſtocked with corn and cattle; and here are now three annual fairs, chiefly for cattle and cheeſe. Several conſiderable manufactories are eſtabliſhed here; a great trade in free-ſtone is carried on with Nottingham; and the malting buſineſs is very extenſive. The church is a commodious ſtructure; and here is a reſpectable free-ſchool, with two ſcholarſhips at Jeſus college, Cambridge, founded by queen Elizabeth in the third year of her reign.

At the diſtance of a mile and half from the town, is the townſhip and chapelry of Mansfield Woodhouſe, which contains

tains 211 houfes, and 1112 inhabitants. In the year 1786, Hayman Rooke, efq. of this place difcovered, within about a mile from the village, two Roman villæ, which he called Urbana and Ruftica; the former containing nine rooms, the latter thirteen; with hypocaufts, baths, and other appendages: the walls of moft of the rooms appeared to have been ftuccoed, and painted in ftripes of various colours; and in the centre-room of the Urbana was a teffellated pavement. Mr. Rooke alfo found the remains of two Roman fepulchres, with urns, bones, &c.: and various fragments of pateræ and pots of Roman ware, with other relics of antiquity, were difcovered in the rooms of the villæ.

Within a few miles from Mansfield are feveral magnificent manfions, *viz.* Workfop, the feat of the duke of Norfolk; Clumber, the duke of Newcaftle's; Thoresby, lord Newark's; and Welbeck, belonging to the duke of Portland. In popular language this part of the country is called the dukery, from the number of feats belonging to dukes. Hiftory of Nottinghamfhire, by Thoroton and Throfby, three vols. 4to. 1797.

MANSFIELD, a townfhip of America, in Suffex county, New Jerfey, fituated on Muffonenunk river, about feven miles S.E. of Oxford, and containing, in 1790, 1482 inhabitants.—Alfo, a townfhip in Briftol county, Maffachufetts, 29 miles foutherly of Bofton, incorporated in 1770, and containing 1016 inhabitants.—Alfo, a townfhip in Chittenden county, Vermont, between La Moille and Onion rivers, about feven miles from each, and 183 miles N. by E. from Bennington. Mansfield mountain rifes in this town. Its inhabitants are 12.—Alfo, a townfhip in Burlington county, New Jerfey, on the S. fide of Black's creek, confifting of 19,000 acres of excellent foil, noted for its fine paftures and large dairies; eight miles W. by N. from Burlington. The inhabitants are for the moft part Friends —Alfo, a townfhip in Windham county, Connecticut, about 30 miles N. of New London; containing 2560 inhabitants.

MANSIATRE, a river on the W. coaft of Madagafcar, which runs into the ftrait of Mozambique. S. lat. 19° 45′.

MANSIELLA, a town of Spain, in the province of Leon; 10 miles S.E. of Leon.

MANSION, MANSIO, *a manendo*, a dwelling-houfe, or habitation, efpecially in the country.

Among the ancient Romans, *manfio* was a place appointed for the lodging of the princes, or foldiers, in their journey; and in this fenfe we read *primam manfionem*, &c. It is with us moft commonly ufed for the lord's chief dwelling-houfe within his fee; otherwife called the capital meffuage or manor place: and manfion-houfe is taken in law for any houfe or dwelling of another; in cafe of committing burglary, &c.

MANSIO, or *Manfus*, was fometimes alfo ufed in the fame fenfe with hide: that is, for as much land as one plough could till in a year.

MANSLAUGHTER, in *Law*, is a fpecies of felonious homicide, and denotes the unlawful killing of a man, without any malice, either exprefs or implied; which may be either voluntarily, upon a fudden heat; or involuntarily, but in the commiffion of fome unlawful act. (1 Hal. P. C. 466.) As when two perfons, who before meant no harm to one another, falling out on fome fudden occafion, the one kills the other; this is voluntarily manflaughter. But in this and every other cafe of homicide upon provocation, if there be a fufficient time for paffion to fubfide, and reafon to interpofe, and the perfon provoked afterwards kills the other, this is deliberate revenge, and amounts to murder. (Foft. 296.) Thus, if a man takes another in the act of adultery with his wife, and kills him directly upon the fpot; though this was allowed by the laws of Solon, as likewife by the Roman civil law, (if the adulterer was found in the hufband's own houfe,) and alfo among the ancient Goths; yet in England it is not abfolutely ranked in the clafs of juftifiable homicide, as in the cafe of a forcible rape; but it is the loweft degree of manflaughter; and therefore in fuch a cafe the court directed the burning in the hand to be gently inflicted, becaufe there could not be a greater provocation. (1 Hal. P. C. 486. Sir T. Raym. 212.) Manflaughter, therefore, on a fudden provocation differs from excufable homicide *fe defendendo* in this; that in one cafe there is an apparent neceffity for felf-prefervation, to kill the aggreffor; in the other no neceffity at all, being only a fudden act of revenge. Farther, if two perfons play at fword and buckler, unlefs by the king's command, and one of them kills the other, this is *involuntary* manflaughter, becaufe the original act was unlawful. (3 Inft. 56.) So where a perfon does an act, lawful in itfelf, but in an unlawful manner, and without due caution and circumfpection; as when a workman flings down a ftone or piece of timber into a ftreet, and kills a man; this may be either mifadventure, manflaughter, or murder, according to the circumftances attending it: if it were in a country village, and he calls out to all people to have a care, it is mifadventure only; but if it were in London, or other populous towns, where people are continually paffing by, it is manflaughter, though he gives loud warning (Kel. 40.); and murder, if he knows of their paffing, and gives no warning at all; for then it is malice againft all mankind. (3 Inft. 57.) The crime of manflaughter amounts to felony, but within the benefit of clergy; and the offender fhall be burnt in the hand, and forfeit all his goods and chattels. By a law of king Canutus, if a man is killed openly and premeditatedly, the murderer fhall be committed to the relations of the deceafed; but if on his trial the fact be proved, and not to have been wilful, the bifhop is to judge him. There is a manflaughter punifhable as murder, by ftatute; by 1 Jac. I. cap 8. if any perfon fhall ftab another, not having then a weapon drawn, or not being ftricken firft, fo that he dies within fix months, although it were not of malice afore-thought, it is felony without benefit of clergy; but this doth not extend to perfons ftabbing others *fe defendendo*, or by misfortune, &c. with no intent to commit manflaughter; and the ftatute relates to the party only that actually gave the ftroke, or ftabbed the other, and not to thofe that were aiding or abetting. Blackft. Com.

MANSLE, in *Geography*, a town of France, in the department of the Charente, and chief place of a canton, in the diftrict of Ruffee; 12 miles N. of Angoulefme. The place contains 1230, and the canton 14,536 inhabitants, on a territory of 269½ kiliometres, in 25 communes.

MANSO GIAMBATISTA, in *Biography*, marquis of Villa, an eminent patron of polite literature, was born at Naples in 1561. He was brought up to the profeffion of arms, and, in the early part of life, ferved in the armies of the duke of Savoy, and in thofe of the king of Spain. After his return to Naples he devoted his time to literature, of which he was a cultivator and patron. He founded at Naples the academy Degli Oziofi, which held its firft affemblies in his houfe. He was the friend of Taffo, who has infcribed his dialogue on friendfhip with the name of Manfo: he patronized the poet Marino, and honoured the memories of each of them with a biographical eulogy. The great Milton was known to him, and treated by him with much kindnefs. He praifed him very highly in a Latin diftich, though at that time only a young man, and in the infancy of his fame. Milton repaid his civilities by addreffing to him a Latin eclogue entitled "Manfus," which is thought to be one of his beft performances in that language. The works of Manfo are chiefly of the light and amatory kind. He was the principal promoter of the college of Nobles in Naples, to which, at his death, he left all his property. Moreri.

MANSORA, in *Geography*, a town of Arabia, in the province of Yemen, and government of Hodsjerie; 18 miles E.S.E. of Taës.

MANSORA, or *Manfoura*, a town of Egypt, on the right bank of the eaftern branch of the Nile, built as a bulwark againft the Chriftians. The Chriftians of Syria, fettled here, are the chief traders; and the principal articles are the fine rice growing round the lake, and fal ammoniac. Here are alfo large chicken ovens. A canal is made from the Nile to the lake Manzaleh. Dr. Pocock fuppofes that Manfora was the ancient Tanis or Zoan of fcripture; 24 miles S.S.W. of Damietta. N. lat. 31°. E. long. 31° 36′.

MANSORA, a town of Africa, in the kingdom of Fez, near the fea-coaft on the river Guir; 60 miles W. of Mequinez.

MANSORAH, or MANSURAH, the fame with Bhakor or *Bekker*; which fee.

MANSORIUS MUSCULUS, in *Anatomy*, a name given by fome writers to that mufcle of the face more generally known under the name of the maffeter.

MANSOURAH, in *Geography*, a ruined town of Algiers, without walls and inhabitants; 12 miles E. of Boujeiah.—Alfo, a river called Sifaris, which runs into the fea; 18 miles E. of Boujeiah.

MAN-STEALING, in *Law*. See KIDNAPPING.

MANSTEIN, CHRISTOPHER HERMAN DE, in *Biography*, a military commander and writer of memoirs, was born at Peterfburg in 1711. He obtained the rank of captain of grenadiers in the Ruffian fervice, and, foon after the death of Anne, was commiffioned to arreft the regent Biren and his family. For this fervice he was rewarded with the rank of colonel, and with an eftate in Ingria. Of both thefe he was deprived on the acceffion of Elizabeth to the throne of Ruffia, and he then, without hefitation, entered into the Pruffian army as a volunteer, obtained confiderable promotion, and was killed by a mufket-fhot in the year 1756. He is known as a writer by "Memoirs of Ruffia, hiftorical, political, and military, from the Year 1727 to 1744," written in the French language. Thefe were fent by the earl marfhal Keith to David Hume, tranflated into Englifh, and publifhed in 1770. They were afterwards publifhed in French at Lyons in two vols. 8vo. They are reckoned valuable as a fair and authentic narrative of the important events which happened during that period, and they are efteemed as remarkably accurate in their accounts of military tranfactions.

MANSUM, in *Geography*, a river of Africa, on the Gold Coaft, which runs into the Atlantic; five miles W. of Frederickfburg.

MANSURA, a town of the Arabian Irak, feated on the Euphrates; 110 miles W.N.W. of Baffora.

MANSURCOTTA, a town of Hindooftan, in the circar of Cicacole; eight miles S.S.W. of Ganjam.

MANSURIA, an ifland in the river Nile; 25 miles N. of Syene.—Alfo, a town of Arabia, in the province of Yemen; eight miles N. of Beit el Fakih.

MANSWORTH, a town of Auftria; nine miles S.E. of Vienna.

MANTA, LA, a town of France, in the department of the Stura, fituated between the Maritime and Cottian Alps; with a caftle placed on an eminence near the town. The gardens are filled with trees of citrons, oranges, and myrtles, and tender plants not capable of enduring the other parts of Piedmont; two miles S. of Saluzzo.

MANTA *Bay*, a bay of the Pacific ocean, on the coaft of Para, about 20 miles S. of the equator, famous formerly for a pearl fifhery, which has been difcontinued, and deriving its name from a multitude of large fifhes called mantas, in the capture of which the adjacent inhabitants are employed.

MANTALINGA, a town of the ifland of Sibu, one of the Philippines, inhabited by natives, exempted from tribute, becaufe they firft acknowledged the fovereignty of the Spaniards.

MANTANNARE, a fmall ifland in the Eaft Indian fea, near the N.W. coaft of the ifland of Borneo. N. lat. 6° 38′. E. long. 116° 27′.

MANTARO, a river of Jauja, fo called from the province it pervades, joins the Maranon at 12° 6′, and ferves to propel the chief river towards the N.E.; the courfe having formerly been towards the N.W. See MARANON.

MANTECU, a fort of preparation of butter ufed by the Turks when they travel with their caravans. This is firft boiled over the fire, and then falted and kept in veffels made of tough leather, worked round a wooden frame, of the fame fhape with the veffels in which they bring their balfam from Mecca.

MANTEGAR, or MAN-TIGER, as it is fometimes written, in *Zoology*, is the tufted ape, with a nofe and head fourteen inches long; the nofe of a deep red, face blue, and both naked; black eye-brows; ears like the human; on the top of the head is a long upright tuft of hair; and on the chin another; two long tufks in the upper jaw; fore-feet like hands, and the nails on the fingers flat; the hind-feet have the thumbs lefs perfect, and the nails imbricated; the fore-part of the body and the infide of the legs and arms naked; the outfide covered with mottled brown and olive hair; that on the back dufky; the buttocks red and bare; and the length from the nofe to the rump three feet two inches. This animal is very fierce and falacious; will fit on its rump, and fupport itfelf by a ftick; and in this attitude hold a cup in its hand, and drink out of it; its food is fruit. Pennant. See SIMIA *Mormon*.

MANTEGNA, ANDREA, in *Biography*, born at Padua, or in its diftrict, of low parents, in 1431, became the pupil of Squarcione, who was fo deeply ftruck with his talents that he adopted him for his fon. He repented of it when Andrea married a daughter of Jacopo Bellini, his competitor. But the cenfure, which now took place of the praife he had before lavifhed on his pupil, only added to his improvement. Certain baffo-relievos of the ancient Greek ftyle, poffeffed by the academy in which Andrea ftudied, captivated his tafte by the correctnefs of their outline, the fimplicity of the forms, the parallelifm of the attitudes, and ftrictnefs of the drapery: the dry fervility with which he copied thefe, fuffered him not to perceive that he had loft the great prerogative of the originals, the foul that animates them. The farcafms of Squarcione on his picture of St. Jacopo, made him fenfible of the neceffity of expreffion and character: he gave more life to the figures in the ftory of St. Chriftophoro; and in the face of St. Marco, in the church of St. Giuftina, united the attention of a philofopher with the enthufiafm of a prophet.

The

The criticifms of Squarcione improved Mantegna in expreffion, the friendly advice of the Bellini directed his method and fixed his principles of colour. During his fhort ftay at Venice he made himfelf mafter of every advantage of that fchool, and in fome of his pictures there are tones and tints in flefh and landfcape of a richnefs and zeft equal to the beft Venetians of his day. Whether he taught the Bellini perfpective is uncertain: Lomazzo affirms, that "Mantegna was the firft who opened the eyes of artifts in that branch."

The chief abode and the fchool of Mantegna were at Mantua, where, under the aufpices of Marchefe Lodovico Gonzaga, he eftablifhed himfelf, with his family; but he continued to work in other places, and particularly at Rome, where the chapel which he had painted for Innocent VIII. in the Vatican exifted, though injured by age, at the acceffion of Pius VI The ftyle of thofe frefcoes proved that he continued fteady in his attachment to the antique; but that from a copyift he was become an imitator.

Of his works in oil, Mantua poffeffes feveral; but the principal one, the mafterpiece of the artift, and the affemblage of his powers, the picture called La Virgine della Vittoria, painted for J. F. de Gonzaga, Marchefe di Mantua, in honour of a victory he gained over the French upon the banks of the Taro, and afterwards placed in the Oratorio de Padri di S. Felippo, is now among the fpoils of the Louvre. The Madonna is feated on her throne with the infant ftanding on her lap, and giving benediction to the kneeling marquis in arms before her. At one fide of the throne ftands the archangel Michael, holding the mantle of the Madonna; at the other St. George, St. Maurice, John the Baptift, and St. Elizabeth on her knees. The fide of the throne is ornamented with figures relative to the fall of Adam: the fcene is a leafy bower peopled by birds, and here and there open to a lucid fky.

No known work of Mantegna equals, in defign, the ftyle of this picture: they generally fhew him dry and emaciated: here he appears in all the beauty of felect forms: the two infants and St. Elizabeth are figures of dignity, fo is the archangel, who feems to have been, by the conceit of his attitude, and the care beftowed upon him, the painter's favourite object. The head has the beauty and the bloom of youth; the round flefhy neck and the breaft, to where it confines with the armour, are treated with great art; the expreffion is, to a high degree, fpirited and characteriftic. The countenance of the Madonna is mild and benign; that of Chrift, humane. The future prophet is announced in the uplifted arm of John. The guardian angel kindly contemplates the fuppliant, who prays with devout fimplicity. The whole has an air of life. All the draperies, efpecially that of St Elizabeth, are elegantly and correctly folded: with more mafs and lefs interfection of furfaces they would be perfect.

The extreme finifh of execution, as it has not here that drynefs which disfigures moft other works of this mafter, does not impair the brilliancy of colour. The heads of the Madonna, of the infant, of St. Michael, have a genial bloom of teints. The lights are every where true, the fhades alone are fometimes too grey, or too impure. The general fcale of the light has more ferenity than fplendour, more the air of nature than of art, but the reflexes are too often cut off too glaringly from the opaque parts. The whole of the picture has preferved its tone to this day, is little damaged, and in no place retouched.

Of the remainder of Mantegna's works, befides fome frefcoes of confiderable merit, but much injured, in a faloon of the caftle of Mantua, and the well known Triumph of Cæfar, in various compartments at Hampton Court, little now remains. His name is more frequent in galleries and collections than his hand: lanknefs of form, rectilinear folds, yellow landfcape, and minute polifhed pebbles, are lefs genuine figns of originals, than correctnefs of defign and delicacy of pencil. It is not probable that a man fo occupied by large works, and fo much engraving, fhould have had time to finifh many cabinet pictures: the feries of his plates confifts of upwards of fifty pieces, executed by his own hand, and though he was not the inventor of the art, he was certainly the firft engraver of his time.

Andrea had great influence in the ftyle of his age, nor was the imitation of his ftyle confined to his own fchool: Francefco, and another of his fons, finifhed fome of the frefcoes which he had begun in the caftle, and added the beautiful ceiling, which fhews that the fcience of forefhortening what the Italians call "del fotto in fu," though Melozio be its reputed author, was carried much farther by Mantegna and his followers. He died in 1505, aged 74. Fufeli's Pilkington.

MANTEIGAS, in *Geography*, a town of Portugal, in the province of Beira; 27 miles S.E. of Vifeu.

MANTELETS, in *Military Language*, a kind of moveable parapets, made of planks about three inches thick, nailed one over another to the height of almoft fix feet, generally cafed with tin, fet upon little wheels, and guided by a long pole; fo that in a fiege they may be driven before the pioneers, and ferve as blinds, to fhelter them from the enemy's fmall fhot.

There are alfo other forts of mantelets, covered on the top, of which the miners make ufe to approach the walls of a town or caftle. See *Plate* VI. *Fortification*, *fig.* 9.

The double mantelets form an angle, and ftand fquare, making two fronts, which cover both the front and flank of the fappers, &c. when at work: thefe have double planks, with earth rammed in between them; they are five feet high, and three in breadth, fometimes covered with plates of iron.

It appears from Vegetius, that mantelets were in ufe among the ancients under the name of vineæ; but they were built flighter and much larger than our's, being eight or nine feet high, as many broad, and fixteen long; they were defended by a double covering, the one of boards, the other of faggots, with the ribs of ofiers; and were cafed without with fkins, fteeped in water, to prevent fire.

MANTERA, in *Geography*, a fmall ifland in the Atlantic, near the coaft of Africa. N. lat. 10 45'.

MANTES, a town of France, and principal place of a diftrict, in the department of the Siene and Oife, feated on the Seine, over which is a bridge of thirty-fix arches. The place contains 4300, and the canton 13,803 inhabitants, on a territory of $132\frac{1}{2}$ kilometres, in 23 communes. N. lat. 48° 59'. E. long. 1° 48'.

MANTICA, in *Zoology*, the name by which Pifo and fome other writers have expreffed the pouch or bag of fkin under the belly of the opoffum, into which the young are received in time of danger.

MANTICLUS, in *Mythology*, a name given to Hercules under which title he had a temple without the walls o Meffina, in Sicily. This temple was built by Manticlus the chief of a colony of Meffenians, about 664 years before Chrift: or, as others fay, the leader of a colony which fettled in the ifle of Zacinthus, now Zante. Pautan. in Meffen.

MANTICORA, in *Natural Hiftory*, a genus of infects of the order Coleoptera, of which there is but a fingle fpecies. The generic character is, Antennæ filiform, the

joints

joints cylindrical; four feelers which are filiform, the thorax is rounded before, and emarginate behind; the head is projecting, and the mandibles are exserted; the shells are united; it has no wings.

Species.

Maxillosa. Body large and black; head subglobular, impressed on each side; mandible toothed at the inner base; thorax impressed in the middle, and elevated behind; the margin rounded and notched at the tip; shells above, flat, rough, deflected at the edge, with a very sharp lateral serrate line; legs simple and black. It is described by M. Olivier, in his "Histoire Naturelle des Insectes," as inhabiting the Cape of Good Hope.

MANTINEA, in *Ancient Geography*, a town of Arcadia, E. of the river Ophis, and N. of Pallantium. This town, in the time of Homer, appears to have been considerable. Antinoe, the daughter of Cepheus, is said to have transported the inhabitants of the old city to a more convenient situation than that which it originally occupied to the banks of the river Ophis; and it is fabulously reported that Antinoe was led to the selection of the spot on which the New Mantinea was erected under the guidance of a serpent, whilst others say that the river derived its name from its winding or serpentine course. After the peace of Antalcidas, so called because he was the ambassador employed by the Greeks in negociating it with the king of Persia, in the year 387 B.C., the Lacedæmonians, under the conduct of their king Agesipolis I., laid siege to Mantinea, as a punishment of its inhabitants for having taken part with the Athenians in the preceding war. Having defended themselves with invincible courage during the summer, the Lacedæmonians availed themselves of the approach of winter by damming up the current of the river, which was thus made to overflow its banks and overwhelm the houses of Mantinea, upon which the inhabitants were constrained to abandon the noble city which they had long occupied, and to retire to their old villages. After the battle of Leuctra, in the year 370 B.C. the Mantineans returned to their city and rebuilt it, deriving assistance in the undertaking from the Thebans: but they afterwards took part with the Lacedæmonians against their coadjutors. A battle was fought near Mantinea by the combining powers, in which, though the Thebans were victorious, they lost their famous general, Epaminondas. Some time after the formation of the Achæan league, Aretas made himself master of Mantinea: but the Achæans were defeated in a subsequent battle by the Lacedæmonians, under the command of Cleomenes, who took several of their cities, and they were reduced to the necessity of seeking the succour of Antigonus, king of Macedon. Thus aided and encouraged, the Achæans obliged Cleomenes to retire with great precipitation to Mantinea. But he was soon constrained to abandon it to the force brought against him by Antigonus, who took possession of it without any great resistance. The Mantineans, in compliment to Antigonus, suppressed the original name of their city, and called it "Antigonia," by which appellation it was distinguished till the time of Adrian, who caused it to resume its ancient name of Mantinea. Pausanias has particularly described this famous city and its magnificent temples. The first was a large edifice, separated into two parts by a high wall; on one side of which was the statue of Æsculapius by Alcamenes, and on the other that of Latona with her children, by the celebrated Praxiteles. Elevated upon a column was a statue of the historian Polybius, who rendered signal service to the Achæans in their wars with the Roman republic. Another temple was that of Ceres and Proserpine, in which was a sacred fire which was kept continually burning. The temple of Juno was situated near the theatre, and the goddess was seated on a throne of ivory, having on both sides of her Minerva and Hebe, all which were the works of Praxiteles. Near the altar was the tomb of Arcas, son of Calisto and grandson of Lycaon. Another temple which disgraced the city was dedicated to the infamous Antinous, who contributed to the licentious debauchery of Adrian. From the centre of the town five roads passed in different directions to the principal places of Arcadia.

MANTINERA, in *Geography*, a small island in the Mediterranean, near the coast of Naples. N. lat. 39° 55'. E. long. 13° 52'.

MANTIS, in *Natural History*, a genus of insects of the order Hemiptera, of which there are sixty-four species scattered over the globe, but none of them are found in this country: two or three of them are worshipped by the Hottentots, as the ibis and ichneumon were of old by the Egyptians.

The generic character is, Head unsteady; mouth armed with jaws; feelers filiform; antennæ setaceous; thorax linear; wings four, which are membranaceous and convolute, the under ones plaited. The fore-legs are compressed, serrated beneath, and armed with a single claw, and lateral jointed process; the hind-legs are smooth, and formed for walking. This is thought to be one of the most singular genera in the whole class of insects, and the imagination can hardly conceive shapes more strange than those exhibited by some particular species.

Species.

Filiformis. Body, as its name imports, is filiform, apterous, and brown; the legs are longer than the body, unarmed. The antennæ are black, and it inhabits South America.

Ferula. Body is filiform, apterous, and green; the legs are longer than the body; the hind thighs are spinous at the tip. It inhabits Guadaloupe: it is large, long, and filiform. The antennæ are of a moderate size, green tipt with brown; body smooth glabrous, without wing-cases; thighs angular; the four hind ones spinous.

Calamus. Body filiform, apterous, greenish; thighs striate. Antennæ yellowish; head smooth yellowish; body cylindrical; legs yellowish; the thighs are striate, with raised lines. It inhabits Santa Cruz in America.

Rossia. Body filiform, apterous, green; thighs toothed; the legs are short and brown, the thighs are toothed beneath. It is found in many parts of Italy.

Angulata. This species is apterous: the head and thorax spinous; wing-cases rounded, very short; thighs angular beneath. This is sometimes denominated the "Mantis gigas," and is an inhabitant of Guadaloupe. The body is of a chesnut brown; the head has two spines and numerous raised dots; thorax with two sharp spines on the anterior lobe, and numerous raised dots, the sides serrate; wing-cases short, rounded, reticulate; thighs very angular, the four hind ones spinous beneath.

Gigas. Thorax rough and roundish; wing-cases very short; legs spinous: with respect to colour, the thorax is speckled with green; the wing-cases are reticulate, the base and tip green, pale in the middle; wings pale with transverse brown bars. It inhabits Amboina.

Cylindrica. Thorax cylindrical; fore-legs united to the fore-part of the thorax; wing-cases grey, the base and beneath rufous; the wings are brown dotted with white.

Its

Its habitation is not clearly afcertained, but it is not found in Europe.

Phthisica. Thorax roundifh, muricate; the wing-cafes are very fhort; the legs are unarmed. It inhabits South America and India.

Necydaloides. In this fpecies the thorax is rough; wing-cafes ovate, angular, very fhort: the wings are oblong. It is found in many parts of Afia The wing-cafes have a raifed flexuous line down the middle; the wings are brown, and as long as the abdomen.

Atrophica. Thorax four-fpined; wing-cafes very fhort, mucronate at the bafe. It inhabits Java. The head is unarmed; the wing-cafes are ovate, truncate at the tip.

Spinosa. Head and thorax fpinous; wing-cafes very fhort and acute. It is found in India. The antennæ are as long as the body; the thorax is brown, rough, with a double fpine each fide on the fore-part; wing-cafes brown; wings brown, convolute, as long as the abdomen; fore-thighs unarmed, the reft fpinous.

Bispinosa. Thorax is rather round, with two fpines on the fore-part; wing-cafes very fhort; wings rofe colour. It inhabits America. The colours of this fpecies are very fine; the antennæ are yellowifh: the head is green, with a fhort fpine each fide on the crown; thorax green, yellowifh on the back; wing-cafes green, ftriate with black; wings large, rofy, the outer margin green; abdomen linear, yellowifh, green at the tip; the legs are fpinous.

Jamaicensis. This, agreeably to its fpecific name, is found in the ifland of Jamaica; and it differs from the laft only in having no fpines on the thorax.

Lateralis. Linear and black; the wing-cafes are very fhort, gibbous, and yellowifh at the fides; the antennæ longer than the body, black; thorax yellowifh at the fides; wing-cafes with a raifed tooth in the middle; wings large, black, edged with yellow; the legs are black. It inhabits Brafil.

Aurita. The head and thorax are fpinous; and the wing-cafes have a fub-compreffed tubercle in the middle. It is found in the Eaft Indies. The antennæ are as long as the body, varied with black and white; head brown, with numerous fharp fpines; thorax brown and fpinous; wing-cafes concave and very fhort; the wings are large and dufky, with a broad pale rufous border on the outer edge, fpotted with black, and marked with a broad white band.

Linearis. Linear, brown; wing-cafes very fhort, fubfpinous at the bafe; antennæ as long as the body; wings long and brown; fore-thighs membranaceous. It inhabits the Eaft Indies.

Rosea. This fpecies is linear and green; front fulvous; wing-cafes very fhort; and the wings are rofy, with a green rib; antennæ longer than the body, brown, with three or four white rings; thorax fmooth, linear, greenifh; wing-cafes vaulted with a black thick fpine in the middle; the wings are ftriate, and the legs yellow.

Flabellicornis. Thorax dilated and membranaceous at the tip; fore-thighs terminating in a fpine, the reft in a lobe; antennæ pectinate: thefe are large, very much feathered and fetaceous at the tip; the front is projecting, narrower in the middle, notched at the tip; wing-cafes and wings longer than the body, dufky, fub-pellucid and dilated at the anterior margin. It inhabits Tranquebar.

Gongylodes. This is one of the moft remarkable of the Mantis genus: from the thinnefs of its limbs, and the grotefque form of its body, efpecially in its dried ftate, it feems to refemble the conjunction of feveral fragments of withered ftalks; which is the cafe alfo of the larvæ of many of the genera, before the wings are formed. The thorax is uncommonly long and narrow; the head is fmall and flat, with two filiform antennæ; behind thefe, two large polifhed eyes are placed; the roftrum has the fhape of an awl, but it is often fplit towards the extremity into two points; the elytra, which cover two-thirds of the body of the infect, are reticulated, and croffed over one another; the wings which they cover are veined and diaphanous; the four hind-legs have the appearance of being winged, on account of thofe large membranous lobes which emerge from their joints; the anterior pair are armed with fpines at their firft articulation, and towards their extremities they are ferrated on one fide. It inhabits various parts of Africa and Afia.

Pauperta. Thorax is linear and fpinulous; fore-thigh terminating in a fpine, the others are lobate. It is found in Coromandel, and alfo in fome parts of Portugal.

Mendica. Thorax margined, toothed; wing-cafes varied with white and green; the margin is dotted with white. It inhabits Alexandria. The head is yellowifh; front horned; legs yellowifh.

Truncata. Thorax dilated each fide at the tip, yellowifh; the wings are black at the bafe, and tipt with white. This is a fmall infect, and inhabits Cayenne. The thorax is linear, rough, membranaceous, and flightly crenate at the tip; abdomen fhort, flat, dilated; wing-cafes as long as the abdomen, and yellowifh, with a brown callous dot in the middle.

Strumaria. This is a green infect. The thorax is much dilated in its whole length; wing-cafes and wings are longer than the abdomen; the body is fhort; and the abdomen yellowifh. It is found in South America.

Tricolor. The fides of the thorax are expanded, lobate; head horned; fore-legs very broad. It inhabits India. The eyes of this fpecies are very remarkable, terminating in fharp ear-like horns; wing-cafes pale, fpotted with white; wings red at the bafe, brown in the middle, and tipt with white.

Cancellata. Thorax dilated at the fides, membranaceous, and flat; the body is of a dull brown colour; the thorax is flat.

Siccifolia. The thorax is denticulate; the thighs are oval and membranaceous. It inhabits India. The infects of this fpecies are ufually denominated walking leaves, from their exact refemblance in colour and fhape to a dried leaf. They have no wings, or, at moft, mere rudiments; the firft two pair of thighs are ferrate, the others fimple; the body is very much dilated and rounded.

Pecticornis. Thorax fmooth; crown fubulate; antennæ pectinate. It inhabits Jamaica.

Oculata. Thorax triangular, filiform; eyes oblong, projecting, fpinous; the head is of a pale colour; the eyes are large, pointed, and conic; the thorax fmooth teftaceous, the angles more dufky; wing-cafes fhorter than the wings, white diaphanous, ftriate, and obtufe; legs long, dufky, and unarmed.

Superstitiosa. Thorax linear, triangular, flightly ferrate on the fore-part; wing-cafes greenifh; the rib of the wings is tranfverfely ftriate. It is a large infect, and is found in Africa. The thorax is rough on the fore-part, fmooth behind; the wings are whitifh, having a rib with tranfverfe raifed brown lines.

Undata. Thorax carinate, grey; wings white, with black waves. It inhabits Tranquebar. The antennæ are filiform and pale; the thorax is filiform, triangular, and rough; wings fhorter than the abdomen; thighs lobate at the tip, fhanks at the bafe; the abdomen is long and filiform.

Irrorata Thorax is fmooth fubcarinate; wing-cafes green,

green, with fcattered ferruginous dots; the wing-cafes are fhorter than the wings. It is found in America.

Striata. Thorax carinate, and flightly ferrate at the fides; wing-cafes obfcure, hyaline, ftriate with brown, and fhorter than the wings; the head is grey; the antennæ are fimple; and the body is brown.

Oratoria, or Camel-cricket, is the chief of the European Mantis genus. It is found in moft of the warmer parts of Europe, and is entirely of a beautiful green colour. It is nearly three inches in length, and in its fitting pofture is obferved to hold up the two fore-legs, flightly bent, as if in the attitude of prayer: hence the common people have conferred upon it the reputation of a facred animal; and a popular notion has often prevailed, that a child or traveller, having loft his way, would be fafely directed by obferving the quarter to which the animal pointed, when taken into the hand. It is, however, in its real nature, a very rapacious animal, devouring all fmaller infects that fall in its way, for which it lies in wait with anxious affiduity. It is alfo of a very quarrelfome nature; and when kept with others of its own fpecies, in a ftate of captivity, will attack its neighbour with the utmoft violence, till one or the other is deftroyed in the conteft. Among the Chinefe, this quarrelfome property in the genus Mantis is turned into a fimilar entertainment with that afforded by fighting cocks and quails to Europeans. To infects of this kind Mr. Barrow is fuppofed to allude in his "Travels in China." He fays, "They (the Chinefe) have even extended their inquiries, after fighting animals, into the infect tribe, and have difcovered a fpecies of gryllus that will attack each other with fuch ferocity, as feldom to quit their hold without bringing away, at the fame time, a limb of their antagonift. Thefe little creatures are fed and kept apart in bamboo cages; and the cuftom of making them devour each other is fo common, that, during the fummer months, fcarcely a boy is to be feen without his cage of grafshoppers." The M. *religiofa*, with the thorax fubcarinate, is a mere variety of this fpecies.

Precaria. Thorax ciliate with fmall fpines; wing-cafes green, with a divided white and brown fpot. An inhabitant of Africa. The head and thorax are of a yellowifh-green; eyes ferruginous; fore-legs with a ferruginous fpot; wing-cafes longer than the body; wings hyaline, fpotted with green. This is the fuppofed idol of the Hottentots, which thofe fuperftitious people are reported to hold in the higheft veneration; the perfon on whom the adored infect happens to light, being confidered as favoured by the diftinction of a celeftial vifitant, and regarded ever after in the light of a faint.

Sancta. Thorax flightly ferrate, yellowifh-green; wing-cafes green, immaculate; wings hyaline. It is found chiefly in the fouth of France. The wings are greenifh at the tip; fore-fhanks with two black fpots beneath.

Simulacrum. Thorax ciliate; wing-cafes green, with a white fpot in the middle. It very much refembles the M. precaria, but the thorax is fhorter, thicker, and more ciliate. It inhabits America.

Monacha. Thorax fmooth teftaceous; wing-cafes and wings green hyaline; the fore-fhanks have two teftaceous dots on the fore-fide. It is found at the Cape of Good Hope.

Obscura. Thorax flightly ferrate, dull grey; wing-cafes with a black fpot at the bafe; the wings alfo have one at the tip. It inhabits Africa. The head is grey, with a black frontal fpot; thorax dufky, with a black dorfal line; fore-legs flightly ferrate; the other parts fimple.

Hyaliana. Thorax ciliate; wing-cafes hyaline, edged with green; front is two-toothed. It is found in America. With refpect to colour, the head is brown; antennæ ferrate; wings hyaline, ftriate with brown at the tip.

Fenestrata. Thorax fmooth; wings hyaline; exterior margin of the wing-cafes brown. It inhabits Africa. The thorax is linear; exterior margin of the wings is brown at the tip; legs pale; fore-fhanks with a few black fpots within.

Bidens. Thorax is rough; wing-cafes green, with black bars; wings brown-black on the difk. It inhabits America. The head is brown; front with two fharp approximate teeth; thorax linear, grey, with a few black raifed dots; wing-cafes with two oblique brown bands; legs brown; thighs pale at the bafe, and tipt with black; fhanks of the fecond pair lobate.

Grisea. Thorax fmooth; wing-cafes and wings grey, hyaline, fpotted with brown. A fpecimen in the Britifh Mufæum is middle-fized. Thighs of the fore-legs a little dilated at the upper margin; fpinous on the lower; the other legs varied with grey and brown.

Ministralis. Thorax rough, crenate, as long as the head, ferruginous on the fore-part; wing-cafes green; the head is yellowifh; antennæ brown; thorax carinate; outer margin of the wing-cafes fubferruginous; fore-thighs fulvous; abdomen brown, pale at the tip. Found in New Holland.

Urbana. Thorax entire; wing-cafes green, with a ferruginous dot and band. It inhabits India.

Rustica. Thorax fmooth, brown; wing-cafes fhorter than the wings, brown hyaline; antennæ hairy. It inhabits the fhores of Patagonia; the head is grey-brown, with globular raifed ftemmata; the legs are yellowifh.

Nasuta. Thorax fpinous and ciliate; front projecting, fpinous, emarginate. It inhabits the Cape of Good Hope. Head flat; front two toothed on each fide, and widely emarginate at the tip; thorax black with a raifed tubercle before and behind; wings and wing-cafes grey hyaline, with numerous brown dots at the nerves; the legs are black and annulate.

Lobata. Thorax three-lobed; front with a bifid horn; eyes conic, pointed. This alfo is found at the Cape, and is particularly defcribed by Thunberg; the mouth is varied with green and brown; the front is greenifh, with a projecting bifid horn between the antennæ; wing-cafes green, with a white bafe and fpot in the middle; wings black, tipt with white; body varied with green and white; margin of the abdomen elevated and lobate.

Pulchra. Thorax green throughout; the wings are brown hyaline, ferruginous at the bafe. It inhabits Tranquebar. The antennæ are brown; head and thorax green, a little yellowifh at the edge; wing-cafes green, the margin yellow at the bafe; abdomen above brown, beneath green; legs yellow.

Fausta. Linear, afh-coloured, fpotted with black. This is an inhabitant of the Cape, and has been defcribed by Thunberg: it is the tutelar deity of the Hottentots.

Perspicua. Dufky; wings and wing-cafes hyaline; but the wings have a brown marginal fpot and tip. It is a fmall infect, and is found at Cayenne; the wing-cafes have a fmall black dot towards the bafe.

Pagana. Wings reticulate, white with a lateral ferruginous fpot; ends of the legs chelate. It inhabits France and Germany. The thorax is cylindrical, and entirely brown.

Minuta. In this the thorax is cylindrical and yellowifh; wing-cafes hyaline, with a greenifh rib. It inhabits South America. The wing-cafes have a fmall white dot in the middle;

middle; the abdomen is greeniſh, and yellowiſh on the back; the legs of a greeniſh colour.

Pusilla. Thorax cylindrical, yellowiſh; wing-caſes and wings hyaline, immaculate. It inhabits Africa.

Carolina. Thorax ſubciliate, carinate; wing-caſes whitiſh, waved with brown. It inhabits Carolina; wings and their caſes ſhorter than the body.

Labiata. This is an inhabitant of India: it is linear, greeniſh, unarmed; ſides of the head green.

Maculata. Cinereous; thorax winged, ſubſpinous; legs ſpotted within with black. This is found in the iſlands of Japan.

Capensis. This alſo is cinereous; the thorax is unarmed; the head is conic entirely. It inhabits Africa and India.

Parva. Livid and ſmooth; wing-caſes and wings hyaline; ſegments of the abdomen edged with black. It inhabits America.

Cingulata. Thorax browniſh; wing-caſes green, reticulate with black, and marked with four blackiſh ſpots; wings blackiſh, with black lines, the edge yellowiſh-brown. It inhabits Jamaica. Abdomen annulate with black; it is two-ſpined at the tip.

Gigantea. Browniſh; neck, thorax, and thighs ſerrate. It inhabits Italy.

Angusta. This is of a greeniſh colour; the tail is forked; the antennæ are filiform, and as long as the body. It inhabits Antigua.

Sibirica. This is ſuppoſed to be a variety of the M. puſilla, and is an inhabitant of Siberia: the body is varied with yellow and brown; wings hyaline with reddiſh nerves.

Brachyptera. Cinereous; thorax toothed; wings half as long as the body. Is found alſo in the deſerts of Siberia.

Pennicornis. The crown of this inſect has a conic ſpine; the antennæ are feathered and linear; the hind thighs terminate in a lobe. It is found in the deſerts bordering on the Caſpian ſea, and very much reſembles in ſhape and colour the M. gongylodes.

MANTLE, or Mantle-*tree*, in *Architecture*, is the lower part of the breaſt or front of a chimney. It was formerly a piece of timber that lay acroſs the jambs, and ſupported the breaſt-work; but by a late act of parliament, chimney-breaſts are not to be ſupported by a wooden mantle-tree, or turning-piece, but by an iron bar, or by a brick or ſtone arch. See Chimney.

Mantle, *Mantling*, or *Lambrequin*, in *Heraldry*, that appearance of folding of cloth, flouriſhing, or drapery, that is in any achievement drawn about the coat of arms. This, properly ſpeaking, is an ornament that was anciently fixed to the helmet, like that now worn round the caps of our light dragoons.

It is ſuppoſed originally to have been the repreſentation of a mantle, or military habit, worn by ancient cavaliers over their armour, to preſerve it from ruſt; or, as others hold, a ſhort covering only worn over the helmet to defend the head from the weather, which, in after-times, was lengthened, and made to hang from the helmet below the whole ſhield. Sometimes it hung in a looſe, flowing, ragged manner; ſometimes it is repreſented as cut or entire, and hanging back over the neck of a warrior, in which caſe it is called a "Cappeline." The forms of theſe ancient mantlings, and the manner in which they uſually waved from the helmet of a warrior, are beſt repreſented on ancient ſeals. In length of time, the uſe and locality of theſe mantlings ſeem to have been forgotten; for we find the heralds, through an unaccountable inadvertency, forming them like cloaks to receive or cover the whole achievement, inſtead of purſuing their ancient mode of repreſenting them, as being coverings for the head, or ornaments flowing from the helmet of the warrior, and of the colour of his arms. According to ſuch modernized manner of bearing mantlings, thoſe of the ſovereigns are ſuppoſed to be of gold doubled with ermine; thoſe of the peers, crimſon velvet, folded, and ermine inſide; and thoſe for knights and gentlemen, crimſon velvet doubled with white ſatin. The prevalency of this mode becoming ſo general, that all ſorts of perſons painted mantles of crimſon and ermine on their carriages, Mr. Edmondſon, in the year 1760, propoſed to ſeveral of the peers to paint (on their carriages) their arms, placed in mantles of crimſon, with their edges thrown back ſo as to ſhew their doublings, or linings, which ſhould be of ermine, and containing a number of rows of ermine ſpots, equal to thoſe of the guards on their coronation robes, expreſſing their reſpective degrees, *viz.* a baron two rows, a viſcount two and a half, an earl three, a marquis three and a half, a duke four, &c. This propoſal having met with general approbation, was carried into execution, and had the deſired effect of ſhewing the diſtinction between the ſeveral ranks and degrees of our nobility. After which Edmondſon formed mantles for the knights companions of the ſeveral orders, taken from the mantle and robes which they wear at their inſtallation.

The mantle is always ſaid in blazon to be doubled, that is, lined throughout with one of the furs, as ermine, pean, vairy, &c. See Coat.

Mantle *of the Knights of the Garter*. See Garter.

Mantle is likewiſe a term uſed in *Falconry*. They ſay the hawk mantles, that is, ſpreads her wings after her legs.

Mantle, *Lady's*, in *Botany*. See Alchemilla.

MANTO, or Olancho el Viejo, a town of Mexico, in the province of Honduras. N. lat. 14° 4'. W. long. 86°.

MANTON, Thomas, in *Biography*, a learned Engliſh divine, was born in the year 1620. He was educated in grammar-learning at Tiverton-ſchool, and when he was about fifteen years of age was entered at Wadham-college, Oxford. Here he took his degrees, and was ordained deacon by the biſhop of Exeter at the age of twenty. He was firſt ſettled at Columpton in Devonſhire, and afterwards at Stoke Newington, in the vicinity of London, where he was highly eſteemed as a preacher and expoſitor of the holy ſcriptures. From Newington he went to St. Paul's Covent Garden, having been preſented to that living by his grace the duke of Bedford. In 1653, he was appointed one of the chaplains of the protector Oliver Cromwell: but in 1660 he took an active part with the Preſbyterian miniſters in general, in bringing about the reſtoration of king Charles II., for which ſervice he was nominated one of the chaplains to his majeſty, and, in conſequence of the king's mandamus, created doctor of divinity. He refuſed to ſubmit to the act of Uniformity, and under the operation of that act he was, in 1662, ejected from his living, after which he held a private meeting in his own houſe, but was perſecuted and impriſoned for exerciſing the miniſterial functions. He was highly eſteemed by perſons of great conſequence in the ſtate, and was conſulted by them with reſpect to all the treaties for the comprehenſion with the eſtabliſhed church. He had great weight among his own brethren, on account of his zeal and activity in their affairs. He died in the year 1677. He was eſteemed a man of great learning as a theologian, and was deeply read in ancient and modern hiſtory. He is characterized by doctor Bates as a divine of rich fancy, a ſtrong memory, and happy elocution, improved by diligent ſtudy.

ftudy. His fermons make five large folio volumes, one of which contains 190 on the 119th Pfalm. The talk of reading thefe fermons to his aunt, when he was but a child, produced a very unhappy effect on the mind of lord Bolingbroke. In a letter to Swift, he writes, "my next fhall be as long as one of doctor Manton's fermons, who taught my youth to yawn, and prepared me to be a high churchman, that I might never hear him read, nor read him more."

MANTRA, in *Hindoo Mythology*. The Afiatics, generally fpeaking, have great faith in charms, talifmans, and fimilar items impofed by craft on ignorance and fuperftition. Among the Hindoos this feeling is very prevalent. They have mantras, and tantras, and yantras; and as many books in the Sanfkrit language are extant on thefe fubjects, their differences and diftinctions are doubtlefs well known to the Brahmans; although, hitherto, thofe books do not appear to have been fufficiently examined (and it may be well queftioned, if they are worth the labour), to be underftood by any of our oriental fcholars. As far as hath been made known, a mantra generally means a curfe, a fort of imprecatory incantation, either ejaculated or written, and compofed of a paffage from one of the Vedas, containing the name of fome tremendous deity. Sometimes it appears rather to affume the form of what we underftand of the word talifman; affecting fupernatural purpofes, fuch as rendering a perfon invifible, &c. Both Hindoos and Mahommedans have great faith in the efficacy of propitiatory incantations, more efpecially the former, and a correfponding dread of thofe of a malevolent tendency. It is, of courfe, the triumph of priefteraft to keep alive thefe impreffions, and the facred and other books of the Hindoos are well calculated for that effect. The malediction of a prieft would ferioufly affect the comfort and quiet of a pious Hindoo. The following paffage from the *Ramayana*, a much efteemed epic poem, as is noticed under that article, will ferve to exemplify this, as well as the accredited femi-omnipotency of the Brahmans: and, with thofe who have faith in thefe doctrines, affords a fufficient reafon to fear the effects of fuch curfes. "Even he who cannot be flain by the ponderous arms of Indra, nor by thofe of Kali, nor by the terrible chakra of Vifhnu, fhall be deftroyed if a Brahman curfe him, as if he were confumed by fire." If the reader be defirous of farther information on the above paffage, he will find, under the article Indra, mention of his "ponderous arms," the vajra; and of the "terrible chakra" under Vishnu. See alfo Kali. A tantra is a fort of hieroglyphic myfterioufly facred to a particular deity. Of thefe tantras there are a great many, as we are informed by Mr. Paterfon, in his "Effay on the Origin of the Hindoo Religion," in the eighth volume of the Afiatic Refearches. (See alfo the Hindoo Pantheon, under Tantra in the Index.) The term, as well as Yantra, is applied to invocations of a fupplicatory tendency, or to defenfive incantations; likewife to a philtre, or charm; and to other fooleries fimilar to our abracadabra and magic fquares. Thefe things are, however, not found in the Vedas, nor even in the Puranas, of the Hindoos, but are taught in great detail by the Agama Saftra, a compilation of much later date; fabricated, as hath been reafonably fuppofed, by perfons, who in thefe, as in other matters, eftablifhed many unjuftifiable practices on the foundations of emblems and allegories, which they mifunderftood.

MANTSALA, in *Geography*, a town of Sweden, in the province of Tavaftland; 37 miles S.E. of Tavafthus.

MANTUA, in *Ancient Geography*, a town of Italy, S.E. of Brixia, and S. of the lake Benacus on the Mincius. Although this town is celebrated for its antiquity, its origin being traced to the Tufci, 600 years B. C., it is ftill more diftinguifhed as the place near which Virgil was born. The town was encompaffed by a lake, which was formed by the waters of the river.

Mantua, in *Geography*, was, previoufly to the arrangements fubfequent to the French revolution, a duchy of Italy, bounded on the N. by the Breffan and Veronefe, on the E. by the Ferrarefe, on the S. by the duchy of Modena, and on the W. by the Cremonefe. In length it is about 50 miles, and in breadth 35. It is watered by the Po, which runs through the middle of it, and alfo by the Oglio, Mincio, Secchia, &c. which difcharge themfelves into the Po. This territory abounds with corn, fruits, and legumes, and it affords fome wine, great quantities of flax, and many good horfes. The fmall duchy of Mantua was taken poffeffion of by Lewis of Gonzaga in the year 1328, and was held by the houfe of Gonzaga from this period; till at length the laft of the family was put under the ban of the empire. In 1703, the emperor transferred to the duke of Savoy that part of the duchy of Montferrat, which had been poffeffed by the dukes of Mantua as a fief. In 1707, the Imperialifts over-run the whole duchy, and duke Charles IV. died in the following year under the ban of the empire. From this time the houfe of Auftria continued in poffeffion of the duchy, annexed to the government of the Milanefe, till by the peace of Luneville it was ceded to the Cifalpine republic, now the kingdom of Italy; and it forms the department of the *Mincio*; which fee.

Mantua, the capital of the late duchy and of the prefent department of the Mincio, fituated on a lake formed by the inundations of the river Mincio; about 20 miles in circumference, and two broad. The two chief bridges leading to this city over the lake are Ponte di Molini, defended by two citadels, and Ponte di St. Giorgio, with fortifications at both ends. The water divides the city into two parts nearly equal, which communicate with each other by fix bridges. In fummer, when the water ftagnates, the infalubrity of the air conftrains the higher clafs of inhabitants to leave the city. The ftreets are, in general, long, broad, and ftraight, with handfome ftone houfes, fine fquares, and ftately churches. On the other fide of the lake are three fuburbs. Mantua comprehends four collegiate churches, 21 parochial, 14 other churches and alms-houfes, 11 oratories, 40 convents; and without the city are three parifh-churches, two other churches, and feven convents. The Jews, of whom there are about 4 or 5000, live in a diftinct quarter. The population, exclufive of the garrifon, was formerly eftimated at 50,000; but it has fince been reduced, fo that at prefent it does not amount to more, as fome fay, than 16,000, or, according to others, 12,000. The pofition and fortifications render it a place of great ftrength. In the cathedral, which is a work of Julio Romano, are paintings of the moft celebrated mafters. The church of Antonio is more famous for relics than any other in the city. The Francifcan church has an elegant infide and a good library. The edifice formerly occupied as the ducal palace is fpacious and roomy; but the ducal gallery and mufeum were pillaged in 1630 by the Imperialifts, fo that it is now empty and in ruins. The palace church, however, has fome valuable relics and other rich furniture, befides two pictures of ineftimable value, *viz.* one of the Baptifm of Conftantine the Great, and the other of the Martyrdom of St. Antonio. The univerfity was founded in 1625. The filk and other manufactures are now inconfiderable. This city, after enduring a long fiege, was taken by the French in February, 1797; 70 miles S.S.W. of Venice. N. lat. 45° 8′. E. long. 10° 44′.

Mantua *Carpetanorum*, in *Ancient Geography*, the ancient name,

name, as some suppose, of Madrid; but others think that it was situated near it, and that the present name is Villamanta.

MANTUANO, in *Biography*. See VENUSTI MARCELLO.

MANTUANUS, the poetical name of *Battista Spagnuolo*, was born at Mantua in 1448; he entered into the order of the Carmelites, and pursued his studies in various cities, and under different masters. He was particularly attached to Latin poetry, but without neglecting his graver studies. He bore several important offices, undertook many journies, and was finally made general of his order in 1513. He died in 1516, and a marble statue, crowned with laurel, was erected to his memory. The fame of Mantuanus once stood so high that some writers placed him in parallel with Virgil: others carried the matter still farther, and thought the Pagan ought not to be mentioned in comparison with the Christian poet. He is said to have written 55,000 verses. Erasmus thought highly of his talents, but Scaliger ranked him with mere versifiers. His "Poetical Works" were published at Bologna, in folio, in 1502; and at Antwerp they were re-published in 1576, in 4 vols. 8vo.

MANUAH, in *Geography*, a town of Hindoostan, in Guzerat, in the gulf of Cambay; 10 miles S. of Goge.

MANUAL, MANUALIS, signifies what is employed, or used by the hand, and whereof a present profit may be made.

Thus, such a thing is said to be in the manual occupation of one, where it is actually used or employed by him.

MANUAL is the name of a service-book used in the church of Rome, containing the rites, directions to the priests, and prayers used in the administration of baptism and other sacraments; the form of blessing holy water, and the whole service used in processions.

MANUAL *Exercise*, in *Military Language*, is the exercise of the musket, independently of powder and ball. About the year 1757, a new manual exercise was introduced into the British army, very much resembling the modern improved system of Frederic, the father of the great king of Prussia; who was the first that caused the manual exercise to be contracted, and the motions performed close to the body. This exercise has of late been simplified and reduced to a smaller number of motions. The following are the seven movements of the present manual exercise: 1. Order arms; three motions. 2. Fix bayonets; one motion. 3. Shoulder arms; one motion. 4. Present arms; three motions. 5. Shoulder arms; two motions. 6. Charge bayonets; two motions. 7. Shoulder arms; two motions. See BATTALION.

About the same time the evolutions, manœuvres, or field movements, which were various in different corps, and very numerous in some, were reduced to one standard, and confined in number to 18. The purposes of these changes were stated in the "Regulations" to be, the reconciliation of celerity with order; to prevent hurry; to insure precision and correctness; to inculcate and enforce the necessity of military dependence, and of mutual support in action; to adopt such motions only as are necessary for combined exertions in corps, rejecting only what is curious on parade; and to make utility, not show, the principal object. See BATTALION, *Formation and Order of the* BATTALION.

MANUBALISTA, the ancient name of the *cross-bow*; which see.

MANUBIÆ, among the *Romans*, the spoils of the enemy, or rather the money made of the booty when sold by the quæstor.

MANUCAPTIO, in *Law*, a writ which lies for a man, who being taken on suspicion of felony, and offering sufficient bail for his appearance, is refused to be admitted thereto by the sheriff, or other having power to let to mainprise.

MANUCMANUC, in *Natural History*, a name given by the people of the Philippine islands to a very beautiful species of parrot, which is found very frequently wild in the woods there. It is of the same bigness with the common parrot, and is variegated with a great many different colours.

MANUCODE, in *Ornithology*. See PARADISEA *Regia*.

MANUCODIATA. See PARADISEA *Apoda*, MEROPS *Flavicans*, and MUSCICAPA *Paradisi*.

MANUCODITOTA. See TODUS *Paradiseus*.

MANUDUCTOR, a name given to an ancient officer of the church; who from the middle of the choir, where he was placed, gave the signal for the choiristers to sing, and marked the measure, beat time, and regulated the music. The Greeks called him *mesochoros*, because seated in the middle of the choir; but, in the Latin church, he was called *manuductor*; from *manus*, and *duco, I lead*; because he led and guided the choir by the motions and gesture of the hand.

MANUEL, COMNENUS, in *Biography*, emperor of Constantinople, was appointed successor to his father, John Comnenus, at his death in 1139, to the prejudice of an elder brother. The soldiery approved of the nomination on account of his military talents and heroism. He is said to have equalled the most renowned champions of chivalry with regard to warlike prowess, but at the same time no one surpassed him in luxury and dissolute indulgence during the intervals of peace. Soon after his accession he marched into Asia with a powerful army, and having recovered several towns in Phrygia, which had been taken by the Turks, he laid siege to their capital Iconium. He was unable to reduce this important place; and after securing the frontiers by garrisons he returned to Constantinople. During his stay in the capital, he married Germana, or Irene, sister-in-law to the German emperor Conrad, but this connection did not prevent him from engaging in a criminal commerce with his own niece Theodora. In the crusade of 1146, led by Conrad, Manuel, jealous of the passage of a number of ferocious bands through his territories, is charged with having used means for their destruction, and it has been affirmed by the Latin historians, that he privately acquainted the Turkish sultan with the designs of the crusaders. Roger, king of Sicily, having made himself master of the isle of Corfu, which was considered as part of the Constantinopolitan empire, and having also plundered Corinth, Thebes, and other towns of Greece, insulted Constantinople itself. Manuel, therefore, assembled a great fleet, with which he recovered Corfu, after which he carried war into the dominions of his enemy, and reduced the greatest part of the provinces of Apulia and Calabria, by means of his lieutenant Michael Palæologus. His success was so great and important, that he even entertained hopes of acquiring Italy and the western empire: with this view he attached to his cause several nobles in Rome itself, and married his niece to one of the family of Frangipani. His expectations were, however, defeated through the jealousies which subsisted between the Roman and Greek churches, and he was obliged to make a treaty and renounce his conquests, retaining only the shadow of a nominal sovereignty. Manuel had been engaged, in perfon, againft the Servians, whom he repulfed with great lofs, and feveral of whofe towns he took and deftroyed. In a progrefs afterwards through his Afiatic dominions, he was fumptuoufly entertained by the princes of the Weft; but an infult which he received from the Turks on his return, induced him to tranfport a powerful army into Afia, with which he ftruck fuch terror into the fultan, that he fued for peace, which was immediately concluded. When Manuel had overcome his foreign and political enemies, he engaged in religious contefts, and difturbed the church by endeavours to introduce heterodox opinions. Finding his life drawing to a conclufion he put on the monaftic habit, determining to retire from the world. He died in 1177, after a very bufy reign of thirty-eight years. He left a fon, Alexius, who fucceeded him. Univer. Hift. Gibbon.

Manuel Palæologus, emperor of Conftantinople, born in 1349, was fecond fon of John Palæologus. His father was not only reduced to a fervile dependence on the Turkifh fultan, but meanly fubmitted, at his orders, to deprive his eldeft fon Andronicus of his fight; he, therefore, affociated Manuel to his fceptre, which now ruled over little more than the metropolis and its immediate diftrict. On the death of John in 1391, Manuel was ferving by compulfion in the army of Bajazet, but upon receiving intelligence he efcaped, and arriving at Conftantinople, mounted the throne. Bajazet immediately invefted the city, and compelled the new fovereign to purchafe a peace on very ignominious conditions, and after carrying on the conteft a fhort time, he refigned the royal power to his nephew, and embarked for Venice. From Venice he made a progrefs through the principal courts of the Weft, to engage the fovereigns to contribute their aid for the defence of the bulwark of Chriftendom againft the Mahometan arms. He vifited Italy, France, England, and Germany, and was every where received with a refpect and commiferation due to his great misfortunes, but he was unable to roufe the princes to any effectual efforts. After an abfence of two whole years he returned, in 1402, to the Morea, where he heard of the defeat and capture of Bajazet by Tamerlane, and of the temporary relief of Conftantinople. He was now reftored to his throne, and his competitor banifhed to Lefbos. He foon after recovered feveral of his provinces, which he enjoyed till his death in 1425, at the age of feventy-fix. Univer. Hift. Gibbon.

Manuel, Don Juan, grandfon of king St. Fernando of Caftile, is frequently referred to in Spanifh hiftory during the reigns of Ferdinand IV. and Alonzo XI. with whom he was fometimes at open war; but having at length effected the marriage of his daughter Coftanza with the infante D. Pedro, then heir of Portugal, peace was eftablifhed between them. He was prefent at the great battle of Salado, in October 1340, after which, the victory being fo complete and tremendous, Spain was never more endangered by the African Moors. He died in 1347. Don Juan Manuel holds a ftill higher rank in the literary than in the political hiftory of his country: his writings are among the earlieft fpecimens of Caftilian profe; they are twelve in number, of which the titles are given in the General Biography, but only one of them, *viz.* "El Conde Lucanor," has yet been publifhed. This was firft printed by Argote de Molina, in 1575, and it was re-printed in 1642. It is a dialogue between the Conde Lucanor and his friend Patronio, in which the latter offers his friend fome good advice, and illuftrates all his precepts by examples. Gen. Biog.

MANUFACTORY, from *manu-factus*, q. d. *made with hands*, a place where feveral artifts and workmen are employed in the fame kind of work, or make a commodity of the fame kind.

MANUFACTURE is popularly ufed to fignify the work itfelf; and by extenfion, the like work carried on independently in different parts of the country.

In this fenfe we fay, the *cotton* manufacture, *woollen* manufacture, *filk* manufacture, *velvet* manufacture, *tapeftry* manufacture, *muflin* manufacture, &c. manufacture of hats, ftockings, &c.

By 23 Geo. II. c. 13. if any perfon exports any tools or utenfils ufed in the filk, linen, cotton, or woollen manufactures, he forfeits the fame, and 200*l.*; and the captain of the fhip, having knowledge thereof, 100*l.* And if any captain of a king's fhip, or officer of the cuftoms, knowingly fuffers fuch exportation, he forfeits 100*l.* and his employment, and is for ever made incapable of bearing any public office. And every perfon collecting fuch tools for exportation, fhall on conviction forfeit them, and 200*l.* (See alfo 14 Geo. III. c. 71.) By 21 Geo. III. c. 37. the above penalties on the captain of the fhip and officer of the cuftoms are augmented to 200*l.*; and a perfon having in his cuftody, or procuring to be made any fuch tool, fhall forfeit the fame, and 200*l.*, and be imprifoned for twelve months. Profecution on this claufe to be within twelve months after the offence committed. By 22 Geo. III. c. 60. any perfon exporting any fuch tools, fhall forfeit the fame, and 500*l.*; and any officer of a fhip, conniving at it, fhall forfeit 500*l.*, and if it be a king's fhip, forfeit alfo his office, and be incapacitated.

Much was done under the aufpices of the magnanimous prince Edward III., for eftablifhing our domeftic manufactures, by prohibiting the exportation of Englifh wool, and the importation or wear of foreign cloths or furs, and by encouraging cloth-workers from other countries to fettle here.

Manufacture, *Cotton*, one of the leading and moft important branches of our national induftry and commerce.

The hiftory of its aftonifhing progrefs in the laft century, the fucceffive improvements in the machinery, which have been made by various inventors, and the extent of the trade, with other curious important facts, are detailed under the article Cotton: it is needlefs, therefore, to recapitulate thefe circumftances, and we fhall proceed at once to defcribe this extenfive manufacture, as conducted on the moft improved fyftem in fome of our largeft cotton-mills. Many of our readers may have viewed a cotton-mill with wonder, but not with intelligence, nor with leifure to trace the fteps by which the wool from the bag ultimately affumes the form of a very fine thread. Bewildered by fuch a complication of machinery all in motion, very few, we imagine, are able to recollect, with diftinctnefs and intelligence, the effential part of the proceffes by which the form of the cotton is fo wonderfully changed. Such readers will not think a page or two mifemployed, in giving a brief account of the different operations the cotton paffes through, from the raw cotton or cotton wool, as imported, to the finifhed thread; and we fhall afterwards enlarge upon each fubject, and defcribe the machinery by which thefe operations are effected in the moft expeditious and perfect manner. For the explanation of thefe, we have appropriated 13 of our plates, which are entitled *Cotton Manufacture.*

Cotton, it is well known, is the produce of a fhrub in the warmer climates of the Eaft and Weft Indies, and even in the more temperate countries which border on the Levant. It comes to us packed in bags, without any further preparation

preparation than being pretty carefully picked out of the pod in which it grows; but ftill much dirt, hufk, and other impurities remain in it. The cotton wool is imported either in bags or in bales: the bags weigh from $1\frac{1}{2}$ cwt. to 5 cwt., and the bales ufually weigh $3\frac{1}{4}$ or $3\frac{1}{2}$ cwt. On arriving at the cotton-mill thefe are unpacked, and the contents examined at the fame time it is turned over and beaten with a ftick, and the grofs impurities picked out with the fingers. This is called *forting*, and the object of the beating is to foften and open the fibre of the cotton, fo as to expofe every part. The forting is performed immediately when the bags of cotton are opened, but it has ftill to undergo a fecond examination, called *picking;* the principal object of the firft examination, or forting, being intended to afcertain the quality of the cotton, and to find what kind of goods it is beft adapted for manufacturing, and in this examination the coarfeft impurities and yellow damaged parts are picked out.

After forting the cotton, it is carried to the *batting machine*, and the coarfer forts of cotton to the *opening machine*, which is known to the workmen by the name of *devil*. In the batting machine, the cotton is fpread upon a platform of ropes ftrained very tight, and a number of rods ftrike very fmartly upon it, by which they open the fibres and loofen the knots of cotton preparative to the fucceeding operations: at the fame time the violence of the batting loofens and fhakes out all dirt, duft, and cotton feeds, of which the cotton in its raw ftate contains a great number, and which would be very prejudicial to the operations of the more delicate machines. The cotton, when firft packed up in the bags, is compreffed very clofely, for the convenience of ftowage, and this condenfes it into a hard matted mafs; but the batting machine, ftriking it violently with fmall fticks, caufes the fibres, by their natural elafticity, and the motion occafioned among them, to gradnally loofen and difengage themfelves, and the cotton, by repeated ftrokes, recovers all its original volume.

The *opening machine* has the fame objects, and produces the fame effects, though in a very different manner, as it confifts of a rapidly revolving cylinder, on which a great number of iron teeth, or fpikes are fixed, which tear and open the cotton againft other fimilar teeth, which are fixed in a ftationary half cylinder or hood, enclofing the other. The batting machine is ufed for the finer kind of cotton; and the opening machine, which acts in a more rapid though lefs effective manner, is employed upon the coarfer forts. After batting or opening, the cotton is again picked, to remove thofe finer particles of dirt which were before enveloped in the cotton, but are expofed by the operation of the machine. It is performed by women, who remove all extraneous matter, and every particle of yellow or damaged cotton. The perfection of the article to be produced, depends in a great degree on the care with which the picking is performed, and this is almoft the only procefs, in the cotton fpinning, which cannot be performed by machinery, becaufe it neceffarily requires a difcretionary power.

The cotton wool being picked clean, is next *mixed*, that is, the contents of different bags are mixed together with a view of obtaining a fimilarity in the quality of the cotton which is to be fpun. In this operation the greateft art of cotton-fpinning confifts, and it is that department in which experience alone guides the manufacturer. By a judicious mixture of different forts of cotton, fome fpinners will produce a very fine and capital yarn, from fuch cotton as would, if fpun alone, or improperly mixed, only produce coarfe and low priced goods. The mixture is effected by making a pile or heap, confifting of fucceffive layers, of the different kinds of cotton which are to be mixed; then by raking away a fmall quantity at a time from the edges of the heap, ftriking the rake from the top to the bottom, through all the different layers, the cotton will be very equally mixed. Sometimes the cotton wool is dyed, and different colours are mixed together. It is now fpread out, very evenly and regularly, upon a long cloth, which is rolled up and carried to the

Carding machine.—This confifts of a number of cylinders, covered with wire teeth or cards, and revolving with confiderable velocity in oppofite directions, nearly in contact with each other, and covered by a dome alfo lined with cards. The cotton, being introduced among thefe, is continually combed, or carded, by the teeth, until almoft every individual fibre is feparated and drawn ftraight, and every little knotty and entangled part difengaged. By paffing gradually through the machine from one cylinder to another, the cotton is difperfed lightly and evenly among the teeth over the whole furface of the laft, or finifhing cylinder, from which it is detached by the mechanifm in a continued fleece. This is drawn off, and lapped upon a cylinder turned flowly round by the machine, until the fleece has made a great number of turns upon the cylinder: it is then broken off, by dividing it at one part, fo that it forms a fleece called a lap, which is the length of the circumference of the cylinder, and confifting of fifteen or twenty thickneffes, by which admirable contrivance very great regularity is obtained in the thicknefs of the lap, becaufe if any one part of the fleece produced by the machine is thinner or thicker than it ought to be, in confequence of any irregularity in the fpreading of the cotton-wool upon the cloth, previous to carding, fuch irregularity will have no fenfible effect upon the ultimate thicknefs of the lap, becaufe it is compofed of thirty or forty ftrata, and there is no probability that the inequalities of thefe feveral ftrata will fall beneath each other, but every chance that they will be equally difperfed through the whole, and thus correct each other. The lap, when taken off, is laid flat on a cloth, which, with it, is rolled up and conveyed to a fecond carding-machine, called the *finifhing card*, while the firft is called the *breaker*. In this fecond card it undergoes a fimilar procefs to the firft, but inftead of the fleece being received on a cylinder, it is contracted by paffing through a funnel, in which the fleece, being hemmed in on both fides, is gradually contracted to a thick roll, which may be continued to any length as long as the machine is fupplied with cotton. This roll or band of cotton is drawn off between two rollers, which comprefs it into a pretty firm, flat ribband, about two inches broad. The rollers deliver it into a tin can, placed to receive it, and in this it is removed to the

Drawing Frame.—This machine confifts of feveral pairs of rollers, between which the cotton is paffed, and every fucceffive pair it is drawn through moves, by means of the wheel-work, with a greater velocity than thofe preceding it, fo as to ftretch out the band or fliver of cotton, in the fame manner as it would be drawn out, if one part of the fliver were held between the finger and thumb of one hand, and another part, at an inch or two diftant, being held in the other hand. Then by drawing the two hands afunder to the extent of four inches, it is evident two inches in length of the cotton fliver would be extended or drawn out to four inches. In like manner, the firft pair of rollers through which the fliver paffes, are preffed together with a fufficient weight to hold the cotton firmly between them. The fecond pair of rollers are fituated at one or two inches diftant, and are made by the wheel-work to revolve more fwiftly than the firft. The difference of velocity, however, is but fmall, though the confequence is, that the fliver will be lengthened in the fame proportion;

proportion; for the fecond rollers take up the cotton much fafter than the firft pair will deliver it out: it muft, therefore, be either forcibly pulled through between the firft rollers, or it muft be ftretched a little, by the fibres flipping among each other, or it muft break. When the extenfion is fmall, the only effect of it is merely to begin to draw the fibres (which are at prefent lying in every poffible direction) into a ftraight and parallel pofition, which is moft favourable for the fubfequent extenfions. The drawing frame contains a third, and fome of them a fourth pair of rollers, by which the fliver undergoes a fecond or third draught; but the combined effect of all thefe drawings is generally to extend the fliver to four times the length it was when firft put to the machine. But as this would reduce the fliver to one-fourth of the fize, which is not intended in this ftage of the procefs, four ends or flivers are introduced between the rollers together, and being drawn into one, which is four times the length, it will of courfe be of the fame fize as any one of the four which is put in. This drawing procefs is repeated three or four times, and the alteration it makes in the cotton is to equalize the fize of the fliver, on the fame principle as before defcribed of the breaking card, *viz.* by repeatedly combining four together, and drawing them into one: it alfo difpofes the fibres longitudinally and in the moft perfect ftate of parallelifm. The operation of carding effects this in a certain degree; yet the fibres, though parallel, are not ftraight, but many of them doubled, as may eafily be fuppofed, from the teeth of the cards catching the fibres fometimes in the middle, which become hooked or faftened upon them.

Though the general arrangement of the fibres of a fliver from the finifhing card is longitudinal, yet they are doubled, bent, and interlaced in fuch a way, as to render the operation we are now fpeaking of abfolutely neceffary.

When the cardings have been paffed four or five times through the drawing frame, every fibre is ftretched out at full length, and difpofed in the moft even and regular direction, fo that each fibre will, when twifted into a thread, take its proper bearing, in confequence of every one being ftraightened and having the fame tenfion.

The fliver in this ftate prefents a moft beautiful appearance, being fo extremely regular in its fize, and all the fibres drawn fo ftraight, that it bears a fine gloffy or filky appearance. It is upon this fliver or ribband of cotton wool that the operation of fpinning begins. The general effect of the fpinning procefs is, to draw out this maffive fliver, and to twift it as it is drawn out: but this is not to be done by the fingers, pulling out as many fibres of the cotton at once as are neceffary for compofing a thread of the intended finenefs, and continuing this manipulation regularly acrofs the whole end of the ribband, and thus, as it were, nibbling the whole of it away. The fingers muft be directed for this purpofe by an attentive eye; but in performing this by machinery, the whole ribband muft be drawn out together and twifted as it is drawn. This requires great art and very delicate management: it cannot be done at once, that is, the cotton roll cannot be firft ftretched, or drawn out to the length that is ultimately produced, from the tenth of an inch of the fliver, and then twifted. There is not cohefion enough for this purpofe, it would only break off a bit of the fliver, and could make no further ufe of it; for the fibres of cotton are very little implicated among each other in the fliver, becaufe the operation of carding and drawing has laid them all parallel in the fliver; and though compreffed a little, by its contraction in the card from a fleece of twenty inches to a ribband of two, and afterwards compreffed between the rollers of the drawing frame, yet they cohere fo flightly, that a few fibres may be drawn out, without bringing many others along with them. For thefe reafons, the whole thicknefs and breadth of two or three inches are ftretched to a very minute quantity, and then a very flight degree of twift is given it, *viz.* about two or three turns in the inch, fo that it fhall now compofe an extremely foft and fpungy cylinder, which cannot be called a thread or cord, becaufe it has fcarcely any firmnefs, and is merely rounder or flenderer than before, being ftretched to about four times the former length. This is called *roving*, and the operation is performed in the

Roving Frame.—This machine is conftructed in a great variety of forms, but all of them have the fame object in view, *viz.* to draw out the fliver, fo as to reduce it from a large band to a coarfe and loofe thread: but as this extenfion would render it fo extremely tender, that it would fcarcely hang together in paffing through the fucceeding machines, the roving frame, immediately after having drawn and extended it to the intended fize by rollers, operating in the fame manner as the rollers of the drawing frame, gives it a very flight twift, as before mentioned, and this loofe thread, which is called the roving, is the firft rudiment of a thread. Although it is extremely tender, and will not carry a weight of two ounces, it is much more cohefive than before, becaufe the twift given to it makes all the longitudinal fibres bind each other together, and comprefs thofe which lie athwart; therefore it will require twice the force to pull out a fibre from among the reft, but ftill not near enough to break it. In drawing a fingle fibre others are drawn out along with it, and if we take hold of the whole affemblage in two places, about an inch or two afunder, we fhall find that we may draw it to near twice its length, without any rifk of its feparating in any intermediate part, or becoming much fmaller in one part than another. It feems to yield equally over all parts.

Our readers will now perceive, that thefe proceffes will enfure all that is wanted, and prepare a roving that is uniform, foft, and ftill very extenfible: in fhort, fit for undergoing the laft treatment of fpinning, by which it is made a fine and firm yarn.

It is evident that the roving produced by thefe operations muft be exceedingly uniform. The uniformity really produced exceeds all expectation; for even although there be fome fmall inequalities in the carded fleece, yet if thefe are not matted clots which the card could not equalize, but only confift of a little more thicknefs of cotton in fome places than in others, this inequality will firft be diminifhed by the lapping of the fleece in the breaking card; and when fuch a part of the fliver comes to the firft roller of the drawing frame, it will be rather more ftretched by the fecond than a thin part would be. That this may be done with greater certainty, the weights of the firft rollers are made very fmall, fo that the middle part of the fliver can be drawn through, while the outer parts remain faft held.

Such is the ftate of the roving as prepared by the roving frame. All the preceding proceffes are to be confidered as the preparations: and the operation of fpinning is not yet begun. Thefe preparations are the moft tedious, and require more attendance and hand-labour than any fubfequent part of the procefs. For the flivers from which the rovings are made are fo light and bulky, that a few yards only can be piled up in the cans fet to receive them from the carding and drawing: a perfon muft therefore attend and watch each roller of the drawing and roving frames, to join frefh flivers as they are expended. It is alfo the moft important department

ment in the manufacture; for as every inch will meet with precifely the fame drawing and fame twifting in the fubfequent parts of the procefs, therefore every inequality and fault of the fliver, indeed of the fleece as it quits the finifhing card, will continue through the whole manufacture, in a greater or leffer degree, being only diminifhed, not corrected, by the drawing, doubling, &c. The fpinning of cotton-yarn now divides itfelf into two branches. The firft performed by what were called jennies, when worked by the hand, but fince they are moved by the power of a mill, they are called mules; the manner of action refembles the ancient fpinning with diftaff and fpindle. The fecond method, called fpinning of *twift*, or *water-fpinning*, becaufe it was the firft fpinning performed by a water-wheel, is in imitation of the fpinning with the fly-wheel, or jack and flyer. The two methods differ in the fame manner, as the old wool or cotton-wheel differs from the fpinning with the flax-wheel. Mr. Arkwright's chief invention, the fubftitution of the machinery for the immediate work of the human finger, was at firft only applied to the manufacture of twift, or water-fpinning. We fhall, therefore, firft direct our attention to this.

The water-fpinning procefs is little more than a repetition of that gone through in making the firft flivers or rovings, which are formed on bobbins, either by the roving frame, or are afterwards bound on bobbins by the hand. Thefe bobbins are fet on the back part of the

Spinning-frame, in which the roving is drawn, and extended to any required degree of finenefs; and the proper twift being given to it, forms it to the required thread. The fpinning-frame is provided with fyftems of rollers, in the manner of the drawing-frame, through which the roving paffes, and is drawn out according to the fize of the thread which is required to be fpun, which varies from four to feventeen times; and it is then twifted more or lefs, as the thread is required to be hard or foft: therefore, the fpinning procefs fcarcely differs from the roving, except in the twift that is given it, after the laft ftretching, in its length. This is much greater than the roving, being intended to give the yarn hardnefs and firmnefs, fo that it will afterwards break rather than ftretch any more. The perfection of the ultimate thread or yarn depends, in a great meafure, on the extreme foftnefs of the roving; for it is this only which makes it fufceptible of an equable ftretching, all the fibres yielding and feparating alike: and this property will be greatly influenced by the quantity of twift given by the roving-frame. For thefe points no very diftinct rule can be given: it varies in different mills, and with different fpecies of cotton wool, as may be eafily imagined. The immediate mechanifm, or manipulation, muft be fkilfully accommodated to the nature of that friction which the fibres of cotton exert on each other, enabling one of them to pull others along with it. This is greatly aided by the contorted curled form of a cotton fibre, and a confiderable degree of elafticity which it poffeffes. In this refpect it greatly refembles woollen fibres, and differs exceedingly from thofe of flax; and it is for this reafon that it is fo extremely difficult to fpin flax in this way: its fibres become lank, and take any fhape by the flighteft compreffion, efpecially when damp in the flighteft degree. But befide this, the furface of a cotton fibre has a harfhnefs or roughnefs, which greatly augments their mutual friction. This probably is the reafon why it is fo unfit for tents, and other dreffings for wounds, and is refufed by the furgeons even in the meaneft hofpitals. But its harfhnefs and elafticity fit it admirably for the manufacture of yarn. Even the fhortnefs of the fibre is favourable; and the manufacture would be very difficult, if the fibre were thrice as long as it generally is. If it be juft fo long that, in the finifhed thread, a fibre will rather break than come out from among the reft, it is plain that no additional length can make the yarn any ftronger, with the fame degree of compreffion by twining. A long fibre will indeed give the fame firmnefs of adherence, with a fmaller compreffion by twining. This would be an advantage in any other yarn; but in cotton, the compreffion is already as flight as can be allowed: were it lefs, it would become woolly and rough by the fmalleft ufage; and it is already too much difpofed to teazle out. Now, fuppofe the fibres much longer, fome of them may chance to be ftretched along the fliver through their whole length. If the fliver is pulled in oppofite directions, by pinching it at each end of fuch long fibre, it is plain that it will not ftretch till this fibre be broken up, or drawn out; and that while it is in its extended ftate, it is acting on the other fibres in a very unequable manner, according to their pofitions, and renders the whole apt to feparate and draw more irregularly. This is one great obftacle to the fpinning of flax by fimilar machinery.

Mule-fpinning.—A great proportion of the cotton is fpun in the mule inftead of the water-frame. The preparation it undergoes for either method is the fame; at leaft the proceffes are fimilar, except that the quantities of draft, and fome other particulars, may be varied in the preparation of the cotton which is to be thus fpun in this machine, which is called a mule, either becaufe it is a kind of machine which might eafily be turned by a mule, or more probably becaufe it is a fort of mongrel, partaking of the nature of both drawing and fpinning, or uniting the action of both the roller and fpindle. It confifts of three fets of fluted brafs rollers, the flutes of which turn into each other. The firft fet goes fafter than the fecond, and the fecond fafter than the third; between which, when the fliver of carded cotton enters, it is a little lengthened out between the firft and fecond, and farther ftill between the fecond and third; after paffing which, it is flightly twifted by the rapid circular motion of the fpindle. This has the fame effect as the fpinning-frame; but the quantity of draft between the rollers, or extenfion of the fliver, is not, like the water-frame, to the full extent which the thread is intended to be. The remainder of the ftretching is performed in this manner: the fpindles of the mule, which give the twift to the thread, are fitted in a frame, fo that they can be moved backward and forward, in a ftraight line, to and from the rollers; a certain length of the roving being therefore given out by the rollers, the fpindles are removed backward to take it up as faft as it comes, and in this motion they twift it flightly: at the fame time, but after a certain quantity of the roving, a yard for inftance, has been given out by the rollers, their motion ceafes; but the fpindle continues to recede from them, another half yard for inftance, continuing to twift the thread all the while. By thefe means, it is evident that the thread will be ftretched from a yard to a yard and half in length: by this contrivance, the cotton will bear a greater degree of extenfion than any other, becaufe it is conftantly twifted at the fame time that it is extended in length.

The invention of mules forms quite an epoch in the hiftory of the cotton trade. A vaft improvement was made, about 35 years ago, by the introduction of the fpinning jennies, by which from twenty to forty fpindles were turned at a time. The fpindles were the fame as the mule, and had the fame motion; but this machine was not provided with rollers to draw out the cotton, previous to twifting, merely depending upon the ftretching, to give it the proper extenfion requifite to form the roving into a thread. But the combination of the jenny with fir Richard Arkwright's invention of drawing, by rollers, forms a method fuperior to both, at leaft

leaft for fine goods. The method of ftretching gives the means, as we have before mentioned, of very great extenfion; but if this be carried fo far as to draw out the coarfe loofe roving to a fine thread, there will be great danger of its drawing irregularly, that is, more in one place than another. In the original method by the jenny, the rovings were prepared by the hand-wheel: they were loofe, coarfe, untwifted threads, partaking fomewhat of the nature of cardings, though approaching in fome degree to fpun twift. They were obliged to be prepared by the hand-wheel, becaufe the cardings, which were prepared by hand-cards, were in detached pieces of a certain length, and regularly tapering towards each end: the joining of thefe together, in fuch a manner as to produce an equal and regular roving, required a care and attention which could not be effected by machinery.

The combination of fir R. Arkwright's fyftem of preparation with the jenny produced the mule, which, without the defects of its original, fpins in the moft expeditious and perfect manner. The advantage of this mode of preparing the threads over that of the jenny is, that the fibres of the cotton are all laid longitudinally, and nearly in as fmall number as is wanted, before they are begun to be much twifted; by which means, threads of any required finenefs are made much ftronger than they were from rovings, made upon the fpindle of the hand-wheel fpun in the jenny, which twifted them too much in the firft inftance; and in the fubfequent extenfion or ftretching, by the removal of the fpindle, for rendering them finer, many of the fibres were neceffarily broken. On one of thefe mules 240 threads are often fpun at once; and two of them may be managed by one woman, with a child to tie the threads which may occafionally break.

It is needlefs, as the jenny has become an obfolete machine in the cotton manufacture, to enter into any further details, particularly as the mechanifm fo nearly refembles the jenny ftill ufed in the WOOLLEN *manufacture*. See that article.

The reader moderately acquainted with mechanics, cannot but perceive that by each of the operations now defcribed, the cotton-wool is prepared, and drawn into a fine ftrong thread, by repeatedly drawing the fliver till its fibres become ftraight, then reducing it in the roving frame to a coarfe thread, and by a flight twift giving it fufficient ftrength to bear fuch an extenfion as will reduce it to the fize intended, and then it is immediately twifted into a hard thread. All thefe proceffes are only a fubftitute for a fingle pull of the finger and thumb of the fpinner, which fhe accommodates precifely to the peculiar condition of the lock of wool which fhe touches at the moment: fhe can follow this through all its irregularities, and, perhaps, no two fucceeding plucks are alike. But when we cannot give this momentary attention to every minute portion, we muft be careful to introduce the roving in a ftate of perfect uniformity, and then every inch being treated in the fame manner, the final refult will be equable, and the yarn will be uniform.

The thread being now finifhed, either by the water-frame or mule, it is carried to the

Reel, by which it is taken off the bobbins of the fpinning frame, or the cops of the mule, and formed into hanks. The hank is a meafure in cotton trade, compofed of feven *leys*, each of 120 yards in length. The reel or frame round which the thread is wound is one yard and a half in circumference, and at every 80 turns (or *bouts*) which it makes, the 80 turns of the thread are tied together to keep them feparate, and this meafures out 120 yards, which is called a ley: but the thread is not cut at the ley, it is continued to be wound on the reel, till feven fuch leys, or 840 yards, are reeled: it is then cut and called a hank, which is tied up.

The different fizes of cotton yarn, or thread, are denominated according to the number of thefe hanks which will weigh a pound. The hank of 840 yards in length is the meafure ufed in all Englifh cotton-mills, and thus affords a very accurate and convenient ftandard for the fize of the cotton. The number is afcertained by weighing each individual hank in a little *weighing inftrument*, which fhews by an index what number of fuch hanks will weigh a pound. Each hank being twifted up is fufpended on the hook of this inftrument, and the number being afcertained, the hank is put on a proper fhelf till they are all forted. Then by a table on purpofe it is feen how many hanks of any number will weigh 10lbs. and this number being counted out from any one fhelf, is packed up in the *bundling prefs*, and tied in papers, marked, and fent away for market Sometimes, the cotton intended for weaving is warped in the warping-mill before it is fent away from the mill: this faves the weaver an immenfe deal of trouble.

Some of the twift is wound on quills for the fhuttle; and others, again, are formed into hanks, fome of which are tightly bound round at certain intervals previous to their being dyed, in order to prevent the parts fo tied from taking the colour. This is done that the threads may be difpofed to warp in the weaving loom, fo as to produce the clouds which are feen in various fpecies of the cotton goods, efpecially ginghams.

Some of the cotton thread is dyed in the hank, and other cotton which is intended for fewing, knitting, &c. or to weave fine goods, is bleached; and becaufe in this procefs, or in dyeing, fome fhrinking takes place, it is wound from the hanks upon bobbins again by the *winding machine*, and from thefe bobbins it is again reeled into hanks, in which it is packed up and fent to market: other cotton thread for fewing, mending, and domeftic ufe, is wound into balls of a figure refembling a cafk, and the many interfections of the thread are fo managed as to produce a very beautiful appearance.

The denominations of the quality of the different kinds of cotton threads are chiefly divided into *yarn* and *twift*, and this is called *mule* twift, or *water* twift, as it is fpun either in the mule or water-frame. That thread which is denominated *water-twift*, is ufed for weaving calicoes, &c. It is fpun hard, that is, with a great deal of twift, fo that it forms a ftrong hard thread. It is manufactured of all numbers, from 10 to 60 hanks *per* pound.

The *mule-twift* is ufed for weaving muflins and the fineft cotton goods. The effential differences between this and the water-twift are, that the mule produces much finer articles than are attempted on the water-frame, at the fame time it makes a fofter thread. As it requires much lefs power to work it than the water-frame, the manufacturer fpins every thing in the mule which will admit of it; but it will only produce the foft kinds of thread. The mule will fpin all numbers, from the loweft to 150 or 170 hanks *per lb.* The trade of Manchefter is chiefly mule fpinning, whilft the water-twift is moftly fpun in the country by water-mills, becaufe the great power it requires is too expenfive for fteam-engines, at leaft the water-mills have the advantage, being ufually in fituations where they have their power at a lefs expence than thofe turned by fteam-engines.

Stocking yarn is fpun fofter than twift, and two threads are afterwards doubled together in the doubling machine, and then flightly twifted round each other in the twifting machine.

chine. Sometimes one of the threads is dyed black, or blue, before the twifting, and then it produces a fpeckled thread, which is called one-thread white. This yarn is chiefly ufed in the ftocking-frame; it is fpun in all numbers, from 10 hanks in the pound up to 60. The threads of ftocking yarn are but flightly twifted, fo that its compofition of two threads is always diftinctly vifible.

Sewing cotton is made either from twift or cotton yarn doubled, and twifted very hard together by paffing it a fecond time through the fpinning frame, fo as to form a ftrong thread, which may be compared to a fmall rope, as the two threads make one very compact and defined thread.

Mending cotton is the fame as fewing, but of lefs twift: indeed the diftinction is trifling.

Knitting cotton is twifted with two or three threads, but not fo hard twifted as fewing cotton, though it is harder than mending. This cotton is frequently bleached after it is twifted.

Candlewick cotton is a very loofe coarfe thread, made from the cheapeft and moft inferior kind of cotton: being only intended for the wick of candles, no great care is ufed in the manufacturing. A great deal of candlewick is made from tow which is bleached, and makes an article fomething like the cotton in appearance, but by no means equal to it in quality. This is known by the cant term of *bump*, and many large mills are employed in fpinning it. The cotton candlewick is known by the name of *Turkey*, which is made from Smyrna or other cheap inferior kinds of cotton. It is fpun generally about $10\frac{1}{2}$ to 11 hanks *per lb.*, and fent off to market wound up in large balls. Oxford candlewick is made from inferior cotton, about feven hanks to the pound. Wiltfhire candlewick is made from wafte cotton, about No. 7. Thefe articles are fpun without the care requifite for yarn or twift: they are ufually fpun by mules, and in fome mills for coarfe goods they do not take the trouble to form them into rovings at all, but fpin the candlewick at once from the flivers, as prepared by the drawing-frame.

To purfue the progrefs of the cotton after being fpun into twift, we muft remove from the cotton-mill to the cottage of the weaver. Here, the warp being fixed in the loom, or, in the language of the weaver, warped, it is divided to give paffage to the weft in the fhuttle, either by two, three, or more treadles: or if the pattern or courfe of changes in the order of raifing and depreffing the threads of the warp be various, fo that the weaver could not manage the requifite number of treadles, it is done by a great number of ftrings which pafs over pullies above the loom, and are drawn one after another by a little boy, above whofe head they are difpofed in two rows by the fides and between two looms. Thefe looms are, therefore, called draw-boys. Thefe boys will fhortly be fet afide for machinery, which is rapidly introducing a fubftitute. For the formation of fprigs, &c. of various colours, there are often as many fhuttles as colours, or a number of little fwivel looms, fuch as they ufe for the weaving of tapes, introduced occafionally, as many as there are fprigs in the breadth of a piece. Quiltings appear to be two diftinct cloths, tied as it were together by ditches, which go through both cloths, and in fome cafes, as in bed-quilts, there is a fhuttle which throws in a quantity of coarfely fpun cotton, to ferve as a kind of wadding. The counterpanes are woven with two fhuttles, one containing a much coarfer weft than the other; the coarfer of the threads is picked up at intervals with an iron pin, rather hooked at the point, fo as to form knobs difpofed in a fort of pattern.

When the goods are come from the loom, moft forts of them, previoufly to being bleached, are fired or dreffed, by being drawn, and that not very quickly, over red-hot cylinders of iron, by which the fuperfluous nap is burnt off. To fee fuch an operation performed upon fo combuftible a fubftance, naturally fills a ftranger with the utmoft concern and aftonifhment. They are then wafhed in a wheel with foap and water, and having been well fcoured with an alkaline lixivium, are dipped in the oxygenated muriatic acid, diluted to its proper ftrength. Thefe preparations are repeated alternately, till the goods have attained the requifite whitenefs; and between each dipping they are laid out upon the ground, and expofed to the action of the fun and air. When completely bleached, they are either fmoothed upon long tables with fmoothing irons, or calendered; that is, ftretched and preffed between a courfe of rollers, by which they acquire a fine glofs. Calicoes are printed exactly in the fame way as the kerfeymeres in Yorkfhire, but the works are ufually upon a much larger fcale. See Printing.

Thickfets, corduroys, velveteens, &c. are cut upon long tables, with a knife of a conftruction fomewhat like the fting of a wafp, terminating in a very fharp point, defended on each fide by a fort of fheath. This point is introduced under the upper courfe of threads which are intended to be cut, and with great eafe carried forward the whole length of the table.

The rapid increafe of the cotton trade appears to have been owing, in a great meafure, to the more liberal introduction of machinery into every part of it, than into any other of our ftaple manufactures. The utility and policy of employing machines to fhorten labour, have been a fubject which has exercifed the pens of many ingenious writers, while their introduction into almoft every branch of manufacture has been attended in the outfet with much riot and diforder. They are undoubtedly wonderful productions of human genius, the progreffive exertions of which neither can nor ought to be ftopped; they enable a manufacturer to produce a better article than can be made by the hand, in confequence of the uniformity and certainty of their operations, and at a much lower price, in confequence of the vaft quantities of goods they are capable of performing. They thus fupport the credit of our manufactures abroad, and enable us under the vaft load of taxes, and confequent increafe in the price of every neceffary of life, to meet our foreign competitors with advantage at market. They can even allow the goods to furnifh in their paffage a confiderable revenue to government. And although they do, undoubtedly, on their firft introduction, throw fome perfons out of employ, by changing the nature and courfe of bufinefs, they almoft immediately make up for the inconvenience by aftonifhingly multiplying the abfolute quantity of employment. If they have taken away work from carders and fpinners, they have returned it them back tenfold, as winders, warpers, weavers, dreffers, dyers, bleachers, printers, &c.

It is this machinery which we have now to explain. An extenfive cotton mill contains moft interefting fpecimens of human ingenuity and refource, and fhews in a ftriking manner what may be done, when the talents of a great number of individuals are directed to one common object, and where the moft trifling part is of fuch importance (from the frequent repetition of it which is neceffary) as to become worthy the confideration of the manufacturer to devife machinery for accomplifhing it in a better or cheaper manner. There is, in the cotton trade, fuch a fpirit of improvement, that they have, as a body, lefs prejudice in favour of old eftablifhed cuftoms than perhaps any other clafs of men: this is doubtlefs a reafon of the great perfection of their art, as they have made trials of new ideas, without thofe years of reflection which men in other trades require before they will venture to embark in any new improvement, though ever fo promifing and favourable in appearance.

Our readers, who are unacquainted with the fubject, will now by this fketch have obtained fuch a general idea of the cotton manufacture, as will enable them to comprehend the technical terms which are neceffary to be ufed in the fubfequent explanation of the machinery, and thofe references which muft fometimes be made from one procefs to another. A large cotton mill is generally a building of five or fix ftories high: the two loweft are ufually for the fpinning frames, if they are for water twift, becaufe of the great weight and vibration caufed by thefe machines. The third and fourth floors contain the carding, drawing, and roving machines. The fifth ftory is appropriated to the reeling, doubling, twifting, and other operations performed on the finifhed thread. The fixth, which is ufually in the roof, is for the batting machine, or opening machine, and for the cotton pickers, who for a large mill are very numerous. This laft is not always fo occupied, many manufacturers thinking it better to have out-buildings for thefe parts of the procefs, and only to have fuch parts in the mill as require the aid of the large water-wheel, or fteam-engine, which turns the whole mill. If the mule is ufed for fpinning inftead of the water frame, then the cards are ufually put below, becaufe they are then the heavieft and moft powerful machinery.

The firft machine we fhall defcribe is the *Batting machine*. *Plate* II. *Cotton Manufacture*, *fig* 1, is an elevation fideways, and *fig*. 2. an elevation endways, the frame being in both defcribed by dotted lines, that it may not obfcure the mechanifm: *figs*. 3, 4, and 5, are detached parts of the machine. The moving power is communicated by the mill to an horizontal axis, on which the fly-wheel, C, is fixed, to regulate the motion. On this axis four cranks are formed, as fhewn at *i*, *i*, *i*, *i*, making equal or right angles with each other; and connecting rods, *i*, *b*, being extended from thefe cranks to the lower ends of the levers *g*, *g*, which are moveable on the centres *f*, caufe them to vibrate alternately when the cranks are turned. There are four of thefe levers fituated on each fide of the machine, all the four on each fide having one common centre at *f*. Each crank on the main fpindle has two connecting rods upon it, to actuate two different levers; but which being fituated on oppofite fides of the machine, of courfe receive their motion alternately: at the upper ends, *e*, *e*, of the levers, which, as the figure fhews, are much longer than the lower ends, that is, the centre of motion, *f*, is placed confiderably beneath the middle of the levers. At the upper ends, *e*, *e*, of the levers joints are formed, by which they are connected with rods, *x*: thefe perform the batting, by ftriking in the manner we fhall defcribe upon the platform A, where the cotton is fpread. This platform is formed of a long cord, which is repeatedly paffed over two rollers, one of which is fhewn at *m*, and the other is at the oppofite end of the machine: the cord paffing round from one of thefe to the other twenty or thirty times, and having all the turns made parallel to each other, at about an inch afunder, it forms an horizontal platform for the fupport of the cotton; but to fill up the interftices between thefe ropes another ftationary fet is placed. Thefe are ftrained between two fixed beams of the frame, as fhewn in *fig*. 4, which is a plan (and a fection is fituated immediately beneath it:) The roller *m*, *fig*. 1, is kept in continual rotation by a train of toothed wheels, marked *k k k k l*, which communicate the motion by a pinion on the main axis from one to another, and laftly to the roller by means of a contrate wheel *l*, in which a pinion acts. By thefe means the endlefs rope, which extends from one roller to the other, and forms one-half of the platform for the cotton, is in conftant motion, and the cotton which is laid upon it at one end traverfes flowly to the other, receiving in its paffage the blows of the rods *x*, which ftrike upon it alternately. Their action is produced in this manner; the levers, *g*, *g*, are forked at the upper ends, as fhewn in *fig*. 5, fo as to afford a fufficient length of bearing for a fhort axis 3, 4, on which the rod *x* moves. The fmall dotted circle 3, in this figure, reprefents the place where the rod unites with the axis, or rather where a fmall iron tube proceeds from the axis; and in the end of this the wooden rod, *x*, is inferted, and held faft by means of a fcrew clamp, or hoop, furrounding the end of the tube, and compreffing it upon the rod, one fide of the tube being fplit down to admit of this compreffion. Upon the fame axis as the rod *x* are fixed two fmall pullies 1, 2, to each of which a ftrap is attached, and, after making a turn round their refpective pullies, thefe are conducted away to a fixed part of the framing, in the manner fhewn in *fig*. 1. Thefe ftraps are of fuch a length, as to hang loofe during a greater part of the time; but when, by the motion of the top of the levers *g*, *g*, *fig*. 1, they come to their tenfion, they operate upon the pullies 1 or 2, *fig*. 5, and turn them half round with their axis, at the fame time turning over the rods *x*, *x*. This motion is more clearly explained by *fig*. 3, which will, at the firft view, be feen to be only a detached fection of the parts already defcribed in *fig*. 1. A reprefents one of the vertical levers (*g*, *fig*. 1.), and F its centre of motion, upon which it traverfes from the pofition A, to that reprefented by the dotted lines B, by the action of the crank rod joined to the lower end of it, as before defcribed; therefore the two pofitions, A, B, are to be confidered as the extremes of its movement. E reprefents the pullies which are fixed on the axis of the batting rod *b*, the two appearing as one in this view. One of the ftraps of thefe pullies is faftened by one end at *n* to a fixed part of the frame, and the other end is made faft to the pulley at *o*. The other ftrap has one of its ends faftened to the pulley at *k*, while the oppofite end is attached at *i* to a lever *i m*, whofe centre, G, is ftationary. The lower end, *m*, of the lever has a ftrap attached to it, which proceeds to the lever A, and is made faft thereto at *l*. The operation of this conftruction may be thus explained: in the pofition B, the ftrap, *i f*, (anfwering to *i k* in the other pofition) hangs flack, as in the figure, while the other ftrap, *r n*, has come to its tenfion, and has turned over the batting rod to the pofition *g*. Now, fuppofe by the action of the crank rod the lever is moved towards the pofition A, it proceeds for fome diftance with the rod *g*, remaining horizontal, and merely drawing along endways; but when it is advanced rather more than half way, the ftraps, *l m* and *i k*, come to their tenfion: the former pulls the lower end, *m*, of the lever, *m i*, after it, and, of courfe, the upper end, *i*, at the fame time moving in an oppofite direction, draws the ftrap, *i k*, with it, turning the pulley E, and the batting rod attached to it, over into the pofition *b*, and ftriking on the cotton fpread on the platform. This motion is performed almoft inftantaneoufly, becaufe, the ftrap *i k* being drawn in one direction, whilft the centre of the pulley it is faftened to moves in an oppofite direction, thefe motions caufe the pulley E, and the batting rod which is attached to it, to turn over with a double velocity, to what it would have had if fimply actuated by the motion of the lever A; fo that this rapid motion caufes the batting rod to ftrike with an exceedingly fmart ftroke upon the cotton laid upon the platform. In

returning

returning back again to the poſition B, which the crank cauſes it to do very ſhortly after having made the ſtroke, it proceeds, as before mentioned, to beyond the half way, with the ſtraps hanging ſlack and having no action; but when it has paſſed rather more than half way, the ſtrap, *n f*, becomes tight, and turns the pulley over, bringing the batting rod to the poſition *g*, ready to make another ſtroke; but in turning it over to this poſition, the rod does not move with ſuch velocity as to ſtrike a blow upon the cuſhion *d*, *fig.* 1, which is placed to receive it, becauſe the ſtrap, *f n*, is fixed to a ſtationary point *n*, inſtead of having a motion in the oppoſite direction to the lever, as the other ſtrap *l k*, which cauſed the ſtroke upon the cotton. In *fig.* 1. the frame is marked B, and *o*, *o*, repreſent the levers *i*, C, *m*, *fig.* 3. The lever *g*, *fig.* 1, which is nearly in a vertical poſition, appears to have two of the rods *x* proceeding from it in oppoſite directions. This appearance is occaſioned by there being two levers in that poſition exactly behind each other, though they are moving in oppoſite directions, therefore one of the rods, *x*, remains upon the cotton at A: the other, which belongs to the lever concealed behind, is repreſented as juſt riſing from the cuſhion *d*. *Fig.* 2. is an edge view of the machine, where A repreſents the ſtrap which communicates motion to the machine by means of two pullies, called the live and dead pulley, from the circumſtance of one pulley being fitted looſe, ſo as to ſlip round freely upon the axis, whilſt the other pulley is fixed faſt upon the axis: therefore, when the endleſs ſtrap is ſhifted upon the looſe or dead pulley, it ſlips round without communicating any motion to the machine; but when it is ſhifted on the other pulley, the machine immediately commences its motion. E repreſents the fly-wheel on the oppoſite end of the axis, and B, B, B, B, are the four cranks which actuate the levers C, C, C, C: *f* is one of the rollers on which the endleſs cord or platform, D, is wound, and it extends from this to a ſimilar roller on which a wheel, *g*, is fixed; then returning again to the roller, *f*, and after having made in this manner more than twenty turns round the two rollers, the ends are ſtrained tight and ſpliced together, ſo that it appears like *fig.* 4, forming a platform on which the cotton lies, and is regularly carried from *f* to *g* by the motion given to the roller *f* through the cog-wheel *e*, and the other train of wheel-work which communicates with the main axis, as before deſcribed. At the ſides of the platform two boards are fixed which form a trough, and prevent the cotton getting off ſideways. The batting rods ſtrike down through openings or notches *d*, *d*, *d*, *d*, cut in theſe boards. The dotted lines repreſent other notches to admit the batting rods on the oppoſite ſide of the machine, which, as this figure ſhews, are not preciſely oppoſite, but the rods on one ſide ſtrike in the interval between thoſe of the others. The cotton, after paſſing along with the moving cords through the machine, is thrown off, and falls upon a table *i*, *fig.* 2, which is covered with an endleſs canvas cloth, and is ſtrained over two rollers *b*, *k*, which are kept in conſtant motion by an endleſs band paſſing round the wheels *b* and *g*. By this motion of the cloth the cotton is conveyed away as faſt as the batting machine finiſhes it, and is taken off this table by women, who diſcharge it into baſkets, in which it is conveyed to the picking room.

The opening Machine, or *Devil*.—This machine comes next to be deſcribed, being uſed for ſimilar purpoſes as the batting-machine, though it is not to be conſidered as one of the ſame ſeries, being uſed for the coarſer ſort of cotton in the ſame ſtage as the batting engine is uſed for the finer ſorts. *Plate* III. contains drawings of one of theſe machines, in which *fig.* 1. is a plan, and *fig.* 2. a ſection. In either of theſe A A repreſents a cylinder, put in rapid motion by an endleſs band paſſing round the pulley R. This cylinder has a great number of teeth fixed into its periphery, and the hood or arch, E E E E, contains a ſet of ſimilar teeth or ſpikes fixed withinſide it. This caſing conſiſts of a number of parallel bars or lags, one of which is ſhewn in perſpective in *fig.* 5: theſe are ſupported by an iron ſemicircle B B, *fig.* 3, alſo erected on each ſide of the frame. Each of theſe circles has a number of pins, P P, projecting from it, and every lag has a notch, or cleft, cut at each end, by which they are hung on theſe pins, forming a very ſimple manner of fixing the lags; but they can be eaſily removed when required, to clear the machine from the flue and impurities which it gets out of the cotton. In front of the cylinder a pair of feeling rollers, *d*, *d*, are fixed, through which the cotton paſſes to the machine: theſe rollers are fluted and placed immediately above each other, as ſhewn in *fig.* 2; then a heavy weight L, being ſuſpended from the pivots of the upper roller, cauſes them to preſs together with a ſufficient force to draw cotton in between them, and the flutes or indentations of the two rollers mutually locking into each other, they take the cotton more certainly. The lower roller is turned round by means of a bevilled wheel *l*, *fig.* 1, fixed on its ſpindle, which receives its motion from a ſimilar bevilled wheel *k*, fixed on the extreme end of a ſpindle I, fixed perpendicularly to the axis of the main cylinder, and receiving its motion therefrom by a wheel *h*, which is turned by an endleſs ſcrew *g*, cut upon the extremity of the ſpindle of the great cylinder.

The cotton is ſpread upon an endleſs revolving cloth, which is ſtrained between two rollers, *a*, *b*, and is in conſtant motion, in the direction of the arrow in *fig.* 2. This motion is communicated to the roller, *a*, by means of equal cog-wheels *d*, *d*, which are connected by an intermediate toothed wheel, as ſhewn in *fig.* 2; M S is a grating, or frame of braſs wire (ſhewn ſeparate in *fig.* 4.) which is extended beneath the cylinder, and againſt this the cotton is urged by the action of the teeth of the cylinder, and the dirt, duſt, and flue, eſcape through it. It ſhould be obſerved, that the frame for the machine is cloſely boarded up on all ſides, to keep in the duſt and flue which is ſeparated from the cotton. *Fig.* 5. ſhews the form of one of the lags, and the manner in which the teeth are diſpoſed in it, ſo that the teeth in the ſeveral rows fall oppoſite the ſpaces between the teeth of the others: at *i* is a ſmall ſlip of ſheet iron, which ſtands up perpendicular to the face of the lag like the ſpikes, and is ſupported by a kind of wedge, or prop of wood, as ſeen in the ſection of the machine, *fig.* 2. Theſe ſlips of iron run acroſs the whole length: the teeth on the cylinder are diſpoſed in a ſimilar manner, and are provided with a ſimilar iron plate. Their uſe is to retain the cotton which is worked in the machine from paſſing through too quickly, and eſcaping without being ſufficiently worked by the teeth. The cotton is ſpread evenly upon the cloth *b d*, which being in conſtant motion towards the cylinder, carries the cotton along upon it, and delivers it between the two rollers *d*, *d*: theſe give it regularly to the cylinder, which is rapidly revolving in the direction of the arrow near A: its teeth take the cotton, and carry it round between the cylinder and the hood, working it between them, to open and unravel every knot or tuft of cotton, part of which gets formed by the action of the cylinder into a ſmall roll at every one of the iron plates *i*, and this roll, by the motion of the cylinder, keeps revolving ſlowly round, ſo that every part of its circumference is ſucceſſively ſubjected to the action of the teeth of the cylinder

 as

as they pafs by them. The plates upon the cylinder act in a fimilar manner, and when the cotton is thrown out finifhed at M, upon the floor immediately beneath the feet cloth, it has been opened in every part, fo as to completely difentangle it, and the duft, cotton feeds, or any other extraneous matter, drops out through the wire grating, S M, upon the floor.

The opening machines ufed in fome of the moft improved mills, are provided with two cylinders revolving againft each other, fo that they refemble two of thefe machines put together, by which means the cotton is more completely worked in paffing through them. The cylinders have then none of the plates fixed upon them, becaufe they are unneceffary, and the fpikes or teeth are arranged in a fpiral line round the circumference of each cylinder, fo that they do not in their motion fall behind each other, and therefore work and open the cotton more effectually. Another great improvement in this double cylinder machine, is the addition of a flue or trunk, which proceeds horizontally from the opening or mouth M, where the cotton is delivered, for a confiderable diftance, and in the bottom of this is a revolving cloth, which receives the cotton as it is thrown out, and conveys it away to the end of the room containing the machine. Here it falls out into a bafket, in which it is conveyed away to the picking room. The flue or trunk at this point rifes up, and leads into a chamber of confiderable fize, and from this returns by a fmall trunk to the back of the machine. The operation of this trunk is, that the wind raifed by the rapid motion of the cylinders proceeds along this narrow trunk with a confiderable velocity, and blowing along over the furface of the cotton, which is traverfing flowly along with the endlefs cloth in the bottom of the trunk, it carries away the flue or fmall cotton with the ftream into the large chamber above-mentioned. Here, in confequence of the large area which the air has to pafs through, the current is very flow, and the flue fubfides quietly on the floor of it, from which it may be taken up in confiderable quantities every week, and is a valuable article for making candlewick, or to mix with inferior cottons for that purpofe; whereas, if fuffered to fly about in the rooms, as in the machine delineated, it does great injury to the work people, for this flue is taken into the lungs by the refpiration, caufing afthma, and pulmonary complaints: but in the improved machine, this flue is preferved for ufeful purpofes.

The next machine, in the order of the cotton manufacture, is the *Carding machine*. This is fhewn in *Plate* IV., where *fig*. 1. is a plan, *fig*. 2. a fection, *fig*. 3. an elevation, and *fig*. 4, various parts to explain the action of this machine. It will not be amifs firft to give a fhort idea of the nature of the operation to be performed by the machine. The card may be compared to a brufh made with wires inftead of hairs, ftuck through a fheet of leather; the wires not being perpendicular to the plane, but all inclined one way in a certain angle. See *fig*. 4. of this plate, where D, C, are thefe fheets of leather for a pair of cards, and A, A, or B, B, reprefent the teeth or card-wires refpectively belonging to each. Beneath is a view of one wire, infulated, fhewing the two teeth, with their bend in the fhank, or what is called knee-bend, by which they are inclined to the leather in the manner before mentioned. Now we may conceive that, cotton being ftuck upon the teeth of one of thefe cards, another may be applied to it, and combed or fcraped in fuch a direction as to ftrike the cotton inwards upon the teeth, rather than tend to draw it out. The confequence of a repetition of the ftrokes of the empty card, in this direction upon the full one, is a more equable diftribution of the cotton upon the furface of the card-teeth; and in doing this, the fibres are combed and laid ftraight. Then if one card be drawn in an oppofite direction over the other, it will, in confequence of the inclination of its wires, take the whole of the cotton out of the card, whofe inclination is the contrary way. In this mode, the operation was formerly conducted by fheets of cards nailed upon boards, which were worked together by hand. To explain how the carding machine imitates this procefs, we muft return to the figures, in which A A is a large cylinder, turned rapidly round by an endlefs ftrap on the pulley R. The furface of the cylinder is covered with cards, the fheets of leather for which are glued or nailed on in ftripes or fheets parallel with its axis, and difpofed in fuch a direction, that when it revolves in the direction of the arrow, the teeth upon it go with their points forward, fo that if a lock of cotton was held againft them, it would be drawn inwards upon the teeth. The cylinder revolves under an arch C C, lined with the fame kinds of cards as fhewn in *fig*. 2; the teeth difpofed to meet thofe of the cylinder. This arch of cards is fupported on two iron arches, fixed on each fide of the cylinder. Thefe iron arches or bridges have fpikes on them, on which the feveral pieces, lags, or flats which compofe the arch are faftened; exactly the fame as defcribed in *Plate* III. of the opening machine.

One of the iron arches is fhewn at E E, in *fig*. 2, but is not drawn off its full breadth, becaufe it would have concealed the furface of the cylinder from the fight; but in *fig*. 1. they are feen at C C, and in *fig*. 3. at *f f*. The card-teeth on the cylinder, and thefe beneath the arch, do not touch each other, but work as clofe together that a half crown can be put in the fpace between them without touching, and they are made very accurately circular, that they may always accurately preferve the fame diftance between.

B is a fecond cylinder of cards, the teeth meeting the firft, as the figure fhews. This cylinder revolves much flower than the firft, its motion being taken from a fmall pinion, *t*, *fig*. 1, on the end of the axis of the great cylinder. This works a wheel, fituated on a ftud or pin *s*; which has alfo a pinion fixed to it, working a wheel *t*, fitted on another ftud, and this carries a fmall pulley *v*, which communicates by an endlefs ftrap with a pulley, E, fixed on the end of the fpindle of the fmall cylinder. As the whole of this train of wheel-work confifts of fmall wheels turning large ones, it is plain the motion of the cylinder, B, muft be very flow. On the oppofite end of its axis is a bevilled wheel W, working another upon the end of an axis *h*, which has, at its oppofite extremity, a pinion, turning a face or contrate wheel *i*, which is on the axis of the fluted feeding rollers between which the cotton paffes, and is delivered to the cylinder. The cotton is, as was before defcribed of the opening machine, fpread out upon a feeding cloth D, which traverfes conftantly round two rollers *k* and *l l*, one of which is turned by a pinion from the feeding rollers by means of an intermediate wheel at *k*. A fmall heavy roller, or cylindrical weight, is put upon the cloth beneath, as fhewn at *f*, *fig*. 2, and, by its weight, always keeps the cloth to its proper tenfion, preferving a flat furface above, for the cotton to be fpread out upon, and then advancing with the cloth, it is thrown in between the fluted feeding rollers, which deliver it gradually and equably to the cylinder, which carries it round, and works it againft the cards fixed withinfide the arch. In this procefs it becomes very equably diftributed over the teeth in the cylinder, and gets carded in fo doing. The cotton continues in this manner hanging fometimes in the teeth of the cylinder, and fometimes in thofe of the arch, but advancing flowly from one tooth to the next, till it has paffed clear through the arch, and then it comes to the fmall cylinder B, which, as before-mentioned, is revolving flowly, in fuch a direction that its

furface

ſurface moves the ſame way as the cylinder, but much ſlower, and its teeth meet the teeth of the cylinder. Now, as before ſtated, it is the property of two cards meeting each other to diſtribute the cotton between them; therefore, the teeth of the cylinder B, having no cotton upon them, receive a full half of what is upon the teeth of the cylinder A, and as it conſtantly turns round, and bringing up freſh empty teeth, which in their turn take away the cotton from the great cylinder in a conſtant ſtream, and would ſoon empty it, but that it is ſupplied again with raw cotton from the feeding roller. The cotton taken up by the cylinder B, proceeds with it beneath, till it comes to the oppoſite ſide, and then it is removed by the *taker off*. This is a rod or iron bar *g g*, ſituated parallel to the axis of the cylinder, and cut on the lower edge with fine teeth like a comb. It riſes and falls parallel to itſelf, by being united to two rods, K, which are guided by ſliding through ſmall holes made in two ſtandards ſhewn in *fig.* 2, and the lower ends of theſe rods are jointed to two cranks *e*, *e*, *fig.* 3, formed on a ſpindle, which is turned by a pulley *p*, with an endleſs ſtrap from a pulley, S, fixed on the main axis, cloſe behind the great pulley R. Now by the motion of theſe cranks, the rod *g* riſes and falls, and at the ſame time moves a little to and from the ſurface of the cylinder B: indeed it deſcribes a kind of ellipſis, and being ſo contrived by the direction of the motion of the cranks (cauſed by croſſing the ſtrap which works them), that it is deſcending at the time when its edge is neareſt to the cylinder, and ſcrapes downwards againſt, or rather between the teeth thereof, and in conſequence removes the cotton from them the whole length of the cylinder at once: and the motion of the crank is ſo quick, that by the time this piece of cotton, ſo detached from the teeth of the great cylinder, has moved round with the cylinder, B, as much as its own breadth, the crank makes another ſtroke, and, in conſequence, the ſecond piece detached from the teeth adheres to the firſt: the third adheres to the ſecond, and ſo on. The cotton is thus *ſtripped* or ſkinned off the cylinder, B, in a continued and connected fleece. The diſpoſal of this fleece conſtitutes the only difference between the breaking and finiſhing card. In the former it is received upon a plain cylinder, about half the ſize of the great cylinder A A, which is turned round with a proper velocity by an endleſs cord from a pulley on the axis of the cylinder B, a ſmall roller reſting lightly upon the top of this cylinder with its own weight, and by its preſſure cauſes the fleece to lap regularly upon the cylinder, which continues to turn until it has made 15 or 20 revolutions. The fleece, being then broken off, forms a ſmall fleece, conſiſting of 15 or 20 thickneſſes, called the lap, which is carried to the finiſhing card, and treated exactly as the raw cotton was at firſt. The advantage of this method of treating the cotton has been explained, in a preceding part of this article, to conſiſt in the great equality thus produced in the thickneſs of the lap, which being fed to the finiſhing card will produce an equable and regular ſliver therefrom, and on this circumſtance the perfection of the ultimate thread very intimately depends.

The finiſhing card is that which is repreſented in *Plate* IV. The fleece or lap produced by the breaking card is ſpread out upon the feeding cloth D, and thus introduced to the machine, which cards it in exactly the ſame manner as we have deſcribed, and the taker off operates in the ſame way. But the fleece F, *fig.* 1, inſtead of going to the lapping cylinder, as we have deſcribed, is gathered up into a tin funnel marked *m* in *fig.* 1, and *l* in *fig.* 2: it then paſſes between a pair of rollers *m n*, which compreſs and flatten the fleece in its contracted ſtate into a pretty firm and connected ſliver or band, and deliver it into a can *n*. Theſe rollers are ſituated upon a ſpindle extending acroſs the frame, and turned round by a pulley upon the end of it, which is connected by an endleſs band with the pulley E, upon the ſpindle of the cylinder B. By theſe means the cotton is reduced from the wool to a fine regular and even ſliver, which is conveyed away in the tin can to the drawing frame, which we ſhall ſoon deſcribe.

The carding engines in many mills are provided with ſmall cylinders, known among the workmen by the technical term of *urchins*. Theſe are covered with cards, and revolve, ſo that their teeth act with the teeth of the great cylinder, through proper openings left between the top lags of the arch. Theſe ſmall cylinders are turned round ſlowly by proper bands and pullies from the main axis. Theſe urchins are ſituated in pairs, one of which operates to take the cotton off the great cylinder, in the ſame manner as deſcribed of the cylinder B; but inſtead of being provided with a taker off, to ſtrip the cotton from its ſurface, it runs cloſe to the other urchin, of ſimilar dimenſions to itſelf, but turning with a different velocity, and the teeth meeting, ſo as to take it off the firſt urchin. This ſecond urchin, having thus become charged with cotton, delivers it again to the great cylinder. The object of this contrivance is to obtain a more perfectly equal diſtribution of the cotton upon the ſurface of the cylinder, at the ſame time the urchins tend, by giving the cotton to the cylinder in a new direction, to work it more, as they prevent the cotton paſſing ſo quickly through the machine. The employment of urchins does not ſeem to afford any very great advantages, and it is not a very general ſyſtem. When an urchin is applied to the lower part of the cylinder, immediately beneath the feeding roller, it is called a *tummer*: in this caſe it takes the cotton from the feed rolls, and gives it to the great cylinder as it revolves. The great cylinder of a carding engine, as well as any other part where the flue can eſcape, ſhould be carefully incloſed by a tin plate, or thin boarding, to prevent its eſcape into the room, where it does great injury to the work people, producing an irritating and inceſſant cough, which is exceedingly hurtful, as well as the pernicious effects of ſuch extraneous matter being received into the lungs. Carding engines have been uſed with two great cylinders, ſurrounded by a multitude of ſmall urchins, in the ſame manner as thoſe uſed for wool. (See Woollen *Manufacture*.) Theſe, having two cylinders, card the cotton ſufficiently at one operation, without uſing a breaking card. The method is not near ſo perfect, becauſe the equality and regularity of the ſliver, produced by doubling the lap of the breaker 15 or 20 times, cannot be ſo completely attained by any other means, but leaves this equalization to be performed in the drawing frame. The double card, however, anſwers very well for coarſe goods, and ſaves a great deal of attendance in conveying the lap of the breaking card to the feeding cloth of the finiſher. Since the time that the drawing for *Plate* IV. was made, the cotton manufacturers have almoſt univerſally adopted what were at that time only partially employed, *viz.* caſt iron frames for the carding machines, and iron circles for the cylinders, which are covered with lags of the beſt ſeaſoned mahogany, or other wood leaſt liable to warp. Theſe circumſtances, though they do not alter the parts of the machine, are great improvements of it, as the ſteadineſs of ſuch framing, and the ſtability of their figure, enables the cylinders to run much cloſer together, without the danger of the teeth of the cylinder coming in contact at times, as they will ſometimes do in wooden frames, and thus deſtroy the card teeth very ſoon, as well as produce leſs perfect work. The ſame remark applies to all the other cotton machines, and, in point of expence, caſt iron is far cheaper than wood when

when a number of the fame part are to be made, fo that they can all be caft from the fame pattern: in point of ftability and duration no comparifon can be made; and when the mill is built fire proof, the fafety from fire is not a trifling advantage, as it faves the manufacturer the heavy expence of infurance, or, what of courfe is nearly equal, the rifk of lofing his property by fire.

The drawing frame comes next to be defcribed. *Plate* V. *fig.* 1. is an elevation of the machine, and *fig.* 2. is a plan of what is called a drawing frame of four heads, which is, in fact, a fyftem compofed of four diftinct machines of exactly the fame conftruction, but arranged on one frame, in the moft convenient pofition to be ufed fucceffively. *Fig.* 3. is a front view of one of the heads or feparate machines drawn detached; and *fig.* 4. is a fection anfwering to it. In *fig.* 1. A reprefents a clufter, confifting of four of the cans brought from the carding machine: the four flivers from thefe are paffed through the rollers of the machine, and united into one fliver, which is received in the can C, the machine having drawn it out, and extended it to four times the length of the others; it is therefore the fame fize as any one of them. The conftruction of the rollers is explained by *fig.* 3, and alfo the figure at the left hand end of *fig.* 2, in which *a b* reprefents a live and dead pulley, upon the fpindle of the principal, or front roller, by which it receives its motion from an endlefs ftrap. This roller is fhewn, in *figs.* 2. and 3, to be double, that is, it has two lengths or acting rollers upon it, each of which receives two diftinct flivers from the cans *l l*, *l l*, *fig.* 2. In *fig.* 4. thefe two lengths of rollers appear like one, being behind each other, and exhibiting the circle marked *a*, the other circle defcribed within this being the neck between the two lengths. This roller has another, marked *b*, placed directly over it, the pivots of which are retained in a vertical notch in the frame, and immediately above the pivots for the lower roller, as is fhewn in *fig.* 1; fo that the whole weight of the upper roller refts upon the furface of the lower one, the bearings or notches in which its pivots are received being only to guide, not fupport it. Another pair of fimilar rollers, *c d*, are fituated at a fmall diftance from the former, and receive their motion by pinions *c*, *d*, *figs.* 2 and 3, which are fixed on the pivots of each refpectively, and are connected by an intermediate wheel, *e*, fitted loofely on a ftud, in the manner very plainly fhewn in *fig.* 1, which alfo expreffes the grooves or notches in the ftandards; in thefe the pivots of the rollers are retained fideways upon one another, but, as before mentioned, the upper one refts upon the lower one. A fmall crofs bar, *i*, *fig.* 4, extends from the pivot, or neck, of one of the upper rollers, *d*, to that of the other one, *b*; and from the centre of this bar an iron rod, with a heavy weight, *f*, at the lower end of it, is fufpended by a hook formed at the upper end; fo that this weight, as well as the weight of the upper rollers themfelves, prefs the upper rollers, *b*, *d*, upon the lower ones, *a*, *c*, and thus the fliver of cotton, *g*, which paffes between them, is held very firmly down on the flutes in the furface of the lower roller, and cannot flip between them. The wheel *c*, *figs.* 2 and 3, which is fixed upon the pivot of the firft roller, is much fmaller in diameter than the wheel, *d*, upon the pivot of the back roller, to which it gives motion by the intermediate wheel *e*; therefore it follows, that the motion of the front rollers, *a*, *b*, *fig.* 4, will be as much quicker than the back roller *c d*, in proportion as the wheel, *d*, is larger than the wheel, *c*, which gives it motion; that is, the number of revolutions they will refpectively make in any given fpace of time (as a minute for inftance) will bear that proportion: but the back roller, *c*, (as fhewn in *fig.* 4.) is much fmaller than the other. The velocity of its circumference will, therefore, be flower than *a*, in a ftill greater proportion than the proportion of the two wheels; and the proportion is fuch, that the roller, *a b*, will, or ought to, draw four times the length of cotton through them which the back pair, *c d*, will permit to pafs in the fame time. The four flivers, therefore, being introduced from the cans *l*, *l*, *l*, *l*, *fig.* 2, between the back rollers *c*, *d*, *fig.* 4, and preffed with fuch force upon the flutes of the lower roller *c*, that they cannot flip through them, and the other pair of rollers, *a b*, holding the flivers in the fame manner at another part, the confequence of their different velocities is, that as the front rollers, *a*, *b*, *fig.* 4, move fo much quicker, they draw the fliver forwards fafter than the back rollers will fuffer it to come; it muft be drawn out, or extended in length, between the two pair of rollers, in proportion to their relative velocities, which, as before-mentioned, is the fame as the proportion between the wheels *c*, *d*, *figs.* 2 and 3, communicating the motion from one to the other, multiplied by the proportion between the diameter of the two rollers, *a* and *c*, *fig.* 4. The four flivers, after paffing through thefe in two diftinct pairs, are all drawn together through a tin funnel *f*, *fig.* 2, by means of a pair of rollers, the upper one, *i*, of which merely preffes upon the fliver lightly by its own weight, and delivers it into the can *k*: the loweft of this pair of rollers receives its motion from the pinion, *c*, on the end of the fpindle of the main, or front rollers, by means of an intermediate wheel, *g*, fitted upon a ftud or pin in the frame, and turning a pinion, *h*, fixed on the extremity of the fpindle of the lower of the two rollers. Thefe pair of rollers do not draw or extend the cotton, their velocities being accurately adapted to take up the four flivers as faft as they come through the others in two diftinct pairs, and by drawing them through the funnel, *f*, to unite the four into one, and the flight preffure of the roller compreffes them into a firm and connected fliver, which, though compounded of four, is only the fame fize as any one of the four put in, becaufe it is drawn out to four times the length, and the effect of the machine has only been to ftraighten and lay the fibres parallel to each other; for the motion the drawing produces among them, always tends to extend each individual fibre to its full length: and it is neceffary to unite feveral flivers together, or the drawing would reduce the fliver to fuch a fmall fize, that it would not bear fufficient extenfion without feparating and breaking acrofs. The plan, *fig.* 2, fhews the difpofition of four diftinct heads, or fets of rollers, A, B, C, D, all fixed upon one iron frame, E, the upright of which is fhewn in *fig.* 1. D is the firft head, or that through which the flivers from the carding engine in the cans, *m*, *m*, *m*, *m*, are firft drawn and united into one, which is delivered into the can *n*. In this head fix cans, or ends, are fhewn entering at once, in two fets of three each, and are all united into one, which will, therefore, if the rollers only draw four times, be rather thicker than thofe put in; but the number of ends put in, as well as the *draught* of the rollers, is optional: and as the command of the cotton-fpinner, who alters them for different kinds of cotton, or different kinds of yarn to be fpun as he finds beft, having the means of changing the pinions for others of different fizes. It is plain that the can, *n*, will be filled with the fliver in one-fourth or one-fixth of the time that the four or fix cans, *m m*, will be exhaufted; and, therefore, it will furnifh four cans, or ends, to the fecond head, *c*, which are placed at *o*, and drawn into one at *p*. Four of thefe, when filled, go to *q*, and are drawn into one by the head B, and delivered into *r*, which is taken to *s*, and by the head A, delivered finifhed into the can *k*, in which it is carried to the roving frame. The feveral heads, as the figure fhews, are reverfed,

reverfed, with refpect to each other, on the frame, to avoid the neceffity of carrying the cans round to the oppofite fide of the frame in paffing from one head to the next. Being thus reverfed, that is, the fliver of one moving in a contrary direction to that next it, it requires the ftraps, which turn the feveral live and dead pullies, and which all come from one common axis, on which as many drums are fixed, to be alternately croffed, and put on in the common manner.

The drawing frame in *Plate* V. has now (1812) been drawn fome years by a gentleman at Manchefter, fince which, the cotton manufacturers have very generally adopted a method of ufing three, and fometimes four pairs of rollers, inftead of only two pair in each head: by this means, they draw the cotton at two or three times, and, by extending it only a fmall quantity at each, it is found to draw much more equably than by taking the whole draught at once. The conftruction of one of thefe heads will be readily underftood, by examining a figure in the drawing (*Plate* IX.) of the fpinning-frame we fhall fhortly defcribe, which drawing the writer of this article made from one of the fpinning-frames in one of the moft complete cotton-mills in the kingdom. The rollers ufed in this fpinning and the drawing-frame are fo nearly alike, that one may be very well underftood from a defcription of the other.

The Roving-frame.—The preceding machines having prepared a fliver, of which the fibres are laid parallel, it is neceffary to reduce this fliver to a convenient fize for fpinning into a fmall thread: but to make a fufficient extenfion to effect this reduction, it is neceffary to give the fliver a flight twift as it is drawn, that it may have fufficient cohefion to undergo the fpinning.

The preparation of fuch rovings as fhall be perfectly regular in fize, and have an equal quantity of twift in every part, and which fhall be exceedingly foft, is a moft effential point in cotton-fpinning. As it is impoffible to correct thefe imperfections in the fpinning, they will be given to the thread. A great number of different conftructions of roving-frame have been in repute, at different periods, among cotton-fpinners; but it is only lately that by a machine, called the double-fpeeder, it has been brought to perfection. The old roving-can frame, firft introduced by fir R. Arkwright, is reprefented in *Plate* VI., which was drawn when that machine was much more extenfively ufed than it is now. The figure immediately beneath the title of this plate is a plan of the roving-can frame, and the figure below is a front elevation: in thefe, A is a horizontal beam fupported by ftandards at each end, and carrying the feveral heads of rollers, and is therefore called the roller-beam. The machine contains four heads or frames of rollers, each of which receives four ends or flivers from the cans, D, D. See alfo the fection in the corner. They enter two together between the back roller *c*, and are drawn out between them and the front rollers, *b*, *d*, to the proper degree of finenefs, but which varies with the quality of the yarn which is to be fpun. The fliver, after paffing through the rollers, is received into a tin can C, through a fmall funnel, N, at the mouth thereof. The can is fupported on a pivot at bottom, and is kept in rapid motion by a band, working on a pulley fixed at the bottom of the can. The neck of the funnel, N, is guided by a collar, to keep the can fteadily upright, as it revolves. The rollers of the machine are the fame as thofe of the drawing-frame: they are turned by endlefs ftraps upon the pullies, *p*, of the front rollers, coming up from fimilar pullies on an horizontal fpindle extended beneath the machine, through its whole length, and receiving motion by a live and dead pulley, E F, from the mill. The fame fpindle has pullies upon it, which, by means of bands, actuate the pullies on the bottom of the can. Thefe bands are of courfe conducted over pullies, to change their directions, from the vertical pullies on the fpindle of E F to the horizontal pullies on the bottom of the cans; but thefe are not fhewn in the drawings. Each of the bands drives two cans, paffing round the pullies of both. The cans are made with a door, to open on one fide, for taking out the cotton-roving, which falls into them from the rollers; and this door is kept clofed by a ring, which fits upon the outfide of the can, and keeps the door fhut, when pufhed down to the largeft part of the cone; but when lifted up to the top, as fhewn near N, the door can be opened, and the contained cotton taken out. L is what is called the clearer: it is a piece of wood placed over the top-rollers, and preffing gently upon them; its ufe is to prevent any part of the cotton *lapping*, that is, adhering to the roller, and being carried round with it, fo as to wind it up, inftead of drawing it through. The manner of action, in this machine, is eafily gathered from the defcription: the flivers pafs two together through the rollers, and are reduced or drawn out therein to the proper degree of finenefs; then falling into the funnels, N, of the revolving cans, they are, by the rapid motion thereof, twifted round; becaufe the centrifugal force difpofes the cotton to lie round the infide of the can in a regular coil, forming as it were a lining of cotton to the whole of the interior furface; and by this means the end of the roving becomes in a meafure attached to the can, and is twifted round by its motion, fo as to form a coarfe loofe thread, with a very flight twift, and a very foft and open fubftance. The cans, when they have been in motion fuch a length of time as the attendant knows, by experience, they will be full of cotton, the ring is raifed up, and the door opened to take out the roving, which is put into a box, and carried to a fimple machine, called the winding-block: fee the figure at the right hand corner of the plate. In this figure, which is an elevation, the box, containing two piles or coils of the roving, is plainly feen: juft above it is a cylinder of confiderable fize, mounted upon a proper fpindle, which is turned round by means of a winch: *k*, *k*, are two fmall bobbins, mounted on a wire, and receiving the end of the roving; they reft with their weight upon the furface of the great cylinder, and are by the motion thereof turned rapidly round, fo as to wind up the roving very quickly on them. The rovings are conducted through holes in a ftrip or ruler of wood, which is moved flowly backwards and forwards, to lay the cotton equally on all parts of the length of the bobbin, and make a cylindric figure to the furface of the cotton wound upon it. It is the neceffity for this winding of the cotton upon bobbins by a feparate procefs, which is the greateft objection to the roving-can frame, becaufe the tender roving is damaged by every operation it undergoes, *viz.* removing it from the cans, and winding it upon the bobbins, which muft be done preparatory to the fpinning. Another objection to the roving-can frame is the uncertainty in the manner of twifting; becaufe, when the cotton applies itfelf to the interior furface of the can, by the centrifugal force, it occafions a ftretching or draught on the roving, tending to lengthen it out before it is fufficiently twifted to make any refiftance to the flighteft draught. This would occafion no inconvenience, if the degree of draught or extenfion thus occafioned was conftant, and uniformly the fame; but this is not the cafe: for it conftantly happens that the roving, by gradually gathering from the circumference toward the centre of the can, in the manner of a fpiral, and when it arrives in the centre it coincides with the axis of the can, and of courfe, as no centrifugal force operates to draw it out in length, it merely twifts it round.

round. In confequence of thefe irregularities in the action, which are conftantly happening, the rovings thus produced are always full of thick and thin places; for when the cotton lies clofe at the infide of the can, it is confiderably ftretched by the centrifugal force, and becomes thinner and longer, and with lefs twift in any given length; but when it happens to fall in the centre of the can, it is of a larger fize, and of a more rapid twift: but the quantity of thefe irregularities is very uncertain, becaufe, even when the end of the roving, where it refts upon the coil of it, which is fettled in the bottom of the can, is in the centre of the can, it is to be prefumed that no draught will take place; but this is not certain, becaufe the roving may fwing out into a belly, and by its vibration will occafion fome draught, though not fo great as in the firft inftance. For thefe reafons, the roving-cans are not found to produce fuch perfect rovings as many other methods, and they are generally laid afide. Sir R. Arkwright faw thefe defects at firft, and in his earlieft machine devifed a pair of rollers to be placed in the mouth of the funnel of the can, which were, by very ingenious mechanifm, kept in conftant motion, with fuch a velocity as to gather the cotton fliver regularly into the can, as faft as it was delivered by the drawing-rollers. By thefe means the fliver was held between thefe rollers, and, from their revolution with the can, received a determinate quantity of twift for every given portion of length. The difficulties of this were very great, to caufe the rollers, in the mouth of the can, to take the fliver with the exact velocity required, as faft as the upper rollers delivered it; and even when this was accomplifhed, the objections we have pointed out would in fome meafure take place within the can; and after all the operation of winding the rovings upon the bobbins, preparatory for the fpinning-frame, by the winding-block, is certain to do them injury, ftretching and extending them improperly. The next improvement in roving was the ufe of *fkeleton-cans:* thefe are light frames of iron, revolving on vertical pivots, in the manner of the cans themfelves, in *Plate* VI. Within each of thefe fkeletons or frames a common tin can is placed, and revolves with them, receiving the rovings as we have above defcribed. Thefe cans, when full, are removed to a machine called the ftretching-frame, which gives them rather more twift, and extends them ftill farther in length, at the fame time winding them on bobbins, which are called cops or coppins, being bobbins with only one end, the other end being a point, fo that the cop in figure refembles a *firball*, or pine-apple. The conftruction of the ftretching-frame is the fame, except in its proportions, as the mule: we muft, therefore, defer the defcription of this method of roving till we have explained the mule, when we come to fpeak of the fpinning procefs. Many mills, where cotton is fpun on the moft improved and economic fyftem, have adopted a method of roving altogether upon the ftretching-frame, producing rovings at once from the flivers of the drawing-frame; and this method is found to fucceed very well, and be a great improvement upon the method of employing the roving-can frame. We fhall next defcribe a roving machine, called by the workmen in cotton-mills,

The Double-fpeeder.—This is a roving-frame, which is extremely perfect in its operation, making better work than any other method: it is an improvement upon fome machines made by fir Richard Arkwright, at a very early period of the cotton manufacture; but the improvements are fo effential and ingenious, that the maker or makers of them deferve the whole credit. Who is entitled to the invention of thefe improvements, we have not been informed; but we have feen machines, made by Samuel Smith of Ramfbottom, near Bury in Lancafhire, which were extremely good. The drawings, entitled *Plate* VII., or roving-frame, *Plate* I. alfo *Plate* VIII. *Cotton Manufacture*, which we have given of this machine, have, like thofe preceding it, been made before the improvements were brought to the perfection they have fince attained; and though the machine has the fame parts, the proportions are fuch, that a machine, made exactly after them, would not operate fo completely as thofe made by Mr. Smith, to whom we refer cotton manufacturers, who wifh to adopt fuch machines, rather than attempting to make them from the drawings in our plates. They will ferve, however, to illuftrate the principles and mode of their conftruction. *Plate* I. is a horizontal plan of the machine; and *Plate* VIII. is an elevation, taken in front of the machine. In this figure, A reprefents the live and dead pulley, which communicates motion to the whole: it is fixed on a fhort axis, on the extreme end of which is a pulley, B, which communicates, by an endlefs ftrap, with another pulley, D, on an horizontal axis *g*: and this has at the end a bevilled wheel, which turns another on a vertical axis *k*, at the lower end of which a conical drum or barrel, H, is fixed; and beneath this it is formed cylindrical, to receive a ftrap, which paffes round the pullies, *h*, *h*, on the lower ends of the feveral fpindles, I, I, I; and then returning to the drum again, the ends are united, and form an endlefs belt, which runs round the whole, turning them all at once with the fame velocity: *l*, *l*, are fmall rollers, fituated at intervals between every two pair of the fpindles; thefe bend the ftrap out of the ftraight line, and thus caufe it to prefs againft the pullies, *h*, *h*, of the fpindles, and apply to a fufficient portion of their furface, to turn them round. This is very plainly fhewn in *Plate* I.: each of the fpindles, I, I, I, has at its upper end a forked piece of iron, *q q*, fixed on, which is called the flyer; and one of the forks is made tubular, to receive the roving as faft as it is twifted by the motion of the flyer, and convey it to the bobbin, which is fitted quite loofely on the fpindle. The cans from the drawing-frame are, as fhewn in *Plate* I., fet behind the machine; and the flivers are drawn through a double pair of drawing-rollers, turned by means of a train of wheel-work from the main fpindle, bearing the live and dead pulley, A, *Plate* VIII. The flivers pafs fingly through the rollers, and are drawn out or extended fingly; they then pafs forwards, and two are drawn together through another double pair of drawing-rollers, the front pair of which are fhewn at *c*, *c*, in *Plate* VIII.: *a*, *b*, are the pair of wheels which turn them from the main fpindle; *f*, *f*, the weights; and *e*, the clearer. Thefe rollers deliver the fliver to the flyers, at the top of the fpindles, I, I, where it firft paffes through a collar, or eye-hole, *r*, formed on each of the flyers, exactly in the centre of the fpindle, and thence it paffes through the tube, *q*, before mentioned, to the bobbin *p*: the two back pair of rollers extend or draw out the fliver twice; then the two front pair, which are fhewn in *Plate* VIII., draw it again, and the fpindles twift it once for every inch and a half. The tube of the flyer, running fwiftly round the bobbin, lays the roving upon it as faft as the rollers deliver it out. The bobbins, *p*, *p*, are conftructed fo as to rife and fall upon the fpindles, I, I, that they may lay the roving, coming from the end of the tube *q*, regularly upon the length of the bobbin. This is done by an horizontal bar, or rail of wood, N, which has holes through it, to admit the feveral fpindles I, I, I, and the weight of the bobbin *p*, *p*, refts upon it; fo that when it rifes and falls parallel to itfelf, it takes the bobbins with it, elevating them as at *p*, in *fig.* 2. In this pofition, the bobbin receives the roving, and winds it on the lower part of them; but as the machine continues to wind, the rail with the bobbins gradually fink down; fo that every turn of the roving falls clofe to, but not upon, the former turn, thus difpofing it equally through

through all the length of the bobbins; and when they have descended to the lowest point, and the bobbins have been filled up to the top, it rises gradually up again. This ascending and descending motion of the rail and bobbins is thus produced: the vertical axis of the conical drum, H, has a bevilled wheel upon it beneath, (not seen in the figure,) which turns another, *s*, fixed on an horizontal spindle; at the other end of which is a pinion, *t*, turning a toothed wheel upon the end of an horizontal axis *v*, which carries a bevilled wheel *w*, turning another, on a vertical axis *y*, which has an endless screw at the upper end, turning a wheel, R, upon a long horizontal axis, which has two pullies or wheels, M, on it: each of these receive a chain, which chains, at the lower end, support the rail N; and when the chains wind up, they elevate the rail with the bobbins; but when they let down the chains, the rail, N, descends. The reversion of the motion which is necessary to effect this, is done by the wheel, *w*, having another bevilled wheel, exactly similar to it, fixed on the same spindle *v*, and very near to the horizontal wheel worked by it: therefore this wheel, on the spindle *y*, being made to work either in one of these wheels or the other, will, in consequence, turn round one way or the other, elevating or depressing the rail N, and the bobbins accordingly: the lower pivot of the vertical axis, *y*, is supported in a horizontal lever, which is, by the motion of the rail N, when it arrives at the highest point of its movement, moved to bring the wheel to work in the opposite bevilled wheel, on the spindle *v*; and then it turns M in a contrary direction, bringing the rail, N, down again; and when it arrives at the lowest point, the bevilled wheel is again thrown in gear with the wheel *w*, and being thus turned in a contrary direction, it raises the bobbins up again. The connecting parts by which the bevilled wheel is shifted every time it is necessary to reverse the motion, are not shewn in the drawing, but they may easily be imagined: *x*, *x*, represent the weights which are suspended from the upper front rollers, the same as those used in the drawing frame.

What we have hitherto explained of this machine is the original roving-frame, tried by sir Richard Arkwright on finding the defects of the roving-can frame. The objections to this machine in its original state were, that the bobbins, when they became filled with roving, required so much more force to turn them round, in consequence of their superior weight, than when they were empty and unloaded; that they acted, to stretch or draw out the rovings, in the same manner as the can before mentioned; for the revolution of the flyer *q*, round the bobbin *p*, gives the twist to the roving at the nose or socket, *r*, of the spindle; and if the bobbin was stationary, it is evident the roving would be lapped round it once for every turn of the spindle: but this would require the roving to be delivered out by the drawing-rollers much faster than they are intended to do. The consequence of the bobbin being fixed would be, that the roving must be stretched out to a sufficient length to supply as much length as the motion of the end of the tube of the flyer, *q*, requires. Now suppose, instead of the bobbin being fixed stationary, it is only retained by the friction of resting its lower end upon the rail N, the roving will then only be stretched with as much force as will drag the bobbin round after the flyer, with as much velocity as the difference between the quantity of motion of the end of the flyer, and of the roving, as delivered out by the drawing-roller: this difference will enable the bobbin to take up all the roving as it is made.

Now it is plain, that to drag a heavy bobbin thus about, must require more strain on the roving than for a light bobbin, and in consequence, it is always drawn out smaller towards the time when the bobbin becomes filled. This is particularly hurtful, because the roving, which will afterwards spin to the greatest advantage, is so extremely delicate as not to be able to bear the slightest strain; and if the machine requires it to undergo any strain, it must be twisted harder, and this will render it less fit to undergo the spinning. The manner in which these objections are obviated in the double speeder, is by introducing machinery which will give motion to the bobbin, and turn it round with such a velocity, that it will take up the roving just as fast as it is produced; but it is necessary, in effecting this, that the velocity shall be altered every time the bobbin has a new layer or roving beginning to be lapped upon it, because every time this happens the bobbin increases in its diameter, and must therefore move in such a manner as will cause its acting circumference to keep the same velocity at all times. To describe this see *fig.* 1, where for every bobbin, *p*, a small pulley is shewn resting upon the rail N, the spindle passing through its centre. The bobbin, which rests upon it, has a hole made in the underside of it, and the wheel having a pin entering this hole, so that the wheel, being turned round, compels the bobbin to turn with it. An endless strap, *n*, passes round all these wheels, having binders *o*, or pullies, which bend the strap, and cause it to act upon a sufficient part of the circumference of the wheels, to take such hold as will carry them round. This endless strap also passes round a cylindrical barrel L, fixed upon the upper end of the conical barrel K, which is of the same dimensions as the barrel H, but inverted, that is, the large end of the barrel, H, is opposite the small end of the barrel K. This being the case, an endless strap, *m*, which is passed round both, will communicate the motion of one to the other, and if the axes of the two cones are parallel, the strap will preserve the same tension, whether it works at one or other end of the two cones, because whatever quantity the strap will be loosed by acting on a small part of one cone, it will at the same time be tightened, or taken up as much, by being upon the larger part of the opposite cone; but it is plain that this alteration of the acting point of the strap will produce a correspondent alteration in the velocity of the motion of the cone K, which is turned round by the strap. Thus, the motion of the cone, H, is equable and uniform in velocity, being actuated by wheel-work from the principal spindle of the machine. Now suppose the strap, *m*, at the top of the cone H, then it acts with a small diameter upon the large diameter of the top of the cone K, which therefore moves much slower than H. Now by shifting the strap lower down upon the cones, the acting diameter of H is increased, while K diminishes till they come to a point, where they will be of equal diameter, and of course have equal velocities; but beneath this point, the diameter of K will be the smallest, and of course its velocity will be greater than H, which actuates it. When the machine is first put to work, and the bobbins are all empty, they must move slowly, because they are required to follow the flyer round, so that they will only take up as much as the rollers produce; for if they were stationary, they would gather up, as before-mentioned, as much as the motion of the end of the flyer, therefore, within certain limits, the slower the bobbin moves, the more it will take up; and if it moved as quick as the end of the flyer, it would take up none at all. For this reason, at first starting the machine, when the bobbins are all empty, the strap, *m*, must be at such a height up the cones, that the bobbins will have their proper velocities to wind up the rovings as fast as they are required, and the bobbins rise or fall, as is requisite, to lap the roving equably upon them; but having thus covered each bobbin with one layer of roving, and beginning to wind another layer upon it, the acting diameter of the bobbin is increased, increafed, and it muft therefore turn fo much quicker, (that is, it muft make fo many more turns in any given fpace of time,) as will caufe the increafed acting circumference to wind up no fafter than it did when it was fmaller. This feems, at firft hearing, to be a paradox, that it fhould be requifite to turn round quicker to wind up no fafter upon the increafed radius; but it is to be confidered that, by the bobbin being moved quicker, it follows and keeps nearer the end of the flyer tube, and therefore winds up lefs, becaufe the quantity which the bobbin will take up depends on the difference between two motions, that is, the difference between the flyer and that of the bobbin which follows it. This increafed velocity of the bobbin is occafioned by the ftrap, *m*, being, at the time when the bobbin is filled with roving up to the top, or down to the bottom, depreffed or fhifted down on the cones a fmall quantity, which occafions, as before-defcribed, a fmall increafe in the velocity of the motion of the cone K, and of the bobbins. The depreffion of the ftrap is performed by a lever, which takes hold of the ftrap with a fork, and when urged, leads it up or down upon the conical barrel. This lever is actuated by a fnail, upon the axis of which is fixed a ratchet-wheel, turned round by proper clicks, levers, and other connecting mechanifm, one tooth every time the bobbins and rail, N, begin to afcend and defcend, or, in other words, arrive at the extreme limits of their motion. Then the fnail acting on the lever depreffes the ftrap a fufficient quantity, to produce the alteration of velocity required.

Thus, as the bobbins increafe in diameter by the addition of fucceffive layers of the roving, they adapt their velocities to that increafe, and taking it up juft as faft as it is produced, and no fafter, fo that the roving, as it paffes from the end of the flyer tube to the bobbin, is never ftretched, and never becomes flack. The intelligent mechanic will readily percieve that this is practicable, but at the fame time he will be fenfible of the accuracy requifite in the adjuftment of fuch a machine to its work, and the difficulty of making this adjuftment for different fizes of roving. This, perhaps, is the only bar to its general ufe, that it requires a fkilful mechanic to attend and take charge of it, becaufe every different fize of roving, which is made in it, will require a different rate of increafe or decreafe of motion, by means of the ftrap *m*, for a large thread caufes the diameter of the bobbin to increafe more rapidly than a fmall one, and therefore the quantity of fhift which the ftrap, *m*, makes every time on the two cones K, H, muft be determined by the fize of the roving, as is alfo the height at which the ftrap fhall ftand when the machine is firft fet to work, and the bobbins are all empty. Thefe adjuftments are made in the lever fnail, and other connecting mechanifm, which are omitted in our plates. We have attended for a long time to the action of feveral double fpeeders of this kind, made by Mr. Smith, and adjufted by him, which performed their work in the moft perfect manner, making a roving fo loofe and foft, that it would part with the flighteft force, but at the fame time as regular and even as poffible, and the yarn fpun from it was greatly fuperior to any which could be produced from the fame material by any other means we have feen. We venture to prognofticate that the general introduction of this machine, when a fufficient number of managers are inftructed how to make it work properly, will be a great improvement of a moft effential department in cotton fpinning.

The rovings, thus prepared on bobbins, are carried to be fpun, either, as before explained, in the water-frame, or mule. We fhall defcribe the former firft: it is conftructed in two very different forms; and though in both the operating parts are the fame, the machinery which actuates them are very different. One is called the water frame, being the original fpinning frame, as firft conftructed by fir Richard Arkwright, whilft the other is a more modern conftruction, and is known by the name of the throftle frame. Their comparative advantages we fhall fpeak of after having defcribed them both by the aid of drawings made from the moft improved machines of both kinds. See *Plate* IX. which contains a drawing of

A Water fpinning frame, taken by the writer of this article from Meffrs. Strutts' mill, Belper, Derbyfhire, whofe works are the moft complete for the water-fpinning trade of any in the country. *Fig.* 1. is an elevation in front of the whole frame; *fig.* 2. an elevation endways, and *fig.* 3. is a plan: the remaining figures are the parts on an enlarged fcale. In all the three firft figures, the fame parts are defignated by the fame letters of reference: A is a bevilled wheel, fixed upon the horizontal axis, which extends through the whole length of the mill. This turns a fmaller bevilled wheel upon a vertical axis B, which has a drum, C, at the lower end, and by a ftrap, *a*, actuates the whole machine. Another ftrap, *b*, goes the other way, and works another frame on the oppofite fide, the drum, C, being common to both. The fpindle, B, paffes through the drum, C, with a circular fitting, fo that it flips freely round within it, without giving motion to the drum, except when it is caft into gear. This is done by two locking bolts, fhewn by dotted lines paffing through the drum, and both fixed into a collar or focket-piece *d*, fitted to flide up and down the fpindle. It has a groove formed round it, in which a fork, at the end of a lever *e*, is received, fo that the fork embraces the piece, *d*, in the groove, and when lifted up, raifes the two locking bolts with it. This lever is raifed by the power of a fecond lever D E, the extremity, E, of which, being depreffed, raifes up the lever *e*, and unlocks the drum from the fpindle B, by withdrawing the locking bolts from their contact with an arm, *f*, of a wheel, *g*, which is fixed faft on the fpindle beneath the drum, and therefore turns with it; but the locking bolts being let down, that their ends may project through the drum, and intercept the crofs arm, *f*, of the wheel, the drum and all the machinery are put in motion.

The endlefs ftrap, *a a*, paffes, as fhewn in the figure, the whole length of the frame, makes a turn round the pulley *m*, and comes back again. Other pullies, 1, 2, 3, of the fame dimenfions as *b*, are fituated, at intervals, in a direct line between the drum *c*, and the pulley, *m*, to bear the ftrap, and in the intermediate fpaces between thefe pullies, the vertical fpindles marked *n* are placed in pairs, exactly oppofite each other. On the lower end of thefe, fmall wheels, *x*, called binders, are fixed, and the ftrap, *a a*, preffing againft them, as fhewn by the figure, turns them round, the object of the pullies 1, 2, and 3 being to bend the ftrap out of the ftraight line fufficiently, to make it apply to the furfaces of the feveral binders and turn them round. The laft pulley, *m*, is fitted in a frame, and can, by a fcrew 4, be moved to ftrain the ftrap tight. Above each binder, and on the fame fpindle, a wheel, *h*, is fixed: it receives two belts *i*, *k*, (*fig.* 3.) which turn four of the fpindles *l*, *l*, *l*, *l*, each belt giving motion to two fpindles. The binders *x*, (fee *fig.* 5.) are fitted to flip round on their fpindles *n*, but can, at any time, be united thereto, to give them motion by a locking bayonet 9, which is caft in or out of action, at pleafure, by a fmall lever 10, in exactly the fame manner as the locking of the principal drum: therefore, by the lever 10, any four fpindles can be detached from the machine at pleafure. The fpindles, *n*, of the binders have each at the upper end a pinion, which turns a face or contrate wheel *p*, fixed upon the fpindle of the front rollers which give out the cotton to the fpindles. Thefe rollers are arranged in diftinct heads or frames, containing four lengths in each, which fupply four fpindles. The

The conftruction of one of the heads is fhewn in *figs*. 4, 5, and 6; *fig*. 4. being a fection of the rollers and fpindle; *fig*. 5. a front view of the rollers; and *fig*. 6. an end view. In thefe, *p* ftill denotes the face wheel, and 4 the lower front roller. Upon this, which is fluted in the acting parts, the upper rollers 5, made in two feparate lengths, reft, and are preffed down upon the lower one by two heavy weights, 6, 6, which are fufpended, by means of hooks, 7, from the necks or fmall parts of the upper rollers, and thus keep them firmly down upon the flutes of the front roller 4. On the oppofite end of the front roller to the wheel *p*, a pinion, *r*, of eleven teeth is fixed: this turns a wheel, *s*, of 28 teeth, which is mounted on a ftud or pin, and has a pinion, *t*, of 16 teeth fixed to it, which works a wheel, *w*, of 32 teeth, fixed on the end of the middle roller, fhewn in the fection, (*fig*. 4.) at 12, whofe motion will be to the front roller nearly as five to one. On the other end of the roller is a pinion of 10, which turns another of 15, on the back roller, 13, by means of an intermediate wheel, fo that this turns only once for one and a half turns of the middle roller; confequently, the roving 14, (*fig*. 4.) which is introduced between the back rollers, from the bobbins or cops fet up in a frame F, (*figs*. 1 and 2.) above the machine, is, in paffing between the back and middle rollers 12 and 13, drawn out one and a half times; then between the middle and back rollers 12 and 14, it is extended five times more, making a draught or extenfion of $7\frac{1}{2}$ times in the whole; and as faft as the rovings come through the front rollers, they are twifted into a thread by the rapid circular motion of the fpindles. But thefe we have to explain; they are ftraight fteel arbors, *l*, *l*, (*fig*. 4.) on the lower end of which the whirls or pullies, which receives the band, *i*, for them, are fixed: thefe fpindles are mounted in a frame common to them all, which confifts of two rails 14, 14; the lower one fupporting the points or toes of the fpindles, and the other having bearings for the cylindrical parts of each fpindle, and a ftrip of wood is fcrewed againft this to keep them up to their bearings. Above this bearing the fpindle is only a ftraight cylindrical wire, and on the upper end of it the flyer, 15, is faftened, either by fcrewing it on, or it is ftuck faft on by friction, which is fufficient to carry it about. The two arms or branches of the flyer are fufficiently diftant for them to revolve round clear about the bobbin 16, which is fitted loofely upon the cylindrical fpindle, and with liberty to flide freely up and down upon it. The weight of the bobbin is fupported by refting on a piece of wood 17, attached by fcrewing to a rail M, which has a flow rifing and falling motion, equal in extent to the length of the bobbin between its fhoulders, by which means the thread, as it comes through the eye formed at the ends of either of the branches 15, of the flyer, and is wound by the motion thereof upon the bobbin, becomes equally diftributed throughout, its length giving it a cylindrical figure, inftead of heaping all the thread at one part, like a barrel, as would happen if the bobbin did not rife and fall. This motion of the bobbin is produced by a bent lever, 16, (*figs*. 1. and 2.) fufpending the rail M, with all the bobbins upon it, from the arm 16; the lower end of the other arm, 17, bears againft, and is moved by a heart or eccentric wheel 18, nearly of the figure of a heart, which is fixed on an horizontal axis extending the whole length of the machine, and at the other end it bears a fimilar heart 18, (*fig*. 1.) fixed on it, which operating upon another lever 16, fufpending the other end of the rail M, thus caufing it, when the hearts are turned round, to rife and fall equally at each end, or parallel, and move all the bobbins refting upon it together. The motion is given to the fpindle of the heart 18, by a fmall contrate wheel on the end of it, which is turned by a pinion on the lower end of the vertical fpindle 19, receiving its motion by a pair of bevilled wheels from an horizontal fpindle 20, in the middle of which is a cog-wheel 21, turned by a fpiral piece of iron 22, which is fixed on the main fpindle B, juft beneath the great bevilled wheel. It operates in the fame manner as an endlefs fcrew, turning the wheel, 21, round one tooth for every revolution of the main fpindle, and this flow motion is communicated by the fpindle 19, and wheel-work juft defcribed, to the hearts, which revolve with fuch a velocity, as will caufe the bobbins to afcend and defcend fo faft, that they lie every turn of the thread clofe by the fide of that preceding it, but not upon it, fo that the figure of the bobbin, when filled with thread, will be nearly cylindrical.

The bobbins of the roving frame are put upon a wire, or temporary fpindle, and in this ftate are fet up in the frame, F, in two rows, one above another, fo that they will all turn freely round when the rovings are drawn off from them. Thefe rovings are conducted over wires, as fhewn in *fig*. 2, to lead them in the right direction, and are brought, two together, through wire ftaples fixed in the board G (*fig*. 4.), then through notches made in the edge of a piece of iron plate fixed on the edge of the board, and projecting up above the furface of it, and after paffing through thefe notches the rovings enter the back roller 13, in *fig*. 4. The board, G, has a fhort traverfing motion backwards and forwards, by which means it caufes the roving to travel backwards and forwards between the rollers, or it would foon, if conftantly conducted through the fame part of the rollers, wear out the flutes at that part, making a fmooth ring round it: but by this traverfing motion the wear is equally diftributed over the whole length of the fluted rollers, and does not act partially at any one part. The motion is caufed, as fhewn in *fig*. 4, where 18 is the fpindle of the hearts 18 (*fig*. 2.), fituated immediately beneath the board G: it has a cog-wheel of 18 teeth fixed upon it, turning another, H, of 36 teeth, on the axis of which a fmall crank, K, is formed, and by means of a connecting rod draws the board, G, backwards and forwards every time it makes a revolution, by means of the cog-wheels, which will be once for every two turns of the hearts. The rovings, two together, as before ftated, enter between the back rollers, and then pafs forwards to the middle pair, receiving in the paffage a draught or extenfion of one and a half; then advancing through the middle rollers to the front, they are, by the motion thereof, drawn out five times, and in this ftate delivered to the fpindle L, which twifts the fibres round each other the inftant their ends come out, before the rollers leave the other ends, or they would fall to pieces, being drawn out fo fine, that the cohefion of the fibres is infufficient to bear any thing, and the twine given to the roving is entirely loft, for it was at firft only one turn in $1\frac{1}{2}$ inch in length; and this $1\frac{1}{2}$ inch, being by the draught of the roller drawn out to more than 13 inches, the twift of one turn in this length is imperceptible, and adds no ftrength whatever to the roving, fo that it is neceffary the fpindle fhould, by the connection of the thread 41, paffing down from the rollers to its flyer, give a twift to the fibres the inftant they come through the roller, fo that by twifting one end of each fibre round the other, whilft the oppofite ends are held faft between the rollers, they will become a thread fufficiently cohefive to advance towards the fpindle, and receive its full quantum of twift to become a hard and ftrong thread: it paffes through a wire eye or ftaple fixed in a board at 34, which changes its

 direction

direction into a line with the fpindle, to which it is connected by paffing through the eye formed at the end of either of the branches of the flyer, which revolves with the greateft rapidity along with the fpindle, and thus give twift to the thread. The bobbin does not partake of the motion of the fpindle, but is retained by the friction of its lower end refting on the piece of wood 17, and this is increafed by a wafher of leather put under it: then, as before explained of the hobbin of the roving frame, the thread, by the motion of the flyer, drags the bobbin about after it with a velocity equal to the difference between the motion of the end of the flyer, and the motion of the thread as delivered out by the front rollers. When the frame has been fo long at work, that the bobbins become filled with thread, the child in attendance, by the handle of the lever 10 (*fig.* 5.), difengages the binder *x*, of the four fpindles from its axis *n*, and then they, as well as the head of the rollers belonging to them, ftop, and the child breaks the thread; then pulling off or unfcrewing the flyer, he lifts off the bobbin, puts on an empty one, on which the end of the thread is previoufly lapped to make a beginning: the flyer is next fixed on, the thread paffed through the eye at the end of the flyer, and it is ready to work again: the eye of the flyer is made open at one part, being curled in the manner of a cork-fcrew juft at the end fo that the thread can be hooked in and out of it by the child, but is in no danger of getting out by the motion of the flyer in its work. When a thread accidentally breaks, it is not always neceffary to ftop the fpindle to unite it, but the attendant takes hold of the broken end which belongs to the bobbin, and draws off a confiderable length, a yard for inftance, from the bobbin, and breaking it, throws this away, becaufe it has every chance of being unfound: then taking the end in the finger and thumb, and applying it againft the end of the roving which is coming through between the rollers, leaving them overlapping a fmall quantity, and letting them go from the finger and thumb, the ends are inftantly twined together, and united into one found thread. But this requires fome dexterity, for if the end of the thread is held fo long between the fingers in applying them together, that the roving coming through the rollers advances the length of the fibres of the cotton before it is let go, and fuffers the fpindle to twift it, the fibres will part and the thread breaks afunder, or is never formed at that part; it is therefore neceffary to catch the roving as clofe as poffible to the rollers, and apply the end of the thread quickly to it, then letting them go inftantly, the fibres are twifted in with each other, and the union takes place fo perfectly, that it cannot be afterwards difcovered where the joint was made. The lower rollers are made of caft iron, turned extremely true, and fluted by an engine; the upper rollers are alfo caft iron, but are covered with leather in the acting parts, fo that this foft fubftance holds the cotton more firmly upon the flutes of the lower one than any other method would, as the roving is not liable to lap round the rollers like the fliver of the drawing frame. No clearer is ufed; but inftead thereof, a fmall wooden roller covered with leather is placed over, between the front and middle roller, but it merely lays upon them, having no pivots or fupport; its furface is rubbed over with chalk or whiting, and this it communicates to the leather of the upper roller, and is found to improve their action, probably by not fuffering the cotton to flip beneath the rollers: *fig.* 4 fhews, that the middle and back rollers have their weights to keep down the upper rollers upon them in the fame manner as the front rollers; but the weights are very different, the front weight, 6, being 20lbs., whilft the middle weights are but a few ounces, and the back rolls have a weight of 2lbs. The reafon for the front roller requiring fo great a weight is, that it is neceffary for them to prefs and hold every one of the fibres of the roving while paffing through them extremely tight; becaufe if it only held a few in the middle of the roving, the others towards the edges of the roving might, by the twifting, be drawn out before their ends were fairly twifted into the thread, and this would render the thread fuzzy in its whole length: the inftant the foremoft end of a fibre comes through between the rollers, it fhould, by the twine of the fpindle, be twifted over the middle of fome other fibres which are coming through, and over the ends of others which have altogether efcaped the roller, and the fmoothnefs of the furface of the thread altogether depends upon this being done inftantaneoufly on the foremoft end prefenting itfelf through the rollers; for the effect of all the preceding operations has been to difperfe the ends of the fibres equally, fo that they effectually break joints with each other, and then being equally twifted, it forms a thread of equal ftrength in all parts.

The numbers of the wheel-work for the rollers of the roving frame, are varied with every different number of cottons which is to be fpun; the draught being altered, when requifite, to produce fuch an extenfion of the fliver in paffing through the rollers, as will make the roving, when finifhed, 4.3 times the weight (length for length) of the yarn it is to be fpun into. This is a pretty general rule in cotton-mills, and the roving is occafionally meafured and weighed, to afcertain if the machines are drawing the proper quantity, and if not, the pinions are changed for others which will produce the proper degree of extenfion. It is in this ftage that the fize of the yarn is determined, and the fpinning frames have, in general, the fame draught; but the velocity of the fpindles with refpect to the roller, fo that they will give a greater or lefs degree of twine to any given length, is varied in fpinning different kinds of twift, whether hard or foft twift. The alteration is made by employing larger or fmaller pullies, or whirls, on the fpindles which caufe them to revolve with a flower or quicker motion. Neither do the rollers of the fpinning-frame give out the fame quantity of roving in a given time when fpinning coarfe or fine goods, or when fpinning very high numbers, as No. 60: the front rollers are adapted by the wheel-work to revolve at the rate of 35 times *per* minute; but for coarfer goods, fome of them will turn 60 times *per* minute: this is becaufe a fine thread requires more twift in a certain length than coarfe.

The frame from which the drawing was taken contained ten heads, or forty fpindles, on each fide, the frame = 80, and the fame on the oppofite fide of the drum, to be driven by the ftrap *b*, making 160 fpindles, actuated by one cog-wheel A.

The conftruction of the locking bayonet *d*, for connecting the drum with the main fpindle, we have explained; but one circumftance was then unnoticed, *viz.* that the bar *f*, *fig.* 1, is not permanently fixed to the wheel *g*, but that the wheel has a groove turned in the edge of it like a pulley; and an iron hoop or clip, made in two halves, fcrewed together, is fitted round the wheel in this groove, and to this clip the crofs-bar, *f*, is united, by the ends of it turning down, and being received between the ends of the clip, the fame fcrew-bolts holding all together. The confequence of this conftruction is, that the machine is not fuddenly jerked into motion when the bayonet is let down, and intercepts the arm *f*, which is revolving rapidly with the fpindle and wheel *g*: inftead of jerking the frame, the bar, *f*, for a moment becomes ftationary againft the point of the bayonet,

bayonet, the wheel, *g*, ſlipping round within the clip, but the great friction of this ſoon ſets the machine quietly in motion; and when it arrives at its full ſpeed, the friction of the clip is ſufficient to keep it in motion, without ſlipping any more, unleſs an accident happens, and then it is very uſeful, as it prevents the machine being broken.

The *throſtle ſpinning-frame* is delineated in *Plate* X. of which *fig.* 1. is a ſection taken acroſs the length of the frame; *fig.* 2. is an end view, and *fig.* 3. is an elevation of the machine in front. After the minute deſcription we have given of the conſtruction and operation of the roving-frame and water-frame, it will not be neceſſary to be very diffuſe in our account of this machine, which has the ſame parts as thoſe machines, but only differs in dimenſions and proportion. The ſame letters of reference are employed in all the figures, and A A repreſents the live and dead pulley actuating the whole, fixed on the end of the ſpindle of a long tin cylinder B, which is called the throſtle, and turns all the ſpindles and other machinery at once. On the main ſpindle of the throſtle a pinion, *a*, is fixed: this turns a wheel *c*, which has a pinion, *b*, fixed on it, turning the wheels D and E (*fig.* 2.) by the intermediate wheels, *d*, on one ſide, and *e* and *f* on the other. The wheels, D and E, are fixed on the ends of the ſpindles of the front rollers X, as is plainly ſhewn in *fig.* 3. Theſe rollers are made in lengths, which ſerve ſix ſpindles, and the lengths are united by connecting boxes, as ſhewn at F, to other lengths, ſo that one train of wheel-work, *a* C *b d e f* E and D, will turn the front rollers for 112 ſpindles, or 66 on each ſide of the frame, and then the rollers are made in 11 lengths. Some frames are longer, others ſhorter than this. Our drawing only contains 12 ſpindles, and two of theſe at each end are removed, to ſhew the works inſide of the frame: at *g* a pinion is fixed on the ſpindle of the front roller, and turns a wheel on the end of the middle roller, by an intermediate wheel and pinion on a ſtud; and at the oppoſite end of the middle roller is a wheel *h*, turning the back roller with its proper velocity by means of an intermediate wheel, ſo that the motion of the rollers in this frame is exactly the ſame as in the water-frame. The ſpindles, *l*, *l*, are all driven by bands from the throſtle cylinder B, the manner in which they croſs being ſhewn at *k*, *fig.* 1. The bands are very looſe, and, as the figure ſhews, are inclined, ſo that their weight tends to draw them tight, and turn the ſpindles, *l*, *l*, about with the proper velocity; but ſtill the child attending the machine can, by preſſing his knee againſt the whirl, as the pulley is called, ſtop the motion of any one ſpindle for a moment whilſt a broken thread is repaired, the band ſlipping round it all the time. The ſpindles, being exactly the ſame as the water-frame, need little explanation, more than to enumerate their parts, which are, the bobbin *m*, the flyer *n*, ſtuck by friction, or elſe ſcrewed on the top of the ſpindle, and its branches ending in a curled hook, through which the thread is paſſed to the bobbin. This is fitted quite looſe on the ſpindle, and reſts its weight on a piece of wood *o*, fixed to the underſide of a rail N, which riſes and falls, to lay the thread regularly in a coil upon the bobbin, as faſt as it is taken up thereby. The riſe and fall are thus produced: the two rails, N, N, on oppoſite ſides of the frame, are ſuſpended by iron rods, *p*, *p*, from horizontal levers G, which are mounted on an axis, extending the whole length of the frame, and having as many of the levers, G, upon it, as are neceſſary to ſuſpend the rail, N, without bending. H is an iron rod jointed to the lever G, and coming down to a ſhort lever I, which, at the oppoſite end to its connection with H, reſts on the ſurface of the heart R, fixed on a ſpindle, which is turned by the following train of wheel-work. The ſpindle of the wheel and pinion, C *b*, paſſes through the frame, and by a pair of bevilled wheels, L (*fig.* 3.), turns a vertical axis M, on the lower end of which is an endleſs ſcrew, giving a ſlow rotation to the ſpindle of the hearts by a tooth-wheel, *m*, thereon, which is turned round one tooth by every revolution of the endleſs ſcrew. A heavy weight, P (*fig.* 1.), is ſuſpended from the lever, G, to counterbalance, and cauſe the end of the lever, I, always to preſs upon the ſurface of the heart R, which, as it turns round, elevates and depreſſes the bobbins on the oppoſite ſides of the frame alternately. The joints of the levers, G and I, with the rods, H and *p p*, are made, as the figure ſhews, adjuſtable; that is, the centre pins are fixed to the levers by fitting in grooves, and are held in by nuts, ſo that they can be fixed at different diſtances from the centre, to accommodate the acting radius of the levers, ſo that the motion given by the heart, R, may be made to correſpond with the length of the bobbin between the ſhoulders.

The bobbins for the roving are ſet up in a frame at S S T, between the two ſets of rollers, X, X, and the roving is conducted immediately between the back rollers: but, as it goes through the ſame proceſs as before deſcribed in the water-frame, it is needleſs to repeat it. The traverſe motion, to prevent the cotton wearing away the rollers in any one part, is ſometimes omitted; but we have ſeen throſtle-frames in which the whole of the frame S T, conſiſting of one board, S, below, and another, T, above, connected by proper pillars, together with all the bobbins of rovings, had a ſmall traverſe motion, which is found to be a great advantage in the wear of the rollers.

Reſpecting the comparative advantages of the throſtle-frame and the water-frame, cotton-ſpinners are divided in their opinions: the ſimplicity, and conſequently low price in the firſt erection of the throſtle, is its recommendation, and it is generally ſtated to be driven with far leſs power, becauſe it has fewer parts. To ſet againſt theſe advantages, it is ſaid, that when the bobbins are filled, and require to be changed, the whole frame of 112 ſpindles muſt be ſtopped at once, by ſhifting the ſtrap to the dead pulley A; whereas in the water-frame, any four ſpindles can be ſtopped together, by caſting off their binder; and it is only neceſſary to ſtop the whole frame by the caſting off the great drum, when the frame is to be repaired, or is out of uſe for a day, or longer period.

We have now explained the manner of ſpinning cotton into a thread by the water-frame, and ſhall proceed to deſcribe the conſtruction of the other method of ſpinning, *viz.*

The Mule.—This machine was introduced by a Mr. Crumpton, who lately received a reward of 5000*l.* from parliament for the invention, which, as before mentioned, conſiſted only in the combination of Hargreave's ſpinning jenny with ſir Richard Arkwright's drawing rollers. *Plate* XI. contains drawings of one of the beſt conſtructions of this machine, in which *fig.* 2. is an end view of the whole machine, and *fig.* 1. an end view of the carriage alone. *Fig.* 3. is a front view, and *fig.* 4. is a view of the operative parts detached: *fig* 5 a ſimilar view in another ſtage of its operation. As this machine is extremely complicated in its movements, it will firſt be proper to explain theſe movements before entering upon the machinery which cauſes them. This is ſhewn in *figs.* 4 and 5, where W repreſents a bobbin of the roving frame ſet up in a proper frame, and the roving is conducted from it, through three pairs of rollers, A, B, and C, which have the ſame draught as the rollers

rollers for the ſpinning-frame, and are moved by ſimilar wheel-work: but the upper rollers, *a*, *b*, *c*, are weighed down in a different manner: thus, *d* is a piece of metal reſting on the neck of the front roller, *a*, at one end, and the other end upon the middle of a ſecond piece *e*, which bears upon the necks of the other two pairs of rollers, *b* and *c*; then an iron rod *f*, coming down from the piece *d*, loads all the three upper rollers *a*, *b*, *c*, at once, by means of a lever *g*, which is hooked beneath a fixed rail of the framing ſupporting the rollers at one end, and the other is made with a heavy knob, ſo that the purchaſe, or leverage of this piece *g*, draws down the wire, *f*, with ſufficient force to load all three rollers with their relative forces: thus it is plain the roller, *a*, muſt bear the principal weight of the lever *g*, becauſe the wire, *f*, is nearer to the roller *a*; but as it acts upon the piece, *e*, with a conſiderable length of leverage it bears lightly upon it, and this again bears upon two, and therefore ſtill leſs upon either, the weight of the end of *d* being divided upon two rollers *b*, *c*; but it bears moſt powerfully upon *c*, the point or end of *d* being neareſt to that roller, ſo that the operation of all theſe pieces is to load the three rollers nearly in the ſame proportion as the rollers of the ſpinning frame: but this proportion can readily be altered by ſhifting the acting lengths of the levers.

The roving, after paſſing through the rollers, is taken up by the ſpindle D G: this is placed rather inclined, but without any bobbin or flyer, like the ſpindle of the water frame; it is merely a plain conical arbor, ſupported at its point, or toe, in a ſtep made on the rail, E, of the frame, and in a bearing at F, againſt another rail. It has nothing to keep it up againſt this bearing, the draught of the band, which paſſes round the pulley *b*, and gives motion to the ſpindle, being ſufficient for this. The end of the thread is merely lapped round the upper end of the ſpindle, and its accumulation upon itſelf ſoon forms a maſs G, which is called a cop, or coppin. Now it is evident that, from the inclined poſition of the ſpindle, it will, when turned round, give twiſt to that part of the thread which is between the end of the ſpindle and the roller A, although the ſpindle and the direction of the thread do not coincide, becauſe, when the ſpindle is turned, the thread will ſlip over the top end of it and receive a twiſt, without winding up upon the cop; but when it is required to wind up, the thread, or wire H, is preſſed down upon the thread. This removes it from the end of the ſpindle to the middle of the cop, as ſhewn in *fig.* 5, and then the motion winds up the thread upon the cop inſtead of twiſting it. The wire, H, is extended at the end of a lever H I, moveable on a centre I, in the manner ſhewn in *fig.* 5, but when left at liberty, the weight of the oppoſite end of the lever reſtores it to the poſition *fig.* 4, and then the ſpindle twiſts the thread inſtead of winding it up.

The operation of the machine is this: the rails E and F, ſupporting the ſpindle, are part of a carriage or frame carrying above 100 ſuch ſpindles, and moving on wheels which traverſe on railways to and from the rollers in a direct line, for the extent of a yard and a half. Now ſuppoſe it wheeled home, that the ends of the ſpindle are cloſe to the front roller A, then ſuppoſe the rollers ſet in motion, they take in the roving from the bobbin W, and draw it out or extend it eight or more times, giving it out between the front roller A, to the ſpindle G, which, with its carriage, recedes, by the movement of the machine, from the rollers, taking up the thread as faſt as it comes out between them; and, at the ſame time the machinery draws the ſpindle back, it turns it round rapidly, giving twiſt to the thread as faſt as the rollers deliver it out, and thus producing ſuch a compreſſion of the fibres by twiſting them round each other, as will form a thread of ſufficient ſtrength to bear *ſtretching*. This means, that when a yard of thread has been given out by the rollers their motion ceaſes, ſo that they deliver no more, but the ſpindle continues to recede from the rollers to the further diſtance of a yard and half, twiſting the thread all the time it ſtretches it out in length, till it forms a fair and ſtrong thread. The twiſting motion of the ſpindle then ſtops, as does alſo the drawing-out movement of the ſpindle, with its carriage. Thus one yard and a half of thread is made and finiſhed. The attendant to the machine now thruſts the ſpindle, with its carriage, home to the rollers, holding the wire H, done in the manner ſhewn in *fig.* 5, and at the ſame time turning round the ſpindle at ſuch a rate, that it will wind up the thread upon the coppin, and the wire H, which is held down by the hand, is ſo humoured, as to make the thread wind up with regularity. The rotatory motion given to the ſpindle is, in this inſtance, done by the other hand of the attendant, and is ſo accommodated, as to wind up the thread juſt as faſt as the advance of the ſpindle towards the rollers requires, and no more; but when it arrives cloſe to them, the wire, H, is raiſed up, and the machinery is put in motion again, the rollers begin to draw out, and the ſpindles to recede, turning all the time. The mechaniſm by which all this is effected is deſcribed by *figs.* 1. 2, and 3; firſt, ſee *fig.* 2, where K is a live and dead pulley for the endleſs ſtrap actuating the whole by the power of the mill. The pulley is mounted on a ſhort ſpindle, having a winch or handle, L, at one end, and on the other a large pulley M, which has a number of different-ſized grooves formed round it, to receive an endleſs rope *i*; ſee alſo *fig.* 2: this rope, after making a half turn round M, paſſes under a wheel *k*, fixed on a pin or ſtud projecting from the frame. From this wheel the rope, *i*, proceeds to another wheel, *l*, at the oppoſite end of the frame, and returning from this goes over a wheel ſituated cloſe behind *k* on the ſame centre pin. The ends of the rope are then joined, and it forms an endleſs band, which, when the ſtrap is caſt on the live pulley *k*, and the wheel, M, turned by it, the rope, *i*, conſtantly runs in a ſtraight line from the wheel *k* to *l*; but in this paſſage the rope makes a quarter turn round a wheel *m*, upon a vertical axis, which is mounted on the frame or carriage E F, for the ſpindles D, G, ſhewn ſeparately in *fig.* 1. The rope, *i*, not only paſſes round the wheel on this ſpindle, but goes forwards into the carriage, and paſſes round a groove upon the upper end of a vertical drum, (not ſeen in the figures,) which has ſeveral bands upon it, each driving two ſpindles, D, by paſſing round the pullies, *b*, of two of them, as ſhewn in *fig.* 3, in which it is alſo ſeen that the bands are all at different heights, that they may not interfere with each other upon the drum, but each take its proper place upon the length thereof. The carriage runs upon four wheels 1, 2, (*fig.* 2.) two of which are placed at each end, and run upon an iron railway, ſo that the carriage containing all the ſpindles and drums runs backwards and forwards, to and from the rollers, for the length of a yard and half. But during this motion, the power of the mill is all the time conveyed to turn the ſpindles by means of the endleſs cord *i*, which, as beforementioned, making a ſtraight line from the wheel *k* to *l*, will not be affected by the motion of the carriage, but will always circulate round the ſeveral wheels, and give motion to the drum which turns the ſpindles: 4, (*figs.* 1 and 2.) is an iron bracket, ſupporting the axis I I′ of the lever, H, *fig.* 4, which ſupports the wire H, and as many of theſe levers are fixed on the axis I, as ſhewn in *fig.* 3, as are ſuffi- cient

cient to make the wire H, ftiff enough to prefs down all the threads together, in the manner of *fig*. 5. The remaining parts of the carriage, being only its frame, are evident from *fig*. 1, and need no farther notice, except a double pulley; that is, a pulley 5, with two grooves upon it, fitted on a ftud or pin in the underfide of the frame, between the two wheels 1 and 2. The ufe of this pulley, with its ropes, as we fhall defcribe, is to make the whole carriage move parallel, or both ends equally, which, in a carriage of twenty feet long, requires fome nicety. As the two wheels 1 and 2 cannot be placed very diftant, and therefore give little fteadinefs to a carriage of fuch a great length, the parallelifm is thus preferved: a rope, 6, is made faft at one end to a fixed part of the framing, then paffes a quarter round the upper groove of the pulley 5, and runs along the whole length of the carriage, and turns a quarter round a fimilar pulley 7, *fig*. 3, and then goes forward parallel to its firft direction, from 6 to 5, and is made faft to the frame in a fimilar pofition to 8, *fig*. 2, but at the farther end of the frame. In the fame manner, another rope is faftened to the frame at 8 and making a quarter turn round the lower groove of the pulley 5, proceeds the whole length of the carriage, makes a quarter turn over the pulley 7, *fig*. 3, and proceeds parallel to the firft direction, from 8 to 5, and is made faft to the frame in a fimilar pofition to 6, but at the oppofite fide of the frame. The two ropes crofs each other in the centre of the carriage, and they always pafs over oppofite fides of the pullies 5 and 7. Their effect, which is not eafily explained without a feparate figure on purpofe, is to make the carriage move equally at both ends, for it muft do this, unlefs one or other of the ropes flip upon the grooves of their refpective pullies 5 or 7, and this they will not do if ftrained tight. We have clearly ftated the paffage of the two ropes 6 and 8, and the mechanic who knows this, will readily fee the manner of its operation, though it is difficult to explain it by words only.

We muft now attend to the wheel-work for the rollers: a bevilled wheel *o*, fixed clofe behind the wheel M, on the main axis, turns another on the end of an inclined axis *p*, *fig*. 2, at the oppofite end of which is another bevilled wheel, turning *q*. fixed on the extremity of the front roller; which being connected with the middle and back rollers by the fame wheel-work as the throftle frame, and the rollers being of a fimilar conftruction, demand no further defcription, except what we have already given in *fig*. 4, of the weights for preffing down the upper rollers. When the rollers are to be caft out of gear, it is done by difengaging the wheel, *p*, from the wheel *o*; for which purpofe the bearing for the upper end of the inclined axis carrying the former, is made in the upper end of a lever *r*, which moves on a centre pin, fixed in the ftandard fupporting the bearings for the axis of the wheel M: the lower end of this lever is connected with the end of a fhort lever *s*, moveable on a vertical centre pin fixed in the frame: this lever has an arm proceeding from the centre at right angles with that feen in *fig*. 2, and is therefore hidden behind the centre, its form being fhewn at Z, which is a plan of this lever. From this fecond arm a wire proceeds to the pendulous lever P *t v*, moveable on the centre pin *t*. Now by moving the end. P, of the lever, P *t*, away from the wheel, M, it draws the wire and arm of the lever *s*, the other arm of which acting upon the lower end of the lever *r*, to throw it inwards, throws the upper end outwards, and brings the wheel, *p*, in contact with the wheel *o*, fo that the inclined axis, and the front rollers alfo, are fet in motion, as long as the end of lever, P, is kept held towards the end of the frame. This holding is performed by its arm *v*, which, as in the figure, may be hooked under and kept down by a fmall catch *w*, and from this a fine wire, 9, proceeds back to the oppofite end of the frame, and is then linked to a fhort lever, which is fitted loofely on the fame centre pin which connects the lower end of the lever, *r*, with the arm of the lever *s*. This lever is fhewn at *z*, in the feparate figure Z, but its ufe is only to fupport the end of the wire 9, and keep it up, fo that a part of the carriage of fpindles, in running back, may, by intercepting the end of it, draw the wire and the catch *w*, thus relieving the arm, *v*, of the lever P, and this, as before explained, throws the wheel, *p*, out of gear, and the motion of the rollers ceafes. On the return of the carriage towards the rollers, a piece of wood, *x*, fixed to it, runs againft the lower end of P, and moves it back fo far that the catch, *w*, engages it. This fets the rollers in motion, which they continue, until, in the retreat of the carriage, a piece of iron *y*, *fig*. 1, projecting up from it, catches the fhort lever, *z*, near *s*, fupporting the wire 9, which being thus drawn, difengages the catch *w*, and then the wheel, *p*, is caft out of the gear with *o*, as before-mentioned, and ftops the motion of the rollers. The motion for drawing out the carriage from the rollers is thus performed: a cog-wheel R, which has a pulley fixed on againft it, receives an endlefs rope, 10, paffing round a pulley, 11, at the end of the frame. One part of the endlefs rope is tied to an iron arm projecting from the carriage, fo that when the wheel, R, is turned round, by engaging its teeth with a cog-wheel fixed upon the end of the front roller, the endlefs rope, 10, traverfes, and moves or draws the carriage out with it. The wheel R, which is called the Mendoza wheel, is made to lock in or out, by fitting it on a centre pin, which is faftened into the upper end of a lever T, (fee the feparate view,) moveable on a pin fixed in the frame. The lower end of this lever is moved by a horizontal lever, feen endways near V, which reprefents its vertical centre pin or ftud. The end of this lever, which is before the ftud, or neareft the eye, is connected by a ftrong wire with the lever P, and therefore, when this lever is pufhed by the motion of the carriage, it engages the Mendoza wheel, and draws out the carriage, at the fame time that the rollers are put in motion, and give out the roving between them; but the carriage, being drawn out to the length of roving which it is to have to ftretch and fpin the Mendoza wheel, is not difengaged the moment the rollers are caft out by the wire 9 and catch *w*, in the manner we have juft defcribed, becaufe the lever, T, carrying that wheel is provided with a catch, fimilar in its properties to *w*, that is, it holds the wheel, R, in its work until the carriage has run a yard and a half, and then it feizes a wire communicating with this catch, thus difengaging the catch holding up the lever T: the Mendoza wheel then falls back, and the drawing-out movement of the fpindles ceafes. This catch and wire are not fhewn in the figures, as it would produce much confufion, but being fo exactly fimilar in this action to the catch *w*, and its wire 9, they may be eafily imagined.

We have now to defcribe the manner in which the rotation of the fpindles is caft in and out. The reader, if not confufed by the complication of this machine, may remember that we explained the connection from the wheel M, by means of the endlefs cord *i*, to the wheel *m*, and thence to the vertical drum turning the fpindles. When this motion is to be thrown in and out, it is done by fhifting the main ftrap, driving the whole machine on the live or dead pulley K, *fig*. 3. The ftrap is guided by paffing through an eye or loop at the extremity of a lever, W Y, fixed on a vertical

vertical axis 12. On the lower end of this axis is a long lever 13, and at right angles to this a ſhorter lever, which being ſeen endways is not apparent, but it advances ſome diſtance forwards from the centre of the lever, and has a wire, 14, jointed to it, which is extended to a lever 15, againſt which the carriage runs when it is puſhed home, and the ſpindles are cloſe up to the front rollers. When this happens it draws the wire 14, which acting on the ſhort lever of the axis, 12, turns it round, and the lever Y W with it, ſhifting the main ſtrap from the dead to the live pulley K, and thus putting the whole machine in motion; at the ſame time that, by the operation we have before explained, the Mendoza wheel is thrown in, and alſo the movement of the rollers. The former of theſe draws back the carriage, till, as deſcribed, the catches are releaſed, and the movement, firſt of the rollers, and then of the Mendoza wheel, are thrown out. At the moment before this happens, the carriage intercepts the end of the lever 13, which is formed like an inclined plane: it is therefore thrown outwards by the carriage running againſt it, and the end of the lever, W, being at the ſame time moved, it ſhifts the ſtrap upon the dead pulley, and the motion of the whole machine ceaſes. The attendant to the machine now takes hold of the handle L, and puſhes the whole carriage back again, till the ſpindle comes cloſe home to the rollers; then by the carriage ſtriking the levers 15 and P, it ſhifts the ſtrap to the live pulley, and puts the ſpindles all in motion together, at the ſame time caſts, in the motion of the rollers, to give out the roving; and alſo it caſts in the Mendoza wheel, which traverſes back the carriage and all the ſpindles to take up the roving as faſt as it comes from the rollers, twiſting it by the motion of the ſpindles all the time.

To deſcribe the operation of this ingeniouſly conſtructed machine, will be only to recapitulate movements which we have repeated ſeveral times over; but this recapitulation will give the order in which they ſucceed each other. The man or woman who attends the mule ſtands in front of the ſpindles, at ſuch a diſtance from the right-hand end of the frame that he can conveniently reach the handle L. In the other hand he holds the axis, I, of the wire H. Suppoſe, to commence, that the ſpindles are cloſer to the rollers, then the movements ſucceed each other as follow:

1. The lever 15, being thruſt back by the carriage running againſt it, draws the wire 14, and by the lever, W, ſhifts the ſtrap upon the live pulley, putting the wheel M, and the wheels *k*, *l*, with the endleſs rope *i*, the wheel *m*, and all the ſpindles in motion.

2. The end of the lever, P, being preſſed by the carriage, engages the wheel for the motion of the rollers, and they begin to deliver out the roving at the ſame time.

3. The Mendoza wheel is caſt into gear, and begins to cauſe the carriage to retreat from the rollers as faſt as they give out the roving. Theſe firſt, ſecond, and third motions, all happen at the ſame inſtant.

4. The ſpinning of the rovings is now performed by the above motions, the ſpindles twiſting the rovings as faſt as they are given out; but the motion of the rollers is ſo quick, that the twiſt now given is ſlight, but having thus extended, or taken out, a yard in length from each ſpindle to the roller, the piece of iron *y*, *fig.* 1, on the carriage, meets the end of the lever *s*, and

5. Diſengages the wheel-work for the rollers, which are therefore ſtopped, and deliver out no more roving; but the retreat of the carriage and the twine of the ſpindles continues for another half yard, ſtretching out the thread, and twiſting it, till the piece of iron, *y*, meets the catch of the next wire, which is not drawn in the figure, and

6. Diſengages the Mendoza wheel, conſequently the carriage draws out no farther. The thread being ſufficiently extended and twiſted,

7. The carriage takes hold of the end of the lever 13, and thus ſhifts the ſtrap to the dead pulley K, *fig.* 3, and the motion of the whole machine ceaſes.

8. The attendant, by turning round the axis, I, of the wire H, preſſes down all the threads together from the points of the ſpindles to the middle of the coppin, in the manner of *fig.* 5; then

9. Takes hold of the winch L, to regulate the winding of the thread on the coppins, when he

10. Drives the carriage home to the rollers. In this motion the ſpindles all revolve, and lap up the thread upon the coppins. The revolution is cauſed by the endleſs rope *i*, which may, when the machine is ſtanding ſtill, be conſidered as a ſtationary rope acting upon the wheel *m*, and the drum for the ſpindles, and as their centres traverſe, turning them all round, on the ſame principle as a carriage wheel is turned by rolling on the ſtationary road. In like manner *m* is turned, by moving along while the rope, *i*, is immoveable. Now the quantity of motion, or the number of revolutions the ſpindles will make during this return of the carriage, is, in all caſes, the ſame, and the quantity of thread to be wound up is always the ſame; but it is evident that it will require a greater number of revolutions to wind up the length ($1\frac{1}{2}$ yard) of thread, when winding upon the ſpindle, or upon the circumference of a ſmall coppin, than when the ſame coppin is increaſed by the accumulated thread to ten or fifteen times the ſize of the ſpindle. To accommodate this, it is neceſſary for the ſpinner to have the handle, L, in his hand, becauſe he can, by turning this one way or the other, add or diminiſh ſo much to the number of turns the ſpindle will make, as will juſt take up the thread as faſt as the carriage advances towards the rollers. Thus, at firſt beginning, when the coppins are ſmall, the handle, L, will require to be turned forwards a conſiderable quantity, to make them wind up the thread ſufficiently faſt: but as the ſize of the coppins increaſe, they will come to ſuch a diameter, that the handle requires to be held quite ſtill. The motion given to the ſpindles by the return of the carriage, being then juſt equal to wind up the thread at the proper rate, any increaſe of the dimenſions of the coppins after this will require the handle, L, to be turned backwards, to diminiſh the motion of the ſpindles, or they would wind up too faſt, and break the threads.

The ſpinner accommodates the motion of the handle, L, ſo exactly by habit, as to keep the threads always to that degree of tenſion as will make the coppin compact, but not injure the thread; at the ſame time by the other hand, which holds the ſpindle of the wire H, he lays the thread regularly on the length of the cop.

The carriage, having with theſe precautions been wheeled up cloſe to the rollers, the ſeveral operations are repeated as before; and thus the mule continues to ſpin a yard and a half upon each ſpindle every time it is drawn out, and then wind it up on the ſeveral coppins. A good ſpinner will draw out 3000 times *per* day of a mule with 240 ſpindles; and many women will attend two machines, having them placed oppoſite to each other; and while one is drawing out ſhe will thruſt home the other. This makes 108,000 yards *per* day upon each mule, or both together will make more than 1200 miles to be ſpun in one day by one woman; who, on the old method of the hand-wheel ſpinning, on which the mule is an improvement, would only have managed a ſingle ſpindle, inſtead of 480; and this ſingle ſpindle would not have ſpun half the quantity of any one in the mules; and with

with refpect to the regularity and accuracy of the thread no comparifon can be drawn. A mule of 240 fpindles has nine drums in the carriage to turn them; all the length, therefore, is nine repetitions of *fig.* 3, which only contains the fpindles turned by one drum.

The motion of the mule can at any time be ftopped, if a thread break, or any other accident happens, by means of a long wooden rail, Y, which is joined to the end of the lever W Y, and extends along over the whole length of the rollers, fo as to give the fpinner the means of ftopping the mule when ftanding oppofite to any part of its length; for it is evident, that by thrufting this rod one way or the other, the ftrap will be fhifted either on the live or the dead pulley, ftopping or putting the wheels in motion at pleafure.

The thread fpun upon the mule is much fofter, and has a fmoother furface than the water-twift: this is owing to the manner in which the extenfion of the thread is made, after it has been twifted flightly, and the fibres thereby compreffed together in fome degree; for the effect of ftretching a flightly twifted thread is, to draw all the ends of the fibres into it. All thefe fibres having affumed a fpirally curved form in the thread, by drawing or ftretching them out in the length of the thread one among another, thefe fibres are drawn along with a fpiral movement, and all their ends are thus brought into, and concealed in the body of the thread. This operation, at the fame time it makes the furface of the thread even and fmooth from projecting fibres, increafes the ftrength of the thread by bringing them all into ufe; and the ftrength obtained by this means does not require the thread to be twifted hard, but leaves it foft and pliable, which is the great recommendation of the mule-twift.

The thread thus fpun, either by the water-frame or mule, has many other operations to go through to prepare it for the market, where it is to be fold to the weaver or manufacturer. The chief end of thefe operations is, meafuring it out in lengths, weighing it to afcertain the number, and packing it up for carriage. The firft machine the thread is taken to after fpinning is

The Reel; fee *figs.* 1 and 2 of *Plate* XII. The former being an elevation of the end, and the other an elevation in front, a very fhort explanation of this machine will fuffice; its framing and fome other parts being evident. A A is a row of the bobbins of the fpinning frame, or for mule-twift, the coppins of the mule ftuck upon pins, on which they will revolve freely and give off their thread. B, *fig.* 1, is another row placed behind the former, and arranged in the intermediate fpaces between the bobbins of the firft row, which arrangement is neceffary, becaufe the bobbins would touch each other if all placed fide by fide. The threads for thefe bobbins are conducted between feveral pins or wires, ftuck up in a rail of wood D, and each thread is twifted once round one of thefe pins, that it may be drawn off with fuch a degree of force, from the friction thus occafioned, as will caufe the thread to lap or wind with a fufficient tenfion upon the reel E E, which confifts of a horizontal fhaft E, from which three fets of arms, F, proceed, fupporting fix rails, G, G, parallel to the axis, and upon thefe the thread is wound, as fhewn in the figures at *r*. The dimenfions of the reel is fuch, that it takes exactly a yard and a half of thread to make one turn round it: this, therefore, is the meafure of length, and the mechanifm which remains to be defcribed is for the purpofe of counting the number of revolutions it has made. The reel is turned round by means of a cog-wheel, H, on the end of the fpindle: this is turned round by a wheel K, on the axis of which is a pulley M, to receive an endlefs rope, which is turned round by the mill; but the bearing for the pivot of the axis, E, is fitted in a groove, formed on the top rail of the frame, fo that the wheel, H, may, by fliding the bearing in this groove, be difengaged from the teeth of the wheel K, and then the movement being thrown out of gear, the reel ftops. On the oppofite end of the axis of the reel, a pinion, *a*, of 14 teeth is fixed, which turns a bevilled wheel of 28 teeth on the upper end of a vertical axis *b*, which has an endlefs fcrew upon it, turning a wheel, *d*, *fig.* 1, of 40 teeth, on the axis of which is a pinion of eight leaves, turning a wheel, *e*, of 56 teeth. This wheel has a fmall circular ring fixed on the face of it, which is formed like a fnail on the front edge, that is, its furface is not parallel to the plane of the wheel, but is inclined to it in fuch an angle, that in turning round it operates upon a lever, *f*, to move it backwards and forwards, and this motion is, by means of a vertical lever, *h h*, communicated to the rails, A B and D, at the top of the reel, which carry the bobbins, and alfo the pins, D, that guide the thread, and having thus a fhort traverfe motion parallel to the axis of the reel, the threads are laid regularly by the fide of each other, without overlaying each other in one place, as they would do without this motion, and by thus enlarging the diameter of the reel, the thread that winds upon the meafure would be incorrect.

By calculating the numbers of the train of wheel-work, *a*, *b*, *d*, &c. which we have before explained, *viz.* by multiplying the number of all the pinions together, and the number of all the wheels together, and dividing one fum by the other, thus, $14 \times 1 \times 8 = 112$, the product of all the pinions: again, $28 \times 40 \times 56 = 62{,}720$, the product of the wheels. Divide 62,720 by 112, and the refult is 560; therefore the wheel *e*, of 56 teeth, will make one turn for 560 turns, or bouts of the reel. The wheel *d* makes only one-feventh of this number, or once for 80 bouts; and a pin being fixed in the back of its rim, feizes the tail of a bell, *m*, once for every turn it makes, confequently this bell rings at every 80 bouts of a yard and a half each, = 120 yards of thread wound upon the reel. The reeler, in beginning, makes the end of each thread faft to one of the rails, G, of the reel, then cafts it on, and fets it going until the bell, *m*, rings; it will then have made 80 bouts, or reeled 120 yards, which is called a ley. The reel is ftopped the inftant the bell rings, and every one of the leys of thread, *r*, *r*, *fig.* 2, is tied up by a piece of thread to keep thefe 80 bouts diftinct; then the reel is fet on again and another ley reeled, which is tied in its turn; and when feven leys have been thus done, it makes 560 bouts, or 840 yards, which length is called a hank: the feven leys compofing it are tied all together, the ends of the thread cut off, and the hanks are removed from the reel. They are got off by what is called ftriking the reel, to do which, the arms fupporting one of the rails, G, are divided acrofs in the middle of each, and united by hinges. When the arms are fet ftraight, and kept fo by a fmall bolt, the reel is of the true dimenfions; but by withdrawing the bolt, and bending the arms on the hinges, the rail falls in towards the centre, and the reel is fo diminifhed in fize, that the hanks hang flack upon it, and can eafily be flipped off at the end of the reel, which is lifted off its bearings for that purpofe.

A reel ufually winds 50 bobbins at once, and the principal care of the attendant is to watch the bobbins, fupplying others, and tying the ends of the threads as faft as they are exhaufted.

The hanks are now twifted up into a knot, by catching one end of them over an iron hook fixed to the wall, then putting a fmall iron rod in the other end, the hank is twifted up very hard, ufing the rod as a lever to turn it round. To prevent its untwifting again, it is taken by the middle of its length, and without fuffering the ends to entwine it is doubled, then the ends are releafed, and the two halves twift over each other, forming a bundle or knot of thread, refembling a piece of thick rope, about eight or nine inches in length, and perhaps two inches girt. The hanks, being thus all knotted, are weighed, to afcertain their number. The weighing inftrument confifts of a fhort pendulum, from which an arm proceeds on each fide, at top paffing through the centre of fufpenfion, fo that it refembles the letter T. From one of the horizontal arms a hook is fufpended, by which the hank is hung on; and at the end of the other arm is an index pointing to an arch which is divided, and has figures upon it, fhewing how many of fuch hanks (as the index is brought to by hanging any one upon the hook) will weigh a pound. The divifions are made by experiment, and frequently verified by means of fmall leaden weights, which the overfeer is provided with.

As faft as the number of the feveral hanks is determined by this index, they are thrown into different bins or fhelves, and when they are to be made up for market, as many hanks of any number as will weigh ten pounds are counted out, weighed, as a check upon the weighing inftrument, and packed up in paper, forming a fmall fquare bundle, which is made compact and tight in the bundling-prefs. This is a fmall fquare cheft, of about eight and a half inches by nine and a half, formed of vertical iron bars fet upon a table, and a lid of iron bars fhuts down over the top, with bolts or other faftenings. The bottom of the cheft is moveable up and down by means of a rack and pinion, a fcrew or other means, which will enable the workman to give a great preffure upwards. The hanks are packed clofely into this cheft with paper round them, and the whole number being packed in, the lid is fhut down and bolted upon them; then by turning a handle the bottom of the prefs is raifed up, and compreffes the bundle together into as fmall a compafs as is required. The bundle in this ftate is tied round with feveral ftrings, the interftices between the iron bars compofing the prefs leaving fufficient room for the admiffion of fuch ftrings, and for the knots to be tied to confine the bundle. In thefe bundles the greateft portion of the twift is fent to market; but what is called hard twift, muft be twifted two threads together, as is alfo ftocking-yarn. Such thread as is intended to be doubled for thefe purpofes, is taken from the fpinning-frame to the

Doubling machine, inftead of the reel. Here the threads, two together, are wound upon bobbins, as preparatory to twifting them round each other. See *Plate* XIII., *figs.* 1 and 2, which reprefent a doubling mill; in front *fig.* 1, and endways at *fig.* 2. A is the pulley which is turned round by the mill: this pulley is loofe on its fpindle, but has a clutch or locking-box at the back which connects it with its fpindle, when the upper end of the lever, B, is moved towards the machine. But when it is moved the other way the machine ftands ftill, though the pulley continues all the time to turn round. A wedge, *a*, being put on either fide of the lever in its mortife through the piece of wood D, retains the pulley, A, either unlocked or locked in gear, with the fpindle which is fixed in the end of a throftle-cylinder, R, and by bands turns all the fpindles, *b*, *b*, together. The bobbins of the fpinning-frame are ftuck upon pins in the top rail, E, of the frame, and the threads defcend to wires, *d*, round which they make a turn, two threads in company, to produce a friction, as before explained, fufficient to lay the turns on the bobbin of the fpindles, *b*, *b*, tight and even. The threads then go through wire ftaples or eyes fixed in a rail, F, fituated oppofite to the bobbins *c*, *c*, which are ftuck faft on the upper ends of the fpindles *b*, *b*, and being turned thereby, wind up the thread from the bobbins at E: the rail, F, is adapted to rife and fall parallel to itfelf, being attached by radial bars to an axis moving on centre pins fixed in the frame. Its motion is occafioned by an iron rod, *f*, which is jointed to it, and connects it to a lever, *g*, fixed on an axis; and at the extreme end of this is a lever, *h*, *fig.* 2, refting upon the circumference of a heart, *k*, fixed on the face of a cog-wheel *i*. This is turned by a pinion fixed againft a wheel *l*, which receives its motion from another pinion upon the end of the fpindle of the throftle cylinder R. By this train of wheelwork the heart is flowly turned round, and raifes and falls the lever, *h*, at the fame time giving a fimilar motion to the rail F, and by that means regularly winding the thread upon the bobbins *c*, *c*, which are turned rapidly round by the motion of the vertical fpindles *b*, *b*, which receive their motion from the throftle cylinder, R, by the bands, as before defcribed. The bobbins are fuch as fhewn feparate at X, and have a hole through them exactly fitting the conical end of the fpindle, on which it fticks fo faft, that the bobbin will, by the motion of the fpindle, wind up the two threads together off the bobbins at E. When the bobbins are filled with double thread, they are removed to the twifting-machine, if it is intended to make ftocking-yarn, or if it is to be what is called hard twift, for fewing, knitting, or mending-cotton, it is done in the water-frame, which, however, undergoes fome alterations, *viz.* the fpindles are made to turn about in a contrary direction to that in which they moved to fpin the thread It is done by turning the whole frame the other way about, but as this would make the rollers move the wrong way, the pinion at the upper end of the fpindle of the binder is placed at the outfide inftead of the infide of the face-wheel on the end of the front roller. The rollers then turn the right way about to deliver the thread to the fpindle, but the back and middle rollers are removed, as it is not required to draw out the thread, the rollers being merely wanted to hold the threads faft whilft they are twifted one about the other, and to deliver it regularly to the fpindle, which operates in the fame manner as for the firft fpinning, except that it twifts in the contrary direction; becaufe when any two threads are to be turned together, it muft be done by a contrary twift to that which compofed the two feparate threads themfelves. After fpinning this hard twift it goes to the reel, and is treated in all refpects as other twift is. When it is merely required to twine the two threads flightly together for ftocking-yarn, the bobbins of the doubling-machine, when filled with double threads, are carried away to

The twifting-machine, fee *Plate* XIII., *fig.* 3. of which is an elevation endways; and *fig.* 4, another elevation taken in front. In this, A reprefents the live and dead pulies turning the whole machine: the ftrap is conducted through an eye at the end of an iron branch *a*, affixed to a rod or beam B, which flides in guides beneath the machine, and can be moved endways by means of a lever *b*, which comes out in the middle of the length of the machine, and the attendant, by applying his foot to this lever, and moving it fideways, fhifts the beam B, and the eye at the end of the branch, *a*, guides the ftrap upon the dead pulley: the machine then ftands ftill. The live and dead pulley is fitted on the end of the fpindle of the throftle cylinder D, which, by bands going to both fides, turns a double row of vertical fpindles on each fide, E *e* and F *f*, the internal row on either fide being placed oppofite the fpaces between the outer row, fo that the

the ſpindles are not crowded too cloſe together. On theſe ſpindles the bobbins are ſtuck in the ſame manner as thoſe of the doubling-mill; and the threads proceeding from the bobbins are conducted through wire eyes, which are fixed in rails, G, of the framing, then each twiſted thread makes a turn round a wire fixed in the rails, H, juſt above G, and theſe have a ſlight traverſe motion backwards and forwards, by which they lay the thread evenly upon the reels, I, K, which take up the threads, as before deſcribed, of the reeling-machine. The reels are ſlowly turned round by a train of wheel-work from the main ſpindle of the pulley A. This train conſiſts, firſt, of a pair of bevilled wheels, one on the main axis, and the other at the lower end of a vertical ſpindle L, which at the upper end has a pinion actuating another wheel, *g*, upon the middle of a horizontal axis, which at each end carries a pinion, turning wheels, M, N, on the ends of the pivots of the two reels. The proportions of the wheels are ſuch, that the reel turns once for about 24 turns of the main throſtle D, or about one for every 72 revolutions of the ſpindles, and as the reel is a yard and a half about, the thread will be twiſted about 72 times in that length by the rotation of the bobbin and the thread with it. The motion of the reel draws the thread off the bobbin as faſt as above-mentioned, ſo that the proportion of the wheel-work determines the quantity of twiſt which ſhall be given in any certain length. The reels are provided with counting wheel-work of the ſame operation as that before explained in the reeling-machine. Thus, on the end of the ſpindle of the reel is a pinion turning a wheel *i*, on the axis of which is a ſcrew turning a wheel *k*, and this has a pinion on it turning a wheel, *m*, by means of the intermediate wheel *l*. The ſpindle of this latter wheel has a nail fixed upon it, which operates upon a lever *n*, the lower end of which preſſes againſt a croſs-bar, connecting the rail, H, with its fellow. On the oppoſite ſide of the machine there is another ſimilar croſs-bar at the other end, and the two rails being thus united, form a frame which is ſupported on iron radial bars *p*, *p*, which move upon centre pins fixed in the rail, G, of the frame; ſo that the frame, with the rails H, H, has a free motion to traverſe without friction, and guide the threads to lay regularly upon the reels I, K. At the oppoſite end of the frame a ſtring is tied which paſſes over a pulley, and has a weight, *r*, ſuſpended from it, which always draws the frame one way, and tends to keep the upper end of the lever, *n*, in contact with the ſnail upon the axis of the wheel *m*. This axis has alſo a pin projecting from it, which every time the ſpindle turns round, rings the bell P. The motion of the wheel-work is ſo calculated, that the bell ſhall ring once for every 280 bouts of the reel, and the ſize thereof is ſuch, that this 280 bouts ſhall meaſure 420 yards, being the length of the double thread hank, *r*, equal to half the length of the ſingle thread hank, which is, as before mentioned, 840 yards, and the number of double thread yarn, is according to the number of theſe hanks of 420 yards each to the pound. The reels, I, K, when filled, are ſtruck, and the hanks taken off them in the ſame manner as the reeling-machine before deſcribed.

Hard twiſt, which is intended for ſewing, knitting, or mending-cotton, after being twiſted and reeled in hanks, is ſent to the bleach-field, and bleached by ſome of the proceſſes deſcribed in our article Bleaching.

But the proceſs which is moſt generally in uſe for bleaching yarn, is thus conducted: an earthen-ware retort is filled with one quart of oil of vitriol, two quarts of ſea-ſalt, and one quart of the ore of mangoneſe. The hood of the retort being put on and luted, it is ſet over a ſmall ſtove or ſand-bath, and the heat ſoon raiſes from it the oxygenated muriatic acid gas, which is received in a ſquare wooden cheſt, about ſeven or eight feet ſquare, and as many deep, forming a ſmall air-tight chamber, in the upper part of which the goods are ſuſpended upon a rack or frame. The lower part of the cheſt, for about three feet deep, is filled with water, ſometimes impregnated with a ley of potaſh, and ſometimes with lime-water, or water mixed with lime. The gas is introduced betwixt the fluid and the goods, amongſt which it aſcends, and by its action upon any colour they may contain, renders them white: at the ſame time, by occaſionally immerſing the goods in the fluid below, it is ſought to modify the action of the acid, and prevent the operation proceeding too rapidly. This is effected by means of a pole or long rod connected with the frame on which the goods are ſuſpended, the centre of which pole moves on a ſwivel fixed in a hole in the partition, or lid of the chamber, which is occaſionally ſtopped with clay, and enables a perſon to raiſe the goods by means of a ſmall crane, or, at pleaſure, to let them down into the fluid, not always, however, without inconvenience, which occaſioned it the name of the *Bedlam proceſs*, as the workmen, if they inhale the gas, are ſtupified.

Previouſly to the yarn being ſubjected to the action of the gas, it is boiled in a ley of pearl-aſhes, then milled for twenty minutes in a fulling mill, and the hanks are hung upon the racks or croſs rails of the ſquare frame in which they are ſuſpended, to be let down into the bleaching-chamber. This frame is, as before-mentioned, attached to a long pole, that ſuſpends it from the crane, which being ſwung over the chamber, is let down therein, and the lid is cloſed over it, the joints being made tight with clay, and the pole coming through a hole in the lid, which is carefully made tight round it by a wet cloth. The gas is now admitted to the chamber, but the yarn is not ſubjected to its action more than ten minutes before it is let down and immerſed into the liquor at the bottom of it, which thus defends it from the action of the gas for a few minutes, until it becomes thoroughly wetted, when it is drawn up again into the gas, and remains in it for half an hour to be bleached: it is then let down again, for a few minutes, into the liquor to wet it; it is then drawn up again, and in this manner the proceſs continues, until ſuch time as it is known, by experience, that the yarn will be ſufficiently bleached. The frame is drawn up by the crane, and the cotton removed from the rails on which it hangs, and being rinſed in clean water, is carried out and ſpread on the graſs in the fields, to be ſubjected to the ſun and air, by which the bleaching is completed. It is not the buſineſs of the preſent article to enter into the theory or chemical principles of this proceſs, which will be found under the article Bleaching.

After the hanks are returned bleached, the yarn is found to be much lighter, ſo that it will generally be two numbers higher: thus, cotton of N 48 hanks to the pound being ſent to bleach, will return ſo much diminiſhed in weight, as to require 50 of the hanks to weigh a pound. But this rule is not ſo exact as is requiſite; the thread muſt therefore be reeled over again, weighed, and packed. A great proportion of the ſewing cotton is wound into balls of a very beautiful appearance by a curious winding machine. As a preparation to this winding, the thread muſt be wound off the hanks in which it was bleached to large bobbins. This is done in a machine provided with ſeveral ſpindles, like the doubling machine, upon which bobbins are ſtuck, and the thread wound on them from the hanks, when they are extended or ſtretched out between two pul-

 lies,

lles, or fmall reels, on which the hank revolves in the manner of an endlefs band. Thefe bobbins are taken to the

Ball Winding Machine, fee *figs*. 3. and 4. of *Plate* XII. the former being a plan of the acting parts, and the latter an elevation of the whole machine on a fmaller fcale. In *fig*. 4. A is the bobbin from the winding machine, which is fluck upon a pin projecting upwards from the bench, and a fmall lead weight is laid upon the top of the bobbin, to load it, and caufe fuch a friction as will make the thread wind with a proper tenfion upon the ball. The principal part of the machine is a fpindle B, which is perforated through its length, and receives the thread: it runs, in bearings, at the top of two flandards *a*, *b*, and at the extreme end of the fpindle, beyond the front flandard, a flyer or branch, D, is fixed, and the end, *d*, of it therefore deferibes a circle when the fpindle, B, turns round by the endlefs band which furrounds the pulley E, and gives it motion from the mill. The fpindle has an endlefs fcrew cut upon it, turning a wheel, G, at the upper end of the vertical fpindle F, which, at the lower end, has an univerfal joint, *e*, connecting it with an inclined fpindle H: this, at the lower end, has a fmall bevilled wheel, *h*, turning another, *f*, on a fmall vertical axis, carrying, at the upper end, an univerfal joint, which communicates motion to an inclined fpindle I, and this, by another fimilar joint at *i*, connects with a vertical axis *r*, which has a pinion, *k*, turning a wheel *l*, upon whofe fpindle, *m*, the thread is lapped to form the ball, as fhewn in *fig*. 3: the fpindle, *m*, is fupported by a piece of metal, K, formed like the letter L, and moveable on a centre pin *n*, which is fituated exactly in a line with the fhort vertical axis of the wheel *f*: M is a circular plate, on which the piece, K, refts, when turned about on its centre pin *n*, and N is the handle by which it is turned about at pleafure upon it. The two fpindles, B and *m*, are, as fhewn in *fig*. 4, on the fame level, but are capable, as fhewn in *fig*. 3, of being fet at any angle to each other by inclining *m* on its centre pin *n*, and this being in the line of the fpindle of *f*, the motion does not tend to lengthen or fhorten the fpindles I and *r*; but they always cunvey the motion, communicated from the fpindle, B, by means of the axes F H I and *r*, to *m*, by the feveral wheels G, *h*, *f*, *k*, and *l*, which have been defcribed: they are fo apportioned, that the fpindle, *m*, turns only once for 48, 60, or 72 revolutions of the fpindle B. Thefe different numbers are ufed in different machines, and the appearance of the ball they will wind materially depends upon this circumflance.

To explain its operation, fuppofe the fpindle, *m*, inclined to B, as in *fig*. 3, the rapid motion of the fpindle, and its flyer D, (over the point, *d*, of which the thread is conducted) laps the thread round the fpindle, *m*, in an oblique direction. At firft, the ball thus formed has no regular figure, but as the thread accumulates and forms a cone, the lapping of the thread in a regular order begins and continues, as in *fig*. 3; here it is feen, that the motion of the flyer will lap the thread obliquely upon the ball from one end to the other, as the figure fhews; but at every fucceeding revolution of the flyer, the ball itfelf has made $\frac{1}{48}$, $\frac{1}{60}$, $\frac{1}{72}$, part of a revolution upon its own axis *m*, according to the proportion of the wheel-work, and thus the thread is not always difpofed on the fame oblique line, but on another parallel to it, and removed a fmall diftance from the former. Now it is plain, that the thread on the underfide of the ball muft be inclined in a contrary direction to that lapped on the upper fide; therefore, when the ball is looked at, the oblique threads of every alternate layer crofs each other, in the manner of the figure. This will, however, be much more readily underflood from an infpection of a ball of this kind, than from any verbal defcription. The length of the ball depends upon the angle which the fpindle, *m*, makes with the fpindle B; it can, therefore, by fhifting the handle N, be wound off of any required figure; but the moft general method is, when about one half the fize of the ball is wound, to give the fpindle a greater degree of obliquity: this occafions the ball to wind longer from that period, as well as a greater diameter: the confequence is, that when the ball is finifhed, on looking at the end of it a circular hollow is feen in it, as though it had been turned in a lathe, and fometimes a thin membrane, confifting of about two or three layers of thread, is extended nearly acrofs the end, leaving the hollow beneath, which can be feen into from a fmall hole in the end. This membrane is made by fetting the handle, N, at the greateft angle it will make, the thread then not only lays over the whole furface of the ball, but is ftretched partly acrofs the end of it; and the interfection of a great number of thefe forms a tranfparent membrane, which has a circular hole in the centre. After laying this layer two or three times over, the handle, N, is returned to its original angle, and winds the ball as at firft.

The bench or table RR, on which the machine ftands, is made long enough to contain fourteen fpindles, all placed in one row; and a throftle cylinder, running along under the bench, gives motion to them all at once. Two children attend the whole fourteen, which they can readily do, having only to lap the thread, at the beginning, upon the fpindle *m*, and then, when the ball has arrived at a certain fize, to turn the handle N; but the period or quantity of this alteration is not of any great importance, as it only influences the figure of the ball, and, as we before defcribed, thofe fancy ornaments within the hollow end: thefe may, by great attention in frequently and artfully fhifting the handle N, be made very delicate and beautiful. The machine we have juft defcribed was made after a model of a machine invented by Mr. Brunell, who firft devifed the means of connecting the fpindles, B and *m*, by wheel-work. The machines, before this, were turned by endlefs bands, from the principal cylinder which gave motion to the whole. The defect of this method was, that the relative diameters of the wheels could not be fo exactly proportioned, as to produce one turn of *m* for exactly forty-eight, &c. of B; that the threads of the fucceffive layers would lay exactly one over the other, becaufe the leaft variation in this refpect would greatly injure the effect of the ball. But in the machine before us, the motions are fo accurate, that, on infpecting the ball, it appears honey-combed, or confifting of regular cells, which gradually diminifh in fize as they approach the centre: the partitions between thefe cells are only one thread in thicknefs, but confifting of a great number, ftretched fo exactly over each other, that they form regular plane fides to the interior of the feveral cells.

We have now prefented our readers with all the operations of cotton-fpinning; but thefe operations are conducted on fo grand a fcale by many manufacturers, that the fyftem of their management, the arrangement of the buildings, the conftruction of their water-wheels, fteam-engines, or other firft movers, and many other particulars, are no lefs admirable, and worthy of defcription, than the machines themfelves. To defcribe all thefe curiofities of the cotton trade would fill a volume; but we muft content ourfelves with defcribing one plate, which contains drawings of one of the moft complete cotton-mills we have ever vifited. It is one of the four mills at Belper, in Derbyfhire, belonging to Meffrs. Strutts, whofe very extenfive works contain almoft every improvement in the cotton trade. The whole of thefe these mills is built fire-proof, being without any timber beams in the floors, or much wood work of large size in any of the machines, which makes them very secure from danger by fire.

Fig. 1. of *Plate* XIV. is a longitudinal section of the whole mill, shewing all the floors, and all the machines upon them, at one view. *Fig.* 2. is a section, across the length of the former; and *fig.* 3. is a similar cross section of the mill, and, at the same time, a longitudinal section of the wing, which extends from the centre of the mill, at right angles, to its length; so that the plan of the mill is of the figure of the letter T. We will first explain the manner of building fire-proof mills without timber, which has been adopted by Messrs. Strutts in their very extensive works.

The side walls A A, B B, and the end walls C C, D D, are built up as usual, and with the usual doors and windows in them; the several floors, E, F, G, H, I, K, are composed of brick arches, as shewn in the figures. In *fig.* 1, these arches are shewn cut across the span; and in *fig.* 2, they are shewn cut through the crown, parallel to the axis. These arches have a very small rise, and their span is nine feet from one to the next. The abutments, or springings of the arches, are supported by iron columns, *a*, *a*, as shewn in the figures, which are erected, one upon another, in the several floors, through the whole height of the mill. They are connected by cast-iron beams or girders, *b*, *b*, shewn in *fig.* 2, one of which extends from the top of every column to the next, and forms a support or springing for the arches. In an opposite direction to these girders, every pair of the columns, *a*, *a*, are tied together, across the arch, by a wrought iron bar, which has an eye at each end, to be hooked over the tops of the columns, and keep them tied together, resisting the lateral thrust of the arch, and preventing the columns from being thrust asunder from each other, as they would otherwise be. Thus, though every floor is formed of a system of arches, like a bridge, as shewn in *fig.* 1, yet the lateral strain of each is supported by iron tyes; so that each arch stands by its own supports, independent of its neighbours. The arches are of only one brick thickness, and are covered over at top by a floor of paving bricks, to make a flat surface above, the haunches of the arches being filled up by rubbish. The iron tyes across the arches are concealed within the brick-work of the arch, so that they do not appear; the ceilings of the rooms, therefore, consist of regular arches, which have a very good appearance, and make the most firm and solid floors above that can be imagined. The roof is of cast-iron, as shewn in *fig.* 2, where the two columns, *d*, *d*, are a continuation of the columns, *a*, *a*, in the lower floors; and a cross or girder beam, *e*, which connects them, is also a support of the cast-iron principals, *f*, *f*, of the roof; and *g*, *g*, are further stays, proceeding from the iron girders uniting the columns of the ceiling, *k*, beneath: the space between the two columns, *d*, *d*, in the roof, forms a small room, which is used as a school-room for the work-people on Sundays. The desks and forms are shewn in the figure.

The mill contains fifteen arches in length, as shewn in *fig.* 1, between the walls C C, D D, which are the end walls of the mills. Besides these is another wall, L, to which the floors are continued by two additional arches, added beyond the end wall, C, of the mill. This space forms a small room on each floor, which is occupied by the counting-house, stair-case, and the stove, which warms the mill in winter; and also a crane of a peculiar construction, for drawing up the goods to the machines on the several floors.

The space of the mill, therefore, between the walls C and D, is appropriated to the machinery, as is also the wing, which consists of six arches, as shewn in *fig.* 3, projecting from the middle of the mill, perpendicular to its length.

The width both of the mill and the wing is, as shewn in *fig.* 3, composed of three lengths of arches, having three iron girders that they rise from, and two columns to support them. The arches in the ground-floor, or cave of the mill, are supported by very strong piers, *m*, instead of iron columns. These piers are founded very firmly in the earth, and every caution taken to prevent them subsiding, or settling under the great weight they have to carry. The columns of the first floor are erected immediately upon the top of these piers: on the top of these columns are those for the second floor; the third surmount these, and so on to the top of the mill: the columns being thus erected, one upon another for the whole height of the mill, forms the staunchest building that can be imagined.

We shall now proceed to describe the machinery of the mill. The whole motion is taken from the great water-wheel M, situated underneath the wing, in the cave, or lowest room of the mill; and as it is of so great a size, namely, 18 feet diameter, and 23 feet long, that no cast-iron girder could be thrown across it strong enough to support the arches for the wing above it, a strong stone arch, N, is thrown across from the wall *h*, which is built up at one end of the water-wheel, to the wall, A, of the mill, which is at the other end of the mill; and to resist the thrust of this arch, two strong iron bolts, *x*, are extended across it, and render it as strong as possible; so that the iron columns of the wing over it may be raised upon it as safely as they could upon foundation piers, *m*, like the others. But as a precaution against overloading the walls, *h* and A, which, as they include the water-wheel, would ruin every thing, if they settled in the least, the arches of the wing immediately over the water-wheel are built, instead of solid brick, with small pots like garden pots, so that they are light, but sufficiently strong to bear any thing which is ever required to be loaded upon them. These small pots are also used to build the arched floor, K, of the roof, that it may be light, and as it has nothing to bear but the school room, they are sufficiently strong to make the floor.

The great water-wheel has a cog-wheel, *o*, upon the end of its shaft, which turns a pinion, *p*, on a strong shaft, that carries a wheel *q*, and thus turns a pinion on a third shaft, *r*: this, at the end, has a bevilled wheel, which gives motion to a vertical shaft, *s*, proceeding up to the top of the mill, and turning the machinery in the several floors. The bevilled wheel on the shaft, *r*, also drives a horizontal shaft, *t*, extending the whole length of the mill, and having upon it, just beneath every arch, a bevilled wheel, turning another on a vertical spindle, which rises up through the two floors D and G. These are the main spindles of the spinning frames, and the great frames are fixed upon them. The frames are all shewn endways in *fig.* 1; but in *fig.* 3, on the floor F, a pair of frames are shewn in front, as they stand side by side, and the floor, G, over it has just the same, as has also the wing, though not put in the drawing; but these last are turned by a bevilled wheel, *v*, *fig.* 1. on the shaft *s*, in the floor G, which turns a horizontal shaft, *v*, *fig.* 3, extending the whole length of the wing, and turning the spindles of the several frames as it passes over them. The two lowest floors, F, G, which are appropriated to the spinning frames, contain 28 frames on each floor, 56 and 12 more in the two floors of the wing, in all containing 4236 spindles, a considerable proportion of which are, however, employed in spinning the hard twist. The two next floors, *viz.* the

the 3d, H, and the 4th, I, are occupied in the body of the mill with carding machines, which ſtand in three rows: they are turned by ſtraps from a horizontal ſhaft, extending the whole length of the mill, over the machines. In *fig.* 1. they are ſhewn endways, and *fig.* 3. ſhews them in front of the floor H, while that above it is juſt the ſame, though not drawn: in all theſe two floors are 64 breaking cards, and 72 finiſhers. The ſame floors, H and I, in the wing, contain 16 drawing frames and four ſtretching frames or mules, in which the rovings are prepared as deſcribed in our account of the different methods of making rovings. The fifth floor, I, contains the reeling, doubling, and twiſting machines, &c. as we have deſcribed; but the numbers of the different kinds of theſe laſt mentioned machines vary in every mill, according to the kind of cotton which is to be ſpun in it, and that branch of trade its proprietor intended to carry on: if it is for ſpinning twiſt for weavers, only reels will be wanted in the fifth floor; or if it is to ſpin ſtocking yarn, doubling and twiſting machines will be wanted. Indeed theſe laſt machines are altered every few years in cotton mills, according as the ſtate of the trade varies from a demand of one article to another.

The ſpace of the mill, between the walls C and L, contains, as before-mentioned, the ſtaircaſe O, which is of ſtone, aſcending from one floor to the next, and alſo the crane P P. This is a moſt ingenious and uſeful machine, which has been adopted by Meſſrs. Strutts in all their cotton mills, and it is applicable to many other manufactories. The crane conſiſts of a large ſquare baſket, or cradle, four feet ſix inches ſquare in the bottom, withinſide, and ſix feet deep: it is open in front. The bottom is a floor of wood, and the ſides wicker or baſket work ſtrongly bound with iron ſtraps. This baſket or cradle is ſuſpended by a rope in a well P, extending from the top to the bottom of the mill, through all its floors. The cradle exactly fills the well, and is guided by iron ſliders in each angle, ſo that it may be ſteadily drawn up from one floor to any other by the power of the mill, and ſtopped or ſet in motion, either up or down, at pleaſure, by pulling two guide ropes, which are always in reach of a little boy who ſits at the top of the cradle in a ſeat made for the purpoſe. Now the machinery for effecting this is the only difficulty: it is neceſſary, in ſuch a crane, that the machinery, when caſt on to draw up the cradle, ſhould move with a regular and equable velocity, without making any ſhock or jerk when it firſt ſtarts; that it ſhould ſtop the inſtant it is required, otherwiſe it would be very difficult to ſet the cradle, with its floor, exactly on a level with any of the floors of the mill, and if not ſo, it would be very inconvenient for the people to get in or out of it.

The cradle muſt alſo be let down by the power of the mill as well as drawn up, becauſe if ſuffered to run down by its own weight, it would always run down too quick or too ſlow, and be dangerous and uncertain: it muſt, at the ſame time, be ſo contrived, that the cradle itſelf will ſtop the machine if drawn up too high, or let down too low, to prevent its being over-wound and breaking the works. All theſe conditions are effected, in the moſt perfect manner, by very ingenious mechaniſm, which was invented by Mr. H. Strutt, and has been adopted in all his father's mills, rendering theſe cranes as ſafe and manageable as poſſible. The rope ſuſpending the cradle in the well is double, to enſure greater ſtrength, and is conducted over a pulley, or grooved wheel, ſituated in the roof of the mill. The other end has ſuch a weight ſuſpended from it, as will balance the weight of the cradle, together with half the weight of the uſual load the crane is expected to carry. This weight, therefore, draws the rope ſo tight upon the grooved wheel, that it will, by turning round one way or the other, elevate or depreſs the cradle at pleaſure, and at the ſame time the balance weight, which has a ſmall well of its own to work in. The axis of the grooved wheel has a cog-wheel on the end of it, which is turned round by a ſmall pinion fixed on the extremity of an axis on which the mechaniſm is placed: it conſiſts, firſt, of a large wheel, like a coach wheel, ſhewn at *x*, *fig.* 1, fixed on the middle of the axis, and on each ſide of this are two broad riggers or drums to receive the endleſs ſtraps, which give the motion againſt theſe riggers on the outſide of each. A dead pulley or rigger is fitted looſely on the axis, and being exactly the ſame ſize as the live riggers or pullies, the ſtrap can be ſhifted from one to the other in a moment. The axis is actuated by two endleſs ſtraps coming from one drawn at *y*, *fig.* 1, which is turned by wheel-work from the ſhaft in the fifth floor of the mill, as the figure ſhews. One of theſe ſtraps is croſſed between the two drums, and the other is not, ſo that the motion of the two dead pullies on which theſe ſtraps act are always in contrary directions to each other, whilſt the axis on which they run is ſtationary. The two ſtraps are guided by paſſing through eyes attached to a ſide rail of a ſquare frame, which includes the axis with both its riggers and great wheel, and is ſuſpended from the top of the machine by four pendulous rods, ſo that it has free motion to ſwing backwards and forwards in a direction parallel to the length of the axis of the pullies, which motion is communicated by a crank formed on a ſpindle, having a grooved wheel on the end of it. An endleſs rope paſſes over this wheel, and then deſcends to the bottom of the well, where it is ſtrained beneath another wheel, ſo that the two ſides of this rope are always in reach of the boy before-mentioned, who rides in a ſeat at the top of the cradle, giving him the means of turning the wheel and crank either way about, for by pulling down one of theſe guide ropes, he turns the wheel and crank, and draws the ſuſpended frame one way, or by pulling down the other guide rope it is drawn the other. The conſequence of theſe movements is, that the endleſs ſtraps are ſhifted both together on one or other of their live pullies, whilſt the other ſtrap will be ſhifted upon the oppoſite dead pulley; conſequently, the ſtrap which is upon the live pulley turns the axis round one way or the other, drawing the cradle up or down, as it happens to be the croſſed ſtrap, or the oppoſite one, which is ſhifted on the live pulley, fixed on the axis at either ſide of the great wheel, which we firſt compared to a coach wheel. This is, in reality, a brake wheel, having a broad ſtrap ſurrounding the lower half of it, both ends of which are conducted over two pullies, and levers with heavy weights draw down the ends, ſo that it has a conſtant tendency to preſs upwards beneath the wheel, to break, or cauſe ſuch a friction upon it, as will ſtop its motion, when the two endleſs ſtraps are ſhifted upon their dead pullies; but when the ſwinging frame is ſhifted either way, by the boy pulling down one of the guide ropes, which go down to the bottom of the well, and either of the ſtraps are thus ſhifted upon the live pullies, the frame ſeizes the tail of a bent lever on each ſide the wheel, and relieves the weights which draw the ſtrap againſt the wheel, and it hangs quite ſlack beneath the wheel, with a conſiderable ſpace all round, ſo that its motion is quite free, and only under the influence of that ſtrap which, being upon one of the live pullies, gives it motion in either direction. The crank before-mentioned for ſhifting the ſwinging frame is ſo contrived, that it always has a tendency, by means of a weight, to aſſume ſuch a poſition, that it will direct the ſwinging frame, and the ſtraps, both upon the dead pullies and the brake ſtrap, being at the ſame time in contact with the lower half of the wheel, the cradle will ſtand

ſtand ſtill; but when the crank, by pulling one of the guide ropes which go down to the bottom of the well, is turned to ſhift the endleſs ſtraps either way, and conſequently put the cradle in motion, the crank drops into a kind of hitch, or catch, which holds it in that poſition, but not ſo faſt but that it can be relieved in a moment by ſnatching the guide or rope, and if left to itſelf it then aſſumes that poſition in which the crane will ſtand ſtill. By this means the crane is in no danger of any accident, as it is always under the action of one or other of the endleſs ſtraps, which cauſe it to aſcend or deſcend, or it is under the brake ſtrap, which makes it ſtand ſtill, and the great advantage of all theſe movements are, that they act ſo ſoftly, without any ſudden jerks or ſnatches in changing from one ſtate to another. The well has a gate fixed up at every floor to prevent people falling down into the mill, and if any perſon, on the fifth floor for inſtance, wiſhes to deſcend to the third, he goes to the gate and calls the boy, who, with the cradle, is perhaps below, to come to No 5, which he does by ſnatching that guide rope which makes the crane draw up, when he ſees the floor of the baſket come exactly oppoſite the floor of the mill No. 5. He ſnatches the oppoſite rope; this jerks the crank out of its hitch, and it ſhifts the ſtraps and brake, ſtopping the cradle in an inſtant, ſo that it is ſeldom half an inch out of level with the floor. The perſon who wiſhes to go down can now open the gate, which he could not do before, becauſe the latch of the gate is lifted up by the cradle, when its floor is level with the floor of the gate, and ſtepping into the cradle he mentions the floor he wiſhes to go to, and the boy pulls down that directing rope which lets him down, and ſtops it at the floor he wiſhes, by ſnatching the other rope; but if he ſhould pull the wrong, no harm can enſue, becauſe the brake will always act to ſtop the machine, if the ſtraps do not act to move it. The bobbins of the ſpinning frame, and the cops of the mule, are ſet up in little frames mounted on wheels, and thus wheeled along by little children to the crane, and drawn up or let down as required, without any hard labour; in fact the ſtairs are ſeldom uſed except for the people to go up and down when they begin and leave off work.

The ſtove which warms all the mill is ſituated down in the cave beneath the ſtaircaſe: it is very ingeniouſly contrived with an iron cockle, or inverted cubical veſſel, beneath which a fire is made, and the ſmoke eſcapes by a flue behind into a chimney. The air is then brought in a current to ſtrike upon the external ſurface of this cockle, and being thus warmed, riſes up through flues into every floor of the building, where it is admitted in any quantity at pleaſure by regiſters, which are regulated to produce an agreeable warmth, but as the warm air eſcapes again with a draught through a proper ventilator, there is nothing of cloſeneſs connected with it.

Our limits will not permit us to deſcribe more of the ingenious contrivances with which Meſſrs. Strutts' extenſive mills at Belper abound, neither could the reader form a good idea of them without additional plates, and we have already exceeded our propoſed number. Meſſrs. Strutts very liberally permitted the writer of this article to viſit their works, for the purpoſe of compoſing it, to take drawings of the principal machines, which are of the very beſt conſtruction of any in the cotton trade. Theſe would have appeared here, but that the firſt ſix plates of our ſeries were drawn and engraved ſome years ago, being intended for the article Cotton, at a time when the machinery was not brought to that perfection, in point of conſtruction, that it is now. Indeed, the mechanical ingenuity called forth in the whole manufacture of cotton, is beyond the conception of thoſe who have not viſited the countries where it is carried on. The tools and implements employed in conſtructing the different machines are very curious; for as there are ſuch immenſe numbers of each part of every machine to be made, it becomes, in the ſame manner as with the clock-maker, worth the machine-maker's trouble to conſtruct complicated tools and engines to expedite the manufacture of the parts; thus cutting engines for forming the teeth of the numerous wheels, ſee *Cutting* Engine. And here we would remark, that Mr. George Gilpin of Sheffield has, ſince the printing of that article, invented a method of cutting wheels from ſolid caſt iron, with as much accuracy and as good a finiſh as braſs wheels have hitherto been cut, making a very great ſaving in the expence of braſs for a large mill, and much more durable when done. Card wires are manufactured in a very extenſive ſcale in Yorkſhire, and many very curious machines have been invented to diminiſh the labour of cutting and bending the wire teeth, and pricking the leathers for them: but a patent has been lately taken out, by Mr. J. C. Dyer, for a machine which cuts and bends the wires, pricks the leathers, and puts them in all at one operation, and with ſuch rapidity, that it completes four *per* ſecond. It is one of the moſt ingenious and perfect machines we ever met with, and it will prick and ſtick any ſort or ſize of teeth, by altering adjuſtments introduced for that purpoſe. Drawings and a full deſcription of this curious machine are lodged in the patent office by the patentee, who brought over the invention from America, where it has been ſome time in conſtant uſe. Curious lathes for turning ſpindles, and various other circular work, are uſed in the workſhops of the cotton mills and fluting machines, for cutting the flutes in the lengths of the rollers of the drawing and ſpinning frames: in ſhort, ſuch works as Meſſrs. Strutts' at Belper, Mr. Arkwright at Crauford, in Derbyſhire, Meſſrs. Phillips and Lees at Mancheſter, Mr. Peeles' and many others, are ſchools for mechanics in almoſt every department of the ſcience; and good ones too, as the cotton manufacturers in general are convinced, that it is their intereſt to attend to every minutia in the conſtruction of their machines, which may render them more durable or their operations more perfect. Among theſe improvements we may mention, what is becoming very general, *viz.* the addition of governors, or regulating balls, to the water-wheel, which turn the cotton mills, as they always keep it moving at the ſame ſpeed, without which all the machines in the mill act irregularly, and it muſt happen that the velocity of the common water-wheel varies, when any number of machines are ſtopped, or caſt in motion; but the regulated water-wheel always adapts its draught of water to the work it has to perform, preſerving an uniform velocity in itſelf and all the machines it turns. This is brought to ſuch perfection, that many ſuch mills have a clock turned by the mill; cloſe to it another clock, regulated in the uſual manner by a pendulum, and the motion of the mill is ſo regular, that theſe two clocks will never vary more than two or three minutes. Both are made with dials and hands exactly alike, but one has a title on the dial, *mill* time, and the other, *clock* time. We ſhall take an opportunity of explaining a regulated water-wheel, under Water-wheel.

We ſhall here cloſe this article, though we have only gone through the detail of cotton-ſpinning, becauſe the ſubſequent proceſſes of weaving cotton-thread into cloth, dreſſing, finiſhing, printing, &c., have been or will be ex-

plained

plained under the following feveral heads; *viz.* for explanations of the weaving proceffes, fee DRAUGHT *of looms*, or CORDING, DRAW-LOOM, DRAFER, DIMITY, DORNOCK. Though the three laft are rather linen than cotton, ftill the fame proceffes apply in part to the weaving of cotton goods; fee alfo FUSTIAN, and laftly, WEAVING. For the dreffing of cloth after weaving, fee CALLENDAR, or rather PRINTING *of Calico*, which precedes the calendar, except for fome particular goods; and as a part of calico-printing fee DIPPING; alfo BLEACHING, DYEING, DISCHARGING, and WASHING-WHEELS. And, as we have before mentioned, a full account of the wonderful rife and progrefs of the cotton manufacture, which is wholly founded upon the improvements in the machinery for fpinning, will be found under COTTON. Under the head of SPINNING, we fhall defcribe thofe variations of the cotton machines, which have been made to adapt them to the fpinning of flax, wool, and worfted.

MANUFACTURERS. Perfons enticing artificers into foreign countries incur the penalty of 500*l.* and twelve months imprifonment, for the firft offence, for each perfon fo feduced, and 1000*l.* and two years imprifonment, for the fecond offence. (23 Geo. II. c. 13.) And fuch artificers not returning within fix months after warning, fhall be deemed aliens, forfeit all their lands and goods, and be incapable of any legacy or gift. (5 Geo. I. c. 27.) By 22 Geo. III. c. 60. if any perfon fhall contract with, or endeavour to perfuade any artificer concerned in printing calicoes, cottons, muflins, or linens, or preparing any tools for fuch manufactory, to go out of the kingdom, he fhall forfeit 500*l.* and be imprifoned for twelve months; for a fecond offence, 1000*l.* and be imprifoned for two years.

MANUGASTA, in *Geography*, a town of South America, in the province of Tucuman; 20 miles S. of St. Yago el Efteros.

MANULCA, in *Antiquity*, that part of the catapulta to which the cord ufed in working it was fixed.

MANULEA, in *Botany*, fo named, as it fhould feem, from *manulea*, a covering for the hand, in allufion to the form of the corolla, the four fegments of whofe limb pointing one way, and the fifth feparate from them, fuggeft the idea of a glove, at leaft in *Manulea Cheiranthus*. Linnæus, who gave this name, fcarcely ever deigned to give any explanation of the names he contrived, and we offer the above as a conjecture only. Profeffor Martyn leaves it unexplained. Linn. Mant. 12. Schreb. 416. Willd. Sp. Pl. v. 3. 327. Mart. Mill. Dict. v. 3. Thunb. Prod. 100. Juff. 100. Lamarck Illuftr. t. 520. Gærtn. t. 55. (Nemia; Berg. Cap 160.) Clafs and order, *Didynamia Angiofpermia*. Nat. Ord. *Perfonatæ*, Linn. *Pediculares*, Juff. *Scrophulariæ*, Venten.

Gen. Ch. *Cal.* Perianth inferior, in five deep, linear, erect, equal, permanent fegments. *Cor.* of one petal, irregular; tube cylindrical, contracted at the mouth; limb fpreading, in five deep awl-fhaped fegments, the four uppermoft of which are moft connected at their bafe, the lower one being reflexed. *Stam.* Filaments four, very fhort; anthers of the upper two in the mouth of the corolla, thofe of the two lower rather oblong, within the tube. *Pift.* Germen fuperior, roundifh; ftyle thread-fhaped, the length of the lower ftamens; ftigma fimple. *Peric.* Capfule ovate, the length of the calyx, with two cells and two valves, which laft when ripe are half cloven; partition double, formed of the inflexed margins of the valves. *Seeds* numerous, fmall, affixed to an oblong, compreffed, central column.

Eff. Ch. Calyx inferior, in five deep fegments. Limb of the corolla in five deep awl-fhaped fegments, the upper four of which are moft connected. Capfule of two cells, with many feeds.

Obf. The above characters are taken from the original fpecies, *M. Cheiranthus* above-mentioned, but they by no means agree, at leaft in the limb of the corolla, with the generality of thofe fubfequently referred to this genus in the *Supplementum* and elfewhere. Bergius gives as the effential character of his *Nemia*, which includes *M. Cheiranthus* and *rubra* of Linnæus, that the two upper anthers are roundifh, the two lower oblong. This however is probably variable, and certainly not very important. Thunberg indicates no generic character, but enumerates a great number of fpecies, 28, in his *Prodromus Plantarum Capenfium*, four of which have entire, 23 toothed or ferrated, and one pinnatifid leaves. Willdenow admits but 17 in all, not having, when he wrote, feen the fecond part of Thunberg's work.—The chief difficulties are found in diftinguifhing between *Manulea*, *Erinus* and *Buchnera*. Ventenat in his Jard. de la Malmaifon, 15, fuggefts that the two former are moft nearly allied, and differ only in the lobes of the corolla of *Erinus* being more or lefs notched or cloven, while thofe of the genus before us are entire. *Buchnera*, according to this writer, differs fo effentially from both as to belong to a diftinct natural order, the *Pediculares* of Juffieu, as having the partition of its fruit, contrary to the valves; whereas the other two genera, having it parallel, belong to the *Scrophulariæ* of that author. As the matter is fo obfcure, and the plants fo little known, we fhall take a view of all thofe in Willdenow, giving what illuftration is poffible from original fpecimens, and adding what we can that has efcaped him.

1. M. *Cheiranthus*. Hand-flowered Manulea. Linn. Mant. 88. Willd. n. 1. (Lobelia Cheiranthus; Linn. Sp. Pl. 1319. Nemia Cheiranthus; Berg. Cap. 160. Cheiranthus africana, flore luteo; Commel. Hort. v. 2. 83. t. 42.)—Leaves obovate-oblong, ferrated, hairy. Stems nearly leaflefs, fomewhat racemofe. Segments of the corolla taper-pointed.—Native of the Cape of Good Hope, as are all the following fpecies. Commelin cultivated it at Amfterdam in 1697, and named it *Cheiranthus*, from the refemblance of the flower to a hand, an etymology that confirms our explanation of the Linnæan generic name above. The *root* is annual, fpindle-fhaped. *Stems* about a fpan high, erect or afcending, nearly fimple, almoft leaflefs, each terminating in a fimple, elongated, bracteated *clufter*, of numerous yellow *flowers*, whofe form is defcribed in the generic character. The *leaves* are almoft all radical, ftalked, obovate or oblong, ftrongly ferrated, more or lefs hairy, paler beneath. The herbage, calyx, bracteas, and even the outfide of the corolla, are befprinkled with filvery dots or granulations. The *capfule* is elliptical and fmooth, its partition formed by the inflexed margins of the valves, and fo far parallel thereto.

2. M. *corymbofa*. Corymbofe Manulea. Linn Suppl. 286. Thunb. Prod. 102. Willd. n. 2.—"Leaves obovate, toothed, fmooth. Flowers in level-topped, fomewhat umbellate, clufters."—We know nothing of this fpecies but the above characters, given by Thunberg and the younger Linnæus. The *ftem* is faid to be naked.

3. M. *altiffima*. Tall Manulea. Linn. Suppl. 286. Thunb. Prod. 102. Willd. n. 3.—Leaves radical, lanceolate, fomewhat toothed, hairy. Stem elongated, almoft naked. Spike ovate-oblong. Lobes of the corolla rounded. —The *leaves* are all radical, about four inches long, lanceolate, tapering down into a footftalk; their edges unequally

equally toothed; their surface clothed with short glandular white hairs. *Stem* two feet high, erect, hairy in the same manner, scarcely at all branched, terminating in a dense, rather corymbose, *spike*, of numerous, large, and apparently handsome, *flowers*, the segments of whose corolla are unequal, spreading horizontally, of a rounded somewhat kidney-like shape; the mouth closed. *Calyx* hairy, divided to the very base. *Capsule* of the structure proper to the genus.

4. M. *plantaginea*. Plantain-like Manulea. Thunb. Prod. 101. (M. Plantaginis; Linn. Suppl. 286. Willd. n. 5.)—Leaves ovate, obtuse, stalked, entire or toothed, smooth. Stems diffuse, nearly naked. Spikes ovate. Bracteas obovate, longer than the flowers. – *Root* long, fibrous, apparently annual. *Stems* three or four, decumbent, divaricated, about two inches long, simple, almost leafless, hairy. *Leaves* not unlike those of a daisy, ovate, obtuse, smooth, fleshy, occasionally toothed, measuring, with their *footstalk*, rather above an inch in length. *Spikes* mostly solitary, short, round and dense, of many small *flowers*, separated by obovate, obtuse *bracteas*, twice their own length, whose base only is hairy. *Calyx* bell-shaped, hairy, not very deeply divided. Segments of the *corolla* rounded, and some of them, if we mistake not, cloven, in which case this plant becomes an *Erinus*.

5. M. *linifolia*. Flax-leaved Manulea. Thunb. Prod. 100. —"Leaves linear, nearly entire, rough with minute hairs." —We received from Kew garden in 1791, specimens by the name of *Manulea*, which answer exactly to the above characters of Thunberg, of whose plant we have no further information, it not being described by Linnæus or Willdenow. Our's has a slender, branched, leafy, nearly smooth *stem*. The *leaves* are opposite, stalked, an inch and half long, about a line broad, bluntish, rough with minute glandular pubescence; their margin occasionally toothed; their base tapering into a slender footstalk. *Flowers* numerous, in loose, compound, terminal clusters, with small oblong *bracteas*. *Calyx* small, obtuse, smooth. *Corolla* slender, above half an inch long, its tube glandular in the upper part, its limb of a rich deep yellow, in five oblong, obtuse segments, whose edges are reflexed, and one of which seems more spreading than the rest, as in the first species.—Can what we describe be *Buchnera viscosa*, Ait. Hort. Kew. ed. 1. v. 2. 357? L'Heritier's figure has never appeared.

6. M. *pinnatifida*. Pinnatifid Manulea. Linn. Suppl. 286. Thunb. Prod. 102. Willd. n. 4.—"Leaves ovate, pinnatifid; their segments toothed."—This we have not met with.

7. M. *capitata*. Capitate Manulea. Linn. Suppl. 286. Thunb. Prod. 101. Willd. n. 6.—"Leaves ovate, serrated, villose. Flowers in globose heads. Branches diffuse."—Such is the Linnæan character, but Thunberg says the *leaves* are oblong and smooth. It seems next akin to M. *plantaginea*.

8. M. *antirrhinoides*. Snap-dragon Manulea. Linn. Suppl. 286. Thunb. Prod. 101? Willd. n. 7.—"Leaves ovate, toothed, smooth. Flowers alternate."—Here again is some contrariety between Linnæus and Thunberg. The latter, who gathered the plant, defines it "leaves ovato-lanceolate, serrated, villose. Heads of flowers globose. Stem erect." Linnæus says it looks like an *Antirrhinum*. We have in vain attempted to determine it by his herbarium.

9. M. *thyrsiflora*. Crowded-flowered Manulea. Linn. Suppl. 286. Thunb. Prod. 102. Willd. n. 8.—"Leaves obovate, downy, toothed. Corymb terminal, elongated, compound."—Thunberg describes the *leaves* as crenate, the *flowers* panicled. We have what seems to be this species, gathered by Sparrmann in shady places at the Cape. The *stem* is somewhat shrubby, and very much branched, hairy. *Leaves* opposite, hairy, strongly toothed. *Inflorescence* at first corymbose, afterwards becoming more loose and panicled. *Calyx* hairy, with long slender divisions, not quite separate to the base. Segments of the *corolla* obovate.

10. M. *argentea*. Silvery Manulea. Linn. Suppl. 286. Thunb. Prod. 102. Willd. n. 9.—Leaves alternate, obovate, wedge-shaped, serrated, besprinkled with silvery dots. Flower-stalks axillary, single-flowered, longer than the leaves. —Thunberg's own specimen, given to Linnæus, here leaves no doubt on our minds, though their definitions of it a little vary. The *stem* is woody, with numerous crowded leafy branches. *Leaves* stalked, small, alternate, with little axillary tufts of still smaller ones; their form obovate or roundish, strongly serrated, wedge-shaped and entire at the base; the under side, more especially, clothed with glandular silvery dots, as is also the deeply-divided *calyx*. Segments of the *corolla* rounded. The *flower-stalks* are solitary, axillary, simple, smooth, about an inch long, much exceeding the leaves. *Capsule* proper to the genus. The plant turns black in drying.

11. M. *oppositiflora*. Opposite-flowered Manulea. Venten. Malmaif. t. 15.—Shrubby, downy. Leaves opposite, ovate, deeply serrated. Flower-stalks axillary, single-flowered, the length of the leaves.—M. Ventenat describes this as a native of the Cape, flowering profusely during the summer and autumn. It has the shrubby habit and aspect of the last, but the opposite *leaves* and *flowers* clearly distinguish it. If *Buchnera pedunculata*, Andr. Repos. t. 84, be, as Ventenat says, generically distinct, and even essentially different in its capsule, from these two species, it must be allowed their habit is too similar to make such a difference credible in all the force he allows it.

Buchnera æthiopica and *capensis* of Linnæus if, as Thunberg now makes them, species of *Manulea*, should follow here, the former being nearly akin in habit to the two or three last described. But as habit seems treacherous with regard to these plants, we dare not decide. See BUCHNERA.

12. M. *tomentosa*, Woolly Manulea. Linn. Mant. 420. Willd. n. 10. Jacq. Ic. Rar. t. 498. Curt. Mag. t. 322. Thunb. Prod. 101. (Selago tomentosa; Linn. Sp. Pl. 877.) —Leaves obovate, downy, bluntly toothed. Stem leafy. Cluster compound, terminal, many-flowered.—Mr. Masson is said in the Hort. Kew. to have introduced this species into the gardens of Britain in 1774. It is we believe naturally shrubby and perennial. The *branches* are round, leafy, and they, as well as the foliage, inflorescence, and even the outside of the flowers, are clothed with dense hoary pubescence. *Leaves* mostly opposite, an inch or more in length, obovate, very obtuse, unequally and bluntly toothed. *Flowers* very numerous, in a dense, compound, hoary cluster, produced from May to November, having, according to Mr. Curtis, "a singular but unpleasant smell, not perceptible at a distance." The outside of the *corolla* is pale yellow, as is the upper side of the limb when first expanded, but the latter gradually assumes a deeper and deeper orange. There is a great affinity between these flowers and those of our M. *linifolia*, n. 5.

13. M. *rubra*. Red Manulea. Linn. Suppl. 286. Thunb. Prod. 102. Willd. n 11. (Nemia rubra; Berg. Cap. 161.)—Leaves lanceolate, toothed, villous. Cluster lax. Flowers nearly sessile. Linnæus had no specimen of this. Bergius describes it with an herbaceous, round, nearly

smooth

ſmooth *ſtem*. Upper *leaves*, (or *bracteas*,) linear, toothed, rough, ſeſſile; the lower he had not ſeen. *Cluſter* terminal, very long and ſlender, its branches alternate, diſtant and erect, the flowers nearly ſeſſile. *Calyx* fringed. Tube of the *corolla* long, ſlender, pale red, thickened and hairy upwards; ſegments of the limb linear-ovate, obtuſe, hairy beneath, ſpreading, nearly equal, revolute in the margin, deep ſcarlet.

14. M. *capillaris*. Capillary Manulea. Linn. Suppl. 285. Thunb. Prod. 101. Willd. n. 12.—"Stem-leaves obovate, ſmooth; thoſe of the branches linear. Spikes ovate." Linn. Thunb.

15. M *cuneifolia*. Wedge-leaved Manulea. Linn. Suppl. 285. Thunb. Prod. 101. Willd. n. 13.—Leaves elliptic-ovate, toothed, nearly ſmooth. Spikes at length oblong. Calyx fringed.—The *ſtem* is ſhrubby, much branched, leafy, round and downy. *Leaves* nearly oppoſite, ſtalked, about half an inch long, ovate, obtuſe, with coarſe blunt ſerratures; both ſides occaſionally ſlightly hairy, often ſmooth. *Spikes* terminal, ſolitary; at firſt denſe and almoſt capitate, with a linear, obtuſe, fringed *bractea* to each *flower*, longer than the flower itſelf. Segments of the *calyx* very deep, linear, obtuſe, fringed with ſoft hairs. As the *fruit* advances, the ſpike becomes very long. The lobes of the *corolla* are rounded, obtuſe and entire. *Capſule* elliptical, narrow, obtuſe, with a ſtrong furrow at each ſide.

16. M. *cærulea*. Blue Manulea. Linn. Suppl. 285. Thunb. Prod. 101? Willd. n. 14.—"Leaves linear, oppoſite, downy, toothed. Flowers racemoſe." *Linn.*—Thunberg defines the *leaves* as lanceolate, the *flowers* axillary and ſolitary. We have ſeen no ſpecimen.

17. M. *heterophylla*. Various-leaved Manulea. Linn. Suppl. 285. Thunb. Prod. 101. Willd. n. 15.—"Leaves linear, ſcattered, villoſe, entire or toothed." *Linn.*—Thunberg ſays "lower leaves ovate, ſomewhat toothed, villous; upper linear entire. Heads of flowers globoſe." We know no more of this than of the laſt.

18. M. *integrifolia*. Entire-leaved Manulea. Linn. Suppl. 285. Thunb. Prod. 100. Willd. n. 16.—Leaves oppoſite, ovate, nearly entire, ſmooth. Flower-ſtalks axillary, ſingle-flowered, the length of the leaves.—This is perhaps next akin to our tenth and eleventh ſpecies, though eſſentially different in its *leaves*, being at moſt but ſlightly ſerrated. They greatly reſemble thoſe of *Thymus Acinos*, and the ſpecies might well have been named *thymifolia* or *ocymifolia*. The *ſtem* is ſhrubby, round, much branched. *Leaves* oppoſite, on ſhort downy footſtalks, which embrace the ſtem; nor are they by any means ſcattered, as Linnæus defines them. *Calyx* ſmooth, its ſegments long and narrow. Tube of the *corolla* ſwelling upwards; ſegments of the limb rounded, obtuſe.

19. M. *microphylla*. Small-leaved Manulea. Linn. Suppl. 285. Thunb. Prod. 100. Willd. n. 17. (Pluk. Phyt. t. 272. f. 7.)—Leaves denſely tufted, ovate, entire, ſmooth. Flower-ſtalks lateral, ſolitary, ſingle-flowered, downy, much longer than the leaves.—Gathered by Sparrmann as well as Thunberg at the Cape. *Stem* woody, with very numerous *branches*, along which are arranged crowded denſe tufts of innumerable, extremely minute, *leaves*, each tuft ſeeming the rudiment of a future branch. The *flower-ſtalks*, ſcattered here and there, are about half an inch long, ſolitary, ſimple, aſcending, rigid. Segments of the *calyx* oblong, obtuſe, downy, deeply ſeparated. Plukenet perhaps repreſents the *calyx*, not the *corolla*; the latter we have not ſeen. His figure was juſtly indicated by Linnæus himſelf on the ſpecimen, though omitted in the *Suppl.*

We ſubjoin the remaining ſpecies of Thunberg, without regard to the order in which they ought to come, as we have no means of correctly aſcertaining it.

20. M. *revoluta*. Revolute Manulea. Thunb. Prod. 100.—"Leaves linear, entire, revolute in the margin. Flowers axillary."—This he places next after his *linifolia*; ſee n. 5.

21. M. *incana*. Hoary Manulea. Ibid. 101.—"Leaves oblong, ſerrated. Spikes level-topped. Calyx hoary."—Before *cuneifolia*, n. 15.

22. M *divaricata*. Spreading Manulea. Ibid.—"Leaves elliptical, toothed. Spike terminal, level-topped."

23. M. *virgata*. Wand-like Manulea. Ibid.—"Leaves obovate, ſerrated, villous. Branches panicled. Flowers alternate, remote."

24. M. *cephalotes*. Great-headed Manulea. Ibid.—"Leaves oblong, unequally ſerrated, ſmooth. Flowers ſomewhat umbellate."

25. M. *hirta*. Hairy Manulea. Ibid.—"Leaves obovate, doubly ſerrated, hairy. Flowers axillary, remote."

26. M. *hiſpida*. Hiſpid Manulea. Ibid. 102.—"Leaves ovate, ſerrated, villous. Stem decumbent."

27. M. *cordata*. Heart-leaved Manulea. Ibid.—"Leaves heart-ſhaped, ſerrated. Stem decumbent, creeping." S.

MANUMISSION, MANUMISSIO, an act whereby a ſlave, or villain, is ſet at liberty, or let out of bondage.

The word comes from the Latin *manus*, *hand*, and *mittere*, *to ſend*; *quia ſervus mittebatur extra manum, ſeu poteſtatem domini ſui.*

Some authors define manumiſſion an act by which a lord enfranchiſes his tenants, who till that time had been his vaſſals, and in a ſtate of ſlavery, inconſiſtent with the ſanctity of the Chriſtian faith.

Among the Romans, the manumiſſion of ſlaves was performed three ſeveral ways. 1. When, with his maſter's conſent, a ſlave had his name entered in the cenſus, or public regiſter, of the citizens. 2. When the ſlave was led before the prætor, and that magiſtrate laid his wand, called *vindicta*, on his head. 3. When the maſter gave the ſlave his freedom by his teſtament. Servius Tullus is ſaid to have ſet on foot the firſt manner; and P. Valerius Publicola the ſecond. A particular account is given of the third in the Inſtitutes of Juſtinian.

It was not neceſſary that the prætor ſhould be on his tribunal to perform the ceremony of manumiſſion: he did it any where, indifferently, in his houſe, in the ſtreet, in going to bathe, &c. He laid the rod on the ſlave's head, pronouncing theſe words, "Dico eum liberum eſſe more Quiritum," "I declare him a freeman, after the manner of the Romans." This done, he gave the rod to the lictor, who ſtruck the ſlave with it on the head, and afterwards, with his hand, on his face and back; and the notary or ſcribe, entered the name of the new freed-man in the regiſter, with the reaſons of his manumiſſion.

The ſlave had likewiſe his head ſhaved, and a cup given him by his maſter, as a token of freedom. Tertullian adds, that he had then alſo a third name given him: if this were ſo, three names were not a token of nobility, but of freedom.

The emperor Conſtantine ordered the manumiſſions at Rome to be performed in the churches.

Of manumiſſion there have alſo been various forms in England. In the time of the Conqueror, villains were manumitted, by the maſter's delivering them, by the right hand, to the viſcount, in full court, ſhewing them the door, giving them a lance and a ſword, and proclaiming them free. Others

Others were manumitted by charter. There was alfo an implicit manumiffion; as when the lord made an obligation for payment of money to the bondman at a certain day; or fued him, where he might enter without fuit; and the like.

MANUPELLA, in *Geography*, a town of Naples, in Abruzzo Citra; eight miles S. of Civita de Chieta.

MANURE, in *Agriculture*, that fort of fubftance or material, whatever its nature may be, that has the property or effect when applied on, and incorporated with a foil, to increafe its fertility, and thereby promote the growth of different kinds of plants, fuch as thofe of the grain, grafs, and other defcriptions.

It may be noticed, that the fubftances capable of being made ufe of in this way, are extremely numerous, and of different natures and properties. It has been ftated by a late writer, that on account of the changes that are continually taking place among bodies in nature, and the new combinations that are formed in confequence of them, a vaft variety of matters are unfolded, elaborated, and prepared for the nourifhment and fupport of vegetables; fome of which poffefs a high degree of fluidity and volatility, as water, various gafeous materials, as oxygen, hydrogen, azote, and carbonic acid, in different ftates of combination, with other more fubtile and elaftic fluids, which are principally formed and applied in or upon the foils on which the plants grow and exift; and in larger or fmaller proportions, according to the feafon of the year, the nature of the climate in refpect to heat or cold, and the ftate or condition of the land in regard to its properties; while others exift in a more grofs and heavy ftate of connection with the different materials, and require to be applied and blended with the foils, or fpread out upon their furfaces, in order that they may exert their influence in promoting vegetation. But it is thefe laft, as being the chief means of fupporting various forts of plants, as crops, that are confidered as manures, though it is plain they muft undergo different changes to fit them for the purpofe. In addition it is likewife remarked, that in the various fubftances applied in this way, there are great differences; "fome are found to yield the matters which are neceffary for the fupport of plants much more readily, and more abundantly than others, as animal, vegetable, and all fuch fubftances as are rich in mucilage, faccharine matter, and calcareous earth, and readily afford carbon, phofphorus, and fome aerial fluids, fuch as have been mentioned; while others that are greatly deficient in all or many of thefe principles, or do not readily part with them, are found to be of much lefs utility, when employed in the way of manures." It is fuppofed that this is "a principal reafon why fome forts of manures or fubftances, when put upon grounds, are fo greatly fuperior to others, ufed at the fame time, and in the fame manner and proportion." But befides thefe there are "other ways in which fubftances, when applied to foils, may render them more fertile and productive, and contribute to the aid of vegetation. Some, befides furnifhing fuch matters as are fuitable for the purpofe of promoting the growth of plants, are known to add confiderably to the quantity of vegetable and other matters contained in the foils on which they are placed, and thereby provide a more fuitable and convenient bed for the reception of the roots of plants; others contribute little in this way, but operate chiefly upon fuch materials as are contained in them, breaking down their organization or texture, and thus fetting at liberty different volatile and other ingredients, by which new compounds are formed, and brought to fuch ftates as are the moft adapted to the fupport of vegetable life; others again act principally by producing certain changes and alterations in the conftitution or texture of foils, fuch as rendering them more open and porous, or more ftiff and compact, and by fuch means bringing them into the moft proper conditions for the bearing of different vegetable productions; and there are ftill others that contribute in all or feveral of thefe ways at the fame time."

By different inquirers thefe fubftances have indeed been conceived to "operate in all the different ways by which vegetation is promoted: by imparting to the foil with which they are mixed the vegetable food which they contain: by communicating to it a power of attracting this food in greater plenty from the air: by enlarging the vegetable pafture: by diffolving the vegetable food which it is already poffeffed of, and fitting it for entering the roots of plants. Some afford nourifhment only; as rape-duft, foot, malt-duft, pigeons' dung, and in general all top or hand-dreffings. Others give nourifhment, and alfo add to the foil; as animal dungs, and all rotten animal and vegetable fubftances. Others again open the foil, and do not nourifh in their own nature; as lime, light marles, fand, &c. And laftly, other manures ftiffen the foil, and at the fame time nourifh a little; as clay, clay marles, and earth." Matters of this kind have alfo been "confidered by different agriculturifts as fimple and compound; as natural and artificial; nutritious and ftimulating, or folvents and mucilages; mechanical or chemical; as animal, vegetable, and mineral, &c." All which diftinctions may have their ufe, but are each attended with difficulties, and liable to objections. "Some of them operate in all the ways above-mentioned; and there are probably none that do not operate in more ways than one. It is a fundamental miftake to fuppofe with Tull, that tillage may be fubftituted in the place of manure. Manures will indeed be of little avail without it; but although good tillage, by feparating the foil, may bring a greater number of nutritious particles within the reach of the crop, yet the foil cannot poffibly continue to be fo completely divided as it is by the fermentation excited by dung and other manures; which are found to enrich the beft pulverized foil again and again, after it is exhaufted by crops; and therefore promote vegetation by increafing the quantity of vegetable food. Some manures lofe part of their ftrength by being long expofed to the air. Thus after dung is fufficiently fermented, the longer it lies, the lefs is its value. Cow-dung dried on the pafture, gathered and laid upon other land, has fcarcely any effect; whereas the fame quantity carried from the cow-houfe, or collected by folding the cattle, enriches the land. Hence this kind of manure contains the vegetable food in itfelf, and does not receive it from the air. Other manures, on the contrary, operate fooner, and with greater violence, the longer they are expofed to the air, before they are ufed. Lime and marles are of this kind. They are obferved to have a ftrong power of attracting certain qualities from the atmofphere; and operate by communicating to the foil with which they are mixed a power of attracting vegetable food from the air." And further, "fome manures exhauft land of its vegetable food, and do not reftore it again when immediately applied. This is thought by fome to be the cafe with lime. Land thoroughly limed, after having carried many very good crops, feems to be exhaufted, and reduced to a worfe fituation than before. When in this cafe lime has been applied a fecond time, its effects have been found to be far inferior to what they were when firft applied. This manure, therefore, feems to operate by diffolving the vegetable food which it meets with in the foil, and fitting it for entering the roots of plants. It may however be noticed, that the exhauftion of land by lime, is owing to bad management and unmerciful forcing it with continued white crops. It is not certain that land will not bear a fecond liming.

 But

But it is certain that the effects of the lime may be long kept up by the proper application of dung and other faponaceous manures; and there have been inftances of the effect of lime continuing forty, fifty, or even a hundred years." It is certain that almoft "all kinds of manures contribute to open the foil. Any perfon may be convinced of this, who will take the trouble to compare a piece of land on which dung or any other manure has been laid, with a piece contiguous that has not been manured; he will find the former much fofter, much more free and open than the latter. It muft be allowed, therefore, that all manures operate by enlarging the vegetable pafture of plants."

Hence, on account of the great differences that are thus met with in the properties and principles, as well as in the agency of the matters that are made ufe of as manures, it is difficult to bring them into any fort of practical arrangement. That which tends to fhew the nature and qualities of the materials from which they are derived, feems to be the moft advantageous in the cultivation and improvement of land.

Manures of the animal Kind.—It may be obferved, that the materials which conftitute this fort of manure, are of very different kinds, but they may be conveniently diftinguifhed into fuch as are of a *foft* and *hard* quality; the former comprehending all forts of animal dungs, and various other animalized materials of a foft nature; the latter including all forts of hard animal matters, fuch as bones, horns, hoofs, and different other fubftances of a fimilar kind. It has indeed been remarked by a late practical writer, that "all fubftances of the animal kind, when reduced by the procefs of putrefaction or other means into a foft, pulpy, or mucilaginous condition, have been fhewn, by the experience of the moft correct and able cultivators, to afford thofe matters which are fuited to the nutrition and fupport of plants, with greater readinefs, and in a more copious manner, than moft other bodies. And chemical analyfis has demonftrated, that the chief component materials of fuch fubftances, fo far as agriculture is concerned, are principally water, jelly, or mucilage, and faccharine oleaginous matters, with fmall portions of faline and calcareous earthy fubftances. Hence animal matters, though they agree, in fome circumftances, with vegetable productions, each having in common water, faccharine and calcareous matters, are far more compounded; and in animal fubftances fome of thefe materials are in large proportions, while in vegetables they only exift in a very fmall degree; and the jelly, which in fome meafure refembles the gum and mucilage of plants, differs likewife from them, in its having much lefs tendency to become dry, as well as in its property of attracting humidity from the atmofphere, and of running with great rapidity into the ftate of putrefaction and decay." And in addition, "all thefe principles of animal fubftances are, it is added, refolved by their ultimate decompofition into other matters, fuch as the different gafeous fluids that have been mentioned above, carbon, phofphorus, lime, &c." It is likewife fuppofed, that "in animal fubftances of different forts, there may be differences in regard to the proportions of thefe feveral ingredients or principles; fome kinds affording one or more of them in greater abundance than others; while others again are deficient in thefe, but abound in fome of the others. On this fuppofition, the different effects of fubftances of the fame clafs, when applied to foils of the fame kind, may, it is conceived, be eafily accounted for."

It is found, that all fubftances of this kind, "on being deprived of their vital principle, have a quick tendency to take on or run into the ftate of putrefaction, a procefs which is confiderably affected and influenced by the circumftances under which it is produced. But in the horny and more compact animal matters, this tendency to putrefaction and decompofition is, under fimilar circumftances, much lefs rapid than in fuch as are of a lefs firm and denfe texture. The procefs of putrefaction is, however, greatly expedited by the conditions under which it takes place being favourable: fuch as the fubftance, of whatever kind it may be, poffeffing fufficient moifture, being expofed to the free action of atmofpheric air, and a moderate degree of heat. On various accounts it would likewife appear, that the decompofition of fuch fubftances may be promoted by moiftening them with water, flightly impregnated with common falt, and perhaps fome other faline fubftances, fuch as the muriats of magnefia and foda, or fea-falt, as ingenioufly fuggefted by the earl of Dundonald."

And it is thought probable, alfo, "that the decompofition of fome of the more hard and folid fubftances of this defcription, fuch as horns, bones, hoofs, and rotten rags, &c. might be greatly promoted, and rendered more immediately ufeful, by being reduced into much fmaller particles than has been ufually the practice, as well as by the application of higher degrees of heat than that of the atmofphere, when it can be done with convenience, and in a fufficiently cheap manner.

It is likewife further ftated, that "as the diffolution of animal as well as vegetable matters, is known to be much impeded by their being excluded from the air, or expofed to fuch degrees of heat as are capable of drying up and taking away their moifture, and by the mixing of fuch earthy fubftances with them as are capable, from their open and porous textures, or vitriolic and other qualities, of depriving them of the fluid matters which they contain; it is evident, why under certain circumftances of their being mixed and applied as manures, they may prove lefs beneficial than in other inftances."

There are other circumftances, befides thofe which have a tendency to render the decompofition of all fuch matters more quick and expeditious, as thofe of their being lightly depofited together, and not in too large heaps, or with too much earth mixed with or depofited upon them, by which the air is prevented from acting upon them fo extenfively as might otherwife be the cafe. The practice of fprinkling common water over them frequently, efpecially in hot and dry feafons, and where they are of the more hard and compact kinds, in many inftances might, probably, be ufeful in promoting their diffolution, and rendering it more fudden and complete, confequently, to fupply the food of plants more readily, and in greater abundance in any given time.

But the principal fubftance, and that which is moft commonly applied as a manure, is the excrement produced by various kinds of animals, which is found in very different conditions, or ftates of preparation and richnefs, in fome meafure according to the kind of food on which the animal has been fed, and the materials with which it is incorporated or intermixed. The writer of the Middlefex Report fays, that "the dung of fat animals is unqueftionably more rich, and, confequently, poffeffes greater powers of fertilization, than the dung of lean ones; and that the quality of the dung of every fort of animal will, in a great meafure, be proportioned to the goodnefs or poverty of its food. Thus, when the animal is fed on oily feeds, fuch as lint, rape, and others of a fimilar nature, it will be the moft rich; when kept on oil cake, or thofe feeds which have been deprived of part of their oily matter, the next fo; on turnips, carrots, and fuch like vegetable roots, the next; on the beft hay, next; on ordinary hay, next; and on ftraw, perhaps, heaps, the pooreſt of all. The dung of lean hard-working cattle, feeding on ſtraw, muſt, he conceives, be poor indeed."

It may be noticed, that the ſoil of privies is ſometimes met with in a ſtate fit to be applied to the ground, when not much mixed with fluid matters, ſuch as urine, and forms a moſt excellent manure. It moſt frequently happens, however, that it is in ſuch a liquid ſtate, as to require other more ſolid ſubſtances to be blended with it, before it can be conveniently applied to the ſoil. In doing this, a late writer ſuggeſts, that "too little regard ſeems to have in common been paid to the choice of the moſt proper materials; but it is obvious, that ſuch as can be the moſt fully acted upon, and the moſt readily converted into the ſtate ſuitable for affording the nutrition of vegetables, by the principles of the matters thus employed as manures, muſt be the moſt adapted for the purpoſe, as well as the moſt beneficial. When, therefore, the manure made uſe of in this way, is either wholly or principally conſtituted of ſuch animalized matters as, from their fluidity, are in an improper ſtate or condition to be ſet on land, without having other ſubſtances previouſly mixed with them, ſuch peaty, boggy, or black vegetable earths ſhould be choſen, as contain large proportions of matter, which the ammonia or volatile alkali ſo abundantly provided by the decompoſition of ſuch ſubſtances may exert itſelf upon, and reduce into that ſtate of ſolubility which is ſuitable for promoting the growth of plants. By duly attending to this practice, which has been ſcientifically handled by the earl of Dundonald, much advantage may be gained, not only in the quantity, but likewiſe in the quality of the manure. The reſults of experiments attentively made in this way, indeed clearly demonſtrate, that an inconceivable loſs is incurred by the inconſiderate practice of exſiccating human excrement, as well as the negligent cuſtom of permitting the liquor or fluid parts of dung heaps to run away. The trials which he has been enabled to make, alſo lead him to ſuſpect, that it is a much more waſteful practice, to apply theſe liquors to the ground in their uncombined ſtate, than in conjunction with ſuch earthy materials as have been mentioned above. Beſides, much of them muſt be imperceptibly carried off by the proceſs of evaporation, even when they are carried out in the moſt favourable ſeaſons of the year; and they cannot, in this way, always be made uſe of on thoſe ſoils that contain a ſufficient quantity of thoſe earthy materials, or principles, with which they can readily form combinations, and exert their moſt beneficial and fulleſt effects."

And it is farther ſtated in the ſame practical work, that "moſt of the later practical writers on agriculture are decidedly of opinion, that the ſoil of privies is a manure of the moſt enriching kind, but that its effects are not ſo laſting as thoſe of many other ſubſtances. In the trials which have been lately made with it by Mr. Middleton, "it is ſaid to have produced ſuch aſtoniſhing fertility, as to induce him to conclude that it exceeds all other ſorts of manure that can be put in competition with it, for the firſt year after its application. The ſecond year he ſuppoſes it of ſome ſervice, but in the third its effects nearly, if not quite, diſappear." The circumſtances which render this ſort of manure ſo immediately active in promoting vegetation, and ſo quickly deprived of its beneficial influence, would ſeem to be the great quantity of elaſtic principles which it contains, in a looſe ſtate of combination, and the ſmall quantity of earthy matter which it is capable of ſupplying to the ſoil, by the laſt ſtages of decompoſition or decay. This alſo further ſhews the advantage of mixing and incorporating with it ſuch kinds of earthy ſubſtances as it may be capable of acting upon, and uniting with. From the cauſes juſt noticed, its moſt active and nutritious properties are almoſt immediately ſet at liberty, and either directly contribute to the growth of plants, or form ſuch new combinations as readily become uſeful for the purpoſe, while but very little of the earthy material is left behind for further decompoſition, and the durable aids of vegetable increaſe. Mr. Middleton alſo farther remarks, that this matter is not only prepared in the moſt ſuitable manner for the purpoſe of perfect vegetation, but that the herbage produced by it is capable of fattening the *largeſt* cattle in *leſs* time than any other. And the firſt of theſe writers knows from repeated experiments, that the fineſt garden vegetables may be produced by it, when properly employed, without the leaſt injury to their taſte, even in the moſt delicate of them, ſuch as cauliflowers, white brocoli, &c. Inſtead of a bad taſte being communicated to herbage by the uſe of this manure, it would ſeem probable, that it conſiderably improves its flavour, as it has been obſerved, in the Annals of Agriculture, that the patches of ſuch paſtures as had been manured with this ſubſtance, were conſtantly eaten *quite cloſe* by horſes, cows, and young cattle, while in other places there was much *longer graſs*."

From theſe facts it is therefore concluded, that "the importance of this ſubſtance as a manure is ſuch, that every poſſible means ſhould be contrived to prevent its loſs, which is ſhamefully permitted, at preſent, to take place in large towns, to the aſtoniſhing extent of more than two-thirds of the whole, and ſome method made uſe of to render its conveyance and application more general and convenient. See NIGHT-SOIL.

It is further noticed, that it is not only this, but the dungs of all thoſe animals which feed on ſuch ſorts of food as conſtitute either wholly, or in a great part, the food of man, as has been ſuggeſted above, that are, from the experience of practical farmers, found to be more effectual in promoting vegetation, when applied as manures to the ground, than thoſe of ſuch animals as are ſuſtained by ſuch kind of matters as are ſeldom or ever made uſe of in that way; "hence it is obvious that the dungs of carnivorous birds, dogs, ſwine, horſes highly fed, poultry, pigeons, and ſuch like animals, muſt be more powerful in their effects as manures, than thoſe of horſes when fed only with hay or graſs, neat cattle, ſheep, and other animals that live in the ſame manner. On the ſame principle, too, it is ſuggeſted as not improbable, but that the excrement of inſects may be leſs efficacious as manures than their bodies, as it is well known that by their deſtruction and decompoſition the fertility of land is conſiderably increaſed in particular inſtances. It is probable likewiſe, that the dungs of ſome animals may, from the ſtate of their ſtomachs, and other cauſes, as well as the nature of their food, be more completely reduced and animalized in its paſſage through their bodies. That this is the caſe, at leaſt in granivorous birds, in which the food is ſubjected to conſiderable trituration in the courſe of its digeſtion, there can be little doubt, and thereby they perhaps become, in ſome meaſure, in a condition more ſuitable to form new combinations, or afford the ſupport of vegetation."

It is conceived, that "this view of the nature of the manures afforded by different animals, ſhould lead the practical agriculturiſt to be more attentive to the ſubject, in order that he may render them more abundant, and be capable of employing them under the moſt favourable circumſtances, which cannot be the caſe while they are, as at preſent, indiſcriminately mixed and blended together in the common dung-heap. That they ſhould not be uſed in this way is clear,

clear, from the contradictory accounts of them that have been presented to us by various writers and experimenters, which would seem to have been caused by employing them in states of mixture with other substances. By some it is asserted that one load of *swine's-dung* is nearly equal to two of most other sorts, and that it is the richest of all animal manures; in this, however, they would seem to be mistaken, as from trials made by others, it has been shewn that *night-soil* is certainly to be ranked much before it. In some of the ingenious experimental attempts of Mr. Young, it is also shewn, that the dungs of rabbits and poultry are superior to that of pigeons, and greatly more durable. But poultry-dung, in the comparative experiments of Mr. Arbuthnot, was found to be more effectual than that of rabbits, and that of the latter greatly superior to wood-ashes. *Pigeons' dung* has, notwithstanding, been proved by much experience to be a powerful and efficacious manure, and probably, from its abounding with volatile alkaline principles, been concluded to be of a hot or stimulating quality." But it is "from the larger animals that the farmer derives the principal part of the dung that is made use of as a manure in the cultivation and improvement of land; the dung of horses as are highly fed being found, as has been already seen, to be much more valuable for the general purposes of agriculture, and some uses in horticulture, than that which is made by horses when fed with hay or grass only. Where the animals are kept in the latter way, it is probably not so good as that of well fed cows and neat cattle in general, as in these it may, perhaps, become more animalized from the circumstance of their food being more intimately blended with the *saliva*, or other juices, during the ruminant state of feeding in such animals. The dung of horses is, however, in common, much more disposed to take on the process of putrefaction, and cause more heat, than that of cows and other neat cattle, and indeed these are the chief distinguishing circumstances between them as manures. The dung of neat cattle may also, on account of its less disposition to run into the state of putrefaction, contribute more of the earthy material to the land on which it is applied. Hence, probably, its superior utility on the leaner and poorer, or thinner sorts of soil. The dung and urine of animals, when newly voided, are not, except when the animals are morbid, in a putrescent condition, the length of time in which they remain in their bodies being too short for its fully taking place; but some degree of, or tendency to putridity, is constantly necessary to their discharge; and the means which are further suited to promote it in these substances have been fully described and explained above, when speaking of the nature of animal substances in general.

With respect to the experiments that have been made with the dung of sheep, they shew "that it is equally valuable with that of many other animals that feed in the same way, but agriculturists have not yet turned their attention sufficiently to the means of collecting and preserving it, so that it may be used alone as a manure. The method by which it is at present applied to land, is by folding the animals upon it, under which method of management, on many soils, a great part of the advantage must be derived from the operation or action of the ammonia of their urine upon the vegetable matters contained in them, as well as from the consolidation produced by their treading upon it. See DUNG.

Besides the above, there are many other *soft animal substances* that may be of use for the purpose of improving land as manures, some of which have yet been but little attended to by the farmer. Of this sort are *graves*, or the residuum which is left after making of candles, and the *scum* which is collected in the boiling or refining of sugar. The author of a late practical work observes, that "different trials upon a small scale, with the former, have fully convinced him, that it is a substance that possesses great powers, when employed as a manure. And although it is a substance which is generally procured at a high price, from its going a great way, and being a lasting manure, it may, probably, be more frequently had recourse to than has hitherto been the case. It is mostly procured in the state of hard compressed square cakes, though sometimes in a soft condition, without having undergone any pressure. When, in the former state, the cakes must be broken down, and reduced into as great a state of division as possible, which may be rather a troublesome and expensive process, except a mill or some proper machine for the purpose be employed. But when it has been even reduced to the finest state possible, it will still be improper for application as a manure, until it has been mixed and incorporated with a pretty large proportion of some rich earthy substance with which it may combine. In the attempts which he has had an opportunity of making with this animal substance, after being much reduced, it has always been blended in the proportion of three or four parts of good vegetable mould, according to the condition of the land, to one of the graves, and then sown as a top-dressing on grass land, where it has never failed to produce a full crop of hay, considerably greater than that by the usual dressings of dung, and a rich sweet after-grass, or such as cattle are remarkably fond of feeding upon.

At Enfield, Dr. Wilkinson found, in his trials, that the animal kingdom furnished the strongest manures; among which, graves was the most powerful and durable in its effects. "From one ton to a ton and a half, he considers as sufficient for an acre, according to the state of the land. The cakes, in his practice, were minutely divided, which, on account of their hardness, is an expensive and laborious operation; and that even in this state of minute division, unless mixed with mould, they frequently prove too strong for corn, as he found by experience, on applying them to barley, the grain of which being injured by the rankness of the straw. They are, he conceives, peculiarly adapted to promote the growth of grass, turnips, and the leguminous plants." And it is further stated, that "eight acres of pebbly loam were manured by him with dung, at the rate of ten loads of the common Middlesex carts *per* acre, except one acre of the poorest and most gravelly, which was dressed with a ton and a half of graves. The turnips where the graves were spread, and the succeeding barley, (which were the crops on the whole piece,) were thicker and more vigorous than where common dung had been laid. He has observed grass rendered so rank, by the use of graves as a manure, that cattle would not touch it till mellowed by the winter's frost; and even in the succeeding years he was able to trace, by the superior verdure of the grass, to what extent this manure had been spread. He has also used, with success, salted fish provisions, particularly herrings, which had been spoiled on ship-board, and has found them equal to the graves. In the same manner he has used salt meat, that has become putrid in a long voyage. His general mode of application has been to mix them with mould raised from the head-lands of the field, where they were intended to be spread. By letting them lie for some time, the earth imbibes the strong smell and virtues of the animal manure. Over these he has spread with advantage the liquor drawn from the graves, and the washings of the casks of salted meat, which has been spoiled. When sprinkled immediately

over

over grafs in the fpring, he has alfo obferved this liquor attended with confiderable efficacy in producing a plentiful crop of hay." He adds, that "laft year (1800) he ufed with fuccefs a combination of lime and graves, mixed with mould from the head-lands, in the proportion of about fifty bufhels of lime to a ton of graves. This compofition refembles *fugar fcum*, which confifts of lime and bullock's blood." On the whole, "from the large experience he has had of the benefits arifing from fugar fcum, he thinks this combination of lime and animal matter deferves further inveftigation." On this it may be obferved, that "there can be little doubt but that by combining lime with animal fubftances, they may be rendered highly active as manures, efpecially when applied on foils that have a fufficiency of thofe earthy fubftances, on which they can exert their full influence. In this way they feem frequently to be rendered more active, than when employed in a fimple uncombined ftate: but experiments are perhaps wanting to fully afcertain the utility and beft means of employing fuch matters." It is however further added, that "lime might thus be combined with bones or woollen rags, or with a compoft of earth and night foil, and would certainly greatly facilitate their converfion into manure, as well as render them more active in producing their effects in the fupport of vegetable crops: and by fome of their properties being abforbed by the lime, during the time of their decompofition, and afterwards parted with more flowly in the foil, they may alfo by fuch means be probably rendered more durable and lafting as manures."

It has been ftated by Dr. Wilkinfon, that "the Arabians, who take great pains to improve their lands, are accuftomed to make large pits: they there put in animal fubftances, and cover them with calcareous or clayey earths; and afterwards thefe earths, which of themfelves are fertile, acquire the properties of the richeft manure." He adds, that "he once ordered a heifer, which died in a field at a diftance from his houfe, to be buried in a compoft of lime and earth. He does not affert that this was its moft profitable application; he had, however, no reafon to complain of his compoft." And "Mr. Wright, in his Survey of the Hufbandry of Scotland, he obferves, mentions a compoft of two parts lime, and one part pigeon's dung, to remain mixed until a confiderable fermentation takes place, which is known by the effluvia. Six bolls of this compoft, it is faid, is fufficient for an acre, and will mark itfelf for many years after it has been applied."

There are various other combinations of this nature, which may be fuccefsfully made ufe of for the purpofes of agriculture, when properly made and applied to the foil.

There are ftill other materials of this clafs, that may be employed as manures on land, fuch as the *refufe of glue-makers*, the *cuttings of felt-mongers*, the *clippings of furriers*, the *fcrapings of oiled-leather*, and the *chips or wafte of fhoe-makers*, where they can be collected in fufficient quantities. Thefe, from their abounding in mucilage and oil, their great attraction for moifture, and their being readily foluble in water, contribute quickly to the fupport of vegetation, but are not probably fo durable in their effects upon land as many other fubftances: hence they fhould only be made ufe of with a view to the immediate crop, which, it is believed, is pretty much the cafe in thofe places where they are capable of being obtained in fuch quantities as to be employed for the purpofes of the farmer.

There are alfo of the fifh kind many fubftances that may be applied in this way, as the *blubber*, remaining after the preparation of oil from the whale, and other large fifhes, and different forts of fmall fifh, both of the fhell and other kinds; likewife the offals of fuch animals, where they can be procured in large quantities, as in large towns, fea diftricts, and where they are cured or prepared in great numbers for the market. Thefe may be found beneficial in various cafes.

All "thefe fubftances may be readily reduced to that ftate which is proper for manure, by mixing with them a fmall portion of the carbonat of lime, and afterwards, according to circumftances, a quantity, two or three times more than the whole, of good vegetable mould. Shell-fifh, fuch as mufcles, are commonly applied without being mixed with earthy matters; but this is certainly a wafteful practice, as much of their valuable principles is diffipated and loft, as is evident from the highly difagreeable ftench that affails the neighbourhood of the ground on which they have been applied." By mixing good vegetable mould, fcrapings of ditches, or peat earth with them, the quantity of the manure would not only be greatly increafed, but the offenfivenefs attending the ufe of fuch manures, in a great meafure, corrected, and the effects of them, in promoting the growth of vegetables, probably rendered more extenfively advantageous to the farmer. And the wafte and refufe of flaughter-houfes and butchers' fhops are likewife capable of being prepared and made ufe of in a fimilar manner to that of fifh: but as the manures formed from thefe animal materials are capable of affording much elaftic volatile matters, during their decompofition, they of courfe require to be well mixed and blended with fuch earthy fubftances as they can combine with, and render foluble, and in proportions fuited to their powers, in order to produce the moft beneficial effects on vegetation, and afford the greateft advantages to the cultivator.

The different forts of woollen rags, hair, feathers, and fuch like fubftances, though frequently made ufe of as manures to land, from their having a lefs portion of oily or mucilaginous matter in their compofition, are probably in their effects inferior. Thefe fubftances muft be cut or chopped into fmall pieces, before they can be advantageoufly applied to the ground as manures.

And the author of "Practical Agriculture" concludes, "from the experiments that have been made with fuch animal fubftances as manures, that it may be inferred, that their effects continue longer than thofe of many fubftances of other kinds;" and that they are highly ufeful materials, in many cafes, for being applied to the foil.

It may be noticed, that among the harder forts of animal fubftances, that are capable of being employed as manures, there are confiderable differences in refpect to their texture and firmnefs: fome being quite firm and folid, fuch as bones, horns, hoofs, fhavings of horn, and fome other fimilar fubftances; while others are more foft and pliable. The bones of all animals are capable of affording much nutritious matter to plants; but thofe which are procured from cattle, that have been killed when fat, are faid to be the beft for the purpofes of manure. Thofe which have been boiled are far inferior, in this view, to thofe which have not undergone that procefs, as by fuch means they are principally robbed of their oily and mucilaginous properties, and confequently muft yield much lefs nourifhment to the immediate crop, whether it be grain or grafs. All thefe forts of fubftances require to be ground down in mills conftructed for the purpofe, or otherwife reduced into fmall pieces, before they are laid on and mixed with the foil, or formed into compofts. It is ftated, that "the ufual method is to reduce them to about the fize of large filberts, but that there can be little doubt but that they would fooner run into the ftate of putrefaction, if they were reduced into ftill fmaller particles,

ticles, and thus be made to afford their nutritive properties much more expeditioufly, as well as more abundantly; by which means, much lefs quantities would probably produce equally full effects with the large ones at prefent made ufe of: as, where the pieces into which they are broken are left large, they remain a great length of time in the foil, and are only gradually decompofed, without yielding that full fupply of nourifhment which is neceffary for the fupporting of crops. And when they have been even prepared in this way, too much earthy materials fhould not be mixed with or applied upon them; as, where this is done, by preventing the free operation of the air, their decompofition is greatly retarded. Nor fhould they, upon the fame principles, when intended to be incorporated with the foil, be ploughed in too deeply; as, by fuch a practice, the crop will be deprived of much of the advantages which it might otherwife have obtained from fuch manure."

It is now well known, that "thefe fubftances are conftituted of a confiderable proportion of mucilaginous or gelatinous matter, a flight portion of fat, and an earthy falt compofed of the phofphoric acid and calcareous earth. If great heat be applied, they afford a large quantity of hydrogen gas, carbonic acid gas, and a volatile alkaline liquor. From the nature of thefe different principles, it is evident that fome forts of fubftances may be blended and united with the reduced particles of bony matters fo as to promote their effects, as manures, in a confiderable degree, fuch as lime, chalk, peat earth, and good vegetable mould, in fuitable proportions, as by fuch means new combinations may be formed highly favourable to the procefs of vegetation." And that "the confuming of bony or horny fubftances, by means of fire, for the purpofe of obtaining their afhes, is a wafteful diffipating practice that ought never to be attempted by farmers, as by it the mucilaginous and oily materials are driven off and loft, and nothing remains but a phofphat of lime, which can be of but little ufe in promoting the growth of vegetable crops." Dr. Hunter found, from the application of reduced bones to a poor calcareous foil, with a grain crop in the proportion of 60 bufhels to the acre, that the crop was much fuperior, where this was ufed, to that which had not been dreffed in the fame way, and the grafs crops afterwards for fome length of time, on the fame place, difplayed a fuperiority, and appeared more early. He alfo found the fame fuperiority in turnip crops in different fields, when dreffed in the fame way. Mr. Young likewife found the effects of bone manures to be very great; but they did not correfpond to the quantities employed, as with 25 cart-loads the crop was better than with 50. This curious fact is, however, explained in the opinion of the firft of the above writers, by his obferving that the foil was an extremely poor one, as in fuch a cafe there could only be a fmall portion of earthy matter for the ammonia and other fubftances afforded by the decompofition of the bone to act upon, and reduced to that ftate of folubility the moft adapted to the fupport of vegetation. Hence the immediate benefit that was derived from the manure probably depended folely on the oily and mucilaginous materials that were afforded on their being firft applied.

But where bony fubftances are not broken down into very fmall particles, it is fufpected, from fome few trials that the firft of the above writers has been enabled to make, that the effects of fuch fubftances will be equally, if not more apparent the fecond than the firft year, whether they be ufed on grafs land, or that which is under the plough.

The trials which Dr. Hunter made with ground and unground bones, feem likewife to fupport this opinion, as he found, that for the immediate crop the unground bones were of little or no fervice, but the ground ones of much benefit. What effect the unground ones had the fecond year is not exactly known; however, from his concluding that thefe fubftances are in general, upon grafs land, more effectual the fecond than the firft year, it may be eafily fuppofed to have been the cafe. See Bones.

Manures of the Vegetable Kind.—There are many different forts of vegetable matters, when deprived of their living property, by undergoing the proceffes of decompofition, that foon become proper for the nutrition and fupport of new plants, and fit for being applied as manure. Their reduction into this ftate is greatly promoted by their being expofed to the full influence of the air, moifture, and a fuitable degree of heat. Under thefe circumftances different fubftances are evolved, and new combinations formed that become ufeful in the fupport of vegetation. Thefe proceffes or decompofitions have been commonly fuppofed to fucceed one another with regularity, from that which is productive of fweetnefs, to that which is the ultimate refult of putrefaction. But Dr. Darwin has fuggefted, "that it is more probable that different forts and parts of organized matters, when dead, may undergo many different forts of chemical changes, and that thefe may be different according to the differences in the degrees of heat, the quantity of water and of air to which they are expofed. He was led to this fuppofition from the faccharine procefs preceding the vinous fermentation, which takes place in certain ftates of animal ftomachs; and from what happens in the germination or fprouting of grain, by which the mealy matter is converted into fugar. And from obferving that the acerb juices of fome kinds of fruit are rendered fweet by baking, he conceives that the faccharine procefs may take place in a degree of heat which is about that of boiling water, and that by it the procefs of fermentation may be altogether prevented from occurring. By deftroying or injuring the life of fruits, it is alfo fuppofed, that the faccharine procefs of their juices may be promoted, as is found in many inftances; fuch as the ripening of fruits after being plucked from the trees; their being fooner ripened after being injured by infects, or other means; and after partially cutting, or otherwife injuring the branches of the trees on which they grow; and this, which is termed the faccharine procefs, it is conjectured, may take place either beneath or upon the earth, in the incipient ftate of vegetable decompofition, before the vinous fermentation, and thus afford a very nourifhing matter to plants." And further, that in the vinous, or procefs which commences after the faccharine, carbon becomes united with pure air in a large proportion; and that probably at the moment of their combination, while they are in the form of a liquid, and before they affume the gafeous ftate, they may be taken up by the roots of vegetables. And that, as in the procefs of putrefaction, carbon is not only changed into carbonic acid, but water decompofed, as is evinced by the fmell of hydrogen, it is fufpected that thefe inflammable fubftances may combine with carbon, as in the cafe of hydrocarbonate gas, and thereby become capable of being taken up as food by the roots of plants, without their paffing into the acid or gafeous ftates. The union of azote with pure air, towards the clofe of the putrefactive procefs, by which nitrous acid is produced, it is likewife conceived, may poffibly tend to promote vegetation. This, however, may be promoted from the circumftance of the pure air or oxygen adhering more loofely to its bafe, the azote, in the formation of this than other acids, and on that account yielding it more readily to the abforbent roots of vegetables. But,

 befides

befides thefe means of fupplying the nutrition of plants, as in the decompofition of vegetable fubftances by the procefs of putrefaction, the conftituent principles of the water which they contain are, as has been juft obferved, in fome meafure fet at liberty, and the hydrogen, one of them, uniting with the azote which is afforded by the diffolution of vegetable matters, though not in fuch large proportions as by animal fubftances, forms ammonia, which, from its ready union with fat and oily matters, and thus rendering them capable of being taken up by the abforbent roots of vegetables, may contribute to the fupport of vegetation. And, in fome inftances, where faline, infoluble, earthy matters, or metallic falts are contained in the foils to which manures of this kind are applied, or in which ammonia may be formed, it may decompofe them, and by that means contribute to the formation of other new and lefs noxious compounds, or fuch as may be more capable of contributing to the growth of vegetables." It is added, that there is another fubftance which generally prevails in vegetables, and which is fuppofed to be a fimple material, obtained in great abundance from the recrements not only of putrifying vegetable, but animal fubftances, and calcareous earth, the latter of which is fuppofed to have been of animal origin in the early periods of the world. This matter, it is thought, when met with in the ftate of folution, may be taken up entire by the abforbent roots of vegetables, as well as occafionally formed and elaborated by them. It is therefore probable, that different matters fitted to the nutrition and fupport of plants, as crops, are formed and evolved during the different proceffes and ftages of decompofition of vegetable as well as animal fubftances. But that in vegetable productions the changes are lefs rapid than in thofe of the animal kind, and probably much more varied, according to the various ftates and textures of the particular fubftances; as it is obvious, from numerous facts and circumftances, that the more luxuriant and juicy vegetables are much more readily decompofed than fuch as are dry, and have a ligneous ftructure. Hence it is, that frefh vegetable matters are much more quickly converted to that ftate of decay, which is fuitable for the fupplying vegetable nourifhment, than fuch as ftraw, hay, wood, and other dry materials of the fame nature. It is not improbable, but that fome vegetable matters may yield fome of the fubftances that are taken up by the abforbent roots of vegetables in much larger proportions than others; as it has been found that different forts of grain vary confiderably in the proportions of mucilaginous, and what is termed vegeto-animal matter, which they contain; and that grain, potatoes, carrots, and many other roots of the fame kind, on being confumed in the open air, afford much larger quantities of alkaline falts than hay, ftraw, or wood; it is undoubtedly from thefe and fimilar caufes, that fome forts of vegetable matters, when reduced by means of putrefaction, are found to be fo much more effectual as manures than others, when applied under the fame circumftances, and to foils in every refpect of a fimilar nature and quality. There is likewife a further circumftance to be attended to in fubftances of this nature, which is, that in general, when refolved by the ultimate procefs of putrefaction, they yield larger proportions of earthy materials to the foils on which they are depofited, than moft matters of the animal kind, and confequently add more effectually to the fubftance of the land. And as this vegetable mould, or earth, from various caufes, is conftantly becoming more extenfively and more intimately blended with the other materials of the foils, and, of courfe, forming new combinations, by which fome of thofe matters which ferve for the nutrition of plants are fet at liberty, and brought into the ftate moft proper for being abforbed by the roots of vegetables; it is evident why thofe manures, which are principally compofed of vegetable fubftances, are more durable in their effects than fuch as are prepared from many forts of animal materials.

It is ftated that the fubftances of this kind which are capable of being beneficially converted to manure, are extremely numerous; and confequently fuggefted that "all kinds of green vegetable productions may be employed in this way; fuch as the luxuriant weeds of rivers, lakes, ponds, and ditches, fern, and the refufe of different kinds of garden vegetables. Where green materials of this nature are made ufe of, they fhould always be cut down while in their juicy ftate, juft before their flowers begin to appear, in order that they may be in the moft fuitable condition for becoming quickly putrid, and to prevent the injury that might otherwife be fuftained from the vegetation of their feeds. They are afterwards to be collected into heaps of a moderate fize, and their putrefaction promoted by their being thrown together as lightly as poffible, and the occafional fprinkling them with water, if the feafon be hot and dry: and as lime is found, when applied to vegetables in their green moift ftate, to difengage from them both hydrogen and azote, by the combination of which volatile alkali is produced, it may be advantageous to blend a portion of lime at firft with the heaps, and afterwards add a fuitable quantity of peat earth, or good vegetable mould, for the alkali thus formed to act upon. By this method, the quantity of manure from fuch fubftances may be greatly augmented, and rendered more valuable. But when dry materials, fuch as hay, ftraw of different kinds, fern, and rufhes, are made ufe of, fuch additions cannot be had recourfe to with equal fuccefs, unlefs where much of the dung and urine of animals have been incorporated with them:" their refolution and decay may, however, be greatly promoted by their being kept in a moderate ftate of moifture, and not permitted to be trodden down too much by cattle, or other means in the farm yards, or other places where they are provided. And another means of fupplying vegetable manure, not fufficiently practifed, is that of providing full fucculent crops of green vegetables; as clover, buck-wheat, tares, vetches, fpurry, peas, beans, turnips, and many other fimilar plants, to be turned down by the plough, in order that they may undergo the putrefactive procefs under the ground, and by that means be converted into manure, and fupply the food of plants. "In this practice it is fuggefted as probable by a late writer, that great advantage might be obtained, on the principles which we have juft ftated, by the fpreading of a fmall portion of lime and peat, or rich vegetable earth, over fuch crops, and then rolling them down, that they may be completely turned in and buried by the plough; an operation which fhould be performed as quickly as poffible afterwards, and where the crops will admit of it, in the fummer or early part of autumn, while the fun has the power of promoting the decay of fuch vegetable matters. By this means, it feems probable that the putrefaction of fuch crops would not only be much expedited, but the principles thereby fet at liberty be capable of exerting their influence much more extenfively than where the plants themfelves are only employed, and little additional expence be incurred by the farmer in executing the work."

Where crops of this nature can be turned down, in fufficiently hot weather, to enfure their running fpeedily into a putrid ftate, it is confidered by fome as a better and more advan-

advantageous practice, efpecially where manures of other kinds are fcarce, than that of obtaining it by confuming them by the feeding or foiling of cattle, which, under other circumftances, is certainly an excellent mode, and one which fhould never be loft fight of by the farmer.

Befides thefe there is another plant of the vegetable kind which is capable of being employed as a manure with great advantage, and which fhould never be overlooked where it is within the reach of the farmer. This is fea-weed, (*quercus marina.*) In the management of this fubftance there is confiderable diverfity: "in fome diftricts it is the practice to fpread it upon the land as foon as poffible after being cut from the borders of the rocks on the different fea-coafts, or collected after being left by the tides, and to plough it in: where this method is adopted, it is advifed that as little time as poffible fhould be fuffered to elapfe after the cutting, or collecting of the weed, before it is ploughed down; for as the plant in its green or fucculent ftate readily decays and becomes putrid, if there be any confiderable delay in the performance of the bufinefs, efpecially when the weather is hot, much of its valuable properties as a manure is diffipated, and carried away by means of evaporation, as is fufficiently fhewn by the pungent and difagreeable fmell that iffues from it, on its being thrown upon the land while undergoing the procefs of putrefaction: and, befides, when it is fuffered to become dry and hard before it is turned into the ground, the parts that remain are confiderably longer before they become decompofed, and reduced into the ftate fuitable for affording the nourifhment and fupport of vegetable crops." It is believed to be, on thefe accounts, as well as that of the weed affording but little earthy matter in proportion to its bulk, on its decompofition, that it is found, in general, to be lefs permanent in its effects as a manure, than fome other vegetable matters. Something may likewife depend on the goodnefs and luxuriance of the weed itfelf, and the ftate which it is in when gathered from the fhores, or cut from the fides of the rocks. As in moft other plants, this will undoubtedly be in the moft proper condition for the purpofes of being converted into manure, when cut or collected in the moft fucculent ftate of its growth, before it has become too old. Another method of practice with this weed, is that of collecting it into large heaps, and letting it remain expofed in that ftate to the influence of the weather until it be completely rotten, and in a condition to be put upon the land; but as the plant contains in its compofition a large proportion of faline matters, which, during the ftate of its decompofition, or decay, are brought into activity, it is plain that by fuch a method of proceeding much lofs muft be fuftained, not only from the diffipation of the volatile and more fluid active parts, by the action of the fun and wind, but by the rains diffolving and carrying down the faline materials that may have been formed. When it is not immediately to be applied as a manure, it would therefore feem to be the moft economical and advantageous mode, efpecially where the weed is frefh, to firft blend a portion of quick lime with the heaps, and then have a fufficient quantity of frefh good earth, mould, or other fimilar material, placed beneath them, as well as mixed with and covered over them, in order that the fubftances afforded by the diffolution of the weed may have fomething to mix with and act upon, and be prevented from being wafhed away by rains. In this way, the quantity of manure may be much increafed, and at the fame time its effects rendered confiderably more lafting in the land. It is the cuftom in the iflands of Jerfey and Guernfey, where this weed is extenfively employed as a manure, to cut it in the early part of the fpring, and about the month of July; the firft cutting, in moft cafes, being immediately made ufe of as a manure for barley and pafture lands, and the latter principally converted to the purpofe of fuel, the afhes only being employed as manure. In the practice of confuming the plant in its dry ftate, however neceffary it may be there from the great fcarcity of fuel, the lofs in manure is extremely great, as the quantity of afhes thus produced are very fmall in proportion to the weed which is confumed. Such weed as is collected after having been thrown upon the fhore by the tides, is found to be much inferior as a manure to that which is cut from the rocks and made ufe of in its green juicy ftate. This fhould, therefore, be well attended to where this plant is in ufe.

Another material of the vegetable kind, that may be had recourfe to as a manure, is that of fuch bark as has been made ufe of for the purpofe of tanning leather. This fubftance, when made ufe of in this way, fhould be collected into moderate fized heaps, before it has become dry by too much expofure to the heat of the fun and wind; and then have a quantity of lime mingled with it, and be kept flightly moiftened with water, as by this means its putrefaction and decay may be greatly promoted. When intended to be applied to grafs lands, it fhould be confiderably more reduced towards the ftate of vegetable mould, than when laid on land for the purpofe of fupporting crops of the grain kind. There is another point that ought to be regarded in this material, which is, that as during its decompofition much heat is produced, and many elaftic matters fet at liberty, it would feem as a manure to be more adapted to the ftiff, cold, and heavy foils, than thofe of the lighter kinds; a fact which the experience of agriculturifts has fhewn to be well founded in general.

And mud taken from the bottom of rivers, ponds, and other places where water has ftagnated for fome time, frefh or maiden earth from the borders of fields or other places, and the fcourings of old ditches, are other fubftances that may be occafionally employed with advantage as manures, as being principally compofed of the recrements of decayed vegetable matters. They fhould not, however, be put upon grounds, efpecially thofe in the ftate of grafs, until they have been reduced into a confiderable degree of finenefs, by means of frequent turning over, and the mixing of portions of lime, rotten dung, or other materials of the fame kind, with them, in order to promote and render the decay of the more folid parts complete. In the application of manures prepared from fubftances of this fort, as top dreffings to land, in the ftate of grafs, they fhould not be fpread on too thickly, or in too large proportions at one time, as where that is the cafe great injury is often done to the fucceeding crop, the grafs not being able to fpread itfelf completely over the furface of the ground.

There is another material in the duft which is feparated from malt in drying, mixed with the tails, ufually denominated *coombs*, which, where they can be procured in large quantities, as in the malting diftricts, may be made ufe of for the purpofe of manure. In a paper, by Mr. Farey, in the Annals of Agriculture, it is remarked, that the black malt-duft, fuch as falls through the kiln-plate in the operation of drying, is greatly preferable to the white, on account of the feeds of charlock, with which it abounds, being deftroyed by the heat, and rendered fit for manure. The heat thus applied, by deftroying the vegetative principle of fuch feeds where they exift, probably renders them and the duft more readily difpofed to take on the procefs of of decay and become putrid, and thereby afford the nutrition of vegetables more quickly as well as more abundantly than in other circumftances. It is well hinted by a late writer that "this, as well as faw-duft, where they can be had at a cheap rate, may be confiderably improved as manures by incorporating them, in pretty large quantities, with the dung and urine of animals, as by ftrewing them in the bottoms of poultry and pigeon houfes, dung heaps, and neceffaries; and alfo in the bottoms of refervoirs into which the urine of cattle, and the foap-fuds after wafhing are emptied; from the action of thefe matters upon them, they are found to become more quickly in a ftate to be ufed with advantage as manures." And it is added, that "manures of this fort have been found very beneficial when applied in the proportion of four quarters to the acre, fown with the crop for which it it employed. See MALT *Duft*.

The hufks, or cakes, which are left after different oily feeds, fuch as thofe of rape, cole, &c. have been fubjected to preffure in mills in order to obtain their oil, are other materials that may be converted to the purpofe of manure. Thefe fubftances are generally prepared for application by being reduced into the ftate of coarfe powder, by mills or other fuitable means, and then fown by the hand, and harrowed in with the feed of the crop for which they are ufed. Some farmers, likewife, advife their being mixed, when thus reduced, thinly, with the materials of fuch dunghills as are deficient in richnefs, as where they have been made by lean ftock with a large proportion of litter. On turning over heaps of this kind, about a ton of cake is recommended to be well and evenly incorporated with every twenty or thirty tons of the dunghill compoft; by this practice a rich and good manure is faid to be formed. It is afferted, that "the fuccefs of thefe fubftances, when made ufe of as manures, has been found to depend, in a great meafure, upon the falling of rain foon after they have been put upon the land, as in dry feafons little benefit has been derived from their application." The reafon of this feems to be, according to a late author, "that as the cake when ufed is moftly in an extremely hard and dry ftate, it does not undergo that decompofition which is neceffary, until it has been moiftened by the rain, by which it is rendered capable of running quickly into the ftate of putrefaction, and confequently of affording fuch matters as are fuitable for the fupport of plants." And it is added, that "when applied without being incorporated with any other fubftance, it is moftly laid on to the amount of four or five quarters to the acre, according to the condition of the land."

And there is ftill another vegetable matter found in the refufe or pulp of pears and apples which have been ground, and the liquor fqueezed from them, that may likewife be converted to the purpofe of a manure, in the diftricts where cyder is prepared in large quantities. But it is advifed that fome heavy fubftance, fuch as good earth with a little dung, fhould be mixed with it before it is put upon the foil, as by being blended with fuch materials it may be more conveniently and more extenfively applied to the land, and probably with better effect.

Manures of the Earthy or Foffil Kind.—It is well known that there are a great many different forts of materials of this nature that may be brought into ufe for the purpofe of improving the condition of lands. The chief of the fubftances of this defcription are of the calcareous kind, which are found to "produce effects more or lefs powerful in promoting the growth of vegetable crops, in fome meafure, according to the ftate and quantity in which they are applied, the nature of the foils in which they are employed, and the properties of the matters with which they are combined. For though calcareous materials have been made ufe of as manures for a very great length of time, and have been applied in various ways, difficulties ftill remain concerning the manner of their operation, in many cafes, which feem principally, however, to proceed from the want of proper difcrimination in refpect to the ftate of the different calcareous fubftances at the time of their application, and their being made ufe of to different foils without a fufficient diftinction as to the properties of the materials of which they are conftituted or compofed." The inquiries of a late experimental writer "have likewife fhewn it neceffary to attend to another circumftance, which is, the fubftances the calcareous material is combined with; as he has found that where magnefia is in union with the calcareous matter, it is not by any means fo beneficial for the purpofes of manure and promoting vegetation, as where no fuch mixture or combination is prefent, efpecially when ufed in the fame proportions." This is, however, a point that requires further examination, and which is by no means fully decided. It has alfo been obferved, "that from fand entering largely into the compofition of lime-ftone or other calcareous matter, in fome cafes, as it is a fubftance of much greater fpecific gravity than pure cauftic lime, confiderable differences in its effects as a manure may be produced." On thefe accounts it is concluded, that though lime may be produced from chalk, marble, different lime-ftones, coral and fhells, by fubjecting them to fuch degrees of heat as are neceffary to expel or difengage the carbonic acid or fixed air that they contain, which is apparently of the fame quality, it may vary in its effects when employed for the purpofes of the farmer. See LIME and LIME-STONE.

It is evident that lime, when newly burned, or before it becomes loaded or faturated with the moifture and carbonic acid, or fixed air, contained in the atmofphere, which, from their ftrong tendencies to combine or unite with it, generally foon takes place, is in its great ftate of activity, and from the power which it poffeffes of breaking down and deftroying the texture and organization of fuch animal and vegetable fubftances as come in contact with it, termed *cauftic* or *quick* lime. When, under thefe circumftances, it is applied to grounds which abound either with frefh vegetable matters, or fuch as have undergone fome degree of change, by being buried in the foil, as in moory and heathy mountain-land, peaty or boggy earth, and all fuch foils as have long remained in their original uncultivated ftate, covered with a variety of coarfe plants, it is faid to be "found to produce beneficial effects; in the firft cafe probably by its ready action on the different materials of the green plants, by which it difengages from them hydrogen and azote, from the fubfequent combination of which ammonia or volatile alkali is produced, a fubftance which has great power in promoting vegetation, as is feen in cafes where fubftances that contain this matter in large quantities are ufed as manures; and in the fecond place, by its combination with the carbonaceous matter of fuch foils, or with that of the various animal and vegetable matters which are contained in them, in fome of the ftages of their putrefaction or decay, and by this means rendering it foluble in water, and thereby capable of being taken up as food by the abforbent roots of vegetables." And, "that though lime in its pure or cauftic ftate retards, in fome degree, the procefs of putrefaction, efpecially when ufed in any large quantity, it is probable, that by its power of corroding and diffolving the hard and fibrous parts of vegetable and other matters, as is fhewn by its quickly reducing the ligneous particles of bark, which has been employed in the procefs of tanning, to the ftate of mould, it may bring the abundant vegetable and other materials contained in fuch forts of land quickly into that earthy condition, in which they afford the nourifhment and fupport of crops, which by the procefs of putrefaction, and infect digeftion, could only have been performed in a very flow and gradual manner." Further, from its well-known property of deftroying different kinds of infects, fuch as worms, fnails, flugs, grubs, &c. which are moftly abundant in rich frefh foils, it may furnifh much nutritious matter for the purpofe of promoting the growth of plants as crops. There is, likewife, another way in which it may contribute to the fame end, which is, from its having a greater tendency to combine with mucilaginous oily matters than with fixed alkalies, as a kind of calcareous foap may in fome cafes be formed that may contribute, in its liquid ftate, to the nourifhment of plants, as has been noticed by Mr. Nicholfon, in his Philofophical Journal.

Befides, it has alfo the power, when mixed with clayey foils which do not poffefs too great a degree of humidity, of rendering them lefs ftiff and tenacious, confequently more fuitable for admitting the fmall fibrous roots of vegetables, which is effected, not only by the heat and other elaftic matters that are evolved during the period of its becoming faturated with the moifture and fixed air, or carbonic acid, which they contain, but alfo by being thereby more intimately and minutely incorporated with them, from the fine impalpable powdery ftate to which it is neceffarily reduced. And when in fuch foils the fulphuric acid is predominant, it may alfo produce good effects, by forming with it a kind of gypfeous compound, and in cafes where other acids are prefent that are prejudicial to vegetation, by the power which it poffeffes of neutralizing them, and thus preventing their hurtful effects. And it is alfo further probable, that when burnt from the magnefian lime-ftone, it may prove ferviceable when applied to clayey or other foils that contain the fulphuric acid, ufually denominated four lands by farmers, by forming a fort of Epfom falt in the ground, a fubftance which the experiments of Dr. Home have long ago fhewn to be favourable to vegetation, when laid on ground in fmall quantities.

It is found that this fubftance, on expofure to the atmofphere for fome time, undergoes a confiderable change, being rendered mild by the abforption of the carbonic acid or fixed air that furrounds it. In this ftate of combination, it has been termed, by modern chemifts, *carbonate of lime*, or *effete* lime: in which condition its power of acting upon, deftroying and breaking down the texture of organized matters, is greatly diminifhed. It has ftill, however, the effect of promoting their diffolution by forwarding the natural procefs of putrefaction, as is proved by the compoft dung-heaps with which it has been blended becoming more quickly in a proper ftate to be applied to land, than in the contrary cafes. By this means it confequently contributes much to the fupport of vegetation: and it has been lately fuggefted, that when incorporated with fuch compoft of foil and manure, as are in a ftate of generating nitrous acid, it may arreft the acid as it forms, by which means a calcareous nitre is produced, and thus the exhalation and ready efcape of a nutritious material be guarded againft. It is further conceived, alfo, that the combination of lime with carbonic acid, by rendering it foluble in water in its fluid ftate, without being expanded into gas or vapour, may fupply much carbonaceous matter for the fupport of vegetation. And by the property it poffeffes of fuper-faturating or overloading itfelf with moifture, by attracting or drawing it away from the air, in contact with the furface of the ground and the earth underneath, and after depriving them of it, and the carbonic acid which they contained, permitting them to efcape again, as is evident in the cafe of new plaiftered walls, it may be of confiderable utility when applied to the dry and fandy forts of foil, by affording moifture and fuch aerial matters to the roots of the vegetable crops; which it is capable of fupplying in a very equal and extenfive manner, from the extreme ftate of pulverization to which it is reduced when flaked by the dampnefs of the atmofphere, or by a very gentle fall of moifture. And in addition to thefe modes of promoting the growth of vegetable crops, it has been fuppofed by Dr. Darwin, that calcareous earth, by containing phofphorus, may be ufeful, as by its union with it a kind of hepar may be produced, and the phofphorus thereby rendered foluble in water, without becoming an acid by means of its combination with oxygen or vital air. It is conceived that phofphorus is probably as neceffary an ingredient in vegetable as animal bodies, as is evident, it is fuppofed, from the phofphoric light feen on rotten wood, in fome of the ftages of putrefaction; in which, it is believed, the phofphorus is fet at liberty from the calcareous earth, or from the fixed alkali, or the carbon of the decompofing wood, and acquires oxygen from the atmofphere, both warmth and light being emitted during their union. And it may, perhaps, more frequently exift in the form of phofphoric acid in vegetables, and be thus readily combined with their calcareous earth, or be feparated from its acid by the carbon of the vegetable, during the time of calcination, as well as in the procefs of putrefaction. It is, therefore, plain, from this account of the nature and properties of lime, that it may be made ufe of in one or other of its ftates more generally to foils, than has been commonly fuppofed. But it fhould never be applied without duly attending to the nature and quality of the foil on which it is to be laid, as upon this circumftance, its fuccefs in a great meafure depends in all cafes.

It may be noticed, that the trials that have been made by farmers with this manure, fufficiently fhew, that the more minutely lime is blended and incorporated with the mould of the land on which it is applied, the more full and complete are the effects which it affords in fupporting the growth of different forts of crops. In fupport of this, it has been remarked by Dr. Anderfon, that "if a heap of lime of a confiderable thicknefs fhall have been ever fo long on one fpot, and be afterwards carried clean away from it, fo that none of the particles of the lime remain to be mixed with the foil, that fpot will not be richer, or carry more luxuriant crops, than the places around it; which, every one knows, is not the cafe with regard to dung." And further, that "if lime be fpread upon the furface of the foil, and allowed to remain there without being ploughed in, its effects will fcarcely be perceived for feveral years, till it has had time gradually to fink through the fward, and mix with the foil; after which its effects begin to be perceived, although much lefs fenfibly than if the fame had been intimately mixed with the foil by means of the plough and harrow." The fame writer adds, that he is not a ftranger to the improvements that have been made in Derbyfhire by means of lime, without the plough; but this, he thinks, is no exception to what he has faid. The effects are flow, though certain. "Thofe who inhabit counties that do not admit of the plough, are often advifed to lay lime upon the grafs, and are made to believe that their pafture will be immediately mended by it, nearly in the fame perceptible manner as if it had been dunged. This he has tried, and has feen it tried by others; but always found tnat the grafs for the firft year was rather hurt than benefited by it; nor was it fo much improved in fucceeding years, as if the fame quantity of lime had been applied and immediately mixed with the foil.

In

In this mode of applying lime, it is long, he conceives, before it yields a proper return; and is not to be recommended to a poor man, unlefs where neceffity obliges him to practife it." On this fuppofition, it is conceived, that lime may be employed much more advantageoufly when made ufe of, even in fmall proportions, than fuch calcareous fubftances as have been reduced into the ftate of powder without calcination; but much muft depend on the mode in which lime is laid on. "If it is fpread as foon as it is flaked, while yet in a powdery ftate, a very fmall quantity may be made to cover the whole furface of the ground, and to touch an exceedingly great number of particles of earth; but if it is fuffered to lie for fome time after flaking, and to get fo much moifture as to make it run into clods, or cake into large lumps, it can never be again divided into fuch fmall parts; and therefore a much greater quantity is neceffary to produce the fame effect, than if it had been applied in its powdery ftate. But if the foil is afterwards to be continued long in tillage, (as thefe clods are annually broken fmaller by the action of the plough and harrows,) the lime muft continue to exert its influence anew upon the foil for a great courfe of years; it will produce an effect nearly fimilar to that which would be experienced, by annually ftrewing a fmall quantity of powdered lime over the whole furface of the foil: but as the price of the lime muft, in the firft cafe, be paid by the farmer altogether at the beginning, which only comes to be fucceffively demanded in the other cafe, this deferves to be attended to, as it may become a confideration of fome importance where lime is dear, and money not very plentiful."

With refpect to the ufe of lime, there is another point to be confidered, which is, the quantity that may be neceffary. The opinions of practical farmers are much at variance in refpect to this point, fome contending that a fmall quantity can only be applied with fafety and advantage, while others maintain that fcarcely too great a proportion can be made ufe of. It is plain, a late writer thinks, "from the differences that take place in foils, that no particular proportion can be fuitable in every cafe, but that it muft be varied very confiderably according to the circumftances, as well as from the fituation or condition of the land on which it is laid, and the proportion of real calcareous matter that may be contained in the lime that is to be applied. As it has been fhewn that lime, when in its moft active ftate, foon becomes reduced fo as to be perfectly mild by its property of abforbing moifture, and the carbonic acid from the air, there can be little danger of injury from its cauftic quality, though it may, on its firft application, have a tendency to unite with and deftroy fuch green or other vegetable productions as may be prefent." It is, however, the remark of an able farmer, that "moft kinds of *ftone-lime* fhould be applied with a fparing hand, and with a confiderable degree of caution, as the *cauftic* quality is many times greater in *this* than in lime made from chalk." He has had many opportunities, he afferts, of feeing total barrennefs induced by *a too liberal ufe of it;* very generally at the feveral places where the carts were ftopped for the men to fpread it, at the bottoms of every heap, and once an entire clofe.

It is well known that lime has been made ufe of as a manure in different proportions, from one hundred to fix or feven hundred bufhels on the acre, on different forts of foil, by fome under fimilar circumftances, with benefits in proportion to the quantities applied. Befides, accidental experiments in Dr. Anderfon's practice have demonftrated that it may be ufed in ftill larger proportions, with advantageous effects. And he concludes, that "on foils which do not naturally abound with chalk, or other calcareous matter, there is lefs danger in giving too much, than too little, except in thofe cafes where an over-luxuriance is dreaded in the land."

It may be obferved, that the permanency of the effects of this material in promoting the growth of vegetable crops, muft be different, according to the difference of circumftances in the land to which it is applied; the proportion of it that is made ufe of, the kind of crop that is cultivated, and other caufes of the fame fort. But from the facts that have been recorded by practical writers, in refpect to its lafting powers of difpofing lands on which it has been laid to the growth of particular forts of crops in preference to others; of rendering the operation of other kinds of manure, and other methods of culture, more effectual than where it had never been ufed; that it affords ufeful changes in the foils to which it is applied. Of this we have an additional proof in the well-known circumftance of the quality of the grain, from fuch lands as have been limed being much improved, having a thinner fkin, and yielding much more flour than that from ground where it has never been employed; which is fuppofed, by a late writer, to proceed from its containing more ftarch and lefs mucilage, on account of the tendency of the lime to promote the converfion of the latter fubftance into the former, by expediting the ripening of the grain. This is a circumftannce which alfo fhews the utility of this manure in thofe kinds of land that are late in bringing their grain crops to perfection, whether from the nature of their foils, fituations, or other circumftances.

It is obvious that this fubftance, with proper care, may be ufeful on many different forts of land, but in its active ftate it is laid on to the moft advantage on thofe of the moory, peaty, heathy, and other kinds that abound in coarfe vegetable matter. On which account it is, perhaps, that it has been found by experience to be equally, if not more beneficial, on poor than on rich foils; and its requiring to be mixed and incorporated with but a fmall portion of earth or mould, to render it highly productive, is in favour of the fame thing. From thefe facts it may be concluded, that this fubftance, befides being ufeful when blended with foils, in rendering the matters they contain proper for the reception of plants, is beneficial in fupplying fuch materials as contribute to their growth and increafe. See Lime.

Other materials, fuch as lime-ftone, and various hard calcareous bodies, which, without being fubjected to the procefs of calcination by heat, may, in fome cafes, as where fuel cannot be procured to burn them into lime, be beneficially applied for the amelioration of land, as has been fhewn by numerous experiments. When thus ufed they fhould be well pulverized, by fuch mechanical means as can be cheaply performed; much of the advantage to be derived from them probably depending upon their being reduced into a confiderable ftate of finenefs, by which they may be more minutely blended with the mould of the foils on which they are applied, and of courfe act upon and afford nutritious principles more extenfively, for the fupport of crops; and at the fame time render the heavy and more cohefive foils lighter, by being more uniformly incorporated with their clayey and earthy materials. But as fuch fubftances can never be reduced, by any fort of machinery, to the fine powdery ftate to which they are capable of being carried by means of calcination it is probable that, when employed upon land, they will be lefs beneficial in many cafes, than when ufed in the ftate of lime. The fame principle likewife holds good, probably, in refpect to the fcrapings of roads, made with calcareous and other fubftances, which are found beneficial in different inftances, [illegible] [illegible] of them is in the ftate of an extremely [illegible], from the attrition caufed in different ways. It has been fuggefted, by the experiments of an able philofophical inquirer, "that even magnefian lime-ftone is made ufe of in this ftate of reduction, without being converted into lime; it may not be fo friendly to vegetation as that which is perfectly calcareous, efpecially when employed in the fame proportions; a circumftance which may, in fome degree, account for the difference which has been obferved in the utility of fuch fubftances as manures." It is obvious that fuch lime-ftones as contain the largeft proportions of argillaceous earth in their compofitions, when employed in this reduced ftate, muft be the moft proper for the thin light foils: as by that means the depth and texture of them may be increafed to the great advantage of the crops. In the application of this fort of material to land, the farmer fhould be attentive to the ftate or condition to which it is reduced, as well as the nature of the foil, and adapt the quantities as much as poffible to them. See LIME-STONE.

Lime-ftone gravel is another fubftance of this nature, which has been fuccefsfully employed in Ireland; it is a kind of ftony marle, which might probably be equally or more beneficial, in much lefs quantities, by having the ftony lumps which it contains firft more perfectly reduced; as it has been found that where the pieces are large, a much greater proportion is required, and the effects are flower than when made ufe of in a more reduced ftate of powder. See LIME-STONE *Gravel*.

And chalk is another material of the fame fort, capable of producing beneficial effects on land, when applied in a proper manner in its uncalcined ftate. From the portion of argillaceous or clayey matter united with it in fome cafes, it partakes of the nature of marle. It has been ftated that, where it is made ufe of to the more ftiff, clayey, loamy, and heavy forts of foil, it fhould, in moft cafes, be as much pulverized and reduced as poffible before it is laid on, in order that it may be fpread with greater exactnefs, and be more regularly mixed and blended with the ftiff and compact materials of fuch lands; from which they may be rendered more capable of admitting the fibrous roots of vegetable crops to fpread themfelves in them, and thereby take in more perfectly the nutritious matters which are prefented to them." That this is an ufeful practice, is evident from the circumftance of farmers, in moft of the diftricts where chalk is employed as a manure, finding it more beneficial when made ufe of in the fpring, after having been dug up in the autumn, and expofed to the froft and moifture through the following winter, as by that means it is much pulverized and broken down. The advantage of breaking down the large lumps is alfo in favour of the fame opinion. It is ftated by the author of Practical Agriculture, that "it would probably, however, be a ftill more advantageous practice to break it down, and apply it as quickly as poffible, after digging it out of the pit; as by leaving it expofed to the atmofphere for fome length of time, it not only becomes hard, but likewife lefs foluble, and therefore lefs proper for the purpofes of manure. Hence it probably is, that farmers, where the chalk hufbandry is practifed, find the dreffings more efficacious when the chalk is dug from a confiderable depth, than where it lies near the furface of the ground. In the dry and light foils too it may, probably, be more ferviceable in this reduced and powdery ftate, from the circumftance of its poffeffing more moifture, on account of a more extended furface being expofed to the air, and the particles of the foil, from which it may abforb and attract it, and afterwards part with or afford it in a more regular and uniform manner, to the abforbent roots of the growing vegetable crops. The obfervations of practical farmers, however, invariably fhew, that on fuch foils it is much more beneficial when made ufe of in the form of compoft, either with rich peat, or vegetable earth and mould, or with good dung; as by this means a great defect in fuch kinds of land, the want of well reduced vegetable matter, is remedied, and a greater proportion of nutritious materials afforded for the fupport of crops."

But in ufing it upon wet and poachy kinds of ground, there is not, probably, the fame neceffity for its being reduced to a great degree of finenefs, as it may be apt, under fuch circumftances, to diffolve, and fink down too much by being fo greatly diluted with water, while in the rounder ftate it may be retained near the furface, and thereby be capable of abforbing and taking away the fuper-abundant furface-moifture more effectually. In fuch foils, where the principal intention is the deftruction of mofs, rufhes, and other coarfe plants, the growth of which depends upon a great degree of fuperficial wetnefs, it may, however, be employed to moft advantage in a ftate of confiderable reduction, as from its greater readinefs to fink down, it may the more quickly take away from their roots the exceffive moifture that fupports them. When acids exift under certain combinations in fuch foils, it may, probably, alfo neutralize them more readily when applied in its pulverized ftate, than in the lumpy one in which it is moftly laid on fuch lands.

It may be ftated, that the quantity or proportion in which it may be applied, muft depend, in a great meafure, upon the ftate of the foil, the nature of the crop, and the intention with which it is employed. In the fouthern diftricts it is laid on the ftiff clayey foils in large quantities, as from twelve to fourteen or fifteen waggon loads, or from fifteen to twenty hundred weight each, to the acre; and on the fandy foils in fome parts of Kent, at the rate of one hundred and fixty bufhels to the acre. On deep and ftrong kinds of foil, the practice is moftly either to lay it on the clover leys while feeding off, or upon the fummer fallows. And it is frequently ufed in the form of compoft on light foils, to the wheat fallows, as well as grafs grounds. But as it cannot be reduced to the ftate of powdery finenefs of lime, and cannot of courfe be fo equally fpread out, or fo minutely blended with the foil, much larger proportions muft be employed to produce the fame effects upon the foil; three or four times the quantity is in moft cafes requifite. On this account it has been fuggefted, that where it muft be carried from a great diftance in its wet, heavy ftate, it may be the moft economical practice to have it firft converted into the ftate of lime, as it will thereby be much more eafily conveyed to the places in which it is wanted. See CHALK.

There is another fubftance of this nature, in fome forts of marle which may be made ufe of as manure to different forts of foils with great benefit, according to the difference of their nature.

Where fubftances of this kind are laid upon land, for the purpofe of fupporting immediate crops of either corn or grafs, the moft crumbly, or thofe the moft readily reducible into a powdery ftate, are the moft proper; but where they are laid on with the intention only of affifting future crops, or of producing more lafting effects, thofe that are more hard, and lefs difpofed to fall into pieces, may be more advantageoufly employed, the firft of which is fhewn to be the cafe, by the obfervation of practical hufbandmen in marling diftricts, that it does not exert its full effects on the foil until it has been well mixed and incorporated with it by frequent aration, and by the practice of letting it remain fome time on the furface of the ground before it is turned

turned down, from which it becomes much reduced into a powdery ſtate: and the latter, by the circumſtance of the harder ſorts remaining a great length of time upon, or within, the ground, before they are fully decompoſed, or broken and carried down into the ſoil to be blended with it.

It is clear that ſubſtances of this kind produce beneficial effects on moſt ſorts of ſoil in their different forms; the ſhell, ſtone, and thoſe kinds of marle which abound moſt with calcareous earth, or which have ſand in their compoſition, are the moſt adapted to the ſtrong, ſtiff, clayey ſoils, as by the inſinuation of ſuch matters they are not only rendered more light and friable, but a great part of the injurious moiſture which they contain is removed. While thoſe in which clay conſiderably predominates, are found more advantageous in the light, dry, ſandy, gravelly, and loamy ſoils, as by ſuch ſubſtances the defects of lightneſs are remedied, and the neceſſary moiſture in ſome meaſure preſerved. The writer of the Middleſex Report ſtates, that "on the ſtronger ſorts of loamy ſoil, clayey marle will moſtly be improper, as it has much tendency to render ſuch ſorts of land more wet and adheſive, by which they may be greatly injured. Theſe have been found to be the effects reſulting from the application of it even upon a temperate loam, in ſome parts of Suſſex. And, beſides, it is ſometimes apt to bring up coltsfoot, a weed which is difficult to be eradicated."

In reſpect to the quantity or proportion of theſe ſubſtances which is applied, it differs conſiderably in different diſtricts, which in ſome degree depends upon the nature of the ſoils; the heavy, clayey, or loamy, demanding in general a much larger proportion than the light, ſandy, or gravelly ſorts. The average quantity employed may be eſtimated at from about one to four or more cubic roods of ſixty-four yards to the ſtatute acre, according to the ſtate of the marle, and particular nature and condition of the ground on which it is laid. According to the Survey of Lancaſhire, "it may in many caſes be the moſt adviſable practice not to apply too thick a covering at one time, but to have recourſe to light dreſſings more frequently, as by ſuch a method the fertility of the land may be better preſerved and kept up, and the crops be rendered more full and abundant."

It is ſtated in a practical work, that manure of this ſort is employed on lands in a courſe of tillage, as well as in graſs. On the former it is often made uſe of as a preparation for barley, turnips, and other ſimilar crops, or applied upon clover or other new leys, previous to their being ploughed up for wheat; in which modes of making uſe of it, the common practice is to leave it ſpread out upon the ſurface for ſome length of time before it is turned in, in order that it may be well reduced into a powdery form; for the more perfectly the marle is broken down and ſpread out, the more effectual it is found in promoting the growth of the crops. It has been noticed, that in its application in the latter caſe "it is frequently laid on in too large quantities, or left too long in its lumpy ſtate; from both which circumſtances diſadvantages are produced to the growth of the graſs, when either to be cut for hay, or fed off by cattle; as by the former, where the marle contains much of the argillaceous material, a kind of cruſt is formed that prevents its ſpringing, as happens where the ſtiff mud of ponds, and ſuch like manures, are too thickly laid on lands; and from the latter, the graſs is not only injured by the ſmall clods, as is experienced where imperfectly reduced clayey earth is applied, but the effects of the manure are prevented from being fully exerted on account of its not being well broken, and carried down to the abſorbent roots of the graſſes, by the frequent rains that may take place after its application." And that "when employed in large proportions, whether upon the heavier or lighter ſorts of land, a conſiderable ſpace of time appears, from experience, to be required to elapſe, before it can with advantage be had recourſe to again: for if this circumſtance be not properly attended to, or too many white crops be ſucceſſively taken, a very great degree of exhauſtion is ſoon produced, as has been experienced in many of the marling counties of England, and in Forfarſhire in Scotland. Theſe injurious conſequences are, however, found to be eaſily prevented, by adopting the alternating ſyſtem of corn and graſs, or other green crops." And it is further ſuggeſted as probable, "that by taking corn and graſs crops in ſucceſſion, or, after having one or two grain crops, letting the land be laid down for two or three years with artificial graſſes, the application of marle in ſmall quantities might be more frequently renewed, to the great advantage of the farmer, and the improvement of the land. In ſome of the places where this kind of manure is made uſe of, as in Lancaſhire, ſomething of this practice is adopted with much benefit. And when mixed with dung and other ſubſtances, in the form of compoſt, it is generally found capable of being repeated, at ſhort intervals, with the moſt beneficial effects." From theſe facts, the writer therefore concludes, "that ſuch injuries are rather to be aſcribed to the mode of cropping, than to the nature of the manure. Something may alſo, he ſuppoſes, depend on the manner in which it is applied, as it has been found to be more efficacious, when well mixed and incorporated with the ſoil, than where this has not been the caſe; and that, as it has been found highly advantageous in promoting and bettering the condition of the graſs-lands in ſome diſtricts, while in others it has been objected to as injuring them, it is ſtill farther probable, he conceives, that much depends on the ſtate and manner of its being put in or upon lands, and that it is only where it is laid on in a moderate ſuitable proportion, and after it has been well broken down and reduced into a fine powdery form, ſo that it may be very minutely and intimately blended with the ſoil, that its beſt effects can be exerted upon the land.

And the general method of digging it up in the ſummer ſeaſon, and ſpreading it over the ground in its lumpy ſtate, in order that it may be acted upon and reduced by the heat of the ſun, and the froſts during the ſucceeding winter, is a proof of the ſame concluſion. See Marle.

Another uſeful material as manure, is found in the ſhelly ſand, found in beds in the hollows, and other parts of the ſea-coaſt, in different diſtricts, as containing not only calcareous matter, in a ſtate of conſiderable fineneſs, but a portion of animal and vegetable ſubſtances, with a ſmall quantity of the muriate of ſoda or ſea-ſalt; the laſt of which, from its well-known property of promoting the proceſs of putrefaction in animal and vegetable matters, when in ſuch proportions, and that of deſtroying different kinds of living inſects, may contribute greatly to the good effects experienced from it. This is rendered highly probable, from the circumſtance of that which is taken from underneath the water, or from ſuch banks and places as are daily covered by the tides, being the moſt efficacious when applied to the ſoil. The proportion of calcareous matter contained in ſubſtances of this ſort vary very much, according to the particular circumſtances of them. It has been obſerved, that "where the quantity of calcareous matter is large, and in a very reduced or attenuated ſtate, it is by much the moſt valuable; as when there is much ſand amongſt it, a much larger quantity will be required, and the expence of application be of courſe much increaſed." It is conceived that this ſubſtance is "more proper for the clayey or loamy soils than those of the lighter kinds, especially where the proportion of the calcareous ingredient is large. When equally spread, and well incorporated with such lands, it is generally found to produce good effects for a great length of time." And it has been observed by Dr. Anderson, that "a considerable less quantity of calcareous matter, when in this fine state, will have a more sensible effect, than when it is in that of any kind of earthy marle, as it admits of being spread over the ground with greater equality, and of being more minutely and intimately blended with the soil."

With regard to the quantity employed, it must obviously be different, according to the nature and circumstances of the soil, as well as the sand; but twenty tons to the acre is, for the most part, considered as a proper dressing. It is said to be frequently applied on the summer fallows for wheat, and sometimes as a preparation for barley; and may likewise be laid on clover or other leys, before they are ploughed down for grain crops, but in such cases so large a quantity is not requisite. When put upon grass-land, in not too large a proportion, it commonly produces great and sudden effects, the crops quickly becoming very luxuriant." And it is also observed, that such lands as have been treated in this way, when again brought into tillage, mostly produce abundant crops of the grain kind. It has been stated by Dr. Anderson, that "the effects of this sort of manure on the west coasts of the northern parts of the island have been very extraordinary, especially upon the heathy or mossy soils; and it is supposed that such kinds of sand are more common on the east coasts than has been generally supposed from the little attention that has been bestowed by the farmer in such situations to procure it for use."

Although common sand cannot be properly considered as a manure, it is often found useful in the stiff, clayey, and loamy soils, in lessening their tenacity, and rendering them more light and mellow. This substance has been laid upon rough pasture and meadow land, with the effect of rendering the surface more equal, and bringing up a close thick crop of grass with much white clover. In these cases, the quantity should be proportioned to the stiffness of the soils; but the best practice is, not to apply too large a dressing at a time, as injuries may be done where a very large portion is put on at one time.

Manures of the saline Kind.—There are various substances of this sort, when in combination with earthy and other ingredients which are found beneficial as manures in many instances, when properly employed. The materials that are principally made use of in this way are the refuse of different manufactures, such as those of bleaching and soap-boiling, where in sufficient quantities, as in the neighbourhood of large towns, and where such businesses are conducted on an extensive scale. The ashes which remain after the combustion of various green vegetable matters, wood, pit-coal, peat, &c. and some other substances, such as soot and sea-salt, are of the same nature. It is suggested in a late practical work, that "it is probably to the different alkaline principles contained in these substances, from the great facility and power which they possess of acting upon and dissolving the parts of animal and vegetable matters, especially such of the latter kind as have been rendered insoluble by the absorption of the oxygen, or pure air of the atmosphere, from long or frequent exposure to it, and even fossil coal, under similar circumstances, and by this means forming new saline compounds which are soluble, that their beneficial effects as manures are chiefly to be ascribed." And "that as such inert or insoluble vegetable or peaty matters, when decomposed or reduced into a state of solubility by alkaline substances, assume a brownish-red colour, and become insipid; the alkalies, in such cases, must enter into combination, and be neutralized by the acid or acids contained in them, which will be found to be the phosphoric and the oxalic, or acid of sorrel; from which will be formed, according to the nature of the alkali contained in the substance made use of, phosphats and oxalats of potash, soda, or ammonia, which are matters capable of promoting the growth of plants." But, beside their forming in the soils, or the earthy materials with which they are mixed, such compounds as are beneficial in promoting the growth of vegetables, they may be useful in many cases, when properly applied, and used in sufficient quantity, in correcting the acidity, in altering the state or condition of the lands, as by taking away moisture from the surface where it prevails in an over-proportion in meadows and pastures, and thereby supports crops of coarse vegetables, and by rendering the texture of such grounds as are under the plough more open and mellow, consequently more suitable for the reception of the roots of grain, and other crops. But some of these materials, such as the bleacher's refuse, contains vegetable and mineral alkali, in such proportions as render it incapable of being made use of without being previously mixed with other materials. For which purpose, it is suggested, that "fresh mould or peat earth should be procured; and after having been well mixed and blended with it in the quantity of about eight or ten parts of the earth to one of the refuse, a proportion of rotten dung, suitable to the purpose for which the manure is intended, may be added, by which means a good manure will be formed." And the waste of soapers is another substance that may be made use of in the same way; but in this, it is observed, there is a considerable portion of lime mixed with the alkaline matter. The lees, or liquors, which are drawn off after making soap, as containing much alkaline saline matter, may likewise, where they can be procured in sufficient quantities, and at a reasonable rate, be made use of in a similar manner.

All these different substances, when combined with good rich vegetable mould, turf or peaty matters, and made use of as manure, are constantly found to be the most beneficial upon the stiff clayey and loamy soils; as in such sorts of land it is supposed that they probably not only contribute to the increase of the crops, by furnishing such soluble matters as can be readily taken up by their absorbent roots, but, by lessening their stiffness and tenacity, render them more proper for their reception."

In regard to the proportion or quantity of these manures which may be necessary, it must, as in other cases, vary according to the particular circumstances of the ground or soil upon which they are applied, and the views of the farmer in their application. But it is usual to apply them upon lands in a state of tillage, as well as under grass; in the first they are generally either put on in the state of compost, at the rate of about ten loads to the acre, just before the seed furrow is given or sown over the surface, and harrowed in with the grain; in whichever mode they may be applied, it is requisite to have them spread as equally as possible, in order that they may produce their effects in the most extensive and perfect manner." In the latter it is observed, that "though they may in some instances be used alone, it is probably a much better practice to have them mixed with such earthy substances as have been just mentioned before they are laid on the swards, as by such a practice their effects as manure may be rendered more complete and permanent. Upon grass lands they are often used to the amount of from one hundred to one hundred and fifty bushels. And most grass lands are improved by the application of such manures, but especially such as are wet, and disposed to the production

tion of coarse sour vegetables, such as rushes, wild sorrel, and various other plants of the same kind. But the ashes, or earthy saline matters, arising from the combustion of different fresh vegetable products, though beneficial as manures, are too wasteful and uneconomical in their production to be made use of, except in particular instances, as where wood and other vegetable productions are very abundant, and used commonly as fuel. Or where they cannot be readily cleared away by other more advantageous methods, as ten or fifteen parts, and in some cases considerably more, of such materials are dissipated and lost during the process. Where they are in sufficient quantities for this purpose, it is suggested that they may probably be employed to the greatest advantage by being mixed with a good portion of rich vegetable mould, or peat earth, and a quantity of well fermented dung; as, in such a compound state, they are capable of being applied more extensively, and at the same time in the most favourable condition for the support of vegetation. When made use of on the heavy soils, the quantity of ashes in the compost should be much greater than on those of the lighter kinds; they are, in general, the most effectual when applied as a top dressing to grass lands, especially such as are commonly termed sour, or have much tendency to the production of moss on their surfaces." See ASHES.

And peat earth is another substance met with in different districts, which, after being cut and dried by the heat of the summer, is made use of as fuel. By the consumption of this sort of earth in this way, a considerable loss in respect to manure is sustained; as it has been found, that, "in many cases, nineteen parts out of twenty of the material are dissipated and carried away in the process of combustion, which, as it has been shewn, that the inert vegetable or peaty matter, produced by the action of oxygen, or the pure air of the atmosphere for a great length of time, is capable of being rendered soluble, by mixing lime in certain conditions with it, and still more effectually by alkaline saline substances, might have been preserved and rendered useful." However, in Berkshire it is the common practice to dig up peat earth, merely for the purpose of burning it into ashes, in order that it may be used as a manure upon land in various cases.

But as it is only from fresh or green vegetable productions that alkaline saline substances can be obtained when burned, none being afforded by the combustion of dead or decayed vegetable matters, it would seem that the ashes of peat earth seldom contain much saline matter. It has, however, been observed by some, that all peat earths afford alkaline saline matters in a greater or less proportion when burned, and that in some it is from a twenty-second to a thirty-second part of their weight. It is stated, that "the ashes produced from the burning of peat about Reading in Berkshire, which long experience has shewn to possess great fertilizing powers, are asserted to contain no alkaline salts, nor, from the hasty analysis of them which was made by lord Dundonald, was any saline matter, except a small proportion of sulphat of magnesia, or Epsom salt, found. But it is added, that "if the analysis had been more carefully made, and when the ashes were newly burnt, they would most probably have been found to contain a hepar of lime, which is a saline substance soluble in water, while gypsum, the substance to which it returns on being exposed to the air, is insoluble." The fertilizing effects of these ashes may, therefore, it is supposed, probably materially depend upon this hepar, a circumstance which is rendered still more probable from the observation of Mr. Middleton, in the Middlesex Report, that "the hills on each side of the meadows which produce the Newbury *peat-ashes*, consist of chalk, easily dissolvable by heavy rain, which washes it off the ridges down the furrows, ditches, and streamlets, to the low grounds, where, mixing with the floods, it is floated over the meadows, and deposited in the peat. Consequently the peat of this district differs from that of most others, by the quantity of chalk which it contains; and, when dug, dried, and burnt, the fire reduces the chalk to lime, and the rest to ashes. Hence Newbury ashes are a mixture of lime and vegetable ashes; and it is very probable that any common peat-ashes, or the ashes of rough grass land, of turf, heath, furze, ling, wood, &c. produced by the operation of paring and burning, being mixed with chalk lime in due proportion, would be as equally fertilizing as these noted ashes." But it has been suggested, that there is another circumstance that may produce a difference in the saline and other substances contained in the ashes of different peaty earths, which is that of the presence of mineral springs. When, by this means, an over large portion of sulphat of iron, or green vitriol, happens to be present in the peat, the ashes produced from its combustion must in consequence become injurious, or at least much less beneficial to the growth of vegetables, than in cases where such a substance is not present. Its prejudicial effects, according to lord Dundonald, may be corrected by the use of either lime, magnesia, alkaline salts, or dung; but that preference is to be given to magnesia and alkaline saline substances, as they not only decompose the vitriolic salt, but form other saline substances, which are found favourable to vegetation or the growth of plants.

And where dung is made use of in such cases, the vitriolated iron is brought into its metallic condition, and the sulphuric acid, thus set at liberty, enters into combination with the ammonia or volatile alkali formed from the dung, and produces sulphat of ammonia; or, by uniting with the calcareous matter, and the additional assistance of the inflammable, or putrescent matter of the dung, it may be converted into a hepar that may be beneficial to the growth of plants as crops.

Ashes of these descriptions may be used as a manure, either by being harrowed in with the grain-crops, or sown over them as a top dressing after they have come up. In the former case it is advised, that they should be employed in a somewhat larger proportion than in the latter; in which "the best practice is to sow them over the crops before they are grown too high; and if the weather be rather inclined to wetness, it will be the more favourable: the quantities commonly employed in this way are from fifteen to twenty bushels the acre, according to the state or condition of the land. Where laid on grass lands, whether those of the artificial or natural pasture kinds, they often produce great improvements, rendering the grasses thicker, finer, and more close and abundant, often removing much of the mossy matter which infests them. See ASHES.

And peaty substances, in the reduced state of dust, are sometimes made use of with great benefit; but it is suggested by lord Dundonald, that this sort of earth may generally be employed to most advantage by being well mixed and incorporated with such substances as contain alkaline salts, or with alkaline hepars, or by a mixture of sulphat of soda with lime in its active state." It is likewise supposed, that the powdery or dusty matter of pit-coal might, probably, be applied with the same advantage if prepared in a similar manner, and it is capable of being rendered soluble in the same way. And it is further asserted by the same writer, "as the result of experimental trials, that the effects of peat earth, mixed and incorporated with alkaline saline substances, are equal, if not superior, to those from dung, the weight of of each being the fame ;" which, if it be well-founded, fhews the fuperiority of employing peat earth in this way, inftead of converting it into afhes, to be much more than has been already believed to be the cafe. See PEAT-*duft*.

And the afhes obtained from pit-coal, when applied as manures, are found to be ufeful in many refpects ; but it is fuppofed, as they can contain faline matter only in proportion to the quantity of frefh vegetable products that may have been confumed along with them, little of the effect which is produced can depend upon it ; much more, probably, arifes from the portion of calcareous earth which they contain. It is alfo added that "fomething, in many cafes, probably depends on the animal fubftances that may have been occafionally burnt, or afterwards mixed with them, before they are made ufe of as a manure. And that "they may alfo be ferviceable on the ftiffer forts of foil, by rendering them more open and difpofed to admit the roots of growing vegetables." This "feems to be fhewn by their utility in the ftiff clayey grounds, from which brick earth has been dug, and on what are generally termed four lands. On the more tenacious loamy foils, they may operate by giving friability, and at the fame time the calcareous principle, in a fmall degree, where it is deficient, which is further fupported by their having been found from experience to be much lefs ufeful in the poorer forts of land, than thofe that are of a good quality."

It may be noticed, that the application of thefe afhes to ftiff foils, from which brick earth has been taken, renders it fufficiently friable to afford good crops of beans, a fort of plant which, though it grows well on heavy foils, could not be produced on lands fo very ftiff as the bottoms of brick grounds, without thefe afhes. However, except in fuch cafes as the above, this manure is probably beft adapted to grafs land as a top-dreffing, and it may be occafionally ufed in this way to young grain crops in particular cafes.

With regard to the proportion in which it may be laid on, it muft be different according to the views of the farmer, the nature of the crop, and the ftate of the ground, as well as other circumftances. See *Coal*-ASHES.

Another faline fubftance is met with in foot, that experience has fhewn to be of much utility, when applied to land as a manure. It is probable, that the beneficial effects refulting from the ufe of this fubftance depend, in a great degree, on the quantity of alkaline faline matter which it contains ; which by its action on the rich vegetable mould of the foil or earth with which it is blended, may render it more capable of fupplying the nutrition of vegetables ; and it may bring the grofs oleaginous matter of the foot into fuch a ftate as to be capable of folution or diffufion in water, and in that way render it fit to be taken up by the abforbent roots of vegetables. It is fuppofed, that "the earthy matter of this fubftance, as well as that of different kinds of afhes, may probably be rendered more fuitable for the purpofe of promoting vegetation, by their having been expofed to the action of fire, as is well known to be the cafe with clay." The great ftate of finenefs in which foot is found, may, likewife, it is fuppofed, be ferviceable, as by that means it becomes capable of being more regularly and more extenfively mixed with the foils on which it is applied. And it is believed, that "the good effects of moft fubftances employed as top-dreffings depend, in fome meafure, upon this circumftance." It is thought probable, that this fubftance, as containing alkaline falt in a confiderable proportion, may probably be ufed with greater advantage by being well mixed or blended in rich mould, or peat-earth, and by fuch a method the quantity of manure would be greatly increafed. This fhould not, however, be attempted where the deftruction of infects forms any part of the defign of the farmer in its application upon his land.

Soot is a fubftance which is chiefly made ufe of as a top dreffing to grain crops and grafs lands. "On the former it has been found extremely ufeful in deftroying the wire-worm and other deftructive infects. This is probably effected by the bitter oleaginous liquid formed from the union of the alkali and the oil of the foot, impregnating thofe parts of the plants on which they feed, and thereby caufing them to be rejected by fuch infects." It may alfo produce fome advantage in this refpect, by promoting a rapid vegetation, and thereby rendering the texture of the plants, very quickly, too firm to be preyed upon by them, as has been obferved by lord Dundonald. That it is very powerful in promoting the vigorous growth of vegetable crops, is fhewn "by the change which takes place after fowing it over fuch young wheat crops as have a yellowifh fickly appearance, as they frequently put on, in a very fhort time afterwards, the healthy green afpect. On meadow and pafture lands, experience has likewife fhewn it to be highly ufeful, not only by encouraging the growth of a finer fort of grafs, but by deftroying or correcting the frequent difpofition of fuch grounds to produce mofs, and fome other coarfe forts of vegetable productions." In refpect to the quantity or proportion that may be applied, this muft vary according to the circumftances of the cafe ; the moft common quantity is generally from about forty to fifty bufhels on the acre. See SOOT.

It is advifed, where any of thefe or other materials that contain faline matters, are to be employed as manures, that "they fhould always be preferved in fheds, or other convenient places, from rains, or the accidental application of water to them, as where this practice is neglected, the faline fubftances are foon diffolved and carried away in a liquid form. It is chiefly from this caufe, that fubftances of this kind, which have been long expofed without being covered, are often found fo inferior in their effects to thofe which are frefh or newly made. On this account alfo, if fuch fubftances are laid on land at too early a period of the feafon, they will be liable to have much of their valuable properties carried away by the rains that may take place."

The muriat of foda, or fea-falt, is a fubftance, the utility of which has been already noticed, but which, "for the purpofes of manure, feems not yet well afcertained, as by fome it is confidered as poffeffing confiderable powers of promoting vegetation ; while others have experienced little or no advantage from its application. But though it may prevent putrefaction when employed in large proportions by its antifeptic property, as has been fhewn by different trials, when ufed in fmall quantities it has a tendency to promote the procefs. On this account, it may therefore, it is fuppofed, be ferviceable when incorporated with farm-yard dung, and other animal or vegetable matters, in fmall portions."

The author of "Practical Agriculture" has fuggefted, that "as every where in the vicinity of the fea a ready means of obtaining this faline material in unlimited quantities offers itfelf, it may deferve more particularly the notice of the agriculturift ; and more efpecially as many other fubftances that are known to contain, or be impregnated with it, fuch as the weed thrown up by the tides, and the fand over which they flow, can be eafily procured."

There is ftill another fubftance of this nature, that "exifts in the bittern, wafte, or refufe of falt works, which generally contains muriat of magnefia in large proportions. It

It has been found to poffefs very great feptic qualities, and may, therefore, be highly beneficial when mixed with dung, or earthy matters. Experience has fhewn it to be capable of promoting vegetation in a great degree.

The above writer thinks, that "in whatever manner fubftances of the faline kind may produce their effects in promoting vegetation, when employed as manures, it is evident, from their containing in themfelves little or nothing of fuch matters as are capable of affording nourifhment to plants, that they may, in moft cafes, be made ufe of to the greateft advantage, by being mixed and incorporated with fuch fubftances as they are capable of acting upon and reducing to a ftate proper for the fupport of vegetable crops; fuch as rich earthy materials, imperfectly reduced dung, and other matters of a fimilar kind. Where fubftances that contain the muriat of foda, or fea-falt, are employed, they may probably be applied to much advantage, by being mixed with imperfectly burnt clay, when reduced to the ftate of powder. And if upon trial they fhould be found effectual in this form, they may be very conveniently made ufe of in the way of top-dreffings to grafs or grain crops in the fpring."

Manures of the mixed or compoft Kinds.—It is extremely evident, from what has been ftated and explained in refpect to the nature of the different fubftances that are capable of being ufed as manures, that many of them may frequently be mixed and blended with each other, or with materials of other kinds, fo as to be not only confiderably increafed in quantity, but often rendered more effectual and proper for application than in their fimple ftates. At the fame time, it is clear, that fome of them may be thus mixed and incorporated with each other with much more benefit than others; for although the conftant experience of farmers has decicidedly fhewn the great importance and advantage of employing compofts, till lately they have paid little regard to the mixing together of fuch matters as are, from the principles which they originally contain, or which are formed from them, in the changes which they undergo in the different ftages of their decompofitions, adapted to act in the moft fuitable manner for producing fuch combinations or alterations in the materials, as are capable of being beneficial in the greateft poffible degree in promoting vegetation, when applied to the land or foil.

It is obvious, that the manure raifed in the farm-yard is the moft common application of any, and which, from its being formed by the gradual decay of various kinds of vegetable matters, as hay, ftraw, fern, and various other materials of a fimilar nature, with which the dung and urine of animals is incorporated and combined, it is to be confidered as a compound manure. And from the largenefs of the proportion in which fuch vegetable productions enter into its compofition, and the quantity of earthy materials that is in moft cafes added, efpecially where the management is judicious, by laying of fuitable foundations or bottoms, it is lefs frequently requifite to blend it with other fubftances than moft other manures. But as moft of the vegetable materials that conftitute the chief part of it are made ufe of in a dry and hard ftate, and do not fo quickly ferment or run into the ftate of decay, notwithftanding the quantity of animalized matters that may be blended with them; it becomes ufeful to turn them over once or oftener, in order that their complete putrefaction may be promoted, and at the fame time the different materials minutely blended together. And it has been fuggefted, that "in forming of this manure, care fhould alfo be conftantly taken, that the heaps be fo fituated, as that they may not become too dry, or too much foaked in water, as in either cafe they muft be greatly injured," and that "whenever it may be requifite to incorporate any earthy material with this fort of manure, the agricultor fhould carefully attend to the ftate or richnefs in which it may exift in the yard, and proportion fuch additions accordingly." It cannot, however, ever demand a portion nearly fo large as that of fuch manures as are almoft wholly compofed of animal fubftances of fuch earthy matters.

After obferving that ftraw or litter is the bafis of farm-yard manure, or what is often termed dung, a late writer fuggefts that, for light and heavy foils, the dung fhould be prepared in different ways, be ufed at different feafons, and applied to different crops. For light foils, he thinks, manure requires to be much higher prepared than is neceffary for clayey foils; and that every ftep of the previous preparation, to be perfect, ought to be executed in a quite different manner. "For foils of the firft defcription, where turnips are taken as a firft crop, dung can hardly be too well prepared; becaufe the nature of the crop, to which it is applied, renders a complete incorporation with the ground abfolutely neceffary, without which the young plants might be ftarved at their very entrance into life. In the beft farmed Englifh counties, which have come under his obfervation, dung is often kept over year, in order that it may be perfectly rotted: and the late Mr. Bakewell was in habits of not applying it till it was reduced to a ftate fomething like black fnuff." He does not, however, approve of fuch protraction; for, when the preparatory fteps are conducted with judgment, there is rarely any neceffity for keeping dung over year upon turnip-farms; befides, fuch a delay caufes a wafte of the article, and moft likely diffipates its ftrength: at all events, a year's intereft of the value of the increafed produce muft be loft. In general cafes, there is not much difficulty in preparing dung upon turnip-farms; becaufe, in the drieft feafon, from the nature of the food ufed, fuch a quantity of liquid paffes from the animals, as to prevent burning, provincially *fire-fanging*, the greateft obftacle to the rotting of dung that can be experienced. If turnip dung is regularly removed; if it is properly mixed with the horfe litter, and other excrementitious matter accumulated upon the farm, it will be found an eafy tafk to prepare all that is made by the middle of April, at which time the fold-yard fhould be cleared. What is produced after that time fhould be ftored up feparately, receive waterings, if the weather is dry, and be referved for clover ftubbles, or other fields that are to be dunged in autumn." But though the middle of April is mentioned "as a good time for clearing the fold-yard, this does not prevent the work from going partially forward through the winter, when fuitable opportunities occur. When drove out of the fold-yard, the dung fhould be laid up in a regular heap or pile, not exceeding fix quarters, or four feet and one half in height: and care fhould be taken not to put either horfe or cart upon it, which is eafily avoided by backing the cart to the pile, and laying the dung compactly together, with a grepe or fork. It is alfo ufeful to face up the extremities with earth, which keeps in the moifture, and prevents the fun and wind from doing injury. Perhaps a fmall quantity of earth ftrewed upon the top might alfo prove ufeful. Dung, when managed in this manner, generally ferments very rapidly: but if it is difcovered to be in a backward ftate, a complete turn over, about the firft of May, when the weather becomes warm, will quicken the procefs; and the better it is fhaken afunder, the fooner will the end in view be gained." A fecluded fpot of ground, not much expofed to wind, and perfectly fecure from being floated with water, ought always to be chofen for the fcite of fuch

pile•

piles or heaps. If the field, to which it is to be applied, is at hand, a little after-trouble may be faved, by depofiting it there, in the firft inftance; but he has always found it moft convenient to preferve a piece of ground, adjacent to the home-ftead, for fuch a purpofe. There it is always under the farmer's eye; and a greater quantity can be moved in a fhorter time, than when the fituation is more diftant. Befides, in wet weather, and this is generally the time chofen for fuch an operation, not only are roads cut up, by driving to a diftance, but the field, on which the heap is made, may be poached and injured confiderably." This he conceives to be "the moft approved method of procuring dung upon turnip or light farms."

However, "upon clay foils, where wheat forms a principal part of the crop; where great quantities of beans are cultivated, and few turnips fown, unlefs for the ufe of milch cows, the rotting of dung is not only a troublefome, but an expenfive affair. Independent of what is confumed by the ordinary farm-ftock, the overplus of the ftraw muft fome how or another be rotted, by lean cattle kept in the fold-yards, who either receive the ftraw in racks, or it is thrown acrofs the yard, to be eaten and trod down by them. According to this mode of confumption, it is evident that a ftill greater neceffity arifes for a frequent removal of this *unmade* dung; otherwife, from the trampling of the beafts, and the ufual want of moifture, it would comprefs fo much as to prevent putrefaction altogether. To prepare dung fufficiently upon farms of this defcription is at all times an arduous tafk, but fcarcely practicable in dry feafons: for if it once gets burnt (*fire-fanged*), it is almoft phyfically impoffible to bring it into a fuitable ftate of preparation afterwards; and, at all events, its virtues are thereby confiderably diminifhed. The ftraw flung out in confiderable portions to the fold-yard, after being compreffed by the trampling of cattle, becomes rather like a well-packed ftack, than a mafs of dung in a preparatory ftate. The fmall quantity of water and dung made by the animals is barely fufficient to caufe a flight fermentation; and this fermentation, when the heaps get into a compreffed ftate, is fure to bring on the injury of *fire-fanging*. To prevent fuch an injury, no meafure can, it is conceived, be fo fuccefsfully ufed, as a frequent removal of this unmade dung, efpecially if the weather is wet at the time. If people can ftand out to work, you cannot have too much wetnefs when executing this operation; for there is always fuch a quantity of the ftraw, that has not paffed through the entrails of the cattle, as renders it almoft impoffible to do injury, in the firft inftance, by an accefs of moifture. What he would therefore recommend, upon every clay-land farm, efpecially thofe of confiderable fize, is a frequent clearing of the fold-yard; and that the greateft care fhould be taken to mix the ftable or horfe-dung in a regular way with what is gathered in the fold-yard, or made by other animals, in order that a regular heat or fermentation may be fpeedily produced. Where the materials confift of a fmall quantity of dung, or excrementitious matter, and a large ftore of unrotten ftraw, only partially moiftened, he is clear that no damage can enfue from putting horfes and carts upon the heap; nay, he rather thinks that a pofitive benefit will be gained from this flight compreffion. He is, however, at the fame time, well aware that the fentiments of many able and judicious farmers are different from his on this point; they being of opinion, that the natural preffure of the materials is quite fufficient, and that any more is attended with injurious confequences. He is, however, fatisfied, that fuch ideas are unfounded; having tried both methods upon an extenfive fcale, and, from the refults, feels himfelf juftified in recommending the management. Perhaps this difference of fentiment may arife from not attending to the very different qualities of dung on different farms; for he has already fully recognifed the propriety of abftaining from putting horfes and carts upon fuch heaps or piles, containing materials which can be called dung, even though it may be in an unripe ftate. He contends, however, that no injury is fuftained in flightly compreffing a mafs of rough materials; nay, that fuch is attended with beneficial effects: for, if the materials were laid up with a fork, or a grepe, as is recommended in the cafe of turnip or half rotten dung, the fmall portion of moifture therein contained would fpeedily be wafted or evaporated; a circumftance which he has repeatedly witneffed, efpecially when dry weather fucceeded the period when the heap was made up. Befides, driving a one-horfe cart over the furface of materials, only one ftage removed from the condition of dry ftraw, will never prevent fermentation. If left in the fold-yard, he grants that the conftant treading of the cattle therein confined, and the daily increafed weight of the heap, would undoubtedly produce that evil; but fuch is effectually prevented by frequent removals, efpecially if rainy weather prevails at the time. The heap or pile, as in the former cafe, fhould be formed in a fecluded fpot, if fuch can be got at hand; becaufe the lefs it is expofed to the influence of the fun and wind, fo much fafter will fermentation proceed. It fhould be conftructed on a broad bafis, which leffens the bounds of the extremities; and feveral feparate heaps are neceffary, fo as too much may not be depofited at once, which, to a certain extent, would bring on the very evil he has been endeavouring to avert. By fhifting the fcene frequently, and allowing each covering or coat to fettle and ferment, before laying on any more, the moft happy effects will follow; and thefe heaps (all fuch as are completed before the firft of May) may reafonably be expected to be in a fit condition for applying to the fummer fallow fields, in the end of July or firft of Auguft. If the external parts get dry at any time during the procefs, it is proper to water them thoroughly, and, in many cafes, to turn over the heap completely. He may add, that he has repeatedly experienced great advantage from laying a thick coat of fnow upon fuch heaps, as, by the gradual melting thereof, the whole moifture is abforbed, and a ftrong fermentation immediately follows. He would continue the fame method of management during the fummer months, fo far as circumftances permitted; though it rarely happens that dung collected at this advanced period is fit for ufe in the fame feafon, unlefs it be fuch as is made by keeping horfes or cattle in the houfe, upon green food. Perhaps, as a general principle, it is proper to thrafh out all grain before fummer arrives, (a fmall quantity for litter and other purpofes excepted,) in order that the full value of the raw materials, when converted into manure, may be gained. Straw thrafhed in the fummer months always wants a good deal of its original ftrength: it is broken and hafhed by the mills, therefore a large portion muft at once be thrown to the fold-yard, where its ftrength is ftill more exhaufted and diffipated. Even when ftacked carefully, it will be found, next winter, to produce much lefs bulk of dung, than if it had been ufed at the proper time; and intereft of the amount for one year is loft; all which things, added together, will be found equal to one-half of the original worth."

It may be obferved that in cafes where animal matters are thrown together in any quantity, a great increafe of good manure may be made by combining with them, as already mentioned, rich furface mould, peat earth, or the fcrapings of old ditches and roads; as in this way the ammonia formed during the decompofition of the animal materials is prevented

vented from efcaping, as would otherwife be the cafe, and which, by combining with and acting upon the earthy materials, quickly renders them proper for the purpofes of manure. And as fubftances of the animal kind have been found to run very rapidly into the ftate of putrefaction, it has been remarked, that " they may frequently be incorporated with fuch vegetable materials as are little difpofed, or with difficulty made, to rot or become putrid, and by fuch means good compofts be more expeditioufly formed. In making ufe of fuch earthy materials, it may be of much advantage to have them expofed to the influence of the atmofphere for a confiderable length of time, frequently turning them over, before they are mixed with the manures, as by fuch means they become in a more pulverized ftate, and are capable of being more intimately blended with fuch materials, and afterwards fpread over the land with much greater equality, a circumftance upon which their effects very much depend. And that when, in performing this bufinefs, the earthy fubftances are formed into a fort of ridge, about five or fix feet in height, and nearly the fame breadth in the bottom, they will be in the moft proper fituation for being united with dung or other matters that may be intended to be blended with them."

By a late writer it has been remarked, that " lime is a fubftance that has often been too indifcriminately made ufe of in the formation of compofts, but which, by attending to the following circumftances, may admit of being employed extenfively and with more beneficial effects. Where the deftruction or decay of green or frefh vegetable matters, efpecially thofe of the more coarfe and hard kinds, is intended, it fhould be ufed in its cauftic ftate in fmall quantities ; as in this condition, thus fparingly employed, it reduces more expeditioufly the ligneous and hard parts of fuch matters to an earthy ftate ; and as, during its action in this way on thefe fubftances, fuch elaftic matters are fet at liberty, as by their fubfequent combination afford ammonia or volatile alkali, it may frequently be a beneficial practice to blend fuch earthy fubftances as have been juft mentioned with them, and thereby prevent the elaftic matters from being diffipated and loft. If a portion of rich farm-yard dung be fome time afterwards incorporated with the materials, a valuable compoft will be formed." And it is added, that " quick lime is likewife found ufeful, fometimes in bringing the hard parts of dead vegetable matters, as tanners'-bark, fern, ftraw, cabbage-ftalks, leaves, &c. quickly into the ftate of earth or mould ; but whenever it is made ufe of in this way, it fhould be had recourfe to only in a very fcanty proportion to thofe of the matters with which it is mixed, as when it is employed in large proportions, it is liable, from the heat that is extricated or difengaged by its combining with the moifture of fuch fubftance, being fo augmented during its flaking, as to convert them into a coaly fubftance that is infoluble, and at the fame time to force off, in the form of gas, their elaftic principles, except fuch a quantity of carbonic acid as may combine with the lime during the procefs."

It is evident that, " by the common practice of blending quick or cauftic lime with farm-yard dung, much lofs is frequently fuftained ; as by its violent operation upon fuch fubftances, fome of the elaftic matters are not only fet at liberty and quickly conveyed into the atmofphere, but, with what remains infoluble faline, compounds are formed which cannot affift vegetation. It is conceived that the complete putrefaction of fuch manures, when neceffary, is beft promoted by the ufe of lime in its mild ftate. But in cafes where it is " to be blended with peat or earth, the moft advantageous method is to ufe fuch lime as has been newly made and well flaked, in the proportion of about one part of the lime to five or fix parts of the peat or mould, which fhould not be too much exficcated, or dried, before it be made ufe of. By this means the heat which is generated will not be fufficient to produce any injurious confequences, either by forming a coaly matter, or forcing off the elaftic principles in the ftate of gas. And the volatile alkali, which is compofed in fuch cafes, by being allowed to enter into combination, as it is formed, with that part of the peat or mould which has not been acted upon by the lime, in confequence of its being employed in fo fmall a proportion, and in its effete ftate, will form a foluble faline fubftance, capable of promoting vegetation."

Lord Dundonald ftates, that there " are other fubftances that may be ftill more beneficially employed in forming compofts with peat earths, when they can be procured in fuch quantities and at fuch cheap rates as render them capable of being made ufe of in this way," fuch as " alkaline faline matters, or fuch fubftances as contain them in any quantity ; as by mixing thefe with the peaty materials as above, they are made perfectly foluble, while by the ufe of lime only, fuch a proportion of them is rendered foluble, as can be acted upon by the quantity of ammonia or volatile alkali formed during the time it is mixed with them." And ftill farther, that infoluble compounds, fuch as have been noticed, are formed in the latter circumftance.

But the practice common, in different diftricts, of making compofts with lime and mould on the headlands, or other parts of the fields on which they are to be applied, which cannot be done to advantage, except where the furface mould is rich in vegetable matter, is not to be much recommended, but wherever fuch compofts are to be formed, the land fhould always be ploughed or dug up to a great depth, and be reduced into as perfect a powdery ftate as poffible ; frefh lime may then be depofited in fmall heaps, along the middle ridge of the headland, and the earth in this fine ftate be thrown over them, in the proportion of about four parts of earth to one of lime, being kept clofe by being beaten down with the back of the fpade. It is obferved, that from the gradual flaking of the lime in this fituation, by the moifture of the earth, elaftic matters are fet at liberty, which combining with the mould or earth, render it ftill further reduced, and by being afterwards very intimately blended by means of the fpade with the very fine particles of the lime caufed by the flaking, a valuable compoft is made for the ftiffer forts of foil, efpecially if a fmall quantity of good rotten dung be well incorporated with them fome time afterwards.

Although farm-yard manure is feldom in a ftate to admit much addition of earthy matter, yet where there is much liquid oozing from fuch compofts, or ftagnating about the bottoms of them, fome of the earthy materials which have been mentioned may be laid around them in order to abforb or take it up, and prevent the great wafte that muft otherwife take place, as may often be obferved in the fituations where dung compofts are made. And it is advifed, that " this fhould be more particularly attended to, where fuch compofts are laid in fituations that have not been properly formed as dung-fteads." In fuch cafes, it may often be an ufeful practice to place a confiderable thicknefs of fuch materials in the bottoms, before the farm-yard compoft is carried out, and laid upon them, as by that means the manure heap may be greatly increafed, and at the fame time a proper fubftance for the volatile alkali contained in fuch liquors to act upon fupplied. This method is fully confirmed by the practice being in ufe wherever any attention is directed to economy in the forming manures of this kind.

With regard to the application of this fort of manure, the nature of the foil, the ftate or condition of the land,

and the goodneſs of the matters, are circumſtances which render a difference in the quantity of ſuch manures neceſſary. The heavy ſorts of ſoil, ſuch as thoſe of a clayey or deep loamy nature, require compoſts conſtituted of the lighter ſorts of earthy materials; while the thinner and more light ſorts ſtand in need of thoſe which are formed of clayey, loamy, or the more tenacious matters. But "in general, the allowance of ſuch manures ſhould be from ſixteen to twenty loads to the ſtatute acre, each containing ſeventeen or eighteen hundred weight. On many occaſions, however, a much larger proportion may be required, and in others a leſs may anſwer the intentions of the farmer." It is added, that "the mixture of dung and litter, and other materials which are gradually collected and formed into heaps in the farm-yard, is, in general, when employed without having any other ſubſtances incorporated with it, laid on ſuch lands as are under preparation for wheat, turnip, or barley crops. It is likewiſe in ſome places laid on for a pea crop, where wheat is intended to be the ſucceeding crop."

The compoſt manures, which are collected from the ſtreets of large towns, are formed of a great variety of ſubſtances, as the recrements of decayed vegetables, putrid animal matters, and aſhes; but from their abounding for the moſt part with ſubſtances of the latter kinds, they may, on the principles juſt ſtated, be in many inſtances greatly increaſed by having rich ſurface mould or peat earth blended with them; and by ſuch a practice, where the manure heaps are in a condition to admit of it, the riſk of waſte by the eſcape or diſſipation of their more fluid contents in the aerial or gaſeous ſtate be effectually prevented. But ſuch additions can only be advantageouſly made where the proportion of animalized materials in the manure is large; in other caſes it is better to employ them in the ſtate in which they are met with when collected.

It is found that compoſt manures are capable of being uſed with great benefit on different ſoils, and in preparation for different ſorts of grain crops, as well as thoſe of the graſs kind. It is ſtated, that "when applied in the proportion of fifteen or twenty tons to the acre, they generally produce great fertility. They ſhould, however, be applied according to the particular circumſtances of the ſoils, and the nature of the crops for which they are made uſe of."

It may be noticed, that the reſult of practical trials fully proves that the moſt beneficial compoſts are all thoſe which are formed by the combination of earthy materials with animal matters. See COMPOST.

Manures, Means of increaſing and preſerving them.—After what has been already advanced, the beſt means of augmenting, preſerving, and managing manures may be conſidered, as upon this in a great meaſure depends the general fertility of farms, and the goodneſs of the crops that are raiſed upon them. It is of courſe a matter of great intereſt and importance to the farmer to ſee that nothing is deſtroyed, waſted, or thrown away, that can in any way be converted to this purpoſe. It has been remarked by a late writer, "that there are many ſubſtances that may be rendered uſeful in this way, which have hitherto been little regarded by the cultivators of land, there can be little doubt, when the daily waſte of animal, vegetable, and other matters that take place in every country, from their being carried away by rivers, or conſumed by fires, is fully conſidered." By greater attention to the cutting of grain, ſo as to preſerve as much ſtraw as poſſible, as well as care in getting together the ſtubble, in many inſtances vaſt advantage may be gained in this view. And that "another great cauſe of loſs in the production of manures is from the want of adopting or putting in practice ſuch modes of management, in reſpect to different ſubſtances, as are capable of rendering them fit for the purpoſe of application in the moſt quick and expeditious manner; for it is obvious, that if by properly attending to ſuch means, the ſame quantity of manure can be prepared in a ſhort ſpace of time, which under other circumſtances muſt have required a long one, much increaſe of manure may be effected, and conſequently great advantages be gained by the cultivators of the ground." It is ſtated, that what is neceſſary to be done in order to facilitate and haſten the decompoſition and reduction of different materials into the proper ſtates for being applied to the ſoil are, as has been ſeen, "in ſome meaſure, the free admiſſion of atmoſpheric air, a quantity of moiſture ſuited to the condition of the matters made uſe of, and a due degree of heat. And alſo the proper blending of animal with vegetable ſubſtances, in the incipient ſtages, and the addition of the lime, according to circumſtances, and in proportions ſuited to the ſtate and nature of the ingredients."

And in this intention, it is obſerved by the ſame author, "as the principal reſource, on moſt farms, is the farm-yard, it ſhould be conſtructed in ſuch a manner, as that every thing may with eaſe and facility be converted to the purpoſe. In general one dung-ſtead may be ſufficient; but where the ſize of the farm is large two or more may be neceſſary, as the putrefaction of ſuch heaps proceeds with greater regularity and expedition, from the acceſs of air and moiſture being more free when they are not made too large; and, beſides, they can be more conveniently turned over or removed. The parts of the yard on which they are ſituated ſhould, while they are convenient for depoſiting the dung, and other matters from the ſheds and other offices, upon, be neither too much elevated, ſo as to cauſe the dung to become dry, nor ſo greatly depreſſed as to favour the ſtagnation of water upon it, and thereby deprive it of the properties moſt eſſential to the promotion of vegetation. Before each of the dung-ſteads a reſervoir or baſin ought to be made, into which not only the drainings from all the different ſheds and places where animals are fed or kept may empty themſelves, but likewiſe the urine from the neceſſaries, the ſuds from the waſh-houſes, and the waſhings of the various utenſils employed in the family. Without theſe advantages in the contruction of farm-yards, much loſs of manure muſt daily occur from the liquid matters of ſuch places continually running away, and being otherways waſted, as well as from their not being made uſe of to forward the converſion of other ſubſtances into the condition of manures." But that, where theſe and other ſuitable accommodations have been provided, the farmer will have little more to do than "be careful in ſaving or providing ſuch matters as are ſuitable for the purpoſe, and cauſing them to be properly placed and removed, in order to have them ſpeedily reduced into the ſtate of manure, and the quantity of his dung-heaps thereby greatly increaſed and extended. With the ſame deſign, various vegetable matters, ſuch as hay, ſtraw, fern, leaves, ruſhes, coarſe graſſes, flags, and many other aquatic plants, ſhould be collected and preſerved in as large quantities as poſſible, by allowing nothing of the kind to be ſold or carried from farms, except in ſome particular inſtances, as where they are ſituated near large cities or towns, where ſuch articles can be advantageouſly diſpoſed of for the purpoſe of feeding and littering horſes, or other animals, and at the ſame time an equivalent in good manure be brought back to the farm; by mowing and raking together the wheat or other ſtubbles, the fern from the commons, and leaves where they can be obtained, as in the vicinity of parks and other wood-lands, and by cutting the coarſe graſſes

and

and aquatic vegetables at fuch periods as they are in the moft juicy and fucculent ftates. The whole, after being fufficiently dried, fhould be carried to the farm-yards, and ftacked up in convenient fituations, either in or near them, for the purpofe of being made ufe of as litter, and by that means being converted into manure. And in addition to thefe means, every leifure opportunity fhould be taken, before the commencement of the foddering feafon, to bring into the farm-yards fuch quantities of peat or boggy earth, rich furface mould, marle, dry mud from ponds or ditches, fcrapings of roads, loam, and other fubftances of the fame kind, as can be conveniently obtained, for the purpofe of being applied as bottoms for the abforption of the liquid matters."

It is farther ftated, that when fuch materials as are neceffary have been thus procured, "the beft mode of proceeding feems to be that of covering the whole of the yards where the cattle ftand and tread, and even the pig-fties, in fome cafes, with layers of thefe earthy matters, eight, ten, or more inches thick, according to the number of cattle and other circumftances; and alfo to depofit in the refervoirs before the dung-fteads proper quantities of the fame fubftances, for the liquid matters which come into them to act upon. Upon thefe earthy bottoms, at the time the cattle are confined, pretty thick litterings of one or more of the materials that have been collected and ftacked up may be placed, and the ftables, cow and ox-ftalls, pig-fties, &c. cleaned out upon them. Where it is the practice to tie up and confine the cattle in the night-time, the ftraw or other fubftances, after having been broken down and reduced by littering them, may be ufed for covering the bottoms of the yards, by which means their decay may probably be rendered more quick and convenient. It appears alfo probable, that where ftubble, fern, rufhes, leaves, or other vegetable matters, the textures of which are hard and ligneous, are employed, their decay or reduction into the ftate of manure may be greatly expedited by means of a flight portion of lime, in its active ftate, being fpread over the earthy bottoms before they are applied, as has been found to be the cafe with tanners' bark." And that, "where the matters made ufe of in the way of manures are liable to be rendered too dry by the weather, their putrefaction and decay may be much promoted, by having them fprinkled over occafionally with water, which may be conveniently and readily performed by having a pump with troughs fixed properly for the purpofe; or where thefe are wanting, from a pond in the yard." And in order "to render the plan the moft effectual it is capable of, the whole of the cattle fhould be ftrictly confined to the fold or foddering yards during the winter, and not turned out, as is frequently the cafe, into the paftures, by which the making of much manure is prevented, great injury in many fituations done to the grafs-lands, and the ftock, from being much expofed to cold and other caufes, benefited in a far lefs degree than is commonly imagined. By purfuing this method, from the great confumption of ftraw and the coarfer forts of food by the young lean cattle, and of hay and luxuriant vegetable roots of plants by the others, fuch quantities of animalized matters are voided, as by mixing with the bottoms of the yards haftens their putrefaction, and affords not only an immenfe increafe of manure, but of fuch as is of a very valuable kind. If there be not a fufficient proportion of animal dung and urine incorporated with the other matters, which can feldom be the cafe where the cattle are not regularly confined to the fold-yards, the manure, though it may be nearly as large in quantity, is found by experience to be very inferior in its effects when applied to land." It is likewife ftated, that "where the number of cattle confined in the fold-yards is great, it may be neceffary, occafionally, to remove the bottoms, and the matters littered upon them, to the dung-fteads, after they have become in fome degree manures, by being well faturated and blended with the urine and other animalized matters. Thefe muft be immediately replaced by others in the way juft noticed. And farther, "the earthy fubftances from the refervoirs fhould alfo be occafionally emptied out upon the dung heaps, and replaced by quantities of frefh materials of the fame kinds, and the ftems of different grofs vegetable products from gardens or other places."

Befides, "at the clofe of the feafon, when the cattle are turned out of the yards, the heaps of manure which have been thus collected and thrown together, fhould be turned over, in order that the animalized matters may thereby not only be ftill more intimately incorporated with the earthy fubftances, but, likewife, that more of the pure air of the atmofphere may be retained among the clods, from their being rendered much fmaller by fuch means, and the putrefactive procefs be thereby more perfectly produced." And, "after this bufinefs has been well performed, as little delay as poffible fhould be fuffered to take place before the manure is applied to the foil; as, from the combination of oxygen or pure air with the carbonaceous material of the dung, and of azote with hydrogen, under thefe circumftances, fuch fluid matters are formed as conftitute its moft beneficial properties, but which are afterwards continually wafting, fo long as it remains unapplied to the ground or foil." Hence, "on thefe accounts, as well as thofe which have been already ftated, manure heaps fhould not be made too large, but of fuch fizes only as that they can be expeditioufly turned over, and put upon the land. And another advantage which attends the having different heaps, and their not being large, is, that one can be prepared and carried away at a time, without the other's being in the leaft injured by any delay that may happen from unforefeen caufes of any kind."

It is noticed in an ufeful periodical work, that "in many fituations where the above-mentioned articles are plentiful, they are fuffered to go to wafte, though they may be ufed to great advantage for littering the ftables and fold-yards. Ferns and rufhes do not rot fo foon as ftraw, but make a rich manure, and if well turned over in the fpring, are fufficiently rotten in June." In winter and fpring, when dung is taken from the ftable or fold-yards to the fields, it is conceived better to throw it up with forks than allow the carts to be taken upon the dung-hills, a practice which prevents a fpeedy or complete fermentation. At thefe times, the quantity of manure may be much increafed by mixing with the dung large quantities of rich earth, taken from old dykes, fediments of ponds formed by running water, and fuch other places as were moft likely to afford it, well mixed with frefh or diffolved vegetable matter." But it is well obferved, that the practice of mixing earth with dung requires to be managed with a delicate hand, efpecially in forming a dunghill with materials that have not been previoufly fubjected to fermentation, for, as in carting upon it, by preffing and confolidating the mafs, it greatly retards, and, in fome inftances, almoft entirely prevents, fermentation; indeed, by mixing any confiderable quantity of foil with dung in an unfermented ftate, by preffing the ftraw and other matters into a fmall fpace, it fo effectually excludes the air, that the dung, at the diftance of feveral months, is found in a ftate very little different from what it was when put in the heap; and, after all, when it is in common language faid to be rotten, it is, upon examination, found to be only decayed, and the produce, in place of abounding in rich mucilaginous fubftances, ſubſtances, which all well-fermented dung does, is found to conſiſt almoſt entirely of vegetable earth. There is, however, it is ſaid, a mode of applying earth to dung-hills, that is not only ſafe, but highly beneficial: "It conſiſts in covering the whole ſurface of the dung-hill lightly, either with common earth or broken peat, every time the ſtables or fold-yards are emptied; a covering of that kind not being heavy enough to preſs materially upon the maſs, does not retard the fermentation, and has the great additional advantage of preventing the loſs daily ſuſtained about moſt farms by evaporation, and the diſſipation of the greateſt part of the valuable gaſſes generated during the proceſs of fermentation, all of which are entangled and retained by the earth; which, by that means, not only acquires high fertilizing powers, but renders the dung more valuable." And that "when a proper ſyſtem is followed of carrying out the manure from the ſtables and yard to the dung-hill—as once a month, if it is ſpread equally over the whole, and a covering of the kind juſt mentioned laid above it, a conſiderable addition may be made to the quantity of manure upon every farm yearly, not only without riſk, but with very great advantage." This ſort of manure has been found upon light gravelly hills, or fertile clays, particularly uſeful. It is ſuppoſed that "the rich earth alone would no doubt have very much improved ſuch ground, but by being mixed with dung, it probably became impregnated with ſomething of a fertilizing nature, which would otherwiſe have been loſt." In ſome caſes, "inſtead of mixing as above, the earth has been occaſionally laid on a foot or two deep, as a foundation to build dung-hills upon; at other times in ſituations where the drainings of fold-yards, or the urine of fat cattle, could eaſily be conveyed into it, and no doubt conſiderable advantages may be reaped from theſe methods of increaſing the quantity of manure. In regard to the propriety of uſing rotten or rank dung, the latter is ſuppoſed very improper management, though purſued by ſome farmers, who do not wiſh to haſten putrefaction by leading out and turning, not only becauſe theſe operations are troubleſome and expenſive, but becauſe they believe that the quantity of dung is thereby leſſened. They certainly leſſen the bulk, but probably not the quantity of good manure. Perhaps they prevent the loſs of ſome very fertilizing particles, which are exhaled by the ſolar heat, or otherwiſe injured by the weather, when the dung is applied in its rough ſtate, and conſequently not properly covered in. There can, however, be no doubt of a ſmall quantity of rotten dung making land more productive than a much larger one of ſuch as is rough or half rotten.

And it is believed that, "by mixing lime with manures compoſed of earth, and dung in the more advanced ſtages of their preparation, ſome increaſe of quantity may likewiſe be produced; and at the ſame time, by its uniting with the nitrous acid during its formation, may prevent that ſubſtance being thrown off into the atmoſphere in a gaſeous form, or readily waſhed down from the compoſts by rains; and thereby preſerve a material that has long been found uſeful in promoting the growth of plants."

As great waſte of manure is continually taking place from the evaporation of the more liquid parts of manure heaps, where they are much expoſed to the influence of the ſun or winds, and the waſhings of the rains, it would tend greatly to the ſaving of ſuch matters, and at the ſame time conſiderably promote their complete putrefaction and decay, to have them placed in ſituations that are much ſhaded by trees or other means. It is ſuggeſted, that, in farm-yards, moveable coverings of ſome light kind of material might probably be highly advantageous for this purpoſe. By means of this nature, the manure heaps, in ſuch places, may be effectually ſcreened from the action of the ſun in the ſummer, and prevented from being injured by the heavy rain or ſnow that falls in the winter ſeaſon. And as a further inducement to adopt ſuch methods, the manures which have been preſerved from the effects of the weather in this way, are ſaid to have been found, by practical trials, to be far more efficacious in promoting the growth of crops, than under other circumſtances; and of courſe capable of going much further in their application to ſoils.

In order to procure manure from the articles of food and other matters produced on the farm, different modes have been purſued in different ſituations. Some have ſtrenuouſly contended, that the moſt advantageous plan is to have the whole of the hay and ſtraw conſumed by the different animals, without employing any of them in the way of litter, floors or ſtandings for them being conſtructed in ſuch a manner, as that they can be tied up, and kept clean and dry merely by ſweeping, without being littered with ſtraw or other ſimilar materials; while others maintain, on the ground of actual experience, that the method of eating the hay by the ſtock, and employing the whole of the ſtraw, as well as other matters, in the way of litter, is by much the moſt certain and effectual in promoting the increaſe of manure. On theſe different opinions, it has been obſerved, that "though each of the methods may be practiſed with more or leſs advantage, according to the nature of the farms;—as where there is much graſs and little tillage land, the former may be preferable; but where the quantity of graſs is ſmall, and that of arable ground large, the latter;—it is probable, that a judicious combination of both may be the moſt beneficial, eſpecially where, in addition to the common articles, coarſe vegetable and rich earthy matters are provided, and made uſe of in the way which has been mentioned, as by ſuch a combination the full effect can only be produced. In the former method, the loſs by means of digeſtion and animalization is probably much greater than has been generally ſuppoſed by thoſe who have maintained the ſuperior utility of the practice."

In the ſoiling of horſes, and different kinds of cattle, with rich green food, as clover, lucern, ſummer tares, and other artificial graſſes, cut freſh every day during the ſummer ſeaſon, and placed in cribs in the ſheds or foddering-yards, the bottoms or floorings of which have been prepared and ſtrewed with earthy materials and litter, in the manner already directed, there is another way of making great additions to dung-hills, as the evacuations of cattle fed in this way are very conſiderable. The earl of Dundonald has ſuggeſted, "that experience only can teach or warrant the belief of how few acres of ground, under the culture of artificial graſſes, when cut green, and daily given to working horſes and other cattle, will ſuffice for their maintenance. The artificial graſſes, or plants beſt adapted to this purpoſe, are, he ſuppoſes, red clover, tares, and ſaintfoin. None of thoſe ſucculent plants with large ſtems and leaves anſwer ſo well to be depaſtured as to be mown; not only on account of the injury they receive in being bruiſed by the treading of cattle, but, by being conſtantly cropped and kept ſhort, they are deprived of the nouriſhment which they principally receive by their ſtems and leaves. Saintfoin is, he thinks, beſt ſuited to chalky or dry ſoils, and to the ſouthern parts of Britain. It has often been tried without ſucceſs in the northern parts of England and Scotland. Winter tares have alſo been ſown, but have not been found to anſwer any valuable purpoſe. Clover and ſummer tares, therefore, ſhould be the only plants of which the cultivation on a large ſcale ſhould in theſe parts be attempted; and every prudent farmer will take care to have a full ſupply of them, as in the

event

event of a ſuperabundant quantity for green food, theſe crops are equally proper for hay. Tares ſhould always accompany the culture of clover, to ſupply the deficiency of herbage between the firſt and ſecond cuttings of the clover."

And "the quantity of manure that may be formed in this way is, probably, much greater than can be ſuppoſed by thoſe who have not actually made a trial of the method. By ſome French writers it is ſtated, that from three to four hundred ſheep, kept in this mode, manure ſufficient for nearly an acre of land may be daily procured; and the manures, thus obtained, are likewiſe aſſerted to be preferable to dung procured in the common method." It has likewiſe the advantage of preventing the great waſte that unavoidably muſt take place in feeding off ſuch crops, and of bringing the whole of them immediately into uſe: beſides, the manure, thus produced, becomes of a ſuperior quality, from the vaſt quantities of worms and other inſects that are generated during the hot ſummer weather, where it is going on to any great extent.

And the author of "Practical Agriculture" ſtates, that "by means of covered ſheep-folds, a great increaſe might alſo be made annually to the ſtock of manure. If this neglected, but highly beneficial, practice were regularly employed here, as is the caſe in many other countries, by having proper ſheds and incloſures for the purpoſe, conſtructed of any ſlight materials near to the fold-yards, or other more convenient places of the farm, ſo that the ſheep might have freſh air, and ſufficient liberty to run about, and, at the ſame time, have the means of being ſheltered from rain, ſnow, and the coldneſs of the winter ſeaſon, the advantage to the flock would likewiſe be conſiderable, beſides the great ſupply of manure that muſt be provided. In order to promote the latter advantage, the bottoms or floorings of ſuch ſheds and incloſures ſhould be covered with ſuch earthy materials as have been recommended for the cattle yards, and alſo littered upon in the ſame manner; all of which ought to be removed and cleared away to a heap, or the common dung-ſteads of the farm-yards, as often as they become perfectly ſaturated and blended with the dung and urine of the ſheep, and freſh materials of the ſame kind ſupplied. In bad weather, it will be advantageous to keep them conſtantly in the covered folds, and feed them with hay in ſtanding racks; but when it is fine, they may be ſuffered to go into the paſtures in the day-time, and only be put into the folds during the night." It is added, that "the practice of keeping ſheep in covered folds is made uſe of in Flanders, for the purpoſe of raiſing manures, with great ſucceſs; and very dry ſand is ſometimes employed for the bottom of the folds, inſtead of litter." And that, "where the houſe-lamb ſyſtem is carried on to any extent, the preparing and littering of the ſheds and yards, into which the ewes are occaſionally put, and the lambs kept and ſuckled, might be practiſed with great advantage, in reſpect to the production of manure; as animals, under ſuch kinds of management, are conſtantly found to void urine and dung in much larger quantities than in the ordinary courſes of feeding." Where deer are kept, the ſame management may likewiſe take place, and much good dung be raiſed. See *Sheep*-Fold.

The ploughing down of full rich green crops of different kinds, in their moſt ſucculent ſtates, is alſo another means of increaſing manure, that may occaſionally be adopted with great advantage.

And the practice of feeding off different green crops on the land by ſheep, bullocks, or other animals, is another method by which much fertility may occaſionally be given to the ſoil at a cheap rate, as the expence of carriage is prevented, and a conſiderable ſaving of manure effected. Mr. Middleton ſtates, that, by this mode of management, the great loſs of urine and dung, that unavoidably occurs in the other methods, may be moſt effectually prevented; "for in the ſtables, cow-houſes, ſheds, fold-yards, and dung-hills, even under the beſt management, there is a great waſte, perhaps of half, including dung and urine: under ordinary management, three parts of this manure is loſt; but in the ſoiling of tares, turnips, cole, clover, &c. in the fields, there is *no* loſs; the whole is immediately applied, without the coſt of carriage, to the enriching of the ſoil." In this way there muſt, however, be much more waſte than is here ſuppoſed: by evaporation, from the action of the ſun and wind over ſo extenſive a ſurface, much of the valuable matters of the manure, in ſuch ſituations, muſt be daily carried away; and the more fibrous or ligneous parts of the materials, which are rejected as food by the cattle, from their being thinly ſcattered over a large ſurface, become dry and hard, and muſt be longer before they decay, or are rendered fit for the purpoſes of manure, than where they are collected together in large quantities, and in more confined ſituations.

Another mean of increaſing manures to a very great extent, is by adopting ſuch methods as may effectually prevent the ſoil and urine of privies, and the various animal and vegetable materials that are continually thrown into them, in cities and large towns, from being uſeleſsly retained in deep pits, or places conſtructed for the purpoſe, or inconſiderately waſhed away and waſted, by being conveyed into rivers or ponds by ſewers and drains. Mr. Middleton has ſtated, that, from want of ſuitable modes of preſerving ſuch ſubſtances, the annual loſs, in this country, is probably not leſs than five millions of cart-loads, which, if turned to the uſes of agriculture, would be worth to the cultivators of the ſoil two millions and a half, and to the community five millions of pounds ſterling! And the eagerneſs which is manifeſted in many other countries to preſerve and promote the increaſe of ſuch manure, ſhews that it is a ſubſtance of vaſt utility, and that an abundant ſource of fertility is thus neglected, and loſt to the public. It is ſuppoſed, by a late practical writer, that "the moſt eaſy and convenient methods of preſerving ſubſtances of this kind, in the country, would be, probably, by having pits formed for the reception of them, as near as poſſible to the dung-ſteads in farm-yards or other places, and prepared with floors of clay, or ſome other material, through which the liquid matters could not readily paſs: theſe might be connected with the privies by proper drains, and have covers fitted to them, in order that a quantity of mould, peat-earth, ſaw-duſt, lime, ſtems of coarſe garden plants, or other ſubſtances of the ſame ſort, might be occaſionally placed in them, and removed to be blended with the common dung heaps, as often as they become fully reduced by putrefaction, and well ſaturated and impregnated. But in large towns or cities, where ſuch manures are produced in great quantities, reſervoirs or baſons of large ſizes ſhould be conſtructed with floors of the above kind, and be connected with the privies of different parts, by means of ſewers or drains. Such reſervoirs ought to be ſo ſituated as to be capable of being emptied with eaſe and facility, as often as neceſſary, by perſons appointed for the purpoſe, and their contents carried away in the night-time. Where there is the convenience of rivers, however, as in London, and many other populous cities and towns, a large proportion of ſuch manures might, in moſt caſes, be readily emptied from baſons of this ſort, formed on their banks for the purpoſe, pole, or perhaps from the extremities of the common fewers themfelves, by means of proper fluices, into covered boats or barges, and thus cheaply carried to a diftance, for the advantage of agriculture; a method, in fome refpects, practifed with fuccefs in Sweden See Communications to the Board of Agriculture, vol. i.

But "as this kind of manure is extremely liable, from the agitation of the carriage in which it is moved, to become fo liquid as to be conveyed with great difficulty, it is probable that, by having fuch earthy or other fubftances as have been mentioned above, or as could be conveniently procured in fuch large cities or towns, fuch as the long littery dung from livery ftables, lime rubbifh from the pulling down of old houfes, and the frefh earth dug up in preparing the foundations for new ones, mixed and blended with it in the pits or refervoirs, for fome time before they are cleaned out, the difficulties attending the carriage of it might not only in a great meafure be obviated, but the difagreeable fmell iffuing from it be much corrected, and the quantity of manure greatly augmented. By fome method of this nature, under the management and direction of proper perfons, vaft ftores of fertility might, it is conceived, be provided in fuch places for the neighbouring diftricts, which inattention or popular prejudice at prefent withhold from the ufe of agriculture." See NIGHT-SOIL.

Befides, in particular fituations, as near the fea, where fhell and other fmall fifhes can frequently be procured in large quantities, by having them well mixed and incorporated with good furface mould, turf, or peat-earth, or other matters of that fort, a vaft increafe of good manure may alfo be provided. The weeds cut from the fides of the rocks, and which are thrown up by the tides, when collected into heaps, and mixed with fmall proportions of lime and fuitable quantities of mould or earth, may likewife contribute greatly to the increafe of the compoft heaps in fuch diftricts and fituations.

Another material, capable of augmenting the manure heap very much, is the rich vegetable mould, and other matter, contained in the bottoms of ditches, and in boggy, hollow places, where water frequently ftagnates, and large crops of aquatic or other plants alternately vegetate and decay. This fhould be occafionally dug up and applied to the foil, for which it is proper, either in the ftate in which it is found, or after having been formed into compoft heaps with dung, lime, or other fubftance of a fimilar nature.

And clay, though not actually a manure, is a fubftance that may alfo be employed with great advantage on fandy and other light foils, and by that means fave the more valuable manures. It has been made ufe of with great effect in its crude ftate, in the practice of an improving Suffolk farmer, but it would feem to be the moft ferviceable for this ufe after being imperfectly burnt in clamps and kilns, probably from the production of oxygen or pure air that is thus combined with it, or with the metallic matters which it contains. It is well remarked, by a late writer, that "it is neceffary, in order to increafe the ftock of manures on farms to the greateft poffible extent, to be careful that none of fuch animal or vegetable fubftances as are capable of being converted into manure, be thrown away or confumed by fire, but that they be all conveyed to the dung-fteads in the farm-yards or other places, or laid in heaps of themfelves, and fuffered to pafs into fermentation, by which they may be fpeedily reduced to manure. Where the matter thus made ufe of chiefly confifts of weeds and the ftems or roots of coarfe plants, fuch as peas, beans, cabbages, docks, nettles, &c. their decay may be greatly promoted by a little quick-lime being blended with them. Such heaps fhould alfo be covered over pretty well with fome of thofe earthy matters that have been mentioned above." It is added, that as "the different materials which are made ufe of for the purpofe of manure, pafs through different ftages of decompofition and decay, in each of which fuch matters of the folid or fluid kinds are formed, as are capable of contributing to the nutrition and fupport of vegetable crops, but which are liable to be diffipated or carried away by the agency of various caufes, it may be neceffary to guard againft fuch wafte by keeping the dung-heaps covered in every fituation, as much as poffible, with earth or foil, both in the early periods in which heat is evolved, and at the latter ones, when ammonia or volatile alkali is formed; as by fuch management the procefs of decompofition, when too rapid, may be reftrained, and the elaftic matters that are gradually fet at liberty be abforbed by thefe coverings, while the more fluid ones are detained by the earthy bottoms on which they had been placed, and thus the whole of the valuable properties of the manure be preferved."

MANURE, in *Gardening*, a term ufed to fignify all fuch fubftances or materials, whether of the dung, compoft, or other kinds, as are ufeful in the improvement of garden ground, fo as to produce good vegetable crops of various kinds.

It is obvious that materials of this kind are neceffary to all foils to recruit them when exhaufted by the growth of vegetables, and cure their defects; being thus beneficial in enriching and fertilizing fuch as are poor, and in rendering fuch as are ftrong or ftubborn more light, loofe, and friable, as well as thofe which are very light, loofe, and dry, more compact and moift, and thofe that are too wet, drier, &c. In thefe views moift ftiff land is the moft improved by light manures, which open and loofen its particles; very light land by the more heavy and moift forts; and wet land by dry light compofts. Some garden foils alfo require manure annually, and others only once in two or three years. See DUNG, &c.

On the whole, the moft proper forts of manure for the ufe of the kitchen-garden are thofe of the ftable, cow, fheep, pigeon dung, foot, lime, loamy marle, fhell marle, fea-weed, wood, whin, fern, and coal-afhes; the vegetable mould of decayed tree-leaves, and decayed vegetables of all kinds, as cabbage leaves, haulm, weeds, &c. And to thefe may be added the fluid fubftance which drains from dunghills, which is capable of affording the nutrition of plants in a very high degree, from the large proportion of carbonaceous matter with which it is loaded.

All thefe feveral materials may be applied either in a fimple or compound ftate; but the latter method is probably in general the moft eligible; as it is fuppofed by fome, that if they have not undergone a proper degree of fermentation, they have the effect of giving a rank and difagreeable flavour to fome fruits and vegetables; and when a large quantity is applied, of producing a confiderable degree of unwholefomenefs, tainting the juices of the plants. This effect is, however, much to be difputed, fince the different fubftances are changed and elaborated in the veffels of the vegetables before they become fit for the purpofe of their increafe.

It is afferted by the author of the Scotch Forcing Gardener, that "a combination of ftable dung, fea-weed, lime, and vegetable mould, which has lain in a heap for three or four months, and has been two or three times turned during that period, will make an excellent manure for moft kinds of garden land." Alfo that of "cow dung and fheep dung, mixed with foot or any of the kinds of afhes;" and that "pigeon dung, marle, and vegetable mould, well mixed, will

make

make an excellent manure for heavy land; or even for lighter ſoils, provided the pigeon dung be uſed ſparingly." But that "pigeon dung, lime, ſoot, aſhes, &c. ſhould never be applied in a ſimple ſtate; the quantity of them required being comparatively ſmall, and the regular diſtribution difficult without the admixture of other matters. It is further obſerved, that he has "witneſſed the aſtoniſhing effects of whin aſhes alone, in producing herbage in a five or ſix-fold degree; which was the more obvious, on account that the field on which they were applied was much alike in quality (a ſtiff, wet, clayey loam), and the aſhes applied partially. The effect was viſible for ſeveral ſucceſſive years. Alſo, on the timber trees with which the field was afterwards planted." He conceives that "marle is an excellent manure for almoſt any ſoil; and may be applied as a ſimple manure with as much propriety as any of the kinds of cattle dung, or even vegetable earth. The kind called ſhell marle is, it is ſuppoſed, much to be preferred; and ſhould be freely applied to ſtrong lands, but ſparingly to light; the loamy kind being beſt adapted to light lands."

Where ſtable dung is uſed in a ſimple ſtate, it "ſhould not," it is ſuppoſed, "be applied in too rank a ſtate, nor ſhould it be too much fermented. It ſhould generally lie in a heap for two or three months; during which time it ſhould be turned twice or thrice. A ton of it in this ſtate is worth three that has been uſed in the hot-bed, and are a year old. This manure, and indeed dung of any kind, when thus applied, ſhould never be carried from the heap to the ground till it is to be digged in; as, by its expoſure to the air, the virtues evaporate, and it is the leſs effectual."

And when made uſe of in a ſimple condition, it is imagined "the neceſſity of the inſtant application of ſea-weed after its landing, is even greater than in the above caſe; as it inſtantly corrupts, and its juices not only evaporate, but flow downwards, and are loſt. If this manure be uſed as a compound, the heap wherein it is compounded ſhould be more frequently turned on its account, that none of the juices may be loſt, but that the other part of the compoſt may abſorb them."

It is his opinion that "vegetable mould may either be uſed in a ſimple or compound ſtate, and may be applied with equal propriety to all ſoils. None can be hurt by it in any degree; ſince almoſt every plant will grow luxuriantly in it entirely, without the aid of any ſoil or manure whatever. It is conceived that manures have the effect of correcting tenacity, crudity, and poroſity in ſoils, exciting their fermentation, communicating nutritive matter to them, and affording nouriſhment to the roots of plants, by which the vegetation and perfect growth of them are promoted and increaſed.

There are likewiſe conſiderable differences in the materials made uſe of as manures, in their affording their nutritious properties, ſome affording them much more readily and more abundantly than others. This is the caſe with animal, vegetable, and all ſuch matters as are rich in mucilage, the ſaccharine principle, and calcareous earth, and which readily afford carbon, phoſphorus, and ſome gaſeous fluids, ſuch as the carbonic acid gas, oxygen, &c. while others which are greatly deficient in all or moſt of theſe principles, or which do not part with them eaſily, are found by experience much leſs beneficial in promoting the growth of vegetables, fruits, &c.

However the effects and importance of manure are now generally acknowledged and underſtood, it would appear to be the indiſpenſable duty of the gardener and cultivator to be particularly careful in the collection of it, and alſo to diſtribute it with the moſt ſkilful frugality. "For this purpoſe, it is ſuggeſted that where it is capable of being formed, a well, ciſtern, &c. ſhould be contrived ſo as to collect the dung-hill drainings; and that in the application of manure of any kind, the greateſt care ſhould be taken to divide it equally, according to the quantity to be applied." Alſo, further, that "the dung-hill may be conſiderably increaſed by throwing the haulm, ſtalks, and leaves of all vegetables into a common heap, letting them remain till well rotted, and afterwards, or, in the proceſs of collection, mixing them with lime, marle, aſhes, ſoot, &c. Watering the whole frequently with the drainings of the dung-hill would alſo greatly enhance its value."

It is likewiſe evident that the ground of gardens may often be greatly ameliorated and improved by proper draining, before the manures are applied, and ſometimes by the uſe of ſandy, gravelly, and other ſimilar materials, that have the power of opening, and rendering it leſs cloſe and adheſive. See MANURE, *ſupra*.

MANURING *of Land*, in *Agriculture*, the application of the various ſubſtances which are capable of being employed as manures to the ſoil, in ſuch a way as to produce the moſt beneficial effects in the production of crops, whether of the grain, graſs, root, or other kinds. In this buſineſs various circumſtances are neceſſary to be conſidered, ſuch as the ſtate or condition of the manures which are to be made uſe of, the nature of the ground on which they are to be laid, the kind of crop that is to be promoted by them, and the ſeaſon of the year in which they are to be put into or upon the land; for as it has been ſhewn that changes are continually taking place from the moment the materials of the dung-heap are thrown together, to the period in which they are reduced into a black carbonic earthy matter; and that in moſt of the different ſtages through which they paſs in this proceſs of decompoſition, ſuch ſubſtances are formed as are capable of contributing to the nutrition and ſupport of vegetable crops; it is conceived "probable, that in caſes where manures are to be turned into the ground, and ſuch crops cultivated as require a ſupply of nouriſhment for a length of time, they ſhould be employed in their long or more imperfectly reduced ſtates, as by the heat which is evolved in the commencement of their diſſolution, the proceſs of early vegetation may be greatly promoted, and their gradual decompoſition and decay afterwards, under the ground, afford a more durable and regular ſupply of nutrient materials, and thereby contribute more effectually to the growth of the crops; but that where they are to be buried in, or applied to the ſurface of the ſoil, and intended merely for the benefit and ſupport of ſuch crops as are of ſhort duration, or quickly arrive at their full growth, they may be more advantageouſly made uſe of after they have been more fully and completely reduced, as in this ſtate the manure is, in the caſe of graſs lands, not only capable of being ſpread out in a more regular and uniform manner, by which it becomes more evenly as well as more generally carried down to the roots of the plants by rains, but it is in the moſt ſuitable condition for allowing the young plants the means of ſpringing up with facility, and at the ſame time, whether uſed under or upon the ſoil, of affording the crops that abundant ſupply of nouriſhment which is neceſſary to their ſpeedy growth and great luxuriance, and by theſe means to contribute moſt perfectly to the promotion of their increaſe." In addition to "theſe advantages of long, or imperfectly decayed manures, they have others that depend on the ſoil into which they are turned, and the nature of the crops that are ſown or planted with them. Where they are employed in ſuch ſtiff, clayey, or loamy grounds, as have a great tendency to become dry

 and

and hard, and thereby incapable of admitting the tender fibrous roots of grains or other plants to ſpread or extend themſelves, and draw in more abundant ſupplies of nouriſhment, they may be uſeful by keeping the earth around them in a more open and porous ſtate, from the ſlowneſs of their decompoſition, and the gradual and continued manner in which the different elaſtic matters are ſet looſe and united with the ſoil. Hence, when barley, or ſuch kinds of grain as require a rather light and open ſtate of ſoil, and thoſe bulbous or knobby-rooted plants, ſuch as potatoes, that require much room to ſhoot and extend themſelves, are cultivated on ſuch ſtiff ſoils, they are generally found to be the more productive, where ſuch long or imperfectly reduced manures have been made uſe of in the preparation of the land." And that "as in the ſlow and gradual decompoſition of the materials which are made uſe of for manures, when ſlightly depoſited beneath the ſoil, there is much leſs waſte of heat and thoſe elaſtic matters which contribute ſo greatly to the ſupport of vegetation, than where they are made to undergo the various proceſſes of diſſolution in large maſſes, as in dung-heaps, they may probably ſometimes on that account be moſt advantageouſly employed in this ſtate." Alſo "on this principle the ploughing down of freſh vegetable crops, in many caſes, in their moſt ſucculent ſtates, may be a more economical as well as more beneficial practice; eſpecially in ſuch light and dry kinds of ſoil, as will more readily admit of their gradual putrefaction and decay, than to cut and take them off for the purpoſe of being by other means converted into manure. It ſeems likewiſe probable, on the ſame grounds, that for the production of crops of the bulbous-rooted vegetables on the more ſtiff and tenacious ſoils, the matters made uſe of as manures may be employed with the greateſt advantage, when put into the earth before they have undergone any great degree of decay by means of putrefaction, as in this way there is no waſte, the whole being ultimately converted and applied, though more ſlowly, to the ſupport of the crops for which they are immediately employed." It has been ſtated as the opinion of a practical farmer, that ſtable dung never anſwers better than when carried on to the land as ſoon as made. He laid it on a piece of wheat in froſty weather, and at harveſt the crop was laid to the ground. And on graſs lands, it is ſuppoſed, when laid on in the ſpring, to ſcreen it from the cold winds, and occaſion it to be more forward, and that in the ſummer the ſtrawy part protects the land from the ſun; and in either ſeaſon it is ſoon grown in and nearly loſt to the eye. See Communications to the Board of Agriculture, vol. iv.

Manures, proper Seaſon of Application.—In regard to the time or ſeaſon of applying manures "with the greateſt benefit and advantage, though in practice it muſt, in ſome meaſure, depend on the ſtate of the land, the nature of the crop, and the convenience of the farmer, it ſhould, in caſes where they are buried in the ground, be as nearly as poſſible to the periods in which the ſeeds, or the roots which they are deſigned to ſupport, are ſown or placed in the earth; where they are to be laid upon the ſurface of the land, it ought probably to be juſt before the crops of graſs, or other vegetables, begin naturally to ſpring or ſhoot forth." As in this practice of depoſiting and blending the manure with the ſoil, nearly at the time the crops are put in, there is ſcarcely any waſte of the fertilizing properties of ſuch ſubſtances, which, as they gradually proceed in their decompoſition and decay under the ground, muſt otherwiſe be the caſe, the roots of the plants not being in the moſt proper ſtates for taking them up and converting them to their ſupport. Beſides, in ſtiff, loamy, or clayey ſoils, they have a tendency, as has been remarked above, to produce a degree of lightneſs and friability that is ſuited to the early proceſs of vegetation." The author of Phytologia has well remarked, that "the atmoſpheric air, which is buried along with the manure in the interſtices of the earth, and which for many weeks, or even months, renders the ſoil looſe and eaſily impreſſed by the foot on walking on it, gradually evolves, by its union with carbon, a genial heat, very friendly to vegetation in this climate, as well as the immediate production of much fluid carbonic acid, and probably of a fluid mixture of nitrogen with hydrogen, which are believed to ſupply much nutriment to plants."

The uſing of ſuch manures as are made uſe of in the way of *top-dreſſings* in the early ſpring, is a practice by which "they are laid on at the moſt favourable period for affording their nutritious principles, and for their being drank up by the roots of plants, and conſequently become uſeful at the time they are moſt wanted for the promotion of the crops, and the great waſte which muſt otherwiſe be cauſed, either by the exceſſive falls of rains and floods in the winter ſeaſon, waſhing down much of the valuable properties into the adjoining rivers and ditches, or the evaporation of their more volatile or elaſtic matters by means of the ſummer heats, is moſt effectually guarded againſt and prevented." It is hinted that the practice common in ſome places of applying manure to graſs lands in the latter end of the ſummer or beginning of autumn, after the firſt crop of hay has been taken from the ground, and the after-graſs has begun to make ſhoots, is not by any means ſo favourable as that of early ſpring, as in the latter caſe the generation of thoſe materials that contribute to the ſupport of vegetation is greatly promoted by the conſtantly increaſing heat of the vernal and ſummer months; while in the former it is conſtantly checked and retarded by the increaſing coldneſs of the autumn and winter ſeaſons. Beſides, the manure, by being ſpread out upon the ſurface of the land under ſuch circumſtances, muſt be the cauſe of great loſs, by contaminating the after-graſs, and rendering it incapable of being eaten off by cattle or other kinds of live ſtock." Yet, "where a ſecond crop of hay is to be taken, it may ſometimes be put on at ſuch times with advantage to it, eſpecially if the weather be not too hot, and the manure in a perfectly fine and reduced ſtate, ſo as not to impede the mowing. It has been remarked by doctor Fenwick, in his ingenious reflections on manures, "that it is ſcarcely poſſible to ſuggeſt a worſe mode of uſing manures on graſs lands, than that which is almoſt univerſally practiſed in the neighbourhood in which he reſides;" and it is the ſame in many other parts of the country, as is evident from the reports that have been lately publiſhed by the Board of Agriculture. "When," ſays he, "a ſevere froſt has bound up the land in a ſtate of impenetrable coheſion, the farmers wheel on their dung, perhaps even when ſnow has covered it. While the froſt laſts, the land can derive no advantage from the manure, and when a thaw ſupervenes, it is evident that the waſh from the melting ſnow, or from the rains which generally fall in ſuch weather, muſt deprive the maſs of every part that is ſoluble. The ground, in the mean time, retains the froſt for many days, and is therefore incapable of abſorbing the wet which falls upon its ſurface; and even when the influence of the milder air has reached it, it can imbibe but little, being in general previouſly filled with water, and the quantity which flows over it being too great for ſoil, under any circumſtances, to drink up." It is believed by the ſame writer, that in ſupport of this deſtructive and waſteful practice, however much it may have been defended on the ground of the farmer's leiſure or convenience, and the little injury

injury done to the turf or fward of the land, there can be only one reafon alleged, which is, that manure, when fpread early in the winter, may protect the roots of graffes from the feverity of frofts. And this, the author of "Practical Agriculture" fays, "is probably a miftaken notion, as it is known to every one that the common graffes are feldom injured by the fevereft frofts; and other kinds of graffes may probably not fuffer lefs injury from the application of manure at fuch a feafon, than from the feverity of frofts." It is therefore concluded, that "on all thefe accounts, farmers fhould contrive as much as poffible to apply the manures, intended as top-dreffings to grafs lands, as early in the fpring as it can conveniently be done, which may be eafily managed on thofe that are dry, and on fuch as are inclined to be wet and poachy, it may probably be greatly facilitated by having fmall light carts conftructed for the purpofe, and placed on broad cylinders as wheels." For he is convinced, from the trials which he has made in applying manures to grafs lands at fuch periods, that the trouble of the farmer will not only be rewarded by much larger crops of hay, but alfo by a confiderable increafe in the quantity of the after-grafs; and, befides, his crops in both inftances will be more forward than in the ordinary methods of putting them on, either in the autumn or winter months, which in many cafes is a circumftance of great importance." There are others, however, who confider the early autumn as by much the beft feafon, as may be feen under the head of manuring new laid down grafs lands at firft. See LAYING *down to grafs*.

In Young's calendar of hufbandry, it is ftated, that "the proper feafon for laying on feveral forts of manure, fuch as foot, coal-afhes, wood-afhes, lime, malt-duft, &c. and in general all thofe that are fpread in too fmall quantities to require a whole winter's rains to wafh them in," is in February. The ufe of thefe manures, and other light dreffings at this period, is, he fays, very beneficial; "but, throughout the management of purchafed manures, experiments fhould be formed for a year or two, before the practice is extended, to fee which, at a given price, will fuit the land beft. Without this precaution, a farmer may probably expend large fums of money to little purpofe. Nor would he advife him to truft to the mere appearance of the effect foon after the manuring; for fome of them, particularly foot and malt-duft, will fhew themfelves after the firft heavy fhowers, in a finer green than the reft of the field; but the proof of the effect does not arife from fine greens, but from weight of hay; for he has himfelf found from experience, that the latter is not always an attendant on the former. Contiguous half-acres, or roods, fhould be marked out, the prices of the manures calculated, and on each piece a feparate one fpread, all to the amount of 20*s.* an acre, for inftance, at hay-time, the crops fhould be weighed. It will then be known which manure, at the given prices, fuits the foil beft. This knowledge will prove true experience, and a very different guide from general ideas." And "this is likewife, he adds, the feafon for fpreading fuperficial dreffings on the green wheats, fuch as foot, afhes, malt-duft, pigeons'-dung, poultry-dung, rabbits'-dung, &c. and many other forts in the neighbourhood of great cities. It is very good hufbandry; but the profit depends on the expences." He therefore recommends "trying them in fmall portions, (a rod, for inftance, to each) before extending the practice to whole fields, efpecially thofe which are not dungs. As to the latter, provided the prices be not extravagant, there can be no doubt of their anfwering to all foils. Whenever a farmer has the choice of manures, never let him hefitate about which to take. He may lay it down as a maxim, that dungs of all forts are excellent. Other manures may be the fame, but they are not, he thinks, fo univerfally beneficial to all foils."

It is alfo ftated, that furriers' clippings are fown by hand from the feed fcuttle, at about 3*d.* *per* quarter, in March, on the land intended to be fown with wheat or barley, and immediately ploughed in, after which the feed is fown and harrowed in, when fuch pieces of the clippings as are left above ground by the harrow, are pricked or fhoved into the ground by the end of a ftick, to prevent their being devoured by dogs or crows, who feize them greedily. From two to three quarters are ufually fown *per* ftatute acre. Thefe clippings are faid to anfwer well on light dry chalk or gravelly foils, where they are fuppofed to hold moifture, and help the crop greatly in dry feafons, but they have little effect on wet foils. And horn fhavings, which are of two forts, fmall and large, are ufed in the fame way and quantities as the above article, except that they want no pricking; and the large are generally ploughed into the land three months before fowing wheat or barley. This fort of fhavings anfwers well in moft foils and feafons, except very dry ones, when they will not work. The fmall fhavings are much the moft ufeful. Woollen rags are alfo fown by hand and ploughed in three months before fowing wheat or barley; the quantity ufed is from fix to ten cwt. *per* ftatute acre. Woollen rags, like furriers' clippings, hold moifture, and are adapted for dry, gravelly, and chalky foils, and fucceed in dry feafons better than moft manures, but they do little good on wet foils. London rags are found much better than thofe collected in the country; but the danger of catching the fmall-pox in chopping and fowing them, deter many farmers from making ufe of them. Sheeps'-trotters, and fellmongers' cuttings, are ufed in the fame way as furriers' clippings, from 20 to 40 bufhels *per* acre, and need pricking in, as dogs and crows are very fond of them. They do not anfwer on wet land, or in very dry feafons; indeed nothing does fucceed in exceffive dry feafons on thefe foils. Malt-duft is alfo fown by hand from 24 to 32 bufhels *per* acre, at the fame time as barley, and harrowed in with the feed. It fuits moft foils and feafons; but it quickly fpends itfelf, and is therefore never fown with wheat; as a top dreffing to wheat in March, at about 30 bufhels *per* acre, it would probably fucceed on thefe forts of foils. Pigeons'-dung is ufed in the fame manner as malt-duft, and does good in any foil or feafon. Soap boilers' afhes have alfo a great effect on cold fward. Hogs' hair, when applied in the fame manner as clippings, is faid to anfwer well. And feal hair, rabbits' dung, and lime, have been tried upon thefe kinds of foils, but not found to anfwer in any very advantageous degree.

Depths of depofiting Manures in Soils.—It is ftated by a late writer, that as "the putrefaction and decay of animal and vegetable matters, whether above or beneath the ground, is greatly promoted by the free admiffion of air and a fuitable degree of moifture, it is evident that they fhould not be buried fo deep in the earth, as that they may be prevented from readily receiving the aid of fuch caufes in forwarding their decompofition; nor, as the procefs is known to be much retarded by the fubftances being rendered too dry, fhould they be placed fo near the furface, or be fo thinly covered as to permit the action of the fun and winds, before the crops have rifen to fuch heights as to prevent it from diffipating and carrying away their nutritious properties. The introduction of the manure to a middling depth, as three or four inches, would of courfe, on thefe accounts, as well as from its contributing more expeditioufly and more fully to the vegetation of the crops that

that may be put in with it, feem, in general, to be the moft advantageous practice; but on the lighter and more friable foils, it may be advifable to plough it into a greater depth than in fuch as are heavy and tenacious. In every cafe, however, whether the manure made ufe of be in a long or a more reduced ftate, it fhould be perfectly covered or ploughed into the earth. The practice of burying manures deep in the foil, has been defended by fome on the ground of its being the nature of elaftic matters to rife or force themfelves towards the furface; but when they are placed to a confiderable depth in the earth, as the procefs of decompofition is thereby ftopped, or fuffered to proceed in but a very flow and feeble manner, little or nothing efcapes for the fupport of vegetation, or it is furnifhed in fo very flow and fparing a way, as to be of fcarcely any fervice to the immediate crops. Thus, in the cultivation of fuch crops as are placed in rows or drills, where the manure is put into a great depth and covered pretty thickly with earth, on digging them up at the end of many months, it may frequently be obferved nearly in the fame ftate it was when firft put into the ground. And the fame thing is often noticed by gardeners, where imperfectly reduced, or long dung is placed in deep trenches and covered to a confiderable thicknefs with mould." It is alfo added, that "in order that manures may produce their effects in the moft perfect manner, they fhould be fpread over the furfaces of the grounds as evenly as poffible, whether they be intended to be turned into the foil or left upon its furface as top-dreffings;" a point that "may be greatly facilitated by placing the manure out at firft in very fmall heaps, as by fuch a practice it may be fpread over the ground with much greater eafe and exactnefs; and on grafs lands much lefs injury will be done by the bottoms of the heaps."

And it is evident, that on tillage lands, manures fhould always be turned in, or otherwife covered, as foon as poffible after they are fpread out; for if this be neglected, much lofs may be fuftained, efpecially in hot feafons, by the quick evaporation that takes place in fuch cafes. The beft practice is, of courfe, not to carry more out from the dung-hill at a time, than can be conveniently fpread upon and ploughed into the earth in a fhort time afterwards. It is obferved in a periodical work, that the fhorteft poffible fpace of time fhould be fuffered to elapfe between the fpreading out the manure, and the ploughing it into the lands, as well as between this laft operation and that of fowing the feed. And it has been fuggefted, that "in fpreading manures employed as top dreffings on grafs lands, much advantage will be gained by breaking and reducing the clods or lumps into as fine a ftate as poffible, as by fuch means they are not only applied more perfectly, but wafhed by the rains much more readily to the roots of the graffes. The fpringing of the young graffes is alfo lefs retarded, where the manures are rendered fine and powdery, than where they are left in a cloddy, rough ftate." The nature of the foil, and the purpofe for which the manure is applied, fhould likewife be carefully attended to in this bufinefs, as no one method is adapted to every cafe that may happen.

It is ftated, in refpect to the economy of their application, that "it feems not improbable but that fome degree of faving may occafionally be made, by applying them on lands under tillage, as well as others, nearly at the time the feeds and roots are put into the ground, or when the graffes begin to fhoot; as from the whole of the manure being in this way made to contribute directly to the fupport of the crops, a lefs quantity may be fufficient for the purpofe: how far they may be fafely diminifhed on this principle, can only be fhewn by actual experiments and accurate deductions made from them; but there are fufficient grounds, from what has been obferved, for fuppofing that it may be confiderably more than can be eafily apprehended by thofe who have not adverted much to this circumftance. There is another economical mode of employing manure, which is, by placing it in the drills or hollows formed for the reception of different crops which are cultivated in rows, as peas, beans, cabbages, potatoes, &c.: by this method, that part of the ground which is intended to bear the crop, is only manured, the intervals or fpaces between the rows not receiving any, from which, where the bufinefs of putting the manure into the drills is properly performed, a great faving muft of courfe be made."

According to the conclufions of fome, "the faving of manure in this way is fo great, as to conftitute one of the chief advantages of the drill fyftem of cultivation. And the calculation of the experienced farmer is, that by "drills being made two feet afunder, and each drill fix inches wide at the bottom, there will be juft one-fourth part of the ground covered with manure; for as fix inches multiplied by four gives two feet, which will be the diftance from drill to drill, and as four multiplied by four makes fixteen, it follows, that if the whole of the land had been covered with manure, fixteen loads would have been required for what is as fully and beneficially performed by four, that is, by one quarter of the quantity ufed by the old method of dreffing, fuppofing it of the fame thicknefs and quality." Befides, from the manure being in this way kept more clofely together, and the crops placed immediately upon it, they muft, he fufpects, receive the advantage of the dreffing in a more full and complete manner than under other circumftances could be the cafe.

Dr. Dickfon, in his work on practical agriculture, fuggefts, that "as it appears probable that in the decay of different materials in the foil, all the nutritious matters as they are formed immediately become ufeful for the purpofe of vegetation, without any wafte being fuftained, as muft always be more or lefs the cafe where they are depofited together in heaps, it may be an economical practice, in cafes where the crops to be benefited by them require a regular and lafting but not large fupply of nourifhment; or where the ground is required to be kept in an open and rather light ftate, for a confiderable length of time, to employ fuch manures in their lefs decompofed ftates, as by the ploughing down of green fucculent vegetable crops, and the turning in of long ftrawy fubftances. By adopting fuch means, the more perfectly formed manures of the farm may be referved for fuch crops of luxuriant vegetables as demand more fpeedy and abundant fupplies of nutrient matters." And in what refpects the advantage of ufing one fort of manure in preference to another, it may be remarked, "that as animal matters are found in general to undergo more fpeedily the procefs of putrefaction or decompofition than thofe of the vegetable kind, and as in moft inftances they afford thofe mucilaginous and elaftic principles that contribute fo largely to the fupport of vegetable life in greater proportions; fuch manures as are either wholly or in a great meafure compofed of them, muft be the moft beneficially employed, where quick and abundant fupplies of nourifhment are required, as in the growth of all the more grofs and luxuriant crops, whether of grain, plants, or graffes; and that as thofe vegetable fubftances which contain faccharine, farinaceous, oily, faline, or mucilaginous principles in the largeft quantities are afcertained from experience to proceed the moft readily into the ftate of diffolution or decay, and confequently to afford more fully and more expeditioufly the nutrient food of new plants, where manures

manures are principally formed from them, they ſhould be preferred to ſuch as have been made from the harder and more ligneous vegetable ſubſtances, that contain ſuch properties in ſcarcely any, or much ſmaller degrees, for all the purpoſes of agriculture." Laſtly, that "ſuch ſubſtances as are found to contain thoſe elementary materials of which vegetables are principally conſtituted in their more ſoluble or looſely combined ſtates, as carbonaceous matter in the black earths or moulds, and oxygen, azote, and hydrogen, in burnt clay, raddle, manganeſe, and calamy, ſubſtances which have hitherto been little employed, as well as in water and air, ſhould be made uſe of in preference to thoſe which poſſeſs them in ſlight proportions or ſcarcely at all."

With regard to the particular modes of preparing and making uſe of the ſeveral articles that are capable of being applied to lands ſo as to ameliorate and improve them in the production of different ſorts of crops, they will be more fully explained under the particular heads to which they immediately relate.

MANUS was anciently uſed for an oath, and for him that took it as a compurgator. And it often occurs in old records: *tertia quarta, &c. manu jurare;* that is, the party was to bring ſo many to ſwear with him that they believed what he vouched was true: and we read of a woman accuſed of adultery: *mulieri hoc neganti purgatio ſexta manu extitit indicta:* i. e. She was to vindicate her reputation upon the teſtimony of ſix compurgators. Reg. Eccl. Chriſt. Cant. If a perſon ſwore alone, it was *propria manu & unica.* The uſe of this word came probably from its being required at a perſon's hands to juſtify himſelf; or from laying the hand upon the New Teſtament, on taking the oath.

MANUS *interoſſei,* in *Anatomy.* See INTEROSSEI.

MANUSCRIPT, a book, or paper, written with the hand. By which it ſtands oppoſed to a printed book, or paper. A manuſcript is uſually denoted by the two letters MS. and, in the plural, by MSS. or MMSS. What makes public libraries valuable, is the number of ancient manuſcripts depoſited in them. See ALEXANDRIAN, CAMBRIDGE, CLERMONT, COTTONIAN, HARLEIAN, VATICAN, &c.

MANUZIO, ALDO, the elder, in *Biography,* a celebrated printer and man of letters, was born at Baſſano, in 1447. Having laid a good foundation, at his native place, in grammar learning, he was ſent to Rome, where he purſued his claſſical ſtudies under Gaſpar da Veronna, and removing thence to Ferrara, he had the advantage of learning Greek from Battiſta Guarino. During his reſidence at the latter city he was employed to give private leſſons to Alberto Pio, prince of Carpi, and to Hercules Strozzi, afterwards a diſtinguiſhed poet. In the war between the Venetians and the duke of Ferrara, in 1482, Aldo was obliged to quit that city, and he took up his abode with that patron of literature John Pico of Mirandola. He afterwards viſited his pupil Pio, and it is probable, that with the aſſiſtance of theſe two enlightened nobles, he ſet up a printing office at Venice, for the purpoſe of giving correct and elegant editions of the Greek and Latin claſſics. His firſt work did not appear till 1494, after the preſs had been eſtabliſhed about ſix years; but in the courſe of the next twenty years he had printed almoſt every Greek and Latin claſſic, as well as a number of other books. He was the inventor of the Italic character, called for a conſiderable time the *Aldine,* and obtained from the ſenate of Venice, and the pope, patents for its excluſive uſe for a number of years. To render the editions that iſſued from his preſs correct, he procured the aſſiſtance of ſome of the beſt ſcholars of the age as editors. Aldo likewiſe eſtabliſhed a kind of academy in his own houſe, at which the literati of Venice aſſembled, on fixed days, to diſcuſs various literary topics. Aldo was very deſirous of rendering his academy perpetual, but it did not long ſurvive him, though it was ſucceeded, not long after his death, by the Venetian academy. He married the daughter of Andrea d'Aſola, from whom he obtained ſome pecuniary aſſiſtance, and with whom he entered into partnerſhip. The wars of Italy impeded their labours, and by theſe Aldo loſt a very conſiderable property, which he took much pains to recover, and in the attempt fell into the hands of the ſoldiers of the marquis of Mantua, by whom he was plundered and impriſoned; but on making himſelf known, he was liberated with much reſpect. This was in the year 1506, and during the ſix ſubſequent years, he printed very little, but in 1513 and 1514 he reſumed his labours; and was cloſely engaged in his employment, when he was carried off by diſeaſe in April 1515. Aldo Manuzio held a ſchool in Venice for the Greek language: that his own learning was conſiderable, there are abundant proofs in the diſſertations and prefaces of his own compoſitions, which are prefixed to his editions of the Greek and Roman authors; and alſo in his Latin letters that have been printed in various epiſtolary collections. He publiſhed a Latin grammar compiled by himſelf; and a treatiſe "De Metris Horatianis:" he tranſlated various pieces from the Greek into Latin, and he compiled with great labour a Greek dictionary. He was viſited by all the learned ſtrangers who came to Venice; but to prevent a waſte of time which he could ill afford, he put up an inſcription over his ſtudy door, deſiring that viſitors would make their ſtay very ſhort, unleſs they had ſomething important to communicate. Though his editions were not, and could not be expected to be, immaculate, yet there are but few perſons to whom literature is more indebted than to Aldo Manuzio.

MANUZIO, PAULO, ſon of the preceding, an eminent ſcholar and printer, was born at Venice in 1512. He received the rudiments of an excellent education at Aſola, whence he was early removed to a more learned inſtructor at Venice, under whom he made extraordinary progreſs. When he had attained to his twenty-firſt year, in 1533, Paulo re-opened the printing office which had been ſhut from the death of Andrea, and the buſineſs was conducted under the joint names of the heirs of Aldo and Andrea. In 1535 he paid a viſit to Rome, on the promiſe of an eſtabliſhment there, but his hopes were for the preſent entirely diſappointed, and the only advantage which he derived from his journey was the friendſhip of ſome learned men in that capital. After his return, he opened an academy for the inſtruction of twelve young men of family, in polite literature: he continued in this employment about three years, and then made a tour through the cities of Italy, for the purpoſe of examining the beſt libraries. His reputation for learning procured him ſeveral offers of profeſſorſhips, but he did not engage in any of them, and his appointment to ſuperintend a printing office ſet up by the academy of Venice gave occaſion to his becoming diſtinguiſhed in his proper profeſſion, by ſeveral very elegant and accurate works; the inſtitution was, however, but of a ſhort continuance. About this time his eyes were ſo weak, or diſeaſed, that he was obliged to quit his ſtudies till he obtained complete relief by the aſſiſtance and advice of Fallopius. A liberal and magnificent plan had been formed at Rome for the printing of all the moſt valuable Greek MSS. in the Vatican. In the mean time, the progreſs of the Reformation, and the ſitting of the council of Trent, had rendered theological works in great requeſt, and it was determined to give Vatican editions of the fathers and other eccleſiaſtical writers, which might furniſh weapons to the defenders

defenders of the church. To unite correctnefs with elegance in thefe editions, the pope, Pius IV., invited Paulo Manuzio to Rome; he accepted the invitation, and arrived in the fummer of 1561. The prefs provided for him was in the Capitol, the palace of the Roman people, whence the works printed at it were infcribed "Apud Paulum Manutium in Ædibus Populi Romani." In 1570, either diffatisfied with his emoluments, or finding the air of Rome injurious to his health, he returned to Venice. From this period he fpent much of his time in travelling from place to place, till at length pope Gregory XIII. engaged him to ftay at Rome by the offer of a penfion, which allowed him to devote all his time to his ftudies. He died at Rome in April 1574, in the fixty-fecond year of his age. The learned world is indebted to Paulo for many valuable works of his own, befides thofe of others which he ufhered into the world. He was the diligent annotator on the works of Cicero and Virgil; he was much attached to the ftudy of Roman antiquities, and was the firft who difcovered the Roman calendar, which he publifhed from his fon's prefs with two tracts, "De veterum dierum ratione," and "Kalendarii Romani explicatio." He had formed the plan of a great work in which every topic of Roman antiquities was to be illuftrated, but of this he only publifhed "De curia Romana." He formed a collection of letters, as well Italian as Latin, and among thefe, his own letters in both languages may be compared with the beft of other writers. His Latin letters have frequently been reprinted, and are truly Ciceronian in their ftyle: the Italian compofitions are valued for their unaffected elegance and fimplicity. He publifhed many other works which were efteemed and applauded by the firft fcholars of his age: and as a printer he has merited high praife, as well on account of the beauty as the accuracy of his editions.

Manuzio, Aldo, the younger, fon of the preceding, was born in 1547. His father paid the utmoft attention to his education, and fo extraordinary was the progrefs of the youth in learning, that he was enabled to give the world "A Collection of elegant Phrafes in the Tufcan and Latin Languages," when he was only eleven years of age. Other juvenile works at different periods marked his advances in claffical literature, and he foon became his father's affiftant in his labours, both learned and typographical. He, when very young, conducted the printing bufinefs at Venice while his father was engaged at Rome. In 1572 he married a lady of the Giunti family, fo well known in the annals of typography, and on the death of his father, in 1574, all the concerns of the Aldine prefs devolved upon him. He was, however, lefs calculated for the bufinefs of a printer, than for the profeffion of an author. In 1577 he was appointed profeffor of the belles lettres in the fchool of the Venetian chancery, in which young men defigned for public employments were educated. This office he held till the year 1585, when he was made profeffor of rhetoric at Bologna. In the fame year he publifhed the "Life of Cofmo de Medici," which was fo well received, that he was almoft immediately invited to undertake the profefforfhip of polite literature at Pifa, which he accepted, although he received an invitation at the fame time to a profefforfhip at Rome, which had been lately held by Muratus. During his ftay at Pifa he received the degree of doctor of laws, and was admitted a member of the Florentine academy, on which occafion he delivered an eloquent oration "On the Nature of Poetry." He now paid a vifit to Lucca in order to obtain materials for a "Hiftory of Caftruccio Caftracani," which he afterwards publifhed, and which is much applauded by De Thou. The Roman profefforfhip being referved for him he removed thither in 1588, and intending to fpend his life there, he caufed his whole library to be brought to Rome from Venice, at a very great expence. He was in high favour with Sixtus V., who gave him an apartment in the Vatican, and a table at the public expence. He was alfo patronized in various ways by Clement VIII. He died in the 51ft year of his age in the month of October 1597. He left no pofterity, and with him ended the glory of the Aldine prefs. His library, confifting of 80,000 volumes, collected by himfelf and his predeceffors, was fold to pay his debts. He was author of many performances befides thofe already mentioned, but the moft celebrated of his works were his "Commentaries on all the Works of Cicero," in ten volumes. His "Familiar Letters," publifhed in 1592, were highly efteemed.

MANWAS, in *Geography*, a town of Hindooftan, in Boggilcund; 30 miles S.E. of Makoonda.

MANWORTH, in *Old Law Books*, denotes the price, or value, of a man's head.

In ancient times, every man, according to his degree, was rated at a certain price, according to which, fatisfaction was made to his lord, if any one killed him.

MANZANARES, in *Geography*, a river of Spain, which paffes by Madrid, and runs into Herares, about eight miles below that city.—Alfo, a river of America, in the Caraccas, which wafhes the city of Cumana. Its refrefhing ftream fertilizes lands otherwife fterile, which are thus rendered productive of fruits and vegetables in abundance.

MANZANAREZ, a town of Spain, in the province of New Caftile and diftrict of La Mancha, the population of which is eftimated at about 6768 perfons. The houfes are built with mud, and the poor are almoft naked. It is one of the principal quarters of the royal Carabineers. The caftle, with a confiderable eftate, and the tithes, belong to the knights of Calatrava, and yield a revenue of 3295*l.* *per annum*. The land about it produces corn, faffron, and good wine. The vineyards are numerous, and this part of the country produces the beft wine in La Mancha, and which is moft efteemed at Madrid. It has the flavour of the richeft Burgundy, with the ftrength and body of the moft generous port.

MANZANEDA, a town of Spain, in the province of Galicia; 20 miles E. of Orenfe.

MANZANELLO, a town of Spain, in the province of Leon; 23 miles E.S.E. of Valladolid.

MANZANILLA Key, a fmall rocky ifland near the S. coaft of Cuba. N. lat. 20° 54'. W. long. 77° 38'.

MANZAT, a town of France, in the department of the Puy de Dôme; 9 miles N.W. of Riom.

MANZEL. See Caravansera.

MANZINSKOI, in *Geography*, a fortrefs of Ruffia, in the government of Irkutfk, on the borders of China; 30 miles S.S.E. of Selenginfk. N. lat. 49° 5'. E. long. 108° 44'.

MANZOLI, Giovanni, in *Biography*, an opera finger of the firft order, born at Florence, and gifted with the fineft *foprano* voice which has been heard on our lyric ftage in our memory. He was, during many years, the firft finger in Italy; and when the court of Spain determined on having Italian operas performed under the direction of Farinelli, Manzoli was engaged for the principal man's part. From Madrid he went to Vienna, at the celebration of the emperor Jofeph's firft marriage. In 1764, he arrived in England, during the opera regency of Meffrs. Gordon and Vincent, at which period the ferious opera acquired a degree of favour to which it had feldom mounted fince its firft eftablifhment in this country.

The

The expectations which the high reputation of this performer had excited were so great, that, at the opening of the theatre in November, with the pasticcio of Ezio, there was such a crowd assembled at all the avenues, that it was with very great difficulty we obtained a place, after waiting two hours at the door. Manzoli's voice was the most powerful and voluminous soprano that had been heard on our stage since the time of Farinelli; and his manner of singing was grand and full of taste and dignity. In this first opera he had three songs, composed by Pescetti, entirely in different styles: *Recagli quell' acciaro*, an animated *aria parlante; Caro mio bene addio*, an adagio in a grand style of cantabile; and *Mi dona mi rende*, of a graceful kind, all which he executed admirably. The lovers of music in London were more unanimous in approving his voice and talents than those of any other singer of the last century.

The applause was hearty, unequivocal, and free from all suspicion of artificial zeal;—it was a universal thunder. His voice alone was commanding from native strength and sweetness; for it seems as if subsequent singers had possessed more art and feeling; and as to execution, he had none. However, he was a good actor, though unwieldy in figure, and not well made in person; neither was he young when he arrived in London; yet the sensations he excited seem to have been more irresistible and universal, than we have ever been witness to in any theatre. This great singer remained in England but one season, when, returning to Italy, he was succeeded by Elisi.

In 1770 we heard Manzoli sing at Florence in a convent at the last consecration of six nuns; he had quitted the stage, and his voice, though in a small chapel, seemed much less powerful than when he was in England; and it was then said by those who had heard him before, that, powerful as his voice appeared to all who heard him for the first time, it had been still better. This great vocal performer and worthy man died at Florence in 1791.

MANZORA, or CHIREIRA, in *Geography*, a river of Africa, which joins the Zambeze, S. lat. 16° 35'. E. long. 34°.

MANZORAH, a river of Hindoostan, which is a branch of the Godavery: this is a considerable river, which rises in the country of Amednagur, and after a circuitous course, joins the main river below Nander.

MANZUREKA, a river of Russia, which runs into the Lena, N. lat. 53 45'. E. long. 106° 34'.

MANZURSKA, a town of Russia, in the government of Irkutsk, at the junction of the Manzureka and Lena; 32 miles S.E. of Vercholensk.

MAO, or MAU, in *Botany*, a name by which some authors have called the *magna Indica*, or Indian mango-tree.

MAO, in *Geography*, a city of China, of the second class, in the province of Se-tchuen; 55 miles N. of Tching-tou. N. lat. 31 38'. E. long. 103° 32'.

MAON, a small island in the Adriatic, near the coast of Dalmatia. N. lat. 44° 44'. E. long. 15° 1'.

MAON, in *Ancient Geography*, a strong city of Palestine, in the tribe of Judah, which gave name to the neighbouring wilderness. It stood on a barren eminence, at a little distance to the S.W. of the Dead sea.

MAOPONGO, in *Geography*, a town of Africa, in Benguela, and capital of a district. S. lat. 10° 30'.

MAOUNA, or MASSACRE *island*, one of M. Bougainville's Navigator's islands in the South Pacific ocean, visited by La Perouse in 1787. This island is surrounded by a reef of coral, on which the sea breaks with great force; but the reef almost joined the shore, and the coast formed several little coves, in front of which were inlets where canoes could pass, and probably, says La Perouse, our barges and long boats. At the bottom of each of these creeks were numerous villages, whence came out a number of canoes in succession laden with pigs, cocoa nuts, and other fruits, which were exchanged for glass trinkets. When M. de Langle and several officers landed, night came on, and the Indians lighted a great fire to make the landing place clear; and hither they brought birds, pigs, and fruit. Upon the first visit, while perfect tranquillity and apparent good humour prevailed, and whilst the casks of La Perouse's frigates were filling with water, he entered a charming village situated in the midst of a wood, or rather orchard, the trees of which were weighed down by fruit. The houses were placed in the circumference of a circle, about one hundred and fifty fathoms in diameter, the centre of which formed a large open place, with a grass plat of the most beautiful verdure, and the trees which overshaded it kept up a delicious freshness. Women, children, and old men accompanied their new visitor, and invited him into their houses, where they spread the finest and freshest mats upon the ground, formed by small picked pebbles, and which they had raised about two feet to protect them from the damp. In the handsomest of these huts, probably belonging to the chief, was a large room of lattice work, equally well executed with those about Paris. This charming country, says our navigator, united the twofold advantage of a soil fertile without culture, and a climate which required no clothing. Bread fruit, cocoanut, banana, guavas, and orange trees furnished the inhabitants with abundance of wholesome nourishment; while fowls, pigs, and dogs, which live on the refuse of these fruits, afforded them an agreeable variety of food. They were so rich, and in want of so little, that they disdained our instruments of iron and stuffs, and coveted only some beads: burdened with real goods, they only wished for things that were useless. Our navigator was ready to pronounce the inhabitants of this richly stored and beautiful island the most happy beings on earth. But he soon found that this pleasant abode was not the mansion of innocence. Although no arms were perceived, yet the bodies of these Indians, covered with scars, proved that they must be at war with their neighbours, or quarrel among themselves; and their countenances indicated a ferocity imperceptible in the physiognomy of the women, whose persons were agreeable, and manners soft, lively, and engaging. Nature, says our author, had without doubt left this stamp on the figure of the Indians to denote, that man, almost wild and in a state of anarchy, is a being more mischievous than the fiercest of the animal creation. This first visit, however, did not pass off without private quarrels, which were terminated by prudent and wary conduct on the part of our navigators. The islanders became in process of time bold and insolent, and regardless of every restraint to which they were subjected. The two frigates had during their stay trafficked for 500 pigs, a great quantity of fowls, pigeons, and fruit, and all at the expence of a few beads of glass. La Perouse gave orders for quitting the island before the storm burst, which he perceived to be gathering, and the harmonious intercourse that had subsisted was interrupted, which he saw likely to be the case; but M. de Langle, the post captain, persisted in his purpose of obtaining a few long-boat loads of water before he left the island: the consequence was disastrous; the islanders became turbulent; and M. de Langle formed a body of 60 men from among the choicest men of the crews, armed them with muskets and cutlasses, and mounted six swivels in the long-boats, and thus prepared, they landed in order to obtain water. The number of canoes increafed, and the number of iflanders, who were collected in hoftile array on the fhore, amounted to 10 or 1200. M. de Langle and his companions betook themfelves to their boats amidft vollies of ftones, and the Indians furrounded them within the diftance of a toife: after a fhower of ftones, M. de Langle had only time to fire his mufket twice, when he was knocked down, and unfortunately fell over the larboard fide, 200 Indians immediately maffacring him with clubs and ftones. Of the 61 men who had engaged in this expedition, 49 faved themfelves by fwimming to the barges of the frigates, but the remaining number fell a facrifice to the relentlefs fury of thefe favages, and all the others were grievoufly wounded more or lefs. M. de Lamanon, the philofopher and naturalift, was one of the number who loft his life on this occafion. Many of the Indians were killed or wounded in this conflict. M. de Vaujuas clofes his narrative of this event with the following general remark: "All thofe who were on fhore can bear witnefs, like me, that no violence, no imprudence on our fide provoked the attack of the favages. Our captain had, with refpect to this, iffued the moft ftrict orders, which no one difobeyed." Captain Edwards calls this ifland "Otutuela." The anchoring place was in S. lat. 14° 22'. E. long. 189° 1'. Peroufe's Voyage, vol. ii.

MAP, a plain figure, reprefenting the furface of the earth; or a part of it, according to the laws of perfpective.

A map is a projection of the furface of the globe, or a part of it, on a plane furface, reprefenting the forms and dimenfions of the feveral countries and rivers; with the fituation of cities, mountains, and other places.

Maps are either *univerfal* or *particular*.

Maps, *Univerfal*, are thofe which exhibit the whole furface of the earth, or the two hemifpheres.

Maps, *Particular*, are thofe which exhibit fome particular region, or part of the earth's furface.

Thofe of each kind are frequently called *geographical*, or *land-maps*, in contradiftinction to *hydrographical*, or *fea-maps*, reprefenting only the feas and fea-coafts; and properly called *charts*; which fee.

There are three qualifications required in a map: 1. That all places have their juft fituation with regard to the chief circles of the earth, as the equator, parallels, meridians, &c. becaufe on thefe depend many properties of regions, as well as celeftial phenomena. 2. That the magnitudes and forms of the feveral countries have the fame proportion as on the furface of the earth. 3. That the feveral places have the fame diftance and fituation with regard to each other, as on the earth itfelf.

For the foundation of maps, and the laws of projection, fee Perspective, and Projection *of the Sphere*.—The application of thefe principles and laws, in the conftruction of maps, is as follows.

Conftruction of a Map, the Eye being placed in the Axis.—Suppofe, *v. g.* the northern hemifphere to be reprefented with the eye on the point of the axis, *v. g.* the fouth pole: for the plane on which the reprefentation is to be made, we take the plane of the equator, and, from all the points of the furface of the northern hemifphere, conceive lines paffing through the plane to the eye; which points, connected together, conftitute the map required.

In this cafe, the equator will be the limit of the projection; the pole, the centre. The meridians will be right lines paffing from the pole to the equator: the parallels of latitude, &c. circles concentric with the equator; and all the other circles, and arcs of circles, as the horizon, vertical circles, &c. ecliptic, &c. conceived in that hemifphere, will be ellipfes, or arcs of ellipfes.

The better to apprehend the projection of the circles of the plane, conceive a radiant cone, whofe vertex is the eye, its bafe the circle to be reprefented, and its fides the rays paffing between the circle and the eye. Suppofe this cone cut by the plane, it is obvious, that, according to the various pofition of the cone, there will be a different fection, and confequently a different line of reprefentation.

For the Application of this Doctrine in Practice.——In a plane, *v. g.* a paper, take the middle point P (*Plate* I. *Geography*, *fig.* 4.) for the pole; and from this, as a centre, defcribe a circle of the intended fize of your map to reprefent the equator. Thefe two may be pitched on at pleafure, and from thefe all the other points and circles are to be determined. Divide the equator into 360°, and drawing right lines from the centre to the beginning of each degree, thefe will be meridians; whereof that drawn to the beginning of the firft degree, we fuppofe the firft meridian.

For the parallels.—There are four quadrants of the equator; the firft, 0.90; the fecond, 90.180; the third, 180.270; the fourth, 270.0; which, for the better diftinction, we will note with the letters A B, C D, B C, D A. Taking one of thefe, *v. g.* B A; from the feveral degrees of it, as alfo from 23° 30', and 66° 30' of it, draw occult right lines to the point D, marking where thefe lines cut the femidiameter A P C; and from P, as a centre, defcribe arcs paffing through the feveral points in A P C.—Thefe arcs will be parallels of latitude. The parallel at 23° 30' will be the tropic of Cancer, and that at 66° 30', the arctic circle. The meridians and parallels thus defcribed, from a table of longitudes and latitudes, lay down the places; reckoning the longitude of each place on the equator, commencing at the firft meridian, and proceeding to the meridian of the place; and for the latitude of the place choofing a parallel of the fame latitude: the point in which this meridian and parallel interfect, reprefents the place: and in the fame manner all the other places may be determined, till the map be complete.

For the ecliptic, half of which comes in this hemifphere, we have obferved, that it makes an ellipfis; fo that the points through which it paffes are to be found. The firft point, or that in which the ecliptic cuts the equator, is the fame with that in which the firft meridian cuts the equator, which is therefore diftinguifhed by the fign of Aries: the laft point of this half ellipfis, or the other interfection of the equator, and ecliptic, *viz.* the end of Virgo, will be in the oppofite point of the equator, *viz.* at 180°. The middle point of the ellipfis is that in which the meridian 90 cuts the tropic of Cancer. Thus we have three points of the ecliptic determined: for the reft, *viz.* for 1° and 15° of Taurus, 1° and 15° of Gemini, 1° of Leo, 1° of Virgo; the declinations of thofe points from the equator muft be taken from a table, and fet off in the map. See Declination, &c.

Thus, where the meridian of 13° cuts the parallel of 5°, that point will be 15 degrees of Aries. Where the meridian 26° cuts the parallel $11\frac{1}{2}$, will be the firft degree of Taurus; and fo of the reft. Thefe points, being all joined by a curve line, will be a portion of an ellipfis reprefenting the ecliptic.

Maps of this projection have the firft qualification above required; but they are defective in the fecond: the furface being ftretched farther, as it approaches nearer the equator. With refpect to the third, they are ftill farther erroneous. By

By this method may almoſt the whole earth be repreſented in one map, placing the eye, *v.g.* in the antarctic pole, and aſſuming for the plane of projection that of ſome circle near it, *v.g.* the antarctic circle. Nothing is here required beſides the former projection, but to continue the meridian, draw parallels on the other ſide of the equator, and complete the ecliptic; but this diſtorts too much for practice.

This projection is the eaſieſt: but that where the eye is placed in the plane of the equator, is preferred for uſe. It is, in effect, of the latter kind that maps are ordinarily made. The former are added to them, in ſmall, by way of ſupplement, to repreſent the intermediate ſpaces left between the two hemiſpheres.—Farther, as the ſituation of the ecliptic, with regard to the earth, is continually changing; ſtrictly ſpeaking, it has no place on the earth's ſurface: but is uſed to be repreſented according to its ſituation, at ſome certain moment; *viz.* ſo that the beginning of Aries and Libra may be in the interſections of the firſt meridian and equator.

Conſtruction of Maps, with the Eye in the Plane of the Equator.—This method of projection, though more difficult, is yet much more juſt, more natural, and more commodious, than the former. To conceive it, we ſuppoſe the ſurface of the earth cut into two hemiſpheres by the entire periphery of the firſt meridian, each of which hemiſpheres we repreſent in a diſtinct map. The eye is placed in the point of the equator 90° diſtant from the firſt meridian: and for the tranſparent plane, wherein the repreſentation is to be, we take the plane of the firſt meridian. In this projection, the equator is a right line, and the meridian, 90° diſtant from the firſt, is alſo a right line; but the other meridians, and all the parallels of the equator, are arcs of circles, and the ecliptic is an ellipſis.

The method is thus: From a point E as a centre (*fig.* 5.) deſcribe a circle according to the intended ſize of the map. This repreſents the firſt meridian, and its oppoſite; for drawing the diameter B D, there ariſe two ſemicircles, the one of which, B A D, is the firſt meridian, the other, B C D, its oppoſite, or the meridian of 180°. This diameter, B D, repreſents the meridian of 90 degrees, of which the point B is the arctic pole, and the point D the antarctic. The diameter A C, perpendicular to that B D, is the equator. Divide the quadrants A B, B C, C D, D A, each into 90 degrees; and to find the arcs of the meridians and parallels, proceed thus: divide the equator into its degrees; *viz.* 180 (as being indeed only half the equator); through theſe ſeveral diviſions, and the two poles, deſcribe arcs of circles, repreſenting meridians, as B 10 D, B 20 D, &c.—How to find centres for deſcribing thoſe arcs, ſee under the word CHORD. See alſo *Geometrical Conſtruction of the* GLOBULAR PROJECTION, infra.

Indeed the operation will be both more eaſy and accurate, if performed by a canon of ſemi-tangents.

Thus, by means of a ſector, divide the equator A C into two lines of ſemi-tangents E A and E C, which will repreſent the degrees of longitude. Then with the ſecant of 80°, as a radius, deſcribe the arc of the circle B 80 D, which repreſents a meridian cutting the plane of projection at an angle of 80°; with the ſecant of 70° deſcribe the arc B 70 D, which repreſents a meridian cutting the plane of projection at 70; and proceed in the ſame manner with the reſt of the meridians, which are uſually drawn at every 10° of longitude, as the parallels are at every 10° of latitude.

To deſcribe the parallels, the meridian B D muſt be in like manner divided into 180 degrees; then through each of theſe diviſions and the correſponding diviſions of the quadrants A B, C B, deſcribe arcs of circles. Thus ſhall we have parallels of all degrees, with tropics, polars, and meridians.

The parallels may be drawn with the tangents for radii, as the meridians are with the ſecants, 1010 repreſenting the parallel of 10°, with the tangent of 80°, that of 20 with the tangent of 70°, &c. The ecliptic may be deſigned two ways; for its ſituation over the earth may either be ſuch, as that its interſection with the equator may be over the place A; in which caſe the projection of its ſemicircles, from the firſt degree of Cancer, to the firſt of Capricorn, will be a ſtraight line, to be determined by numbering 23° 30′ from A towards B, and from the extreme of that numeration drawing a diameter through E; which line will be half the ecliptic in this ſituation, and may be divided, as before, into degrees, to which the numbers, ſigns, &c. are to be affixed. But if the ecliptic be ſo placed, as that its interſection with the equator is over the place A, in the firſt meridian, its projection in that caſe will be a ſegment of an ellipſis: whereof two of the points are A, C; a third, that wherein the meridian 90 cuts the tropic of Cancer. The other points muſt be determined in the manner laid down above; *viz.* by taking the declinations and right aſcenſions of 15° of Aries, 1° of Taurus, 15° of Gemini, &c. For where the parallels, according to their ſeveral degrees of declination, cut the meridians, taken according to the ſeveral right aſcenſions, thoſe points of interſection are the points of the 15° of Aries, &c. A curve line therefore being drawn, theſe will give the projection of the ecliptic.

Nothing then remains to complete the map, but to take the longitudes and latitudes of places from a table; and to ſet them off on the map; as was directed under the former method.

In this projection the whole ſurface of the earth may be repreſented in one map; if, inſtead of the plane of the firſt meridian, ſome other plane parallel to it, but very near the eye, be taken; for by this means the entire parallels and meridians will be deſcribed. But as this diſtorts the face of the earth too much, it is ſeldom uſed; and we rather make the two hemiſpheres in two diſtinct tables.

One great advantage in this projection is, that it repreſents the longitudes and latitudes of places, their diſtance from the pole and from the equator, almoſt the ſame as they really are on the earth. Its inconveniences are, that it makes the degrees of the equator unequal; being the greater as they are nearer the firſt meridian D A B, or its oppoſite B C D; and for this reaſon equal tracts of the earth are repreſented unequal; which defect may be in ſome meaſure remedied, by removing the eye far from the earth. And, laſtly, the diſtances of places and ſituation, with regard to each other, cannot be well determined in maps of this projection.

Conſtruction of Maps on the Plane of the Horizon, or wherein any given place ſhall be the centre or middle. Suppoſe, for inſtance, it is deſired to have London the centre of the map. Its latitude we will ſuppoſe to be 51° 32′. The eye is placed in the nadir. The tranſparent table is the plane of the horizon, or ſome other plane, if it is deſired to repreſent more than a hemiſphere. Take then the point E (*fig.* 6.) for London; and from this, as a centre, deſcribe the circle A B C D to repreſent the horizon, which you are then to divide into four quadrants, and each of theſe into 90 degrees. Let the diameter B D be the meridian, B the northern quarter, D the ſouthern; the line of equinoctial eaſt and weſt ſhews the firſt vertical, A the weſt, C the eaſt, or a place of 90 degrees from the zenith in the firſt vertical. All the verticals are repreſented by right lines drawn from the

the centre E to the feveral degrees of the horizon. Divide B D into 180 degrees, as in the former methods; the point in E B, reprefenting 51° 32′ of the arc B C, will be the projection of the north pole, which note with the letter P. The point in E D, reprefenting 51° 32′ of the arc D C (reckoning from C towards D), will be the projection of the interfection of the equator and meridian of London, which note with the letter Q; and from this, towards P, write the numbers of the degrees, 1, 2, 3, &c. As alfo from Q towards D, and from B towards P; *viz.* 51. 52, 53, &c. Then taking the correfponding points of equal degrees; *viz.* 99 and 99, 88 and 88, &c. about thofe, as diameters, defcribe circles, which will reprefent parallels, or circles of latitude, with the equators, tropics, and polar circles. For the meridians, firft defcribe a circle through the three points A, P, C. This will reprefent the meridian 90 degrees from London. Let its centre be M in B D (continuing to the point N, which reprefents the fouth pole), P N being the diameter; through M draw a parallel to A C; *viz.* F H, continued each way to K and L. Divide the circle, P H N F, into 360 degrees, and from the point P draw right lines to the feveral degrees, cutting K F H L; through the feveral points of interfection, and the two poles P, N, as through three given points, defcribe circles reprefenting all the meridians. The centres for defcribing the arcs will be in the fame K L, as being the fame that are found by the former interfection; but are to be taken with this caution, that for the meridian next B D N towards A, the moft remote centre towards L, be taken for the fecond, the fecond from this, &c. The circles of longitude and latitude thus drawn, infert the places from a table, as has been directed.

Conftruction of Maps on the Plane of the Meridian.—This projection is taught by Ptolemy, and recommended by him as proper for that part of the earth then known. In this the equator and parallels are arcs of circles, and the meridians arcs of ellipfes; the eye hanging over the plane of that meridian which paffes over the middle of the inhabited world. But in regard the defcription of thefe ellipfes is fomewhat perplexing, and becaufe this method feems calculated only for a part of the earth, it is not now ufed.

There is a fecond method, fomething akin to it, which reprefents the circles of latitude by right lines, and the meridians by arcs of ellipfes: as muft be the cafe, if lines be conceived to fall from the feveral points of each hemifphere perpendicularly on the plane of the firft meridian, and the eye be fuppofed at an infinite diftance from the earth, fo that all the rays emitted from the places of the earth to it may be accounted parallels, as well as perpendiculars to the plane of the firft meridian.

In his "Companion to a Map of the World," (London, 1794, 4to.) Mr. Arrowfmith has offered the following remarks on projection; and as they are immediately connected with the fubject of the conftruction of maps, we fhall here fubjoin them.

"As the earth is of a form approaching very near to a globe or fphere, it is evident that the only map which can truly reprefent the figure of the various countries, and their relative bearings and diftances, muft be delineated on the furface of a globe. But as globes of a fize proper to exhibit a map fufficiently accurate, and containing all the information that is neceffary or defirable, muft be very bulky, and very expenfive, it is neceffary to have more portable and cheaper maps, executed upon a flat furface; thefe, fince the art of copper-plate printing has been in ufe, have generally been made upon paper.

"It is obvious that fuch a map, wherein is attempted to reprefent upon a plane furface that which is really fpherical, muft depart confiderably from the truth; efpecially if it comprehends the whole, or a confiderable portion of the world. It has, therefore, been an object which has engaged the attention of the moft eminent geographers, to difcover a projection (or arrangement of the proportional parts of the map) which fhould be liable to the feweft errors.

"The moft natural method of reprefenting a fphere upon a plane feems to be to divide it into two equal parts, and infcribe each of them in a circle: but as the equator and the polar axis, which interfects that circle at right angles, and makes one of the meridians, muft be fuppofed equal in length to the half of the periphery (of which it is not quite two-thirds), it follows, of courfe, that the countries delineated upon or near thefe lines muft be reduced to fomewhat lefs than two-thirds of the fize of the countries of equal extent, which lie at the extremity of the circle; and that the lines drawn to meafure the latitude, which are parallel to each other, or nearly fo, muft, in order to preferve as nearly as poffible their proportional angles at the points of interfection with the meridian, form fegments of circles, of which no two are parallel or concentric.

"There may be as many different projections as there are points of view, in which a globe can be feen; but geographers have generally chofen thofe which reprefent the poles, at the top and bottom of the map: thefe, from the delineation of the lines of latitude and longitude, are called the ftereographic, orthographic, and globular projections." See Projection.

"I do not propofe to detain the reader with a defcription of all the projections; fome of which are fo numerous (for the purpofe of conftructing of maps) as to deferve being configned entirely to oblivion. But as projections of maps form a pleafing and inftructive exercife, and, indeed, indifpenfibly neceffary to the right underftanding of geography, by ftudents, I fhall defcribe the manner of conftructing the map that accompanies this work; but firft hint at the ftereographic projection. (The great geographer, d'Anville, has conftructed his map of the world upon this projection, adapting it to Caffini's fyftem of the figure of the earth, which makes the polar diameter longer than the equatorial.) Among the various pofitions affignable to the eye, there are chiefly two that have been adopted, wherein the eye is placed either in the point D (*fig.* 7.) or removed to an infinite diftance; and hence this projection is liable to the great error of diftorting the form of the countries, reprefented upon it, much more than is neceffary. The only advantage is, that the lines of latitude and longitude interfect each other at right angles.

"This being obferved by that excellent aftronomer, M. de la Hire (Hift. Acad. Sc. 1701), he invented a remedy for the inconvenience, by affigning to the eye a pofition at the point O (*fig.* 7.) the diftance of which, from the globe at D, is equal to the fine of 45°; and hence the right line, G O, which bifects the quadrant B C, alfo bifects the radius E C, and produces the fimilar triangles O F G, and O E I; and thus the other parts of the quadrant B C, and, in like manner, of the whole femicircle A B C, are reprefented in the projection nearly proportional to each other, and to the eye perfectly fo.

"This projection, as coming the neareft to a true reprefentation of the globe, is called the "Globular Projection;" it is equal to the ftereographic in point of facility, and vaftly fuperior to it in point of truth.

"*Geometrical Conftruction of the* Globular Projection.—From the centre C (*fig.* 8.), with any radius, as C B, defcribe a circle; draw the diameters A B, and 90, 90, (being careful to draw them at right angles), and divide them into nine

nine equal parts; likewife divide each quadrant into nine equal parts, each of which contains 10 degrees: if the fcale admits of it, every one of thefe divifions may be fubdivided into degrees: next, to draw the meridians, fuppofe the meridian 80° W. of Greenwich. we have given the two poles, 90, 90, and the point 80 in the equator, or diameter A B; defcribe a circle to pafs through the three given points, as follows; with the radius 90 C, fet one foot of the compaffes on the point 90, and defcribe the femicircles X X and Z Z; then remove the compaffes to the point 80 on the equator, and defcribe the arcs 1, 1, and 2, 2; where they interfect the femicircle, make the point as at 1 and 2, and draw lines from 2 through the point 1, till they interfect the diameter B A, continued, in E, then will E be the centre from which the meridian 90, 80, 90, muft be drawn, and will exprefs the meridian of 80° W. longitude from Greenwich. The fame radius will draw the meridian expreffing 140° W. longitude in like manner. Draw the next meridian with the radius C B, fet one foot of the compaffes in the point *d*, and defcribe the arcs *a a* and *b b*; then draw lines as before, which will give the point D, the centre of 90° W. longitude, and fo of all the reft.

"The parallels of latitude are drawn in the fame manner, with this difference, that the femicircles X X and Z Z muft be drawn from the points A and B, the extremities of the equator." See *Conftruction of Maps, with the Eye in the Plane of the Equator*, fupra.

"In the manner above-defcribed, with great labour and exactnefs, I drew all the meridians and parallels of latitude to every degree in two hemifpheres, which laid the foundation of the map now before us.

"We fhall now drop a few hints on the advantage and difadvantage of Mercator's projection.

"A method has been found to obviate fome of the difficulties attending all the circular projections by one, which, from the perfon who firft ufed it (though not the inventor), is called "Mercator's Projection." In this there are none but right lines; all the meridians are equidiftant, and continue fo through the whole extent; but, on the other hand, in order to obtain the true bearing, fo that the compafs may be applied to the map (or chart) for the purpofe of navigation, the fpaces between the parallels of latitude (which in truth are equal, or nearly fo) are made to increafe as they recede from the equator in a proportion which, in the high latitudes, becomes prodigioufly great.

"The great advantages peculiar to this projection are, that every place drawn upon it retains its true bearing, with refpect to all other places; the diftances may be meafured with the niceft exactnefs by proper fcales, and all the lines drawn upon it are right lines. For thefe reafons, it is the only projection in drawing maps or charts for the ufe of navigators." See CHART.

"Its only difadvantage is, that the countries in high latitudes are of neceffity increafed beyond their juft fize to a monftrous degree.

"Thus it appears, from this fhort view of three of the beft modes of projecting maps of the world upon a plane furface, that each of thofe which have been more particularly defcribed, is attended with advantages and difadvantages peculiar to itfelf; it is obvious, that the only means to acquire a juft idea of the various countries upon fuch a furface, is by a comparifon of two maps, one laid down on the Mercator's projection, and the other upon the beft of the Circular projections." See PROJECTION.

MAPS, *General*, are the hemifpheres; which are for the moft part conftructed ftereographically.

MAPS, *Rectilinear*, are thofe wherein both the meridians and parallels are reprefented by right lines, which by the laws of perfpective is impoffible; in regard there can no fuch pofition be affigned to the eye and the plane, as that the circles both of longitude and latitude fhall be right lines.

In the firft method above laid down, the meridians are right lines, but the parallels are circles: in the fifth, the parallels are right lines, and the meridians ellipfes. In all other perfpective methods, both kinds of circles are curves: one method indeed muft be excepted, wherein the meridians are right lines, and the parallels hyperbolas; as when the eye is placed in the centre of the earth, and the plane, through which it is viewed, is parallel to the firft meridian: but this method is rather pretty than ufeful.

Rectilinear maps are chiefly ufed in navigation, to facilitate the eftimate of the fhip's way. See CHART

Conftruction of particular Maps.—Particular maps of large tracts, as Europe, Afia, Africa, and America, are projected after the fame manner as general ones; only let it be obferved, that for different parts, different methods may be chofen. Africa and America, for inftance, as the equator paffes through them, cannot be conveniently projected by the firft method, but much better by the fecond. Europe and Afia are moft conveniently reprefented by the third; and the polar parts, or the frigid zones, by the firft.

To begin then, draw a right line on your plane, or paper, for the meridian of the plane over which the eye is conceived to hang, and divide it into degrees, as before, which will be the degrees of latitude. Then from the tables take the latitude of the two parallels, which terminate each extreme. The degrees of thefe latitudes are to be noted in the meridian; and through them draw perpendiculars, bounding the map towards north and fouth. This done, meridians and parallels are to be drawn to the feveral degrees, and the places to be inferted, till the map is complete.

For particular Maps of lefs extent. In maps of fmaller portions of the earth, the geographers take another method. Firft, a tranfverfe line is drawn at the bottom of the plane, to reprefent the latitude, wherein the fouthernmoft part of the country, to be exhibited, terminates. In this line, fo many equal parts are taken as that country is extended in longitude. On the middle of this fame line erect a perpendicular, having fo many parts as there are degrees of latitude between the northern and fouthern limits of the country. How big thefe parts are to be, may be determined by the proportion of a degree of a great circle to a degree of the parallel reprefented by the tranfverfe line at bottom. Through the other extreme of this perpendicular, draw another perpendicular, or a parallel to the line at bottom, in which are to be feen as many degrees of longitude as in the lower line, and thefe, too, equal to each other, unlefs the latitudes happen to be remote from each other, or from the equator. But if the loweft parallel be at a confiderable diftance from the equinoctial, or if the latitude of the northern limit go much beyond that of the fouthern; the parts or degrees of the upper line muft not be equal to thofe of the lower, but lefs, and that according to the proportion which a degree of the more northern parallel has to a degree of the more fouthern. After parts have been thus determined, both on the upper and lower line, for the degrees of longitude; right lines muft be drawn through the beginning and end of the fame number, which lines reprefent the meridians; then through the feveral

veral degrees of the perpendicular erected on the middle of the first transverse line, draw lines parallel to that transverse line: these will represent parallels of latitude. Lastly, at the points wherein the meridians of longitude and the parallels of latitude concur, insert the places from a table, as before directed. But though there are various modes of constructing these maps, they are, in general, defective, so as not to be applied with accuracy and facility to the purposes intended, in determining the courses or bearings of places, their distances, or both.

Suppose it were required to draw the meridians and parallels for a map of Britain. This island is known to lie between 50° and 60° of latitude, and 2 and 7° of longitude. Having therefore chosen the length of your degrees of latitude, you must next proportion your degrees of longitude to it. By the table of degrees of longitude corresponding to every degree of latitude, under Degree, you will find that in the latitude of 50°, the length of a degree of longitude is to one of latitude, as 39.054 is to 60; that is, a degree of longitude in lat. 50°, is somewhat more than half the length of a degree of latitude. The exact proportion may be easily taken by a diagonal scale; after which you are to mark out seven or eight of those degrees upon a right line for the length of your intended map. On the extremities of this line raise two perpendiculars, upon which mark out 10° of latitude for the height of it. Then, having completed the parallelogram, consult the table for the length of a degree of longitude in lat. 60°, which is found to be nearly one half a degree of latitude. It will be always proper, however, to draw a vertical meridian exactly in the middle of the parallelogram, to which the meridian on each side may converge; and from this you are to set off the degrees of longitude on each side. Then having divided the lines bounding your map into as many parts as can conveniently be done, to serve for a scale, you may by means of these set off the longitudes and latitudes with much less trouble than where curve lines are used. This method may always be adopted where a particular kingdom is to be delineated, and will represent the true figure and situation of the places with tolerable exactness. The particular points of the compass on which the towns lie with respect to one another, or their bearings, cannot exactly be known, except by a globe or Mercator's projection. Their distances, however, may thus be accurately expressed, and this is the only kind of maps to which a scale of miles can be truly adapted.

The Rev. T. Bowen has just published an excellent apparatus for describing the lines of longitude and latitude on maps, on a scale adapted for the use of schools. In like manner, these lines may be described on maps of any size with unerring accuracy.

The apparatus consists of a scale and a pair of compasses sufficiently large to describe the proposed lines, with a book to explain the method of using them. The short lines at each end of the scale represent the equators, the meridians, the north, the south, the east, and west lines graduated; from which the outlines of the maps are to be constructed, and the degrees laid down. The lines extending the whole length of the scale on the other side, contain the centres of the different circles which compose the lines of longitude and latitude mathematically found. The radius of each line to be described on the map, is the distance between that line and its corresponding number on the scale; consequently, by placing one limb of the compasses on the central point on the scale (when adjusted according to the directions given), extending the other to its corresponding number on the meridian, and then moving it from east to west, the parallel of latitude is formed; from north to south through its corresponding number on the equator, and the line of longitude is described.

For an abstract of La Croix's paper on the projection of maps, see Pinkerton's Geography, vol. i. Introd.

For Maps of Provinces, or small tracts, as parishes, manors, &c. we use another method, more sure and accurate than any of the former. In this, the angles of position, or the bearings of the several places, with regard to one another, are determined by proper instruments, and transferred to paper. This constitutes an art apart, called *surveying*.

Maps, *the Use of*, is obvious from their construction. The degrees of the meridians and parallels shew the longitudes and latitudes of places, and the scale of miles annexed, their distances; the situation of places, with regard to each other, as well as to the cardinal points, appears by inspection, the top of the map being always the north, the bottom the south, the right hand the east, and the left the west; unless the compass usually annexed shew the contrary.

Maps *of Estates*, in *Agriculture*, such plans or outlines of lands as are necessary to direct their management in the most easy and economical manner. In an useful work on "Landed Property," it is advised that the different distinct parts or farms into which they are divided, should be outlined, coloured, and introduced on a general map, as well as each separately delineated, more particularly on a small pocket one, so as to shew the farms with distinctness, or the lands intended to be laid into them, with the wood-lands, waters, &c. &c. that are in hand. The pocket maps should exhibit at once the outlines, the names, and the contents of the different fields, or pieces of land of which they are severally constituted, which by being coloured according to occupancy, the several fields of the existing farms (or intermixed parts of farms intended to be united), though scattered, may be readily distinguished. And "if separate columns of contents be indorsed on the backs of the maps, one of them of the intended farm, the other of the existing farms or parts of farms, with their totals subjoined; all the doubts and perplexities which are wont to arise on large estates, from the intermixture of farm-lands, will be avoided."

And these maps of farms should be of a portable size, as ten inches by eight, and be bound up in volumes corresponding to the general maps; so that the superintendant-manager in going over any part of the estate, may have with him the maps that belong to it. Each map should be folded double, and be hung in loosely within flexible covers, by a guard or slip of paper pasted on the back, in order that when opened each may lie flat and fair, and be conveniently portable when shut.

Maps, *Geognostic*. The idea of exhibiting in maps, by means of signs or illumination, the principal geognostic features of a given tract of country, the aspect of its surface, the nature of its rocks, their alternation and relative position, is as new as the science which teaches us to distinguish from each other the manifold materials that compose the crust of the earth as far as we are acquainted with it. Several methods have been lately adopted for accomplishing the above object; of all which that of colouring the spaces occupied by the different rocks appears by far the most convenient. It is this method which has been improved and carried to a high degree of precision by the celebrated Werner, who has happily removed all those obstacles which hitherto prevented its general adoption. We are indebted to to profeffor Jamefon for an account of the Wernerian method of colouring maps, communicated in the firft volume of the "Tranfactions of the Wernerian Society" lately publifhed.

The following rules fhould be obferved in illuminating maps for the above purpofe: 1. In every cafe fuch colours are to be ufed as will allow the ground-work of the map or delineations of the mountains to appear through them diftinctly. 2. The colours fhould agree as nearly as poffible with nature; they fhould correfpond with the moft common colour of the rock, or, at leaft, differ from it as little as poffible, and agree with the tranfition fuite of the colours. 3. The ufe of all bright colours muft be avoided. 4. The colours muft not be too pale or too deep, and they ought to be laid on as much as poffible of the fame intenfity: perfectly dark and light coloured rocks are exceptions to this rule. 5. The colours of mountain-rocks muft form fuites or tranfitions, in order to exprefs the tranfitions of the rocks into each other; at the fame time they muft be fufficiently diftinct from each other.

The following colours are employed by Werner for diftinguifhing the particular rocks:—quartz; reddifh-white, inclining a little to yellow:—topaz-rock; pale brick red:—granite; pale cochineal red, approaching carmine-red:—white-ftone; pale flefh-red:—gneifs; lilac-blue:—mica flate; pearl-grey:—primitive clay-flate; greenifh-grey, approaching to blue:—alum-flate; pale blueifh-black, approaching to grey:—fletz-flate; deep afh-grey:—grey-wacke-flate and grey-wacke; greenifh-grey, paffing into yellow:—trap-rocks, fuch as granular primitive trap, green-ftone, green-ftone flate, hornblende flate, blackifh-green inclining to blue:—bafalt; greenifh-black:—porphyry-flate; pale greenifh-black:—amygdaloid; pale greenifh-black, flightly inclining to brown:—ferpentine; pale piftachio-green:—talc and chlorite-flate; pale grafs-green:—porphyry; pale reddifh-brown, flightly inclining to yellow:—fienite; pale reddifh-brown, inclining to blueifh, that is, clove-brown paffing into blueifh-red:—granular primitive lime-ftone; pale Berlin-blue:—compact primitive lime-ftone; fmalt-blue, faintly inclining to red:—tranfition lime-ftone; indigo-blue, flightly inclining to grey:—fletz-lime-ftone; pale blueifh-grey:—chalk; blueifh-white:—calcareous tuf; fmoke-grey:—gypfum; pale fky-blue:—rock-falt, and rocks from which falt-fprings iffue; pale verdigris-green:—coal-formation; pale blackifh-brown, approaching to yellowifh-brown:—alum-earth and brown coal; liver brown:—conglomerate and clay-ftone; pale orange-yellow, flightly inclining to reddifh-brown:—fand-ftone; ftraw-yellow:—loam and clay; yellowifh-grey paffing into ochre-yellow:—iron-clay and calamine; pale ochre-yellow:—turf and peat; liver-brown ftreaks:—bog-iron ore; ochre-yellow ftreaks. All thefe rocks may, likewife, be diftinguifhed by particular figns or fymbols; for which, if they fhould be deemed ufeful, we refer to the Wernerian Tranfactions.

Not only particular rocks, but alfo formation fuites, may be reprefented in colours. Thus, the flate formation fuite will be red fhaded into blue, the blue into grey; this latter into green, and the green into yellow. The inflammable foffils, fubordinate to thefe formations, will be dark brown. The lime-ftone formation fuite will be blue, which will pafs into grey, and laftly into white. The falt and gypfum formation fuites, which are allied to the preceding, will be greenifh-blue and blueifh-green; the trap fuite, greenifh-black and blackifh-green, fhaded into blue; the porphyry fuite, light brown; the talc and ferpentine fuite, pale yellowifh-green.

The relative pofitions of the different rocks, Werner expreffed in the following manner: boundaries of fuperimpofed rocks are to be marked with a broad line of the fame colour as the rock, only darker; and where we are uncertain as to the fuperpofition of the rock, the junction is to be merely ftreaked. Beds, when they appear at the furface, fhould have their boundaries diftinguifhed by a broad, but darker, line of the fame colour as that of the rock of which they are compofed. When the beds are inclined, the lower fide fhould be marked with a broad line of the fame colour as the bed itfelf; but its upper fide by a broad dark line of the colour of the rock that refts on it.

Veins are reprefented by lines drawn in the direction of the veins of the diftrict. Metalliferous veins fhould be pointed out by red lines; and veins filled with mountain-rocks, by lines of the fame colour as the rock of which they are compofed.

The dip of the ftrata is expreffed by black coloured arrows, whofe length fhould be in proportion to the angle of inclination, and their direction to the point of the compafs towards which the ftrata dip or incline. When the ftrata are vertical, or under any angle from 90° to 80°, they are marked by two crofs lines, thus ×; horizontal ftrata, or ftrata under any angle from 0 to 10°, by two lines croffing each other at right angles, and having a head of an arrow at each extremity. The intermediate angles from 80° to 10° are marked by fimple arrows, one-eighth, one-fourth, and half an inch in length. The arrow one-eighth of an inch in length intimates that the ftrata are inclined at any angle between 80° and 60°; the arrow one-fourth of an inch in length, that the ftrata are inclined at any angle between 60° and 40°; the arrow half an inch in length, that the ftrata are inclined at any angle between 40° and 10°. The firft or fhorteft arrow is meant to point out ftrata inclined under an angle of 70°; the fecond arrow, ftrata under an angle of 50°; the third arrow, ftrata under an angle of 25°. Probably, according to Mr. Jamefon, an equally convenient mode would be, to mark the angle of inclination alongfide the arrow, and proportion its fize to the length of the map. Thus, if the map were on a large fcale, the arrow might be three-quarters of an inch long; if on a fmaller fcale, half an inch, or even one-quarter of an inch in length. The higheft points on a mountain-range, Werner diftinguifhes by a crofs, +; a level, by a figure refembling a door, ∩; and a fhaft, by a fmall parallelogram, ▭.

MAPANA, in *Geography*, a lake of Thibet, from which the Ganges is faid to iffue. The head of this majeftic river is compofed of two ftreams, which run weftward; and the fouthernmoft of thefe branches runs through two lakes, the firft of which is named Mapana, and the fecond "Lanken."

MAPANIA, in *Botany*, a name in Aublet, of whofe derivation or meaning no account is given, but which is retained by Juffieu and Vahl. Aubl. Guian. v. 1. 47. Vahl. Enum. v. 2. 391. Juff. 27. Lamarck Illuftr. t. 37.—Clafs and order, *Triandria Monogynia*. Nat. Ord. *Calamariæ*, Linn. *Cyperoideæ*, Juff.

Gen. Ch. *Cal.* Involucrum many-flowered, of three very large, fpreading, equal, ovate, acute, fmooth leaves, much longer than the flowers. Perianth inferior, of fix ovate, acute, concave leaves. *Cor.* none. *Stam.* Filaments three, inferted into the receptacle, capillary, longer than the calyx; anthers oblong, quadrangular, of two cells. *Pift.* Germen ovate, fuperior; ftyle thread-fhaped, equal to the ftamens; ftigmas three, awl-fhaped. *Peric.* none. *Seed* one, roundifh, naked.

Eff. Ch. Involucrum of three leaves. Perianth inferior, of fix leaves. Corolla none. Seed one, naked.

1. M. *fylvatica*. Aubl. t. 17.—Native of marfhy forefts, about

about the rivers Aroura and Orapu in Guiana, where Aublet found it flowering in June. One of his fpecimens is before us. *Root* perennial, creeping, firm, throwing up feveral fimple, triangular *ftems*, about two feet high, rough with minute harfh points or prickles, and clothed at the bafe with feveral fheathing, imbricated, membranous, reddifh *fcales* or *leaves*. The reft of the *ftem* is naked, but its top is crowned with the three fpreading *involucral leaves*, each five or fix inches long, obovate, pointed, ribbed, entire, fmooth, green, and foliaceous, in whofe centre is ftationed a round feffile head of feveral *flowers*. Vahl, who had examined a fpecimen, juftly remarks, that the leaves of the calyx are not toothed, as Aublet defcribes them, but entire.

MAPELLA, in *Geography*, a town of Italy, in the department of the Mincio.

MAPLE, in *Botany*. See ACER.

MAPLE *Tree*, in *Agriculture*, the common name of a tree of the deciduous kind, cultivated for the purpofes of timber and ornament in plantations and other grounds. There are feveral fpecies and varieties of this tree, as the great maple or fycamore, the common or fmaller maple, the afh-leaved Virginia maple, the Montpelier maple, the plane-tree like Norway maple, the fcarlet flowering maple, the fugar maple, the Tartarian maple, the Italian maple, the Pennfylvanian mountain maple, and the Cretan maple.

And there are two varieties of the great maple or fycamore, one with broad leaves and large keys, the other with variegated leaves: the latter, when blended in large plantations, affords a pleafing variety. This tree is frequently known by the name of *fycamore*, *mock plane*, and *plane tree*. See SYCAMORE.

The common maple is a tree of much humbler growth than the great maple, and by no means fo ornamental; it may, however, be ufeful in extenfive plantations and pleafure grounds. It is alfo very good for timber, being clofe in the grain of the wood. When cut down, it affords an excellent underwood.

The afh-leaved maple fhould be made ufe of in fituations that are not much expofed to the winds, as it is faid to be apt to be fplit by them. The wood is foft and brittle, and of courfe lefs ufeful as timber.

The Montpelier maple is chiefly ufeful for the variety it affords in ornamental plantations.

And the Norway maple is principally ufeful for affording fhelter, and alfo as a timber tree. There are two varieties, one with variegated or ftriped leaves, and the other with cut leaves.

There are two varieties of the fcarlet-flowering maple, the Virginian fcarlet-flowering maple, and fir Charles Wager's maple. Both of them are chiefly propagated for the fake of the flowers, which are of a fcarlet colour. The fort called fir Charles Wager's, produces larger clufters of flowers than the other, on which account it is in more eftimation.

In America, the inhabitants tap the fugar maple in the fpring, and boil the liquor, which affords an ufeful fugar. The fycamore, the afh-leaved, and the Norway maples alfo abound with a faccharine juice, from which fugar might probably be prepared with advantage in fome fituations.

The Italian maple is common in many parts of Italy, and is a lofty tree, and, from its having a fpreading head, adorned with large and beautiful foliage, deferves the attention of ornamental planters. It may be alfo ufeful as a timber tree, in fome cafes.

The Cretan maple is only ufeful as an ornamental tree. There is a variety of it, in which the leaves continue green moft part of the year, when fheltered, and which is denominated the evergreen Cretan maple.

It may be noticed, that all the forts and varieties of the maple are of eafy cultivation; each being capable of being raifed by feed, and many of them by layering, cuttings, and budding. They thrive well in moft foils and fituations, provided they be not too moift; the common forts fucceeding the beft in fuch as are deep and inclined to moifture, but not hard or ftiff; and the American kinds in thofe that have a dry and rather clofe ftate of mould or foil. In raifing them in the firft method, as the feeds do not, in all the forts, ripen well in this country, the beft way is to procure them from the places where they grow naturally. A cool fhady place is the moft fuitable for this purpofe. The mould being made fine, and nurfery beds marked out four feet wide, with length proportionate to the quantity, in thefe the feeds are to be regularly fown in the autumn, fifting over them the fineft mould to the depth of half an inch. When the plants are come up, they muft be kept clean from weeds, and frequently watered during fummer. In the fpring following, the ftrongeft may be drawn out and planted in nurferies, in rows two feet afunder, and at the diftance of a foot from each other in them, leaving the others to gain ftrength. In the fecond fpring, thefe alfo muft have the fame culture; and they may remain in the nurfery, without any other trouble than keeping the ground clean in the fummer, digging between the rows in the winter, and taking off all ftrong and irregular fide-fhoots, till they are fit to be planted out. The trees raifed in this way grow fafter, and arrive at greater heights, than thofe from layers; but they do not in general produce fuch quantities of flowers, which makes the latter mode more eligible for thofe who want thefe plants for low fhrubbery ufes. In thefe cafes, they fhould always have four or five years growth before they are finally planted out. It is, however, advifed by fome, that the feeds of the common or Norway maples fhould not be put into the foil immediately after becoming ripe, but be dried and preferved in fand till February or March, as the feafon may prove favourable, when they may be fowed in drills or beds eighteen inches broad, with alleys the fame width, and covered three quarters of an inch thick with mould. In the following February or March, the alleys fhould be dug, and the roots of the plants cut about five inches under ground, which may be eafily performed by means of a fharp fpade, drawing the plants out where too thick. Thefe may be replanted in any good mellow foil, in rows eighteen inches afunder, and eight or nine inches from each other in the rows. In October, when the plants in general will be about two feet high, both the feedlings and thofe that were tranfplanted fhould be raifed, fhortening their tap-roots, cutting off any crofs lateral branches, and removing them into rows two feet and a half apart, and fifteen inches diftant in them, in order that they may continue for a year or two. Remove them again at the fame feafon the fucceeding year, and plant them in rows five feet afunder, and two and a half from each other, that they may continue four years. Thefe will now be from twelve to fifteen feet high; and if required of a ftill larger fize, they may be removed, and planted again eight or ten feet afunder; when, any time after two and not exceeding eight or ten years, they may be finally planted out where they are to remain. The ufe of removing thefe trees frequently when young is, that they are apt naturally to grow with tap-roots, which this management prevents, and makes the plants root better, and become more eafy and certain in their growth, when tranfplanted at a large fize. The timber forts are beft raifed from the feeds, without being removed at all. Though all the

the ſpecies are capable of being propagated by layers, it is never practiſed for the common maple. In this method the young ſhoots may be laid down at any time, in the autumn, winter, or early in the ſpring; but the firſt is probably the beſt. By the ſame time in the following year they will have ſtruck root, and have become good plants, when the ſtrongeſt may be ſet out in the places where they are to remain; while the weakeſt may be planted in the nurſery, in the ſame manner as the ſeedlings, for a year or two, in order to gain ſtrength.

But in propagating by cuttings, though all theſe trees are capable of it, it is a method chiefly practiſed on the aſh-leaved and Norway maples, as they take root this way more readily. The cuttings ſhould be taken from the bottom part of the laſt year's ſhoots early in October, and be planted in rows in a moiſt ſhady place. In the ſpring and ſummer following they ſhould be watered, as often as dry weather makes it neceſſary, and be kept perfectly clean from weeds. In the autumn they will be fit to remove into the nurſery; though if the cuttings are not planted too cloſe, they may remain in their ſituations for a year or two longer, and then be finally ſet out without the trouble of being previouſly planted in the nurſery. Theſe trees are alſo to be raiſed by budding and grafting, but as the other methods are more eligible, theſe are ſeldom or ever practiſed, except for the variegated ſorts and the large broad-leaved kind. The latter indeed is to be continued in no other way than by budding it on ſtocks of the common ſycamore; as the ſeeds, when ſown, afford only the common ſycamore. But the ſeeds of the variegated kinds produce variegated plants; which renders the propagation of theſe ſorts very expeditious where plenty of ſeed can be had. But where it is not to be obtained, in order to propagate theſe varieties, recourſe muſt be had to budding; in performing which ſome plants of the common ſycamore one year old, are to be taken out of the ſeed-bed and placed in the nurſery in rows a yard aſunder, and about a foot and a half diſtant from each other in the rows. The ground muſt e kept clean from weeds all ſummer, and be dug, or, as the gardeners call it, *turned* in the winter; and the ſummer following the ſtocks will be of a proper ſize to receive the buds, which ſhould be taken from the moſt beautifully ſtriped branches. The beſt time for this operation is about Auguſt; as, if it is done earlier the buds will ſhoot the ſame ſummer, and when this happens a hard winter is apt to kill them. Having budded the ſtocks the middle or latter end of Auguſt, the eyes, or buds, being inſerted on that ſide the ſtock which faces the north towards the beginning of October, the baſs by which it was tied may be removed, as it will begin to pinch and confine the bark as well as the bud too much. In the ſpring, juſt before the ſap begins to riſe, or the trees begin to ſhoot, the head of the ſtock ſhould be cut off in a ſloping direction juſt above the inſerted; by theſe means, and that of rubbing off ſuch ſhoots as come from the ſtocks, the ſhoot from the inſerted bud will be rendered more ſtrong and healthy. The trees thus raiſed may remain in their ſituations for a year or two longer, or be tranſplanted into the places where they are intended for, in the autumn or ſpring following; care being conſtantly taken to keep the land between the rows well dug, ſo as to prevent their being injured by the growth of coarſe weeds, and the ſide buds trimmed from their ſtocks occaſionally.

In reſpect to the time of planting, the autumn ſeaſon is upon the whole the beſt time for planting theſe and other deciduous trees, when they are ſtrong and well rooted; yet when very young they are apt to be injured by froſts, and to be thrown out of the ground in ſevere winters, when planted in that ſeaſon of the year. In ſuch caſes the ſpring is better.

MAPLE *Sugar*, a kind of ſugar made from a ſpecies of the maple, called by Monſieur Sarazin, *acer Canadenſe ſaccchariferum fructu minori*. M. Sarazin, a phyſician at Quebec, intending to inquire at large into the nature of this ſort of ſugar, obſerved that there were four ſpecies of maple common in the places where it was made, all which he ſent over to the garden at Paris. One of theſe ſpecies, diſtinguiſhed from the reſt by the ſmallneſs of its fruit, is called the ſugar-maple; this grows to ſixty or eighty feet high, and its juice, which is very redundant in the months of April and May, is eaſily made into a very good ſugar. They procure this juice from the tree by piercing a hole into the trunk, and placing veſſels to receive it. This juice, being evaporated, yields about one-twentieth part of its own weight in pure ſugar. A middle-ſized tree, of this ſpecies, will yield ſixty or eighty pints of this juice, without receiving any damage as to its growth; and much more than this may be drawn, but then the tree manifeſtly ſuffers for it.

M. Sarazin obſerved ſome very remarkable particulars in regard to the ſaccharine quality of this juice, without which it never had it in the proper perfection. 1. The tree, at the time that the juice is drawn out, muſt have its bottom covered with ſnow; and if it is not naturally ſo, the Indians know ſo well the neceſſity of it, that they always bring ſnow from elſewhere, and heap it up round it. 2. This ſnow muſt afterwards be melted away by the ſunſhine, not gradually thawed by a warm air. 3. There muſt have been a froſty night before the opening of the hole in the trunk. It is remarkable that theſe circumſtances are ſuch as cuſtom and experience alone could have pointed out, ſince they ſeem contrary to reaſon; and ſo it is in many of the operations in chemiſtry, where the moſt ſeemingly rational means fail, while thoſe which ſhould ſeem quite contradictory to reaſon ſucceed. It is obſerved, that if the juice of the maple be not in a condition to become ſaccharine while the ſnow lies at its root unthawed, that it almoſt immediately becomes ſo on the melting of the ſnow, and its penetrating into the earth. Mem. Acad. Par. 1730.

The juice of the maple, unboiled, has been drank as an antiſcorbutic; the ſugar and molaſſes, which are ſaid to be leſs ſweet than thoſe extracted from the ſugar-cane, are ſuppoſed to be more medicinal in diſorders of the breaſt.

MAPLE *Iſlands*, in *Geography*, two ſmall iſlands of America, in lake Superior, near the E. coaſt. N. lat. 46° 44'. W. long. 84° 54'.

MA-POU-HOTUN, a town of Corea; 46 miles E.N.E. of Peking.

MAPOURIA, in *Botany*, Aublet. Guian. v. 1. 175. t. 67, a ſhrub of Guiana, found by Aublet on the banks of the river *Sinemari*, flowering in September. It is called by the natives *Maypouri-crabli*, becauſe the *maypouris*, or wild cattle, are fond of the leaves and branches, and thence the above name was conſtructed. The *root* throws up many ſoft, brittle, juicy *ſtems*, about eight or nine feet high, clothed with a greeniſh bark. *Leaves* oppoſite, each pair croſſing the next, oval, pointed, entire, pliable, ſmooth and ſhining, with one rib, and numerous tranſverſe parallel veins; each leaf eight inches long at moſt, and about half as broad, ſupported by a *footſtalk* an inch in length. *Stipulas* intrafoliaceous, in pairs, ovate, large, deciduous. *Panicle* terminal, trichotomous, many-flowered, with oppoſite minute *bracteas* at its ſubdiviſions. *Flowers* ſmall. *Calyx* ſuperior, of five teeth. *Corolla* white, of one petal, its

its limb in five fegments, about twice the length of the tube. *Stamens* five, as long as the limb, inferted into the tube between the fegments. The mouth of the tube is befet with white hairs. *Germen* inferior, oval; ftyle fimple, as long as the ftamens; ftigma of two oblong lobes. *Fruit* unknown.

Juffieu, Gen. 205. prefumes this plant to be of the fame genus with the *Simira* of Aublet, t. 65, and perhaps with his *Palicourea*, t. 66. The latter is the *Stephanium* of Schreber, of which we fhall fpeak in its proper place, and was referred by Solander to *Muffaenda*. They appear to us very near to *Pfychotria*, at leaft to fome plants referred to that genus. They all belong to the *Pentandria Monogynia* of Linnæus, and to the feventh fection of Juffieu's great natural order of *Rubiaceæ*.

MAPPARIUS, an officer among the Romans, who in the public games, as thofe of the circus, and of the gladiators, gave the fignal for their beginning, by throwing an handkerchief (*mappa*) which he had before received from the emperor, conful, prætor, or other fupreme officer then prefent.

MAPPIA, in *Botany*, received its name from Schreber, in memory of Mark Mappi, M.D. formerly a phyfician and botanift at Strafburgh, who in 1691 publifhed a 12mo. catalogue of the plants in the public garden of that univerfity. He alfo publifhed, as Profeffor, fome inaugural differtations on tea, coffee and chocolate, and on the rofe of Jericho. His *Hiftoria Plantarum Alfaticarum* appeared in 1742, after the author's death, by the care of Dr. Ehrmann, of the fame place. This is a quarto volume of 335 pages, with a few plates, difpofed in alphabetical order. Mappi died in 1701, at the age of 69. Schreb. Gen. 806. Mart. Mill. Dict. v. 3. (Soramia; Aubl. Guian. 552. t. 219. Juff. 433. Lamarck Illuftr. t. 463.)—Clafs and order, *Polyandria Monogynia*. Nat. Ord. uncertain, Juff.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in five deep, roundifh, concave, permanent fegments, coloured on the infide. *Cor.* Petals five, roundifh, fpreading, fcarcely longer than the calyx, fupported by fhort claws. *Stam.* Filaments numerous, (about 60,) the length of the corolla, capillary, dilated upwards, inferted into the receptacle; anthers ovate. *Pift.* Germen fuperior, globofe; ftyle cylindrical, incurved; ftigma capitate. *Peric.* Berry ovate, of one cell. *Seed* folitary, large, ovate, involved in a thick vifcid tunic.

Eff. Ch. Calyx of five leaves. Petals five. Berry fuperior, of one cell. Seed folitary, involved in a vifcid tunic.

1. M. *fcandens*. (Soramia guianenfis; Aubl. Guian. t. 219.)—Found by Aublet on the banks of the river Sinémari, bearing flowers and fruit in May. The *ftem* is fhrubby, with tuberculated branches, and twines about the trunks of trees, climbing to their fummits, where the ultimate fhoots become very long and pendant, bearing alternate, obovate, entire, fmooth, flefhy *leaves*, fix inches long at the utmoft, and about half as wide, each fupported by a *footftalk* an inch in length. *Flowers* white, in fmall, lax, axillary or lateral, corymbofe clufters. *Stamens* about 60, according to Aublet's French defcription, which is always the moft authentic; the Latin one, made from it by other hands, fays 160, an error which Schreber has incautioufly adopted. *Berry* red, the fize of a cherry, crowned with the permanent ftyle; its fubftance firm, flefhy, flightly acid. The tunic of the *feed* is thick, white and vifcid. Permanent *calyx* flefhy and deep red.

MAPROUNEA, the barbarous name in Aublet, who gives no account of its meaning or derivation, for a fmall tree of Cayenne, the *Aegopricon betulinum*, Linn. Suppl. 63. 413. Sm. Plant Ic. t. 42. (Maprounea guianenfis; Aubl. Guian. 895. t. 342.) See AEGOPRICON. We beg leave to correct one of our predeceffors as to the origin of this name. It feems to be formed of αἴξ, *a goat*, and κόπρος, *dung*, in allufion to the fhape of the fruit, which refembles the dung of goats or fheep. It ought rather therefore to have been written *Aecopricon*.

MAPUNCO, in *Geography*, a town of Africa; in the kingdom of Angola.

MAQUALBURY, a river of Africa, which runs into the Atlantic, about 10 miles S.E. from the Scherbro. N. lat. 6° 50'. W. long. 10° 30'.

MAQUEDA, a town of Spain, in New Caftile; 32 miles S.W. of Madrid.

MAQUILAPA, a town of Mexico; 15 miles S.W. of Chiapa.

MAR, in *Rural Economy*, a provincial term fignifying a river or fmall lake.

MARA, in *Mythology*, a name of the Hindoo god of love, *Kama*; which fee.

MARA, *Madame*, in *Biography*, born Schmeling, a native of Germany, arrived in England in 1760, with her father, during childhood, when fhe acquired a very correct pronunciation of our language, which is never done by foreigners but in youth. She could not be more than nine or ten years old when fhe came hither, yet fhe was then a notable performer on the violin; and as there were feveral children at that time in London of uncommon proficiency on different inftruments, a concert was made for them at the Little Theatre in the Haymarket, in which they feverally difplayed their talents; Baron and Schmeling on the violin; Mifs B. on the harpfichord, and Cervetto on the violoncello.

After ftaying two or three years in England, and, we believe, performing on the violin in different parts of the kingdom, to the great furprife and pleafure of the lovers of mufic, fhe returned with her father to Germany, and we heard no more of her till the year 1771, when we received from a very intelligent mufical friend at Hambro' the following letter.

"At Berlin there is now a German opera finger, that aftonifhes every one who hears her. People who have been a long time in Italy, and who have formerly heard Fauftina, Cuzzoni, and Aftrua, affure me that fhe furpaffes them all. Indeed, when I heard her at Leipfic, two years ago, I was enraptured. I never knew a voice fo powerful, and fo fweet at the fame time; fhe could do with it juft what fhe pleafed. She fings from G to E *in altiffimo* with the greateft eafe and force, and both her *portamenta di voce*, and her volubility are, in my opinion, unrivalled; but when I heard her, fhe feemed to like nothing but difficult mufic. She fung at fight, what very good players could not play, at fight, on the violin; and nothing was too difficult to her execution, which was eafy and neat. But, after this, fhe refined her tafte, infomuch that fhe was able to perform the part of "Tifbe," in Haffe's opera, which requires fimplicity and expreffion, more than volubility of throat; and in this fhe perfectly fucceeded, as Agricola, the tranflator of Tofi's "Arte del Canto," and our beft finging mafter in Germany, affures me. The king of Pruffia, a great connoiffeur, was aftonifhed at it. Her name is Schmeling, fhe is about twenty-four years of age, and was in England, when a child, where fhe played the violin; but fhe quitted that inftrument, and became a finger, by the advice of Englifh ladies, who difliked a *female fiddler*." The next year, in travelling through Germany, this account was fully corroborated by feveral intelligent muficians who had heard her; and previous to our arrival at Berlin, we were informed that his Pruffian majefty,

majefty, who, at firft, with difficulty was prevailed on to hear "a German finger," exclaimed, "I fhould as foon expect to receive pleafure from the neighing of my horfe." However, after his majefty had heard her fing one fong, he was faid to have fought among his manufcript mufic for the moft difficult airs in his collection, in order to try her powers, as much as to gratify his own ear; but fhe executed, *at fight*, whatever he commanded her to perform, in all ftyles, as well as if fhe had practifed each of thefe compofitions during her whole life.

When, afterwards, we had an interview with her at Berlin, we find in our journal the following account of her perfon: "She is fhort, and not handfome, but is far from having any thing difagreeable in her countenance; on the contrary, there is a ftrong expreffion of good nature impreffed upon it, which renders her addrefs very engaging. Her teeth are irregular, and project too much, yet, altogether, her youth and fmiles taken into the account, fhe is rather agreeable in face and figure."

We found that fhe had preferved her Englifh; indeed fhe fometimes wanted words, but having learned it very young, the pronunciation of thofe which occurred was perfectly correct. She was prevailed upon by a friend, who had procured us this interview, to fing foon after our entrance. She began with a very difficult *aria di bravura*, by Traetta, which we had heard before at Mingotti's in Munich. She fung it admirably, and fully anfwered the great ideas which we had formed of her abilities, in every thing but her voice, which was a little cloudy, and not quite fo powerful as we expected. However, fhe had a flight cold and cough, and complained of indifpofition; but with all this, her voice was fweetly toned, and fhe fung perfectly well in tune. She has an excellent fhake, a good expreffion, and a facility of executing and articulating rapid and difficult divifions, that is aftonifhing.

Her fecond fong was a *larghetto*, by Schwanenburg, of Brunfwick, which was very pretty in itfelf; but fhe made it truly delightful by her tafte and expreffion: fhe was by no means lavifh of graces, but thofe fhe ufed were perfectly fuited to the ftyle of the mufic, and idea of the poet.

After this, fhe fung an *andante*, in the part which fhe had to practife for the enfuing carnival, in Graun's "Merope;" and in this acquitted herfelf with great tafte, expreffion, and propriety.

In a fecond vifit to Mademoifelle Schmeling, fhe favoured us with feveral fongs of uncommon rapidity and compafs; her powers in thefe particulars were truly aftonifhing; but we found that fhe was frequently compelled to abufe thofe powers by the airs which were given her to execute, in which fhe had paffages that degraded the voice into an inftrument; indeed fuch as a player of tafte would be afhamed to execute on any inftrument. Breaking a common chord into common *arpeggios* of no meaning, fuch as may be feen in the fecond allegros of Corelli's firft and third folos, does not feem to reflect much honour, either upon a compofer or performer. Geminiani, in transforming thefe folos into concertos, omitted thefe violin *folfeggios* or exercifes for the hand in private practice.

We found in this fecond vifit to Mademoifelle Schmeling, a little want of brightnefs in the middle of her voice; and we then imagined it poffible for her ftill to improve in finging adagios, though not in the execution of allegros. She did not then indeed feem to be placed in the beft fchool for advancement in tafte, expreffion, and high vocal finifhing.

In the fpring of 1784, Mademoifelle Schmeling arrived in England under the name of Mara, having been fome time married to a performer on the violoncello, in the fervice of prince Henry, brother to the king of Pruffia, with whom fhe was connected in 1772, when we faw her at Berlin. There had been a correfpondence opened between this admirable finger and the proprietors of the Pantheon, who wifhed much to engage her as a fucceffor to the Agujari; but the king of Pruffia would not let her quit his capital; and after fhe had executed an article which engaged her in the fervice of the Pantheon, and money had been remitted to her to defray the expences of her journey, on his Pruffian majefty difcovering that fhe intended to quit his fervice *a la fourdine*, he had her arrefted and thrown into prifon; and it was with extreme difficulty that fhe contrived, by means of our ambaffador, fir James Harris, to let the proprietors of the Pantheon know that fhe could not fulfil her engagement, and entreated them, for God's fake, not to write to her any more. She, however, very honeftly returned the money that had been advanced to her by the proprietors of the Pantheon.

At length, however, fhe obtained her difmiffion, and engaged herfelf to perform fix nights at the Pantheon; 1784 was not an aufpicious year for the Pantheon. The diffolution of parliament and general election happening foon after her arrival, the audiences to which fhe fung were not very numerous, nor had her performance the effect it deferved, till fhe fung at Weftminfter Abbey; where fhe was heard by near three thoufand of the firft people in the kingdom, not only with pleafure, but extacy and rapture.

In 1786, the opera regency, after a bankruptcy, being fettled, and fir John Gallini inverted with the power of ruining himfelf and others, "Didone Abbandonata," a pafticcio ferious opera, was brought out previous to the arrival of Rubinelli, and had confiderable fuccefs. But this muft be wholly afcribed to the abilities of Madame Mara, who fung on our opera ftage for the firft time. Indeed, fhe was fo fuperior to all other performers in the troop, that fhe feemed a divinity among mortals. The pleafure with which fhe was heard, had a confiderable increafe for her choice of fongs; which, being in different ftyles by Sacchini, Piccini, Mortellari, and Gazzaniga, were all feverally encored during the run of the opera; a circumftance which we never remember to have happened to any other finger, except Manzoli.

The manner in which fhe fung Handel's oratorio mufic in Weftminfter Abbey, and continued to fing it elfewhere, had gained her more applaufe and favour with the Englifh public, than her aftonifhing execution.

This great vocal performer, except a few fhort excurfions to the continent in fummer, continued to refide in England, and to enjoy the favour and admiration of the public, till the latter end of 1802; when fhe returned to Germany, and is faid to have been received at Berlin, and heard with the fame enthufiafm which fhe had excited 30 years ago. We have done ample juftice to the talents of this extraordinary finger on many occafions. But we cannot quit this article without a few difcriminative reflections, not to injure or extend her fame, but to manifeft our fincerity as well as candour in drawing characters.

We have never been able to difcover of whom the Mara, after quitting the violin, learned to fing; but we are inclined to think that it was not of an Italian mafter; and that if it was of a German, it was of an inftrumental performer. Perhaps the whole of her ftudy in finging was to imitate the inftruments of great performers. In the humble ftate in which fhe had travelled with her father, fhe could have had no opportunities of hearing fine Italian finging by performers of the firft order. And it has often been obferved by thofe accuftomed to exquifite Italian finging, that her cadences, expreffion, and execution, however excellent, favoured more of inftrumental perfection than vocal. Her recitative was not fpoken with Italian energy; and when we confider what a good performer fhe had been, early in life, on the violin, and what a good player fhe afterwards became on the piano-forte; or, in other words, what an excellent mufician fhe was, and with what facility fhe could execute all kinds of difficulties, we have been often furprized at the little novelty, variety, and refined tafte, there was in her clofes. Indeed it will perhaps be faid, that fhe brought here, and left behind her, in this country, fcarcely a new vocal paffage; as all other great fingers, fuch as in our own memory, Mingotti, Elifi, Manzoli, Pacchierotti, Rubinelli, and Marchefi had done; but all thefe remarks only confirm old proverbs, that neither human nature, nor human art, are ever to be perfect, and that we cannot have every perfection in one and the fame individual.

MARA, in *Geography*, a mountain of Malacca, near the Straits. N. lat. 1° 55′. E. long. 104 39′.

MARAASCIAN, a town of Turkeftan, on the Sirr; 130 miles S.S.E of Andugar.

MARABAD, a town of Perfia, in the province of Segellan; 120 miles N N.E. of Zareng.

MARABEA, a town of Arabia, near the Red fea, formerly a fea-port, but fince the harbour has been filled up, moft of the inhabitants have fettled at Loheia; eight miles N. of Loheia.

MARABONA BAY, a bay on the N. coaft of Jamaica. N. lat. 18° 31′. E. long. 77° 21′.

MARABOU, an inlet of the harbour of Alexandria, in Egypt, fituated at its weftern extremity, commanding one of the channels, and feparated from the continent by a range of rocks 140 yards in extent. The length of the iflet is not above 300 yards, and its breadth 150. The French, during their abode in Egypt, conftructed a ftrong regular fort on this iflet round a tower, which was formerly a mofque.

MARACA, a fmall ifland in the Atlantic, near the coaft of Guiana. N. lat. 2′. W. long. 51° 26′.—Alfo, a town of South America, in the government of Caraccas; 50 miles S.W. of Leon de Caraccas.

MARACAGUACO, a branch of the Amazons' river, which joins the main ftream; 40 miles S.W. of Pauxis.

MARACAJA, in *Zoology*. See FELIS *Tigrina*.

MARACAIBO, a province of South America, in the government of Caraccas, furrounding a lake of the fame name; bounded on the N. by the Caribbean fea; on the E. by Venezuela; on the W. by the government of Rio de la Hache, dependent on the vice-royalty of New Granada; and on the S. by Varinas, and the kingdom of Santa Fé. This province covers but a fmall extent from E. to W., but ftretches more than 100 leagues towards the fouth. The foil of Maracaibo is, for a certain diftance from the capital, ungrateful; on the eaftern bank the lake is dry, unhealthy, and unfruitful. On the weft bank of the lake, the land does not begin to be fertile at more than 25 leagues to the fouth of the city. All that lies to the fouth of the lake may vie with the beft lands of South America. The population is eftimated at 100,000. In this province are 300 European regular troops, 100 artillery-men, and 810 militia.—Alfo, a lake of this province, lying from N. to S., communicating at one extremity with the fea. Its length from the bay to its moft fouthern receſs, is, according to Oviedo, 50 leagues, its greateft breadth 30, and its circumference upwards of 150. This lake may have owed its formation to the flow and gradual excavation occafioned by numerous rivers, which, flowing from E., W., and S., here terminate their courfe. It is eafily navigated, and carries veffels of the greateft burden. All the produce and provifions of the interior, intended for confumption or fhipping at the town of Maracaibo, are conveyed by the rivers which difcharge themfelves into this lake. Hurricanes are not unfrequent in this lake, and yet there is always a kind of undulation on the furface of the water, fo that, on particular occafions, its waves are fufficiently agitated to bury under them the canoes and fmall craft. At this time the waters of the fea force themfelves into the lake, and give a brackifh tafte to it as far as Maracaibo; but at all other times it is frefh and fit for drinking as far as the fea. The baths which are ufed there, and which the intenfe heat of the country renders indifpenfible, are attended with very falutary effects. All the different kinds of fifh furnifhed by the rivers of South America abound in this lake. To the N.E. of it, in the moft barren part of the borders, and in a place called "Mena," there is an inexhauftible mine of mineral pitch, which, mixed with fuet, is ufed for graving veffels. The bituminous vapours iffuing from this mine are eafily inflamed, and in the night luminous corrufcations are vifible, which refemble lightning, and which are denominated the lanterns of Maracaibo, becaufe they ferve for a light-houfe and compafs to the Spaniards and Indians who navigate the lake. The fterility, and alfo the noxious atmofphere of the borders of the lake, difcourage culture and population. The Indians are fo unhealthy, that they prefer dwelling on the lake itfelf to taking up their abodes on its borders. The Spaniards found on this lake feveral villages, built without order, and without apparent defign, but with folidity. Hence they gave them the name of "Venezuela," a diminutive of Venice, which they have not retained, but which has fince been applied to the whole province. Four of thefe villages remain, and the Indians who inhabit them have a church, which is under the care of a curate, who is entrufted with the charge of adminiftering fpiritual aid among the aquatic Indians. The great refource and chief employment of thefe people is the hunting of wild ducks, which they take by thrufting their heads into empty calabafhes, clofed fo that they may fee without being feen, and fwimming to the place where the ducks are, which they lay hold of by the legs, before they are alarmed, and tying them to their belts, thus bring them to the fhore.

The goodnefs of the foil in the weftern part has induced fome Spaniards, regardlefs of the infalubrity of the air, to fix their habitations there, in order to raife cocoa and provifions. Thefe fettlements, which were very much difperfed, were not able to command fufficient funds for laying the foundation of a village, much lefs of a city. There is but one chapel, placed nearly in the centre of the fcattered habitations, and a curate for performing divine fervice, and adminiftering the facrament. The fouthern extremity of the lake is uncultivated and uninhabited. The northern part is quite as hot as the other parts, but much more healthy.—Alfo, a town or city which is the capital of the province of the fame name, fituated on the left bank of the lake to the weft, at the diftance of about fix leagues from the fea, on a fandy foil, and in a hot dry climate, chiefly experienced from March to October; but in July and Auguft the air feems to proceed from a furnace. The only antidote is to bathe in the lake; and endemial diforders are unknown. The thunder-ftorms and torrents are here terrible; and if they fail, earthquakes certainly follow. Although many houfes are built of lime and fand, and with confiderable tafte, moft of them are meanly covered with reed, and there is no water but that which is derived from the lake, which is falubrious, though not pleafant, efpecially in March and April, when the ftrong breezes impregnate it with fea-fpray. The principal part of the city is on the fhore of a fmall gulf, one league in depth, which

which forms the lake towards the weſt. The other part is to the north, in the neck of the lake, which at this place is three leagues wide, whence it begins to extend towards the ſouth. The point where the city begins is called "Maracaibo Point;" that where the gulf commences "Point Arića," ſituated almoſt oppoſite to "Point St. Lucia." According to an enumeration in 1801, there were about 22,000 inhabitants; and they were increaſed by the Spaniſh refugees from St. Domingo. With this acceſſion, the population was raiſed to about 24,000 perſons, who are diſtributed into four claſſes; the nobility, conſiſting of about thirty families; white planters, compoſed of Europeans or Creoles, who apply to agriculture, navigation, commerce, the fiſheries, &c. and live comfortably; ſlaves and freemen, who exerciſe all kinds of trades, joiners, tailors, ſhoe-makers, carpenters, maſons, and ſmiths. The ſlaves do not exceed 5000. The habit of failing on the lake encourages the ſpirit of navigation, and many of the natives become ſeamen. Even in the dry Savannas they contrive to feed numerous herds; and the youth are celebrated for intelligence and ingenuity; but the inhabitants are rather noted for want of probity. The women are fond of the harp, which reſounds in the ſtreets in the evening. In their youth they are diſtinguiſhed by their modeſty, and, when married, are faithful affectionate wives and excellent mothers, directing their attention to domeſtic cares, and the education of their children. Here is only one church, aided by a chapel of eaſe, and a convent of Franciſcans. At Maracaibo they adore a virgin, which bears the ſurname of "Chiquinquira," which was the name of a village in the kingdom of Santa Fé, where ſhe made her firſt appearance. Her paſſion is to paint herſelf on diſh-clouts, and in the midſt of filth. A temple, on the diſcovery of her in 1586, was dedicated to her; and, as the fabulous tradition reports, a fountain roſe under the altar where ſhe was placed. She communicated to its waters miraculous virtues, which have given to her permanent reputation among the Spaniards. The image of this virgin is placed in the chapel of eaſe of St. Juan de Dios, where ſhe is invoked by all mariners as their imaginary protectreſs. The foundation of this town was laid, in 1571, by captain Alonſo Pacheco, an inhabitant of Truxillo, under the name of New Zamora, now known only under that of Maracaibo. At the entrance into this port is a bar of quick-ſand, ten or twelve feet under water, which excludes large veſſels, and admits ſmall ones with difficulty, and not without the conduct of a ſkilful pilot. As ſoon as the bar is cleared, there is plenty of water and a good harbour, which is defended by three forts. The manufactures and merchandiſes that are brought hither from places near the lake are put on board Spaniſh ſhips that come hither to purchaſe them. Maracaibo is the ſeat of a governor, who enjoys the ſame ſalary, and exerciſes the ſame functions, as the governor of Cumana. This place is very convenient for ſhip-building: 270 miles E. of Carthagena. N. lat. 10° 30′. W. long. 71° 46′. Depons' Travels in South America.

MARACANA, a town of Braſil, in the government of Para, on a river which runs into the Atlantic; 80 miles N.N.E. of Para. S. lat. 0° 27′. W. long. 49°.

MARACANA, in *Ornithology*, the name of a bird of the parrot-kind, but larger than the common ſpecies, and covered all over with blueiſh-grey feathers. It is very common in the Braſils. See PSITTACUS *Cinereus*.

The natives alſo call another bird of the parrot-kind by the ſame name, which is of a fine green on the head, neck, and back, but the crown of the head looks a little blueiſh; the tail is mixed of red and a blueiſh-green; the under part being red, as is alſo the under part of the wings; at the origin of each wing, it has alſo a red ſpot; and on each ſide of the head a brown one. The noiſe this bird makes is oe, oe, oe. See PSITTACUS *Severus*.

MARACANDA, in *Ancient Geography*, a very conſiderable city of Aſia, and capital of Sogdiana, which was captured by Alexander the Great, who, after leaving a ſtrong garriſon there, burnt and laid waſte all the plains. See SAMARCAND.

MARACAPA, in *Geography*, a town of South America, and capital of a diſtrict of the ſame name, in the province of Cumana; 42 miles W. of Cumana.

MARACAXAO, in *Ornithology*. See FRINGILLA *Melba*.

MARACAY, in *Geography*, a beautiful new village of South America, in the government of Caraccas, ſituated in the rich vales of Aragoa, 40 miles S.W. of Caraccas; famous for the culture of chocolate. The induſtrious inhabitants, moſtly Biſcayans, have been computed at more than 8000, and the vicinity is crowned with numerous plantations of cotton, indigo, coffee, and grain.

MARACCI, LEWIS, in *Biography*, a learned Italian, was born at Lucca in the year 1612: in his youth he applied himſelf moſt diligently, and with great ſucceſs, to the ſtudy of the eaſtern languages, particularly to the Arabic. His ſkill in this tongue led to his appointment to the profeſſorſhip of Arabic in the college of wiſdom. He was alſo ſelected by pope Innocent XI. as his confeſſor, which mark of high confidence and honour would have been followed by a cardinal's hat, but the humility of Maracci led him to decline that diſtinction. He died in the year 1700, at the great age of eighty-eight. He had a conſiderable ſhare in editing the "Arabic Bible," which was publiſhed at Rome in the year 1671, in three volumes folio: he is known alſo for a work which he printed in Padua but two years before his death, entitled "Alcorani Textus Univerſus Arabicè et Latinè," in two vols. folio. This verſion is accompanied with notes, a refutation of the Mahometan doctrines, and a life of the Pſeudo-Prophet. The work, though not wholly free from errors, is highly applauded by the learned. Maracci was author alſo of "The Life of Father Leonardi," the founder of the congregation to which he belonged, and of numerous other pieces.

MARACU, in *Geography*, a river of Braſil, which runs into the Atlantic, S. lat. 2° 40′. W. long. 45° 31′.

MARADECANUM, a town of Hindooſtan, in the circar of Cicacole; 15 miles N.E. of Tickely.

MARÆNA, in *Ichthyology*. See SALMO *Maræna*.

MARAGA, MARAGHA, or *Mirga*, in *Geography*, a town of Perſia, in the province of Adirbeitzan; 30 miles S. of Tabris. N. lat. 37° 20′. E. long. 46° 22′.—Alſo, a town of Egypt, on the left bank of the Nile, the environs of which are ſaid to yield the beſt wheat in Egypt; 6 miles S. of Taha.

MARAGAL, a town of Perſia, in Adirbeitzan; 42 miles S. of Tabris.

MARAGHA, a town of Syria, in the Deſert, where an obſervatory was erected by order of Hulaku, one of the deſcendants of Jenghiz Khan, and furniſhed with inſtruments for aſtronomical obſervation; 75 miles E.S.E. of Aleppo.

MARAGNON. See MARANON.

MARAH, or MARRA, a town of Syria, in which the Roman Catholics have a church, and the Greeks a church and convent; 15 miles N.E. of Damaſcus.

MARAHBUTS, or MARABOUTS, derived from a word which ſignifies a monk, or a man engaged to the performance of his vow, denote Mahometan prieſts, who are diſperſed through various parts of Africa. Thoſe of the Mandingo nation

nation apply themſelves, beſides religious matters, to the ſtudy of phyſic, as far as it depends on mere experience, without entering into the inveſtigation of the cauſes of diſeaſes. They are alſo often called upon by the kings and chiefs to give their opinion in caſes of law and equity. Moſt of them are well verſed in the Arabic language of the Mauritanic dialect, and they are the only people of letters among the blacks; for none of the black nations about Senegal and Gambia have even an alphabet, much leſs any writings in their own languages. The ſelling of charms is ſaid to conſtitute the greateſt part of their revenue; and the more reputation any one of them has acquired, the dearer is it ſold. Theſe charms uſually conſiſt in nothing but a few lines taken from the Koran, written on a little piece of paper, which, after being nicely ſewed up in leather or cloth, are worn by the purchaſers about their necks. They are deſigned to protect and defend them in danger; but as one charm has only the power of preſerving them from one kind of danger, they are obliged to have many of them; ſo that many of the blacks are covered with them in different parts of the body; and they have ſuch a ſtrong faith in them, that when they are ſurpriſed in the night-time by an enemy, they will not take up arms for their own defence, though in the moſt imminent danger, till they have dreſſed themſelves with theſe charms, and then they will meet him undauntedly. This faith in charms, however, is a corruption of the Mahometan religion; and the Moors, who live on the north ſide of the river Senegal, obſerving it in its purity, make no uſe of them.

The Marahbuts of the black nations, as well as thoſe of the Moors, are alſo the principal merchants, and the moſt opulent people among them, and the gum trade on the river Senegal is chiefly carried on by thoſe of the Moors. The Marahbuts are alſo the only people who can travel with any ſafety into diſtant kingdoms, which no layman can well do without running the riſk of being made a ſlave. Their religious profeſſion protects them every where; they are even reſpected among thoſe nations who are not Mahometans; and they are conſidered by them as a godly and virtuous people, and men of wiſdom. They make proſelytes every where to the Mahometan religion, and are induſtrious in ſpreading it all over Africa. Some Marahbuts of the Foolah nation who viſit Senegal, are pretty well verſed in the Old Teſtament, and are partly acquainted with the inſtitutes of the new one. The Marahbuts reaſon very well on ſuch ſubjects as they are acquainted with, but their manner, like that of the eaſtern nations, is that of adducing parables or ſimiles in their arguments, which do not always bear the ſtricteſt reſemblance to the caſe in hand; though they are very perſuaſive with ſuch people as are not capable of inveſtigating the points in which they differ from the caſe in queſtion. Their converſation is inſtructive and pleaſing. The Marahbuts of the Moors are more learned and ingenious in every reſpect than thoſe of the black nations. Phil. Tranſ. vol. lxxiii. p. 90.

MARAI, a town of Hindooſtan; 45 miles S.W. of Allahabad.

MARAJO, an iſland between the mouths of the Amazons and Para rivers, reſembling in its form an oval and triangle; about 160 miles in its greateſt length, and 120 in its greateſt breadth.

MARAJON, a town on the eaſt coaſt of the iſland of Marajo; 24 miles N.W. of Para.

MARAISAH, a town of Tunis, near the ſea, with the remains of a ſmall harbour.

MARAKUNDA, a town of Africa, in the kingdom of Badelu.

MARALDI, James Philip, in *Biography*, a learned mathematician and aſtronomer, was born at Perinaldo, in the county of Nice, in the year 1665. It is not known where he was educated, but at the age of twenty-two we find him at Paris, purſuing his maturer ſtudies under his uncle, the celebrated Caſſini, to whom he implicitly reſigned the direction of his purſuits. When Caſſini found that the young man's advancement in ſcience, his extraordinary diligence, and above all his accuracy, had qualified him to become an uſeful aſſiſtant in his aſtronomical labours, he, by the leave of the Royal Academy of Sciences, aſſociated him with himſelf in making obſervations on the celeſtial bodies. He ſoon opened the way to celebrity, by important diſcoveries with regard to the planets, particularly with reſpect to Jupiter: he found likewiſe that the parallax of the planet Mars was leſs by one ſecond, than had been determined by Caſſini in 1672. He ſpent the whole of the year 1674 in obſervations on the planet Saturn, and ſhewed how the diſappearance of the ring, at that particular period, confirmed the theory of Huygens. He beſtowed incredible induſtry in perfecting the tables of Jupiter's ſatellites, and found that the eclipſes of theſe bodies were of different durations, even when the diſtance of their nodes was the ſame. He applied himſelf to the conſtructing a catalogue of the fixed ſtars, and by his long and accurate attention to this object, became ſo well acquainted with theſe bodies, that on being ſhewn any one of them, however ſmall, he could immediately tell to what conſtellation it belonged, and its preciſe place in the conſtellation. Maraldi would ſometimes relax in his aſtronomical labours, and apply ſteadily to objects of natural hiſtory, on which ſcience he drew up a number of intereſting papers, which were inſerted in the different volumes of the memoirs of the Academy of Sciences, of which diſtinguiſhed ſociety he was a member. In the year 1700, he was employed by Caſſini in prolonging the French meridian to the northern extremity of France, and had a very conſiderable ſhare in that important undertaking. When his buſineſs was finiſhed, he paid a viſit to Italy, where the aſtronomers gladly availed themſelves of his advice and aſſiſtance in making their obſervations. At Rome, on the invitation of pope Clement XI., he aſſiſted at the aſſemblies of the congregation then ſitting in that city, for the purpoſe of reforming the calendar. He alſo took a part in conſtructing the great meridian line at the baths of Diocleſian. While at Rome he had a fine opportunity of obſerving an eclipſe of the fourth ſatellite of Jupiter, from which he was led to the concluſion, that its inclination is three minutes leſs than that fixed by Caſſini. He returned to France in 1703, with a rich treaſure of ſubjects in natural hiſtory, chiefly collected at Verona, which he preſented to the Academy of Sciences. In 1718 he was employed, with three other academicians, in prolonging the French meridian to the ſouthern extremity of that kingdom. Amidſt his various labours the greateſt part of his time was occupied within the walls of the obſervatory of Paris, where he was inceſſantly employed in aſtronomical purſuits, and in completing his catalogue. This laſt great work he did not live to finiſh; he died in December 1729, in the ſixty-fifth year of his age. He is characterized as a man of great ſeriouſneſs, integrity, and purity of morals, and as poſſeſſing an intereſting ſimplicity of manners. He publiſhed nothing but papers in the tranſactions of the academy: theſe, however, are very numerous and very valuable, and are to be found in almoſt every volume that was printed between the years 1698 and 1730. Moreri.

MARAMBAYA, in *Geography*, a ſmall iſland near the coaſt of Brazil. S. lat. 23° 10'.

MARA-

MARAMER, a town of Morocco, near Cape Cantin, encompaffed with old walls, but not ftrong either by nature or art; 9 miles from Saffi.

MARANA, John Paul, in *Biography*, was born of a noble family at or near Genoa in the year 1642. He received an education adapted to the fphere of life in which he moved, and being led to think and feel upon political fubjects, he was, at the age of twenty-feven, involved in the confpiracy of Raphael della Torre to deliver Genoa to the duke of Savoy. On this account he was thrown into prifon, where he remained four years. On his liberation he employed himfelf in writing an account of this confpiracy, and of the war between the republic and the duke of Savoy, and took a journey to Spain for the purpofe of collecting documents. When the work was finifhed, it was feized by the fpies of government, and examined, nor cou'd he get it returned for publication. In 1681 he abandoned his country and went to France, where he recompofed his work, and publifhed it in the year 1682, under the title of "La congiura da Rafaello delle Torre, con le moffe della Savoia contra la Republica di Genova." Marana is chiefly known as an author by the "Turkifh Spy," written in the French language, which has given birth to feveral imitations, on the fame model, though the original is not much fought after. He lived at Paris in a ftate of decent mediocrity till the year 1689, when he returned to Italy, where he died in about two years. Moreri.

Marana, in *Botany*, a name by which fome authors have called the ftramonium, or thorn-apple, a plant kept in fome gardens.

MARAND, in *Geography*, a town of Perfia, in the province of Adirbeitzan; 42 miles N. of Tauris.

MARANHAO, or Maranon, a jurifdiction of South America, in Brazil, belonging to the Portuguefe, who firft fettled here in 1599, upwards of 60 years after the difcovery. Its name is derived from an ifland at the mouth of three rivers, about 42 miles in circumference, which is fertile and well inhabited. The French feized on the ifland in 1612, and built a town called "St. Luis de Maranhao," but the Portuguefe recovered it out of their poffeffion. It is now very ftrong, having a caftle built on a rock towards the fea, which commands a very convenient harbour.

It is the fee of a bifhop, under the archbifhopric of St. Salvador de la Baya. The ifland is difficult of accefs, on account of the rapidity of the three rivers by which it is formed, fo that it can be vifited only at particular feafons, and with proper winds. There are two other lefs confiderable towns. The natives have about 27 hamlets, confifting each of four large huts, which form a fquare in the middle, from 300 to 500 paces in length, and about twenty or thirty feet in depth; all thefe are built of large timber, and covered from top to bottom with leaves, fo that each may contain from two to three hundred inhabitants. The air is ferene, feldom incommoded with ftorms, exceffive drought, or moifture, except during the periodical rains from February to June. The foil is rich, and produces every thing in perfection, without labour or manure. The inhabitants go naked, but paint their bodies and faces of various colours, and cover their hands and arms with a variety of feathers: the children, though born white, acquire an olive colour by being anointed with oils. They are ftrong and healthy, live to a great age, and are feldom afflicted with difeafes. Their only weapons are bows and arrows, in the ufe of which they are dextrous; but they are fierce and cruel, efpecially to their prifoners. The capital, St. Filipe, or St. Luis de Maranhao, is fituated in S. lat. 2° 30'. W. long. 45° 30'.

MARANO, a town of Italy, in Friuli, on the coaft of the Adriatic; containing about 1000 inhabitants, with a garrifon; 18 miles S. of Udina. N. lat. 45° 50'. E. long. 13° 50'.

Marano, or *Mariano*, a town of Italy, in the Veronefe; 8 miles N.N.W. of Verona.—Alfo, a town of Naples, in Lavora; 6 miles N.W. of Naples.

MARANON, or Maragnon, called alfo the river of the *Amazons* (fee Amazon), is celebrated as the moft diftinguifhed river not only in South America, but in the whole world. Of this river we have already given fome account under the article Amazon; but it deferves, on account of its magnitude and length, as well as the fertility and commerce that are diffufed along its fhores, a more particular and ample notice. Condamine, whofe account of this river we have curforily mentioned, computed its navigation at 1000 maritime leagues, or 3000 miles; to which recent difcoveries enable us to add at leaft 4 or 500 leagues: fo that if the countries, through which it purfues its courfe, were poffeffed by induftrious and populous nations, a fhip of 4 or 500 tons might afcend this wonderful river to the extent of 4500 miles of navigation. As the courfe of the Maranon, for more than one-third of its progrefs, is from north to fouth, it confiderably exceeds the whole breadth of South America; but eftimated in a line nearly direct, the length on a map will be found to be about 2500 geographical miles. If we thus eftimate the Kian of China, it will be found to reach 2000 miles, and the Ob of Siberia 1900. The Miffouri of North America may probably be eftimated at 2000 miles. But the pre-eminence of the Maranon has been very much increafed by recent difcoveries. This prodigious river, this torrent-fea, as it has been called, is not only fuperior in the length, but in the breadth and depth of its majeftic courfe; and receives on all fides, as tributaries, rivers of fuch power, that any one would enrich the defarts of Africa, and might fpread fertility, trade, and civilization, throughout a wide empire. Where the Beni joins the Maranon, it is half a league in breadth, (the Spanifh league being four Britifh miles;) the Tunguragua or falfe Maranon from the weft, the Llavari or Madera from the fouth, and the Negro from the north, are all rivers of this furprifing defcription. In fhort, through more than one-half of the great continent of South America, almoft every advantage of a maritime fhore might be diffufed by the Maranon, and its confluent ftreams. We fhall here avail ourfelves of the abftract given by Mr. Pinkerton, of the principal difcoveries that have recently been made, with regard to the fource and tributary rivers of the Maranon. Near its fource this river is called the Apurimac, which rifes to the fouth of the mineral mountains of Cailloma, perhaps in the lake of Vilque, as laid down by La Cruz, S. lat. 16° 10'; but probably ftill more to the fouth, perhaps even 17°; for after being joined by the Monigote or Panguana, in Cailloma, it is fo deep, when it enters the province of Canes and Canches, that a bridge is already neceffary. This bridge is probably that mentioned by Alcedo, on the high-road between Lima and Cuzco, fupported by ropes, and eighty "varas" in length, being almoft due weft of Cuzco, and which paffes the real Apurimac, according to La Cruz, while the Vilcamayo is on the eaft of Cuzco. After running two leagues below this bridge, it burfts through the chain of the Andes amidft precipices of incredible height, and which fupply numerous ftreams. The chief rivers which join the Maranon are as follow: the river of Pampas or Charcas from the weft, at 13° 10'; the Vilcamayo, a great river, nearly equal to the Apurimac or Maranon, at 12° 15': this river, like the others, has feveral names, according to the provinces through which it paffes, fuch as

Quillabamba,

Quillabamba, Urubamba, &c. The Mantaro, or river of Jauja, fo called from the province it pervades, but by La Cruz erroneoufly ftyled the ancient Maranon, joins the Maranon at 12° 6′, and feems to propel the chief river towards the north-eaft, the courfe having previoufly been towards the north-weft. The great river Paucartambo, called by La Cruz Ynambari, joins the Maranon at 10° 45′; the Perene, which rifes about two leagues from Tarma, runs through that town, and receives many ftreams from the heights of Bombom and Pafco, having joined it on the oppofite fide or weft, at 11° 13′. From the confluence of the Perene to that with the beautiful river Pachitea, at 8° 26′, that is an interval of 2° 52′, or 172 geographical miles, though by numerous windings increafed probably to 500, the Maranon receives no lefs than 40 copious rivers; but more particularly two of prodigious power, the Paucartambo already mentioned, and the Beni, the moft remote fprings of which lie eaft of the province of Sicafica, in about 19° of latitude. This river runs from fouth to north, with fome inflections, receiving various rivers from the mountainous territory which it interfects; among the moft remarkable of which is the Coroyco, iffuing from the province of La Paz, and entering it on the weft. The Beni, purfuing its courfe in 13° of latitude, throws off a branch, in an eaftern direction, which enters a confiderable lake, named Rogagado, that extends upwards of 10 leagues E.W., and of 5 N.S. From the eaftern fide of this lake rifes an arm, which runs to the Mamori; and three others are thrown off in a northern direction, *viz.* the Yutay, the Tefi, and the Coari, which purfuing a north-eaft courfe, empty themfelves into the Maranon. The Beni, having fupplied this arm, flows to its incorporation with the Apurimac, which it enters with an aperture of half a league, and by the name of Para. Three leagues beneath the junction of the Paucartambo, the Maranon is joined by a river, about two Britifh miles, or half a Spanifh league in breadth, of fuch force that the courfe of the Maranon is changed for a certain diftance, and bent towards the chain of the Andes. This river, however, wide and powerful as it is, is only a branch of the grand river Beni, already mentioned. Indeed it has been queried whether the Beni or the Apurimac be the principal ftream forming the Maranon. The fource of the Beni, near Sicafica, is about 2° 30′ farther to the fouth than that of the Apurimac; but as its courfe is far more direct, the actual length of the navigation bears no comparifon with that of the Maranon, which at this junction acquires the name of the Grand Para or Pare. The navigation of the Beni might conduct the adventurer to the mines of Potofi, and that of the Apurimac to Cuzco and Lima. At 8° 26′, the Pachitea joins the Maranon. The Pachitea is efteemed the moft beautiful of all thefe tributary ftreams: it rifes in 10° 46′, firft running eaft, then north, and in the early part of its progrefs is called the Pozuzu, efpecially at its confluence with the Mayro, where it forms a noted haven, whence there is an open navigation to the Maranon. The next remarkable ftream that joins the Pachitea is the Piachiz. The courfe of the Maranon here varies from due north to north-eaft; fo that the map of La Cruz muft be erroneous in the great wefterly inflection of its courfe, thereby approaching the Gualaga too nearly by one-half. The Aguaytra alfo joins the Maranon from the weft, at 7° 35′; the Manoa or Cuxniabatay, at 7°; the Saraiacu, at 6° 45′; the Tapichi or Canopocati, oppofite to San Regis, at 5°, which laft river feems alfo to communicate with the Tunguragua. This Tunguragua, Lauricocha, or Jefuitic Maranon, falls into the Maranon at 4° 55′, where the latter is divided into three branches, the chief of which is not lefs than 55 fathoms in depth. The courfe of the Maranon now turns to the eaft. The true Maranon, or Ucaial, as it is alfo called in part of its courfe, is the moft important of all the ftreams which defcend from the grand chain of the Andes. In 1794 it was explored by Father Girval, who navigated it from its junction with the falfe Maranon to its confluence with the Pachitea, and found it of a ferene current, and abounding with fifh, while animals of chace fwarm on the fhores. The favage tribes on this fuperb river are generally pacific, and feem to fpeak dialects of the fame language. From its junction with the river Beni to that with the falfe Maranon it is navigable for large veffels more than 400 leagues; and in the courfe of 300 leagues prefents 132 iflands. The true Maranon, or Ucaial, is navigable at all feafons. The firft Portuguefe ftation that occurs is Sapatinga, and the next San Pablo. Loreto, a Spanifh fortrefs, ftands at the diftance of 12 leagues from Sapatinga; from which latter Pevas, a Spanifh village, is 74 leagues, Napo 104, Iquitos 132, Omaquas 154, the junction of the Ucaial 164, the village of San Regis 184, that of Urarinas 224, and the mouth of the Gualaga 234. See GUALAGA.

The banks of this large river are generally crowned with vaft forefts of lofty trees, among which are many of a rare and medicinal nature. Serpents of prodigious fize are found in the marfhes, and alligators are alfo common. It feems certain, from the difquifition of Condamine, that fome female warriors ftill exift toward the north of this great river. Near its mouth the Bore rifes from 12 to 15 feet in height; and the noife of this irruption is heard at the diftance of two leagues. This effect, called "pororoca," is chiefly obfervable towards the cape del Norte, on the mouth of the Arowary. See BORE.

The fucceffive voyages of Father Girval are rendered interefting, not merely by his having explored the Ucaial or genuine Maranon, but by the account he has given of the different tribes of Indians who inhabit the adjacent territory. Embarking on the lake of the great Cocama, he proceeded to Omaguas, at the confluence of the Maranon and Tunguragua, commonly called St. Joachin, as diftinguifhed from St. Pablo, or St. Paul de Omaguas, one of the firft Portuguefe fettlements at the linear diftance of about 3°, or 180 geographical miles to the E. Having two canoes with 14 Omaguan Indians, robuft and dextrous rowers, he foon paffed from the Tunguragua into the Maranon, which he afcended with refolute and laudable perfeverance, though he fometimes met with little fleets of canoes filled with Indians of unknown tribes, whom he foothed and efcaped by his prudence. The "Conibos" will employ a whole year to hollow out a canoe from one tree, 16 or 20 yards in length, and from five to feven quarters broad, which they accomplifh by means of fharp ftones and fire. The poop is fquare, and the prow drawn to a pyramidal point. Among their flaves were fome of the Mayoruna tribe, who dwell towards the fources of the river Tapichi, and are called Barbudos, becaufe their beards are as ftrong and abundant as thofe of the Spaniards; but they are believed to be defcended from Spanifh foldiers, fcattered in thefe forefts in confequence of a former expedition. After 14 days of navigation, there appeared on the W. a chain of mountains, running S.E. and N.W. Two days after they arrived at the little fettlement of Saraiacu, among the "Panos," and foon after reached the habitation of Anna Rofa, an Italian lady, educated at Lima, who greatly lamented the tragical death of the miffionaries in 1767, committed by the "Chipeos," who had been feverely chaftifed by her nation. Continuing the afcent he reached the river Manoa, alfo called by the Indi-

ans

ans Judiabalay, on account of the rapidity of the ftream, which neverthelefs he afcended with a view of difcovering a nearer paffage from the Gualaga to the Maranon than the circuit by the Tunguragua. The paffage by land was found difficult, on account of thick woods and precipices; and difcovering a large river, which was the winding Manoa, our traveller defcended the Maranon, and arrived at the miffions of the Maynas, and foon after at Cumbaza, after an abfence of four months. This firft voyage feemed to obliterate the idea, which he had entertained, of the cruelty of the nations on the Maranon. The Indians in general were found to be tall and robuft, and the "Conibos" could vie with the Europeans in fairnefs, if they did not difcolour themfelves, and fuffer moreover from the ftings of the mofquitoes. They bind their children with bandages of flax, that they may grow ftraight: the forehead is alfo flattened in infancy, by boards faftened before and behind, as in their opinion a wife head fhould refemble a full moon: but by this practice, it is faid, they are almoft utterly deprived of memory. The girls are wholly naked, while the married women wear a flight cincture; but among many other tribes complete nakednefs is univerfal. They are painted and tattooed; they do not marry within certain degrees; and the caziques alone ufe polygamy; but the men and women are free to quit each other. They feem to believe in one god, of a human form, who retired to heaven after making the earth; but they do not venture to offer their humble adorations except during earthquakes, which they believe to proceed from the footfteps of their god who vifits the earth, in order to judge by their voices how many men exift. Hence, on occafion of the flighteft earthquake they run from their hovels, caper, and ftamp on the ground, crying out, "here we are, here we are." They alfo believe in an evil fpirit, of whom the moft fagacious, for the fake of emolument, have declared themfelves the priefts, and regulate in his name amours, intrigues, health and ficknefs, and the little campaigns of war. They have alfo many charms and amulets; and yet their fkill in medical herbs is far from being contemptible. They alfo believe in another life, but imagine that thunders are the battles of that diftant world, and that the milky way is a fine foreft for their diverfion. Some believe in tranfmigration, and fuppofe that the fouls of their chiefs and nobles animate tigers and monkies. The dead are difinterred after a certain period, and the bones wafhed and preferved, but fome tribes eat the flefh, that nothing may be loft. Befides the chace and fifhing, they cultivate a few herbs, particularly the "yuca," with which they make the "mazato," their only drink and confolation. The water is generally bad, owing to the heat and the numerous marfhes which taint the rivers. In the cultivation of the "yuca," they cut down the trees with axes of ftone; but they have alfo axes of copper, the firft metal ufed by favages, being often found native and eafily beaten into form, while iron is obdurate and requires the fkill of a more advanced fociety. The ground is flightly moved with a wooden fpade, and the "yuca" being interred the labour is finifhed. They alfo gather cotton, which ferves for their little cinctures. Their darts and arrows are often tinctured with active poifon, drawn from noxious plants. Their confidence in its power is fuch, that they will excite the fury and await the attack of the ftrongeft and fierceft jaguar. They laugh when he prepares to fpring: the arrow flies, and he is dead. But they never employ poifoned weapons in their conflicts, not fo much from liberality of fentiment, as from the fear of a retort. Large fifh are killed with arrows aimed at their heads; the fmall are taken in fnares, or with hooks of bone. From the age of five years boys and girls manage the canoes. Their ruling paffion is war, and it is the bufinefs of the whole tribe, prefided by the cazique or intended general. The tobacco tubes are lighted; the jars of "mazato" pafs round; and as foon as drunkennefs begins, this important fubject becomes the matter of deliberation: the firft and moft folemn queftion being, "with what nation fhall we go to war?" And the next is, "what fhall be the caufe of quarrel?" The caufes are generally fome petty robbery or offence; and the weakeft tribe is generally felected as the moft convenient enemy. When the expedition is refolved upon, the "moans," or priefts of the evil fpirit, take charge of their chiefs, and treat them with fuch abftinence and artificial horrors, that at the end of fome days they come forth rather dead than alive. Thefe favages impute all fuccefs in war to the evil fpirit, and carefully conceal from their deity their proceedings on fuch an occafion. Hence the "moans" are held refponfible for the refult of the expedition; and if it be adverfe they receive a thoufand maledictions, and are beaten almoft to death, becaufe their prayers to the evil fpirit had not been acceptable. As their petty warfares are inceffant, their villages, or large houfe, are prepared for defence; being conftructed in the form of a crefcent, with the convex part towards the wood, and with one door towards fome hill and another to a plain. When the enemy attack at one door a party oppofes; while the others turn the wings of the houfe, and attack the foe on the plains.

Father Girval, in his fecond voyage 1791, entered the mouth of the Ucaial, or true Maranon, and though unaccompanied by any foldier, or white perfon, he was received by the favages with great cordiality, though he was afraid of encountering the "Cafibos" on the eaftern fhore, who are reputed the moft ferocious tribe in thofe regions. But the chief navigators of this part of the Maranon are the "Conibos," who are more humane; and the found of their rude flutes or cornets is the fignal of peace and hofpitality. Canoes of the "Panos" afterwards appeared: and the Father arrived at Saraiacu with a bark and 60 canoes of friendly favages. The cazica, Anna Rofa, conducted the proceffion to a little convent which fhe had founded, and the Indians obeyed her orders with great punctuality. A tribe called the "Piro" inhabit the borders of Maranon, in the latitude of Torma, being about 20 days navigation from Saraiacu or the Manoa. He found abundance of cinnamon trees, and began to inftruct the natives in its cultivation, hoping that this precious fpice would foon become an effential article of commerce. This fettlement was thought of importance, as it prevented the Portuguefe fhips from purfuing their excurfions on the Maranon; and with the fort on the Mayro, inclofed the "Pampas del Sacramento" on both fides, fo as to render it a decided Spanifh province.

The "Panos" and "Conibos," and even the "Chipeos," who had murdered the firft miffionaries, began, it is faid, to fhew fome difpofition for embracing the faith. Some "Piros" were exported from the vicinity of the Mantaro, and the frontiers of Guanta and Jauja, paffing in their canoes on the Maranon; but the "Cafibos" near the Mayro, and on the banks of the delightful Pachitea, a ferocious race, were fcarcely expected to become amicable; having no intercourfe with any other nation, and never leaving their own country, as they have no utenfils for making canoes. They furprife and kill any ftrangers whom they find within their boundaries; and having cooked them with great care, eat them with correfponding comfort, fo that a traveller rarely returns to publifh any account of foreign parts. Thefe favages form the only obftacles to impede the navigation from Manoa to Mayro; but a few regular troops would eafily extirpate thefe irreclaimable tigers. Of thefe miffionaries it is juſtice to add, that occupied in teaching theſe ſavages the arts of life, and of innocent ſuſtenance, whatever a Proteſtant may think of their religion, he cannot withhold the applauſe due to their fortitude and beneficence. Pinkerton's Geog. vol. iii.

Maranon, *Falſe* or *Jeſuits'*, called by the natives *Tunguragua*, and alſo *Lauricocha*, a river of South America, which riſes from the lake of Lauricocha, about eight miles to the N. of Paſco, and after paſſing the Pongo, becomes navigable till it falls into the Ucaial or true Maranon. We may here ſtate, on the authority of father Girval, the reaſons alleged by thoſe who aſſign the ſupremacy to the Ucaial. In the firſt place, its ſources are far more diſtant than thoſe of the Tunguragua, or pretended Maranon of father Fritz: ſecondly, the Beni, Paucartambo, and the Apurimac, are navigable up to a latitude where the falſe Maranon has no exiſtence: thirdly, becauſe the Ucaial, far from being inferior in the quantity of water, is on the contrary broader, and forces the falſe Maranon out of its courſe: fourthly, becauſe all the ancient hiſtorians of the kingdom have acknowledged the Apurimac as the genuine Maranon: fifthly, becauſe, till the year 1687, the very name of Ucaial was unknown, that river being called Apoparu, *i. e.* the great Paro, which is the name alſo given by the natives to the Maranon, or the river of Amazons, after it is joined by the pretended Ucaial. In the year above-mentioned, a law-ſuit aroſe between the Franciſcans of Lima and the Jeſuits of Quito, for the village and miſſions of San Miguel de los Conibos. The Royal Audience demanded maps in order to determine with greater certainty; upon which father Fritz drew the map, which was afterwards engraved at Quito in 1707, and in which the Tunguragua is ſtyled the Maranon, and the Paro is ridiculouſly called "Ucayali," a word, which merely ſignifies a *confluence*, and ſpecially applied by the tribe of the Maynas to that of the Paro and Tunguragua; whence originated the error of father Fritz; while father Acuna aſſerted, with equal boldneſs, that the Napo was the Maranon! The great credit of the Jeſuits led people blindly to follow the nomenclature of father Fritz. Upon the whole it is ſufficiently manifeſt, that the great river Maranon is that denominated the Ucaial by a mere manœuvre of the Jeſuits, in oppoſition to the moſt palpable facts and the ancient hiſtory, traditions, and preſent accounts of the natives; and that the river Ucaial or Apurimac ought to retain to its very ſource the real and juſt appellation of the Maranon: while to the falſe Maranon, in fact a tributary ſtream, and recent appellation confeſſedly erroneous, whether ariſing from artifice or miſtake, the ancient name of Tunguragua ought to be reſtored. This new Maranon, Tunguragua, or Lauricocha, was navigated by Condamine from near the town of Jaen, where it begins to be navigable; thence paſſing N. E. it arrives at the exterior ridge of the Andes, which it cleaves at a paſs called the Pongo, a word which in the Peruvian language ſignifies a gate. This ſublime ſcene diſplays the Lauricocha confined between two parallel walls of an almoſt perpendicular rock. From a breadth of 250 fathoms the river is here contracted to 25; but the rapidity is not extreme, and a raft paſſes the two leagues in about an hour. Pinkerton's Geog. vol. iii.

MARANS, a town of France, in the department of the Lower Charente, and chief place of a canton, in the diſtrict of Rochelle; ſituated in the midſt of ſalt marſhes, on the Sevre, about ſix miles from its mouth. The trade of the inhabitants is conſiderable in ſalt, malt, corn, and meal; 12 miles N.N.W. of La Rochelle. N. lat. 46° 18'. E. long. 0° 54'.

MARANT, or Amarant, a town of Perſia, in the province of Adirbeitzan, containing 2500 houſes, each of which has a garden, ſituated near a river, and watered by canals. Cochineal is found in the neighbourhood. Tradition reports, that Noah was buried here; 50 miles N. of Tabris

MARANTA, in *Botany*, was ſo named by Plumier, in commemoration of Bartholomew Maranta, a native of Venuſia, who died in 1554. He was one of the chief Italian botaniſts of his time, and examined the native plants of his country, while he cultivated exotics in his garden, and commented on Dioſcorides with great diligence and ſagacity. He wrote alſo on the Theriaca and Mithridate, in Italian. Plum. Nov. Gen. 16. t. 36. Linn. Gen. 3 Schreb. 4. Willd. Sp. Pl. v. 1. 13. Mart. Mill. Dict. v. 3. Roſcoe Tr. of Linn. Soc. v. 8. 339. t. 20. f. 2. Ait. Hort. Kew. ed. 2. v. 1. 2. Juſſ. 63. Lamarck Illuſtr. t. 1.—Claſs and order, *Monandria Monogynia*. Nat. Ord. *Scitamineæ*, Linn. *Cannæ*, Juſſ.

Gen. Ch. *Cal.* Perianth ſuperior, of three ſmall, equal, lanceolate, permanent leaves. *Cor.* of one petal, irregular. Tube longer than the calyx, compreſſed, oblique, inflexed. Limb double, unequal, the three outermoſt ſegments ſmalleſt, equal, alternate, oblong, one of them inferior, two ſuperior; innermoſt in two roundiſh lobes, very large, deflexed, conſtituting the lip, ſometimes undivided. *Stam.* Filament one, oppoſite to the lip, dilated, reſembling a ſegment of the corolla; another linear, attached to one edge of the filament, of two cells. *Piſt.* Germen inferior, roundiſh; ſtyle dilated, petal-like, the length of the ſtamen, to which it is united below; ſtigma obſoletely triangular, inflexed. *Peric.* Drupa roundiſh, ſomewhat triangular, dry and leathery, of one cell. *Seed.* Nut ſolitary, oblong, rugoſe, hard, of three cells, two of which are generally abortive.

Eſſ. Ch. Calyx of three leaves. Corolla of one petal, in five ſegments. Anther ſimple, on the edge of the filament. Style petal-like. Stigma ſomewhat triangular. Nut ſolitary, of three cells.

Obſ. This genus belongs to that ſection of the Linnæan *Scitamineæ*, which is characterized by a ſimple anther of two cells, not a double one whoſe cells are diſtant from each other and embrace the thread-ſhaped ſtyle. The term *Cannæ* is reſtricted by Mr. Roſcoe and Mr. Brown to the ſection in queſtion. Juſſieu extends it to the whole of the *Scitamineæ*.

1. M. *arundinacea*. Indian Arrow-root. Linn. Sp. Pl. 2. Redout. Liliac. t. 57. Willd. n. 1. (M. arundinacea, cannacori folio; Mart. Cent. 39. t. 39. Canna indica, radice albâ alexipharmacâ; Sloane Jam. v. 1. 253. t. 149. f. 2.)—Stem branched, herbaceous, annual. Leaves ovato-lanceolate, ſomewhat hairy. Flowers panicled. Fruit nearly globoſe.—Native of South America, and perhaps of ſome of the Weſt India iſlands. It is now cultivated in many of them, the juice of the root being reputed a remedy for wounds inflicted with poiſoned arrows, as well as againſt the ſtings of venomous inſects. If the powder ſold in the ſhops of London be really prepared from this root, which we have no reaſon to diſbelieve, its mucilaginous quality may readily account for the above-mentioned virtues. The potatoe might prove efficacious in the ſame way. This *Maranta* is ſaid to have been ſent to England, either by means of ſeeds or roots, by Houſtoun, before the year 1732. It is cultivated in the ſtove, flowering in July and Auguſt, but is not ornamental enough to be very popular. The *root* is perennial, ſomewhat creeping, knotty or tuberous, with many long white fibres. *Stems* ſeveral, erect, herbaceous, a yard

yard high, branched, ſlender, finely hairy, leafy, rather knotty at the joints, dying down to the root every year. *Leaves* alternate, ſolitary at each joint, with long, ſheathing, ribbed, ſomewhat hairy footſtalks; ovate at their baſe; lanceolate or tapering towards the end; entire, with one rib and numerous tranſverſe parallel veins; paler and ſomewhat hairy beneath; each about four inches long. When dry they are involute, marked, on the upper ſide, with fine ſtreaks parallel to the veins, and on the under, with equally fine tranſverſe corrugations, contrary thereto. *Panicles* terminal, long, lax, and ſpreading, their ſtalks ſlender, tumid and hairy at the baſe, furniſhed at every ramification with a ſolitary, long, linear, narrow, ribbed, at firſt ſheathing, *bractea*. Germen ſomewhat hairy. *Calyx* green, ſmooth. *Corolla* white; its tube about half as long again as the calyx; lip above half the length of the tube, its ſegments ſeparate to the baſe, obovate, ſlightly emarginate. *Fruit* nearly globular and equal, with three obſolete angles, the ſize of a ſmall currant, the ſurface corrugated when dry.

2. M. *gibba*. Gibbous-fruited Arrow-root.—Stem branched, ſhrubby, perennial. Leaves ovate, taper-pointed, ſmooth. Flowers panicled. Germen ſilky. Fruit gibbous at one ſide.—Native of Barbadoes, from whence it was ſent by the earl of Seaforth, when governor of that iſland, to the botanic garden at Liverpool. The curator, Mr. Shepherd, favoured us with a freſh ſpecimen, flowering in November, 1808. The latter obſerves, that the *ſtem* does not die down in winter. In general appearance this much reſembles the foregoing, but the *leaves* are quite ſmooth, except the knot which combines them with their footſtalks, which is, as in the former, very hairy upwards. The *flowers* are ſmaller; their *germen* beautifully ſilky, with denſe ſilvery hairs, though the *ſtalk* below, and *calyx* above, are perfectly ſmooth and naked. All the *fruits* we have ſeen, five in number, were ſo gibbous at one ſide as to be ſemi-globoſe. They loſe their pubeſcence in ripening. A plant was raiſed from the ſeed of this ſpecies, ripened at Liverpool.

3. M. *ſylvatica*. Wood Arrow-root. Roſcoe Tr. of Linn. Soc. v. 8. 340.—Stem much branched, ſhrubby, perennial. Leaves ovate, acute, ſmooth, with a hairy central line above. Flowers panicled. Germen hairy upward.—This was likewiſe ſent from Barbadoes to the Liverpool garden, by lord Seaforth. It flowers leſs freely than the laſt, and had not in 1808 ſhewn any ſign of forming ſeed. The *ſtem* is hard and knotty, ſomewhat in the ſtyle of a bamboo. *Leaves* numerous, about two inches long, ovate, ſcarcely taper-pointed, ſmooth, except a conſtant hairy line, cloſe to each ſide of the nerve, above. They are ſtriated above and below, in this and the laſt, exactly as in M. *arundinacea*. The knot between the leaf and the footſtalk is thick, ſhort, hairy upwards. *Flowers* few and ſmall. *Calyx-leaves* broader, and not half ſo long as in either of thoſe before mentioned, being quite elliptical. *Corolla* not twice the length of the calyx. *Germen* clothed, in its upper part only, with a few long white hairs, which appear ſoon to fall off.

4. M. *Tonchat*. Eaſt Indian Arrow-root. Willd. n. 2. (Donax Arundaſtrum; Loureir. Cochinch. 11. Arundaſtrum, vel Tonchat ſeytam; Rumph. Amboin. v. 4. 22. t. 7.)—Stem branched, ſhrubby, perennial. Leaves elliptic-ovate, pointed, ſmooth. Flowers panicled. Germen ſilky. Fruit globoſe. Corolla five times the length of the calyx.—Native of woods, plains, and vallies in the Eaſt Indies, from whence it was brought us by lord viſcount Valentia. Rumphius ſays it is more plentiful in Ceram and Celebes, than in Amboyna. Loureiro gathered it in the woods of Cochinchina. (See DONAX.) The *ſtem* is eight feet high, ſhrubby, hard, round, ſmooth, and ſolid; ſimple and naked in the lower part; branched and leafy above. *Leaves* broad-ovate, with a ſmall point, ſcarcely three inches long in our dried ſpecimen; Rumphius deſcribes them as a ſpan in length, and the breadth of five or ſix fingers. They are ſmooth, with many lateral veins, but not ſtriated lengthwiſe or tranſverſely as in the three foregoing. The knot at their baſe is cylindrical but ſhort, ſomewhat hairy, ſometimes curved. *Panicle* erect when in flower, drooping in fruit. *Bracteas* large and long. *Flowers* white, conſiderably larger than any of the former. *Calyx-leaves* tapering from a broad baſe to the point, ſtrongly ribbed, a quarter of an inch long. Tube of the *corolla* ſcarcely exceeding the calyx; ſegments of the outer limb above an inch long, linear; lip ſtill longer, ſtalked, with broad dilated rounded lobes, whoſe number and poſition we cannot, from the dried ſpecimen, aſcertain. The *germen* is ſhort and broad, very denſely clothed with white ſilky down. *Fruit*, according to Rumphius and Loureiro, nearly globoſe, exactly agreeing with our generic deſcription. This ſpecies is, as Ventenat has obſerved under M. *arundinacea*, very different from M. *Tonchat* of Aublet, which may be merely a variety of the firſt ſpecies; but this we have no means of determining.

5. M. *lutea*. Yellowiſh Arrow-root. Jacq. Collect. v. 4. 117. Ic. Rar. t. 201. Roſcoe Tr. of Linn. Soc. v. 8. 339.—Stem branched, ſhrubby, perennial. Leaves ovate. Branches of the panicle ſomewhat ſpiked. Bracteas ovate, imbricated, coloured.—Native of moiſt woods in the Caraccas. It flowered with Jacquin, in the ſtove, from June to Auguſt, ripening fruit in September and October. It has the tuberous creeping *root*, and general habit, of the four foregoing ſpecies. The *ſtems* are ſeveral, ſix feet high, perennial, branched, ſmooth, and ſhining. *Leaves* ſeveral, in two ranks from the root; thoſe of the ſtem alternate, ovate, about a foot long and four inches wide; their *footſtalks* about the ſame length. *Panicle* erect, of a few alternate zigzag branches. *Bracteas* two-ranked, imbricated, ovate, folded, about an inch long, each enfolding a two-flowered partial ſtalk, with a much ſmaller internal bractea. *Calyx-leaves* elliptical, of the ſame dirty or tawny-yellow as the bracteas. *Corolla* white; the lip three-lobed. *Germen* ſmooth. Coat of the *fruit* firmly adhering to the nut. Our account is taken from Jacquin's works, but a ſpecimen brought, we believe, from the Braſils, by the late ſir G. L. Staunton, agrees with it, as far as we can examine.

6. M. *gracilis*. Slender-ſpiked Arrow-root. Rudge Guian. 8. t. 3.—Stems ſimple. Leaves ovate, pointed. Spikes terminal, ſolitary. Bracteas imbricated, ſheathing, cylindrical.—Native of Guiana, communicated by T. F. Forſter, eſq. This has the habit of a bamboo, except that the ſtems are ſimple, and only a foot high. They are ſlender, ſmooth, and leafy. *Leaves* near three inches long, light green, taper-pointed, rounded at the baſe, ſmooth, except a hairy line along the nerve on the upper ſide; their veins tranſverſe, as in the other ſpecies, not parallel to the rib, as in the above plate; the knot at their baſe very ſlender, hairy on its upper ſide; ſheath ribbed, ſmooth, dilated upwards. *Spikes* ſolitary at the tops of the ſtems, about four inches long, ſtraight, erect, ſlender, cylindrical, acute, being cloſely enveloped in five, ſix, or more, cylindrical, imbricated *bracteas*, about an inch long, from each of which, in ſucceſſion, ſpring a couple of *flowers*, whoſe tube is very long, incloſed in the bractea; the outſide of their *calyx* hairy; their *lip*, as far as we can diſcern, undivided.

7.* M. *obliqua.* Oblique-leaved Arrow-root. Rudge Guian. 8. t. 2.—Leaves elliptical, oblique at the point, on very long footftalks. Spikes cluftered. Bracteas crowded, fheathing, cylindrical.—Found by Mr. Alexander Anderfon in the Weft Indies, according to the Bankfian herbarium. Mr. Rudge had it from Guiana. Of the form of the whole plant we are uncertain, but by our fpecimen it appears herbaceous, the *leaves* being radical, on *footftalks* two feet long, fheathing in their lower part, and crowned with a cylindrical, fcarcely fwelling knot, above an inch in length. The *leaf* itfelf is about a foot long, and fix inches broad, elliptical or fomewhat ovate, terminating in a very fhort, oblique or lateral, curved point; fmooth on both fides; the veins tranfverfe, extremely numerous and clofe, five times as numerous as in Mr. Rudge's figure. *Spikes* apparently terminal, three together, either accompanied by a fheathing-ftalked leaf, as in the figure juft mentioned, or by one common *bractea* larger than the reft, as in our fpecimen. Each *fpike* is about a foot long, almoft perfectly fimple, flightly zigzag, flender, cylindrical, acute, clofely enveloped in numerous, alternate, cylindrical, crowded, but fcarcely imbricated, hard, downy *bracteas*, above an inch long, each containing two *flowers*. About half a dozen lanceolate cartilaginous bodies are feen projecting juft beyond the point of each *bractea*, looking like the anthers of a grafs. Thefe appear to us the tips of a number of linear, membranous, internal *bracteas*, about three of which furround each flower, and which might be taken for the *calyx*, were they not inferted below the *germen*. There are alfo two or three broad membranous *bracteas*, external with refpect to thefe, but inclofed within the common fheathing one. Of the real *calyx* or *corolla* our fpecimen gives no opportunity of judging. The *germen* appears to be turbinate, crowned with denfe upright hairs. *Style* compreffed, the length of the bracteas, with the proper inflexed ftigma of the genus. Mr. Rudge reprefents the *corolla* as about twice the length of the external *bractea*, with a long flender tube, and a ftructure analogous to the preceding fpecies. The *lip*, it feems, is undivided.

8. M. *fpicata.* Long-ftalked Spiked Arrow-root. Aubl. Guian. 4.—Leaves ovate-oblong, unequal-fided, oblique at the point, on long footftalks. Spike fimple, folitary, on a long ftalk.—Gathered by Aublet in a boggy foreft in Guiana. One of his leaves was given by fir Jofeph Banks to the younger Linnæus, who has, in his herbarium, accompanied it with a rough drawing of the fpike of flowers, and a note in Swedifh, faying he had "feen four leaves, all of the fame ftrange fhape." Thefe materials, though imperfect, are valuable, as Aublet has given no figure of this, any more than of his M. *Arouma*, *humilis*, or *lutea*, about which therefore following botanifts have been much in the dark. Our *leaf* of M. *fpicata* is a foot long and three inches broad, fmooth and fhining, with numerous principal, as well as intermediate, tranfverfe veins; the bafe is rather unequal, and the two halves of the leaf upwards much more fo, one margin being curved, the other ftraight; the midrib running up perfectly ftraight till it reaches the former margin, when it turns fuddenly into the very fhort lateral or oblique point. The *footftalk* is, perhaps, as long as the leaf; bordered or fheathing below; crowned with a cylindrical finely downy knot, an inch long, where it joins the leaf. *Spike* erect, three inches in length, fupported by a very long, round, fimple, erect, naked *ftalk* (which we may prefume to be radical), and fubtended by a large ovate fheathing *bractea*. Each *flower*, or perhaps pair of *flowers*, appears alfo to have an appropriate much narrower *bractea*, an inch long, and thefe *bracteas* are about ten in all, imbricated in feveral rows. Aublet fays they are firm and coriaceous, and the *flowers* white.

9. M? *Allouia.* Lateral-tufted Arrow-root. Aubl. Guian. 3. (Naru kila; Rheede Malab. v. 11. 67. t. 34.)—Leaves radical, ovate, acute, on long ftalks. Head of flowers feffile, from a lateral cleft in the footftalk. We venture to adopt this fpecies from Aublet, becaufe the figure he cites in the *Hortus Malabaricus* gives an idea of what he intends. He found his plant in the fame marfhy foreft with the laft. The *root* is furnifhed with knobs of various fizes, good to eat when roafted. *Leaves* radical, large, on long *footftalks*, fome of which bear a lateral tuft of numerous white feffile *flowers*; a mode of flowering analogous to that of the *Acorus*. The genus however of this fpecies muft depend on Aublet's authority. His three others above-mentioned, fee n. 8, we muft leave in the uncertainty in which we find them.

10. M? *comofa.* Leafy-headed Arrow-root. Linn. Suppl. 80. Willd. n. 4. Rofcoe Tr. of Linn. Soc. v. 8. 340. (Curcuma nova; Amoen. Acad. v. 8. 251.)—Leaves radical, elliptical, on long ftalks. Flowers in a terminal tuft, crowned with leafy *bracteas*.—Sent by Dalberg from Surinam. The *leaves* have the habit of the laft. Both fpecies feem to want the knot at the top of their *footftalks*, which is a ftrong prefumption of their being no true *Marantæ*. Indeed Linnæus himfelf expreffes his doubts of the prefent plant. The *flower-ftalk* is radical, three feet high, round, fimple, fmooth and naked, except at the top, where it bears a fine crown of elliptic-lanceolate leafy *bracteas*, like that of an *Eucomis*, under which the *flowers* are ftationed, in feffile drooping tufts. We find their habit and ftructure very unlike what are proper to this genus, and the *ftamen* is more like that of an *Alpinia*, to which we fhould, at a venture, remove this plant, without much fcruple.

We omit M. *malaccenfis*, Willd. n. 3, adopted by that author from Burmann (Galanga malaccenfis; Rumph. Amb. v. 5. 176. t. 71. f. 1.), as the figure of Rumphius fhews it to be, in habit and character, an *Alpinia*, to which genus Mr. Rofcoe has referred it in Tr. of Linn. Soc. v. 8. 345. S.

Maranta, in *Gardening*, contains plants of the herbaceous, perennial, exotic kind, of which the fpecies cultivated is the Indian arrow-root (M. arundinacea).

The root of this plant, when wafhed, pounded fine, and bleached, makes a fine nutritive powder, which is made ufe of as food in many cafes where the ftomach is weak and incapable of digefting more folid kinds.

Method of Culture.—All the plants of this fpecies may be increafed by dividing the roots and planting them in pots of light rich earth, in the fpring, juft before they begin to fhoot, plunging them in the bark hot-bed of the ftove, where they muft be kept in general, being frequently refrefhed with water, when in a ftate of growth, having free air, after they become of fome ftrength, admitted to them.

Ornament and variety are afforded by them in ftove collections among other tender plants.

MARANTABUAN, in *Geography*, a fmall ifland in the Eaft India fea, N. of Borneo. N. lat. 6° 55′. E. long. 117° 29′.

MARASA, a town of Africa, in the kingdom of Wangara, on the Niger. N. lat. 16°. E. long. 17°.

MARASCA, a town of Italy, in the department of the Upper Po; three miles W. of Cremona.

MARASCH, or Merasch, a town of Afiatic Turkey, and capital of a Sangiacate, under the pacha of Caramania,

nia, and the fee of a Jacobite bifhop; 140 miles W.S.W. of Diarbekir. N. lat. 37° 24′. E. long. 36° 35′.

MARASIND Islands, two fmall iflands in the Eaft India fea. S. lat. 5° 15′.

MARASKER, a fmall ifland on the E. fide of the gulf of Bothnia. N. lat. 63° 21′. E. long. 21° 25′.

MARASMUS, in *Medicine*, from μαραινω, *to wafte*, is a term applicable to every chronic difeafe, in which great emaciation of the folids take place. A marafmus is faid to be prefent in the laft ftage of every fpecies of confumption or decline; but the term is more efpecially ufed to denote the *mefenteric* confumption, or that fpecies of decline which occurs in children, and originates in derangement of the abdominal vifcera. This difeafe will be found defcribed at length under the article Infants, *Difeafes of*, § 4.

MARASNA, in *Geography*, a town of Africa, in Wangara. N. lat. 14° 52′. E. long. 16° 12′.

MARAT, John Paul, in *Biography*, a native of Switzerland, who became a prominent actor in the French revolution, was born in 1744: he went to Paris to ftudy phyfic, and, probably, not having patience to purfue the profeffion in a regular courfe, he became an empyric, felling his medicines at an extravagant price. On the breaking out of the revolution, he took the lead among the moft violent and favage of all the factions that difgraced the capital. He publifhed a periodical paper, entitled the "Publicifte Parifien," in which he, without fcruple, and without any regard to decency and truth, attacked the virtuous Neckar, and other men eminent for their integrity and public talents. This journal did not laft long, but the author had other projects in view, and he next fet on foot a paper, entitled "The Friend of the People," in which he unblufhingly exhorted the people to revolt, pillage, and murder. He excited the troops to ufe their arms againft their generals, the poor to plunder the rich, and the people at large to rife againft the king. After the depofition of Lewis XVI he was named a deputy of the department of Paris, to the convention, in which affembly he appeared armed with piftols. In April, 1793, he publicly denounced the leaders of the Briffotine party, accufing them of treafon againft the ftate; he was fupported by Robefpierre, a violent tumult enfued, but Marat and his friends were fubdued, and himfelf impeached and profecuted; in a few days being brought to trial he was acquitted. The triumph of his party was now unbounded, and they foon gained fuch an afcendancy over their enemies, that they murdered or banifhed all that attempted to obftruct the progrefs of their nefarious projects; till at length their leader Marat fell a victim to the enthufiaftic rage of a female, Charlotte Corde, who had travelled from Caen, in Normandy, with a determination of refcuing, as fhe hoped, her country from the hands of barbarians, by the affaffination of one of the chief among them. He died unpitied by every human being who was not of the atrocious faction which he led, having, for fome weeks, acted the moft favage parts, and been the means of involving many of the moft virtuous characters in France in almoft indifcriminate flaughter. Previoufly to joining in revolutionary politics, he was known as an author, and publifhed a work "On Man, or Principles of the reciprocal Influence of the Soul and Body," in two volumes, 12mo: alfo, fome tracts on Electricity and Light, in which he attacked the Newtonian Syftem. New Ann Reg 1793.

MARATE, in *Geography*, a low defert ifland in the Eaft India fea, about eight miles from the coaft of Africa, four miles in circumference. On the S. coaft is a good haven, fecure from all winds, formed by two points of land, inclofing a fpacious harbour, narrow at the mouth, where lies a very long flat ifland with fome fand-banks: the depth is three fathoms in the fhalloweft place. N. lat. 18° 35′.

MARATHON, in *Ancient Geography*, a fmall city of Attica, near the fea, about 40 miles from Athens, famous for the victory of the Athenians over the Perfians. The Perfian army commanded by Datis confifted of 100,000 foot, and 10,000 horfe; that of the Athenians amounted in all but to 10,000 men. This latter had 10 generals, of whom Miltiades was the chief; and thefe 10 were to have the command of the whole army, each for a day, one after another. It was a fubject of great difpute among thefe officers, whether they fhould hazard a battle, or expect the enemy within their walls. The latter opinion was that of a great majority; Miltiades and Ariftides were for rifking an immediate engagement, and this meafure was adopted. Ariftides, well knowing that a command which changed every day muft neceffarily be feeble and fluctuating, judged it prudent to veft the whole power in a fingle perfon, and in order to induce his colleagues to adopt this plan, he himfelf fet the firft example of refignation. When his day of command occurred, he refigned it to Miltiades, as the more able and experienced general. The other commanders followed his example; fo that Miltiades had the fole command. When the day of battle arrived, he endeavoured, by the advantage of the ground, to gain what he wanted in ftrength and number. Accordingly he drew up his army at the foot of a mountain, that the oppofing army might not be able to furround him, or charge him in the rear. On the two fides of his army he caufed large trees to be thrown, in order to cover his flanks, and render the Perfian cavalry ufelefs. As foon as the fignal for battle was given, the Athenians ran againft the enemy with all imaginable fury, which was the firft inftance, fays Herodotus, in which the Grecians thus began an engagement. The battle was fierce and obftinate. Miltiades had made the wings of his army very ftrong, but had left the main body more weak and not fo deep. As he had but 10,000 men to oppofe to a very numerous army, it was impoffible for him to make a large front, or to give an equal depth to his battalions. He therefore concluded that he could fucceed only by the efforts which he fhould make with his two wings, in order to break and difperfe thofe of the Perfians; not doubting that when his wings were victorious, they would be able to attack the enemy's main body in flank, and complete the victory without much difficulty. This was the plan which Hannibal afterwards followed at the battle of Cannæ. The Perfians attacked the main body of the Grecian army, and made their greateft effort upon their front. This was led by Ariftides and Themiftocles, who fupported it for fome time with intrepid bravery, but were at length obliged to give way. At that inftant came up the two victorious wings, and totally routed the Barbarians. The Athenians purfued them to their fhips, fet many of them on fire, and took feven. They had not above 200 men killed on their fide in this engagement; whereas on the fide of the Perfians above 6000 were flain, without reckoning thofe who fell into the fea as they endeavoured to efcape, or thofe that were confumed with the fhips fet on fire. The Perfians had thought themfelves fo fure of victory, that they had brought marble to Marathon, in order to erect a trophy there. The Grecians took this marble and caufed a ftatue to be made of it by Phidias, in honour of the goddefs Nemefis, who had a temple near the place where the battle was fought. The memory of thofe Athenians that were flain in the battle was honoured by illuftrious monuments erected to them in the place where the battle was fought; upon which their own names, and that of their tribes, were recorded. Miltiades's was afterwards erected in the same place. All the honour that was paid to Miltiades, the great deliverer of Athens and of all Greece, was, that in a picture of the battle of Marathon, drawn by order of the Athenians, he was represented at the head of the 10 commanders, exhorting the soldiers, and setting them an example of their duty. This picture was painted gratis by the celebrated Polygnotus, of the isle of Thasos, one of the finest painters of his time, and it was preserved at Athens in a gallery, adorned and enriched with different paintings, excellent in their kind, and done by the greatest masters. The battle of Marathon was fought in the 3d year of the 72d Olympiad, B.C. 490.

In the plain of Marathon, and N.E. of it, was a large lake, which received a river, that ran from the N.W. There was also a mountain of Attica of the same name. Marathon, once so famous, is now an inconsiderable village of European Turkey, in Livadia, consisting only of a few houses, but retaining its ancient name. The spot where the brave Athenians were buried is situated near a lake, from which a river runs into the bay of Negroponte; nine miles N.N.E. of Athens.

MARATHUS, a large and rich town of Phœnicia, situated between Batanea and Carnæa, according to Strabo. This town obtained liberty from one of the successors of Alexander, with the privilege of being governed by its own laws. A war occurring between this city and that of Arad, the inhabitants of the latter place took it, razed it, and divided its territory among themselves.

MARATHUSA, a town in the interior of the isle of Crete.—Also, an island of Asia, upon the coast of Asia Minor, near Ephesus, according to Pliny, but according to Thucydides and Steph. Byz, before Clazomenes.

MARATROCAMPO, in *Geography*, a town of the island of Samos; six miles W. of Cora.

MARATTA, Carlo, in *Biography*, an historical painter, and one of those fortunate men who receive during their lives their full portions of praise and emolument. He was born at Camurano, in the marquisate of Ancona, in the year 1625. He was the disciple and friend of Andrea Sacchi, with whom, to the death of the latter, he pursued his studies, and continued his attachment.

Although he enjoyed during his life, and perhaps deserved, the reputation of the best painter in Europe, yet when compared with the truly great, he never rose above mediocrity. It is very seldom that enlarged and grand conception reigns in his compositions; but a certain suavity and loveliness in his madonnas, which he seems to have acquired from Correggio's works, of grace in his angels, and devout character in his saints, render his pictures always agreeable, and are the source of his renown. From his first performances being chiefly madonnas, his contemporaries treated him with the appellative of Cartuccio delle Madonini, and probably by that very circumstance excited him to employ his talents upon more extended and difficult subjects, in which he exhibited his superior taste and skill. He evidently appears to have studied the works of Raphael, but never felt the beauty of his simplicity, nor understood the principles of his design and composition. For the well understood draperies and judicious introduction of folds which we see in the best pictures of that great master, Maratta resorted to a fulness and overwhelming quantity; arranged in the style of Sacchi; but hiding too much of the figures, and giving them by that means a heaviness, and often a bad proportion. His colouring is in general clean and freely wrought, but sometimes his shadow colour partakes too much of red, which does not unite in a friendly manner with the lighter tones, and destroys the brilliancy of effect which he generally aims at.

There is a great number of his works in the churches and palaces of Rome, which bear testimony of his popularity, and they were sold at prodigious prices during his life. Of late, since a more just taste in art is arisen, they have fallen in the scale to their proper level; but still are, as they deserve to be, held in much estimation.

He lived to the advanced age of 88, and practised his art to a very late period of his existence.

MARATTIA, in *Botany*, was so named by Dr. Swartz, in commemoration of John Francis Maratti, abbot of Vallumbrosa, lecturer on botany, and superintendant of the botanic garden, at Rome. He published three small Latin tracts in that city. First a description of the flowers of dorsiferous ferns, in 1760, which is rather a description of their fruits; for the author certainly has in some cases mistaken the latter for the former; in others delineated as organs of impregnation, what are, at most, very doubtfully such. Yet this essay occasioned Dr. Swartz to choose a genus of ferns to bear his name; and he has certainly fallen on one of the most singular, distinct, and elegant, in nature. Maratti's second work, printed in 1772, is a definition, with figures, of two supposed new genera, entitled *Romulea* and *Saturnia*; the former of which is *Ixia Bulbocodium*, the latter *Allium Chamæmoly*. His last publication, dated 1776, is on the Zoophytes and Lithophytes of the Mediterranean; of which, considered as plants, he treats systematically, in the Linnæan style, with synonyms. All these tracts are of rare occurrence in England. Swartz. Prodr. 128. Fil. 168. Sims and Kon. Ann. v. 2. 309. t. 10. f. 6. Sm. Plant. Ic. 46. Mem. de l'Acad. de Turin, v. 5. 419. Tracts, 259. Sprengel Crypt. 180. Mart. Mill. Dict. v. 3. (Myriotheca; Juss. 15. Lamarck Illustr. t. 866.)—Class and order, *Cryptogamia Filices*; sect. *exannulatæ*. Nat. Ord. *Filices dorsiferæ*.

Eff. Ch. Capsules oval, scattered, bursting longitudinally on their upper side, disclosing a row of cells in each division. Involucrum none.

This very remarkable and beautiful genus ranges next in affinity to Danæa; see that article. It differs however essentially, in the capsules being formed of two lobes, at first cohering longitudinally, by what afterwards becomes their upper surface, and discloses a row of from four to ten cells in each lobe, opening each by a separate orifice, smaller than the internal diameter of the cell, in the said upper surface. The entire capsule therefore is oval, with a determinate number of cells, very different from the indefinite aggregation of single-celled capsules, seen in *Danæa*. Nothing is known of the flower, or mode of impregnation. The capsules stand separately on the veins of the frond, without any involucrum, and in a young state appear like little smooth grains. When mature they are generally the size of half a mustard-seed. Their seeds are inconceivably minute.—Five, or at most six, species are known.

1. M. *alata*. Wing-stalked Marattia. Swartz Prodr. 128. Sm. Plant. Ic. t. 46.—Frond doubly pinnate. Leaflets sharply serrated. General stalk scaly; partial ones winged. Native of Jamaica, where it has been gathered by several botanists. This appears to be an herbaceous *fern*, perhaps three or four feet high, but we have not seen either the *root* or the lower part of the *frond*. The upper part is doubly and oppositely pinnate, with square scaly *stalks*, the whole of which in the branches, and the upper part of the main stalk, is winged with a leafy entire border, contracted at the insertion of every leaflet. The *leaflets* are sessile, an inch long, more or less, very nearly, if not entirely, opposite,

ovate

ovate-oblong, bluntiſh, ſharply and rather deeply ſerrated, eſpecially towards the extremity, veiny, the veins always dividing ſoon after they leave the mid-rib, each branch ending in one of the ſerratures. The upper ſide is ſmooth, with a prominent rib; under ſide paler, minutely ſcaly about the rib and veins. The lower *leaflets* are often lobed or pinnatifid; the upper ones diminiſh gradually, become confluent, and form an elongated ſerrated point to each branch. The truly remarkable *capſules* are three, four, or five on each ſide of the mid-rib of moſt of the leaflets, towards the margin beneath, each ſtationed on a branch of a vein, and about the ſize of a garden-poppy ſeed, externally pale brown. When the lobes ſeparate, their upper ſide appears of a pale ſulphur-colour, ſtriated tranſverſely where the cells are to open, and more or leſs crenate at the edges. At length the whole capſule becomes browner, and the cells open by about five oval-oblong orifices in each lobe.

2. M. *lævis*. Smooth-ſtalked Marattia. Sm. Plant. Ic. t. 47.—Frond doubly or triply pinnate. Stalks ſmooth; the partial ones winged. Leaflets bluntly ſerrated; the uppermoſt confluent.—Gathered by M. Thierry de Menonville in Hiſpaniola, not in Dominica.—This has a general reſemblance to the foregoing, but is partly triply pinnate, and quite deſtitute of ſcales on the ſtalks or veins. The ſerratures of the *leaflets* are blunter; partial ſtalks of the lower ones very broadly winged; and the *capſules* are ſhorter, almoſt globoſe before they open, having but four, rarely five, cells in each lobe. Their margin moreover is quite entire, not crenate or cracked. *Seeds* extremely minute, white. It may alſo be remarked that the principal ſubdiviſions of the *frond* in this ſpecies are more generally alternate, and the veins of the *leaflets* are moſt of them ſimple, not divided.

3. M. *fraxinea*. Aſh-leaved Marattia. Sm. Plant. Ic. t. 48.—Frond doubly pinnate. Stalks ſmooth, ſimple. Leaflets alternate, lanceolate, ſerrated, all diſtinct.—Native of the iſland of Mauritius. Our ſpecimen was given by the celebrated M. Thouin to the younger Linnæus, when at Paris. It is one of the moſt magnificent, as well as curious, of its whole natural order. We have only a branch of the *frond*, which ſhews the whole to be at leaſt doubly pinnate, in an alternate order. This *branch* is above a foot long, and much reſembles the leaf of ſome ſort of aſh, conſiſting of 22 alternate ſeſſile *leaflets*; beſides the terminal one, which is not larger than the others. The *ſtalks* are very ſmooth and naked, ſimple, except a very ſlight wing near the very top. *Leaflets* two or three inches long, on very ſhort ſtalks, ſmooth, bright green, lanceolate or ſlightly ovate, ſcarcely an inch wide in any part; their point elongated; their margin copiouſly, ſharply, and pretty equally ſerrated; their baſe wedge-ſhaped and entire; their tranſverſe veins numerous, parallel, moſtly ſimple, ſometimes forked, quite deſtitute of ſcalineſs. *Capſules* diſpoſed near the margin, not very abundantly or univerſally, rather larger than thoſe of the firſt ſpecies, roundiſh-oval, brown; each lobe quite entire at the edge, and furniſhed with about ſix cells. Dr. Swartz erroneouſly quotes the author of the preſent article, as ſaying the branches (*pinnæ*) are oppoſite.

4. M. *ſorbifolia*. Service-leaved Marattia. "Bory de St. Vincent's Voyage, v. 1. 267." *Swartz*.—"Frond doubly pinnate. Branches alternate. Leaflets linear-lanceolate." *Sw.* Native of the iſle of Bourbon.—We know this merely by what we have here copied from Dr. Swartz, not having acceſs to the book he quotes. The author we follow ſuſpects this to be the very ſpecies figured by Lamarck in his Illuſtrations of Genera, tab. 866; but we ſhould rather ſuppoſe that figure to be taken from *M. fraxinea*, except poſſibly the ſeparate leaflet. The *capſule* and its diſſections are all copied from Sm. Pl. Ic. t. 48.

5. M. *oppoſitifolia*. Oppoſite-leaved Marattia.—Frond .... Leaflets oppoſite, linear-lanceolate, ſharply ſerrated.—Native country unknown. We have a mutilated ſpecimen of this, without any mark whatever, in the herbarium of the younger Linnæus. It conſiſts of near four inches only of the *rachis*, or ſtalk, which is as thick as a gooſe-quill, ſmooth, convex beneath, marked with a narrow furrow above. This appears to be but a very ſmall portion of the branch, or whole frond, we cannot tell which. It bears four pair of oppoſite *leaflets*, all nearly of an equal ſize, not quite four inches long, almoſt an inch wide, linear-lanceolate, taper-pointed, finely, ſharply, and equally ſerrated throughout, except at the baſe, veined like *M. fraxinea*, and ſupported on very ſhort ſtalks. The upper ſurface is ſmooth; the under paler, its veins rough with fine linear ſcales. *Capſules* very numerous on every leaflet, rather larger than thoſe of the *fraxinea*, but otherwiſe like them, and containing the ſame, or occaſionally a greater, number of cells. Theſe *capſules* form a continued line near each margin, except at the baſe and point, being from 40 to 50 in each row. We ſhould, by the name, have ſuppoſed this the *ſorbifolia* laſt mentioned, had the *leaflets* of that been deſcribed as oppoſite. The ſhape and ſize of each *leaflet* well agree with Lamarck's ſeparate one, fig. *b*, but his footſtalk is too long, and capſules not ſufficiently copious or crowded.

6. M. *ſalicina*. Willow-leaved Marattia.—Frond ſimply pinnate? Stalk ſmooth, ſimple. Leaflets alternate, ſtalked, linear, very ſlightly crenate, with ſerrated points.—Our ſpecimen of this nondeſcript fern was communicated by the late Rob. Moleſworth, eſq., as a native of New South Wales. As it was accompanied by a large collection of other plants, undoubtedly the produce of that country, and by no others, we preſume the account muſt be correct; yet there being no *Marattia* mentioned in Mr. Brown's *Prodromus*, cannot but induce ſome ſuſpicion. It is however a moſt curious and diſtinct ſpecies. We cannot poſitively ſay whether our ſpecimen be the whole plant, from the root; in which caſe the *frond* is ſimply pinnate; or a branch rudely torn from a more compound *frond*. The *ſtalk* is two feet long, ſmooth, ſimple and even, ſomewhat quadrangular, very firm and ſtrong. *Leaflets* numerous, (about 40), on ſhort ſtalks, alternate, ſpreading, linear, ſharp-pointed, four or five inches long and half an inch broad; ſmooth and of a fine green above; rather paler, and having capillary ſcales on the lower part of the rib, beneath; the margin is ſo very ſlightly and obtuſely crenate it might almoſt be called entire, but the ſhort taper point, beyond the capſules, is ſerrated; the veins are much like the foregoing. The *capſules* are exceſſively numerous, forming a cloſe row, along each edge of the leaflet, every vein bearing one, ſo that there are near 100 in every row. They are larger than in any other known ſpecies, and have nearly a double number of cells, whoſe orifices are linear, and crowded cloſe together.—When we conſider the poſſible rate of increaſe in ſuch a plant as this by ſeed, it is as ſtupendous as that of the Ling-fiſh, whoſe progeny, if uninterrupted, would, according to the calculation of Linnæus, in 20 years fill the whole ocean. Here are perhaps 8000 capſules, each having about 20 cells, which makes 160,000, and we can hardly conceive the quantity of minute ſeeds in each cell; at leaſt it is impoſſible to count them with any degree of exactneſs. The number of ſeeds however in ſome ferns, is probably much greater.

Not having yet been able to procure the volume of Willdenow's denow's Sp. Pl. which treats of ferns, we know not how far our new ſpecies may accord with any of his. S.

MARATTOUR, in *Geography*, a town of Hindooſtan, in the circar of Guntoor; 28 miles N. of Mootapilly.

MARATUBA, an iſland in the Eaſt Indian ſea, about 24 miles in length from N. to S. Its breadth varies from 12 miles to 4. It is the largeſt of a cluſter, to which it gives name; the next in ſize is Kakkabban; the reſt are very ſmall. N. lat. 2° 14′. E. long 118 30′.

MARAUA, a town of Arabia, in the province of Yemen; 16 miles N.N.E. of Hodeida.

MARAUDING, from the French, *maraude*, in *Military Language*, is a term applied to a party of ſoldiers, who, without any order, go into the neighbouring houſes or villages, when the army is either in camp or garriſon, to plunder and deſtroy, &c.

MARAVEDI, a little Spaniſh copper coin, worth ſomewhat more than a French denier, or half a farthing Engliſh.

The word is Arabic, and took its riſe from the *Almoravides*, a dynaſty of Moors, who, paſſing out of Africa into Spain, impoſed their own name on this coin, which by corruption was afterwards changed into *maravedi*.—Mention is made of it in the decretals, as well as in other Latin writers, under the name of *marabitini*.

The Spaniards alſo count by maravedis, both in commerce and in their finances, though the coin itſelf is no longer current among them. Thirty-four maravedis vellon are equal to the real vellon, which is the moſt general money of account. Madrid, and all Caſtile, with moſt of the adjacent provinces, and alſo Bilboa, Malaga, and Gallicia, keep accounts in reals and maravedis vellon. The real of new plate is double the real vellon, and is alſo reckoned at 34 maravedis of new plate. This real is repreſented by an effective coin of baſe ſilver; but books are not kept in any part of Spain in this money. The real of old plate is alſo reckoned at 34 maravedis of old plate. Cadiz and Seville keep accounts in reals and maravedis of old plate. The real of old plate is worth about 5*d.*; and the real vellon $2\frac{1}{2}$*d.* nearly; or, more accurately, 1*l.* ſterling = 48 reals $20\frac{2}{3}$ maravedis of old plate, or 91 reals 17 maravedis vellon. See REAL and SPAIN.

This ſmallneſs of the coin produces vaſt numbers in the Spaniſh accounts and calculation; inſomuch that a ſtranger or correſpondent would think himſelf indebted ſeveral millions for a commodity that coſt but a few pounds.

In the laws of Spain, we meet with ſeveral kinds of maravedis; Alphonſine maravedis, white maravedis, maravedis of good money, maravedis Combrenos, black maravedis, and old maravedis. When we find maravedis alone, and without any addition, it is to be underſtood of theſe mentioned above. The reſt are different in value, fineneſs of metal, time, &c. Mariana aſſerts, that this coin is older than the Moors; that it came from the Goths; that it was anciently equal to a third part of the real, and conſequently of twelve times the value of the preſent maravedi. Under Alphonſus XI. the maravedi was ſeventeen times; under Henry II. ten times; under Henry III. five times; and under John II. two times and a half the value of the preſent maravedi.

MARAVI, in *Geography*, a country of Africa, with a city of the ſame name, built on the S. ſide of the lake, about 250 miles from the Indian ſea. S. lat. 13° 15′.—Alſo, a lake of Africa, in S. lat. 10°, of great extent, laid down by M. d'Anville as more than 350 Britiſh miles in length, but of inadequate breadth; ſome ſay 30 miles. This lake may perhaps, like that of Baikal, lie at the foot of the Table land on one ſide, as that of Aquilunda, of much ſmaller extent, does on the other.

MARAUTSCH, a town of Upper Carniola; 11 miles E. of Stein.

MARAUZGUIR, a town of Hindooſtan, in Myſore; 30 miles E.S.E. of Ouſſoor.

MARAWA, a town on the eaſt coaſt of the iſland of Banca. S. lat. 2 15′.

MARAWAR, a country of Hindooſtan, bordering on the coaſt oppoſite to Ceylon; about 60 miles in length, and 40 in breadth. It was conquered by the Britiſh troops in 1773, and the rajah killed. It is covered with thick foreſts, and little cultivated. In the flouriſhing ſtate of the empire of Hindooſtan, Marawar yielded a revenue of five covres of rupees.

MARAWIL, a town of the iſland of Ceylon, on the W. coaſt; 14 miles N. of Negombo.

MARAYAN, a town of Hindooſtan, in Bahar; 25 miles E. of Bahar.

MARAYAT BAY, a bay on the W. coaſt of the iſland of Luçon. N. lat. 14° 37′. E. long. 120° 21′.

MARAZION, or MARKET JEW, a market-town in the pariſh of St. Hilary, hundred of Penwith, county of Cornwall, England, is ſituated on the ſide and at the bottom of a hill, near an arm of the ſea, called Mount's bay, three miles E. of Penzance, and 286 W. from London. It derived its principal ſupport, if not its origin, from the reſort of pilgrims, and other devotees, to a neighbouring ſacred edifice on St. Michael's Mount; but that attraction being counteracted by the changes of opinion which commenced at the Reformation, and the then new town of Penzance drawing within its vortex many merchants and tradeſmen, with their connections and dependants, the conſequence of Marazion decreaſed. By ſome authors its name is derived from the Jews, who are reported to have traded here ſeveral centuries ago, and to have held an annual market for ſelling various commodities, and purchaſing tin and other merchandize in return. Richard, king of the Romans, granted two fairs to this town, for the benefit of the priory at St. Michael's Mount; but this charter was ſuperſeded by another in the thirty-ſeventh year of queen Elizabeth, by which the government of the town was veſted in a mayor, eight aldermen, and twelve capital burgeſſes, with power to hold one weekly market and two annual fairs. In the preamble to this charter it is ſtated, that "Marghaſiewe was a trading borough of great antiquity;" from which expreſſion, and from a corroborating correſpondence between the ſheriff of Cornwall and the mayor of Marazion during Cromwell's protectorate, it ſeems probable that this town was anciently repreſented in parliament. Two members were actually elected and returned in Cromwell's time; but they do not appear to have taken their ſeats: the endeavours of the inhabitants to regain their dormant rights proved ineffectual. In the Survey of the year 1801, purſuant to act of parliament, Marazion was ſtated to contain 224 houſes, occupied by 1009 perſons. The trade conſiſts chiefly in the importation of timber, coals, and iron, for the uſe of the inhabitants of the place, and for the neighbouring mines. The pariſh-church of St. Hilary is nearly two miles diſtant from the town: but here is a chapel of eaſe, ſupported by private ſubſcription. Quakers and Methodiſts have alſo their reſpective meeting-houſes.

Between Marazion and St. Michael's Mount is a place called the Chapel Rock, where the pilgrims who came to viſit the priory of St. Michael performed certain devotionary ceremonies, in a kind of initiatory chapel previous to their admiſſion to the more ſacred Mount.

The

The peculiar ſituation of St. Michael's Mount, and the ſingular character it aſſumes from appearing to riſe immediately from the waves, intereſt the imagination of the obſerver; though, when viewed from the land, its magnitude is apparently diminiſhed, from the vaſt extent of the horizon, and the expanſe of water which ſurrounds its baſe. At high tides it appears a completely inſulated aſſemblage of rocks, riſing to a conſiderable height, and gradually decreaſing in ſize, till, aſſiſted by the tower of the chapel on the ſummit, it aſſumes the form of a perfect pyramid. At low water it may be approached from the ſhore over a cauſeway of ſand and rock, which is ſubmerged by every riſing tide, and the Mount again rendered a perfect iſland. Some of the maſſes of rock in the intermediate ſpace are very large, and all are compoſed of granite of a cloſe texture, with its feldſpar of a pink colour. The Mount itſelf conſiſts of a hard granite, in which tranſparent quartz is the preponderating ſubſtance. The origin of the Mount, and its firſt conſecration to religious purpoſes, are unknown: the earlieſt time in which it appears on record, as a place of devotion, is the fifth century; though it ſeems probable that it was then highly celebrated, as St. Keyna, a holy virgin, daughter of Braganus, prince of Brecknockſhire, is ſtated to have come hither on a pilgrimage about the year 490. Upwards of 500 years afterwards, Edward the Confeſſor founded on this ſpot a priory of Benedictine monks, on whom he beſtowed the property of the Mount. This priory was held in high eſtimation, and was formed with peculiar privileges by pope Gregory, in the year 1070. King Henry VI. granted the priory to King's college, Cambridge; and it was afterwards beſtowed by Edward IV. on the nunnery of Sion, Middleſex. At the diſſolution, its revenues, valued at 110*l.* 12*s.* *per annum*, were conferred, together with the government of the Mount, then a military poſt, on Humphry Arundel, eſq. a branch of the family from which the preſent lord Arundel is deſcended. After ſeveral transfers, it was, about the cloſe of the ſeventeenth century, ſold to John St. Aubyn, eſq., whoſe deſcendant, ſir John St. Aybyn, bart. ſtill poſſeſſes it. The Mount has been the ſcene of ſeveral military tranſactions: the earlieſt recorded was in the reign of Richard I. when it was fortified in ſupport of prince John, then earl of Cornwall, in his endeavours to uſurp the throne during the king's abſence in the Holy Land, or his ſubſequent impriſonment in Germany. "From this time forward," Carew ſays, "this place continued rather a ſchoole of Mars than a temple of peace." It was a long time defended againſt Edward IV. by John, earl of Oxford, in behalf of king Henry. During the Corniſh inſurrection in the reign of Edward VI. the Mount was the refuge of many of the ſuperior families, who were here beſieged by the rebels. The civil contentions in the reign of Charles I. were the cauſe of the fortifications of the Mount being increaſed, till, according to an hiſtorian of that time, they were "impregnable, and almoſt inacceſſible." They were, however, reduced, after a vigorous defence by the king's adherents, in April 1646, by colonel Hammond, who obtained great celebrity by a ſervice of ſuch difficulty and danger. This was the laſt military occurrence that took place on this romantic ſpot, whoſe inhabitants appear to have been then driven away; for at the commencement of the laſt century, here was but one dwelling-houſe beſides the fortreſs. The improvements that have ſince been effected, and the increaſe of the buildings, are to be attributed to St. John St. Aubyn (grandfather of the preſent baronet), who, about the year 1726, rebuilt and enlarged the pier, ſo as to contain upwards of fifty ſmall veſſels. The ſecurity thus given to fiſhing-boats, induced ſeveral inhabitants of Marazion to erect ſome houſes at the bottom of the rock: the number has been ſince augmented to ſeventy, occupied by about 250 perſons. The circumference of the Mount is rather more than a mile; and its height, from the ſand to the top of the chapel-tower, as aſcertained by Hadley's quadrant, is 250 feet, being 48 feet higher than the Monument in London. The diſtance from the ſhore at Marazion is about 400 yards. The aſcent to the top of the Mount is by a ſteep and craggy paſſage fronting the north, defended about the midway and near the top by batteries. The whole ſummit is occupied by the remains of the ancient monaſtic buildings, which have been improved and beautified by the preſent poſſeſſor, under whoſe direction the chapel has been repaired. Beauties of England and Wales, vol. ii.

MARBAA, a town of Arabia; 10 miles W. of Mecca.

MARBACH, a town of Saxony, in the circle of Erzgeburg; 8 miles N. of Freyberg.—Alſo, a town of Auſtria, near the Danube; 9 miles S.W. of Aggſbach.

MARBACK, a town of Sweden, in the province of Smaland; 20 miles E.S.E. of Jonkioping.

MARBASIS, in *Botany*, a name given by ſome to a kind of plant which they ſay climbed up trees, and there hung down from their branches in form of long jointed and naked filaments.

The word ſeems to be only a corruption of the word *anabaſis* of Pliny, which he calls alſo *ephedra*, and gives the ſame character to.

The marbaſis of the ancients ſeems to mean our *uſnea*.

MARBECK, John, in *Biography*, organiſt of Windſor. The premature reforming zeal of this muſician nearly made a martyr of him, in the time of Henry VIII. He had indeed the honour of being brought to the ſtake, with three other perſons, who were actually burnt for hereſy; but was pardoned at the interceſſion of ſir Humphrey Forſter.

Fox, in his "Acts and Monuments," and Burnet, "Hiſtory of the Reformation," give a circumſtantial detail of the troubles in which Marbeck was involved, on account of religion. He however ſurvived Henry, and not only ſaw the reformation completed, but in 1550 was the firſt to publiſh the whole Engliſh cathedral ſervice, including the preces, prayers, and reſponſes, ſet to muſical notes under the title of

The Booke of Common Praier, noted 1550. Imprinted by Richard Grafton, Printer to the Kinge's Majeſtie, *cum privilegio ad imprimendum ſolum.*

Marbeck was admitted, in 1549, to the degree of bachelor in muſic, at Oxford, according to Anthony Wood (Faſts Oxon.) who erroneouſly calls him James Marbeck. He is honourably mentioned by Bate, becauſe he had been perſecuted by the Catholics; and his name is omitted by Pitts, for the ſame reaſon. See Music a Cappella, and Chanting.

MARBELLA, in *Geography*, a ſea-port of Spain, in the province of Granada, on the coaſt of the Mediterranean, beautifully ſituated in a valley, with its harbour ſcreened from the E. wind by a promontory, and defended by a caſtle, which is furniſhed with ſome guns. The exports from this town are wine, dried raiſins, leather, black ſtone, charcoal, and wood. In its neighbourhood is an extenſive ſugar plantation; 26 miles S.W. of Malaga. N. lat. 36° 31'. W. long. 4° 59'.

MARBEUF, a town of the iſland of Corſica; 10 miles W.S.W. of Vico.

MARBLE, in *Technical Mineralogy*, thoſe finer varieties of granular and compact limeſtone, which, being of a cloſer grain, are ſuſceptible of a ſuperior poliſh, and are remarkable either for their whiteneſs, or the beauty and variety of their colours. In former times the appellation of *Marmor* (derived

rived from the Greek μαρμαιρειν, *to ſhine*, or *glitter*, and afterwards corrupted to *marmol*, *marmel*, *marble*, *marbre*,) was indiſcriminately given to many ſtony maſſes that admit of being poliſhed, and accordingly we find alabaſter, ſerpentine, baſalt, porphyry, &c. deſcribed under that name, which is now confined to ſuch maſſive carbonats of lime as come under the above definition; which, however, does not exclude the varieties containing foreign ſubſtances imbedded in, or mixed with, the principal calcareous maſs, ſuch as ſerpentine, hornblende, quartz, &c.

Moſt of the external, phyſical, and chemical characters of the pure marbles are, of courſe, the ſame as thoſe of *compact and granular Limeſtone*; which ſee.

Marbles are eaſily diſtinguiſhable from gypſeous and calcareous alabaſters, with which they are frequently confounded; from the former by the application of ſome diluted nitric or muriatic acid, which produces a ſtrong efferveſcence, by expelling the carbonic acid; from the latter (which belong to ſtalactitical limeſtone, and are, therefore, acted upon in the ſame manner by the acids) by inferior hardneſs, a ſlighter degree of tranſlucidity, and, if coloured, by the abſence of regularity in the ſtripes and undulations that characteriſe the calcareous alabaſter: nor is the latter ever found in maſſes of conſiderable dimenſions.

The ſpecific gravity of marble varies in the ſame manner as that of the different varieties of common limeſtone, whence no diſtinctive character can be derived from it: Wallerius and Gmelin ſtate the ſpecific gravity of the former to be leſs, while others conſider it as greater than that of common limeſtone; but, according to Gerhard and other writers, it is, on the whole, equal in both.

Some granular marbles, when cut into thin ſlabs, exhibit a degree of elaſticity or flexibility, ſimilar to that of the well-known ſandſtone found in Brazil. This phenomenon was firſt obſerved in ſome pieces of marble preſerved in the palace of prince Borgheſe at Rome. But afterwards another marble, (of the variety called Dolomite,) having the ſame property, was diſcovered by Fleuriau de Bellevue, in the Val-Levantine of mount St. Gothard. Dolomieu (who deſcribed the Borgheſe marble) is of opinion that this property is owing to a ſtate of deſiccation which has leſſened the adherence of the molecules of the ſtones; and Fleuriau de Bellevue has proved this conjecture to be well founded, not only by the appearance and nature of the ſtone he diſcovered on St. Gothard, but alſo by his imparting the ſame property to ſeveral inflexible varieties of marble by merely expoſing them to ſuch a degree of heat as produced complete deſiccation. Some wrought granular (ſtatuary) marbles acquire a ſimilar property after a long expoſure to the action of the atmoſphere and the ſolar rays; a circumſtance which ſometimes takes place in ſtatues, cauſing thereby the more projecting parts to exfoliate, and to crumble to pieces. Dolomieu has firſt made this obſervation on an Italian marble called *Betullio*.

The various tints of the uni-coloured and variegated marbles, are generally produced by oxyds of iron, the ſolution of which has, either wholly or partially, penetrated the maſs previous to its complete induration. Blue and green marbles often owe their tints to minute particles of hornblende; this is the caſe, for inſtance, with the ſlate blue variety called *turchino*, and with ſome green German marbles. The black varieties are coloured by charcoal, and alſo by bitumen, when they paſs into ſtinkſtone. In marbles containing petrifactions, theſe appear ſometimes to have derived their colour from the ſame fluid which coloured the maſs; while at other times the colour of the ground is quite different from that of the petrifactions it contains.

All that has been ſaid of the fracture of granular and compact limeſtone, is applicable to marbles; but it is often difficult to draw the line between the two former. In general it may be ſaid, that the white ſtatuary marbles belong to the granular, and many of the variegated to the compact. Nor is it in all caſes eaſy to determine whether a given ſpecimen belong to the older or newer formation of limeſtone. It is, therefore, evident, that the diviſion of marbles into primary, with ſhining fracture, and into ſecondary, with dull fracture, is far from being practically uſeful; indeed, many varieties of marbles, as for inſtance, moſt of thoſe of the Hartz, &c. cannot be referred to either.

Baumer, Bertrand, Scopoli, Daubenton, Gmelin, and others, have arranged the varieties of marble after the colours they preſent; but this ſyſtem muſt neceſſarily aſſign two or more different places to one and the ſame kind of marble, variable in the number of its colours, and is, therefore, applicable only to ſmall ſpecimens. A far more convenient and uſeful diſtribution is the one adopted in the "Traité des Pierres précieuſes, &c." by Brard, whom we ſhall follow in the preſent article. The marbles are by this author divided, according to their localities, into claſſes, and theſe ſubdivided each into eight diſtinct diviſions, *viz.*

1. Uni-coloured marbles: this diviſion contains only the white and the black marbles.

2. Variegated marbles: thoſe with irregular ſpots and veins.

3. Madreporic marbles: this diviſion, eſtabliſhed by Faujas, comprehends all marbles containing remains of madrepores, or of related animals which generally preſent themſelves in the ſhape of white or grey ſpots, with regularly diſpoſed dots and ſtars in the centre.

4. Shell marbles: marbles that contain only a few ſhells, and are not, like

5. Lumachella marbles, entirely compoſed of ſhells.

6. Cipolin marbles: containing veins of greeniſh talc.

7. Breccia marbles: formed by a number of angular fragments of various marbles united by a cement. Theſe are ſubdivided into *ſmall breccias*, with ſpots having generally leſs than an inch in diameter; and into *large breccias*, with the generality of ſpots exceeding that dimenſion.

8. Puddingſtone marble: formed, like the breccias of fragments united by a cement, but which, inſtead of being angular, are rounded.

A. *Antique Marbles.*

Antique marbles are ſuch as were made uſe of by the ancients, and the quarries of which are no longer known. The moſt remarkable of theſe, both on account of their beauty and the uſe made of them in the arts, are

Parian marble (Lychnites of the ancients). Of a yellowiſh-white colour; texture fine ſcaly; ſcales ſhining and placed in all directions. Dipœnus, Scyllis, Malas, and Micciades employed this marble, and were imitated by their ſucceſſors. The ancients called it lychnites, becauſe its quarries were wrought at lamp light. The principal ſtatues of Parian marble ſtill extant are, the Venus of Medicis, Diana venatrix, Venus leaving the bath; the coloſſal Minerva (called Pallas of Velletri), Ariadne (called Cleopatra), Juno (called Capitolina), &c. It is alſo Parian marble on which the celebrated tables at Oxford are inſcribed. See Arundelian and Parian *Marbles*.

Pentelic Marble, from mount Penteles near Athens. This marble much reſembles the preceding, but is more denſe and fine-grained; it ſometimes exhibits faint greeniſh zones, produced by greeniſh talc, whence the Italian name *Cipolino ſtatuario*. The principal monuments of Athens were of Pentelic

telic marble, ſuch as the Parthenon, the Propylees, and the Hippodrome. Among the ſtatues of this marble in the Napoleon Muſeum, at Paris, are the Torſo; a Bacchus in repoſe; Jaſon, (called Cincinnatus); a Paris; the Diſcobolus repoſing; the bas-relief known by the name of the Sacrifice; the throne of Saturn; the tripod of Apollo; and the two beautiful Athenian inſcriptions known by the name of "Nointel Marbles," becauſe M. Nointel cauſed them to be brought from Athens to Paris in 1672.

Greek white Marble. The marble to which the ſtatuaries of Rome give the name of *Marmo Greco*, is of a very bright ſnow-white colour, cloſe and fine-grained, and of a hardneſs which is rather ſuperior to that of other white marbles. It takes a very fine poliſh. This is one of thoſe varieties which, being found near the river Coralus, in Phrygia, were called coralitic or corallic marble by the ancients. According to Pliny it was found in Aſia, in maſſes of ſmall dimenſions; and Argenville maintains that a ſimilar kind occurs on mount Caputo, near Palermo, in Sicily. The Greek marble was obtained from ſeveral iſlands of the Archipelago, ſuch as Scio, Samos, &c.; that of the iſland of Leſbos or Metelin ſometimes preſents ſpots on its ſurface. Among the ſtatues of this marble in the Napoleon Muſeum, the moſt remarkable are; a Bacchus, Zenon the philoſopher, as alſo the buſt known by the name *Faune à la tache*. Brard obſerves that this latter buſt appears rather to be of the true Coralic marble of the ancients; and that the ſpot at the neck, from which the buſt has derived its name, is foreign to the marble, and cauſed by contact with a piece of copper. Some ſuppoſe the Apollo of Belvedere to be of Greek marble, but the general opinion is that it is marble of Luni.

Tranſlucid white Marble (Marmo *ſtatuario* of the Italians). This much reſembles Parian marble, but differs from it by its more conſiderable tranſlucidity. There are at Venice, and in ſeveral other towns of Lombardy, columns and altars of this marble, the quarries of which are perfectly unknown.

Flexible white Marble, of a beautiful white colour, and fine grain. There are five or ſix tables of it preſerved in the houſe of prince Borgheſe at Rome; their length is about two feet and a half, the breadth about ten inches, and the thickneſs a little leſs than three. They were dug up, as the abbé Fortis was told, in the feod of Mondragone. Being ſet on end they bend, oſcillating backward and forward; when laid horizontally, and raiſed at one end, they form a curve, beginning towards the middle; if placed on a table, and a piece of wood laid under them, they make a ſalient curve, and touch the table with both ends. We refer to what has been ſaid above reſpecting this property.

White Marble of Luni, on the coaſt of Tuſcany. It is of a ſplendent white, and of a fine and cloſe grain; it takes a very fine poliſh, and may be employed for the moſt delicate work, whence it was preferred by the Grecian ſculptors both to the Parian and Pentelic marbles. It appears to be even finer than that of Carrara, and is moreover free from thoſe grey veins which are not unfrequently found in the latter. Moſt mineralogiſts coincide in their opinion that the Apollo of Belvedere is of Luni marble; but the Roman ſculptors look upon it as Greek marble. Of the Grecian ſtatues of this marble in the Napoleon Muſeum, the moſt remarkable are, the Antinous of the Capitol; the Antinous in bas-relief; the bas-relief repreſenting the ceremony of the conclamation.

White Marble of Carrara, between Specia and Lucca. Of a fine white colour, but often traverſed by grey veins, ſo that it is difficult to procure middle-ſized pieces without them; its fracture is granular and ſhining, and its grain fine enough for the purpoſes of ſculpture. It is not ſo ſubject to turn yellow as the Parian marble. This marble, which is almoſt the only one made uſe of by modern ſculptors, was alſo quarried and wrought by the ancients, as is proved by the great number of antique ſtatues ſtill extant in this marble. Its quarries are ſaid to have been opened in the time of Julius Cæſar. At preſent its two principal quarries are thoſe del Pianello and del Polvazzo. In the centre of the blocks of this marble very limpid rock-cryſtals are ſometimes found, which are called Carrara diamonds. It is alſo ſometimes, like the Pentelic marble, traverſed by veins of a greeniſh talc, when it is called in Italy *Cipolinacio di Carrara*. The average price of this marble is ſeventy-two livres the cubic foot.

White Marble of Mount Hymettus in Greece. This is not a very pure white variety, but inclines a little to grey. Pliny informs us that Lucius Craſſus, the orator, was expoſed to the ſarcaſms of Marcus Brutus, becauſe he had adorned his houſe with ſix columns, twelve feet high, of Hymettian marble. The ſtatue of Meleagre, in the Napoleon Muſeum, is of this marble.

Theſe are the chief white marbles which the ancients uſed for the purpoſes of architecture and ſculpture. The Thaſian and Arabian are likewiſe mentioned as antique white marbles, but we are not acquainted with any monuments executed in them.

Black antique Marble (*Nero antico* of the Italians.) This differs from the modern black marbles by the ſuperior intenſity of its colour; ſo much ſo, that if placed beſide thoſe of Dinan and Namur, it makes them appear grey. It has been affirmed that the ancients procured this marble from Greece; what we know for certain is, that Faujas has rediſcovered quarries of real antique black marble that were wrought by the ancients, and of which the remains are ſtill to be ſeen at the diſtance of two leagues from Spa, towards Franchimont, not far from Aix-la-Chapelle. This marble is extremely ſcarce, and occurs only in wrought pieces.

Red antique Marble (*Roſſo antico* of the Italians, *Ægyptum* of the ancients.) This beautiful marble is of a deep blood-red colour, here and there with white veins, and if cloſely examined is found to be ſprinkled over with minute white dots, as if it were ſtrewed with ſand. Of this kind is the Egyptian Antinous in the muſeum at Paris. But the moſt eſteemed variety of roſſo antico is that of a very deep red, without any veins, ſuch as it is ſeen in the two antique chairs, and in the buſt of an Indian Bacchus, in the ſame muſeum. The white points, which are never wanting in the true red antique marble, diſtinguiſh it from others of the ſame colour, ſuch as the griotte, &c. It is not known from whence the ancients obtained this marble; the conjecture is that it was brought from Egypt. There is in the Grimani palace at Venice, a coloſſal ſtatue of Marcus Agrippa in roſſo antico, which was formerly preſerved in the Pantheon in Rome.

Green antique Marble (*Verde antico* of the Italians.) This may be conſidered as a kind of breccia, the paſte of which is a mixture of talc and limeſtone, and the dark green fragments are owing to ſerpentine more or leſs pure. The verde antico of the beſt quality is that of which the paſte is of a graſs-green, and the blackiſh ſpots are of that variety of ſerpentine which is called noble ſerpentine. This marble is much eſteemed in commerce, but large pieces of a fine quality are ſeldom ſeen. There are four fine columns of it in the Napoleon Muſeum; but much more beautiful ones are preſerved at Parma. It was known to the ancients under the name of marmor Spartum or Lacedæmonium. This verde antico, properly ſo called, muſt not be confounded with the

 marbles

marbles known by the names of *vert-de-mer*, or *vert d'Egypte*. The real verde antico is a breccia, and is never mingled with red ſpots, while thoſe juſt mentioned are veined marbles mixed with a dull red ſubſtance, which gives them a browniſh hue.

Red ſpotted green antique Marble.—Its ground is very dark green, here and there marked with ſmall red and black ſpots. It alſo contains fragments of entrochi changed into white marble. The quarries of this marble are loſt, and it is found only in ſmall pieces, which are made into tablets, &c.

Leek Marble (*Marbre poireau* of the French lapidaries). This is likewiſe a mixture of limeſtone and a talcoſe ſubſtance of a light green, ſhaded with a blackiſh-green, and related to ſerpentine. Its texture is filamentoſe, and as it were ligneous; its fragments are ſplintery. When poliſhed it exhibits long green veins. Like all other talcoſe marbles it ſoon decompoſes in the open air. There is a table of it in the hotel de la Monnoie at Paris. Its quarries are loſt to us.

Marmo verde pagliocco of the Italians. This marble, which is of a yellowiſh-green colour, is only found in the ruins of ancient Rome.

Marbre petit antique of the French lapidaries. It is traverſed by white and grey veins, the two colours being diſpoſed in uninterrupted threads; the tables made of this marble are irregularly ſtriped their whole length, which has a very fine effect. It is much eſteemed, and only made uſe of for inlaying ornamental furniture. Its quarries are unknown.

Blue antique Marble.—This belongs to the variegated marbles. It is of a reddiſh-white colour, with ſlate blue ſpots repreſenting feſtoons. It is very ſcarce, and only ſeen in ſmall tablets. The quarries of this marble are loſt.

Cervelas Marble.—Of a deep red, with very numerous grey and white veins, from the colour and diſpoſition of which its name is derived. It is much eſteemed in commerce, and is ſaid to be found in Africa

Yellow antique Marble (*Giallo antico* of the Italians.) Of this we have three varieties: the firſt has more or leſs the colour of the yolk of an egg, and is nearly of an uniform tint; the other is marked with black or deep yellow rings, and the laſt is merely a paler coloured variety of the firſt. Theſe different marbles, for which the Sienna marble is a good ſubſtitute, are found only in ſmall detached pieces, and in antique inlaid work. It is in this manner that the two tables of lazulite in the Napoleon Muſeum are ſurrounded by a border made of the deep yellow variety.

Red and white antique Marbles.—Theſe marbles, to which ſeparate names have been given, are not ſufficiently diſtinct from each other to require ſeparate articles. The following are from Ferber's letters: red and white marble, called *Porta ſanta fiorita*, becauſe it was employed for ornamenting the door of St. Peter's church at Rome.—*Seme ſanto*, or *Arlechino*, the ſpots of which reſemble ſeeds, is made uſe of for ſeveral holy buildings.—*Pavonazzo;* white with red ſpots reſembling ribbons.—*Marmo occhio di pavone;* red, white, and rather yellowiſh. Ferber mentions a number of other red and white antique marbles, ſuch as the Serpentelo, Roſſo annulato, Purichiello, Vendurino, Fiorito, Cotonello, &c. which are only found among the ruins of the ancient monuments in Rome.

Marble called *Grand Antique*. This variety, which is a breccia, containing ſome ſhells, conſiſts of large fragments of a black marble, united by veins or lines of ſhining white. This ſuperb marble, the quarries of which are loſt, is ſometimes found in detached pieces and wrought There are four columns of it in the muſeum at Paris. A leſs valuable variety is that in which the ſpots, inſtead of being an entire intenſe black, are of a grey colour.

Antique Cipolin Marble.—Cipolin is a name given to all ſuch marbles as have greeniſh zones cauſed by green talc; their fracture is granular and ſhining, and ſhews here and there plates of talc. They are never ſeen to contain marine bodies. The ancients have made frequent uſe of the Cipolin. It takes a fine poliſh, but its ribbon-like ſtripes always remain dull, and are that part of the marble which firſt decompoſes when expoſed to the open air. There are modern Cipolins as fine as that uſed by the ancients.

Purple antique breccia Marble (*Brèche d'Alep* or *d'Alet* of French lapidaries). This ſhould not be confounded with the African breccia. There is perhaps no marble, the colour and ſpots of which are ſo variable as that of the violet breccia. The following are the chief varieties. The firſt is that from which the name of the marble is derived; it has a purpliſh-brown baſe, in which are imbedded large angular fragments of a light purple colour, and others of a white colour. This firſt variety can be employed only in large works, on account of the ſize of its ſpots, which are ſometimes a foot in diameter. There is a beautiful table of it in the Muſée Napoleon. The ſecond variety is as it were the miniature of the firſt; it exhibits the ſame ſpots, but within a much narrower compaſs, ſo that it may be uſed for leſs gigantic works than thoſe for which the other is employed. The third variety is known in commerce by the name of roſe-coloured marble (marbre roſe); in this the ſpots, inſtead of being white and light purple, have a very pleaſing roſe colour. It is ſcarce and never ſeen in large pieces. The fourth, which is the moſt beautiful, appears, at firſt view, to be perfectly diſtinct from the others, but it is nevertheleſs a mere variety of the purple breccia: its ground is of a yellowiſh-green colour, and the ſpots, which are of various ſizes, are white, green, purpliſh, and yellow mottled with red; theſe various ſpots are traverſed by ſtraight lines of a greyiſh-white colour. This fourth variety is very ſcarce; there are, however, two tables of it at Paris, one at M. Faujas, the other in the poſſeſſion of M. Dedré. From one of the names by which this precious marble is known, we ſee that the neighbourhood of Aleppo in Syria is ſuppoſed to be the place where it is found; but this is erroneous, for Brongniart informs us that the name is derived from a place called Alet, near Aix, in France.

African breccia Marble, (called *antique African breccia.*) Its ground is black, variegated with large fragments of a greyiſh-white, of a deep-red, or of purpliſh wine colour; but theſe latter are always ſmaller than the former. This is one of the moſt beautiful marbles exiſting, and has a ſuperb effect when accompanied by gilt ornaments. Though rather leſs vivid in its colours than the preceding violet breccia, it is yet, upon the whole, more beautiful. Whether Africa is the part of the world where it is found, as its name implies, is not certain. The pedeſtal of Venus leaving the bath, and a large column, both in the Napoleon Muſeum, are of this marble.

Roſe-coloured antique breccia Marble—The baſe of this ſmall breccia is light red, and variegated with ſmall roſe-red ſpots, and other ſtill ſmaller ſpots of a deep black colour; there are ſome other middle-ſized ſpots of a beautiful white; the whole producing a very pleaſing mixture. This marble, of which the locality is entirely unknown, is very ſcarce, and only ſmall tablets are ſeen of it in collections.

Yellow antique Marble Breccia.—Two varieties may be united under this name; the one known in Italy by the name of *Giallo brecciato*, which is of a light yellow colour, ornamented

ornamented with much deeper coloured ſpots; the other, called *Breccia dorata*, preſents yellow ſpots ſeparated by red intervals, which contain ſmall white ſpots. Both are found only in ſmall pieces among the ruins of ancient Rome.

The Arlequin breccia, or *Brecciato traccagnina* of the Italians. The ground of this antique breccia, which, on account of the roundneſs of its ſpots, approaches to the pudding-ſtone marbles, is of a pale yellow, and contains a number of ſmall fragments of marble of all colours, which has procured it its name. There are two columns of it in the Napoleon Muſeum.

Red and white breccia Marble (*Breccia pavonazza* of the Italians.) Its baſe is white, the fragments are red. According to Ferber, the interior of the Muſeo Clementino is ornamented with this marble, the quarries of which are loſt.

Breccia di Porta Santa, ſo called from the uſe that has been made of it for adorning the door of St. Peter's church in Rome. It is a mixture of unequal, white, blue, red, and grey ſpots.

Marbre brèche vierge antique of the French lapidaries. This ſmall antique breccia, of a chocolate-brown colour, is ſpotted with a multitude of minute angular fragments of white marble, beſides which it contains ſome ſmall red ſpots. It is ſo ſcarce that only one tomb is known to exiſt of it in Rome. Small tablets of it are ſold at a very high price.

Peach bloſſom Marble (Marmo *fior di Perſica* of the Italians.) This antique marble is to be referred to the breccias, of which it has all the characters. It exhibits large purpliſh ſpots, united by a white cement. A column made of it is preſerved in the Napoleon Muſeum. Several other marbles paſs under the name *fior di Perſica*, that have no reſemblance to the one here deſcribed, which is very ſcarce. Brard ſuſpects that it is nothing but a variety of the purple breccia.

Yellow lumachella Marble, called alſo *lumachelle Caſtracani*. Its baſe is of a very deep brown colour, and contains a great number of ſhells, forming a ſort of well-defined ſmall circles of a very lively orange-yellow. This beautiful marble is very ſcarce, and occurs only in ſmall tablets. It is often called lumachella of Aſtrachan, and ſuppoſed to be found in the neighbourhood of that city; but this is erroneous. D'Argenville and others affirm that ſmall pieces of it are dug up among the ruins of ancient Rome.

Black and white antique lumachella Marble, (called *panno di morto*, the funeral pall.) Its baſe is of the deepeſt black, ſprinkled with white ſhells, like ſnails, from an inch to eighteen lines in length, and diſtributed rather regularly all over its ſurface. This ſhell-marble, the locality of which is unknown, ranks among the fineſt of its kind, on account of the beauty of its colour, the neatneſs and diſtinctneſs of its ſpots, and the exquiſite poliſh it takes. It is, moreover, very ſcarce, a circumſtance which much enhances its value.

B. *Modern Marbles.*

British Marbles.

Great Britain is by no means poor in fine varieties of marble, as has been inſinuated by ſome writers on this ſubject; though, on the other hand, it muſt be confeſſed that thoſe are equally wide of the truth who imagine that its marmoric treaſures will ever rival thoſe of Italy, Spain, or France. There can be no doubt, however, that the number of Britiſh marbles we are at preſent acquainted with, will be conſiderably augmented when accurate reſearch ſhall have been extended to thoſe parts of the united kingdom, that are moſt likely to furniſh this intereſting ſubject of economical mineralogy.

English Marbles.

Black marble is found in Derbyſhire, at Aſhford, Matlock, and Monſaldale.

Black and white marble in the north part of Devonſhire; the varieties from Brideſtow, South Tawton, and Drewſteignton, are ſome black, others inclining to blueiſh-black. Some of the Chudley marble, and thoſe of Staverton and Berry pomeroy, have a black ground, with large veins of calcareous ſpar traverſing it in all directions; alſo red, ſtraw-coloured, and greeniſh veins are ſeen in it. Black with white veins occurs at Buckfaſtleigh, and black with yellow and white veins at Bickington, near Aſhburton, in the ſame county. Intenſe black marble, with diſtant white ſpots, is found alſo in Somerſetſhire.

The variegated marbles of Devonſhire are generally reddiſh, browniſh, and greyiſh, variouſly veined with white and yellow, and the colours are often intimately blended. At Waddon there is a quarry of dunniſh coloured marble veined with green; there is another at Cherſton. The marbles from Torbay and Babbacombe diſplay a great variety in the mixture of their colours, ſo much ſo that one and the ſame block often exhibits ſamples very diſtinct from one another both in tint and delineations.

The Plymouth marble is principally of two ſorts; one aſh colour, ſhaded with black veins; the other blackiſh-grey and white ſhaded, in concentric ſtripes interſperſed with irregular red ſpots.

The cliffs near Marychurch exhibit marble not only of great extent, but of ſuperior beauty to any other in Devonſhire; being for the moſt part either of a dove-coloured ground with reddiſh-purple and yellow veins, or of a black ground mottled with purpliſh globules. In a valley below the cliff, about 400 yards wide, there are looſe unconnected rocks of this marble, owing their ſituation probably to the falling down of the ground into the ſea; for there are very large rocks even on the beach. The huge fragments of rock ſcattered over the valley, by which we eaſily deſcend to the ſea, give it a groteſque appearance, and have been whimſically called a petrified congregation; and the pleaſantry of this fancy has been heightened by a rock, ſuppoſed to be about forty tons, in a very erect poſition, which has been, ludicrouſly enough, entitled "the parſon." Polwhele's Devon.

The green marble of Angleſea is not unlike the *verde antico*; its colours are greeniſh-black, leek-green, and ſometimes dull purpliſh, irregularly blended with white; but they are not always ſeen together in the ſame piece. The white part is limeſtone; the green ſhades are owing to magneſian ſtones, among which is alſo aſbeſt in narrow veins. This is an elegant marble, but apt to be interſected by ſmall cracks; nor is it ſuſceptible of a high poliſh in thoſe places where there are aſbeſtine veins. The quarry is ſituated on the lands of Monachy-ty, in the pariſh of Llan-Fair-Ynghornwy, and is found again in the iſle of Skerries, off this pariſh.

There are ſeveral fine varieties of marble in Derbyſhire, particularly ſuch as are compoſed of petrifactions. The largeſt quantity of the mottled grey marble is got in the neighbourhood of Moneyaſh. It may be diſtinguiſhed into two kinds; the ground of the one is light grey, and that of the other has a ſlight blueiſh caſt. The former is rendered extremely beautiful, by the number of purple veins which ſpread upon its poliſhed ſurface in elegant and irregular branches. But the chief ornament of the mottled grey marble is the number of entrochi with which it abounds. The longitudinal and tranſverſe ſections of them produce an almoſt incredible variety in its figure. The purple veined marble is got at Ricklowdale near Moneyaſh; that with the blueiſh ground at the village itſelf. There is another variety at a ſmall diſtance from hence, at a place called Highlow; it is known by the name of *Birdeye marble* (Pilkington.) The marble of Purbeck, in Dorſetſhire, is compoſed of fragments of ſhells, united by a compact limeſtone, partly of a yellow colour, and mingled with a greeniſh martial earth, and black and yellowiſh particles of bitumen.

A ſhell marble, which is far from being beautiful, but which in former times has been much employed for architectural purpoſes, is the *Petworth marble*, from a place of that name in Suſſex. It is thus deſcribed by Woodward: "The ground grey, with a caſt of green. 'Tis very thick ſet in all parts of it with ſhells, chiefly turbinated. Some of them ſeem to be of that ſort of river ſhell that Dr. Liſter (Hiſt. Cochl. Angl. p. 133.) calls *cochlea maxima, fuſca ſ. nigricans, faſciata*. Several of the ſhells are filled with a white ſpar, which variegates and adds to the beauty of the ſtone. That ſpar was caſt in the ſhell before this was repoſited in the maſs of marble, as is demonſtrable from a view of this and other like maſſes. This is of about the hardneſs of the white Genoeſe marble. The ſlender round ſcapi of the pillars of the abbey church in Weſtminſter, and of the Temple church, are of this ſort of marble. So likewiſe are thoſe of the cathedral church of Saliſbury. Some perſons that are leſs ſkilful in theſe matters, fancy theſe ſcapi that occur in moſt of the larger Gothic buildings of England are artificial, and will have it that they are a kind of fuſil marble, caſt in cylindric moulds. Any one who ſhall compare the grain of the marble of thoſe pillars, the ſpars and the ſhells in it, with thoſe of this marble got in Suſſex, will ſoon diſcover how little ground there is for this opinion, and yet it has prevailed very generally. Camden has entertained the ſame notion of thoſe vaſt ſtones of Stonehenge; but is fully refuted by Inigo Jones. Stonehenge reſtored, p. 33."

Scottish Marbles.

Scotland abounds in marbles, but only a few of them are generally known. A particularly fine variety of white marble is found, in immenſe beds, at Aſſent in Sutherland, out of which blocks of any ſize may be cut. The beſt ſort is ſeen in the bed of the river, about a mile or two ſouth of the church.

Mr. Williams, in his Natural Hiſtory of the Mineral Kingdom, points out ſeveral other places where he has ſeen excellent varieties of marble. An exquiſite ſaline marble of a pure white occurs near Blairgowrie in Perthſhire, not far from the high road ſide, towards the north; it may be eaſily raiſed in blocks and ſlabs perfectly free of blemiſhes, and in every reſpect fit to be employed in ſtatuary and ornamental architecture.

Another white marble, compoſed of fine ſhining broad grains, like ſpangles, may be ſeen in the duke of Gordon's lands, in the foreſt of Glenavon; but the ſituation is remote and difficult of acceſs.

A beautiful aſh-grey marble, of a fine uniform grain, and ſuſceptible of a fine poliſh, preſents itſelf in Lochaber, on the north ſide of the ferry of Ballachyliſh. It is finely ſprinkled throughout with grains of bright pyrites, and alſo contains diſſeminated lead ore of a fine texture, which to the eye appears to be rich in ſilver. This marble is capable of being raiſed in blocks of any ſize.

A black variety flowered with white, is found in the farm of Blairmachyldach, about three miles ſouth of Fort William, in the bed of a river. It is of a cloſe grain, but not very hard; the flowering in it is light and beautiful, like fine needlework, or rather reſembling the froſty fretwork on glaſs windows in a winter morning; and diffuſed through all parts of the maſs.

A dark brown variety beautifully variegated with white, is mentioned by Dr. Meek, as being found in the pariſh of Cambuſlang, in the county of Lanark. Of this marble, which takes a very good poliſh, there are ſeveral ſlabs in the palace of Hamilton; a chimney-piece in the college library of Glaſgow, and three pair of ſolid *jambs* in Mr. Dundas's houſe at Duddinſtoun. The ſtratum, which has been hitherto ſeen, is from ſix to twelve inches thick, and extends over a conſiderable part of the pariſh.

Alſo the red and white marble of Boyne; and the white with long veins of a different tint from Durneſs, are mentioned by authors.

Profeſſor Jameſon deſcribes ſome varieties of marble found in the iſland of Skye. A white marble veined with aſh-grey; it is very heavy, and by expoſure to the air it waſtes down into a powder. An aſh-grey variety, variegated by beautiful lemon-yellow ſtripes which traverſe it in different directions, and which ſeem to be owing to an intimate combination of chlorite, or hornblende, with the marble. A variety of a pure white colour, with a ſlight admixture of blueiſh-grey, in which alone it differs from the fine marble of Carrara.

But one of the moſt beautiful varieties is that from the hill of Belephetrich in Tirie, one of the Weſtern iſlands of Scotland. It is now generally known by the name of *Tirie marble*. Its colour is pale blood-red, light fleſh-red, and reddiſh-white; theſe colours are often ſeen in one and the ſame piece: the darker ſhades generally as ſpots and waved ſtriæ. What renders this marble particularly curious is the hornblende, and the other green ſubſtance which it contains diſſeminated, and part of which appears to belong to that ſpecies of the hornblende family, which is now generally called ſahlite; the lighter coloured particles have been conſidered as corundum. It is mixed in different proportions with the marble, ſo as to produce pale blackiſh-green, dark aſparagus-green, and a colour approaching to leek-green. Alſo particles of calcareous ſpar are ſeen intermixed with this ſubſtance; as alſo ſmall rounded quartzy particles of a bright red colour, and ſome mica in plates. Some of its varieties have the appearance of granite.

Beſide this, profeſſor Jameſon mentions a white marble of the ſame kind, found with the one juſt mentioned; its colour is white, or very light blue; it contains ſcales of mica and cryſtals of hornblende, which latter, when minutely diffuſed, give the marble a green or yellowiſh-green colour, and when very intimately combined with the maſs, form beautiful yellowiſh-green ſpots.

Another intereſting variety of compact marble, is that of Iona, deſcribed by count Bournon. It is of a fine dull white, and has at firſt ſight the appearance of pure compact feldſpar. It is an intimate mixture of tremolite and pure compact carbonat of lime; ſometimes with yellowiſh or greeniſh-yellow ſpots, owing to a leſs intimate admixture of a ſteatitic ſubſtance. It occurs in magneſian rocks, ſometimes alternating with clayey and ſlaty ſteatite or magneſian ſlate.

A dark coloured ſhell marble occurs in the limeſtone quarries of the pariſh of Cummertrees in the county of Dumfries,

Dumfries, and large blocks of it (according to the anonymous defcriber of that parifh) have been worked up for chimnies and hearths, fome of which have been fent to London. The fhells and other petrified bodies with which it is mixed, greatly add to its variety and beauty, as the whole receives a very fine polifh.

Irish Marbles.

Ireland alfo has its valuable marbles, and quarries of them are wrought in various parts.

The variety beft known in England is the *Kilkenny marble*, with black ground, more or lefs varied with white marks produced by petrifactions. This marble contains a great variety of impreffions of madrepores, of bivalve and turbinate fhells: mytilites, turbinites, pectinites, tellinites, tubiporites, nautilites, and ammonites may be diftinguifhed. The fpar which occupies the place of the fhells, fometimes affumes a greenifh-yellow colour; in fome places there are fpots, though rarely, that reflect iridefcent colours; and fometimes martial pyrites is imbedded in the marble. A kind of flaw fometimes appears in the ftone, which, from its irregularly indented figure, is ftyled by the workmen a *fkull*, as it refembles the futures of a cranium.

The quarry of this marble, of which Mr. Tighe has given a full account, is called the black quarry: it is fituated in the limeftone diftrict of Kilkenny, half a mile fouth of the town, near the right bank of the river Nore. The ftrata of marble, each of which is known by its particular appellation, fucceeded in this order:

	Feet.	Inches thick.
Rock bed, about -	4	0
Thin bed - -	1	4
Silver bed, from -	1	6 to 2 feet.
Bad bed - -	2	0
Halfmoon bed -	2	6
Bottom bed - -	3	0
Lower thin bed - -	1	6
Black bed - -	1	8
Griddle bed - -	2	0

The halfmoon and the bottom bed are reckoned among the beft: the former is fo called from the number of impreffions of bivalve fhells which it contains; the fections of the fpaces they occupied, now filled with white fpar, being more or lefs lunated: the black bed and the filver bed are both efteemed. The marble which approaches neareft to black is moft valued at Kilkenny. The white marks on the polifhed ftone, it is faid, appear more ftrongly, or increafe, by long expofure to the air.

This marble, from experiments mentioned by Mr. Tighe, may be confidered as confifting of 97 *per cent.* mild calx, two *per cent.* carbon, and one *per cent.* magnefia and iron, of which the former is in the largeft proportion.

Some coarfe work of Kilkenny marble is finifhed at the quarry; a few of the blocks are fplit in the town by hand faws, where a little of the polifhed work is alfo done, and tomb-ftones are cut, which are raifed from a different quarry. But the principal work is done at the marble mill, which is on the left bank of the river, near two miles from Kilkenny.

The importation of the marble into England and Scotland has been hitherto prevented by a duty of two fhillings the cubic foot; what is exported, therefore, is in the rude block. Tighe's Survey.

The quantity exported is about fifty tons annually. The marble fent to Dublin is conveyed on cars as far as Leighlin bridge, where it is embarked on the Barrow; that which is exported is ufually fent to Waterford, and goes by land, at leaft as far as Thomaftown. The blocks exported are configned chiefly to Liverpool and Glafgow. Wakefield's Ireland.

Black marble, exceedingly fine, has been raifed at Crayleath, in the county of Down. It is fufceptible of a very high polifh, and, if well chofen, is free from thofe large white fpots which are fuppofed to disfigure fome of the Kilkenny marble. Dubourdieu's Survey.

In the county of Waterford different kinds of marble are difcovered, as at Toreen, a fine variegated fort, compofed of chocolate colour, white, yellow, and blue, blended into various fhades and figures, which takes a good polifh. A black marble, without any mixture of white, has been found near Kilcrump, in the parifh of Whitechurch, of the fame county; as alfo a grey marble beautifully clouded with white, fpotted like fome kinds of fhagreen, and fufceptible of a good polifh.

At Loughlougher, in the county of Tipperary, a fine purple marble is found, which, when polifhed, looks exceedingly beautiful. Smith.

There are feveral fine variegated marbles in the county of Cork; Smith defcribes one with purplifh ground, and white veins and fpots, found at Churchtown; a blueifh and white variegated marble, from the fame place, with which, and a black variety, like that of Kilkenny, the chancel of the parifh church is floored; feveral fine afh-coloured varieties of marble, as that of Caftle Hyde, &c.

The county of Kerry affords feveral variegated marbles, fuch as that found near Tralee, not unlike the Kilkenny marble, except that the white fpots are much larger, and the colour of the mafs is not of fo deep a black, but inclining more to the blue: it takes a fine polifh, and may be raifed in blocks large enough for tables, chimney-pieces, &c. Marble of various colours is found in the fame county, in the iflands near Dunkerron, in the river Kenmare. Some is black and white, others are purple and white, intermixed with yellow fpots, and fome beautiful fpecimens have been feen of a purple colour veined with dark green, refembling the veins in blood-ftone. Sir William Petty had feveral quarries opened in thefe iflands in his time, in order to carry on a marble manufactory; but they are now worked chiefly for the making of lime.

French Marbles.

Brard has given a very complete account of the numerous varieties of marble found in France, of which the following is an abftract:

Department of the Arriège: the black marble of Moulis, faid to have been known to the ancients. Purple breccia marble, from Seix, fimilar to the Italian purple breccia. There are feveral more fine varieties of marble found in this department, efpecially in the mountains called Du Cos.

Department of the Aude: the variety called *marbre de Languedoc*, or *de Sainte Beaume*; it is of a fiery red, with white and grey zones, formed by madrepores. The eight columns which adorn the new triumphal arch, in the Caroufel at Paris, are of this marble, which was formerly only employed for the decoration of the royal palaces. The quarries are at Sainte Beaume. The neighbourhood of Narbonne furnifhes feveral valuable marbles, fuch as that improperly called marbre de Languedoc, which is white mixed with blueifh-grey; a fhell marble of an intenfely black colour, with white belemnites; a purple marble with yellow fpots, &c. This department is particularly rich in marbles.

Department

Department of the Mouths of the Rhone: among the beautiful varieties of marble with which this department abounds are, the breccia marble of Marfeille, called *brèche de Memphis;* it is reddifh, and contains fmall white, grey, and brown fragments; a marble mixed of white, red, and yellow, known in the country by the name of marbre de Sainte Beaume, but very diftinct from the marble of the department de l'Aude, to which this name properly belongs.

Department of Calvados: a marble of a dirty red, with large, grey, or white veins, compofed of madrepores, called *marbre de Caen*, from the place where it is quarried; tables made of it are very commonly feen in the coffee-houfes, &c. of Paris.

Department of the Côte d'Or: befides feveral fpotted and breccia marbles, there are found in this department two varieties of lumachella, the one of a reddifh-yellow, the other of a grey colour, both of which are known in commerce under the name of *lumachelles de Bourgogne.*

Department of the Herault: one of the moft efteemed French varieties of marble is that called *griotte*. Its colour is a deep brown, with blood-red oval fpots, produced by fhells. This marble has obtained its name from its brownifh colour, being fimilar to that of a variety of cherries, likewife called griotte; but it alfo fometimes contains large white veins, which are fituated in a tranfverfal direction to the other fpots, and which, as deftroying the harmony of the other tints, are confidered as a defect. The lapidaries dignify the variety which is deftitute of thefe white veins with the epithet *Italian;* but the fact is, that both varieties occur in the department of the Herault, and that neither of them is found in Italy. Some of the ornaments of the triumphal arch of the Caroufel are made of griotte; which is now much employed in the decoration of public monuments, and of fplendid furniture. It is fold at about 200 francs the cubic foot. Several other varieties of marble are found in the fame department, and ufed at Montpelier and in other neighbouring places.

Department of the Ifère: a light grey marble, with fragments of a lively rofe-red of different fhades, and with fpots of a chocolate-brown colour, from Tenfin in Dauphiné. This fine marble takes a good polifh.

Department of Jemappes: the madreporic marble of Mons, called *petit gris*, or *petit granit* by lapidaries; its colour is blackifh-grey, dotted with grey-coloured fragments of madrepores. There are many more varieties of marble in this department, but moft of them not employed in commerce.

Department of Maine and Loire: a grey and white marble veined with red, improperly called peach-bloffom marble.—Grey, with white veins, known by the name of marble of Angers.

Department of Montblanc: a fhining white marble, with grey veins, at Pons-de-la-Bride; being mixed with filiceous earth it has the property of giving out fparks with the fteel; it is alfo much harder and more folid than the common marbles, and its fpecific gravity is greater. The Romans have employed it for the conftruction of feveral of their monuments. A breccia marble, called *brèche de Tarentaife:* it confifts of a purple bafe, with fmall fragments of white, yellow, and fometimes blackifh marbles. This marble, which is found at La Villette, above Moutier, is much efteemed, both on account of its fine colour, and the fuperior polifh it takes. Alfo, a yellow breccia marble, not unlike fome antique varieties, is found in this department.

Department of the North: a white and reddifh-brown marble, with white, afh-grey, and blue veins, called *marbre de Rance*, from the place in Hainaut, where it is found. It is efteemed on account of its beauty, and as an article of commerce. The black marble of Barbançon, with white veins, the grey variety with black fpots, and white and aurora red veins from Clermont, the breccia marbles of D u'ers, and Eftroing-la-Rouillie, are alfo among the many valuable varieties furnifhed by this department.

Department of the Ourthe: the grey and white variety with blood-red fpots, called *marbre de Hon*, is well known. It comes from the neighbourhood of Liege, and is made ufe of for tables, chimney-pieces, vafes, &c.

Department of the Straits of Calais: a yellowifh-brown marble, with white, grey, and yellowifh-red veins, has been lately difcovered at Boulogne, and employed for the conftruction of the column placed there in commemoration of the victories of the French emperor, whence it has obtained the name of *marbre Napoléon*. Its ftructure is lamellar in fome places, and compact in others. It takes a good polifh, and, what adds much to its value, it may be procured in very large blocks, which, though folid, are of very moderate weight: the cubic foot weighing about 180 pounds. There are feveral other varieties of marble furnifhed by this department, fuch as the brocatello of Boulogne, the marbles of Stingal, Lingeu, &c.

Departments of the Pyrenees: the marble of Bayonne in the Lower Pyrenees, (called there *marbre vierge*, on account of its whitenefs) is rather lefs fine-grained than Carrara marble. It is ufed in thofe parts for purpofes of fculpture, but has the defect of turning yellow and fpotted in a fhort fpace of time. More generally known is the *marble of Campan* in the High Pyrenees; this is a mixture of limeftone and a talcofe fubftance, which latter forms the entangled veins obfervable on its furface. There are three varieties of Campan, which, however, are often united in the fame piece; the firft, called *green Campan*, is of a very pale fea-green colour, and exhibits on its furface lines of a much deeper green, and forming a kind of network; the fecond, called *Ifabel Campan*, is of a delicate rofe colour, and, like the firft, furnifhed with undulated veins of green talc; the third variety, the *red Campan*, is of a deep red colour, with veins of a ftill deeper red, and in fome meafure refembles fome parts of the griotte. In order to form a correct idea of the Campan marble, properly fpeaking, we muft imagine that thefe three varieties are united, fo as to form large ftripes of from a few inches, to two, three, or even fix feet wide, which produce a very grand and pleafing effect when viewed in large maffes. Where, therefore, the Campan marble can be employed in the large way, it may be looked upon as the moft beautiful and fplendid of all marbles. It fhould not, however, be expofed to the weather, fince, by fo doing, the talcofe fubftance exfoliates, and leaves hollow places, which render its furface uneven and rough; but it anfwers extremely well in the interior of buildings, for chimney-pieces, flabs for tables, &c. There are immenfe quarries of this valuable marble at Campan, near Bagnère, in the High Pyrenees. The marble of Sarencolin, in the High Pyrenees (in the ci-devant Gafcogne) exhibits on its furface large ftraight zones and angular fpots of a yellow or blood-red colour, fo that at firft view it bears fome refemblance to the marble called Sicilian. This is commonly known by the name of *Sarencolin* or *Sarancolin;* that of fuperior beauty has become fcarce, and it is even faid that the quarry which yielded the moft perfect fort is entirely exhaufted. The marble vulgarly called *brèche Caroline* appears to be nothing but a modification of the Sarencolin. The variety of marble called *marbre d'Antin*, has a white ground, and exhibits at its furface fire-red veins, which

which fometimes produce very pleafing appearances. It is found at Verey, in the High Pyrenees. According to M. de Cambry it derives its name from the Celtic words *an tin* (of fire) or fire marble. In the High Pyrenees a moft beautiful breccia is likewife found, the mafs of which is of a light orange colour, containing fmall fragments of a brilliant whitenefs. It takes an excellent polifh, and may be manufactured into vafes, tablets, &c. The breccia, called *brèche des Pyrenées*, is likewife held in great efteem; its bafe is brownifh-red, and exhibits black, grey, and red middle-fized fpots. It admits of a good polifh. Befides thofe here enumerated, a number of other marbles are met with in the Pyrenees, than which no chain of mountains is richer in fine varieties.

Department of the Sambre and Meufe: the colour of the marble of Dinan is a fine black, but perhaps inferior in point of intenfity to that of the antique black marble. It is ufed in fculpture: the arabefques in relief which ornament the church of St. Vaudrin at Mons, are made of it. There are two other black marbles found in this department, *viz.* that of Theux and that of Namur; the former, which is fprinkled with grey dots, is wrought with facility, and takes a very good polifh, but emits a flightly fulphureous odour when rubbed or ftruck with a hard body; the latter, which often inclines to greyifh-black, and is traverfed by grey veins, is exported to Holland in fquare flabs, and conftitutes a valuable article of commerce. All thefe black marbles are in great requeft for the flooring of churches, for tomb-ftones, &c. The grey marble of Sainte Anne fprinkled with white fpots, the remains of madrepores, has been much ufed at Paris for tops of commodes, chimney-pieces, tables, &c.; but ever fince the introduction of the unfightly marble from Jemappes, called petit granit, it has greatly funk in eftimation. The breccia marble of Vaulfort, between Dinan and Givet, alfo known by the name of *brèche de Dourlais*, has a reddifh bafe with black, grey, and white fpots; the pillars in the church of Saint Roque are covered with large flabs of this marble, which is fufceptible of a good polifh.

Specimens of the preceding varieties, and of the following Batavian marbles, are in the ftar of the rotunda before the library of the Central School (*ci-devant* palace of the governors of the Netherlands) at Bruffels: marble of Agimont, near Namur; brownifh-red mixed with grey, traverfed by thick white veins.—Of Avennes-le-Seigle near Valenciennes; a white ftatuary marble, eafily to be wrought, and becoming harder when expofed to the air.—Of Bourtombe; pale blue and reddifh, with large white clouds.—Of Bray, near Roculx, dep. of Jemappes: deep grey, mixed with white.—Of Clermont, near Valcourt, Sambre and Meufe; pale grey, with large white fpots.—Of Devignes, pale grey, fhaded with deep grey, and marked with fome white fpots.—Of Dourlaipe; a calcareous breccia with reddifh-grey bafe, incrufted with grey fragments of different fhades and fizes.—Of Eftrée, near Namur; a mixture of blueifh-grey and pale grey, with whitifh veins.—Of Franchimont near Florenne, Sambre and Meufe; pale red and pale blue, with white veins.—Of Fiery-le-petit, between Mons and Namur; white, with yellow and grey granular fpots.—Of Gerfontaine, pale red fhaded with blue, and traverfed by large white veins.—Of Goghenée near Florenne, Sambre and Meufe; pale reddifh-grey, waved with red in equal portions.—Of Grofghoux; dark grey, fhaded with pale grey, with fmall white veins.—Of Haire, near Charlerny; pale blue and pale red, in clouds, with large white fpots.—Of Lorraine; blueifh-grey, a little veined with grey and white.—Of Limburg; brown, with white granular fpots, appearing like fmall belemnitæ.—Of Mouchène; greyifh and white blended, with natural fiffures.—Of Ourdin near Valenciennes; a white marble for ftatues and architectural ornaments.—Of Pegagne; blueifh-grey, with large white fpots.—Of Rancé; near Beaumont, dep. of Jemappes; reddifh with various veins; ufed for chimney-pieces.—Of St. Renir, near Luxemburg; red, with brown, green, and blue veins, being one of the moft beautiful marbles in Europe. It fometimes contains Mytili and other fhells.—Of Renly; red and grey in large clouds, with white veins and fpots.—Of Royailles; grey fhaded, with white veins.—Of Roy-Soire, Sambre and Meufe; pale grey, with white zigzag ftripes.—Of Solré; greyifh-blue, with many white veins. Another variety from the fame place, of a blueifh-grey bafe, with differninated fmall white fhells.—Of Somme; grey fhaded, with fome white veins; with natural fiffures.—Of Strée, near Thuin, Jemappes; grey veined, with white fpots.—Of Thuillé, near Thuin; dark grey, with white veins, and fragments of fhells.—Of Vaufart; pale blue, fhaded pale red, with white ftripes.—Of Zoude-Bart; dark grey with fmall clouds, mixed with grey and white.

Department of the Lower Seine: feveral varieties of yellow marbles, ftreaked with darker yellow, and exhibiting black dendritæ, are found at St. Etienne, near Rouen: they are capable of a good polifh, and M. Tory has invented an economical mode of polifhing them.

Department of the Seine and Marne: an elegant marble called *Chateau-London*, of a very pale yellow, containing fmall inconfpicuous fhells and white tranflucid veins, has but lately been difcovered in this department. The beautiful bridge of Namours is conftructed of it.

Department of the Var: the highly efteemed marble called *Portor*, on account of the brilliant yellow veins in its deep black ground; the moft beautiful variety comes from St. Maximin.

Department of the Vofges: an excellent quarry exifts near Framont, in the mountain called the Mathifkopf, in which the marbles are difpofed in horizontal beds; their principal colours are white, penetrated by red or black, and grey.

Department of the Po: a white ftatuary marble, of a finer grey than that of Carrara, is found at Ponté, near Turin; of this marble are conftructed the maufoleums of the kings of Sardinia in the vaults of the church de la Supergue, near Turin.—*Verde di Sufa* is a green and white marble, refembling the verde antico; it is found at Suza, in Piemont.—*Marmo di Gaffino*, called fo from the place near Turin where it is found, is light grey fpotted by fhells which are eafily detached from the mafs; beautiful columns have been made of it.

The territory of GENOA furnifhes feveral beautiful varieties of marble, the moft remarkable of which is the *polzevera di Genoa*, called alfo in French *vert d'Egypte* and *vert de mer*. This marble is a mixture of granular limeftone, with a talcofe and ferpentine fubftance difpofed in veins; but fometimes thefe latter fubftances conftitute by far the greater part of the whole, while the white granular limeftone appears only here and there in veins and patches. It is fometimes mixed with a reddifh fubftance. This marble was formerly much employed in Italy, France, and England for chimney-pieces, &c.; but owing to its fombre appearance is come into difufe.

CORSICA poffeffes, among other varieties, a good ftatuary marble of a fine and clofe grain, and pure milky whitenefs, quarried at Ornofrio; it is comparable to that of Carrara.—Alfo a grey marble (bardiglio), a cipolin, and

and ſome other varieties occur in Corſica. The iſland of Elba has immenſe quarries of a white marble with blackiſh-green veins.

Among the innumerable varieties of ITALIAN MARBLES the following deſerve more particular notice.

The *rov[illegible]io* is a white marble found at Padua; it is uſed for architectural purpoſes, but is inferior in quality to thoſe of Carrara and Genoa.—The white marble of St. Julien, at Piſa, is of a finer grain than that of Carrara, but takes no good poliſh; the cathedral and the celebrated tower of Piſa are conſtructed of this marble.—The Biancone marble is white with a ſlight tinge of grey; it is quarried at St. Gregoire, Magurega, &c. and chiefly employed for altars and tombs. Near Mergozzo the white ſaline marble with grey veins is found, with which the cathedral of Milan is built.—A white marble ſprinkled with little ſpots and dots of blood red, occurs at Luni, on the coaſt of Tuſcany.—Another white variety variegated with red and yellow ſpots and veins, is found in different parts of the Venetian territory.

The black marble of Bergamo is called *paragone* (derived from the black colour of touchſtone); it is the moſt pure and intenſe tint, and ſuſceptible of a fine poliſh.—The black marble of Como, in the Milaneſe, is alſo greatly eſteemed on account of the intenſity of its colour. Near the lake of Como and at Valerano, there are, likewiſe, quarries of excellent black marble, which has been employed in the cathedral of Sienna.

The *polveroſo* of Piſtoya is a black marble ſprinkled with dots, which gives it the appearance of being covered with duſt; there are beautiful ſlabs of it on the walls of the famous chappel of San Lorenzo.—A moſt beautiful white marble with black ſpots from the Lago Maggiore, which has been employed for decorating the interior of many churches in the Milaneſe.

The Margorre marble, found in ſeveral parts of the Milaneſe, is blueiſh veined with brown. Part of the dome of the cathedral of Milan is built of this marble.

The green marble of Florence owes its colour to a copious admixture of ſteatite. Another green marble, called *verde di Prado*, is found near the little town of Prado, in Tuſcany; it is marked with ſpots of a deeper green than the reſt, and paſſing even into blackiſh-blue.

The beautiful *Sienna marble*, or *brocatello di Siena*, has a yellow colour reſembling the yolk of an egg, and diſpoſed in large irregular ſpots, ſurrounded with veins of blueiſh-red, paſſing ſometimes into purple. It is by no means uncommon in this country. At Montarenti, two leagues from Sienna, another yellow marble is found, which is traverſed by black and purpliſh-black veins. This is frequently employed throughout Italy.—The marble of Brema is yellow with white ſpots.

The *mandelato* of the Italians is a light red marble, with yellowiſh-white ſpots, found at Lugezzana, in the Veroneſe. Another variety, bearing the ſame name, occurs at Preoſa. They are both employed for columns and various other works.—The red marble of Verona is of a red, rather inclining to yellow, or hyacinth; that of a brighter red, and which contains ſome ammonites, is highly eſteemed, and the tomb of Petrarca, at Arquo's, recently engraved by Faujas, is of this variety; the other variety, of a dull red, has been employed by the Romans, as may be ſeen, for inſtance, in the vaſt amphitheatre of Verona, which is entirely built with it. Another marble is found near Verona, which Faujas calls *oſſeous marble*, becauſe he ſuppoſes the large white ſpots in the reddiſh and greeniſh paſte to be owing to the remains of bones, of which they ſtill retain the figure. Very fine columns have been made of this marble.

Another Italian ſhell-marble is the *occhio di pavone*, the ſhells of which form large orbicular ſpots, red, white, and blueiſh. According to Da Coſta, the peacock's eye is of a bright cinnabar colour, with ſpots and veins of milk-white ſpar; many of the ſpots, forming circles about the ſize of a ſixpence, are filled with a red ground, and from an imaginary reſemblance have conferred the name. (P. 213.) A madreporic marble, known under the name of *pietra ſtellaria*, much employed in Italy, is entirely compoſed of ſtar madrepores, converted into a grey and white ſubſtance, and is ſuſceptible of an excellent poliſh.

Among the Italian breccia marbles are: the violet, called in France *brèche d'Italie*, the ground of which is reddiſh-brown, veined white; it is a beautiful marble, but requires much care, ſince it becomes ſoon ſpotted by coming into contact with greaſy ſubſtances. The village of Bretonico, in the Veroneſe, furniſhes a ſplendid breccia marble, compoſed of yellow, ſteel-grey and roſe-coloured ſpots. That of Bergamo conſiſts of black and grey fragments, in a greeniſh cement.

Florence marble, alſo called *ruin marble*, is a calcareous *marle*; which ſee.

SICILY abounds in marbles. Baron Borch, in his Sicilian mineralogy, deſcribes upwards of a hundred varieties, of which the following appear to be the moſt important.

The principal and moſt valuable marble of Sicily is that frequently called *Sicile*, or *Sicile antique*, and by Engliſh ſtonecutters *Sicilian jaſper*; it is red, with large ſtripes like ribbons, white, red, and ſometimes green, which here and there revolve, forming petty acute angles. At Biſachino a milk-white and an apple-green variety occur; both take a fine poliſh. Trapani preſents a red marble with deeper red ſpots, and another with green ſpots: at the ſame place is found the variety called *bigio bianco*, being grey with white ſpots, another ſpotted with ſeveral colours; and one (called *pidochioſo*), formed by the union of ſmall red and yellow grains or ſpots.—That of Caſtronuovo is yellow ſpotted with red.—Taormina furniſhes ſeveral varieties: red with black ſpots; red with white veins, and deeper red ſpots; greeniſh mixed with bright brown ſpots; purpliſh, with particular reflections. The marble of Santa Maria del Boſco is of a deep black with yellow veins, not unlike that called *Portor*. At Termini we find a greeniſh marble with white veins and red dots. Near Sciacca they quarry a bright green marble, waved with deeper green and yellow.

Among the Sicilian breccia marbles are thoſe of Gallo, the one of a light grey colour, preſenting elegant roſe-coloured ſpots of ſeveral ſhades; and the other alſo grey, veined yellow, and exhibiting on its ſurface white tranſlucid ſpots. The breccia marble of Monte Alcano is light grey, with round and roſe-coloured ſpots. That of Taormina has a deep red ground, and preſents at its ſurface yellow and greyiſh-white ſpots.

SPANISH MARBLES.

Spain rivals Italy in the abundance and beauty of its marbles. The vicinity of Valencia, Cadiz, Burgos, Grenada, Molina, Carthagena, offer a great number of them. A mountain entirely compoſed of beautiful marbles exiſts at the diſtance of three leagues from San Felipe; the Tagus takes its courſe partly through hills of marble that conſtitute its bed, and the Carpentine mountains are equally provided

provided with them. Hence it is that the monuments of antiquity in Spain, thofe of the middle ages, and of modern times, are profufely decorated with indigenous marbles. The vault of the beautiful theatre of Toledo is fupported by 350 marble columns. The mofque of Cordova, erected by caliph Abdoulrahman III., is ornamented with 1200 columns, moft of which are of Spanifh marble: among the ruins of ancient Merida (Augufta Emerita), which was built 28 years before Chrift, fragments of the moft valuable marbles are ftill difcovered; and finally, the church of the Efcurial, and the palace itfelf, are decorated with the moft beautiful marbles, and the fame may be faid of the principal churches of Madrid.

The milk-white marble of Cordova is very fit for fculpture; it has a fine grain and takes a good polifh. Near Filabres, three leagues from Almeria, in Grenada, there is a mountain of about a league in circumference, and 2000 feet in height, which is entirely compofed of the pureft white marble, capable of the fineft polifh. The rocks which furround the town of Molina, in New Caftile, are compofed of a white marble, which has been employed in the palace of the Alhambra, at Grenada. The white faline marble of Grenada is flightly tinged with red. Alfo the white marble of Badajoz has rather a reddifh tint, but its grain is finer and clofer than that of the preceding. A white variety with large grey fpots, at La Mancha, in New Caftile. A greyifh marble is quarried at Toledo, and one, grey with white veins and fpots, at Elvira.

The black marble of La Mancha is of a very intenfe colour, and fufceptible of a high polifh. Another of the fame colour is found near Segovia, and a deep black variety with grey dots at Moron. Bifcay furnifhes a black marble veined with white, and another of greyifh-black colour with yellow veins: this latter is often called *Spanifh portor*, but it is much inferior in beauty to that from St. Maximin, in the department of the Var.

A beautiful deep red variety, with fhining white and bright red fpots and veins, called *red Seville marble*.—Flefh-coloured, veined with white, from Santiago; and an entire mountain of this kind near Antiguera.—A dull red marble, with black capillary veins, found in Meguera, in Valencia, is much employed in Spain for tables.—Near Molina there is an entire hill of a red, yellow, and white marble, with granular and brilliant fracture, like fugar.—The mountains of Guipufcoa furnifh a red marble veined with grey, and clofely refembling that of Serancolin: Patrin even conjectures that it may be of the fame bed. At Cortegana, in Andalufia, a fawn-coloured variety powdered with grey.

The violet marble, fpotted with bright yellow, from Tortofa, is much admired on account of its fine colours and the polifh it takes.—A marble of a dull violet colour, like winelees, with orange-yellow angular fpots, is found near Valencia; it is not fufceptible of a high polifh.—A green marble, refembling the verde antico, prefents itfelf at Grenada.

Near Morviedro there is a hill of black marble, veined with white, which, towards the fummit, gradually paffes into a yellowifh-blue and reddifh breccia.—A beautiful breccia marble is found at Riela, in Arragon; it confifts of angular fragments of a black marble imbedded in a reddifh-yellow bafe.—The breccia of Old Caftile is of a bright red, dotted with yellow and black, and inclofes middle-fized fragments of a pale yellow, brick-red, deep brown, and blackifh-grey: it is much employed at Paris.

One of the moft celebrated Spanifh marbles (which may be regarded as a fhell-marble), is the *brocatello*; its chief colour is claret-red, variegated with numerous fmall fpots, and points of ifabell-yellow, yellowifh-grey, and a tranflucid white. All the greyifh fpots in this marble, when clofely examined, prove to be fragments of fhells, but the irregular yellow and red fpots are not owing to remains of organic bodies. The name of brocatello is given to all thofe marbles that refemble gold cloth and embroidered filk ftuffs of the fame kind.

Portuguese Marbles.

Portugal appears to be poor in marbles; there are, however, feveral varieties mentioned by authors; fuch as that of Villa-viciofa, in Alentejo, fpotted with grey, and (as Bowles has it) refembling the marble of Mount Atlas. The chain of mountains of Arrabeda, in Eftremadura, likewife furnifhes fome efteemed marbles.—The marble of Troncao is pale yellow, with greyifh veins, and contains alfo remains of marine bodies.

The church of Alfara is built with marble of Cintra, a village on a mountain feven leagues diftant from Lifbon.

Swiss Marbles.

The marbles of Switzerland, at leaft thofe which are objects of commerce, are not numerous; nor is there great variety of colours among thofe few that are found in its mountainous regions.

At Roche, near Aigle, in the canton (now department) of Leman, is a quarry of a marble veined with red, white, grey, and black; it is wrought on the fpot, and is almoft the only fort ufed at Geneva, and all over the Pays de Vaud: polifhed flabs of it are fent as far as Lyons. It often prefents pectinites and madreporites, which have affumed the nature and grain of marble, fo that the fhells feldom or never appear in their original form.

The localities of fome other marbles, which we know to be Swifs, are not indicated by any writer on the mineralogy of Switzerland. There was formerly a marble mill at Bern, from which the fineft varieties found in Switzerland were fent into France, Germany, and England; but this we fuppofe does no longer exift.

German Marbles.

The marbles of Germany are very numerous, and many of them far more beautiful than thofe foreign kinds which its wealthier inhabitants are fo eager to obtain. A great number of them are even left unnoticed in the writings of topographical authors of that extenfive country.

Auftria, fo rich in mineral treafures, excels alfo in the number and variety of its marbles.

The moft efteemed of thofe of Lower Auftria are the marbles of Schottwien, of Lilienfeld, Seitenftätten, and the Kammerguth. That of Lilienfeld is of an intenfe black colour.

Thofe of Stiria (of Lambrecht, Röthelftein, Zell, Maria-troft, &c.) are of the firft quality.

Carinthia has fome fine white marbles, and alfo poffeffes the moft beautiful of all known fhell-marbles, *viz.* that of Bleyberg, called *fire-marble*, or *opalefcent lumachella*. The colour of the marble itfelf is not particularly ftriking; it is brownifh-grey, fhaded with a darker tint, which latter belongs to the fragments of fhells of which the mafs is chiefly compofed. But what diftinguifhes this variety of fhell-marble from all others, are the opalefcent fragments of a fpecies of nautilus, here and there diffeminated in its mafs: the tints which they reflect are red, green, and blue, of confiderable intenfity. This moft efteemed of all varieties of lumachellas is feldom feen in large pieces. The

 greateft

greateft variety of boxes and other articles made of it, exifts in the collections of Vienna.

In Carniola are found, among others, a flefh-coloured and grey marble, veined with white and blue; nearly the fame as that called by the Italians *Marmo breccia antica grifata*.—A yellow and dark red variety, with fhrub-like veins; the fame with that improperly called *Diafpro di Sicilia a vene*.—A pudding-ftone marble, with pale red bafe, including grey and whitifh rounded pieces; the fame as the *Marmo breccia catinata* of the Italians.—A flefh-red marble, traverfed by fome calcareous fpar, and called by the neighbouring Italians *Palmone di Porta Santa;* this is the moft common variety of marble in thofe parts.—A black marble occurring in beautiful perpendicular ftrata; it is ufed for architectural purpofes.—A white marble, not unlike that of Carrara, but mixed with dirty fpots; nor can it be quarried in large blocks. Hacquet mentions feveral white varieties in other parts of Carniola, equalling and even furpaffing the Carrara marble in whitenefs and delicacy of ftructure.

Of Bohemian marbles, the fineft white variety is that of the circle of Königfgrätz; and among the variegated we have thofe of Czeftin, Koftel, and Sternberg, in the circle of Kaurzim. But ftill finer are thofe in the circle of Beraun: thus we have at Telin a brown-red, at Hermanomierftiz a light blue, at St. Juan a red and yellow, and red and white variety; the marble of Kofors is black, with imbedded petrifactions, belemnites, entomolithus paradoxus, &c. Alfo Karlftein and Dobrzichowitz of the fame circle furnifh fine varieties of marble. That of St. Juan only is found in fmall pieces; all the others occur in confiderable beds.

Moravia, though lefs rich in marbles than Bohemia, ftill furnifhes fome very valuable kinds in thofe of Hoftienitz, in the circle of Brünn, and of Niklafburg (which latter is a beautiful lumachella); not to mention feveral others, the quarries of which are not wrought.

In Franconia we have the rich quarries of Hoff, which, among others, yield a fine black marble, a curious liver-brown variety with red fpots, a fea-green, blueifh, and feveral kinds of red marble. The marbles of Bayreuth prefent a great diverfity of colour and delineation, and are of a fine clofe grain. There is a manufactory of various articles in thefe marbles, at the houfe of correction, in the capital of the principality.

The Hartz mountains in Lower Saxony produce fome good marbles. Thofe of Blankenburg have been defervedly praifed, on account of the pleafing colours they exhibit; there are fome of a beautiful black, with ftraight and orbicular white ftripes; others of the fame colour, and with green and white fpots; others with red fpots; grey varieties, with white, brown, and red fpots; and numerous red marbles, variegated with white, brown, greenifh, and other colours. Several of thofe with a black, grey, and brown ground, contain madrepores and corallites. There were marble mills at Blankenburg, but there is very little employment for them at prefent.

At Langenftein, near Halberftadt, they quarry a very fine marble, another of a light green colour, and two white ones, with large brownifh-red and yellow fpots, of a fine appearance.

Norwegian Marbles.

Several of them are mentioned by Pontoppidan in his Hiftory of Norway, but it is dubious whether the worthy prelate has been correctly informed in this particular. Indeed, according to Mr. Neergard, there is only one quarry in Norway, *viz.* that of Gillebeck, feven leagues diftant from Chriftiania; but as the marble which it furnifhes is faturated with a great quantity of pyrites, it generally becomes decompofed in a few years. The great church of Frederick, at Copenhagen, which is unfinifhed, is built with this marble. Neergard has often feen fome pretty tablets of it, which contained garnets and actinote.

Swedish Marbles.

Only a few of thefe are mentioned by authors, fuch as that found in the province of Jemtland, which is black and white, and alfo of an unmixed black; that of Kolmorden, in the province of Eaft Gothland, compofed of white granular limeftone and ferpentine. Neergard has given us an account of the quarry of Fagernech, fituate between the two little towns of Norkiöping and Nykiöping, and about thirty leagues from Stockholm. It belongs, at prefent, to Mr. Eberftein, and to baron Unger, who purchafed it from count Gyllenberg for only 200,000 francs, on account of its bad condition. This marble, which is white, with veins of green talc, the fracture brilliant, began to be wrought about 150 years ago, in the reign of queen Chriftina. The fpace where it is found is about 2000 fathoms in length, but its breadth is inconfiderable. They make of it tomb-ftones, flabs for tables, vafes for butter, falt cellars, and mortars; and the fale of thefe different articles amounts annually to about 20,000 francs. There are magazines of it at Stockholm, at Gottenburg, at Carlfcrona, and at Abo. The manufactory employs about twenty workmen, who receive each two livres ten fous daily; and its pofition is fine and well adapted for working, as it is near the Baltic fea.

In the parifh of Pargos, near Abo, in Finland, a very fine white marble is faid to occur.

Russian and Siberian Marbles.

The vaft Ruffian empire may naturally be fuppofed to abound in marble quarries; they are found in the Finnic and Taurian mountains, on the Caucafus, in the Ural, the Altaic, Sajanic, Krafnojaric, and Dauric mountains; in the northernmoft parts of Siberia, on the fea of Ochotzk, at the Penfhinfk bay, on Tfhutfkoinof, Kamtfhatka, the Kurile and Aleutean iflands. The following varieties are enumerated in Georgi's "Befchreibung des Ruffifchen Reichs:" white faline marble in the Olonfk mountains, near the lake Gifh, where there is a quarry near Tifdowa; alfo on Novaga Semla. A greyifh variety, with needles of fhorl, in the Onega iflands; and another of the fame colour, with green fpots, on the banks of the Onega. A greyifh-white faline marble, containing much tremolite in fafcicular and radiating acicular cryftals, in the quarry of Tifdowa. White fcaly marble is found in various parts of the Ural and Altaïan mountains, in the Kirgeefe Steppe, in Nertfchinfk, &c. &c. Pearl-grey, glimmering, granular limeftone on the Ui and Tagil of the Tobol; in the Siberian marble quarries. Blueifh-grey granular marble, with copper green, on the banks of the Lower Tfhuflowaja. Grey-clouded marble, near the Pereguba of the Onega; in the marble quarries of Catherineburg, &c. Brown granular marble on the banks of the Irtifh, near Jempalat; near Tfhittinfk, in Nertfchinfk. Black faline marble, at Kexholm; a variety of the fame colour, but confiderable hardnefs, in the vale of Alufhta, in Tauris. A blackifh-green variety, refembling ferpentine, on the banks of the Tfhuftowaja, at Severfkoi Sawod, and in the Guberlinfkian Ural. A light green variety in Dauria, at Kiächta; and another of the fame colour, with dark green fpots, on Janfa, an ifland island of the lake Ladoga. Reddish saline marble at Olonez. Dark red marble in Klimezkoi, one of the Onega islands, also in the Ural of Catherineburg. A variety of a light red colour, on the Argun of Dauria. Red saline marble, with brown stripes, near the Ui of Tobol, at Atagul, where it is quarried in large blocks. Yellow saline marble in the northern Ural, in the bay of Caria, near the Isel of Tobol, on the banks of the Irtish, at Jamushewa. A greyish-yellow variety, with dendritæ, near the lake Ilmen. Dark and light red saline marble, with white veins, in the Olonefki quarries. Blackish-brown, with white veins, on the banks of the Onega. White marble, with black veins, on the banks of the Donez, at Bachmut. A grey variety, with white veins, on those of the Ik, at Wosnesenskoi Sawod. Greyish, with red veins, on those of the Tura, at Turinskoi Sawod. Red, with white veins, also dark green striped marble, in the Ural of Catherineburg, &c. White marble, with veins of white calcareous spar, and shorl-like spots, at Catherineburg. Blackish-grey marble, with veins of quartz, near the Loktewka, in Kolywan, and the Kokbukta of the Upper Irtish. A blackish-blue variety, with white veins of spar, at Nertshinskoi Sawod. Black saline marble, with brown stripes, at Tiwdewa, in Olonez. Marble, with stripes of various colours, in the mountains of Kolywan, the Ural, and Kirgeese mountains. Marble, with dots of various colours, in Olonesk, near the Ui of Tobolsk, &c. Spotted and flamed marble of various colours in Tiwdewa, on the banks of the Ladoga, in various parts of the Ural, &c. Black marble, with yellow spots, at Nertshinsk. Clouded uni-coloured and variegated marble, mostly with grey for its base, in the quarries of Finnland and Catherineburg. This is quarried in very large blocks: it is very durable, and therefore employed for the construction of balconies, &c. in the imperial palaces. Scaly marble, of a white colour, mixed with red, in Finnland, on the banks of the lake Gish, in the Ural. The same, of a grey colour, mixed with red, having dark spots, on an island of the lake Lishma, &c. A blue variety, mixed with red, on the northern banks of the lake Ladoga. Parti-coloured marble, a mixture of greenish, blackish, and white, at Kiächta, in the mountains of Dauria, &c.

Patrin, who during a residence of eight years examined the mineral treasures of those regions, has given the following account of the Siberian marbles. The Ural mountains furnish the finest and most variegated marbles. The greater part is taken from the neighbourhood of Katerinburg, where they are wrought, and from thence transported into Russia, and particularly to Petersburgh. The late empress caused an immense palace to be built there for Orlof her favourite, which is entirely coated with these fine marbles, both inside and out. This empress built the church of Isaac with the same marbles, on a vast space, near the statue of Peter the Great. This church was not finished in 1787. Patrin saw there columns of very large dimensions, which seemed to be of a single block, of a white and blueish marble in large veins. Only this kind of marble was used in that church. The palace of Orlof has many varieties, which are distributed in compartments. Patrin found no white statuary marble in the Ural mountains; but in that part of the Altaian mountains which is traversed by the river Irtish, he in two places saw enormous rocks of marble, perfectly white and pure, from which large blocks might be hewn. The only use made of it is to convert it into lime for the service of the fortresses situated along the Irtish.

ASIA is probably very rich in marbles, but they are little known.

Shaw makes mention of a red marble with dendritic delineations from mount Sinai.

Of Syrian marbles we have no other account but that given in Russel's Natural History of Aleppo. They have at that city an inferior kind of yellow marble, which takes a tolerable polish, and is used for the ornamental parts of buildings, and for paving the court-yard. But a variety of other marbles is brought from parts more distant. From Damascus they receive a red marble; thence also and from Khillis, a coarse black sort; and from Antioch they procure various ancient fragments. The common Aleppo marble is brought to resemble the Damascus red by rubbing it with oil, and letting it stand some hours in an oven moderately heated.

Some Persian marbles are mentioned by Chardin, particularly a translucent white one. Mr. Morier, in his interesting "Journey through Persia, &c." just published, mentions the latter under the name of marble of Tabriz. The tomb of Hafitz, the celebrated Persian poet, is constructed with this beautiful substance; and the wainscotting of the principal room of the Hafl-ten, near Shiraz, is likewise of Tabriz marble: one of the largest slabs is nine feet in length and five feet in breadth. Its colours are described, by this author, as a combination of light greens, with here and there veins of red and sometimes blue; he adds that it is not procured near the city of Tabriz, or taken from a quarry, but that it is said to be rather a petrifaction found in large quantities, and in immense blocks, on the borders of the lake Shahee, near the town of Meraugheh. We should take this substance to be a variety of calcareous alabaster, were not the size of the pieces above-mentioned against this supposition.

The marbles of Hindoostan are unknown to us, and the same may be said of those of Siam and China: we are told that in the latter the streets of some towns are paved with marbles of all colours, and most public buildings, bridges, and monuments are constructed of it. Mention is made by authors of a quarry of white marble in the neighbourhood of Pekin. Laboubère speaks of a quarry of a beautifully white marble near the capital of Siam.

Some of the antique AFRICAN MARBLES have been mentioned in their proper place. A slate-blue variety (according to Brongniart) is still found at Sitifi in Mauritania; it is called *turchino*, or *marbre bleu turquin*, on account of its colour, which Tondi has found to be owing to the amphibole by which the marble is penetrated.

AMERICA.

There are many curious varieties of marble in North America. The chief quarries in the territories of the United States are at Stockbridge and Lanesborough, Massachusetts; in Vermont and Pennsylvania; in New York, and in Virginia: some of which are said to equal the finest kinds from Europe. At Marble town, near Hudson river, are quarries of fine black marble, spotted with white shells.

Marble of various qualities, (as professor Hall informs us,) has been found in many places on the west side of the green mountains in Vermont. A few years since a valuable quarry was discovered in Middleburg, a town situated on Otter Creek, eleven miles above Vergennes. The quarry forms one bank of the creek for several roods, and extends back into the side of a hill to a distance at present unknown. The stone lies in irregular strata, varying considerably in thickness, but all more or less inclined to the north-west. The marble is of different colours in different parts of of the bed. On one fide it is a pure white, and of a quality little, if at all, inferior to Italian white marble; but this feems to conftitute but a fmall portion of the whole mafs. The colour that predominates through moft parts of the quarry is a grey of different intenfities. The marble of both kinds is folid, compact, free from veins of quartz, and fufceptible of an excellent polifh. A mill of peculiar conftruction has been erected for the purpofe of fawing the ftone into flabs. It contains fixty-five faws, which are kept almoft conftantly in operation. During the years 1809 and 1810 thefe faws cut out 20,000 feet of flabs, and the fales of marble tables, fideboards, tomb-ftones, &c. in the fame period, amounted to about 11,000 dollars.

Part of the marbles of South America will probably be illuftrated in Von Humboldt's travels in thofe interefting regions. Thofe of Chili, defcribed in Molina's work on the natural hiftory of that part of South America, are of various kinds. The varieties of a fingle colour hitherto difcovered are, white ftatuary marbles, black, greenifh, yellow, and grey. Two mountains, the one in the Cordelera of Copiapo, and the other in the marfhes of Maule, entirely confift of marbles in zones of feveral colours; but in fuch ftrata as furround the mountains, from their bafe to the fummit, with a fymmetry that feems an artifice of nature. The variegated marbles are the grey with white, yellow, and blue veins; green, fpeckled with black; and yellow with black, brown, and green irregular fpots. This latter, the quarry of which is at San-Fernando, the capital of the province of Colchagua, is in great efteem, becaufe it is eafily wrought, and hardens in the air. All the marbles of Chili are generally of a good quality, and all take a good polifh. Perfons who have had occafion to examine the Lower Andes, have affured Molina that thofe mountains abound in marbles of different qualities, and nearly of all colours. In the plains near the city of Coquimbo a white fhell marble has been found, fomewhat granular, three or four feet under the vegetable earth. The fhells in it are more or lefs entire. The bed of this marble extends in length and breadth more than three miles; its thicknefs, generally about two feet, varies, and depends on the number of the beds, which are fometimes five, fometimes eight. Thefe beds are almoft always divided by very thin layers of fand. This ftone increafes in hardnefs in proportion to its depth: the firft beds only prefent a coarfe friable ftone, of no ufe but to make lime; the following, although compact, eafily yield to the iron inftruments ufed to cut it, and raife it from the quarry; but in building acquire a fufficient hardnefs to refift any impreffion of the air or water. Molina, p. 77.

Marbles, *Artificial.* The ftucco, whereof they make ftatues, bufts, baffo-relievoes, and other ornaments of architecture, ought to be marble pulverifed, mixed in a certain proportion with plafter; the whole well fifted, worked up with water, and ufed like common plaifter. See Stucco.

There is alfo a kind of artificial marble made of the flaky felenites, or a tranfparent ftone, refembling plafter; which becomes very hard, receives a tolerable polifh, and may deceive a good eye. This kind of felenites refembles Mufcovy talc.

There is another fort of artificial marble, formed by corrofive tincture, which penetrating into white marble to the depth of a line or more, imitate the various colours of other dearer marbles

There is alfo a preparation of brimftone in imitation of marble.

To do this, you muft provide yourfelf with a flat and fmooth piece of marble: on this make a border or wall, to encompafs either a fquare or oval table, which may be done either with wax or clay. Then having provided feveral forts of colours, as white-lead, vermilion, lake, orpiment, mafticot, fmalt, Pruffian blue, &c. melt on a flow fire fome brimftone, in feveral glazed pipkins; put one particular fort of colour into each, and ftir it well together; then having before oiled the marble all over within the wall, with one colour quickly drop fpots upon it of larger and lefs fize; after this, take another colour and do as before; and fo on, till the ftone is covered with fpots of all the colours you defign to ufe. When this is done, you are next to confider what colour the mafs or ground of your table is to be: if of a grey colour, then take fine fifted afhes, and mix it up with melted brimftone; or if red, with Englifh red ochre; if white, with white-lead; if black, with lamp or ivory black. Your brimftone for the ground muft be pretty hot, that the coloured drops on the ftone may unite and incorporate with it. When the ground is poured even all over, you are next, if judged neceffary, to put a thin wainfcot board upon it: this muft be done whilft the brimftone is hot, making alfo the board hot, which ought to be thoroughly dry, in order to caufe the brimftone to ftick the better to it. When the whole is cold, take it up, and polifh it with a cloth and oil, and it will look very beautiful. Smith's Laboratory, p. 248.

Marble, *Colouring of.* The colouring of marbles is a nice art, and in order to fucceed in it, the pieces of marble, on which the experiments are tried, muft be well polifhed, and clear from the leaft fpot or vein. The harder the marble is, the better it will bear the heat neceffary in the operation: therefore alabafter, and the common foft white marble, are very improper to perform thefe operations upon.

Heat is always neceffary for the opening of the pores of the marble, fo as to render it fit to receive the colours; but the marble muft never be made red-hot, for then the texture of the marble itfelf is injured, and the colours are burnt, and lofe their beauty. Too fmall a degree of heat is as bad as too great: for, in this cafe, though the marble receives the colour, it will not be fixed in it, nor ftrike deep enough. Some colours will ftrike, even cold; but they are never fo well funk in as when a juft degree of heat is ufed. The proper degree is that which, without making the marble red, will make the liquor boil upon its furface. The menftruums ufed to ftrike in the colours muft be varied according to the nature of the colour to be ufed. A lixivium made with horfe's or dog's urine, with four parts quick-lime, and one part pot-afhes, is excellent for fome colours; common ley of wood-afhes does very well for others; for fome, fpirit of wine is beft; and finally, for others, oily liquors, or common white wine.

The colours which have been found to fucceed beft with the peculiar menftruums are thefe: ftone-blue diffolved in fix times the quantity of fpirit of wine, or of the urinous lixivium; and that colour which the painters call litmus, diffolved in common ley of wood-afhes. An extract of faffron, and that colour made of buckthorn berries, and called by the painters fap-green, both fucceed, well diffolved in urine and quick-lime, and tolerably well in fpirit of wine. Vermilion, and a fine powder of cochineal, fucceed alfo very well in the fame liquors. Dragon's blood fucceeds very well in fpirit of wine, as does alfo a tincture of logwood in the fame fpirit. Alkanet-root gives a fine colour, but the only menftruum to be ufed for this is oil of turpentine; for neither

neither spirit of wine, nor any lixivium, will do with it. There is another kind of *sanguis draconis*, called dragon's blood in tears, which, mixed with urine alone, gives a very elegant colour. Phil. Transf. N° 268, or Abridg. vol. iv. part ii p. 205.

Beside these mixtures of colours and menstruums, there are some colours which are to be laid on dry and unmixed. These are dragon's blood of the purest kind, for a red; gamboge for a yellow; green wax for a green; common brimstone, pitch, and turpentine, for a brown colour. The marble for these experiments must be made considerably hot, and then the colours are to be rubbed on dry in the lump. Some of these colours, when once given, remain immutable; others are easily changed or destroyed. Thus the red colour given by dragon's blood, or by a decoction of logwood, will be wholly taken away by oil of tartar, and the polish of the marble not hurt by it.

A fine gold colour is given in the following manner: take crude sal ammoniac, vitriol, and verdigris, of each equal quantities: white vitriol succeeds best, and all must be thoroughly mixed in fine powder.

The staining of marble to all the degrees of red, or yellow, by solutions of dragon's blood or gamboge, may be done by reducing these gums to powder, and grinding them with the spirit of wine, in a glass mortar; but for smaller attempts, no method is so good as the mixing of a little of either of these powders with spirit of wine, in a silver spoon, and holding it over burning charcoal. By this means a fine tincture will be extracted, and with a pencil dipped in this, the finest traces may be made on the marble, while cold, which, on the heating of it afterwards, either on sand, or in a baker's oven, will all sink very deep, and remain perfectly distinct in the stone. It is very easy to make the ground-colour of the marble red or yellow by this means, and leave white veins in it. This is to be done by covering the places where the whiteness is to remain with some white paint, or even with two or three doubles only of paper, either of which will prevent the colour from penetrating in that part. All the degrees of red are to be given to marble by means of this gum alone; a slight tincture of it, without the assistance of heat to the marble, gives only a pale flesh-colour; but the stronger tinctures give it yet deeper; to this the assistance of heat adds yet greatly; and finally, the addition of a little pitch to the tincture gives it a tendency to blackness, or any degree of deep red that is desired.

A blue colour may be given also to marble by dissolving turnsol in a lixivium of lime and urine, or in the volatile spirit of urine; but this has always a tendency to purple, whether made by the one or the other of these ways. A better blue, and used in an easier manner, is furnished by the Canary turnsol, a substance well known among the dyers. This needs only to be dissolved in water, and drawn on the place with a pencil: this penetrates very deep into the marble, and the colour may be increased by drawing the pencil, wetted afresh, several times over the same lines. This colour is subject to spread and diffuse itself irregularly; but it may be kept in regular bounds, by circumscribing its lines with beds of wax, or any other such substance. It is to be observed, that this colour should always be laid on cold, and no heat given even afterwards to the marble; and one great advantage of this colour is, that it is therefore easily added to marbles already stained with any other colours, and it is a very beautiful tinge, and lasts a long time. Mem. Acad. Par. 1732.

This art has in several people's hands been a very lucrative secret, though there is scarcely any thing in it that has not at one time or other been published.

Kircher has the honour of being one of the first who published any thing practicable about it. This author meeting with stones in some cabinets supposed to be natural, but having figures too nice and particular to be supposed to be nature's making, and these not only on the surface, but sunk through the whole body of the stones, was at the pains of finding out the artist who did the business; and on his refusing to part with the secret on any terms, this author, with Albert Gunter, a Saxon, endeavoured to find it out; in which they succeeded at length very well. Their method is this: take aqua fortis and aqua regia of each one ounce, sal-ammoniac one ounce, spirit of wine two drachms, about twenty-six grains of gold, and two drachms of pure silver; let the silver be calcined and put into a phial, and pour upon it the aqua fortis; let this stand some time, then evaporate it, and the remainder will first appear of a blue, and afterwards of a black colour; then put the gold into another phial, pour the aqua regia upon it, and when it is dissolved, evaporate it as the former; then put the spirit of wine upon the sal-ammoniac, and let it be evaporated in the same manner. All the remainders, and many others made in the same manner from other metals dissolved in their proper acid menstrua, are to be kept separate and used with a pencil on the marble. These will penetrate without the least assistance of heat, and the figure being traced with a pencil on the marble, the several parts are to be touched over with the proper colours, and this renewed daily till the colours have penetrated to the desired depth into the stone. After this the mass may be cut into thin plates, and every one of them will have the figure exactly represented on both surfaces, the colours never spreading. The nicest method of applying these, or the other tinging substances, to marble that is to be wrought into any ornamental works, and where the back is not exposed to view, is to apply the colours behind, and renew them so often till the figure is sufficiently seen through the surface on the front, though it does not quite extend to it. This is the method that of all others brings the stone to a nearer resemblance of natural veins of this kind. The same author gives another method to colour marble by vitriol, bitumen, &c. forming a design of what you like upon paper, and laying the said design between two pieces of polished marble; then closing all the interstices with wax, you bury them for a month or two in a damp place. On taking them up, you will find that the design you painted on the paper has penetrated the marbles, and formed exactly the same design on them. Kircher's Mund. Subter. lib. viii. § 1. cap. 9.

Wallerius, in his Mineralogy, vol. ii. p. 128. recommends the last method of Kircher; and the first method is copied in the Phil. Transf., N° 7.

The art was practised by Mr. Bird, a stone-cutter at Oxford, before the year 1666; but his method is not recorded. Mr. Robert Chambers, of Minching Hampton, in Gloucestershire, discovered and practised a method of colouring marble, which he kept a secret. Mr. Da Costa has published an account of experiments made on several pieces of marble stained by this artist. Phil. Transf. vol. li. art. 5. p. 30, &c.

Spots of oil stain white marble, so that they cannot be taken out. See Staining *of Stones*.

Marble, *Polishing of.* The art of cutting and polishing marble was, of course, known to the ancients, whose mode of proceeding appears to have been nearly the same with that employed at present; except, perhaps, that they were unacquainted with those superior mechanical means which now greatly facilitate the labour, and diminish the expence of the articles thus produced. There are many celebrated manufactories

factories of this kind generally called marble mills, on the continent, and also in Great Britain; but as the principle on which they proceed is nearly the same in all, it will suffice in this place to give the description of one or two of the latter. The following description, together with some preliminary observations, communicated by a person practically acquainted with this subject, relate to the manufactory of Messrs. Brown and Mawe at Derby.

An essential part of the art of polishing marble is the choice of substances by which the prominent parts are to be removed. The first substance should be the sharpest sand, so as to cut as fast as possible, and this is to be used till the surface becomes perfectly flat. After this the surface is rubbed with a finer sand, and frequently with a third. The next substance after the finest sand is emery of different degrees of fineness. This is followed by the red powder called tripoli, which owes its cutting quality to the oxyd of iron it contains. Common iron-stone powdered and levigated answers the purpose very well. This last substance gives a tolerably fine polish. This, however, is not deemed sufficient. The last polish is given with putty. After the first process, which merely takes away the inequalities of the surface, the sand employed for preparing it for the emery should be chosen of uniform quality. If it abounds with some particles harder than the rest, the surface will be liable to be scratched so deep as not to be removed by the emery. In order to get the sand of uniform quality, it should be levigated and washed. The hard particles, being generally of a different specific gravity to the rest, may by this means be separated. This method will be found much superior to that of sifting. The substance by which the sand is rubbed upon the marble is generally an iron plate, especially for the first process. A plate of an alloy of lead and tin is better for the succeeding processes, with the fine sand and emery. The rubbers used for the polishing, or last process, consists of coarse linen cloths, such as hop bagging, wedged tight into an iron plane. In all these processes, a constant supply of small quantities of water is absolutely necessary.

The sawing of marble is performed on the same principles as the first process of polishing. The saw is of soft iron, and is continually supplied with water and the sharpest sand. The sawing, as well as the polishing of small pieces, is performed by hand. The large articles, such as chimney-pieces and large slabs, are manufactured by means of machinery working by water or steam. We shall next give a description of this branch of manufacture in the large way, as carried on by Brown and Mawe at Derby, and in London, N° 149 Strand, who have justly attained great celebrity as workers of spar and marble into different ornaments.

Fig. 1. *Plate* XXIII. *Miscellany*, is a side view of a mill for sawing and polishing slabs of marble; *fig.* 2. being a ground plan of the same, and marked with corresponding letters. A B C is a frame of wood, suspended by the upright frames of wood, D, E, F, G, from the beams H, H, H, H, so as to be capable of an oscillatory motion. Motion is given to this frame by the rod I communicating with the crank O K, which is turned by water or steam.

This frame, being put in motion, gives motion to the saw frames L, L, M, M, and to the polishing arms N, P, Q, which work on the pivot P, and are pushed backwards and forwards by the connecting iron rods *n*, *n*. The saws are iron plates shaped like a common saw, and fastened into oblong rings by means of pins. These rings are put upon the cross bars E, E, *b*, *b*, and the saws are stretched tight by the screws *s*, *s*, *s*, and C. R, R, S, S, are four upright posts constituting a frame, in which are placed the blocks of marble to be sawn into slabs, which are at the same time to guide the frame of the saw. At each end of this frame there are a number of upright square bars of iron *i*, *i*, between which the saws pass which bars, act as conductors. The posts R, R, can be removed to a greater distance, so as to make the frame longer for receiving different sized blocks. The part T, to which the saw is attached on the moveable frame, slides upon the upright post A C. It is suspended by a rope, which goes over a pulley *c*, and is counterbalanced by the weight W. By this means the saw may be made to press upon its work with any degree of force. It will be evident that the moveable frame, from its pendulous motion, does not move in a straight line, but a curve. The sliding part T, therefore, serves to induce a rectilineal motion of the saw. The upright bars of iron *i*, *i*, and C, are of a size equal to or less than the thinnest slabs, so that the saws may be placed at different distances, according to the thickness of the slabs. In order to alter the saws for this purpose, nothing more is necessary than to loosen the screws *s*, *s*, &c. and shift the oblong rings which contain the saws.

The slabs of marble to be polished are laid upon the carriage *h*, so as to correspond with the rubber Q, which passes over it in the direction of its length. In order to extend the rubber to the other parts of the slab, the carriage, *h*, has a lateral motion, by means of four grooved wheels running upon the iron guiders let into the beams *g*. *g*. The endless screw *e*, in the main shaft, turns the wheel *r*. This gives motion to the lever *w*, *fig*. 2, by means of the crank *q*. The lever communicates with the crank *k*, and turns the wheel *l*, more or less of a revolution, according to the length of this crank, which can be altered at pleasure by shifting the temporary pin *e*. By this latter motion the wheel, *k*, works the ratch *v*, and gives the lateral motion to the carriage. By this means the whole of the surface is exposed to the action of the rubber. Round articles of spar, gypsum, and marble, are turned in the lathe with pointed instruments of hardened steel. The pieces to be turned are attached to a wooden chock by means of cement. The gypsum is very soft, and turns with great facility. The fluor spar and marble require the tool to be very hard, while the part to be turned requires a constant supply of water, which drops from a vessel above. After the articles are turned into the given shape, they are dressed with sand and emery, and afterwards polished with tripoli and putty.

Small specimens for collections of marbles are generally polished upon a lap, which runs in a lathe. These laps, however, ought to run with the axis perpendicular to the horizon, the face of the lap being truly flat and horizontal. The lap used for the first process should be of iron; the second of an alloy of lead and tin; and the third, which is for polishing, should be of iron with pitch. By means of some auxiliary machinery, a number of pieces might be polished in this way at once, which would save much manual labour. Small pieces of marble may also be polished on the large machine, by cementing them with plaster on the surface of a large slab. By being placed on the same level, the large rubber sweeps them all at once.

The marble mill in the neighbourhood of Kilkenny, in Ireland, mentioned under the article IRISH MARBLES, *supra*, and which was invented by alderman Collis, grandfather of the present proprietor, is remarkable for the simplicity of its structure, and for the powers it exerts. One wheel, ten feet diameter, with twelve floats or ladles, gives motion, by a crank at one end of its axis, to a frame containing twelve saws, which do the work of about twenty men. By a

crank

crank at the other end, it moves a frame of five polifhers, which do the work of about ten men. At this end Mr. Collis has lately fitted a frame beneath the polifhers, with eight faws, to the motion of which he has found the power of the machine fully equal. This mill may be fairly faid to do the conftant work of forty-two men daily. During the night the mill ftopped, a conftant attention being required to fupply the faws with fand, and to attend the polifhers. The faws are made of foft iron, and laft about a week; they are conftantly fupplied with water and fand; the latter is taken out of the bed of the Nore, and wafhed till nothing remains, but very fine and pure filiceous particles. A faw cuts ten inches in a day, and twelve when the water is ftrong; it would require two men to do the fame with a hand faw. The marble taken from the mill is firft polifhed with a *cove-ftone*, that is, a brown fand-ftone imported from Chefter, and which takes its name from being ufed in chimney coves. It is afterwards polifhed by a *hone-ftone*, which is a piece of fmooth nodule of the argillaceous iron ore, found in the hills between Kilkenny and Frefhford. It receives the laft polifh in the mill with rags and putty. By means of this mill, the marble is fo eafily worked as to be fold at a very moderate price.

A great improvement in cutting marble and other ftones, but particularly columns by machinery, was invented in Ireland by the late fir George Wright, bart., who procured a patent for it. By this a number of hollow columns can be cut from a folid block, each decreafing in fize, fo that nothing of the ftone is loft, except what is converted into duft by the faw.

MARBLE *Harbour*, in *Geography*, a bay in the Mergui Archipelago, on the E. coaft of Sullivan's ifland. N. lat. 10° 58'.

MARBLE *Ifland*, a fmall ifland of the Mergui Archipelago, at the entrance of Marble harbour.—Alfo, an ifland in Hudfon's bay. N. lat. 62° 35'. W. long. 91° 30'.

MARBLED, fomething veined, or clouded, refembling marble. Marbled paper is a paper ftained with various clouds and fhades, refembling, in fome meafure, the divers veins of marbles; the method of making which, fee under PAPER.

MARBLED *China-ware*, a name given by many to a fpecies of porcelain or China-ware, which feems to be full of cemented flaws. It is called by the Chinefe, who are very fond of it, *tfou-tchi*.

It is generally plain white, fometimes blue, and has exactly the appearance of a piece of China which had been firft broken, and then had all the pieces cemented in their places again, and covered with the original varnifh. The manner of preparing it is eafy, and might be imitated with us. Inftead of the common varnifh of the china-ware, which is made of what they call oil of ftone and oil of fern mixed together, they cover this with a fimple thing made only of a fort of coarfe agates, calcined to a white powder, and feparated from the groffer parts by means of water, after long grinding in mortars. When the powder has been thus prepared, it is left moift, or in form of a fort of cream, with the laft water that is fuffered to remain in it, and this is ufed as the varnifh. Our cryftal would ferve full as well as thefe coarfe agates, and the method of preparation is perfectly eafy. Obferv. fur les Coût. de l'Afie.

The occafion of the fingular appearance of this fort of porcelain is, that the varnifh never fpreads evenly, but runs into ridges and veins. Thefe often run naturally into a fort of mofaic-work, which can fcarcely be taken for the effect of chance. If the marbled China be defired blue, they firft give it a general coat of this colour, by dipping the veffel into a blue varnifh; and when this is thoroughly dry, they add another coat of this agate-oil.

MARBLEHEAD, in *Geography*, a port of entry, and poft-town of America, in Effex county, Maffachufetts, containing one epifcopal, and two congregational churches, and 5211 inhabitants. The harbour lies in front of the town S.E. extending from S.W. to N.E., about a mile and a half in length, and half a mile broad. A battery and citadel were erected here in 1795, for the defence of the place, by order of Congrefs. The bank-fifhery employs the principal attention of the inhabitants, and more of this bufinefs is done here than in any other place in the ftate. The exports of the year 1794 amouted to 184,532 dollars. Marblehead was incorporated in 1649, and lies 4 miles S.E. of Salem, and 19 N.E. of Bofton. N. lat. 42° 30'. W. long. 69° 49'.

MARBLES, PLAYING, are moftly imported from Holland, where it is faid they are made by breaking the ftone alabafter, or other fubftance, into pieces, or chips of a fuitable fize; thefe are put into an iron mill which turns by water: there are feveral partitions with rafps within, cut floatways, not with teeth, which turn conftantly round with great fwiftnefs; the friction againft the rafps makes them round, and as they are formed they fall out of different holes, into which fize or chance throws them. They are brought from Nuremberg to Rotterdam, down the Rhine, and from thence difperfed over Europe.

MARBLETOWN, in *Geography*, a townfhip in Ulfter county, New York, on the W. fide of Hudfon river, N.W. of Pultz, adjoining. It contains 2847 inhabitants.

MARBLING, the art or act of painting or difpofing colours in fuch a manner, that they may reprefent marble. Thus we marble books, paper, wood, &c. See PAPER, and *Colouring, &c. of* BONE.

MARBLING *of Books*, among *Binders*, denotes the fprinkling over the cover of a book firft with ink, and afterwards with weak aquafortis. See BOOK-*binding*.

They alfo marble books on the edges; but, in this marbling, there is no black ufed, but, in lieu thereof, red, blue, &c.

MARBŒUF, in *Geography*, a town of France, in the department of the Eure; 12 miles N. of Conches.

MARBOS, a town of France, in the department of the Ain; 8 miles N. of Bourg-en-Breffe.

MARBURG, a town of the duchy of Stiria, feated on the Drave, which had formerly counts of its own; 31 miles S. of Gratz. N. lat. 46° 40'. E. long. 15° 37'.

MARBURG, or *Marpurg*, a town and capital of Upper Heffe, on the W. fide of the Lahn, defended by a caftle, in which the landgraves of Heffe formerly refided. This town has an univerfity, founded in 1527 by the landgrave Philip the Magnanimous, alfo an academy for claffical literature, and three Proteftant churches. About the beginning of the thirteenth century, this place was raifed from a village to a town. In 1261 and 1319 it was wholly deftroyed by fire. In 1759 it was garrifoned by French troops, who were foon after obliged to furrender themfelves prifoners of war; 36 miles N. of Francfort-on-the-Maine. N. lat. 50° 48'. E. long. 8° 48'.

MARC, in *Biography*. See MARCOSIANS.

MARCA, PETER DE, a celebrated French prelate, was born at Gant, in the principality of Bearn, in the year 1594. Having laid a good foundation in claffical learning and polite literature, he went through a courfe of philofophy under the Jefuits at Touloufe: after this he ftudied the law, and at the age of twenty-two was nominated by Lewis XIII. counfellor in in the ſovereign council of Pau, in which, though he was the only Catholic in that court, he conducted himſelf with ſo much prudence, that he maintained perfect harmony with all his coadjutors, and was ſucceſsful in bringing back ſeveral of the reformed into the boſom of the Catholic church. In the midſt of other important engagements, he devoted much of his time to the ſtudy of theology and eccleſiaſtical antiquities. In 1639 he was called to Paris, and was honoured with the rank and dignity of counſellor of ſtate. In the following year he publiſhed his "Hiſtory of Bearn," which tended greatly to confirm the reputation that he had already acquired for learning and abilities. About this time M. Herſent publiſhed an artful defence of the Papal pretenſions over the Gallican church, in the form of a ſatire on the policy of cardinal Richelieu, which, it pretended, aimed at the ſeparation between the churches of Rome and France, ſimilar to the ſchiſm produced by Henry VIII. in England; and the erection of a patriarchate in France in the perſon of the cardinal. To counteract the effects of this work, Richelieu employed the pen of M. de Marca, who, in 1641, publiſhed a piece entitled "De Concordia Sacerdotii et Imperii, ſive, de Libertatibus Eccleſiæ Gallicæ." This was a very learned, and generally eſteemed excellent, vindication of the rights and liberties of the French church and ſtate, and it was received with great applauſe by thoſe Catholics, who, though ſteadily attached to the doctrines of the church of Rome, reſiſted the tyranny and injuſtice of its aſpiring pontiffs: but in the court of Rome it excited much indignation againſt the author, of which he ſoon felt the effects. The king appointed him to a biſhopric, which the cardinals, by certain manœuvres, prevented him from entering upon, till he had retracted or explained away every ſentiment that had given offence at Rome, and by declaring his unreſerved ſubmiſſion of what he had written, or might in future write, to the ſovereign judgment of the holy apoſtolic ſee. Having by this ſervile conduct appeaſed the reſentment of the papal court, he was ordained prieſt, and immediately afterwards conſecrated biſhop. This was in the year 1648, and in 1652, as a reward for other ſervices, he was nominated archbiſhop of Toulouſe, but, by a new oppoſition from the court of Rome, he was not tranſlated till the year 1655. In 1658 he was made a miniſter of ſtate, and followed the king to Lyons, after which he was appointed to preſide over the ſtates of Narbonne, upon the death of the archbiſhop. After Cardi al Mazarin had concluded a peace, he was ſent to Rouſſillon for the purpoſe of determining, with the commiſſioners of the king of Spain, the preciſe limits between France and Spain, according to the boundary line of the ancient geographers. Upon the death of the cardinal, in 1661, Marca was ſelected as one of the perſons to preſide over eccleſiaſtical affairs, and in the following year he was, in conſequence of the reſignation of cardinal de Retz, nominated to that dignity, but he did not live to enjoy, or even to take poſſeſſion of this high office. He died about the ſixty-eighth year of his age: he was a man of profound erudition, of a fine underſtanding, and of an extraordinary genius for buſineſs. He was a great politician, a good lawyer, a learned divine, and an able critic. He never ſcrupled to make his principles give way, if by ſo doing he could promote his own intereſts. A few months before his death he dictated to his ſecretary "A Treatiſe on the Infallibility of the Pope," with the expreſs view of recommending himſelf to a cardinal's hat. The beſt edition of his celebrated work "De Concordia" was publiſhed after his death, in 1704, in which the conceſſions with which he had purchaſed the papal bull to obtain the prelacy, were, by his order, directed to be omitted, and the work given in its original ſtate. He was author of ſeveral other pieces, among which were "Marca Hiſpanica," containing a curious and valuable geographical and hiſtorical deſcription of Catalonia, Rouſſillon, and the neighbouring countries: "An Account of what paſſed in the Aſſemblies of the Biſhops in 1653:" "Theological Treatiſes;" and two volumes of "Opuſcula." Moreri.

MARCANTHUS, in *Botany*, is a genus of Loureiro's, ſo called by an unaccountable, though we preſume accidental, miſtake for *Macranthus*, ſince the derivation of its name being avowedly from μακρος, *long*, (which he erroneouſly writes μαρκος,) and ανθος, *a flower*; the genus being very remarkable for the great length of its flowers. Loureir. Cochinch. 460.—Claſs and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminoſæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, tubular, coloured, downy, permanent, cloven into four, acute ſegments, the two lateral ones ſhorter. *Cor.* papilionaceous, very long, almoſt cloſed. Standard ovate, emarginate, connivent, longer than the calyx. Wings oblong, erect, thrice as long as the ſtandard. Keel longer than the wings, with an acute, aſcending point. *Stam.* Filaments ten, ſimple and nine-cleft, all linear-turbinate, acuminated and ſtraight, four of them three times as thick as the reſt; anthers of the thicker ones ovate, incumbent; of the others oblong and upright. *Piſt.* Germen ſuperior, oblong, cylindrical; ſtyle thread-ſhaped, hairy all over, the length of the ſtamens; ſtigma obtuſe, roughiſh. *Peric.* Legume ſtraight, nearly cylindrical, thick, pointed. *Seeds* numerous, nearly ovate.

Eſſ. Ch. Keel and wings very long. Legume thick, ſomewhat cylindrical.

1. M. *cochinchinenſis*. Loureir. Dâu meò, of the natives.—A native of cultivated ground in Cochinchina.—The *ſtem* is herbaceous, long, round, twining, branched. *Leaves* ternate, ovate-rhomboid, hairy. *Stipulas* thread-ſhaped. *Flowers* white, with a calyx of the ſame colour, on many-flowered, axillary ſtalks. *Legume* eſculent, although neither well taſted nor ſalubrious.

MARCAPATA, in *Geography*, a town of Peru, in the juriſdiction of Quiſnicanchi.

MARCARIA, a town of Italy, in the department of the Mincio, on the Oglio; 14 miles S.W. of Mantua.

MARCASI, three ſmall iſlands in the Pacific ocean, near the coaſt of Peru. S. lat. 11° 30′.

MARCASITE, in *Mineralogy*, *Arſenical Pyrites* of Kirwan. See Arsenic.

MARCAY, in *Geography*, a town of France, in the department of the Vienne; 7 miles S. of Poitiers.

MARCEL, St., a town of France, in the department of the Ardèche; 24 miles S. of Privas.—Alſo, a town of France, in the department of the Mouths of the Rhône; 5 miles E. of Marſeilles.—Alſo, a town of New Navarre; 130 miles S.W. of Caſa Grande.

MARCELLIANISM, in *Eccleſiaſtical Hiſtory*, the doctrines and opinions of the Marcellians, a ſect of ancient heretics, towards the commencement of the third century, ſo called from Marcellus of Ancyra, their leader, who was accuſed of reviving the errors of Sabellius.

It is generally ſuppoſed that Marcellus, biſhop of Ancyra, in Galatia, was preſent at a council of Ancyra in 314, as biſhop of that city. He was alſo at the council of Nice in 325, where he ſignalized himſelf againſt the Arians; and it is concluded, from the teſtimony of Epiphanius, that he died in 372, when he had been biſhop almoſt 60 years, and had lived almoſt or quite a century. Socrates ſays, that in oppoſing Aſterius, againſt whom and other Arians he wrote a book a book in the year 334 or 335, Marcellus went into the other extreme, and embraced the opinion of Paul of Samofata, who fays, that Jefus Chrift is a mere man. He was depofed by an affembly of bifhops at Conftantinople, in 336, but reftored by the fynod at Sardica in 347. His book, which was a large work, and the only one he had publifhed, was anfwered by Eufebius of Cæfarea, from whofe quotations and arguments, as well as from Marcellus's letter and confeffion of faith, delivered to Julius, bifhop of Rome, about the year 341, which is preferved by Epiphanius, that he received the fame fcriptures with other Chriftians, and paid them a like refpect. Socrates and Sozomen feem to have fuppofed, that he adopted the opinion of Paul of Samofata; but Eufebius continually charges him with Sabellianifm. Theodoret fays, that he denied a trinity of perfons. However, there have been formerly, as well as lately, different apprehenfions concerning the real fentiments of Marcellus; but, according to Dr. Lardner, there is fufficient reafon to think, that he was a Sabellian or Unitarian. Montfaucon is of opinion, that not long before his death, about the year 372, he fent a deputation to Athanafius, with a confeffion of his faith, completely orthodox; but this ftory, as Dr. Lardner thinks, is not well fupported. If the doctrine of Marcellus be carefully examined, it will appear, fays Mofheim, that he confidered the Son and Holy Ghoft as two emanations from the divine nature, which, after performing their refpective offices, were to return again into the fubftance of the Father; and every one will perceive, at firft fight, how incompatible this opinion is with the belief of three diftinct perfons in the Godhead. Lardner's Works, vol. iv. Mofheim's Eccl. Hift. vol. i.

MARCELLIN, St., in *Geography*, a town of France, and principal place of a diftrict, in the department of the Ifére; 30 miles S.E. of Vienne. The place contains 3047, and the canton 14,589 inhabitants, on a territory of 240 kiliometres, in 16 communes.—Alfo, a town of France, in the department of the Rhône and Loire; 9 miles S.S.E. of Montbrifon.

MARCELLINO, a town of Naples, in Calabria Citra; five miles E. of Scalea.

MARCELLINUS, Ammianus, in *Biography*. See Ammianus Marcellinus.

Marcellinus, pope, a native of Rome, fucceeded to the fee of that city in the year 296. He was accufed by the Donatifts of having apoftatized under the Dioclefian perfecution; of having given up the fcriptures to be burnt by the Pagans; and of offering incenfe even to the gods. It fhould, however, be obferved, that the innocence of Marcellinus was defended, and his conduct juftified by St. Auguftine and Theodoret, who affirm that he acquired great glory during the perfecution. He prefided over the Roman church fomething more than eight years, and died in the year 304. Moreri.

Marcellinus, count of Illyria under the emperor Juftinian, drew up a chronicle, commencing at the point in which Jerome finifhes, and carrying it down to the year 534. It is much applauded by Caffiodorus, who fays that the count alfo compofed a very minute defcription of Conftantinople and Jerufalem. The chronicle has been feveral times printed, firft by Schoonhovius, in the fixteenth century: then by Jofeph Scaliger, and ftill more correctly by father Sirmond. Moreri.

MARCELLO, Benedetto, a Venetian nobleman, defcended from one of the moft illuftrious families of that republic; he had cultivated mufic fo ferioufly and fuccefsfully as a dilettante in the art, under the guidance of the celebrated Venetian maeftro di capella, Gafparini, that no contemporary profeffor was more reverenced for mufical fcience, or half fo much praifed for his abilities as a compofer, as Marcello. This accomplifhed nobleman, befides his mufical productions, confifting of pfalms, operas, madrigals, fongs, and cantatas, was frequently his own poet, and fometimes affumed the character of lyric bard for other muficians. It is probable that Marcello had received fome difguft in his early attempts at dramatic mufic; for, in 1720, he publifhed a furious fatire upon compofers, finging-mafters, and fingers in general, under the title of "Teatro alla Moda," or "An eafy and certain Method of compofing and performing Italian Operas in the modern Manner." But his great mufical work, to which the late Mr. Avifon's encomiums and Mr. Garth's publication to Englifh words, have given celebrity in our own country, was firft printed at Venice in eight volumes folio, under the following title: "Eftro poetico-armonico, Parafrafi fopra i primi 50 Salmi, Poefia di Girolamo Afcanio Giuftiniani, Mufica di Benedetto Marcello, Patrizj Veneti, 1724 & 1725." There is a long and learned preface to the firft volume, in order to give weight and authority to the author's plan and ftyle of compofition. But befides the great difplay of mufical reading, fagacity, and fuperior views to any of his predeceffors, letters are prefixed to each volume from the author's friends and admirers, in the fame encomiaftic ftrain as the recommendatory verfes, with which almoft every book was ufhered into the world during the feventeenth century. But not dazzled by thefe, or the hyperbolical praifes of Algarotti or Avifon, we have confcientioufly examined the whole eight volumes of the Italian edition, and find, though there is confiderable merit in the work, that the author has been *over-praifed*: as the fubjects of many of his fugues and airs are not only common and old-fafhioned at prefent, but were far from new at the time thefe pfalms were compofed. But Marcello was a Venetian nobleman, as Venofa was a Neapolitan prince; both did honour to mufic by cultivating it; but both expected and received a greater return in fame, than the legal intereft of the art would allow. Marcello was a difciple of Gafparini, and died in 1741.

We found ftill fubfifting at Venice, a fociety for the performance of Marcello's compofitions exclufively, and were invited to one of its meetings. Several of Marcello's pfalms were here very well fung by the Abate Martini and fome other dilettanti, among whom one had a very good bafe voice, and between the pfalms, fung Marcello's famous cantata, called Caffandra, where this compofer has entirely facrificed the mufic to the poetry, by changing the time or ftyle of his movement at every new idea which occurs in the words; this may, perhaps, fhew a compofer to be a very fenfible man, but at the fame time it muft difcover him to be of a very phlegmatic turn, and wholly free from the enthufiafm of a creative mufical genius. And, indeed, fince melody has been allied to grace and fancy, mufical disjointed thoughts on various fubjects would be but ill received by the public. One of thefe gentlemen performers was old enough very well to remember Benedetto Marcello, and favoured us with feveral anecdotes concerning him and his family which ftill fubfifted, and the head of it then was ambaffador from the ftate to the Porte.

Marcello was not only his own poet in dramas which he fet to mufic, but fometimes furnifhed words to other mufical compofers. He was author of a drama called "Arato in Sparta," which was fet by Ruggieri, and performed at Venice in 1704; and in 1710 he produced both the words and the mufic of an oratorio, called "Giuditta." He fet the

"Psyche" of Cassini, about the same time. In 1718, he Published sonnets of his own writing, without music: and in 1725 he both wrote and set a serenata, which was performed at the imperial court of Vienna.

To some of his madrigals and cantatas, of which we prefer the composition to that of many of his psalms, we were told at Venice that he was his own poet.

But we have lately been favoured with a complete score of an oratorio by Marcello, of which we had never before heard of the existence. Its title, which is somewhat long, and its subject singular for an oratorio, is the following:

"Il Trionfo della Poesia, e della Musica, nil celebrarsi la Morte, la Esaltazione, e la Incoronazione, di Maria sempre Vergine assunto in cielo, Oratorio sagro a 6 voci 1733. Musica e Poesia di Benedetto Marcello."

The interlocutors are Poetry, Music, Painting, Sculpture, and chorus of Poets, Liberal Arts, and Old Musicians.

But these personifications are not so wide from sacred subjects as Alexander's Feast, and Semele, which are indeed sacred subjects of Paganism. And though the subject of this drama may be too playful, and the airs too gay for an oratorio, yet it is amusing to see how a great man may amuse himself in trying to amuse others. The airs are much superior to those of the noble author's psalms, and more ingeniously accompanied.

The overture, which begins with a spirited movement, ends with an admirable fugue in double counterpoint, instead of an air. There are ingenious airs and duets in echo, in the first part, and the coro finale is an alla-breve fugue on the hexachords.

In the second part there are many curious airs, duets, and chorusses, well accompanied; and all in clear and good counterpoint, and though it is called an oratorio, the movements are as gay and cheerful as any secular music of the same period. It must be owned that the chorusses and accompaniments of Handel's oratorios have made the English fastidious about sacred music. But Marcello must ever be admired for Italian grace and smoothness, and Handel for German force and vigour.

Marcello, *St.*, in *Geography*, a town of France, in the department of the Dora; 5 miles S.E. of Aosta.

MARCELLUS, surnamed Empiricus, *the Empiric*, in *Biography*, was a native of Bourdeaux, and held an appointment under the emperors Theodosius and Arcadius. He died in the reign of Theodosius, the younger, who ascended the throne of the eastern empire in the year 408. It does not appear that Marcellus pursued the study of medicine as a profession, but took it up as an amateur, without acquiring any profound skill in it. He compiled from authors, both ancient and contemporary, and especially from Scribonius Largus, whom he copies literally without acknowledgment, and also from popular report, a collection of medicines and receipts for all the diseases of the body; in which, however, his superstition is more conspicuous than his judgment. Nevertheless his work has been preserved, and printed under the title of "De Medicamentis empiricis physicis et rationalibus Liber à Jano Cornario versus," Basil, 1536, &c. and was included among the "Medicæ Artis Principes," collected by Henry Stephen. Marcellus dedicated this compilation to his children, in an epistle which is preserved, with a view of teaching them the means of relieving their diseases by simple remedies; but at the same time he counsels them not to neglect the more compound ones when necessary, and to consult the most expert physicians before they employ them. Eloy Dict. Hist.

Marcellus Donatus, a physician of the sixteenth century, quitted the practice of his profession, and became secretary to the duke of Mantua. He is known as the author of a compilation of medical cases and observations, collected from the Greek, Arabian, and later writers, who had preceded him. This work was first published at Mantua, in 1586, quarto, and afterwards at Venice, 1588, and 1597, in six books, with the title of "De Historiâ Medicâ Mirabili Lib. VI." Horstius afterwards republished it at Franckfort, in octavo, in 1613, with a seventh book, on diseases reputed magical, and on extraordinary abstinence. Marcellus was also author of a tract, "De Variolis and Morbillis," printed at Mantua in 1569, quarto, and 1597, octavo, with another tract, "De Radicé purgante, quam vocant Mekoakan." Eloy, loc. cit.

Marcellus, Marcus Claudius, a celebrated Roman general, descended from a plebeian, but an ancient and consular family, entered early into the military service of his country, and obtained many honorary rewards for his valour and heroism. He was elected consul with Cn. Cornelius Scipio in the year 222 B.C. They were, immediately after their election, obliged to take the field against the enemies of the republic; and Marcellus was singled out by Viridomarus, king of the Gæsatæ, for single combat. The consul soon destroyed his enemy, and consecrated his spoils to Jupiter Feretrius, which being reckoned propitious to his designs, he attacked the enemy, and gained a complete victory. On account of this success, a triumph was decreed to Marcellus, of which the noblest ornaments were the *opime* spoils, that is, those taken from a slain king. The greatness of this distinction may be inferred from the lines which are referred to him in Virgil's prospective view of the Trojan progeny:

"Aspice ut insignis spoliis Marcellus opimis
Ingreditur, victorque viros supereminet omnes."
Æneid vi.

In the second Carthaginian war, Marcellus was appointed prætor of Sicily, and had got ready a fleet for that service, when the event of the fatal battle of Cannæ induced the senate to send him to take command of those who survived that disaster. He threw himself into Nola, which was threatened by Hannibal with a siege, and gave that commander a considerable check, which revived the courage of the Romans, and saved the place. In the year B.C. 215, Marcellus was again unanimously chosen consul, but a thunder-storm happening at the time of assembly, it was thought the election was displeasing to the gods, and he refused to accept the office, though pressed to it by the people. Fabius Maximus was elected in his stead, and Marcellus was continued in a proconsular command over the troops at Nola. After this he was chosen consul in connection with Fabius Maximus, and thus it was said, Rome was defended at the same time by her *sword* and her *shield*, which were the epithets applied to these two great commanders. Marcellus was now called to active exertions in Sicily, in which island the Carthaginian interest was very prevalent; he invested Syracuse, the capital, then one of the richest and strongest cities in this part of the world. He first proposed terms of accommodation, which being rejected, he laid siege to the city by land and by sea, taking command of the Roman fleet upon himself, while the prætor Appius commanded the land forces. This siege was rendered very remarkable by the various mechanical contrivances of the great Archimedes for its defence. By their means, the first attempts of the Romans were defeated with great loss: and Marcellus, converting the siege into a blockade, led the greater part of his troops against the revolted cities of Sicily, many of which he reduced to obedience.

dience. After his confulfhip was expired, he was continued as proconful in the chief command in Sicily, and bent every effort to the finifhing a fiege upon which the eyes of all parties were attentively fixed. Marcellus determined on making an affault upon Syracufe, and fixed on the enfuing feftival of Diana for this purpofe, in which it was imagined the garrifon would probably be buried in wine and fleep. At the appointed time a choice band of troops fcaled the walls without difcovery, and certain quarters of the city were taken without refiftance Marcellus, furveying from an eminence the vaft and opulent city which was about to fuffer all the miferies of a capture, is faid to have fhed tears, becaufe he could not perfuade the inhabitants to fave themfelves from plunder by a timely furrender. They were deaf to remonftrances, and Marcellus had to fuftain a furious attack from the Carthaginians without, and the Syracufans within, which he repulfed with vaft lofs to the affailants. A plague which broke out in Syracufe added to the calamities of that unfortunate city: it ravaged likewife the Carthaginian camp to fuch a degree as to break it up after carrying off the commander. It was not, however, till the end of three years, that Syracufe was taken by affault, when it was impoffible to fave the inhabitants from the effects of a fack : the houfes were pillaged, and many citizens were put to the fword, among whom was Archimedes, whofe fate was particularly afflicting to Marcellus, and who was flain while he was calmly working a mathematical problem. The Roman commander, as foon as he was able, put an end to the atrocities of his foldiers, and difplayed much perfonal clemency and humanity to the vanquifhed, but he carried away all the public monuments of art which decorated Syracufe for the ornament of Rome. Marcellus continued fome time longer in Sicily, but his laft action ended in a confiderable victory obtained over the combined forces of Hanno and Epicydes, after which he returned to Rome with great glory. In the year 210 B.C. he was again chofen conful, when he was accufed by the Syracufans with cruelty and a violation of treaty. He was, however, after due enquiries, acquitted of the charges, and his fubfequent behaviour would have done honour to any man : he raifed up the Syracufan deputies, who had been his accufers, and had fallen at his feet to implore forgivenefs, affured them not only of his pardon, but of his future protection, and obtained of the fenate that the people of Syracufe fhould be reinftated in their liberties, and confidered as the allies of Rome. They, unwilling to be behind in refpect for his manly virtues, expreffed their gratitude to him by a decree, that when he or any one of his family fhould vifit Sicily, the people fhould walk in proceffion before him, crowned with garlands, and celebrate the day with public facrifices ; and that thenceforth the whole ifland fhould be under the peculiar patronage of the Marcelli. After this Marcellus was a fecond time called upon to oppofe Hannibal. He difplayed as ufual his great military talents in his operations againft this general, but was not fufficiently vigilant againft the fnares of his adverfary. He imprudently feparated himfelf from his camp, and was killed in ambufcade in the 60th year of his age, and in his fifth confulfhip, being the year 208 B.C. When the body of this great commander was brought to Hannibal, he furveyed it a confiderable time in thoughtful filence ; and caufed it to be buried, or, as others fay, to be burned on a funeral pile, and then fent the afhes enclofed in a filver urn, and crowned with laurel, to his fon. Plutarch.

MARCELLUS I., pope, a native of Rome, became a prefbyter under Marcellinus, and was his fucceffor in the bifhopric of that city in the year 308, after the fee had been vacant for more than three years and a half. The particulars relating to this pope are not given on fufficient authority. It is faid, in his epitaph, written by pope Damafus, that his firmnefs in maintaining the difcipline of the church, and in obliging thofe who had fallen during the times of perfecution to give proof of the genuinenefs of their repentance, excited againft him the general hatred, which was not confined to private difputes and divifions, but ended in public tumults, bloodfhed, and murders. He adds, that Marcellus was fent into banifhment, and died in the fecond year of his pontificate, in the year 310. The church of Rome has given him a place in her lift of martyrs, but in the moft ancient martyrologies he has only the title of confeffor. Moreri. Bower.

MARCELLUS II., pope, a native of Fano, in the Marche of Ancona, was fon to the receiver-general of the revenues of the holy fee. He was educated at Sienna, and honourably diftinguifhed himfelf in literary purfuits. He afterwards went to Rome under the pontificate of pope Paul III., who appointed him his principal fecretary. He accompanied cardinal Farnefe, the nephew of the pope, to attempt to bring about a reconciliation between Francis I. and the emperor Charles V.: he at this time had the title of bifhop, and was promoted to three different fees in fucceffion, and upon his return to Rome, Paul created him cardinal prefbyter of the holy crofs of Jerufalem, and nominated him one of the prefidents of the council of Trent. He fucceeded to the popedom on the death of Julius III., in the year 1555. He is reprefented as being a man of inflexible integrity, of invincible refolution and conftancy, and as having formed great defigns for the reformation of the court and of the clergy, but he died before he could carry any of them into execution, and within a month of his confecration. Bower. Moreri.

MARCELLUS, in *Geography*, a military and poft-town of America, in Onondago county, New York, fituated on Skaneatates lake, 11 miles W. of Onondago caftle ; incorporated in 1794, and containing 909 inhabitants.

MARCENAT, a town of France, in the department of the Cantal, and chief place of a canton, in the diftrict of Murat. The place contains 2058, and the canton 8957 inhabitants, on a territory of 282½ kiliometres, in 7 communes.

MARCENOPOLI, a town of Bulgaria, anciently Marcianopolis: it was deftroyed by Attila; 20 miles W.N.W. of Varna. N. lat. 43° 10'. E. long. 27° 24'.

MARCGRAVE, or MARGRAVE, a kind of dignity in Germany, anfwering to our marquis.

The word is derived from the German *marche*, or *marke*, which fignifies *a frontier*, formed, as Junius conjectures, from the laft fyllable of the Greek τεκ-μαρ, which fignifies both *a mark*, and *a limit ;* and *graffe, count, governor ;* marcgraves being originally governors of cities lying on the frontiers of a country or ftate.

MARCGRAVIA, in *Botany*, was named by Plumier, in memory of George Marcgraf de Liebftad, a native of Saxony, who travelled with Pifo in the Brafils, and fubfequently vifited the coafts of the Mediterranean. He died in paffing over to Africa, at the age of 34, in 1644. His account of the plants, animals, and inhabitants of the Brafils, has been publifhed by De Laet, along with fome of the writings of Pifo, in a folio volume, dated 1648, illuftrated with wooden cuts. The eighth book of this is repeated in another edition of the works of Pifo, with thofe of Bontius, publifhed at Amfterdam, in 1658. Marcgraf is mentioned by Pifo, p. 107 of the laft-mentioned volume, as "his excellent and very diligent domeftic, of fome of whofe drawings and obfervations he has made ufe, which he acknowledges,

acknowledges, left evil-minded perfons fhould accufe him of enriching his works with ftolen decorations." Linnæus fays, *Crit. Bot.* 79, that a relation of Marcgraf has accufed Pifo of deriving all his information from the papers of the former, after his death. He is reported, moreover, to have been himfelf the fervant of the man he attempts, in that refpect, to debafe. It feems that Marcgraf was of a good family, unlefs his furname (de Liebftad) merely, as Haller fuppofes, indicates the place of his birth. Pifo became a phyfician at Amfterdam. (See PISONIA hereafter in its proper place.) Linn. Gen. 260. Schreb. 347. Willd. Sp. Pl. v. 2. 1127. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 3. 284. Juff. 244. Plum. Gen. 7. t. 29. Lamarck Illuftr. t. 447.—Clafs and order, *Polyandria Monogynia.* Nat. Ord. *Putamineæ*, Linn. *Capparides*, Juff.

Gen. Ch. *Cal.* Perianth inferior, permanent, of fix imbricated, roundifh, broad, concave leaves; the two outermoft largeft. *Cor.* of one petal, vertical, ovate, fomewhat conical, undivided, covering the organs of impregnation like a cap, at length feparating all round at the bafe, deciduous. *Stam.* Filaments numerous, awl-fhaped, fhort, fpreading, deciduous; anthers large, ovate-oblong, erect. *Pift.* Germen fuperior, ovate; ftyle none; ftigma capitate, permanent. *Peric.* Berry globofe, coriaceous, of many cells, and many imperfect valves. *Seeds* numerous, fmall, oblong, lodged in foft pulp.

Eff. Ch. Corolla of one petal, vertical, cap-fhaped, deciduous. Calyx of fix imbricated leaves. Berry of many cells. Seeds numerous.

1. M. *umbellata.* Climbing Marcgravia. Linn. Sp. Pl. 719. Jacq. Amer. 156. t. 96. (M. fcandens; Browne Jam. 244. t. 26. Plum. Ic. t. 173. f. 1.)—Native of woods in South America and the Weft Indies. Browne fays it is frequent in Jamaica. The *ftem* is at firft flender and weak, climbing up the trunks of large trees, by means of fibres like thofe of ivy, and furnifhed with alternate heart-fhaped, emarginate, entire *leaves*, on very fhort footftalks. When it reaches the fummit, it "lays its trunk," fays Browne, "more commodioufly over fome of the larger branches of the tree: then it begins to ftrengthen, and cafts many flender, dependent and fubdivided branches from the upper parts. But as it increafes at the top, the ftem grows thicker, feparates from the fupporter, throws off its now ufelefs leaves and roots (fibres), and appears a ftrong withey fhrub, whofe trunk is frequently no lefs than four or five inches in diameter." The pendulous *branches* are a foot or two in length, roundifh, warty, bearing numerous, alternate, elliptic-oblong, pointed, entire, fmooth, fomewhat flefhy *leaves*, on fhort ftalks, fpreading in two directions, each about three inches long, furnifhed with a ftrong rib, and feveral fmall tranfverfe veins. *Stipulas* none, except a little intrafoliaceous gland, juft above the infertion of each footftalk. *Umbel* terminal, pendulous, folitary, fimple, of about a dozen *flowers*, on widely fpreading downy ftalks, fwelling upwards, above an inch long. The *flowers* appear to be turned downwards. Their *corolla*, while it remains, gives them the appearance of fmall acorns, being about one-third of an inch long, and might eafily be miftaken for a feed-veffel. Of its colour we find no mention. The *fruit* is the fize of a moderate goofeberry, with a thick rind, which is but imperfectly difpofed to fplit into valves. The internal partitions originate from it, and are narrow and thin. The pulp and *feeds* are faid to be of a vivid fcarlet. We prefume, from the natural affinities of this plant, that it is of a poifonous quality. Its greateft peculiarity confifts in four, five, or more appendages to the umbel, placed in the centre, each on a ftalk half the length of the flower-ftalks. Thefe are above an inch long, tubular, obtufe, and clofed at the extremity, but furnifhed with a dilated lip at their orifice where the ftalk is inferted. Being, from the pofition of the umbel, pendulous, Browne fays they catch the water that trickles down the branch in rainy weather; but their ufe has not been fully explained. Linnæus fuppofed them *nectaries*. If fuch, they may ferve to tempt infects or humming-birds to frequent the flowers, and affift impregnation, as in numberlefs other cafes.

Willdenow has adopted another fpecies, *M. coriacea*, from Vahl's *Eclogæ*. Of this magnificent plant we have been favoured by Mr. T. F. Forfter with a fine fpecimen from Guiana. It has the habit of *M. umbellata*, but more elliptical, obtufe, coriaceous, fhining, and almoft veinlefs, *leaves*. The *umbel*, like all the other parts, is much larger. The fuppofed *nectaries*, or pouches, grow, without any ftalks, on the lower part of each flower-ftalk, and are fhorter and more inflated than thofe of the former. This plant has certainly all the habit of the genus in queftion, but neither Vahl nor Willdenow feems to have known any thing of the *corolla*, which is totally different, confifting of five feparate concave *petals*, fo that it proves to belong to Schreber's genus *Afcium*, the *Norantea* of Aublet; which differs in that refpect only from Marcgravia, having exactly the fame fort of pouches, though they have been called *bracteas*, becaufe the inflorefcence in Aublet's plant is racemofe. *Marcgravia*, therefore, differs from *Afcium* exactly as Swartz's *Calyptranthes* differs from *Myrtus*, and no further; for the difference in their inflorefcence, which might have been thought of fome moment, is done away by this new fpecies, which is in that refpect a *Marcgravia*, though in generic character an *Afcium*. See ASCIUM and CALYPTRANTHES.

MARCH, MARTIUS, in *Chronology*, the third month of the year, according to the common way of computing.

Among the Romans, March was the firft month: and, in fome ecclefiaftical computations, that order is ftill preferved; as particularly in reckoning the number of years from the incarnation of our Saviour, which is done from the 25th of March.

In England, (before the alteration of the ftyle,) March, properly fpeaking, was the firft month in order, the new year commencing from the 25th; though, in complaifance to the cuftoms of our neighbours, we ufually ranked it as the third; but, in this refpect, we fpoke one way, and wrote another.

Till the year 1564, the French reckoned the beginning of their year from Eafter; fo that there were two months of March in one year, one of which they called *March before Eafter*, and the other *March after Eafter*; and, when Eafter fell within the month of March, the beginning of the month was in one year, and the end in another.

It was Romulus who divided the year into months: to the firft of which he gave the name of his fuppofed father Mars. Ovid, however, obferves, that the people of Italy had the month of March before Romulus's time; but that they placed it very differently, fome making it the third, fome the fourth, fome the fifth, and others the tenth month of the year.

In this month it was that the Romans facrificed to Anna Perenna; that they began their comitia; that they adjudged their public farms and leafes; that the miftreffes ferved the flaves and fervants at table, as the mafters did in the Saturnalia; and that the Veftals renewed the facred fire.

The month of March was always under the protection of Minerva, and always confifted of thirty-one days. The ancients

cients held it an unhappy month for marriage, as well as the month of May.

March, in *Geography*, a market-town in the parish of Doddington, hundred of Witchford, isle of Ely, Cambridgeshire, England, is situated 26 miles distant from Cambridge, 15 from Ely, and 81 from London, nearly midway between Chatteres and Wisbech, on the banks of the river Nene; from which circumstance it has the advantages of a considerable trade. The population, as returned to parliament in the year 1801, was 2514, occupying 555 houses. The chapel is a spacious edifice, with a spire, erected about the year 1343. A market is held on Fridays, and three fairs annually. Many Roman remains have been discovered in this vicinity. When the road was making from March to Wisbech, in the year 1730, three urns were dug up, full of burnt bones and ashes; and also a pot, containing 160 Roman denarii, of all the emperors from Vespasian to Antoninus Pius, but chiefly of the latter. Various other coins have been found, and an altar 21 inches high. Beauties of England and Wales, vol. ii.

March, in *Military Language*, is in general the motion of a body of men from one place to another.

The beat of the drum, upon particular occasions, is likewise called the *march*; which see. It is likewise a word of command, when a battalion is to alter its disposition.

Neither music nor drums are now used to regulate the march, which is in three measures. 1. Ordinary time, in which 75 paces are taken in a minute. 2. Quick time, in which there are 108 steps in a minute. 3. The quickest time, or wheeling march, which is at the rate of 120 steps of 30 inches each, or 300 feet in the minute. This last is used only for wheeling. For a more particular account of the subject of this article, see Battalion.

As many accidents may happen in the march of an army from defiles, marshes, woods, and the like, it is the prudence of a general to order his march accordingly, and to take care that the columns of his army have a free communication one with the other. The march of an army is composed of an advance guard, the main body, and the rear guard, and is sometimes in two, four, six, or eight columns, according as the ground will allow.

The order of march of the troops must be so disposed, that each should arrive at their rendezvous, if possible, on the same day. The quarter-master-general, or his deputy, with an able engineer, should sufficiently reconnoitre the country, so as to obtain a perfect knowledge both of that and of the enemy, before he forms his routes. Before a march, the army generally receives several days' bread. The quarter-masters, camp-colour men, and pioneers, parade according to orders, and march immediately after, commanded by the quarter-master-general, or his deputy. They are to clear the roads, level the ways, make preparation for the march of the army, &c. The "general," for instance, beats at two, the "assembly" at three, and the army commence their march in 30 minutes after. Upon beating the "general," the village and general officer's guards, quarter and rear-guards, join their respective corps, and the army pack up their baggage. Upon the "assembly," the tents are to be struck, and sent, with the baggage, to the place appointed. The companies draw up in their several streets, and the rolls are called. At the time appointed, the drummers are to beat a march, and fifers play at the head of the line; upon which the companies march out from their several streets, form battalions as they advance to the head of the line, and then halt. The several battalions will be formed into columns by the adjutant-general, and the order of march, &c. be given to the general officers who lead the columns. The cavalry generally march by regiments or squadrons. The heavy artillery always keep the great roads, in the centre of the columns, escorted by a strong party of infantry and cavalry. The field-pieces move with the columns. Each soldier generally marches with 60 rounds of powder and ball, and three good flints; one of which is to be fixed in the cock of his fire-lock. The routes must be so formed, that no column may cross one another on the march. See Battalion.

March, in *Music*, a military air played by martial instruments to regulate and mark the steps of the soldiery, to which the drums usually beat time. There are military pieces for field instruments on the parade, which are called *marches*, though the regiment or corps is stationary.

In Persia, according to Chardin, when a building is to be pulled down, the ground to be levelled, or any work to be performed that requires dispatch, and the united efforts of a multitude, all the inhabitants of a district are assembled, who work to the sound of instruments, and the business is done with more zeal and promptitude than it would be in silence.

Marshal Saxe, in his Reveries, shews, that the effect of drums is not confined to a mere useless noise; but as the pulsations are more or less rapid, they naturally inform the soldier to accelerate or retard his pace. It may also be said, that the melody or movement of marches should have different characters, according to the occasions upon which they are played; and this is implied by the names given to certain beatings of the drum, as the general, the retreat, the charge, &c.; but all the advantages of such signals have not been taken that might be. The measures that are beaten or played, have hitherto been confined to one style, to suit the common beat of the drum. And there are many airs that are denominated marches which fulfil that object very imperfectly. The French troops (said Rousseau, in 1768,) having few military instruments for the infantry, except fifes and drums, have likewise very few marches, and these, in general, ill composed; but how admirable are those in the German troops. It is only the infantry and light horse that have particular marches. The kettle-drums of the cavalry have no regular march; the trumpets have only a single note sometimes, and never more than a *tantare*, or flourish. The march, pace, or movement, in music, is used figurately by the French in speaking of the succession of sounds in melody, which follow each other in a certain order; as the base and treble proceed by contrary motion, the base moves in quavers, the treble in semiquavers, &c. For the argreement between the musical air and the military steps, Rousseau has given the first part of the march of the Mousquitaires of the king of France at the time when his Dict. de Mus. was printed, which we have copied in our musical plates. It was found by English travellers, four or five years after Rousseau's Dict. was published, that the French military music in Flanders was very much improved by the adoption of the instruments and style of music used in the bands of the Walloon and German regiments in the Austrian Netherlands. German Musical Tour, vol. i.

In the Supplement to the first edition of the Encyclopédie, it is truly said, that a march should be always composed in common time, with an odd crotchet or quaver at the beginning; and that it is almost impossible to march in cadence to a movement in triple time, unless it is composed in such a manner that the cæsura is felt at the end of every two bars; that is to say, unless the composer has written an air in common time, as if it were in triple.

The arsis, or up part of the bar, naturally marks the lifting up of the foot in marching; on which account the air usually begins with an odd note.

Of

Of the marches and military mufic of our anceftors, we may form fome judgment by the remains of our venerable compofer, William Bird, tranfcribed in the Virginal book of lady Nevil, which is ftill preferved, and in the poffeffion of Dr. Burney. This book, curioufly written in 1591, contains no lefs than forty-two pieces by the admirable Bird; among which are the following military movements, fet for the Virginal by that venerable compofer, and very neatly copied on fix-line paper.

The orthography of the names of the tunes, and of the copyifts termination of the MS. are here preferved.

The March before the Battell.
The Battell.
The March of Footmen.
The March of Horfemen.
The Trumpetts.
The Irifhe March.
The March to Fighte.
Tantara.
The Battells bejoined.
The Retreat.
The Galliarde for the Victorie.

We fhall give the motivo, or fubject, of fome of thefe pieces, on one of the mufic plates.

The copyift of this curious MS. having terminated his labour, has made the following record of his achievement.

finis:

ffinifhed and ended the feventh of September in the yeare of our Lorde God, 1591, and in the 33d yeare of the raigne of our fofferaigne ladie Elizabeth by the grace of God queene of Englande, &c.

By me Jo: Baldwine of Windfore:
Laudes: Deo.

March, Ausias, in *Biography*, the beft known of the Limofin poets, was born in Valencia, of Catalan parents, and flourifhed about the middle of the 15th century. He was educated in the duke of Gandias houfhold, and married a woman of noble family, but, like Petrarch, whofe example he followed, he fell in love with another man's wife, and fpent his time in writing verfes upon her in the Provençal ftyle. Could the Catalans have fhaken off the yoke of Arragon, againft which they ftruggled, their dialect would have become a cultivated tongue, and Aufias March would have been the father of its poetry. As it is, his reputation is very great, confidering the obfolete language in which he wrote. His poems have been frequently printed: the earlieft edition is that of Valencia, in 1539. The Valladolid edition of 1555 contains a copious gloffary, with obfervations on the grammar and pronunciation of the language. Gen. Biog.

MARCHAND, Prosper, born towards the clofe of the 17th century, was brought up in the bookfelling trade at Paris, and acquired a great knowledge of books and literary anecdotes. His attachment to the Proteftant religion, and his connection with Bernard, the continuator of the "Nouvelles de la Republique des Lettres," induced him to remove to Holland, where he acted fome time as a bookfeller, till at length he entirely devoted himfelf to literature. His ftudies led him chiefly to bibliography and French hiftory, and on thefe topics he was occafionally confulted by perfons from all parts of Europe. He took an active and leading part in the "Journal Literaire," and he furnifhed other literary journals with curious extracts, which he had collected by his extenfive courfe of reading. He died at an advanced age in 1756, and left his library and manufcripts to the univerfity of Leyden. He had publifhed, in 1740, "L'Hiftoire de l'Imprimerie:" "Dictionnaire Hiftorique; ou, Memoires Critiques et Literaires;" and a new edition of "Bayle's Dictionary and Letters."

Marchand, John Lewis, a celebrated French organift during the early part of the laft century, ufually performed at the Jefuits' church of St. Benoit, rue St. Jaques, and at the Cordeliers, where he was followed by all Paris, and always heard with new pleafure. Rameau, his friend and moft formidable rival, frequently declared, that the greateft pleafure of his life was hearing Marchand perform; that no one could be compared to him in the management of a fugue; and that he believed no mufician ever equalled him in extempore playing. The Germans relate a ftory, which no French writer has confirmed: that Marchand, being at Drefden, challenged to a trial of fkill all the organifts of Germany, which none but Sebaftian Bach ventured to accept. It was an honour, fays M. Marpurgh, for Pompey to be only defeated by Cæfar, and to Marchand to have no fuperior but Bach. His independent and difinterefted fpirit, fays M. Laborde, prevented him from ever thinking of his fame or his fortune. As he chiefly loved to play extempore, he feldom committed his thoughts to paper, and has left only two books of harpfichord leffons behind him. He was more happy in his mind and fancy when he played the organ to two or three real connoiffeurs, during the hours that the church was fhut, than when on feftival days he drew together a crowded congregation to hear him. It was at fuch times that he chiefly exerted himfelf and feemed infpired; on other days he only performed what belonged to the fervice of the mafs. This mufician was born at Lyons in 1669, and died at Paris in 1732.

MARCHANTIA, in *Botany*, fo named by John Marchant, in the Memoires de l'Acad. des Sciences for 1713, in honour of his father Nicholas, author of feveral effays in the fame collection. There feems to be a confufion betwixt thefe two perfons, and Nicholas the fon of the former, in Haller's Bibl. Bot. and Dryander's Bibl. Banks. Linn. Gen. 565. Schreb. 763. Mart. Mill. Dict. v. 3. Hedw. Theor. 96. t. 24—26. Spreng. Crypt. 342. Hudf. 519. With. v. 1. 388. t. 15. f. 60—67. v. 3. 884. Juff. 9. Lamarck Dict. v. 3. 107. Illuftr. t. 876. Mich. Gen. 1. t. 1. (Hepatica; Mich Gen. 3. t. 2. Lunularia; ibid. 4. t. 4. Lichen; Dill. Mufc. 515. t. 75—77.)—Clafs and order, *Cryptogamia Algæ*, Linn. *C. Hepaticæ*, Schreb. Nat. Ord. *Algæ*, Linn. *Hepaticæ*, Juff.

Gen. Ch. Male, either ftalked or feffile. *Cal.* Perianth a membranous border, undivided or lobed, permanent, furrounding a tuberculated horizontal difk. *Cor.* none. *Stam.* Filaments none; anthers numerous, oval, of one cell, immerfed vertically in the difk, each encompaffed by a vertical ring, and opening by a pore at the furface of the difk.

Female, on the fame, or a feparate, plant. *Common Cal.* large, ftellated, hemifpherical or conical, flowering underneath, the florets pointing downwards. Perianth feffile, bell-fhaped, membranous, tender, coloured, with four or five teeth. *Cor.* Veil feffile, fhorter than the perianth, oblong or fomewhat globofe, membranous, very thin, crowned with the ftyle, and at length fplitting at the top into from two to five fegments, one of which retains the ftyle at its fummit. *Pift.* Germen feffile, oblong, fomewhat globofe, invefted with the veil; ftyle ftraight or incurved, fhort, prominent from the top of the veil; ftigma fimple. *Peric.* Capfule attached by a capillary fhort ftalk, obovate, of one cell, opening at the top with from five to ten, ufually eight, teeth, which at length become revolute. *Seeds* very numerous, globofe, attached to feveral elaftic, fpirally contorted, threads.

Obf.

Obſ. Some ſpecies bear, beſides the flowers, little cups, toothed at their edges, full of grains which prove to be buds, *gemmæ*. Linnæus, truſting to Dillenius, miſtook theſe for the female fructification, and the real female flowers for male ones, the ſeeds being ſuppoſed the pollen. The true male flowers, aſcertained by Hedwig, were, in the ſpecies in which they were obſerved, thought a mere variation of form.

Eſſ. Ch. Male, Calyx ſalver-ſhaped. Anthers numerous, annulated, imbedded in its diſk.

Female, Calyx peltate, flowering underneath. Capſules deflexed, opening at the top by ſeveral revolute valves. Seeds attached to elaſtic filaments.

This genus is next akin to *Jungermannia*, (ſee that article,) with which it very much agrees in habit, eſpecially with thoſe ſpecies that have no ſtem ſeparate from the leaves, and grows like them in damp umbrageous places. The herbage however is, on the whole, of larger dimenſions than in *Jungermannia*, and the fructification more elaborate, or at leaſt better defined, as well as eſſentially diſtinct in characters.

Five ſpecies are deſcribed as natives of Britain, and Linnæus has two beſides, and we add an eighth from Scopoli, his *triandra*.

1. M. *polymorpha*. Star-headed Marchantia. Linn. Sp. Pl. 1603. Bulliard, t. 291. Hudſ. n. 1. Engl. Bot. t. 210. (M. ſquamis marginalibus, calyce plano; Schmid. Ic. 38. t. 9. Marchantiæ 1—5; Mich. Gen. 2. t. 1. Lichen fontanus major, ſtellatus æquè, ac umbellatus, et cyathophorus; Dill. Muſc. 523. t. 76. f. 6. L. domeſticus minor, ſtellatus æquè, &c.; ibid. 527. t. 77. f. 7.)—Calyx of the female flowers cloven into about ten narrow ſegments.—Very common in damp places, about ſprings, wells, and ſhady court-yards, throughout Europe, varying much in ſize, in proportion to the moiſture of its ſituation; being often a moſt troubleſome weed in gardens, over-running pots that are obliged to be kept moiſt, as well as beds of alpine or American plants. It flowers about Midſummer, and is perennial. Few plants are endowed with ſuch ample and pertinacious powers of propagation. The *fronds* ſpread horizontally, creeping cloſe to the earth, ſtone, or wall, by means of denſe, fibrous, ſoft, and ſilky radicles of a ſhining brown. They are ſeveral inches in extent, bluntly lobed, of a dark ſhining green, fringed with ſcales, and more or leſs reticulated; leſs reticulated and ſhining in Dillenius's t. 77. f. 7, though Schmidel obſerves that it is hardly poſſible to draw a line between theſe two varieties, or ſuppoſed ſpecies. The latter ſeems to grow in drier ſituations than the former. The upper ſurface of the *leaf* or *frond* is ſtudded with ſeveral pale cups, toothed at their edges, half filled with green lenticular buds, as mentioned above. By theſe the plant is copiouſly increaſed, in leſs moiſt places, where it does not readily flower. The proper *flowers* grow from marginal clefts, on erect ſimple ſtalks, from one to three inches high, thoſe of the females talleſt, and on a ſeparate plant. The common *calyx* of the latter is deeply cut into eight or ten deep, linear, radiant, obtuſe ſegments, from the under ſide of which, towards their baſe, the flowers are produced. The ſeeds are yellow, and the ſpiral filaments to which they are attached, have an apparently ſpontaneous motion, which however ariſes merely from their elaſticity, and exquiſite ſuſceptibility of moiſture.

2. M. *chenopoda*. Gooſe-foot Marchantia. Linn. Sp. Pl. 1603. (Lichen anapodocarpos; Plum. Fil. 143. t. 142. Dill. Muſc. 531. t. 77. f. 8.)—Calyx of the female flowers halved, palmate, with four obtuſe ſegments.—Native of the Weſt Indies, on moiſt rocks. The ſegments of the *frond* are oblong, ſinuated or wavy at the edge. *Fruit-ſtalks* nearly terminal. *Common calyx* of the female flowers remarkable for being cut away on one ſide, all its four ſegments being directed the other way, like the fingers of a hand, or toes of a web-footed bird. We have from Jamaica, gathered by Browne, what ſeems to anſwer to Plumier's figure and deſcription, which Dillenius has copied; we have alſo the ſame from Dr. Swartz. In both ſpecimens the upper ſide of the *frond* is beſprinkled with fine pellucid dots or grains. Mr. Dickſon eſteems theſe ſpecimens a different ſpecies from the original one of Plumier.

3. M. *cruciata*. Croſs-headed Marchantia. Linn. Sp. Pl. 1604. Hudſ. n. 2. (Lichen ſeminifer lunulatus, florifer pileatus, tandem cruciatus; Dill. Muſc. 521. t. 75. f. 5. Lunaria vulgaris; Mich. Gen. 4. t. 4.)—Calyx of the female flowers in four deep, croſs-like, tubular ſegments. Native of ſhady damp places in Italy, France, and England, fructifying in July. The *fronds* are ſmaller than in M. *polymorpha*, and dilated outwards. *Flower-ſtalks* each from a toothed cup on the diſk of the leaf. *Common calyx* of the female flowers at firſt conical, but ſoon becoming deeply divided into four ſpreading, cruciform, tubular ſegments, from whoſe extremities the *capſules* and *ſeeds* are protruded. Dillenius has a remark unworthy of ſo great a philoſopher, that "the flowers are rarely produced, but the ſeeds very frequently." Surely, as no ſeeds can come without flowers, this might have led him to diſcover that what he took for ſeeds were really buds!

4. M. *tenella*. Slender Marchantia. Linn. Sp. Pl. 1604. (Lichen pileatus parvus carinatus, capitulis fimbriatis; Dill. Muſc. 521. t. 75. f. 4.)—Calyx of the female flowers hemiſpherical with a little point; its margin radiated.—Gathered by Gronovius in Virginia. The *frond* of this delicate ſpecies ſpreads circularly, but is not all together much above an inch broad. The *ſtalks* are nearly terminal, very ſlender, above an inch high. *Calyx* very convex, crowned with a minute blunt point, and fringed with numerous ſegments that bear the *capſules*.

5. M. *hemiſphærica*. Hemiſpherical Marchantia. Linn. Sp. Pl. 1604. Hudſ. n. 3. Engl. Bot. t. 503. Schmid. Ic. t. 34. (Lichen pileatus parvus, foliis crenatis; Dill. Muſc. 519. t. 75. f. 2. Hepatica media, capitulo hemiſphærica; Mich. Gen. 3. t. 2. f. 2.)—Calyx of the female flowers hemiſpherical, cloven into about five oval ſegments. Stalks naked at the baſe.—Native of Europe, about the banks of rivers and ditches, or the moiſt crevices of rocks, ſometimes in expoſed ſituations, flowering in the early ſpring. The *fronds* are lobed, forming broad patches; their upper ſurface granulated, of a fine green, often purpliſh at the edges. *Stalks* not above an inch high. *Calyx* convex, rounded, without any terminal point; the margin in five, or more, oval ſegments. *Capſules* and *ſeeds* black. By a ſtrange overſight, a barren ſpecimen of this ſpecies was deſcribed as a new genus by Forſter, under the name of *Aitonia*, ſee his *Genera*, t. 74; and adopted by the younger Linnæus, by that of *Rupinia*; ſee his *Suppl.* 69 and 452.

6. M. *triandra*. Three-celled Marchantia. Scop. Carn. ed. 2. 354. t. 63. Web. Goett. 163. (M. tenella; Thunb. Prod. 175.)—Calyx of the female flowers hemiſpherical, undivided, of three or four cells.—Found by Scopoli in Carniola, by Weber in Hercynia, and by Thunberg at the Cape of Good Hope; for the original ſpecimens of the *tenella* of the laſt-mentioned author prove to be this plant. We have others from Siberia, which appear the ſame, but their condition is not ſufficiently good for us abſolutely to decide. This is a ſmall ſpecies, whoſe *fronds* are at moſt but an inch long. *Stalks* half an inch high, or thereabouts, purpliſh. *Calyx* convex, granulated, without a point; its margin

margin wavy, not cut or lobed. *Cells* three or four, very prominent underneath, furnifhed with long, taper, briftle-like appendages. The fpecific name alludes to the old Linnæan idea, of the female being the male flowers.

7. M. *androgyna*. Monoecious Marchantia. Linn. Sp. Pl. 1605. Dickf. H. Sicc. fafc. 4. 21. Crypt. fafc. 2. 17. With. 886. (Lichen pileatus anguftifolius dichotomus; Dill. Mufc. 520. t. 75. f. 3. Hepatica minor anguftifolia, capitulo hemifphærico; Mich. Gen. 3. t. 2. f. 3.)—Calyx of the female flowers hemifpherical, half four-cleft, of four cells.—Native of Italy, France, Switzerland, and Scotland. This is much larger than the laft. *Fronds* two inches or more in length, various in breadth, fmooth. *Stalks* one and a half or two inches high. *Calyx* very convex, fmooth, its margin in four blunt lobes, beneath which the four *cells* are very prominent. Linnæus miftook his Siberian fpecimen above mentioned, which we judge to be *triandra*, for the true *androgyna*, and therefore erred in his fpecific character of this latter. We conceive Scopoli's M. *quadrata*, Carn. ed. 2. 355. t. 63, to be no other than the real *androgyna*.

8. M. *conica*. Conical Marchantia. Linn. Sp. Pl. 1604. Hudf. n. 4. Engl. Bot. t. 504. Schmid. t. 31. (Lichen vulgaris major, pileatus et verrucofus; Dill. Mufc. 516. t 75. f. 1. Hepatica vulgaris major, vel officinarum Italiæ; Mich. Gen. 3 t. 2. f. 1.)—Calyx of the female flowers ovate, pointed, with five marginal notches. Male flowers in feffile warts.—Common in damp fhady places in Britain and other parts of Europe, but the female fructification is rare. The *fronds* are broad, reticulated, bluntly lobed, highly aromatic and fragrant, giving their perfume to the air, efpecially after rain, like many *Jungermanniæ*. *Stalks* from clefts between the lobes, two inches high, white and tender. *Calyx* conical, with four fmall marginal lobes. *Capfules* and feeds black. On feparate plants from thefe are found hemifpherical feffile warts, fuch as M. *androgyna* appears to bear on the fame plant with the capfules, and which Hedwig believes to be the male flowers. We prefume, however, that what are reprefented on a portion of a frond in *Engl. Bot.* are not thefe, but gemmiparous cups, like thofe of M. *polymorpha*, by which the plant is ufually propagated. S.

MARCHAUX, in *Geography*, a town of France, in the department of the Doubs, and chief place of a canton, in the diftrict of Befançon. The place contains 382, and the canton 8894 inhabitants, on a territory of 220 kiliometres, in 38 communes.

MARCHE, Oliver de la, in *Biography*, fon of a gentleman of Burgundy, entered, in early life, into the fervice of Philip the Good, duke of Burgundy, by whom he was highly valued. After this Charles the Bold raifed him to the pofts of mafter of the houfehold and captain of his guards, and knighted him at the battle of Montlheri, in 1465. He was with that prince at the fatal battle of Nancy, and was made prifoner. We find him next, firft mafter of the houfehold to Maximilian of Auftria, and afterwards to his fon the archduke Philip, by whom he was fent on an embaffy to the court of France after the death of Lewis XI. He died at Bruffels in 1501, leaving behind him "Memoirs or Chronicles," relating to the two dukes of Burgundy: thefe were publifhed at Lyons in 1562, and again at Bruffels in 1616 He alfo wrote "Le Parement et le Triomphe des Dames d'Honneur:" "Traitè fur les Duels et Gages de Battaille," and other pieces. Moreri.

Marche, *La*, in *Geography*, was before the Revolution a province of France, bounded on the N. by Berri, on the E. by Auvergne, on the S. by Limofin, and on the W. by Poitou; lying between 45° 45′ and 46° 35′ N. lat., and between 0° 45′ and 2° 31′ E. long.; being from N. to S. 10 leagues, and 20 from W. to E. Its rivers are the Torion, the Great Creufe, the Gartempe, and the Vienne. This province was formerly under the dominion of the Romans, Vifigoths, and Franks. Under the laft of thefe powers it was governed by counts, and was confifcated by Philip the Handfome. Francis I. annexed it to the crown A.D. 1531. Some tracts of this province are tolerably fertile, yielding grain and fruits, and others are covered with excellent pafturage. The foil is compofed of fandy and friable loams, fome on granite, and others on a calcareous bottom. The chief towns in Upper Marche, on the eaftern divifion, are Gueret, Ahun, Aigurande, Aubuffon, Felletin, Bourganeuf, Grandemont, and Benevent; and thofe in Lower Marche are Bellac and Dorat. This province now principally conftitutes the department of the Creufe, and part of that of Vienne.

Marche, a town of France, and principal place of a diftrict, in the department of the Sambre and Meufe, fituated on the Marfette, in the road from Paris to Liege. The place cantains 1257, and the canton 6382 inhabitants, on a territory of 250 kiliometres, in 25 communes. The parifh-church is a handfome ftructure; 20 miles S.E. of Namur.

Marche, *La*, a town of France, in the department of the Vofges, and chief place of a canton, in the diftrict of Neufchateau, fituated near the fource of the Mouzon; 27 miles W.N.W. of Luxeuil. The place contains 1554, and the canton 13,928 inhabitants, on a territory of 335 kiliometres, in 26 communes. N. lat. 48° 4′. E. long. 5° 22′.

Marche, *La*, a fmall territory of Switzerland, in the canton of Schweitz, fituated S. of the lake of Zurich.

MARCHECK, or Marek, a town of Auftria, on the Marfch; 14 miles N.W. of Prefburg. N. lat. 48° 15′. E. long. 16° 56′.

MARCHENA, a town of Spain, in the province of Seville, fituated on a hill, having in its fuburbs the only well in the town or neighbourhood; feven miles S. of Carmona. It was anciently called "Colonia Marcia."

MARCHENOIR, a town of France, in the department of the Loir and Cher, and chief place of a canton, in the diftrict of Blois; 15 miles N. of Blois. The place contains 421, and the canton 8340 inhabitants, on a territory of 260 kiliometres, in 18 communes.

MARCHERS, or *Lords* Marchers, in our *Old Writers*, noblemen that lived on the marches of Wales, or Scotland. Thefe, in times paft, according to Camden, had their laws, and power of life and death, &c. like petty kings. But fuch powers were abolifhed by the ftat. 27 Hen. VIII. cap. 27, and 1 Edw. VI. cap. 10.

MARCHES, Marchia, from the German, *march*, *i.e. limes*, or from the French *marque*, *viz. fignum*, being the notorious diftinction between two territories, are the limits between England and Wales, or Scotland; which laft are divided into weft and middle marches. (4 Hen. V. cap. 7. 22 Edw. IV. cap. 8. 24 Hen. VIII. cap. 9.) And there was formerly a court, called the court of the marches of Wales, where pleas of debt or damages, not above the value of 50*l.* were tried and determined; and if the council of the marches held plea for debts above that fum, &c. a prohibition might be awarded.

Marches, *Les*, in *Geography*, a town of France, in the department of Mont Blanc; four miles W. of Montmelian.

MARCHESI, Luigi, in *Biography*, one of the greateft vocal performers which Italy has produced on the opera ftage fince the firft eftablifhment of the mufical drama, arrived

rived in England in April, 1788. This finger, whofe talents have been the fubject of praife and admiration in every great theatre of Europe, where mufical dramas are performed in the Italian language, firft appeared at Rome in 1774, in a female character, the ufual introduction of a young and promifing finger, with a foprano voice and beautiful perfon. In 1775, he performed the fecond man's part at Milan with Pacchierotti, and at Venice with Millico; but the fame year he was advanced to the principal character at Trevifo. In 1776 and 1777, he fung as firft man at Munich and Padua; and in 1778, he had worked his way to the great theatre of San Carlo at Naples, which is the criterion and poft of honour of an opera finger. He continued here two feafons, and has fince performed with increafing celebrity at Pifa, Genoa, Florence, Milan, Rome, Peterfburg, Vienna, and Turin.

The "Giulio Sabino" of Sarti, was the firft opera in which Marchefi performed on our ftage. The elegant and beautiful mufic of this drama did not pleafe fo much here as it ought, and had done in other parts of Europe. Several of the fongs, indeed, had been previoufly fung here at concerts, and did not appear new. Marchefi's ftyle of finging is not only elegant and refined to an uncommon degree, but often grand and full of dignity, particularly in his recitatives and occafional low notes. His variety of embellifhments and facility of running extempore divifions are truly marvellous. Many of his graces are new, elegant, and of his own invention; and he muft have ftudied with intenfe application to enable himfelf to execute the divifions, and running fhakes from the bottom of his compafs to the top, even in a rapid feries of half notes. But befides his vocal powers, his performance on the ftage is extremely embellifhed by the beauty of his perfon, and grace and propriety of his geftures. We expected a great finger, but that does not always include a fine actor.

As Marchefi was the laft of three great fingers who appeared on our ftage at the latter end of the eighteenth century, and as each had his exclufive admirers, it would be difficult to draw a ftudied parallel between them to the fatisfaction of all parties; comparative praifes, as well as cenfure, would be thought invidious. But as we have received great pleafure from the talents of each of thefe exquifite performers, and never expect to find abilities exactly fimilar in different fingers, we are always thankful for the good we find, and endeavour to hear the reft with candour.

In difcriminating the feveral excellencies of thefe great performers, we fhould without hefitation fay, that Pacchierotti's voice was naturally fweet and touching; that he had a fine fhake, an exquifite tafte, great fancy, and a divine expreffion in pathetic fongs. That Rubinelli's voice was full, majeftic, and fteady; and befides the accuracy of his intonations, that he was parfimonious and judicious in his graces. And that Marchefi's voice was elegant and flexible; that he was grand in recitative, and unbounded in fancy and embellifhments.

All feem to have ftudied their art with great diligence during youth, and to read mufic as eafily as their native language.

As actors: Pacchierotti feemed in earneft on the ftage, and confequently interefted the fpectator. Rubinelli had great dignity in his deportment, though he difcovered but little fenfibility by his geftures or tone of voice. Marchefi, with an elegant figure and pleafing countenance, is at once graceful and intelligent in his demeanour and action.

Marchefi has continued to fupport his character of a great and refined finger, ever fince he quitted England fifteen years ago, and we believe ftill continues to exercife his talents on the ftage.

When the French firft invaded the Milanefe, during the revolution, report fays that he was treated by the military with favage indignity, for declining to obey a peremptory order to fing to the Gallic general's lady; to which he felt a repugnance from gratitude to the Auftrian government, under which he had frequently refided, and been not only honourably but kindly treated. On his not inftantly obeying the ungracious order that was fent him, he was feized by a party of foldiers, who, to deface his perfonal charms, deprived him of one eye-brow, and of half his fine head of hair.

MARCHESINA, in *Geography*, a town of Italy, in the department of the Montagna; 10 miles S.W. of Lecco.

MARCHESVAN, in *Chronology*, the eighth month of the Jewifh ecclefiaftical year, anfwering to part of our October and November.

MARCHET, or MARCHETTA, a pecuniary fine, anciently paid by the tenant to his lord, for the marriage of one of the tenant's daughters.

This cuftom obtained, with fome difference, throughout all England and Wales, as alfo in Scotland; and it ftill continues to obtain in fome places. According to the cuftom of the manor of Dinover in Carmarthenfhire, every tenant, at the marriage of his daughter, pays ten fhillings to the lord, which, in the Britifh language, is called *gwahr-merched*, i. e. *maid's-fee*. See AMABYR.

In Scotland and the north parts of England, the cuftom was, for the lord to lie the firft night with the bride of his tenant; but this ufage was abrogated by king Malcolm III. at the inftance of his queen; and, inftead thereof, a mark was paid by the bridegroom to the lord: whence it is called *marcheta mulieris*. See BOROUGH-*Englifh*.

MARCHETTI, LA, in *Biography*, a finger from Bologna, engaged for the Pantheon in 1774. She had a powerful, brilliant, and fweet-toned voice, with which fhe might have become a finger of the firft clafs, if want of health had not prevented her from that perfevering practice, which is fo neceffary to the vanquifhing of vocal difficulties. Befides finging at the Pantheon during her refidence in England, fhe performed the fecond woman's part in Sacchini's operas of "Nitteti" and "Perfeo."

MARCHETTI, PETER DE, a phyfician, was profeffor of anatomy at Padua, his native place, where he continued to teach that art from 1652 until 1669, when he was allowed to refign his chair to his fon Anthony. In the year 1661, he alfo obtained the appointment to the firft profefforfhip of furgery, the duties of which he fulfilled at the fame time with thofe of his anatomical chair. His merits in thefe departments of the profeffion obtained for him the honour of knighthood of the order of St. Mark. At the age of 80 years, he retired altogether from the univerfity; and, after having enjoyed a fhort period of repofe, he died in April 1673. He left the following works: "Anatomia," in 4to. Venice, 1654. "Sylloge Obfervationum Medico-chirurgicarum rariorum," Padua 1664, which was afterwards feveral times reprinted, and was tranflated into German. It contained fifty-three cafes of fome intereft, and three tracts on ulcers, on fiftulæ of the urethra, and on fpina ventofa.

His two fons, DOMINIC and ANTHONY DE MARCHETTI, were likewife both profeffors in their native univerfity of Padua. The former was author of a good compendium of anatomy, according to the judgment of Haller, which

paffed

paſſed through ſeveral editions, under the title of "Anatomia, cui Reſponſiones ad Riolanum, Anatomicum Pariſienſem, in ipſius animadverſionibus contra Veſlingium, additæ ſunt," Padua 1652, &c. Eloy Dict. Hiſt. de Med.

Marchetti, Alexander, a poet and mathematician, was born at Pontormo, in the Florentine territory, in the year 1632. Being deprived at a very early period of his father, he was intended for a mercantile life; but it being ſoon diſcovered that he had decidedly a literary turn, he was placed with a profeſſor of the civil law. This proved as little adapted to his taſte as trade; and he was ſent by the kindneſs of Leopold, cardinal de Medici, to the univerſity at Piſa, where he purſued his favourite ſtudies in belles lettres, in conjunction with philoſophy and mathematics, in the latter of which he enjoyed the particular inſtructions of Borelli. He took a doctor's degree in 1659, and became profeſſor of logic in that univerſity, and alſo taught the elements of geometry to a private claſs under Borelli. In 1669 he publiſhed a mathematical work, entitled "Reſiſtentia Solidorum;" and in a ſhort time after, another with the more general title, "Exercitationes Mechanicæ." By the former he gained a high reputation; but the latter did not at all anſwer the expectations which he had raiſed by the other. About the ſame period he accompliſhed his tranſlation of Lucretius, "De Rerum Natura," into Italian blank verſe, which has contributed more to eſtabliſh his fame than all his other pieces. It has been ſaid that it ſurpaſſes almoſt every other claſſical verſion in modern language, in dignity, elegance, and clearneſs. Marchetti was deſirous of dedicating this performance to Coſmo III., great duke of Tuſcany; but the piety of that prince was ſo much ſhocked by the impious doctrines of the Epicurean philoſophy, that he not only refuſed the dedication, but prohibited the publication of the work in his dominions; and it was not printed till after the author's death, by Paul Rolli, in the year 1717. It has ſince been frequently reprinted, and is allowed a place among ſtandard works of the kind. He died in the year 1714, in his eighty-third year. In his youth he had tranſlated the firſt five books of the Æneid, and likewiſe the odes of Anacreon. He had alſo compoſed ſeveral original poems, eſpecially of the lyric kind, which were reckoned to poſſeſs great merit. Theſe and other pieces have been printed in collections of Italian poetry. Marchetti had a very high opinion of his own talents as a mathematician and philoſopher; but he was, at the ſame time, mild and eaſy, and ready to do good offices to any perſons. He had been in habits of correſpondence with many literary characters of diſtinguiſhed eminence.

MARCHETTO da Padova, an intelligent writer on muſic in the thirteenth century, of whoſe works we found two inedited MSS., preſerved in the Vatican library, N° 5322. The firſt is entitled "Lucidarium Artis Muſicæ planæ," beginning, "Cum inquit," &c.; and the ſecond, "Pomerium Artis Muſicæ Menſurabilis: quatuor ſunt Cauſæ," &c. The Lucidarium is frequently mentioned by Franchinus, Pietro Aaron, and other old muſical writers of Italy.

There was a copy of this laſt-mentioned tract in the Ambroſian library at Milan, in 1770, D. 5, in folio, where it is ſaid to have been begun at Ceſena, and finiſhed at Verona, 1274: "Lucidarium in Arte Muſicæ planæ, inchoatum Ceſena, perfectumque Veronæ," 1274. The copy of his works in the Vatican was dedicated to Charles, king of Sicily, about the year 1283: "Marchettus Paduanus qui ſuum opus Karolo Regi Siciliæ dedicavit circa annum 1283."

We obtained large extracts from this MS., as it contained the moſt early mention that we had met with of the *dieſis*, or accidental *ſharp*, of *chromatic counterpoint*, *diſcords*, and the proportions of ſuch concords and diſcords as are uſed by the moderns in practical harmony.

His examples of counterpoint, in the MS. whence our extracts were made, like thoſe of Franco, are written upon only one ſtaff of four, five, ſix, or more lines, according to the diſtance of the intervals, with two clefs, one for the baſe, and one for the tenor or upper part, with this peculiarity of notation, that the notes of the upper part are written in *red* ink, and the lower in *black*.

This MS. contains many curious attempts at infant harmony. Marchetto is the firſt who ſpeaks of diſcords and their reſolution; and lays it down as a rule, that no two ſevenths, or fourths, uſed as diſcords, ſhould ſucceed each other; and that after a diſcord, the part which has offended the ear ſhould make it amends by becoming a concord, while the other ſtands ſtill: indeed he never mentions the preparation of diſcords.

Marchetto Cara, an Italian ſinger, mentioned with Bidon, another contemporary vocal performer, with great eloge, by Caſtiglione, in his "Cortegiano," written about the beginning of the ſixteenth century. What kind of ſecular muſic the Italians cultivated, before the general uſe of counterpoint was eſtabliſhed, we know not; but we find in the Lives of their firſt Painters, that many of them had been brought up to muſic, as a profeſſion. Leonardo da Vinci was a great performer on ſeveral inſtruments, and invented a new ſpecies of lyre, in the ſhape of a horſe's ſkull. (Da Teſchio di Cavallo. Vaſari, Vite di Pitt.) Italy had likewiſe, at this time, ſingers with great talents for execution and expreſſion; for Caſtiglione, ſpeaking of the variety and power of contraſt in the arts, obſerves, that "inſtances of diſſimilar things producing ſimilar effects that are equally pleaſing and meritorious may be given in them all; particularly muſic, in which the movement is ſometimes grave and majeſtic, and ſometimes gay and animated, yet equally delightful to the hearer. Thus, in ſinging, what can be more different than the performance of Bidon and Marchetto Cara? The one artificial, rapid, nervous, vehement, and impaſſioned, elevates and inflames the ſoul of every hearer; while the other, more gentle, pathetic, and inſinuating, ſooths, calms, and affects by a ſorrowful and tender ſweetneſs, which penetrates the heart, and affords it the moſt exquiſite pleaſure of a different kind." This deſcription the late Mr. Galliard (Tranſlation of Toſi, p. 170.) has thought applicable to the different powers of the two great female ſingers, Fauſtina and Cuzzoni, the ſuperiority of whoſe abilities was ſo diſputable when they performed on the ſame ſtage in England, 1727, that the patrons and friends of the one became inveterate enemies to thoſe of the other.

Great natural powers will ſometimes aſtoniſh and charm without much aſſiſtance from art; and ſo late as the year 1547, Pietro Aaron (Lucidario in Muſica, fol. 31.) gives a liſt of ſuch extraordinary performers as were able to *ſing by book*, *cantori a libro*; by which we may ſuppoſe that the art was new and uncommon. And according to Tartini, (Trattato di Muſica, p. 17.) "The old Italian ſongs being only made for a ſingle voice, were ſimple in the higheſt degree; partaking of the nature of *recitative*, but *largo*:" (as the gondoliers at Venice ſtill ſing the ſtanzas of Taſſo.) "None were confined to regular bars; and the key was determined by the kind and compaſs of voice that was to ſing them."

However, during the ſixteenth century, when the works of of Paleſtrina appeared, the Italians may with juſtice be ſaid to have given inſtructions to the reſt of Europe in counterpoint, as, ever ſince operas were eſtabliſhed, they have done in ſinging.

MARCHI, Francis, a famous military engineer, who flouriſhed in the ſixteenth century, was a native of Bologna. He is chiefly known by a book, entitled "Della Architectura Militaire," which was publiſhed in 1599, in folio. This, which contains 161 figures, is an extremely ſcarce book; a circumſtance that has been attributed, by ſome Italian writers, to the ſuppreſſion of moſt of its copies by certain French engineers, who paſſed off his inventions for their own. It was probably a work of vaſt labour, as it was begun in the year 1546, and was not compleated till after the death of the author. It is ſaid to contain the germ of ſeveral contrivances, which have ſince been adopted. The Italian writers maintain, that in it is to be found the origin of Vauban's method of fortification; but the French admit only a trifling reſemblance between the two authors. Gen. Biog.

MARCHIENNES, in *Geography*, a town of France, in the department of the North, and chief place of a canton, in the diſtrict of Douay; 7 miles E.N.E. of Douay. The place contains 2309, and the canton 13,493 inhabitants, on a territory of $112\frac{1}{2}$ kiliometres, in 16 communes.

MARCHING, in *Military Language*. See March and Battalion.

Marching *Regiments*, a denomination given to thoſe corps who had not any permanent quarters, but were liable to be ſent not only from one extremity of Great Britain to another, but to the moſt diſtant of her poſſeſſions abroad. Although the term "marching" is inſenſibly confounded with thoſe of "line" and "regulars," it was originally meant to convey the notion of ſomething more than a mere liability to be ordered upon any ſervice; for by marching the regular troops from one town to another, the inhabitants, who from time immemorial have been jealous of a ſtanding army, loſt their antipathy to *real* ſoldiers by the occaſional abſence of regular troops. At preſent, the guards, militia, and fencibles, may be conſidered more or leſs as marching regiments. The marines and volunteer corps have ſtationary quarters.

MARCHIONIS Pulvis, in the *Materia Medica*, a term uſed for a certain compound powder, preſcribed in the Leyden Diſpenſatory, and greatly recommended by many as an anti-epileptic and abſorbent.

The ingredients are, male piony-root, half an ounce, wood of miſletoe of the oak, raſpings of ivory, elks' hoof, ſpodium, the tooth of the unicorn-fiſh, or, in its ſtead, the antlers of the ſtag's horn, red and white coral, and pearls, of each a dram. Theſe are all to be rubbed into a powder, with twenty leaves of pure gold, and given half a dram twice a day.

MARCIAC, in *Geography*, a town of France, in the department of the Gers, and chief place of a canton, in the diſtrict of Mirande; 10 miles W. of Mirande. The place contains 1479, and the canton 8008 inhabitants, on a territory of $177\frac{1}{2}$ kiliometres, in 22 communes. N. lat. 43° 31'. E. long. 0° 14'.

MARCIANA, a town of Etruria; 30 miles E. of Florence.

MARCIANISI, a town of Naples, in Lavora; 10 miles N. of Naples.

MARCIANUS, in *Biography*, emperor of the Eaſt, was born of obſcure parents about the year 391. His father ſerved in the Roman army, into which he himſelf entered as a private ſoldier. Owing to ſickneſs, he quitted the ſtation in 421; and upon the return of his health, he repaired to Conſtantinople, and enrolled himſelf among the troops commanded by Ardaburius, and his ſon Aſpar. By his talents and good conduct he was raiſed to the poſt of ſecretary, in which quality he attended Aſpar into Africa in 431. He was there taken priſoner by Genſeric, who agreed, after a time, to liberate him upon a promiſe never more to ſerve againſt the Vandals. He ſoon attained the rank of tribune and ſenator; and on the death of Theodoſius the younger, in 450, he was aſſociated in the empire with Pulcheria. Attila was, at this time, threatening both empires. He had already ſent an inſolent meſſage to the court of Conſtantinople, demanding the annual tribute which had been extorted from the weakneſs of Theodoſius. The newly crowned emperor was not to be ſo treated: he boldly replied, "that he had gold for his friends, but had prepared ſteel for his enemies." This determined ſpirit was probably the reaſon that Attila turned his arms againſt the weſtern empire, rather than the eaſtern. By the death of Pulcheria, he became ſole poſſeſſor of the throne. He executed with the moſt pious fidelity her laſt wiſhes, by which ſhe left a vaſt property to the church and the poor. After the death of Attila, ſeveral tribes of barbarians deſerted the banners of his ſons, and obtained permiſſion from Marcianus to ſettle in Thrace and Illyrium; which countries had been almoſt depopulated by the incurſions of the Huns. He died, much regretted, in the year 457, after a reign of about ſix years and a half. His piety and zeal in defence of orthodoxy were highly applauded by eccleſiaſtical writers: his rigorous edicts againſt heretics, and his kindneſs in recalling thoſe who had been exiled on account of tenets which he eſpouſed, gave him a high rank, and the title of ſaint in the Greek church; and he is entitled to general praiſe for his having beſtowed his promotions only on perſons of known abilities and unblemiſhed character, whence the departments of the ſtate were at all times filled with credit. Univer. Hiſt. Gibbon.

MARCIGLIANO, in *Geography*, a town of Naples, in Lavora; 9 miles N.E. of Naples.

MARCIGNY, a town of France, in the department of the Saone and Loire, and chief place of a canton, in the diſtrict of Charolles; 12 miles S.W. of Charolles. The place contains 2414, and the canton 10,403 inhabitants, on a territory of 200 kiliometres, in 12 communes. N. lat. 46° 17'. E. long. 4° 7'.

MARCILLOT, a town of France, in the department of the Allier, and chief place of a canton, in the diſtrict of Montluçon. The place contains 1414, and the canton 10,002 inhabitants, on a territory of 255 kiliometres, in 16 communes.

MARCILLY a la Hayer, a town of France, in the department of the Aube, and chief place of a canton, in the diſtrict of Nogent-ſur-Seine. The place contains 488, and the canton 6049 inhabitants, on a territory of 400 kiliometres, in 24 communes.

MARCIONITES, or Marcionists, *Marcioniſtæ*, in *Eccleſiaſtical Hiſtory*, a very ancient popular ſect of heretics, who, in the time of St. Epiphanius, were ſpread over Italy, Egypt, Paleſtine, Syria, Arabia, Perſia, and other countries: they were thus denominated from their author Marcion.

Marcion was of Pontus, the ſon of a biſhop, and at firſt made profeſſion of the monaſtic life; but he was excommunicated by his own father, who would never admit him again into the communion of the church, not even on his repentance. The cauſe of his father's diſpleaſure is ſaid by Epiphanius to have been a criminal connection with a young woman;

woman; but Beaufobre and Lardner have alleged a variety of reafons that render this ftory incredible, and that lead them to fuppofe that it was a fabrication of Epiphanius. Beaufobre fuppofes that the crime of this herefiarch, for which his father expelled him from the church, was his errors, which he had began to publifh in his own country. On this excommunication, he abandoned his native land, and retired to Rome, where he became acquainted with Cerdon, and, as fome have faid, became his difciple; and adopting his opinions, zealoufly propagated them.

Cave fuppofes that he came to Rome in the year 127; and that about the year 130 he became a follower of Cerdon, and an open heretic. According to Pagi, Marcion came to Rome after the death of Hyginus, which, he thinks, cannot be deferred beyond the year 141. But he had before broached his opinions in Syria, probably in the reign of Adrian, or at leaft in the beginning of the reign of Antoninus the Pious. When he came to Rome, the fee was vacant by the death of Hyginus; but as the prefbyters did not receive him, he returned to Afia, and fpread his tenets with lefs difguife and greater zeal, about the year 144, where Tertullian and alfo Petavius place him. As Juftin Martyr wrote againft Marcion, and his "Apology" was written in the time of the elder Antoninus, in the year 140, or not long after, it is reafonable to think, fays Dr. Lardner, that Marcion had appeared in the year 130, or very foon after; for Marcion had many followers when Juftin wrote that Apology: and when he fays that Marcion was ftill living, it is implied that he had made a figure for fome time.
