MACHINERY.

MACHINERY *for manufacturing Ships' Blocks*, in the royal dock-yard at Portfmouth. Thefe machines are the invention of Mark Ifamberd Brunel, efq.: they are the moft ingenious and complete fyftem of machinery for forming articles in wood, of any this kingdom can produce, being not lefs creditable to the country as an exhibition of mechanical talent, than advantageous to the government in the economical fupply of an article of fuch immenfe demand for the navy. The great celebrity thefe machines have obtained, and the valuable information their publication will convey to mechanics, has induced us to devote feven of our plates to their explanation, and will apologize for our entering into fo long an account of the manufacture of an article fo trifling as a fhip's block; though even this fhould not be defpifed, when its importance in naval affairs is confidered, and how often the fafety of a veffel may be endangered by the failure of a fingle block, regulating any important action in a fhip's working. It is of great confequence that thefe, in common with every other part of a fhip's rigging, fhould be made in a moft accurate and fubftantial manner.

The block machines are particularly worthy of notice, as performing moft of the practical operations of carpentry with the utmoft accuracy and difpatch, and will be found applicable to many other purpofes befides the fabrication of fhips' blocks. Indeed, in the dock-yard all the fmall wooden articles required in the navy can, in fome part or other, be executed by the machinery in the *wood mill*, as the building containing them is very properly called, and the largeft timber is converted and fawn up into any fcantling, by feveral curious circular and reciprocating faws adapted to various purpofes. The fucceeding operations, performed by the fmaller machines, are boring, mortifing, many very ingenious applications of turning for a variety of purpofes, both in wood and iron, rivetting, drilling, broaching, burnifhing iron pins, &c. as we fhall defcribe at length. The different kinds of blocks ufed in the rigging of a fhip are defcribed in our article BLOCK, and alfo the manner of conftructing them by the old method which was then in practice, the machines in queftion having been erected fince the printing of that article, or, at leaft, brought into ufe, or we fhould have defcribed them in their proper place; but even here they are by no means mifplaced, being the beft examples of practical machinery, of any we could felect from the numerous manufactures our country contains, being adapted to perform operations which are generally underftood, but which have hitherto been executed by manual labour and dexterity only.

The blocks for the royal navy were for many years previous to 1807, when the machines were fet to work, fupplied, on contract, by Mr. Taylor, of Southampton, who employed a large mill, containing powerful fawing machines, for converting the timber into the proper fcantling for the blocks, but left them to be formed by manual labour, as related in our article BLOCK: the mill alfo gave motion to lathes of the common conftruction for making the fheaves. Except what was done at this manufactory, and fome few curious machines devifed by general Bentham, the credit of bringing the block manufacture to its prefent perfection is due to Mr. Brunel, who has difplayed as much judgment in the divifion of the operations by the feveral machines, as ingenuity in the contrivance of their parts, which are admirably well calculated to produce their intended effects. The greateft attention has been every where paid to that form of conftruction which would admit of the moft perfect workmanfhip in the execution; in this, the ideas of the ingenious inventor have been ably feconded

Strahan and Prefton.

by Mr. Henry Maudflay, of Weftminfter-road, London, who made thefe machines with the moft fcrupulous attention to accuracy and durability, at the fame time preferving an elegant proportion in their form, which is very agreeable to the eye. The framing of all thefe machines is made of caft iron, and many of thofe parts which are expofed to violent and rapid motion are made of hardened fteel to avoid wearing: and where this is impracticable, fuch parts are formed fo that they can be readily renewed when worn out. A better proof of their durability cannot be defired, than the circumftance, that the machines have been now finifhed four years, and have been in continual work during that period, fome of them being fubject to very violent and rapid action; yet, among forty-three of them, nothing has happened to require any repairs of fufficient confequence to engage the affiftance of the maker or inventor; the trifling repairs of the cutting tools, &c. being made by the workmen on the fpot, and of all fuch parts they have duplicates provided, by which any failure can be reftored in a few minutes. Thefe circumftances we particularly recommend to the attention of manufacturers who have occafion to employ extenfive fets of machinery; for this, when well conftructed, though expenfive in the erection, is cheaper in the end than imperfect works, which require conftant repair, the expence of which is the leaft evil; as it generally happens that a machine will fail at that time when it is moft wanted, in confequence of being then moft worked; and the lofs occafioned by the ftoppage of great works, particularly where many people are employed, is too evident to require our notice. In the fame manner, an attention to neatnefs, in the appearance of machinery, has its advantages, by inducing the workmen to be careful of the machines they work at, to preferve them from the flighteft injury, and to keep them clean from duft, which, trifling as it may appear, is a very effential point in the prefervation of thofe parts which are in rapid motion with friction againft other parts, for duft getting between fuch furfaces grinds them away very faft, and in their moft effential points.

Workmen and people employed about machines have no intereft in their prefervation, farther than to avoid fuch figns of violence and careleffnefs as may be immediately detected by their fuperiors; but by introducing an emulation among them, of having the neateft machines in the factory, and of keeping them in the beft order, they may be induced to take as much care of them as if they were their own property. This fact is well known to fome of the largeft proprietors of cotton and woollen mills, though as much neglected by others. The machines contained in the *wood mill* at Portfmouth may be feparated into four claffes. 1. The fawing machine for converting the large timber into proper dimenfions for the fmall machines to operate upon, confifting of the large machines for fawing up the elm trees from which the fhells of the blocks are to be made, and the fmaller fawing machines for cutting up the lignum vitæ for the fheaves. 2. Thofe machines which are employed in forming the fheaves. 3. Thofe which form the iron pins for the blocks. And, 4. Thofe by which the fhells of the blocks are manufactured. They are all fituated in one large mill, which confifts of two very tall buildings, or wings, having a fmaller and lower one between them, lighted by fky-lights in its roof. The lower part of one of the wings is appropriated to the two fteam engines, which actuate the whole, as alfo fome immenfe chain pumps, which are occafionally employed in draining the dry docks. The mill has two engines of thirty horfe power, one erected by Meffrs. Boulton and Watt, and the other by Meffrs. Murray and Wood of Leeds. Either of thefe can be applied indifferently to work the chain pumps, or for turning the wood mill, and their power is tranfmitted by a train of wheel-work to an horizontal fhaft, extending along the centre of the middle building, very near its roof, and upon this are a number of wheels and drums, which, by endlefs ropes and ftraps, communicate motion to the various machines for making the block fhells, which are fituated on the ground, in the central building. They are feventeen in number: fourteen of this number conftitute three complete fets for making blocks of different fizes following each other, from four inches in length to eighteen; the length in inches being the denomination of the fize of fhips' blocks. There is alfo a large machine for boring parts of thofe very large blocks which are called made blocks, and cannot wholly be made by the machines; it alfo cuts fhot racks by tools for the purpofe: and here are two machines for turning *dead eyes*, which are blocks without fheaves, for attaching the fhip's fhrouds to her fides.

The ground-floor of the wing oppofite to that containing the fteam engines, is appropriated to feven large fawing machines for cutting up the trees; and the floor over it contains three fawing machines for cutting up the trees of lignum vitæ: alfo, the fmall machines for making the fheaves, which are thirteen in number, and a fmall room, containing five machines, where the iron pins are turned and polifhed. In the upper parts of both wings of the mill are warehoufes for containing the immenfe ftock of finifhed blocks, which are always kept in ftore for armaments, and feveral workfhops with common lathes, worked by the mill, for making and finifhing various fmall articles of a fhip's furniture. Many of them are, in part, made by fome of the block machines, in addition to all thofe kinds of blocks which we have explained under Block. Some of thefe articles are *dowels*, for uniting fhips' timber; *treenails*, *marling fpikes*, *ferving mallets*, *pump buckets*, and many other trifles which it is unneceffary to particularize. At the top of one building is a large water ciftern, kept always full by a pump belonging to the engine, and provided with pipes which conduct the water to every part of the works, and are in every room furnifhed with fcrew caps, at any of which an engine hofe can be fcrewed on in the event of a fire, which is fomewhat to be dreaded when they work by lamps in the winter time, as the great quantity of chips and faw duft, always lying about in every part of the mill, might be fet on fire. To avoid this danger as much as poffible, the lamps are included in glaffes of a fimilar figure to a long cafk, with a cap on the top, which has holes to allow the fmoke to pafs out, but fo contrived, that it is impoffible a fpark fhould efcape. Upon the roof-leads at the top of all, are racks for fetting up the very large blocks to feafon by gradual expofure to the weather, or they would, if all at once fubjected to the fun or rain, crack and fplit in all directions, fo as to fall to pieces.

We fhall commence our defcription of this ingenious mill by an enumeration of the feveral proceffes the blocks and their fheaves are fubjected to, beginning with the rough elm and lignum vitæ trees, and tracing them through their various ftages to the finifhed blocks with their fheaves, and, in like manner, the pins for them.

The elm trees are firft cut into fhort lengths, proper to form the various fizes of blocks, by two large fawing machines, one a *reciprocating*, and the other a *circular faw*. Thefe lengths of the trees are next cut into fquares, and ripped or fplit up into proper fizes by four *fawing benches*, with

with circular ſaws, and one very large *reciprocating ſaw*, which is uſed for cutting up the pieces for very large blocks. Theſe are the ſeven machines in the wing.

The ſcantlings, thus prepared for the blocks, are perforated in the three *boring machines*, with a hole through each, to contain the centre pin for the ſheaves of the block, and as many other holes in a perpendicular direction to the former, as the number of ſheaves it is to have, theſe holes being intended as the commencement of the ſeveral mortiſes to contain the ſheaves.

The blocks are now mortiſed in the three *mortiſing engines*, which elongate the holes above-mentioned to their proper dimenſions.

The angles of the blocks are now cut off by three *circular ſaws*, preparatory to reducing them to the elliptical figure they are to have.

The outſide ſurfaces of the blocks are next formed to their true figure by the three *ſhaping engines*, each of which forms every part of ten blocks together.

The ſcores, or grooves, are next formed round the block, to receive the rope or ſtrap by which they are ſuſpended; this is done by the two *ſcoring engines*.

The blocks are now trimmed by hand labour, to ſmooth and poliſh them.

For making the ſheaves, the firſt proceſs is cutting pieces or flakes off the end of the trees of lignum vitæ, of a proper thickneſs to form the ſheaves: this is performed by three *converting machines*, one a reciprocating ſaw, and the other two circular ſaws.

Theſe flakes are made circular, and the centres pierced in two *rounding* and *centering* machines, or trepan ſaws.

A hole is now excavated in the centre of each ſheave, to inlay the coak or piece of bell metal which is fitted into the centre of each ſheave, to form a ſocket for the centre pin.

The coaks, being put into their places, are rivetted faſt by the two rivetting hammers.

In ſome kinds of ſheaves, three ſmall holes are drilled through each ſheave, and alſo paſſing through the coak, by the *drilling machine*; and ſhort wire pins, cut by the *cutting ſheers*, are put through theſe holes; then they are rivetted down at the ſame time with the reſt of the coaks by the rivetting hammer. This method is not always adopted, the coaks being found to be firm enough without theſe pins or rivets.

The centre holes through the coaks are next broached out to a true cylinder in the three *broaching engines*.

The laſt proceſs is turning the faces and edges of the ſheaves to a flat ſurface, in the three *facing lathes*, which alſo form the groove round the edges of them, for the rope which encompaſſes them when in the block. This completes the machines for making the ſheaves. The iron pins are forged by two ſmiths, in the uſual manner of ſuch articles, between two ſwages or tools, each having a ſemicylindrical cavity formed in it, ſo that the two, when put together, form a cylinder. The heated iron being laid in one of theſe, the other is put over it, and beat with a hammer, by which means it forms the pin to a cylinder. The end of the pin is left ſquare for a very ſhort length. They are in this ſtate turned ſmooth and true in the *pin turning lathe*, and afterwards poliſhed and made perfect on the ſurface in the *poliſhing machine*.

Such blocks as are from four to ſeven inches in length, are generally fitted with wooden pins, which are turned in a ſimple lathe called a *whiſtet*.

There are alſo two machines for making *dead eyes*, and a large apparatus or boring machine for making the largeſt ſizes of blocks, of that denomination called *made blocks*, ſome of which are as much as four feet in length, and with four ſheaves. They are of courſe made up of planks, and this machine is uſed for boring the holes of the numerous bolts which are uſed to unite theſe parts: it is alſo uſed occaſionally to cut out ſhot racks. The whole of this liſt contains 43 machines.

We ſhall now proceed to a deſcription of the ſeveral machines, beginning with the large ſawing machines for elm trees, contained in the ground-floor of one of the wings of the mill. In the centre of this room is a vertical ſhaft turned by the machinery, having a capſtan on the lower end of it, round which a rope is paſſed, to draw any log of timber into the mill from the yard, where the ſtore of elm is kept. The trees are by this means conducted to the firſt machine, which cuts them off acroſs into proper lengths, to form ſuch blocks as the tree ſeems beſt adapted for. Two machines are employed for this purpoſe, one a circular and the other a reciprocating ſaw: the latter we ſhall deſcribe firſt.

The great croſs-cutting Saw.—The tree ſubjected to the action of this machine is placed on a long frame or bench raiſed a little from the floor, and at the end of it is erected a frame, compoſed of vertical poſts and croſs timber, in the manner of a ſmall and low door-way: through this frame the end of the tree is drawn by the capſtan above-mentioned, its end projecting as much from the ſurface of the frame as is intended to be cut off; and it is faſtened in the frame from rolling ſideways, by a lever, which can be readily made to preſs upon it and hold it down. The ſaw itſelf is a ſtraight blade, fixed into a wooden handle or pole at each end, to lengthen it: one of theſe handles is connected by a joint to the upper end of a lever, bent like an L, and having its centre beneath the floor: the horizontal arm of the lever is connected by a ſpear rod, with a crank on the end of a ſpindle near the cieling of the room, the motion of which is regulated by a fly-wheel. By this means the ſaw has a reciprocating motion from right to left, nearly in a horizontal poſition, and exactly acroſs the log it is to cut off, imitating in its motion the carpenter's hand ſaw, conſidering his arm as the arm of the bent or L lever. The teeth of the ſaw are of courſe on the lower ſide of the blade, and are ſloped ſo as to cut in drawing towards the lever. It riſes and falls freely upon its joint at the end of the lever, and can be lifted up by the handle, at the oppoſite end of the blade, to take it off its work, which it follows up, by its own weight. The machine being at reſt, is prepared for work, by fixing the log in the frame as before mentioned, ſo that the ſurface of the frame interſects the log at the place where it is intended to be croſs-cut. The ſaw, which was before lifted up by its handle, to be clear above the log, is now ſuffered to reſt upon it, in the place where the cut is to be made; and to guide it at firſt ſetting in, the back of the ſaw is received in a ſaw kerf, made in the end of a piece of board, which is attached to the frame over the ſaw, but ſlides up and down in a groove to reach the ſaw at any height, according to the thickneſs of the log lying beneath it. Being thus prepared, the machine is put in action by a rope or ſtrap which turns the fly-wheel and its crank. This giving a vibration to the bent or L lever, cauſes the ſaw to reciprocate horizontally acroſs the tree, until it cuts it through: it follows up its cut by its own weight alone, but the attendant can at any time lift up the ſaw from its work, though its motion continues, by means of a rope which ſuſpends the handle of the ſaw when required. As the ſaw gets into the tree it quits the guide above-mentioned, which becomes the leſs neceſſary as the ſaw goes deeper; a ſaw having no tendency to alter its firſt courſe, when cutting acroſs the

 grain

grain of the wood. We admire the ſimplicity of this machine, which nevertheleſs executes its work with much accuracy and expedition. It might be very uſefully employed in many ſituations where great manual labour is ſpent in croſs-cutting large logs of timber.

The croſs-cutting circular Saw.—This machine is for ſimilar purpoſes, and ſtands cloſe by the former. It is a circular ſaw, whoſe ſpindle is ſo mounted, as to move in any direction parallel to itſelf; the ſaw all the while continuing in the ſame plane, and revolving rapidly upon its axis, cuts the wood it is preſented to, and as it admits of being applied at firſt on one ſide, and then on another ſide of the tree, a ſaw of moderate dimenſions will be ſufficient to divide larger trees, than could otherwiſe be done by it.

Plate I. (*Block-Machinery*) contains two plans and two elevations of this machine. *Fig.* 1 is an elevation, ſhewing the tree A A (which is to be cut) lengthways. *Fig.* 2 is taken in the other direction, and therefore ſhews the tree endways. *Fig.* 3 is a plan, anſwering in its poſition to *fig.* 1, and ſhews the whole of the mechaniſm; but the plan (*fig.* 4) only contains the lower parts. The ſame letters of reference refer to all the figures. A A, as before mentioned, is the tree intended to be ſawn acroſs: it lies upon a framing of timber B, which may be conſidered as its bench or ſupport. Acroſs the end of this frame a ſtrong timber, or ground ſill, C, is framed, and in this two uprights, R, S, are erected, which, with a croſs beam at top, form the frame, which gives the means of confining the tree upon the bench B while it is cut. This is done by means of a lever D, one end of which is hitched under a bolt put in a hole in the poſt S of the frame, to ſerve as a fulcrum, and the other end paſſes between the face of the poſt R, and a piece of wood, *a*, fixed thereto, and the lever, being forced down upon the tree, is kept down by a bolt put through a hole in the piece *a*, and alſo into the poſt. The other end of the lever is retained by a piece of wood ſimilar to *a*, (ſee *fig.* 1.) fixed to the poſt S; by this means the tree is held ſteadily whilſt it is ſawn. T is a roller, or capſtan, to advance the tree forwards on the bench: it is turned round by means of the handſpike E, which is fitted looſely upon the centre pin of it, and has a ſmall click engaging the teeth of a ratchet wheel *b*, fixed faſt upon the gudgeon or centre pin. The handſpike, being worked in the manner of a pump, turns the roller about a few teeth of the wheel at every ſtroke, and by a rope wound on the roller draws up the tree: *d* is a click which detains the teeth of the ratchet wheel, and prevents the roller running back, after being moved by the handſpike. A framing of wood is placed beneath the tree at F, to form a continuation of the bench B, but leaving a ſpace between it and the front of the beam C, for the ſaw to deſcend into when it divides the tree, when the frame, F, will ſupport the piece cut off. A piece of wood is faſtened down upon the frame F, at *f*: by means of a ſcrew, it acts as a ſtop to the end of the tree, and meaſures out the quantity to be cut off from the end of it: it is of courſe adjuſtable, and may be fixed at any diſtance from the end of the bench B, according to the length intended to be cut off the end of the tree. We now come to deſcribe the mechaniſm connected with the ſaw, which is ſhewn by G, fixed on the end of a ſpindle *g*, mounted in a frame conſiſting of two ſide-beams, H, H, connected by croſs pieces, I, I, K, L, and ſtrengthened by diagonal bolts or tyes, *e*, *e*: the top croſs piece is formed of iron, as ſhewn in *fig.* 3, and its ends are jointed to the end of a frame M M, poiſed in the manner of the balance-beam of a draw-bridge, on a fulcrum ſupported by the fixed framing of the machine, conſiſting of two poſts, N, extending from the floor to the ceiling, and connected by a croſs beam O O. By this means, the ſpindle of the ſaw can be moved in any direction at pleaſure, but always preſerves its paralleliſm, aſcending and deſcending by the inclination of the frame, M M, upon its fulcrum, and moving from right to left by the frame H, ſwinging upon the joints connecting and ſuſpending it: from the former the ſaw receives its motion from the mill by a ſtrap *h*, which encompaſſes a pulley *i*, *figs.* 1 and 2, contained in an opening of the iron top, L, of the frame H; it is faſtened on a ſhort ſpindle, which is exactly in a line with the joints connecting the two frames, M M and H: upon the ſame ſpindle is another pulley *k*, which by the ſtrap, P P, gives motion to a pulley *l*, fixed on the ſpindle of the ſaw; *m*, *m*, *figs.* 1 and 2, are two ſmall wheels to guide the ſtrap, and tighten it up, if neceſſary, when it ſtretches; the main ſtrap, *h h*, is guided over pullies *n*, which, being near the centre of motion of the frame M, are not materially affected by the motion of the frame either to tighten or looſen the ſtrap which paſſes round a large drum, turned by the mill. The attendant has government of the machine, to move the ſaw in different directions by two winch handles, V and W: the latter of theſe is on the end of an axis *w*, having two pinions upon it, which operate upon two racks at the end of wooden rods, Q, Q, *figs.* 1 and 2, which are connected with the end of the great frame, M M, at the ſame joints which connect the two frames together; ſo that by turning this winch, W, in one direction, it elevates the ſaw, and in a contrary direction, depreſſes it, by inclining the frame, M, on its centre. In like manner, the handle, V, gives motion by a wheel and ſpindle to a ſimilar ſpindle *v*, which actuates by its pinions two rods, X, X, jointed to the ſuſpended frame H, and therefore moves the ſaw nearer or farther from the workman who ſtands at the frame N N; the two frames, H and M, are greatly ſtrengthened by the rods, Q, Q, and X, X, being connected with them; for as the two pinions act equally upon the two rods, and thus move both ſides of the frame alike, they preſerve them from twiſting, which would cauſe the ſpindle of the ſaw to deviate from the paralleliſm; but to have this effect, it is neceſſary that the pinions ſhould fit their racks accurately. For this purpoſe, the rods, Q and X, to which the racks are affixed, are ſupported behind by two rollers, *y*, *y*, applied to the back of each. Theſe rollers are fixed in a triangular iron frame, the third angle of which is fitted upon the axis of the pinions; and by this means, the teeth of the racks and pinions are always kept in accurate contact, though the racks neceſſarily alter their inclination at times, according to the poſition of the frames to which they are joined.

The operation of this very ingenious machine is almoſt evident from the deſcription. The tree being fixed, the attendant takes the handles V and W, one in each hand; and by turning one or the other, directs the ſaw at pleaſure to any ſide of the tree. At firſt he applies it, as in *fig.* 2, and it cuts half through the tree from that ſide, with very great rapidity; then he gradually raiſes it up by the handle W, and cuts into the log at the top ſide; but all the time the ſaw continues in the ſame plane: and at laſt he brings it over to the oppoſite ſide, and cutting through it there, the log is ſeparated, even if it is nearly of the ſame diameter as the ſaw. The ſaw is now moved by its handles to be clear of the tree, the piece removed, and the tree advanced to cut another length. This machine is ſo expeditious and accurate in its performance as to take the lead of the other, except for ſuch trees as are of a ſize too great for the circular ſaw. It has, ſince its firſt erection, received an addition of a rack and pinion to the frame R S, for holding the tree, which preſſes down the tree inſtead of the lever, and holds the wood in the manner of a vice or preſs: by this means, the ſaw can now be ufed for fawing the pieces into fquares, after they are cut off the tree; and for cutting them up to form different fized blocks, or for fawing up any other timber. The next machine we fhall defcribe is

The great reciprocating Saw, for cutting up trees lengthwife.—In this machine the faw works vertically: it has an horizontal carriage, on which the timber is faftened; this paffes through a vertical frame with grooves, in which another frame flides up and down in the manner of a window-fafh, and has the faw ftretched in it. The faw-frame is moved up and down by means of a crank on an axis beneath the floor, which is turned by means of an endlefs rope. At every time the faw rifes and falls, it turns a ratchet-wheel round, by means of a click, a few teeth; and this has on its axis a pinion, working a rack attached to the carriage of the tree, which by this means is advanced: at every ftroke, the faw makes a proper quantity for another cut. The faw-frame is adapted to hold feveral faws parallel to each other, for fawing a tree into feveral boards at once, when required. Befides thefe machines, the wing contains four of

The circular fawing Benches.—Thefe machines are ufed for cutting the wood ftill fmaller, after the other machines. Thefe machines are a bench, fimilar to a carpenter's, having a fpindle extending acrofs it juft beneath the boards, with a circular faw fixed upon it, which comes up through a crevice in the bench; and as it revolves, the workman applies a piece of wood to it, which it cuts with amazing rapidity. The wood is guided by a long wooden ruler, fixed on the bench, parallel to the plane of the faw. The wood is applied to this guide-ruler when cutting, and this regulates all the wood it cuts to the fame breadth; but the guide-ruler can be quickly adjufted to any diftance from the faw, being attached to the bench by radius bars fimilar to a parallel ruler, fo that it will always be parallel to the faw. We have been thus concife in defcribing thefe circular faws, and the great reciprocating faw, as they are the only machines in the mill which do not fhew a completely original defign, or which have any refemblance to other machinery. The reciprocating faw is fuch as is common on the continent and in America, and the circular faws have been long in ufe in this country. See SAW-*Mill*.

One of the fawing benches is much longer than the others, being continued the whole length of the houfe. It is ufed for fawing the edges of long planks to a ftraight line, after they have been cut up from the trees by the great reciprocating faw. It has a carriage for holding the plank, which is advanced towards the faw by a rack and pinion, which the workman turns by a winch in front of the bench: the plank is held in the carriage by its ends, one end being applied againft a ftop, fimilar to that which a carpenter's bench has for ftopping a piece of wood, while it is planed; the other end of the plank is forced up to this ftop by a fcrew, attached to the carriage, but in fuch a manner that it can readily be fixed at any part of its length, to hold planks of different lengths. The plank, when of great length, is kept down to bed firmly upon the carriage, while it is fawn by a roller, which preffes upon it very near that part of the plank which is paffing the faw. This roller is preffed down on the plank by the weight of a long beam of wood fet up on end, the roller being fitted in the end of it. This beam is fitted, in guides which permit it to rife and fall, to accommodate any inequalities in the thicknefs of the wood or plank which paffes beneath it. This concludes our defcription of the machines in the wing on the ground-floor. The machines contained in the floor over the great fawing machines are devoted to converting or fawing up the tree of lignum vitæ, for the fheaves, and the fmall machines for forming the fheaves. The firft is

The reciprocating Saw for converting the Lignum Vitæ.—This machine is fomewhat fimilar to that firft defcribed for the elm trees, but made on a fmaller fcale and with more accuracy. The faw is ftretched in a wooden frame, which is neceffary, becaufe, being for the hard wood, it is cut with a much finer tooth, and the blade is much thinner, fo that it waftes lefs wood in faw-duft than the former. The tree of lignum vitæ is placed horizontally, being held in a machine, which is, in fact, an enormous vice, though very different in appearance: it is opened and fhut by two fcrews inftead of one, as the common fmith's vice, and thefe fcrews are both moved at the fame time by means of cog-wheels connecting them, fo as to move the jaws of the vice parallel. This machine is ufed for cutting the ends of the tree into flakes of the proper thicknefs, to form thofe fheaves which the diameter of the tree is beft adapted to make with the leaft wafte. The vice which holds the tree is provided with a fcrew, which advances the whole together towards the faw a proper quantity at every time a fheave is cut off, to cut another of the intended thicknefs. For this purpofe, the vice is ftationed upon a carriage fitted upon proper fliders, fo that it advances truly parallel, in order that the pieces it cuts off may have parallel fides. This machine is only ufed for converting the largeft trees of lignum vitæ, which are drawn up to the floor on which thefe machines are fituated by a crane worked by the mill, fo as to occafion little more trouble than if they were upon the ground: the fmaller trees are cut up in a very curious machine.

The circular Saw for converting the Lignum Vitæ.—This operates with a revolving faw, which is applied to the outfide of the tree, which at the fame time turns round to prefent every part of its circumference to the action of the faw. By this means the faw will cut a tree of nearly as great a diameter as itfelf, and make a very flat fection. We have been compelled, from the number of our plates, to omit a drawing of this machine, and muft, therefore, attempt a verbal defcription.

The fpindle of the circular faw is fitted in an iron frame, which moves in a fixed vertical axis, in the manner of a gate or door. The faw fpindle being vertical, the faw itfelf is of courfe horizontal, and its centre defcribes the arc of a circle when fwung upon its axis of motion, but continues in the fame plane. It is turned, like the other machines, by an endlefs band, which is conducted over pullies, on an axis concentric with the axis of motion for the faw-frame; by which means the band continues with the fame degree of tenfion in all pofitions of the frame fupporting it. The vertical axis of this faw-frame is fupported between the points of centre fcrews belonging to an iron ftandard, which is attached to two vertical iron columns, extending from the floor to the ceiling of the room, and which conftitutes the chief framing of the machine. The tree of lignum vitæ, being previoufly cut into lengths of two or two and a half feet, is fixed in a chuck or clam at the top of a vertical fpindle, which is fitted in a focket, in the middle of a crofs-bar, fliding between the two vertical columns. This crofs-bar has two iron rods extending up from it to another fimilar one, alfo fliding between the columns, thefe forming an iron frame which rifes and falls at pleafure, in the manner of a fafh frame, by means of a large fcrew, which is received into a nut, formed in the middle of the upper crofs-bar of the frame. The lower end of the fcrew refts in a ftep in the middle of a fixed crofs-bar extending acrofs from one column to the other, and perforated with two holes for the

iron

iron rods forming the fides of the frame to pafs through as they rife and fall. The fcrew has an iron crofs forming four handles to turn it by, and a ratchet wheel and click to prevent its running back. The chuck or clam at the upper end of the vertical fpindle is of that kind called univerfal, and has two jaws, between which it will hold trees of different dimenfions; but both clams approach or recede from the centre by the fame movement, fo as to keep the tree always nearly in the centre of the vertical axis. It is accomplifhed by fitting both clams in a groove formed acrofs the face of the chuck, and both are moved by one fcrew, one part of which is cut with a left, and the other with a right-handed thread, fo that in turning the fcrew by a wrench, the jaws open or fhut, and the wood can be fixed in with as much eafe as in a vice, but always very nearly in the centre of the chuck. A rotatory motion is communicated to the vertical fpindle by a cog-wheel fitted in a focket made in an iron plate, which is the bafement of the two columns. The centre of this wheel is exactly in the line of the vertical fpindle, which is formed to a fquare, and is received through a fquare hole in the centre of the cog-wheel, but has liberty to flide freely up and down through the wheel. This is turned round by means of a pinion fixed on the lower end of an upright axis, which rifes up a confiderable height by the fide of one of the vertical columns, and has a fmall winch upon the top of it, by which the workman turns it round, and thus caufes the great cog-wheel with the vertical fpindle and wood to revolve at whatever elevation it may be, according to the height the fliding frame is raifed by its fcrew.

The operation of the machine is this; the wood, being fixed at the top of the vertical fpindle, is raifed by turning the great fcrew to fuch a height, that the faw is oppofite that place in the tree where it is intended to be divided. The faw is in conftant motion by the mill, and the attendant preffes it by a lever (fixed to the faw-frame) againft the wood, which it cuts into very rapidly. At the fame time he is doing this, he turns the vertical fpindle (with the wood) round by means of the winch, which communicates with it by the wheelwork, fo that the tree applies all parts of its circumference in fucceffion to the action of the faw, which will by this means cut through a tree nearly twice its own radius, and in confequence of its revolution makes a very flat fection, which will be exactly parallel to the laft it cuts off, fo that the flakes will be of the fame thicknefs in all its parts. When the piece is thus feparated, the workman fwings the faw out of the way of the wood, and turns the fcrew by its crofs handle, to raife up the frame, with the fpindle and tree, the proper quantity to cut off fuch a thicknefs as will form the fheave intended. This quantity is meafured by the fcrew, which, as before ftated, has a ratchet wheel upon it, with a click to prevent it running back, which the weight of the iron frame, fpindle, and wood fupported by it, would otherwife force it to do. The workman counts a certain number of thefe teeth by the noife they make in paffing the click as the meafure of the proper elevation of the wood: by this means the operation proceeds with great rapidity, and another piece is cut off, until the whole length is cut up, when the workman relieves the click and the fcrew runs back, letting down the fpindle ready to receive another length of tree which is cut up in its turn. There are two of thefe machines clofe to each other, one for the larger and the other for fmall trees.

The plates of lignum vitæ, thus cut off the end of the trees, are fawn to a circular figure, and a hole pierced through the centre of each preparatory for turning them by

The Crown or Trepan Saw.—See *Plate* II. *figs.* 1, 2, and 3. *Fig.* 1 is a horizontal fection through the centre of the axis. *Fig.* 2 is an elevation of the whole; and *fig.* 3 an end view. A A is a cylindrical faw with teeth formed upon the end of it, in the manner of a furgeon's trephine, or the crown wheel of a watch. This faw is fixed upon a chuck B, (*fig.* 1.) which is faftened, by fcrewing to the pulley D, turned by an endlefs belt. This pulley and faw are fitted to flip round freely upon a fixed axis or tube E, fupported by being fcrewed to a ftandard F, erected upon the iron frame R R, on which the whole machine is built. G is a ftandard, having a fcrew H through the top of it, and exactly in a line with the centre of the tube E. At the end of it is a cup *h*, which, when advanced by the fcrew, exactly meets the end of the fixed tube E, and between thefe two furfaces, or rings of furfaces, the piece of wood to be rounded is held, by fcrewing the fcrew tight up. The wood is fhewn in a fection at I, *fig.* 1, within the faw. The faw flides backwards and forwards upon the fixed tube E, and can be thus prefented as it revolves againft the piece of wood, to cut through it, and reduce its circumference to a perfect circle of the fize of the interior diameter of the faw. The fixed tube E has a cylindrical fpindle K fitted withinfide of it, which is turned round by a pulley I fixed in the middle of it, and turned round like the other by an endlefs ftrap or belt. This fpindle has a drill fcrewed into the end of it, to perforate the centre hole in the fheave; and it can be moved endways to bring it up to its work in the fame manner as the other. Indeed, it is caufed to advance or retreat at the fame time with it, by means of two connecting rods *b*, *b*, which pafs through holes in the ftandard F, and are at their ends united by fcrews, to collars which are fitted upon fockets, formed in the central part of the pullies D and L, fo that the collars admit the pullies to turn round freely, independent of them; but when either pulley, with its fpindle, is moved endways, it obliges the other to partake of the fame movement. The two collars are fhewn feparately at X and Y, and the ftandard F between them. The farther end of the fpindle K is fupported by a collar in a ftandard M, alfo erected upon the frame R. The motion endways is given to the faw and drill by a lever N, fituated beneath the frame R. The vertical arm *n* of this lever is forked at the upper end, as fhewn feparately at Z, and has notches cut in the extremity of each fork, to receive two pins projecting from the fides of a collar *e*, fitted on the end of the fpindle K, which turns round freely in the collar, but commands the motion of the fpindle endways. The lever N is raifed up, and the fpindle kept back by means of a fpring O fixed to the frame of the machine, fo that when left to itfelf, the faw and drill always retreat back as far as they can. In this ftate the workman takes a piece of the lignum vitæ, which is of an irregular figure, being the fhape of the fection of the tree. This he places againft the end of the fixed tube E, and fcrews it faft by the fcrew H. He now depreffes the handle N, and thus advances the faw and drill, as they are turning all the time, againft the wood, which the former perforates in the centre, while the latter cuts off thofe parts which project beyond the circle, leaving the wood round on the edge and ready for the next operation, which is performed by

The Coaking Engine.—This machine prepares the fheave for the reception of a bell-metal bufh, or centre piece, called the *coak*, one of which is fitted into each fide of the fheave, to furround its centre pin, and avoid wearing. This piece of bell-metal, or coak, is fhewn in *fig.* 9 of the plate: it has a cylindrical part *a*, which paffes through the centre hole of the

the fheave, and has a hole through it for the pin of the fheave. This, which is called its *barrel*, has at the end a fhoulder, or flaunch, of the form of *d*, that is, a circle having three ears projecting from its circumference, which are inlayed into the wood, and thus keeps the coak from turning round in the fheave. This is fhewn at *fig.* 4 of the plate: *e* is a ring of the fame fize and form as the flaunch at the end of the coak: it is inlayed into the other fide of the fheave, but has a large hole through its centre to receive the part, *b*, of the other coak, where it comes through the centre of the fheave. This part being rivetted down into the ring *e*, fecures the two coaks together; but, in fome kind of fheaves, they are further faftened by means of a wire-pin put through the centre of each of the three ears, which is alfo rivetted down. The firft operation which is therefore performed on the fheave, after rounding and centering the wood for it, is cutting a hole, of a proper figure, for the reception of the brafs coak. The engine for performing this is defcribed in the lower part of *Plate* B, of which *fig.* 4 is a front view of it; *fig.* 5, an elevation taken on one fide; *fig.* 6, a plan of the top of the frame; and *fig.* 7, a plan of the lower part where the fheave is fixed. This is, in all the views, marked A: over this a fmall fpindle, B, is fituated; it is mounted in a frame C C, and turned round with great velocity by an endlefs band paffing round its pulley *a*, and conducted over the pullies D, D, *fig.* 5, away to a drum, turned by the mill. The end of the fpindle has a cutter fcrewed into it, fuch as is fhewn feparately at X, formed out of one piece of fteel, with three cutting edges, which cut out a circle of the fize of each of the three ears projecting from the edge of the coak. The frame, C C, of the fpindle is fitted to flide up and down on two vertical rods E, fixed in the framing; and the depth to which it falls is determined by a fmall fcrew *b*, *fig.* 5, on the point of which the frame refts. The fheave, A, is fixed to a chuck F, which has a very fhort axis, received into a focket in the middle of the lever G, attached to the frame by a centre-pin, *e*, at one end, and the other is ufed in the manner of a handle, to move the lever on its centre, and by this means remove the fheave away from the fpindle, fo as to give it any required excentricity from the fpindle; in which cafe, the cutter, X, will cut out a circular hole in the fheave, at any required diftance of the centre thereof. The chuck, on which the fheave is fixed, has three arms, 1, 2, 3, *fig.* 7, projecting at equal diftances from it: thefe are detained at pleafure by a detent *f*, which is forced towards it by a fpring: the frame of the fpindle, when raifed to its greateft elevation, is fufpended by a fpring-catch H; and in this ftate the cutter is raifed up out of the way. The workman now prepares the fheave for coaking, by fixing it on the chuck F. To explain the manner of doing this, fee *fig.* 8, where N is a fcrew paffing down through the centre of the axis and chuck, and has a fcrew cut on the lower end; and by means of a nut M, *figs.* 4 and 5, tapped upon it, the pin can be forcibly drawn down through the axis. The upper end of the pin is, as its figure fhews, of a conical figure, and fills a hole through the centre of a fteel ring O, which is fituated upon the face of the chuck, immediately over its centre. The external diameter of this ring fits the infide of the hole, through the centre of the fheave, which is by this means fixed to the chuck: but to hold it faft thereupon, the ring is divided by a faw into three fegments, and a piece of watch-fpring, P, being put round them, in a groove formed for its reception, keeps the three together, and always collapfes them upon the central pin N; but on turning the nut, M, the pin is drawn down, and its conical head expands the three fegments, fo as to jamb them faft into the infide of the fheave, and by this means fixes it faft. This contrivance of an expanding chuck, which will faften into holes of different fizes, within certain limits, and always preferves its concentricity, is extremely ingenious, and is a very valuable tool for turning many fmall articles in the lathe. The workman thus fixes the fheave to its chuck, to perform which, with convenience, he pulls the end of the lever, G, fo far forwards, that the axis comes as far as it can within the circular frame K, which fupports the machine; but when the fheave is fixed he returns it, fo as to come nearly concentric with the fpindle. This point is determined by fhooting a fmall bolt *g*, *fig.* 4, beneath the lever, G, forwards, and then its end ftops againft the fixed point of an adjufting fcrew *h*. He now, by relieving the fpring-catch H, fuffers the fpindle to defcend till it refts on the point of the ftop-crew *b*. In this ftate, the end of the cutter is as much beneath the furface of the fheave as the thicknefs of the fhoulder *d*, *fig.* 9, of the coak; but the cutter is within the centre hole, at leaft in part, though, in defcending as it revolves, it cuts away the wood, on one fide the hole, as much as will enlarge its diameter on that fide to the fize of the circle of the fhoulder, *d*, of the coak from which the three ears proceed. The workman now draws the handle of the lever, G, away from the fpindle, until the bolt is ftopped againft the point of the oppofite ftop-fcrew *k*, as it appears in *fig.* 7. In this fituation, the fheave is in that pofition, that the cutter is fo far removed from the centre of the fheave, as to cut out the cavity to contain one of the femi-circular ears of the coak. The lever, G, is now preffed againft the other ftop-fcrew *h*; the catch, *f*, is relieved from the arm, *i*, of the chuck, by which it is turned round; and in this motion the cutter enlarges the centre hole to the third of a circle of the proper diameter to receive the coak: when the fucceeding arm, *g*, comes to the detent, he moves the lower, G, out from the centre again to the ftop-fcrew *k*, and thus cuts the fecond ear. The lever is now returned; the chuck turned round; and a third cavity formed in the fame manner as the former; the lever being returned again to the fcrew *h*, the chuck is turned round to where it fet out, and thus completes the enlargement of the centre hole, and the cavity is prepared for the reception of the coak. The fheave, being removed from the chuck, is put on again, with the other fide uppermoft; and to enfure the ears being exactly oppofite to each other on the different fides of the fheave, a fmall button is let into a hole in the face of the chuck, at the fame diftance from the centre as the femicircular ear, and of the fame diameter as that is; being, therefore, of the fame diameter as the cutter, this button is forced upwards by a fpring; but while the firft fide of the fheave was cutting, it was preffed down flufh with the furface of the chuck, and was not in ufe: when the fecond fide is to be cut the fheave is turned round on its centre pin (which is the ring O), before fixing, until the button fprings up into one of the cavities for the ears, and is placed in fuch a part of the chuck, that it determines the pofition of the fheave upon it, fo as to caufe the ears to be oppofite to each other. Being thus fixed, the operation of cutting the fecond fide is exactly the fame as the firft. This coaking engine is a very complete and ingenious machine, and operates in the moft perfect manner to inlay the coaks, and will ferve many different fizes, as will be underftood from its various adjuftments. Thefe are; the ftop-fcrew *h*, which regulates the degree of enlargement the centre hole fhall have to receive the fhoulder of the coak: the fcrew, *k*, determines the diftance of the centre of the ear from the centre of the fheave; the diameter of the ear muft have the cutter *x* fuited to it, for which purpofe it fcrews to the fpindle: and laftly, the fcrew, *b*, governs *b*, governs the depth to which the cavity is excavated, and muſt be equal to the thickneſs of the ſhoulder *d*, *fig.* 9. of the coak. Two coaking machines are uſed at Portſmouth, both effecting the ſame purpoſe as that we have deſcribed, but one of them in its ſtructure differs very materially from our drawing. This is the largeſt machine. The ſpindle of the cutter is fitted in a frame, which is connected by joints with a ſecond frame, having a ſwinging motion on a vertical axis in the manner of a double folding door, or more exactly like the frames of the great circular ſaw firſt deſcribed, if the ſpindle of it was placed vertical inſtead of horizontal; and it receives its circular motion by ſimilar means. This ſpindle has not the power of aſcent and deſcent, but it is evident it can, by the two frames, be moved to any ſpot near the centre of the ſheave that is placed beneath it. The cutter is made to cut out the proper ſhape, by means of a hole cut in a piece of fixed braſs plate, which is of ſuch a figure, that a pin or collar, concentric with the ſpindle, being traced round its interior ſurface, will guide the cutter ſo as to excavate the proper figure in the ſheave, which is fixed on a chuck beneath it, but cannot be turned round, which, from the conſtruction of this machine, is unneceſſary, as the cutter traverſes all the ſpace which is to be cut out, but cannot move any further, being limited by the braſs plate. The chuck for the ſheave is fixed at the top of a frame which riſes and falls with the ſheave, to adjuſt the depth the cutter ſhall cut, and the chuck is let down clear of the end of the cutter every time the ſheave is to be ſhifted. This riſing and falling is performed in a very convenient manner by means of a ſcrew which elevates the frame, and has upon it a barrel, round which two cords are wound in oppoſite directions. Theſe cords are conducted over pullies to two treadles ſituated beneath the frame of the machine, ſo that by preſſing the foot on one treadle, the chuck and ſheave are raiſed up, and by the other, it is let down, and in either caſe the ſcrew retains it where it is placed. The frame is provided with a ſtop-ſcrew, which will determine the height to which it ſhall riſe, and conſequently the depth to which the cutter excavates in the face of the ſheave.

The bell-metal coaks are caſt in ſand, in the manner deſcribed in our article CASTING, from accurate patterns made for the purpoſe, of which they have a great variety of all ſorts for the different ſizes. The pattern, or core, which is inſerted in the ſand for forming the hole through its centre, is not a ſmooth cylinder, but has two projecting threads which encompaſs it ſpirally, in the manner of a very coarſe ſcrew; ſo that when caſt, the interior ſurface of the central hole through the coak is not a ſmooth cylinder, but has two ſpiral cavities, or chambers, winding round within it, in the manner of the ſpiral ſcores within a rifle gun barrel; but theſe cavities do not reach the ends of the hole, which is therefore circular at the two ends. Theſe chambers are intended to contain a ſupply of greaſe to the centre pin, when the block is in uſe, as will be more fully deſcribed.

The coaks, being put into their places, have holes drilled through the centre of each ear, by a very ſimple

Drilling Machine.—This bears a great reſemblance to a common turning lathe, to the ſpindle of which a ſmall drill is fixed, immediately oppoſite to it. In the place of the back puppet of the lathe, is a flat plate or tablet, againſt which the ſheave is placed, and by a ſcrew advanced againſt the drill, which is all the time in rapid motion. The proper place for drilling the hole is determined by marks punched in the pattern from which the coaks are caſt, and thus occaſion ſimilar marks in the centre of each of the ears of every coak, by means of which the drill point is guided to the right place, and quickly penetrates through both the coaks and the ſheave alſo. The pins to fit into theſe holes are made of copper wire, which is chopped or cut into lengths in the moſt expeditious manner by a ſtrong pair of ſhears, having a ſtop or guage fixed at the proper diſtance behind its blade, to ſtop the end of the wire, and point out the proper mark where it is to be cut. Theſe pins are driven into the holes through the ſheave, and in this ſtate the ſheave is ready for rivetting, to faſten the pins in, and to unite the two parts of the coak firmly to each other. This is done by

The Rivetting Hammer.—It is delineated in *figs.* 1, and 2, of *Plate* III.; the firſt an elevation, and the other a plan of the machine. Its frame is a flat iron plate A A, which is ſituated on a ſtrong bench: upon this two ſtandards B, B, are caſt, and ſupport an axis *a*, turned round by means of a belt on the pulley *b*. The other pulley, *c*, is fitted looſely upon the end of the ſpindle *a*, and when the ſtrap is upon it, the machine ſtands ſtill, becauſe the pulley turns round upon its axis. On the middle of this ſpindle is a wheel D, having three cogs, which operate, as it revolves, to lift up the tail of the hammer E, which is fixed upon an axis F, ſupported in the ſame frame, B B, as the main axis. A ſmall anvil or ſtake, G, is fixed to the bottom plate of the frame A, immediately beneath the face of the hammer, and the ſheave, H, is preſented between them to receive the ſtrokes of the hammer, which is lifted by the cogs of the wheel D, and falls upon the ſheave three or four hundred times *per* minute. The hammer would not fall ſo quickly by its own weight, as to reach the ſheave before the next cog of the wheel, D, lifted it up: a ſpring, I, is therefore applied to act beneath the tail of the hammer, and by raiſing it up to throw down the face of the hammer. This ſpring is ſcrewed upon a lever K, which is fixed on an axis, L, extended acroſs the frame, and the other end is ſuſtained by reſting on the ſurface of an excentric circular wheel M, fixed upon an axis, which alſo has a wheel, N, fixed by the ſide of it, and a rope being faſtened round this, deſcends to a treadle beneath the bench, and the workman preſſing this with his foot turns the wheel round, and its excentric circle acts upon the lever, K, to raiſe it up, which cauſes the ſpring to act with greater force, and the hammer to make a more powerful ſtroke. In uſing this machine, the workman takes a ſheave, and, lifting up the hammer, applies it beneath the face of it; then by ſhifting the endleſs ſtrap, which is all the time in motion, upon the live pulley *b*, the axis, *a*, is turned round, and the hammer beats upon the rivets, ſo as to faſten them effectually in a very ſhort time. By this the end of the barrel of one coak is firmly rivetted into the other coak on the oppoſite ſide, and the barrel being, at the ſame time, ſhortened by the rivetting, the ſides of the coak are drawn into their cavities with ſuch force as never to be in danger of getting looſe. Some kinds of ſheaves are found to do as well by merely rivetting down the end of the barrel without uſing any pins: theſe were firſt applied to prevent the poſſibility of any coaks getting looſe; but having been found, in ſome years practice, to be a needleſs precaution, it is accordingly diſcontinued, except in ſome particular inſtances.

Broaching Engine.—The ſheaves, after being coaked and rivetted, are broached, to make the interior ſurface of the centre hole perfectly ſmooth and cylindrical. For this purpoſe, the ſheave is fixed on a flat chuck, at the upper end of a vertical ſpindle, which turns round, and the broach or borer is forced down perpendicularly through the centre hole of the coak, while the ſheave is turning round, boring out the hole as it deſcends to a true cylinder. The manner of fixing the ſheave to the chuck in an expeditious manner, and getting it concentric with the axis, is very well contrived. The vertical ſpindle is hollow for a conſiderable

depth

depth down it, and the borer is a cylindrical rod which exactly fits into this hole in the end of the fpindle, and alfo fits pretty truly into the centre hole of the coak, in the ftate it comes from the rivetting hammer. This cylindrical rod has a fmall tooth of fteel fixed into it, and projecting a fmall diftance from the circumference of the cylindrical rod, which, as before ftated, is of the fame fize as the hole through the coak of the fheave, and its tooth projects as much as the hole is intended to be enlarged in the operation of broaching.

In fixing on the fheaves, the machine being at reft, the broach is drawn up (by the fcrew movement which is ufed to force it down into the fheave), fo as to be clear out of the end of the fpindle: the fheave is then laid upon the flat chuck, at the top end of the fpindle, which is much larger than the fheave itfelf: the cylindrical borer is next put down through the centre of the fheave, and entered into the hole in the end of the fpindle. By this means the fheave is placed on the chuck, exactly in the centre of it, and both being flat, it only requires to be fcrewed or clamped faft againft the chuck, fo as to be turned round at the fame time with it. This is done by a clamp, confifting of an iron ring of a fmaller diameter than the fheave, having two fhort bars projecting from the oppofite fides of it. Thefe bars extend acrofs the face of the chuck, to which one of them is connected by a joint or hinge, and the other by a fcrew; or, in other words, the clamp may be confidered as one bar, having a large hole through the middle of it, one end being hinged to the chuck, and the other drawn towards it by a fcrew fimilar to a vice fcrew; but is fo conftructed as to be quickly unhooked, and then the clamp bar may be lifted up upon its joint, in the manner of a book lid, to place the fheave under it. The ring or hole through the centre of the clamp, when fcrewed down upon the chuck, is concentric with the fpindle, and thus leaves the centre of the fheave free and clear for the operation of the borer. The fheave is thus, by means of this clamp, faftened down upon the face of the chuck in a moment, and the workman fets the machine in motion. He now, by turning a handle, gives motion to a wheel over head, in the centre of which is a nut, through which the fcrew in a line with the borer is fitted to work; and this fcrew as well as the borer being prevented from turning round by appropriate fitting at the end of it, is caufed to defcend, and force the borer down till its cutting tooth meets the bell-metal coak, and cuts its way through, enlarging the hole to its intended dimenfions, and making it truly cylindrical to fit the pin on which it will turn when in the block. It is to be obferved, that the interior furface of the hole has two fpiral grooves or cavities withinfide it, which are formed in the cafting, as before defcribed. Thefe are too deep to be taken out in the broaching, and form receptacles for greafe, which is thus always kept fupplied to the centre pin, both to diminifh friction and avoid wear of the parts. This is a great improvement in the blocks, as, without fuch receptacles, the pin, if well fitted into its centre hole, as it is and fhould be, would afford no room for greafe, and then the block would require conftant attention to keep it fupplied, or would always be in want of it. The two fpiral cavities do not come to the ends of the hole in the coak, which is therefore a complete circle. By this means, when the pin is in its place, the cavities have no external communication at which the greafe can efcape.

The Face-turning Lathe.—The fheaves in this ftate are turned to make the two faces perfectly fmooth, and the circumference truly circular, as well as to form the groove or hollow round the edge of it, to receive the rope. The turning is performed in a very complete lathe adapted for the purpofe, fee *Plate* III. *figs.* 3, 4, 5, 6, and 7. *Fig.* 3 is an elevation, and *fig.* 4 an end view; *fig.* 5 is an horizontal plan, and *fig.* 6 are various parts fhewn feparately; *fig.* 7 is a crofs fection anfwering to *fig.* 4. A is the fpindle or mandril of the lathe, mounted in the ufual ftyle between two ftandards B, C, which are erected upon the main frame or bed D of the machine: it is turned round by an endlefs band on the pulley E, and F is an idle or dead pulley, on which the band is fhifted when the lathe is intended to be at reft, becaufe it turns freely round upon the axis without moving it. On the end of the fpindle a chuck, G, is fcrewed, to which the fheave, H, is fixed by means of an expanding ring chuck, fuch as defcribed belonging to the coaking engine, except that the fcrew, N, is tapped into the chuck G, inftead of having a nut behind it in the manner of the coaking engine, and this fcrew is turned with a fcrew driver, which has a fquare end, and the end of the fcrew has a fquare hole to receive it. The tool *a*, which cuts or turns the face of the fheave, is carried in a ftraight line acrofs it, from the centre to the circumference by a fliding reft, which confifts of two fliders placed acrofs each other. One is fixed faft down upon the frame of the lathe at I, and has a metal frame, K, fitted acrofs it, which flides upon it by means of two parallel pieces *k*, *k*, which are attached to it on the lower fide, and fit upon the dovetailed edges of the lower flider I. A fcrew, the handle of which is fhewn at M, is fitted within the lower flider, and operates by a nut fixed beneath the frame K. To move it along the flider I, when the fcrew is turned by the handle, M, upon the end of it; the frame, K, has two pieces or rulers *n*, *n*, fcrewed down upon it, forming a dovetail groove, in which a flider, N, is fitted and moved in a direction acrofs the frame by a fcrew L, which is alfo provided with its handle P. This laft flider has a frame Q, erected upon it, in the top of which is a groove, to receive the tool *a*, and a piece of metal, *b*, covers it, and can be drawn down upon it by means of a fcrew, fo as to form a clamp which holds the tool down firmly upon the flider. The handle, P, of the fcrew, L, is only ufed occafionally, to traverfe the tool acrofs the face of the fheave; it is in general moved by means of a pulley O, fitted to flip round freely thereon. This pulley is turned round by means of an endlefs band *d*, which makes a turn round the pulley *e*, and then paffes away and goes round a pulley R, which is fixed on the extreme end of a fpindle S, mounted in a frame T, fixed perpendicularly acrofs the great frame D D. This fpindle has a wheel, V, fixed upon it, having fine teeth formed round the edge of it, which are engaged with the threads of an endlefs fcrew W, cut upon the main fpindle A. By this means the pulley, R, receives a flow motion from the main axis, and by means of the endlefs band, communicates a ftill flower movement to the pulley O. The band, after having made the turn round this, is conducted round a pulley *e*, which is fixed at the upper end of a flexible fpring X, attached to the legs of the frame, and thus preferving a proper tenfion of the band, though the fituation of the pulley, O, is conftantly altering the pofition of its centre by the movement of the flider N, and its frame, K, upon the lower flider, I, by the fcrew M. The manner of ufing the machine is this: the fheave is attached to the chuck by a turn of the fcrew N, in the centre of the expanding fteel ring, as before defcribed of the coaking engine, and the direction of the fpindles movement is fuch, that the drift of the work always makes the chuck tighter, by working the fcrew farther in and expanding the ring more powerfully into the hole in the centre of the coak, to make it turn the fheave about with the chuck. Being thus prepared, the ftrap is fhifted to the live pulley E, and caufes the fpindle to revolve and the fheave with it: the ſcrew, L, is turned by its handle P, to bring the point of the tool oppoſite the centre of the ſheave: the ſcrew of the lower ſlider is now turned by its handle M, to advance the point of the tool, to touch the face of the ſheave as it revolves, and then the ſcrew, P, is put in motion by this means. The pulley, O, is, as before ſtated, in conſtant motion, but ſlips upon the end of the ſcrew. This, at a ſhort diſtance from the pulley, is formed into a ſquare, and has a clutch or ſhort lever fitted upon it, ſuch as is ſhewn at Y, *fig.* 3. This has a center-piece or ſocket, having a groove formed round it for the reception of pins attached to a forked lever Y, *fig.* 5, in the manner ſhewn at Z. This admits the clutch to turn round freely within the fork, but is obliged to move an end upon the ſpindle, to draw it away from the pulley O; and in this ſtate the pulley ſlips round: but when the lever is moved to thruſt the clutch towards the pulley, a pin projecting from it intercepts the arm or lever of the clutch, and turns the ſcrew round with it. In this ſtate the ſlider, N, traverſes ſlowly along, and the point of the tool, *a*, advances from the centre of the ſheave to the circumference, turning the face of it all the way perfectly ſmooth and true; to prevent the ſcrew forcing the ſlider, N, too far, and injuring or breaking it, a rod, *z*, is provided, which is jointed to the end of the lever *y*, and is received through an eye, *x*, attached to the ſlider N. The rod ſlides freely through this eye; but by the time the tool has arrived at the circumference of the ſheave, the eye, *x*, has intercepted a nut, *p*, at the end of the rod, and drawing it, removes the lever *y*, and by this means diſengages the ſcrew from the connection with the pulley Q, and thus prevents the danger of breaking the ſcrew: for as ſoon as the ſlider arrives at the end of its motion, the ſcrew is diſengaged, and its motion ceaſes.

The groove round the edge of the pulley is turned, at the ſame time the tool is turning the face of the ſheave, by a gouge which the workman holds over the edge or reſt, marked &, which is fixed oppoſite the edge of the ſheave, in the manner repreſented in *fig.* 7, though it is omitted in the other figures. This part of the turning is performed in the uſual manner of turning by hand; and the workman has plenty of time to do it, whilſt the machine is turning the face of the ſheave, which it does without any attention on the part of the workman, except at the firſt ſetting out, when he has a little trifle to perform: this is, as ſoon as the tool has advanced acroſs the face of the metal coak, (and therefore finiſhed the turning of it,) to double the velocity of the machine; for it is found by experience, that the proceſs of turning will be performed to the greateſt advantage, when the work revolves with a certain velocity for braſs or bell-metal; but in turning wood, it is proper to move nearly twice as quick, being a ſofter ſubſtance, and not liable to heat and ſoften the edge of the tool, as metal would, if turned with the ſame velocity. The change of ſpeed in the machine before us, is effected by the wheel which gives motion to the ſtrap, turning the ſpindle of the lathe: it has another wheel ſituated cloſe to it, upon the ſame ſpindle, but revolving with twice the velocity of the other. They are ſo near each other, in the ſame manner as the live and dead pulley upon the ſpindle A, that the ſtrap can readily be ſhifted from one to the other while they are at work. Thus, when the machine is firſt ſet in motion, and as long as the tool continues turning the bell-metal, the ſtrap is upon the ſlow pulley; but as ſoon as the workman ſees the tool is beginning to cut the wood, he ſhifts the ſtrap upon the quick pulley, by which its velocity, and conſequently that of the lathe, is immediately doubled, and continues ſo until the ſheave is finiſhed turning; and then the workman returns it back again to the ſlow pulley, and immediately after ſhifts the ſtrap to the idle pulley upon the ſpindle A, which ſlips round upon it, and the motion ceaſes. The ſlider, I, is not fixed to the frame. D D, in a direction perfectly parallel to the ſpindle, and therefore the ſlider, N, is not exactly perpendicular to it, by which means it gives a convex ſurface to the ſheave; and when it is fitted into its block, it will be certain to touch it only in the centre, and thus avoid all unneceſſary friction. The chuck G, as ſhewn by its ſection in *fig.* 3, is turned hollow, and the ſheave only applies to a prominent edge at the circumference of it, by which means it will receive the convex ſurface, when the ſecond ſide is to be turned, as readily as it did the flat ſurface, when the firſt ſide was turned. The angle of inclination of the ſlider is very trifling, becauſe the ſheave is not required to be very convex; and this convexity will be double the angle the ſlider, I, makes with the ſpindle, or, what is the ſame thing, the difference of the other ſlider from the perpendicular to the ſpindle. The ſcrews which faſten the ſlider, I, down upon the main frame D, are adjuſtable to increaſe or diminiſh the convexity at pleaſure.

The turning duſt, which this machine makes, is winnowed in a machine, ſimilar to that uſed in corn-mills, to ſeparate the wood-chips from the metal-turnings, which are returned to the foundery to be re-melted, and uſed in caſting other coaks.

This machine completes the ſuite for making the ſheaves. All the machines we have deſcribed diſplay great ingenuity, and much originality of thought, particularly the expanding chuck for holding the ſheaves in the coaking and turning machines. Among all the multitude of ingenious tools, uſed by turners for chucking or fixing their various works in the lathe, nothing was completely adapted to the circumſtances of the preſent caſe: for as the coak is to be turned to the very centre, and the ſheave all acroſs the face, and alſo upon its circumference at the ſame time, ſo that nothing elſe than holding it by the inſide of the centre hole would ſucceed. It is a valuable tool for many other ſimilar uſes. The converting machine, or circular ſawing machine, is extremely well adapted to its purpoſe; and the contrivance of turning the log round, while it is ſawing, is moſt excellent, as it enſures a perfect flat ſurface, and parallel to the former cut; conditions which would be extremely difficult to fulfil in any other manner. Indeed the great reciprocating ſaw is not found to be at all equal to it, and is therefore never uſed, except for ſuch large trees as the circular ſaws cannot cut through: it would have been unwieldy to have made ſo large a machine on the conſtruction we have deſcribed for the circular ſaw, many of the trees being eighteen inches and more in diameter. The whole ſeries are calculated for operating upon large or ſmall work; and this is one of the greateſt merits of the machines. More than 100 ſizes of ſheaves are made by them, of all diameters and all thickneſſes. It will be proper for us to review all the ſuite, and point out the means by which they are adapted to the different ſizes. In the firſt converting or ſawing machine, the number of teeth of the ratchet wheel on the ſcrew, which the workman paſſes every time, regulates the thickneſs of the ſheave, and this very accurately; for the ſcrew is cut with a coarſe or rapid thread, and the ratchet wheel having ſeveral teeth, it gives the means, by counting one tooth more or leſs, to cut them with the greateſt preciſion to any thickneſs required.

In the rounding and centering machine, the chuck of the trepan ſaw is ſcrewed to the ſpindle, in the ſame manner as a lathe chuck, and can readily be removed, and another of any ſize ſubſtituted, for the different ſizes of ſheaves: the drill in the central axis alſo ſcrews into it, and a great variety

 variety

riety of all ſizes are provided. The whole of this machine is very ingenious and expeditious in its operation.

The coaking machine is univerſal, and will cut any ſize, as we have before deſcribed. The coaks are caſt from a great variety of patterns, ſuited to the various ſizes.

The rivetting hammer, having no parts which are attached to the ſheave, will of courſe apply to any thickneſs indifferently.

The broaching engine holds any ſized ſheave, and the clamp which faſtens them to the chuck adjuſts to different thickneſſes: the borer or broach is eaſily changed for any ſize; it is, as before ſtated, a cylindrical rod of the ſize to fit the centre of the rough coak, and its cutter projects enough from it to clear the hole out.

The facing lathe is provided with a variety of expanding chucks, like the coaking machine, and adapted to all ſizes. They are put on by merely removing the conical ſcrew in the centre of the chuck, and putting in another ring around it; the lower ſlider accommodates for different thickneſſes of ſheaves, and the common turning reſt, *fig.* 7, for the different diameters.

This operation finiſhes the ſheaves, which are now ready to be fitted into their ſhells or blocks, the manner of forming which we have yet to explain; but we ſhall firſt notice the machines for making the iron pins, ſituated in a ſmall room up ſtairs. Theſe are of two kinds: firſt for turning, and others for poliſhing or burniſhing them afterwards. The pins are forged between ſwages, by two workmen, in the uſual manner of ſuch articles, and are cylindrical, except a ſmall part at one end, which is left ſquare, to be inſerted into the cheeks of the block, that the pin may not turn round when it is put together, by the friction of the ſheave upon its pin.

Pin-turning Lathe.—The lathes for turning the iron pins are the beſt finiſhed machines of the whole ſuite, being the laſt which are made, and by no means the leaſt important in their uſe, as they turn the largeſt iron pins, perfectly cylindrical, from end to end in a very ſhort time, and without attendance, except at firſt; an operation which is very tedious and laborious, when performed, in the uſual manner, by hand. We ſhall be able to give a tolerable idea of this machine without a drawing on purpoſe, it being compounded of the parts of many machines we have deſcribed in our different plates. The reader muſt ſuppoſe a lathe with a triangular bar, in its form ſimilar to that deſcribed in our article LATHE, but its reſt removed from the bar. This is to be fixed over a ſtrong ſquare iron frame, but the puppets of the lathe not vertical; that is, a perpendicular line let fall from the central line of the mandril, will fall clear before the triangular bar, one ſide of which is upright. This is neceſſary, becauſe water is uſed to drop upon the turning tool; and if it fell upon the bar, it would cauſe it to ruſt and ſpoil the fittings. The ſquare iron frame, over which this lathe is fixed, has on one of its ſides a long ſliding reſt, which is in its properties ſimilar to that belonging to the face-turning lathe, except that its long ſlider is parallel to the direction of the mandril; the tool being ſupported by a ſmaller ſlider perpendicular to this, and moving along upon the long ſlider by a long ſcrew, which can occaſionally be turned by a motion from the mandril, or may be turned by a handle. The tool itſelf is a cylinder of ſteel, cut off obliquely, ſo as to preſent an elliptic face, the ſmall end of which is the cutting edge; it is held in a holder at the end of the ſmall ſlider, of ſimilar form to that uſed for the ſhaping engine, as will be particularly deſcribed hereafter. The lower or long ſlider, which, as before mentioned, is parallel to, and as long as the lathe, conſiſts of a rectangular frame (or it may be conſidered as a large flat bar, with an opening or mortiſe through its upper ſide, and extending its whole length, giving it the appearance of a frame), and in this the ſcrew is fitted. On the upper ſurface of the frame two rulers are ſcrewed at the ſides, forming between them a dove-tailed groove reaching the whole length of the frame, and in this groove a ſmall flat plate is fitted, and traverſes, by the action of the long ſcrew, from one end of the lathe to the other. The flat ſliding plate has a cap-piece or ſocket ſcrewed down upon it, forming between them a ſocket for the reception of a ſhort triangular bar or priſm, which is the upper ſlider carrying the tool, and traverſes through this ſocket in a direction perpendicular to the former ſlider; it therefore advances or recedes directly to and from the pin which is turning in the lathe. The end of the triangular ſlider has a ſocket or holder in it, which holds the tool in an inclining poſition, a little removed from the vertical, in the manner of the ſhaping engine: the ſlider has a ſcrew behind it to force it forwards towards the work: the flat plate, which moves in the groove of the lower ſlider, has an iron arm proceeding from it, which turns upward behind the pin in the lathe, and has a little table on the top of it, to ſupport a ſmall veſſel of water, which ſupplies a ſmall ſtream to drop upon the turning tool. The ſcrew of the long ſlider has a ſmall wheel fixed on the end of it, which is turned by an endleſs ſcrew formed on the end of a ſmall ſpindle, perpendicular to the direction of the lathe, and is turned by a band, which receives its motion from pullies on the mandril of the lathe. The pivot of the ſpindle of this endleſs ſcrew is fixed in a piece of metal which moves on a centre, to allow the ſcrew to fall down clear of the teeth of the wheel; but when the ſcrew is engaged with the wheel, the piece ſupporting its pivot is kept up by a catch, which is provided with a rod, in the ſame manner as the facing lathe: this diſengages the catch, and conſequently, by letting fall the endleſs ſcrew, diſengages the motion of the long ſcrew, when it has turned the length of the intended pin, ſo as to avoid the danger of injuring the machine. The pin is, as before ſtated, forged with a ſquare part at one end: this ſquare end is received into a chuck ſcrewed to the end of the mandril, the form of which is an hollow ſquare priſm; but two of its oppoſite angles are cut clear away, ſo that it catches the pin by only two of the angles of its ſquare, and by being forced deeper into the priſm, it is ſure to fit and hold it correctly by theſe two angles, and with leſs danger of altering its poſition, than if there were four angles to the chuck, being certain of a correct bearing. The pin is prepared for turning by a ſmall hole being punched in the cylindric end of it, a ſimple tool being uſed to enſure the punch being ſet truly in the centre of the end of the pin. The operation of this turning lathe is thus: ſuppoſe the motion caſt off, and the wheel-work of the long ſcrew diſengaged, the tool is moved by turning this ſcrew with its handle to ſtand at that end of the long ſlider which is fartheſt removed from the mandril. The pin is now put in, by inſerting its ſquare end into the chuck, and ſcrewing the back centre into the hole punched in the other end of the pin, which being thus mounted, the lathe is put in motion, and the tool advanced, by the ſcrew of the upper ſlider, towards the pin, until its edge meets it, and cutting it as it turns round to a true circle juſt at the end. Being thus ſet in, the wheel at the end of the ſcrew of the long ſlider is, as before deſcribed, engaged with the wheel-work which gives it motion, and this traverſes the tool from one end of the ſlider to the other, cutting a thick ſhaving off the pin, and turning it cylindrical in its whole length; the ſmall veſſel of water

 before

before mentioned being attached to the focket for the flider carrying the tool, therefore moves along with it all the way. This cock is fet to drop a fmall ftream of cold water on the tool to keep it cool; but the water falls, together with the fhavings, clear down through the iron frame, and is caught in a ciftern below. The motion of the tool, when it arrives at the intended length of the pin, cafts itfelf off, as before ftated, fo as to be in no danger of breaking the flider or fcrew. Three of thefe machines are in conftant ufe for different fized pins After being turned, the pins are truly cylindrical and ftraight, but have fpiral lines or fcratches traced upon them, in confequence of the edge of the tool not being always perfectly keen. To remove thefe, and make them perfect, the pins are burnifhed in

The Polifhing Machine.—This confifts of three fteel dies fixed in a box, and regulated by ftrong fcrews to form a triangular opening of any required dimenfions. The pin being drawn through thefe dies, and turned round at the fame time, receives a moft violent preffure and friction, which burnifhes and polifhes the whole of its furface in the moft perfect manner imaginable. The dies are of courfe immerfed in oil, to avoid the heating of the pin or dies from the friction. This is the general conftruction of the machine: the pin is faftened, by means of a ftrong hand vice, to the lower end of a long fcrew, with which it forms a right line: this fcrew and pin are placed in a vertical pofition exactly over the dies, and the fcrew is enclofed in a nut or female fcrew, which is made in two halves, and fhuts up in the manner of a pair of tongs round the fcrew, fo that they can be opened, and then the fcrew can be raifed or lowered at pleafure, it being properly balanced and fufpended by tackle, which gives the means of lifting it with eafe. Exactly beneath the fcrew the dies are fixed, being fitted into an iron frame or box containing the three, each fitted into a proper groove, and adjuftable by a fcrew behind it, to form a triangle of fuch dimenfions as the pin will exactly fill. The interior furfaces of thefe dies are highly polifhed, and as hard as fteel can be made. The box or frame for the dies is contained in a pan which is filled with oil, and has a vertical tube beneath it, to admit the pin to defcend into as it paffes through the dies. To prevent this tube and pan overflowing by the immerfion of a large pin, a copper pipe proceeds from the vertical tube, and communicates with a large pan, fixed at a little diftance behind the dies, and on the fame level with the pan which furrounds them. By means of this communication, the united furfaces of the two pans are fo large, as not to be materially raifed by the immerfion of a pin.

In the operation of this machine, fuppofe the fcrew at the top of its movement, the pin is faftened to it by the vice at the lower end, biting the fquare end of the pin. One of the fcrews of the dies is now fcrewed back, and this opens or enlarges the triangle between them, that the pin may pafs clear through it without forcing. The nut at the top of the fcrew is now opened, and the pin let down till its fquare end comes to the dies. The fcrew of the die is now fcrewed up hard to bite the pin; and the nut is clofed round upon the fcrew. The machine is now put in motion, and the fcrew being turned by it turns the pin round, and at the fame time draws it up through the dies, which burnifh the furface in the moft perfect manner; and when they come out, have as high a polifh as it is poffible for iron to bear, and the furface receives a kind of cafe-hardening, which enables them to refift wear in a moft effectual manner. It is found to facilitate the procefs of polifhing, to rub the pin over with foap before it is put in, as this prevents any danger of the pin having fpecks in it which are not perfectly polifhed, owing to fome properties in that part of the iron which caufe the dies to abrade or rub up the furface of the iron rather than burnifh it down to a polifh; but the ufe of a flight quantity of foap is found to render the procefs certain.

Machines for making the Shells of the Blocks.—We have now to notice thofe machines which are devoted to the fabrication of the fhells for the blocks: they are, as before ftated, contained in the central building of the mill, in the roof of which is the fhaft that drums upon it, giving motion to the whole, with very convenient contrivances for detaching any movement at pleafure. This fuite of machines, perhaps, difplays the greateft ingenuity, or at leaft the greateft novelty, of any in the whole work; feveral of the operations, particularly the mortifing and fhaping, being new principles of working wood by machinery, and are valuable inventions, being applicable to many other ufeful purpofes, when wood is to be formed into fmall articles, of which a great number are required of the fame kind.—The firft operation to which the blocks of wood intended to form the different fhells are fubjected to, is boring in the

Boring Machine.—The pieces of elm to form the different blocks being prepared, and converted to the proper dimenfion by the fawing machines firft defcribed, have two holes perforated through each in different directions; one through the centre of each, which is intended to receive a centre pin from the fheave, and as many others as the block is intended to have fheaves in a direction perpendicular to the former, being intended as the commencement of the feveral mortifes which are to contain the fheaves. *Figs.* 1 and 2 of *Plate* IV. are elevations of this machine, *fig.* 3 an end fcrew of one fpindle, *fig.* 4 is a detached view of fome part, and *fig.* 5 is a plan of the whole machine, the fame letters of reference being every where ufed. A, B, reprefent two fpindles turned by their refpective pullies *a*, *b*, and mounted in a frame fimilar to the mandril of a lathe; both are provided with borers C, D, formed to edges in the manner of a carpenter's centre bit. The block marked X is held in an iron frame, E L L, by the end of a fcrew, F, being forced down upon the top of it, and the borers are prefented to it by the action of two levers *g* G *k* and *h* H *i*, which move on centre pins fixed in the frame of the machine at *g* and *h* (but at different heights from the frame, as is fhewn in *fig.* 6.) Thefe levers act upon pins fixed in the frames of the two fpindles, which frames are fitted upon dovetailed fliders I and K, fo that they advance towards the block when the workman moves the handles, *i*, *k*, at the ends of the levers in that direction; and the borers, being in rapid motion by their pullies, penetrate the wood very quickly. The proper fituation for fixing the block, that the borers may enter at the proper points, is determined in this manner: the frame E L, as the plan fhews, confifts of three legs rifing from the main frame, and uniting together to fupport the focket in which the fcrew, F, acts. Two of thefe legs unite together before they reach the focket. (See L, *fig.* 2; and L L, *figs.* 1 and 5.) In this double leg three fmall fcrews, *d*, *e*, *f*, are inferted, their heads forming a fupport, againft which one fide of the block is firmly held, before the fcrew, F, is fcrewed down upon it, and holds it faft upon the head of a fcrew K, which is the fupport of the block. But thefe three fcrews only determine the pofition with refpect to the borer D; and that it fhall pierce it perpendicularly to the fide of the block, the borer, C, is caufed to penetrate the centre of the block by a gauge, formed out of a piece of iron, fhewn feparate in *fig.* 4. It has a groove in it, through which the fcrew, K, paffes to fix it down to the

the frame, and a blade, R, ftanding up perpendicular, juft beneath the borer D, *fig.* 1, as fhewn there at R. One fide of the block being preffed in contact with this blade, while the other fide is held againft the heads of the three fcrews, determines its fituation, fo that the borers will form the holes in the exact points required, and which being adjufted by experiments for one block, will bore any number of the fame fize in the fame places. The adjuftment for blocks of different thickneffes, is made by the three fcrews, *d*, *e*, *f*, being fcrewed to project more or lefs from the frame, that when the fide of the block is applied to their heads, the borer, D, will perforate the block in the middle of its width, and perpendicular thereto.—In the fame manner, by the gauge, R, being fixed a greater or lefs diftance from the fcrew K, the borer, C, may be adjufted to bore exactly through the centre of the fide it is prefented to. The lengths of different fized blocks is accounted for by putting collets of different thickneffes beneath the head of the fcrew K, which raifes the fupport for the block to the proper height. The flider, I, on which the frame of the fpindle, A, moves, is firmly fixed down upon the frame of the machine, but the flider, K, for the other fpindle is formed on the top of a frame S S, which has a motion on an axis formed by the points of two fcrews, T, T, paffing through ftuds projecting from the frame. This frame, and the flider it fupports, can be rendered immoveable at pleafure, by the points of two ftop-fcrews *m* and *n*, which may be alfo fet to allow it any required latitude of motion. In the former cafe, when the frame is fixed ftationary, as we have confidered it in what we have before ftated, the machine is adapted for boring fingle fheaved blocks, the borer, D, perforating the block in the centre. When double blocks are to be bored, the points of the ftop-fcrews *m* and *n* are fet at a proper diftance afunder, and the frame, being held firft to one of them, bores a hole for one fheave, and being then turned over to the oppofite ftop-fcrew, formed a fecond hole at a proper diftance from the firft. The difference of height between the two borers is rather more than the femidiameter of the fheave, becaufe one is level with the centre, and the other, D, is by the end of the mortife, to adjuft this difference for the different diameters of blocks; the frame, S S, has feveral holes in its fides, at fmall diftances apart, to receive the points of the fcrews T, T, and the frame, being pitched on any of thefe different centres, will raife or deprefs the point of the borer, D, to the proper height for the different fized blocks. The fcrew, F, has a lever N, fixed upon the top of it, and loaded at the ends with two weights, in the manner of the fly prefs, and the block being, as before-mentioned, held in its true pofition, the fcrew is forced fmartly down upon it, and by the momentum of the balls preffes very powerfully upon the wood. The fcrew is provided with a fteel ring, fitted upon its point, which has a fharp edge beneath, and this penetrates the end of the block, deeply marking a ring round in it, which is exactly in the centre of the end, and is ufed to fix the block in a proper pofition in fome of the fucceeding machines. The blocks, being thus bored, are fubjected to the action of

The Mortifing Machine, which cuts out the mortifes for the reception of the fheaves. It is delineated in *Plate* V. where *fig* 3 is an elevation in front, and *fig.* 5 a vertical fection of the lower parts taken parallel to the former; *fig* 1 a horizontal plan, as is alfo *fig.* 4 at a different level; *fig.* 3 is an elevation of the whole machine. The machine works as many chiffels as the block is to have fheaves; thefe, as fhewn at A, *figs.* 2 and 3, are attached to a frame B *a a k*, which rifes and falls with great velocity, forcing the chiffels through the block X, fixed in a carriage C D, which advances after every cut the chiffels have made, the thicknefs of the chip, it is intended to cut out of the end of the mortife at the next ftroke. But this advancing movement of the carriage ceafes as foon as the mortife is enlarged to its proper length. The reciprocating motion of the frame for the chiffel is occafioned by a crank *d*, on the end of the main axis E, which is fupported in bearings at each end, one in a crofs-bar, F, of the frame, and the other in a ftandard G, which is erected from the caft iron ground fill, which is the foundation of this whole machine. The axis has a rapid rotatory motion communicated to it by an endlefs ftrap, encompaffing the pulley H, and the velocity of the motion is regulated by the fly-wheel I. The crank, *d*, has a fpear or connecting rod, K, jointed to it, and connected by a joint at the upper end with the fliding frame B, which is formed to a triangle at top, and has a cylindrical rod, *k*, rifing from its vertex, and accurately fitted into a focket, fupported by framing, erected on the top of the main columns which form the framing. The fides of the lower part of the frame, B *a a*, are formed into dovetail fliders, and received into grooves in the edges of metal bars *b*, *b*, *fig.* 3, attached by fcrews to the vertical pillars of the frame. By this means the frame flides freely up and down, without being capable of any deviation from the perpendicular, and the chiffel, being firmly fixed to it, moves in the fame manner when they defcend into the mortife. The frame has two bars, *a*, *a*, acrofs it, againft which the chiffels, A, A, are held, by means of a clamp provided to each, which lies behind the bars, and its two ends, *z*, *z*, come over them in front, with holes to receive the chiffels and fcrews to faften them. By means of thefe fcrews, the chiffels are preffed forcibly againft the bars, and attached to the frame, but in fuch a manner that they can be fixed at any diftance afunder, or any number may be put on at pleafure, by their refpective clamps, to mortife either fingle, double, or threefold blocks. The carriage C D, in which the blocks are fixed, is an iron frame, fliding on proper bearing in the main frame, and the advancing movement is communicated to it by means of a fcrew L, fitted through a nut in the centre of the ratchet wheel M, which turns round in a focket, formed in a crofs bar, N, of the framing: thus, when the wheel is turned round, it operates upon the fcrew to advance it, with the carriage and block at the fame time: the ratchet wheel is turned round at intervals, by means of a tooth, formed in a rod *e*, *fig.* 5, attached by a joint to the end of a bent lever O, which receives its motion by the other end of the lever, having a roller *g*, which applies itfelf to the circumference of an excentric circle or camm, *h*, fixed on the main axis E. By this means, at every revolution of the main axis, the rod, *e*, moves backwards and forwards, and in the period when the chiffels are nearly at the height of their afcent, the tooth of the pall or rod, *e*, turns the ratchet wheel one tooth, and by the fcrew, L, advances the carriage and block the thicknefs of the chip, the chiffels are intended to cut from the end of the mortife, at the fucceeding ftroke. The ratchet wheel, M, has a cog-wheel, P, fixed to it, which has its teeth engaged by a fmaller cog-wheel Q, fixed on a long fpindle R, extending to the front of the machine, and has a handle, S, fixed upon it, by means of which the workman can, at any time, turn the wheel round fo as to bring the carriage to the proper point for the commencement of the mortife. The motion of the fcrew is caft off at the proper time by this means; the rod is fupported at its extremity, by refting upon the extremity of a lever *n*, the oppofite end of which is moveable on a centre pin fixed in the column of the frame. This lever is fupported by a fecond lever *i*, moving on a centre in a fmall ftandard erected

 for

for it. The oppofite end, *o*, of this lever is loaded with a heavy end, that will overbalance the lever, *n*, and rod *e*, and lift them up, fo that the tooth of *e* paffes clear over the teeth of the ratchet wheel, without interfering with them, and in this ftate the carriage is at reft. The end, *o*, of the lever *i o*, when the machine is mortifing, is fupported upon a ruler of iron *p*, *fig.* 3, which is faftened by fcrews to the fide of the carriage C D. This fuffers the rod, *e*, to defcend fo low, that its tooth turns the wheel round at every revolution, and advances the carriage; but when it has proceeded the length of the intended mortife, the ruler gets beyond the heavy end of the lever *n o*, which drops down and relieves the fcrew from any farther motion, fo that there is no danger of cutting the mortife longer than is proper.

A very ingenious part of this machine is the contrivance for giving it motion or ftopping it at pleafure. The fly-wheel I, and alfo the pulley, H, for the ftrap, are fitted upon a round part of the main axis E, fo as to flip round freely thereon, when the machine is to be at reft. When it is to be worked, the pulley and its axis are united by a wheel R, *fig.* 1, fitted on the axis by means of fillets, fo that it is conftrained to turn round with the axis, but has liberty of fliding along it. The latter motion is given to it by a lever, V, extending acrofs the frame, to which it is connected at one end by a centre pin, and in the middle it has an aperture large enough to receive the centre piece of the wheel R, in which a groove is turned to admit the points of two fcrews *v*, *v*, which operating in the fides of the groove, confine the wheel endways upon its axis; but the wheel turns round without interference with the lever. The wheel, R, is formed conical upon its edges, and can be by the lever, &c. jambed to fit in a fimilar cone formed withinfide the pulley H. In this ftate, the friction of the two conical furfaces is fufficient to turn the machine; but when the wheel, R, is drawn back on the axis, fo that its conical edge is difengaged from the conical cavity formed within the pulley H, the fly-wheel flips upon the axis at the fame time the cone on the back of the wheel, R, is jambed into an iron ring, W, firmly fixed to the frame. It is formed conical withinfide, in the fame manner as the infide of the pulley H, and when the wheel is jambed into it, fixes the axis motionlefs. This is a very proper provifion, as the friction of the fly-wheel running fo quickly upon its axis, when it is caft off, might be fufficient to move the machine flowly, and the momentum it acquires would, in addition to this, keep it in motion for fome time; but the conical wheel being jambed in the fixed ring, W, as foon as it is withdrawn from the pulley, deftroys the motion of the machine at once.

The chiffels are provided with fmall teeth *r*, *r*, *fig.* 6, which are fitted into dovetailed notches formed in the blade of the chiffel. Thefe are called *fcribers:* they have a fharp edge projecting a fmall diftance beyond the infide edge of the chiffel, and, therefore, in defcending through the mortife, the fcribers cut the fides of the mortife fair, and cut two clefts which feparate the chip (which will be cut out at the next ftroke) at its edges from the infides of the mortife, fo that the chip comes out clear without fplitting at the edges, and this makes the infides of the mortife as clean and fmooth as poffible. Each chiffel has a piece of fteel *t*, *fig.* 6, fixed on before the edge, by a fcrew which projects from the middle of it, and is fcrewed into the blade of the chiffel: the upper end of the piece being received in a notch or groove formed in the chiffel attaches it faft thereto. This piece, or nofe, is for the purpofe of clearing the chips out of the mortife as faft as the chiffel cuts them; for though, in general, when the fcribers are in proper order, the chips fall down through the block like pieces of pafteboard, yet it may happen that they will ftick in, and then without this nofe-piece would clog up with the chips, fo that the chiffel could not be got down through them. The block is faftened into the carriage by means of a fcrew *r*, which has on the point of it a ring of the fame dimenfions as that on the fcrew of the boring machine, and is inferted into the impreffion made in the end of the block by that ring There are three of thefe fcrews, for the purpofe of holding one or more blocks at the fame time. The centre fcrew is ufed for fixing one double or threefold block; or, the two other fcrews are ufed, when two fingle blocks are to be fixed in at the fame time. The centre fcrew is then ufelefs. By means of thefe fcrews, the true pofition of one end of every block is determined, fo that it will fall exactly beneath the chiffel A. The other end of the block is gauged into its place by ftops: thefe are attached to a crofs-bar, 1, placed acrofs the carriage, its ends being received into notches made in the fides, and thefe notches afford the means of fixing the bar at any place correfpondent to the length of the block which is to be mortifed. Againft this crofs-bar, the ends of the blocks are preffed by means of the fcrews *r*, *r*, and oppofite to each is a fharp-edged fteel ring to penetrate and hold faft the block: but to prevent it from turning round, on thefe two rings as a centre, each of the rings fixed on the crofs-bar has two fmaller rings infcribed within it, which alfo penetrate the wood, and thus faften the block in the firmeft manner. This is fhewn at *fig.* 5. The gauges before-mentioned, for guiding the block to its true fituation, are formed on a piece of iron 2, which has two arms, 3, 3, projecting from it. Thefe have other arms rifing from them at the ends in a vertical pofition, and againft thefe one fide of each block is applied to make it vertical. A fmall piece of iron 4, which is fitted upon two vertical pins 5, 5, and can flide up and down upon them, and faften at any elevation by means of two clamp fcrews, forms the guage for the height of the block, and is by thefe fcrews adjuftable for blocks of different breadths. The two arms, 3, of the piece 2, are formed at the fame diftance afunder as the fcrews, *r*, in the front of the carriage, fo that when one is fet in the pofition for a block to be held by one fcrew, the other block will be at the proper place for the other fcrew. The adjuftment for the different thickneffes of the blocks, is made by fliding the whole of the piece, 2, endways, for which purpofe the fcrew which faftens it to the crofs-bar 1, paffes through a groove in the piece which admits this adjuftment, and gives means of faftening it at any place correfponding with the thickneffes of the blocks.

The operation of the mortifing machine is as follows: the block brought from the boring machine has the point formed by the fcrew thereof applied to the end of one of the fcrews at *r*, *r*, in the carriage of the mortifing machine, and by fcrewing it tight, the block is fixed between its point and the double circle points before mentioned on the crofs-bar 1, and the ftops fituated on this bar guide the block to its proper pofition, which is, that the hole bored for the commencement of the fheave hole fhall be vertical. The block being thus fixed, the handle, *s*, is turned till the hole is brought beneath the chiffel A. The machine is now put in motion with the lever V, as before defcribed, by jambing the wheel R into the cone within the pulley H of the fly-wheel. At the firft defcent of the chiffels, they cut down through the whole depth of the holes previoufly bored, fo as to cut a flat fide to them. When they rife up, the excentric, circle *b*, moving the bent lever and rod, *e*, moves the ratchet wheel M round one tooth, and advances the block a very minute quantity forwards from the fly-wheel, fo that the chiffels, in defcending, cut a frefh fpace, and, in afcending, the block advances; and in this manner it proceeds with aftonifhing rapidity through the whole length of the intended mortife,

mortife. At this time, the loaded end, *o*, of the lever, *i o*, drops off the ruler fixed at the fide of the carriage C D, and rifes the levers *n* and *e*, fo that the farther advance of the block is prevented. The attendant to the machine, as foon as he obferves this, ftops the motion by moving the lever V, and he takes care to do it at the inftant when the chiffels are at the higheft point, which is effected by a dextrous movement, for the fixed cone, W, ftops the machine inftantaneoufly.

The finifhed block is now removed, and a frefh one put in the handle, *s*, turned back to return the carriage, and bring the block to the proper point, when the machine is ftarted, and proceeds as before.

Three mortifing engines of different dimenfions are ufed at the mills, correfponding with the different fizes of blocks to be manufactured. The fmalleft and largeft of thefe is what we have defcribed in our *Plate*. The intermediate machine was made before the others, and with fome difference in its conftruction, though none in its effect. The motion of the fliding frame for the chiffels is communicated to it by means of a long working beam or lever, extending the whole length of the frame at the top of it. At one end, it is united by a connecting rod with the chiffel frame; and at the other, it is fixed to an axis, which is fupported by the framing, and which forms its centre of motion. A connecting rod is joined to it in the middle of the beam; and the lower end of this is worked by a crank, formed in the middle of the main axis, which is fituated in a direction perpendicular to that which we have defcribed, and is fupported in the framing. It is provided with the cone for cafting off the movement. This machine operates equally well with the others, from which, indeed, it does not differ in any effential point. But the movement of the machine we have drawn, is that which is moft complete, and lefs fubject to violent ftrain in any part. The engine with the beam acts with furprifing rapidity, as it makes upwards of 400 ftrokes *per* minute, at every one of which it cuts out a chip from each mortife as thick as pafteboard. Its movement is fo extremely quick, that the chiffels cannot be diftinctly feen when it is at work, and the mortifes are obferved to lengthen, and chips fall out without any evident caufe. The blocks, being thus mortifed, have their angles fawn off, as a preparation to giving them their elliptical figure, by

The Corner Saw.—This is a circular faw, fhewn at *figs.* 8 and 9 of *Plate* IV. where *fig.* 7 is a plan of the bench, *fig.* 8 a front elevation, and *fig.* 9 an end fection. In thefe, A is a circular faw, fixed upon a fpindle *a*, mounted in an iron frame B, like a lathe fpindle, and turned by a band round the pulley C. The block is placed upon an inclined table D, which prefents it to the faw, fo as to remove a proper portion of the angle, and prepare it for the fhaping engine, which forms the exterior furface of the block. The block lodges againft the ledge, E, of the table, which guides it whilft it is fawn, by keeping it to the fame diftance from the faw. It is accommodated for blocks of different dimenfions, by placing wooden rulers of proper thickneffes againft the ledge E, to bring it near to the faw. In one of thefe machines, the ledge, E, is fitted with connecting bars in the ftyle of a parallel ruler, fo that it can be fixed at any diftance from the faw, but always parallel thereto. The faw is fixed on a chuck, which is attached to the fpindle for fawing, fo that it can be quickly removed to fharpen the faw.

The Shaping Engine.—The fhaping engine confifts of a double wheel, called its *chuck*, in which ten blocks are fixed at once. Thefe being turned rapidly round, a gouge is fixed fo as to intercept them, and form their external furfaces to fegments of the circles in which they all revolve. This is the general principle of the machine. Its particular conftruction is explained by *Plate* VI. where *fig.* 1 is an elevation; *fig.* 2, an edge view; and *fig.* 3, a plan. The detached figure parts we fhall foon explain. The feparate figures at X and Y, in the corner of the plate, are introduced to explain the ftate of the block when it is brought to this ingenious machine, and to fhew alfo the change made upon it. *Fig.* X is a front view, and Y an edge view of a double fheave block. The outlines fhew the form of it when finifhed in the fhaping engine, and the dotted lines its form before it is put into it. Thus the four angles are fhewn as cut off in *fig.* X by the corner faw, preparatory to giving it the elliptical figure it is to have. The other view fhews nothing cut off by the corner faw, the whole alteration being made by the fhaping engine. This figure alfo fhews the ftate of the mortifes.

The machine, as before-mentioned, contains ten blocks, which are all fhaped at the fame time, being fitted in a large wheel, or rather, between the circumference of two wheels A A and B B, having a common axis C C. The blocks are fhewn at the letters E, E; and the plan, *fig.* 3. explains the manner in which they are held between the wheels by a fcrew, *a*, having a fteel ring fitted upon the point of it, which is exactly the fame in all refpects as the ring on the point of the fcrew of the boring machine; and the ring of the fcrew *a*, being inferted into the impreffion made in the end of the block, fecures one end; the other is retained by a ring, *b*, of the fame dimenfions, containing two others within it, which enter the impreffion made in the other end of the block by the double rings in the carriage of the mortifing machine, to which they are exactly a counterpart. The double ring, *b*, is formed in the end of a fhort fpindle, fitted in a focket through the rim of the great wheel A, exactly oppofite the fcrew *a*, and has on the outfide of the wheel a fmall toothed wheel *d*. The fcrew, *a*, being tightened up by a winch, the block becomes faftened in between the point of it and the fpindle *b*, as it were in a lathe. The compound wheels A A, B B, or more properly the chuck, as we fhall in future call it, being thus filled with blocks, has a rapid circular motion given to it by means of an endlefs rope encompaffing the pulley, F, on the main axis. Now it is evident that a cutting tool, being prefented to the blocks as they revolve, will form their exterior furfaces to fegments of circles, of the fize of that which they revolve in. This tool, which is a gouge, is held in a fliding reft, fhewn feparately in *figs.* 4 and 5, and is alfo feen in the other figures. It confifts of a dovetailed flider G, accurately fitted into a groove, which is part of a frame H, that is attached to a long metal bar I K, curved to a fegment of a circle; fee *fig.* 1. At one end, K, it is fitted on a centre piece, fixed in a crofs-bar of the frame, exactly beneath the centre of the axis of the chuck: the other end of this bar, which may be called the radius, refts upon a part of the framing L, which is curved to a circular arch, and on this the radius refts, as it fweeps on its centre from one fide to the other of the machine. The flider G, for the gouge *g*, is advanced towards its work by a lever M, having a handle *m*, *figs.* 3 and 4, at one end; and the other is fitted on a centre pin *n*, fixed in a projecting part of the frame of the groove H. To the middle of the lever a fhort connecting bar, *h*, is jointed, and communicates the power of the lever to the flider G, and confequently advances the gouge *g*, which is held in the end of it, towards its work: but the quantity of this advance is determined by a roller *e*, the axis of which is fitted in a focket attached to the flider G: it bears againft a guide or pattern ruler N, which is fupported on two pillars from the frame of the machine. The pattern ruler has fuch a degree

gree of curvature, as ſhewn in the plan, that when the roller, *e*, of the ſlider, G, is kept in contact with it by a preſſure on the handle, *m*, towards the machine, and the whole ſlide reſt is ſwept along its curved reſt L, the edge of the gouge, *g*, will deſcribe that curve which the ſurface of the block is intended to have, as ſhewn by the dotted line at E. The manner of action in this machine is eaſily gathered from what we have ſaid. The chuck being filled with blocks, as before related, the ſliding reſt is moved quite to the end of its ſlider L, and in this ſtate the machine is put in action. The workman now holds the handle, *m*, in one hand, and the long handle, R, (which is attached by a joint to the frame H,) by the other hand: with the former he preſſes towards the machine to keep the roller, *e*, in contact with the ruler N, and by the latter he ſweeps the gouge ſlowly and ſteadily from one ſide of the frame to the other. In this circuit, the edge of the gouge removes the angles of all the ten blocks at once, reducing them on the outſide to the figure of the dotted line E in the plan, which, as before explained, is determined by the curve of the pattern ruler. This being done, the machine is ſtopped, and it is receſſary to turn all the blocks round one quarter upon their reſpective axes to preſent another ſide outwards, that it may be ſhaped to its proper curve in its turn. This is accompliſhed in a very ingenious manner. Each of the ſmall ſpindles, *b*, has, as before ſtated, a ſmall wheel, *d*, fixed upon it, and to every one of theſe an endleſs ſcrew is adapted. The axes of all theſe ſcrews marked *f*, tend to the centre of the chuck, and each has a ſmall bevelled cog-wheel upon it; and all theſe are turned by one large bevelled wheel O, which is fitted upon the main axis, but ſlips round freely thereupon. It has a pin projecting from a part of its circumference, which is detained by means of a ſtop Q, *fig.* 1, jointed to the frame at the lower end, and forked at top, to catch this pin when it is moved on its joint ſo as to approach the wheel; but when thrown back by a ſpring in its joint, into the poſition of the figure, it is out of action. When the blocks are to be turned round one quarter, this ſtop is preſſed towards the wheel, and the pin, by turning the chuck round, catches in the forked top of it, and prevents the wheel from turning. The workman now, by taking hold of the chuck, turns it round four times, as he determines by obſerving a mark made upon one part of the run of the chuck coming oppoſite to ſome part of the framing. In theſe four turns of the chuck, the centre wheel, O, remaining ſtationary, the blocks are, by means of their endleſs ſcrews *f*, turned round one-fourth of a circle, and the next face of each block is turned outwards to be ſubjected to the action of the gouge. But the ſides, now expoſed, being thoſe in which the mortiſes are made, are of a more rapid curvature, being of an elliptical figure, as ſhewn at X, in the corner of the plate, while the former was only ſlightly rounded. To give this difference of curvature, a new moulding ruler, N, is employed. This is fixed immediately beneath the other one, as ſhewn by *figs.* 1 and 2, and the roller, *e*, of the ſlider, G, is adapted to act upon either; its axis being let down in its ſocket, and retained at the proper level to work with either, by a clip or claſp (not ſhewn in the figures,) which enters either of the two grooves formed round in the ſpindle of the roller; and for the purpoſe of elevating or depreſſing the roller, its ſpindle has a head, S, fixed on the top of it. The roller being now ſhifted to the proper pattern ruler and all the blocks, the turning of theſe ſides is performed in the ſame manner as the firſt, but, of courſe, giving it a different curvature correſponding to the difference of the two moulding rulers. The machine is now ſtopped, the blocks ſhifted to another quarter, the guider roller, *e*, returned to its firſt ruler, becauſe the machine is now to form thoſe ſides of the blocks oppoſite to what were firſt done, and therefore the ſame curve. The chuck being again ſet in motion, the third ſide is turned. The movement is now ſtopped, the roller, *e*, ſhifted to the ſame ruler as for the ſecond ſide, and the blocks being turned round another quarter, the laſt ſide is finiſhed, and they are removed from the machine to make way for another ſet.

This ingenious machine is adapted to receive blocks of different dimenſions by the following means: the length of the blocks are allowed for, by placing the wheels, A A, B B, of the chuck at a greater or leſs diſtance aſunder upon their axis C. This is done by the five ſcrews, T, which unite them. The wheel, A, is fixed faſt to its axis, and the other ſlides upon it, to regulate their diſtance; the ſcrews, T, have nuts upon them, both within and without the wheel B, ſo that they hold it quite firmly at the intended diſtance from the other. The next adjuſtment, dependent on the ſize of the block, is that the edge of the gouge ſhall deſcribe its curve at the proper diſtance from the centres of the ſeveral blocks, to make them of the intended dimenſions. This would be adjuſted by placing the pattern rulers, N, at a greater or leſs diſtance from the blocks; or, what has the ſame effect, altering the diſtance between the centre of the roller *e*, which applies to the rulers, and the edge of the gouge *g*. For this purpoſe, the ſocket for the ſpindle of the roller is fitted into a groove in the ſlider G, and is regulated by a ſcrew, P, at the end of the ſlider. The trial is made by ſetting the gouge oppoſite the centre of the block, as in the plan, and turning the ſcrew P, until the edge of the gouge very nearly touches the block in the centre, becauſe it is intended only to take off the corners of the block, little or nothing being removed from the middle. This adjuſtment is neceſſarily made every time the gouge is removed from the ſlider to ſharpen. The gouge is faſtened into the holder, at the end of the ſlider G, by means of a ſcrew, as ſhewn in *fig.* 5.

Three moulding rulers are ſhewn in the figures, though we have only explained the uſe of two. Double and ſingle ſheave blocks of the ſame lengths have both the ſame curvature on the edges in which the mortiſes are, and therefore they may be ſhaped indifferently from the ſame pattern ruler: but conſidering them in the other direction, *viz.* that in which the plan exhibits them, the gouge is required to traverſe its curve at nearly twice the diſtance from the centre of a double block, to that required for the ſingle ſheave; and this is effected by providing an additional pattern ruler for the ſingle blocks: therefore, in the machine as repreſented, one ruler is adapted for ſhaping the edges of either ſingle or double blocks, a ſecond for the outſides of the cheeks of double blocks, and a third for the cheeks of ſingle blocks: all the three rulers can be quickly removed from the machine, and others of a different curvature ſubſtituted, being only fixed by two ſcrews to the pillars which riſe from the reſt L; and a great variety of theſe patterns are provided to ſuit all kinds of blocks, of which an amazing number of ſhapes are in uſe in the navy. As this ſhaping engine is a machine which would be very eaſily applied to other purpoſes, it may not be unintereſting to deſcribe the manner of forming a pattern ruler to ſhape any curve. It is done experimentally by chooſing ſuch a block as is of a proper figure, or forming one by hand to the intended curvature, and fixing it in the chuck; then ſubſtituting any blunt tool in place of the gouge, and fixing a ſharp tracing point on in the end of the centre pin of the roller *e*: a piece of board is fixed in place of the pattern ruler. The tool is now

now applied to the block fixed in the chuck; and being kept in contact with it, while the fliding reft is fwept from one end to the other, the point in the centre of the roller traces a curve upon the board: the block is then to be removed, or turned out of the way. Now by placing the fliding reft fucceffively at different parts of its fweep, and thrufting the flider, G, towards the machine by its lever M, the tracing point will defcribe ftraight lines upon the board, all tending to the centre of the machine, or rather to the centre, K, of the radial bar; and as many of thefe being made at fhort intervals as is thought proper, the board is removed. A pair of compaffes being now opened to the exact radius of the roller *e*, this diftance is fet off, from the traced curve, upon every one of the radial lines, thus transferring the curve as much nearer to the centre as the femidiameter of the roller. A curve is now drawn through thefe points, and the board being cut to it, will have the curve defired, and may be ufed as a pattern to caft a metal ruler from, which being fixed in the fame points as the board was, will fhape the blocks to the form of that which was employed as the pattern for it.

Three fhaping engines are employed for blocks of different fizes: the largeft, which was laft made, is that we have defcribed; the fmaller one is very nearly like it; but the intermediate fize, like the mortifing machine, is of a lefs perfect conftruction, and fhews the progrefs of invention: it holds but a fmall number of blocks, and thefe are turned round on their axes, one by one, by the workman. A circular plate, with four notches in its edge, which are caught by a click, is the gauge for fetting them correctly to one-fourth of a turn each time they are fhifted. Even this machine is a very excellent one for the purpofe, though greatly improved in the fecond and third, which were made by the introduction of the wheels and fcrews for fetting all the blocks together, which is a moft ingenious contrivance.

The large machine has a contrivance, very fimilar to the mortifing machine, for checking its motion as foon as the movement is caft off; for otherwife the momentum of the chuck loaded with blocks would be confiderable. The machine in our plate is reprefented with a wheel, V, upon it, which is furrounded by a brake or gripe: this is relieved from the wheel by a fpring, when the machine is in motion; but when the workman preffes a lever (omitted in the drawing), it encompaffes the wheel by its gripe, and caufes a friction, which quickly ftops the machine. The framing fupports a number of iron bars, which enclofe the chuck as it were in a cage. This precaution is very neceffary to the fecurity of the workman; for if the blocks fhould get loofe, as has once happened, they would be thrown by the centrifugal force with the velocity of bullets, and might do ferious injury. The accident alluded to was occafioned by one of the wheels of the chuck cracking in the rim, fo as to let loofe the blocks, and they all flew out behind the machine, paffing through a window, into the fteam-engine houfe, where they ftruck the governor or regulating balls of it, and broke them in pieces. It is fingular that, in paffing through the window, all the blocks followed each other through the fame pane of glafs with great violence.

Scoring Machine.—We now come to the laft machine in the feries: this is the fcoring machine, which forms the fcore round the block for the reception of the ftrap or rope, by which it is fufpended in the rigging of the fhip. The fcore is a groove, deep enough at the ends of the block to receive one-half of the rope or ftrap, but is diminifhed to nothing where it croffes the pin of the block. The machine is reprefented in *Plate* VII., where *fig.* 1 is a horizontal plan of the upper part of the machine, and *fig.* 2 a plan of that part containing the blocks; *fig.* 3 another plan taken immediately below the former; *figs.* 4 and 5 are elevations of the machine taken in two directions at right angles to each other. Two blocks, in the ftate they are finifhed by the fhaping engine, are fcored at once by this machine: one of thefe is marked Y, the other is dotted. The groove is formed by a circular cutter A B, fituated exactly over each block: thefe cutters are circular wheels made of brafs, and formed round upon the edge. In two oppofite points of the circumference are two openings, as *a*, *a*, *fig.* 4, in which cutters with round edges are fixed to project a little beyond the rim of the wheels, in the manner of a plane iron; and they cut the wood in exactly the fame manner, except that they move in a circle inftead of a ftraight line. Thefe cutters are both fixed on one fpindle C, which is turned by a band round the pulley D, in the middle of it. This fpindle is mounted in a frame E E F F, *fig.* 1, which moves on an axis, F F, centred in the frame, (fee *fig.* 4.) fo that the fpindle has liberty of afcent and defcent by the handle H, but always keeps parallel to itfelf. The blocks are held in a frame erected upon a ftrong plate G, *fig.* 5, and fhewn feparately in *fig.* 2, which fwings on the points of two centre fcrews, *b*, *b*, in the manner of an axis: it is moved by the handle I, and governed by a pendulum K. By this motion, all parts of the blocks can be prefented to the cutters: each of the blocks is faftened in the frame by means of two pins, *d*, *d*, erected from the plate G, the block is preffed with fufficient force to hold it in between thefe by a fcrew *l*, which operates upon a clamp *e*, connected by a joint with the lower plate G. The upper end of this clamp has a half ring formed in it, which catches in the impreffion made in the end of the block by the preceding machines, and thus fixes it, fo that its centre comes beneath the cutter; and as the block is fhaped equally on each fide of its centre, it will affume the true pofition, by being forced between the two pins *d*, *d*, without regard to the fize of the block. The frame, E F, has a curved piece of iron fixed beneath it, which is formed fo as to inclofe the pulley, D, on the lower half, as clofe as it can be not to touch, and is therefore concentric with the axis C. This piece of iron comes down upon the edge of a metal plate L, which is the pattern for fcoring the block, as it regulates the depth to which the fcore fhall be excavated, being nothing at the centre of the block, and deep enough at the ends to bury half the ftrap. The action of this machine is fimple. The blocks being fixed as before mentioned, the workman takes one handle, H and I, in each hand, and by the upper one keeps the curved iron always in contact with the pattern, L, beneath it: at the fame time, by depreffing the handle I, the blocks are inclined, fo that they traverfe beneath the cutters A, B, to form the fcores from their centres to the ends of them, the two pins *d*, *d*, admitting the cutters between them quite to the ends of the blocks, and in depth as much as the pattern, L, allows the cutters to defcend beneath the furfaces of the blocks. Now it will eafily be feen, that by raifing up the handle I, the other ends of the blocks might be fcored in the fame manner, and fo indeed they are in the firft machine that was made, and which is ftill in ufe at Portfmouth: but the objection to the method is, that the cutters cut againft the grain of the wood, fo as to be rough, in the fame manner as when a carpenter planes the edge of a board obliquely to the direction of the grain, if he planes from one end it will cut fmooth, but in the other direction it will cut ragged and rough. To avoid this in the machine before us, the plate G, to which the blocks are immediately fixed, is united to another plate M beneath it, by a centre a centre pin *m*, which is exactly beneath the pattern L, and also in the middle between the two blocks and cutters: on this as a centre, the upper plate, G, turns round, and is detained by a spring catch *n*, which is fixed to the lower plate, and falls into a notch made in a projecting part of the upper plate G, when the two blocks are in their proper position. The first quarters of the scores of two blocks being cut as before described, the workman relieves the catch *n*, and turns the plate, G, half round on its centre, when the catch again detains it in this position, by which the blocks are reversed, having exchanged situations, and their finished ends are outwards; consequently, the other ends, where the screws *l*, *l*, are, are beneath the cutters; the handle I being, therefore, depressed as before, cuts the second quarter of the score, and in the same manner as the first, being in the proper way of the grain of the wood to cut smooth. This completes one half, and the blocks are taken out to be turned the other side upwards, to cut the scores in them by a repetition of the same process as we have described. The axis of the frame, E F, has a lever proceeding from it behind, which is loaded with a sufficient weight to counterpoise the weight of the frame and cutters, giving them a constant tendency to rise upwards, and thus keep out of the way when the handle is left to itself. The pattern L, which determines the depth of the score, and therefore depends upon the curvature of the block, can be quickly removed from the machine, to make way for any other shape being fixed to the plate, G, by only two screws. A great variety of these patterns is required, as well as for the shaping engine, and their curvature is determined by the same means as we have before described of that machine.

The operation of scoring is the last which is performed by machinery upon the shells of the blocks, which are now completely formed, and only require to be rasped and filed to a smooth surface, which the machines will not always do, though they cut them perfectly correct to the intended forms; but the wood is not always so hard and perfect in its texture as to make them smooth, small pits being left in various parts, which require the aid of files and rasps to remove them; though, by a little labour of this kind, they are made as neat as can be wished. The machines will, when their cutters are in order, and the wood of good quality, cut as smooth as any thing can be expected. Of this we are convinced by having seen the performance of a set of working models of these machines, which we hesitate not to say are the most perfect and elegant models that have ever been made of any kind of machines: they are about four times the size of the drawings in our plates, and are all placed upon one large table, so as to exhibit the whole of the operations, as they succeed each other, at one view. A very elegant model of a steam-engine, made on Mr. Maudslay's pattern, actuated the whole. These models are deposited in the Admiralty house, Westminster. They operate in a more precise manner than the large machines, their cutters being kept exceedingly keen, and the wood they work upon being of a harder and better kind. The blocks at Portsmouth are made of elm, which is a very proper wood for them, not being liable to split: the sheaves, as we have before-mentioned, are made of lignum vitæ.

In the operation of dressing the blocks by hand, we must notice a plane, for making the insides of the mortises perfectly smooth and flat; for though the mortising engine will, when in very good order, cut as correctly as possible; yet it is advisable to plane the insides, to be certain that they are not rough, for that would occasion a great friction at the sides of the sheave. The plane is of the same form as a carpenter's, but is made of brass and very thin, that it may enter the mortise. It is fixed projecting horizontally from the edge of a work-bench, and the workman, taking the block by its end, inserts the end of the plane into the mortise, and thrusts it forwards. The plane cuts a shaving from the inside of the mortise, in a direction across the grain, and thus at two or three strokes finishes them, and they are ready for putting together, which completes the blocks. As connected with this subject we shall describe the

Machine for making dead Eyes.—This is a very ingenious and complete machine, and it forms the whole of the article at once. The pieces of wood being sawn to the size, have the holes bored through them in the boring machine, for the reception of the rope which is to be reeved through them. Two of these holes are equi-distant from the centre of the block of wood; and by means of these two holes, it is fixed in the machine, which shapes and scores it at twice fixing. This is represented in *Plate* VII. where *fig.* 6 is a plan of the whole machine, and *fig.* 7 an elevation in front. The frame or bench sustaining it, is omitted, only the working parts being shewn. It is a lathe, to which proper mechanism is added. A B is its spindle, supported between the standards Y, Z, and C the pulley for turning it by a band D. *Fig.* 6 is a chuck, screwed to the end of the spindle: this chuck has a double screw, *a b*, in it; that is, a right and left handed screw, which operates upon two sliders, carrying two round pins, *x*, *x*, which project from the face of the chuck: one of these sliders is moved by the right hand part of the screw, which is the end *a*; and the other by the left hand part, which is the end *b*; and the screw being retained by a collar in the centre of the chuck, the two pins, *x*, *x*, with their sliders, mutually advance or recede, when the screw, *a b*, is turned with a wrench applied to the square ends *a* or *b*, *fig.* 6. By means of these pins, the block, *f*, is readily fixed to the chuck D. The screw, *a b*, is turned till the pins, *x*, *x*, are at the same distance asunder as the two holes in the block *f*, which is then hung on the pins, and the screw being turned, forces the two pins farther from the centre, and thus fastens it firmly to the chuck; and as the pins are always equally distant from the centre, they chuck it always truly. The turning tool, which is a gouge, is applied by a sliding rest, and apparatus of the same kind as that of the shaping engine. E is the circular iron rest on which the tool sweeps, and is supported to bear the pressure of the work. F is the radius bar, turning round on a centre pin, fixed in the frame immediately beneath the work, in the line of the spindle; and this radius is in one piece with the frame H, which is the foundation of the sliding rest. This consists of the dove-tailed slider, G, fitted into a groove formed on the top of the frame H: this slider is advanced to its work by the lever M, which has a handle, *m*, at one end, and the other is fitted on a centre pin, *n*, fixed in an arm projecting from the frame H. N is the shape or pattern ruler, supported by two columns, O, O; and is the roller which applies to the shape when the handle, *m*, is pressed towards the machine, as shewn by a dotted circle in *fig.* 6. The whole rest is swept round on by E, a handle similar to that of the shaping engine, but no part of which is shewn in these figures. The angles of the block are removed by the corner saw before it comes to the machine in which it is chucked, as before-mentioned, and then the spindle, A B, is put in motion. The workman, by the two handles, as before explained, of the shaping-engine, sweeps the tool one quarter round on the centre of its radial bar, F, and the roller applying to the shape, N, gives the dead eye, *f*, its intended curvature. The machine being stopped, the dead eye is removed from the chuck, and reversed; the other side being presented

to

to the tool is ſhaped in the ſame manner : the ſcore now remains to be cut round its circumference. If this was merely a groove all round, it would be eaſily turned by a gouge, but cuſtom has eſtabliſhed, that it ſhall not continue quite round the dead eye, but have one point, (where the ends of the ſtrap are to unite,) left ſolid. This is ſhewn in the plan *fig.* 6, and alſo in the other view, *fig.* 7, by the dotted line, *n*, being the ſolid part. This being the form of the ſcore, it requires ſome particular mechaniſm to cut it, which is effected in this manner ; a ſpindle, P, with a cutter, Q, ſimilar to the ſcoring engine, is mounted in a frame, R S, which moves on a centre at S, ſo as to approach or recede from the work at pleaſure. The ſpindle has a very rapid motion given to it by a band paſſing round the pulley T, and the cutter, being applied to the work, excavates the ſcore as the block and ſpindle are turned round. The depth to which it is permitted to cut is determined by a roller, *d*, ſituated at the end of a rod, which is fitted on the axis, S, of the frame R S, and attached firmly to the frame by an arch V ; in which is a groove to receive a clamp ſcrew, which gives the means of faſtening it at any point, and the roller then becomes a part of the moving frame R S. This roller applies itſelf to a pattern, or ſhape-wheel, W, fixed on the ſpindle, and turning with it. Its figure is circular, except a projecting knob on one ſide, *w*, as ſhewn by the dotted lines in *fig.* 7.

The manner of uſing this ſcoring apparatus is as follows : the ſhaping being performed as before deſcribed, the motion of the ſpindle is caſt off : the workman now goes to the oppoſite ſide of the machine, and taking hold of the frame, R S, by one hand, and the pulley, C, of the ſpindle by the other, then applies the cutter (which before hung back out of the way), at the ſame time turning the work ſlowly round by its pulley : this cuts out the ſcore, the pattern-wheel determining its depth, and the projecting part, *w*, of the pattern-wheel, when it comes round, lifts the cutter out altogether, leaving the ſolid, or unformed part of the ſcore at *n*, as we have before deſcribed.

This machine readily adapts itſelf to receive different ſizes : the two pins *x*, *x*, firſt mentioned in the face of the chuck D, ſcrew into the ſliders of the chuck which are moved by the double ſcrew *a b*, and can be removed to put on any ſize correſponding with the ſize of the holes bored through the dead eye : theſe pins are made hollow, to avoid unneceſſary weight in the moving parts. The ſcrew, *a*, in the chuck will (as before-mentioned) expand the pins to hold any ſized block. The ſcrew *r*, at the end of the ſlider, regulates the poſition of the roller which applies to the ſhape N, and thus adapts to the thickneſs of the dead eye. The operation of this adjuſtment will be underſtood by referring to the ſhaping-machine. The ſhape, N, is readily changed, to make different ſizes, by introducing others of a different curvature : for this purpoſe, it is only held on the pillars O, O, by notches, as ſhewn in the plan, and nuts being ſcrewed upon it to hold it faſt. The ſcore is always in the middle of the dead eye ; and, therefore, for different thickneſſes, the cutter, Q, muſt be ſhifted endways : this is done by ſliding the whole frame, X, ſupporting the centres, S, on which the frame, R S, of the ſpindle moves as a centre ; the ſcrews, *t*, *t*, which hold it, are fitted in grooves to admit of this motion, and the pattern-wheel, or ſhape W, as well as the roller, *d*, which applies to its circumference double the neceſſary width, to allow this variation, without loſing their bearing. The projecting part, *w*, of the pattern-wheel, conſiſts of an iron bridge, ſcrewed on to the rim of the wheel : it is made very light, and has a balance weight on the oppoſite ſide of the rim to balance its weight ; for, if this was not attended to, the rapid revolution of any unbalanced weight would, by its centrifugal force, acting ſucceſſively on all ſides, cauſe a tremor of the whole machine, and a great wear and friction on the centres of motion ; but when truly balanced, the motion is pleaſant and equable.

MACHISCHEVO, in *Geography*, a town of Ruſſia, in the government of Tobolſk ; 36 miles W. of Iſchim.

MACHLIS, in *Natural Hiſtory*, a name uſed by Pliny and ſome of the old authors, for the elk, and alſo for the rein-deer.

MACHONOWHA, in *Geography*, a town of Poland, in the palatinate of Braclaw ; 60 miles E. of Braclaw.

MACHRIANICK BAY, a bay of Scotland, on the W. coaſt of Kintyre. N. lat. 55° 27′. W. long. 5° 43′.

MACHSA, a town of Arabia, in the province of Yemen ; 25 miles E.S.E. of Zebid.

MACHUA, a town of Hindooſtan, in the circar of Sirowy ; 20 miles N. of Jalour.

MACHUL, an inſtrument of muſic among the Hebrews : Kircher apprehends that the name was given to two kinds of inſtruments, one of the ſtringed and the other of the pulſatile kind. That of the former ſort had ſix chords. Though there is great reaſon to doubt whether an inſtrument requiring the aid of the hair-bow, and ſo much reſembling the viol, be ſo ancient. The ſecond kind was of a circular form, made of metal, and either hung round with little bells, or furniſhed with iron rings, ſuſpended on a rod or bar that paſſed acroſs the circle. Kircher ſuppoſes that it was moved to and fro by a handle fixed to it, and thus emitted a melancholy kind of murmur.

MACHYNLLETH, or MACHYNLLAETH, in *Geography*, a market town in the hundred of the ſame name, in the county of Montgomery, North Wales, is ſituated at the conflux of the rivers Dulas and Dovey, 37 miles diſtant from the county town, and 207 from London. It has a claim to high antiquity, being generally ſuppoſed to have been a Roman ſtation, named the Maglona of the Itinerary : many ancient coins have been diſcovered in the vicinity. In this town, Owen Glendwr, in the year 1402, when, from repeated ſucceſſes, he was in the meridian of his glory, aſſembled the eſtates of Wales, and held a parliament ; by which his title to the principality was ſolemnly acknowledged, and he was formally inaugurated ſovereign of Wales. On this occaſion he narrowly eſcaped falling a victim to the hatred of his brother-in-law Dafydd Gam, who attended the aſſembly with intent to aſſaſſinate him ; but his deſign was timely diſcovered. An old houſe, now divided into tenements, is ſhewn as being that in which the parliament was holden. The inhabitants of this town are chiefly employed in handicraft buſineſs ; that of tanning being carried on to a conſiderable extent, as is alſo the manufacture of flannel, and of what are provincially termed webs, and Welſh plains or cottons. Theſe are a coarſe ſort of thick white cloth, made in pieces from ninety to one hundred and twenty yards in length : this article formerly conſtituted a portion of the export trade, but latterly has been appropriated to clothing the army, and for home conſumption. Seven annual fairs are held here, and a weekly market on Wedneſday. The population of the pariſh, which includes, with the town, the townſhips of Is Carreg and Uwch Carreg, was, in the year 1801, returned to parliament as 1825, occupying 372 houſes. Pennant's Tour in Wales. Carliſle's Topographical Dictionary of Wales.

MACIAS, EL ENAMORADO, in *Biography*, a Spaniſh poet, celebrated as one of Love's martyrs, was born in Galicia towards the cloſe of the fourteenth century, and educated in the houſehold of the famous Henrique de Villena, maſter of Calatrava, who was very friendly to him.

 He

He fell in love with a damfel of the fame houfehold; the paffion was mutual, but effectually concealed from all other perfons, and when Macias was abfent, the mafter gave her in marriage to a knight who refided in Porcuna. Macias on his return grew defperate, which occafioned his imprifonment at Arjonilla; here he employed himfelf in making verfes on his miftrefs, fome of which were carried to the hufband; who, in a fit of rage, mounted his horfe with a fpear and fhield in his hand, rode to the prifon, and flew the unfortunate captive as he was finging a fong in honour of his love. Other accounts fay that he bribed the keeper of the prifon to untile a part of the roof, and flew him from above. He was buried in the church of St. Catalina, at Arjonilla, and this fhort epitaph was infcribed on his tomb "Aqui yace Macias el Enamorado." The lance was preferved upon his grave, and fome Spanifh verfes written under it. In fuch cafes, fays the biographer, the Spaniards generally take part with the hufband; but Macias was a poet, and the poets took up his caufe. Their works are full of allufions to this ftory. The fong which occafioned his murder is preferved in the Efcurial, and has been printed by Argote de Molina in his "Nobleza de Andalucia," and by Sanchez in his notes upon the marquis of Santillana's letter. Gen Biog.

MACIECOW, in *Geography*, a town of Poland, in the palatinate of Chelm; 40 miles E. of Chelm.

MACJEJEWICE, a town of Poland, in the palatinate of Lublin; 44 miles W.N.W. of Lublin.

MACIGNO, in *Mineralogy*, the Italian name of a rock, which is employed for the purpofes of building at Florence, and throughout Tufcany, where it is faid to conftitute entire mountains of a ftratified ftructure. Patrin, who calls it "une pierre marneufe et micacée," has given the following account of this ufeful ftone. There are two varieties of macigno with regard to colour; one of them, called *pietra bigia,* is of a greyifh-yellow; the other, denominated *pietra ferena,* of a blueifh-grey colour. This latter, of which moft of the houfes of Florence are built, has the inconvenience of becoming black when expofed to the air, and at length to decompofe. The *pietra bigia*, which contains much oxyd of iron, poffeffes greater folidity, and is lefs acted upon by the atmofphere; it is calculated for the exterior of buildings, while the *pietra ferena* fhould only be employed for the interior.

The upper ftrata in the macigno quarries are more clayey than the others; they refift the action of the fire fufficiently well, fo that they are made ufe of for the conftruction of furnaces and hearths. The fame hills exhibit ftrata or beds, fome of which are of a lefs folid texture than the macigno, and appear often to be nothing but indurated clay; thefe layers are called *bardellone.* The others, on the contrary, are much harder than macigno; they are of a white colour, and bear the name of *pietra forte.* This latter is the ftone which is employed for paving the ftreets of Florence.

Ferber is of opinion, that the two kinds of macigno, together with the *bardellone* and the *pietra forte*, are varieties of one and the fame rock, in which clay, calcareous earth, and mica, are by turns predominating.

The *pietra forte* varies as much as the macigno with regard to colour; it is often greyifh or blueifh-yellow, and fometimes thefe two colours are even united in the fame piece.

In the quarry of Campora, fituated two miles from Florence, and yielding the ftones with which the ftreets of Florence are paved, the pietra forte is difpofed in horizontal layers that have only a few inches in thicknefs, and are fometimes feparated from each other by fimilar layers of bardellone; and not unfrequently a cruft of calcareous fpar, of about a line in thicknefs, intervenes between the latter and the pietra forte. Ferber fuppofes, that it is this calcareous fubftance which, by penetrating into a layer of bardellone, converts it into pietra forte.

Patrin adds, that this ftone exhibits a remarkable appearance in its interior ftructure; which is, that it divides into rhomboids feparated from each other by diffepiments of calcareous fpar. This author is of opinion, that the calcareous and argillaceous particles have been depofited at the fame time; that afterwards a feparation has taken place by elective attraction, and that the calcareous particles, tending to arrange themfelves in rhomboidal forms, have imparted to the pietra forte the fame character which is communicated by them to the fandftone of Fontainebleau.

It is in thefe macigno hills that the beautiful varieties of marle, exhibiting landfcapes, ruins, &c. and known by the name of *Florentine marble*, are found. See MARLE.

The above is all that is known of the nature of the ftone of the neighbourhood of Florence; it fhould, however, be obferved in this place, that the *bardiglione*, properly fpeaking, appears to be a different fubftance from that defcribed by Patrin and Ferber under the name of *bardellone;* the former being the anhydrous fulphate of lime, (anhydrite and würfelfpat of Werner,) on which count Bournon has given a memoir in vol. i. of the Tranfactions of the Geological Society.

MAC-INTOSH, in *Geography*, a county of America, in the lower diftrict of Georgia, between Liberty and Glynn counties, on the Alatamaha river. It is divided into four towns, and contains 2660 inhabitants; of whom 1819 are flaves.

MACK, in *Agriculture*, a provincial term fometimes applied to a fort or kind of grain, or breed of cattle or live ftock.

MACKALLY, in *Geography*, a town of Bengal; 35 miles S.S.E. of Moorfhedabad.

MACKENZELL, a town of Germany, in the bifhopric of Fulda; nine miles N.E. of Fulda.

MACKENZIE, *Sir* GEORGE, in *Biography*, an eminent Scotch lawyer and mifcellaneous writer, was born of a noble family at Dundee in 1636. He ftudied at the univerfities of Aberdeen and St. Andrews, and finifhed the ufual courfe of claffics and philofophy; at the age of fixteen he was fent to Bourges in France, where he paffed three years in the ftudy of the civil law. On his return to Scotland, he was admitted to the bar, and foon became diftinguifhed for his talents as a pleader. He was appointed, in 1661, the advocate for the marquis of Argyle, impeached of high treafon, and fpoke with fo much fervour and boldnefs in behalf of his client, as to draw down upon him a reprimand from the bench. This, however, did not ftop his career, and in a fhort time after he was raifed to a feat on that bench in the criminal court. A piece of fervice which he rendered to the court in 1674, by effecting a reconciliation between the lords of feffion and the faculty of advocates, caufed him to be knighted, made king's advocate, and one of the lords of the privy-council in Scotland. In the contentions of that period the poft of king's advocate, which is analogous to that of attorney-general in England, was equally important and arduous. Sir George, who had embraced the doctrine of paffive obedience, exerted fo much zeal in his new office, that he obtained from the covenanters the title of the "blood-thirfty advocate, and the perfecutor of the faints of God." Notwithftanding this, he introduced into the form of criminal trials feveral alterations favourable to the accufed, and fo far from endeavouring to extend the power of his office, he confiderably retrenched it. Like other

other officers of the same rank, he has been charged with endeavouring to stretch the law of treason, especially in the cases of Baillie of Jerviswood, and the earl of Argyle, the sentence against the latter of whom was rescinded by act of parliament in the reign of William and Mary. When James II. abrogated the penal laws, sir George, who was sincerely attached to the Protestant religion in the episcopal form, resigned his office. The king, however, gladly restored him to his post, when he was convinced of the necessity of pursuing different measures, and he firmly adhered to his master's interest in the subsequent change. He opposed in council the proposed address from Scotland, to the prince of Orange on his landing in 1688, and he wrote also a memorial to that prince exhorting him to adhere to the terms of his declaration. At the convention of the estates he argued very warmly against the declaration of a vacancy in the throne, and the election of William for sovereign, and when he found his opposition ineffectual, he retired to Oxford, where he was admitted a student. He died in London in 1691, and was interred with signal funeral honours in the church-yard of the Grey-friars in Edinburgh. As a statesman, the character of sir George Mackenzie stands high for learning and talents, and he was much esteemed for public and private worth. People of different parties and feelings will judge differently of his political exertions, but his integrity and good intentions seem unquestionable. In the midst of all his public business he found leisure to compose several literary pieces, among which are "Aretino, or a Serious Romance;" "Religio Stoici;" "A moral Essay on Solitude;" "Moral Gallantry," and a play and poems. These pieces gave him the reputation of an elegant writer and sound moralist. As a lawyer, he published "A Discourse upon the Laws and Customs of Scotland, in Matters criminal;" "Idea Eloquentiæ forensis hodiernæ, una cum Actione forensi ex unaquaque Juris Parte," "The Institutions of the Laws of Scotland;" and "Observations upon the Acts of Parliament." As an advocate for monarchy, he wrote "Jus Regium," or the just and solid foundation of monarchy in general, and more especially of the monarchy of Scotland, and several other pieces. As an antiquarian and national historian, he wrote "Observations on the Laws and Customs of Nations as to Precedency, with the Science of Heraldry, as Part of the Law of Nations; and a Defence of the Royal Line and Antiquities of Scotland;" the latter treatise involved him in a controversy with Dr. Lloyd, bishop of St. Asaph, and Dr. Stillingfleet. He wrote a work likewise respecting an union between England and Scotland, entitled "Reflections upon the Advantages and Disadvantages that would happen by an incorporating Union between the two Kingdoms." Besides these, several additional moral and miscellaneous treatises issued from his pen, which demonstrated the fertility and variety of his speculations; and his aptness as a writer on almost all topics. He was the founder of the advocates' library in Edinburgh.

MACKENZIE's *River*, in *Geography*, on the N.W. part of America, rises in Slave lake, runs a N.N.W. course, and after receiving a number of large rivers, discharges itself into the N. sea at Whale island, in N. lat. 69° 14', and between 130° and 135° W. long., its course from Slave lake having been 780 miles. It derived its name from Mr. M'Kenzie, who ascended this river in the summer of 1789. The Indian natives inhabiting the W. side of the river from the Slave lake are the Strong-bow, Mountain, and Hare Indians; those on the E. side the Beaver, Inland, Nathana, and Quarrelers.

MACKERMORE, a small island near the W. coast of Scotland; about five miles E. from the island of Jura. N. lat. 55° 57'. W. long. 6° 43'.

MACKERTER's Head, a cape on the E. coast of the island of Ilay. N. lat. 55° 52'. W. long. 5° 59'.

MACKEY, John, in *Biography*, an Englishman, who followed James II. to France after the revolution, and was admitted by that unfortunate monarch to his confidence, which he scandalously betrayed, by giving information to king William of every secret with which he was entrusted. As an author he is known by his "Picture of the Court of St. Germain," which was published in 1691; and his "Memoirs of the Court of England, in the Reigns of William and Anne," published at the Hague in 1733; this work abounds in curious anecdotes. He died in 1726 at Rotterdam.

MACKNIGHT, James, a learned clergyman of the church of Scotland, was born at Irvine, in Ayrshire, in the year 1721. Having laid a good foundation in grammatical learning, he was at the age of fourteen sent to the university of Glasgow, where he displayed a most ardent thirst for knowledge, and secured to himself the approbation of his tutors. After he had completed the usual course of his studies at the Scotch college, he crossed the sea to Holland, and attended the lectures at the university of Leyden. His favourite study was theology, and on his return to Scotland he was licensed as a preacher by the presbytery of Irvine, and chosen to officiate at the Gorbals, near Glasgow. From thence he removed to Kilwinning, on the invitation of Mr. Ferguson, then minister of that place, and acted for some time as assistant in the duties of the parish. Here he established a character as a judicious and useful minister, and upon a vacancy taking place at Maybole, he obtained that living. He was ordained pastor in the month of May 1753, and continued to discharge the duties of that office full sixteen years. During this period, and amidst his various professional occupations, he composed his "Harmony of the Gospels," and his "New Translation of the Apostolical Epistles." Although the plan of the "Harmony" differed considerably from that of former harmonies, in supposing that the Evangelists have not neglected the order of time in the narration of events, the reception which it met with from the most competent judges was so favourable, that the author undertook a second edition in 1763, with improvements, and considerable additions, which consisted chiefly of six discourses on Jewish antiquities. A third edition was called for in 1804, which was published in two volumes 8vo. In the year 1763, Mr. Macknight published another work of great merit, entitled "The Truth of the Gospel History," which was the fruit of his studies and researches during the intervals between the two editions of his "Harmony." Its great object was to illustrate and confirm the internal, the collateral, and the direct evidences of the gospel history. On account of these publications the degree of doctor of divinity was conferred upon him by the university of Edinburgh. In 1769 he was chosen moderator or president of the general assembly of the church of Scotland, and was in the same year translated to the living of Jedburgh, which he held three years, when he was elected minister of lady Yester's parish in Edinburgh: from this he was translated, in 1778, to the old church, in which he continued during the remainder of his life. Dr. Macknight now devoted his time and talents to the promotion of various useful institutions as well as to the exemplary performance of his pastoral duties. He took a lead in the management of many different charitable institutions, and particularly of the

fund

fund eftablifhed by act of parliament, for a provifion to the widows and fatherlefs children of minifters in the church of Scotland. As an author, Dr. Macknight occupied a confiderable portion of his time in the execution of his laft and greateft work on the apoftolical epiftles. This was the refult of an almoft unremitting labour during thirty years: he is faid to have ftudied eleven hours in each day, and that before the work was fent to the prefs, the whole MS. had been written five times with his own hand. A fpecimen was publifhed in 1787, being his verfion of the epiftles to the Theffalonians: this was fo well received, that in 1795 the whole was given to the public in four large volumes in quarto, under the title of "A new literal Tranflation from the original Greek of all the Apoftolical Epiftles; with a Commentary, and Notes, philofophical, critical, explanatory, and practical." The whole is interfperfed with effays on feveral important fubjects, and to the fourth volume is added a life of the apoftle Paul, which includes a capital compendium of the apoftolical hiftory. Having finifhed this great work, which he had been accuftomed to regard as the grand object of his life, he was defirous of enjoying the remainder of his days free from laborious purfuits, and refufed, though earneftly folicited, to undertake a fimilar work with regard to the acts of the apoftles. He probably felt the powers of his mind failing him, and had prudence and wifdom to obey the voice of reafon and nature; and in a very fhort time after the decline of his faculties became manifeft to his family. Towards the clofe of the year 1799 he caught a violent cold, which was the fore-runner of other complaints that put an end to his life in January 1800. "Dr. Macknight," fays his biographer, "had acquired an early tafte for claffical literature, and ftudied the writers of antiquity with much critical fkill. He was deeply read in metaphyfical, moral, and mathematical fcience. His piety was fincere, rational, and without oftentation, and to be ufeful in the caufe of truth and virtue was his higheft ambition. In that branch of the paftoral office, which in Scotland is called lecturing, and confifts in a familiar expofition of the facred writings, his learning and ability were much admired, and never failed to pleafe as well as to inftruct and edify in a degree which has feldom been equalled. As a preacher, without pretenfions to the graces of elocution, he had a certain earneftnefs of manner, evidently proceeding from the heart, and from a fincere anxiety to be ufeful, which always commanded the attention, and excited the intereft of the hearers." See the Harmony of the four Gofpels, third edition.

MACKREDIPET, in *Geography*, a town of Hindooftan, in Golconda; 30 miles S. of Indelavoy.

MACKREL, SCOMBER, in *Ichthyology*. See SCOMBER.

This fifh was in high efteem among the Romans, becaufe it furnifhed the precious garum. The beft time of taking mackrel is during a frefh gale of wind, which is thence called the mackrel gale. See *Mackrel* FISHERY.

MACKREL. *Horfe*. See SCOMBER *Trachurus*.

MACKUM, in *Geography*, a town of Holland, in the department of Friefland, on the Zuyder fee; 25 miles W. of Bolfwaert.

MACLAURIN, COLIN, in *Biography*, defcended of an ancient family, the poffeffors of the ifland of Tirrie, upon the coaft of Argylefhire, was born at Kilmoddan, in the month of February 1698. His grandfather, Daniel, on leaving his ifland, removed to Inverara, and contributed very much to reftore that town, after it had been almoft entirely ruined in the time of the civil wars. John, the fon of Daniel, and father to the fubject of this article, was minifter of Glenderule; where he was greatly diftinguifhed as a faithful and diligent paftor: he was employed by the fynod of his province in completing the verfion of the pfalms into Irifh, which is ftill ufed in thofe parts of the country in which divine fervice is performed in that language. This gentleman, whofe character was highly exemplary, died within fix weeks of the birth of his fon Colin, the care of whom devolved in a good meafure upon an uncle, Daniel, who was minifter of Kilfinnan. He was ably affifted in the charge by Mrs. Maclaurin during her life, which was extended only to the year 1707, when fhe died, leaving the care of all her children to the management and fuperintendance of an uncle. In 1709 Colin, though only eleven years of age, was fent to the univerfity of Glafgow, where he continued five years applying himfelf with the utmoft diligence to his ftudies. As he was a lad of confiderable abilities, it need not be added that his fuccefs was fully proportioned to his exertions. He was accuftomed to keep a diary, in which he inferted an account of almoft every hour in the day; of the commencement and progrefs of every particular ftudy, enquiry, or inveftigation, and of his converfations with learned men. In Dr. Robert Simfon, and feveral other diftinguifhed fcholars, the youth met with ardent friends, who feemed to vie with each other who fhould moft encourage him in his purfuits by opening to him their libraries, and admitting him into their fociety and moft intimate friendfhip. The genius of this young man for mathematical learning difcovered itfelf very accidentally, when he was only twelve years of age. He met with a copy of the Elements of Euclid, and in a few days made himfelf mafter of the firft fix books without any affiftance, and thence following the natural bent of his inclination, he made fuch a furprifing progrefs, that very foon after he engaged in the moft curious and difficult problems. In his fifteenth year he took his degree of mafter of arts with much applaufe, on which occafion he compofed and publicly defended a Thefis on the power of gravity. He now turned his attention to theology, and having fpent a year in the ftudy he quitted the univerfity, and lived in retirement with his uncle, till the autumn of 1717, when he prefented himfelf a candidate for the profefforfhip of mathematics in the Marifchal college of Aberdeen, which he obtained; and was afterwards the happy means of reviving the tafte for mathematical learning, and raifing it higher than it had ever been in that univerfity. During the vacations of 1719 and 1721, he went to London, and was, in his firft journey, introduced to Dr. Hoadly, Dr. Clarke, the illuftrious Newton, and feveral other eminent men, whofe notice and friendfhip he ever after reckoned the greateft honour and happinefs of his life. In his firft journey he was admitted a member of the Royal Society: two of his papers were inferted in their Tranfactions, and his book, entitled "Geometria Organica," was publifhed with the approbation of their prefident. In 1721 he became acquainted with Martin Folkes, efq. afterwards prefident of the Royal Society, with whom he cultivated a moft entire and unreferved friendfhip, frequently interchanging letters with him, and communicating all his views and improvements in the fciences. In the following year lord Polwarth, plenipotentiary of the king of Great Britain at the congrefs of Cambray, engaged Mr. Maclaurin to become travelling tutor and companion to his eldeft fon, who was then fet out on his travels. After vifiting Paris and fome other cities and towns of France, they fixed on Lorrain as the place of their refidence, where Mr. Maclaurin gained the efteem of the principal perfons of the court. Here he wrote his piece on the percuffion of bodies, which gained the prize of the Royal Academy of Sciences for 1724. The fubftance of this tract was afterwards inferted in his treatife of Fluxions, and is likewife to be found in the fecond book of his "Account of the Difcoveries of Newton." Shortly after they quitted Lorrain, Mr. Maclaurin's pupil was feized with a fever which terminated fatally, to the great grief of the preceptor, who mourned for him as for a companion and the friend of his heart. He immediately returned to Aberdeen; and was in a fhort time, by the recommendation and intereft of fir Ifaac Newton, chofen affiftant to Mr. James Gregory in the profefforfhip of mathematics at Edinburgh. He foon became a very popular lecturer, and feldom had lefs than a hundred young perfons attending his courfe. Thefe, according to their ftandings in the univerfity, he divided into claffes: in the firft he taught the firft fix books of Euclid's elements, plain trigonometry, practical geometry, the elements of fortification, and an introduction to algebra. With the fecond clafs he entered more largely into algebra, read the 11th and 12th books of Euclid; and inftructed them in fpherical trigonometry, conic fections, and the general principles of electricity. The third advanced in aftronomy and perfpective, and read a part of fir Ifaac Newton's Principia, and had a courfe of experiments for illuftrating them performed and explained to them. He afterwards read and demonftrated the elements of fluxions: with the next clafs he read a fyftem of fluxions; and introduced the pupils to the doctrine of chances, and explained the remainder of Newton's Principia.

Befides the labours of his public profeffion, Mr. Maclaurin was engaged in many other important avocations. If a new or uncommon experiment was faid to have been any where exhibited, the curious among Mr. Maclaurin's friends were defirous of having it repeated by him; or if a comet or eclipfe was to be obferved, his telefcopes were always in readinefs. Amidft all the hindrances which he almoft perpetually was experiencing, he continued to purfue his ftudies with the utmoft affiduity, and took from the ordinary hours of fleep, what he beftowed on his fcholars and friends, a circumftance that is thought to have impaired his health and fhortened his valuable life. In 1733, Mr. Maclaurin married Anne, the daughter of Mr. Walter Stewart, folicitor general to king George I. for Scotland, by whom he had feven children; of thefe, five furvived him. In 1734, Dr. Berkeley, bifhop of Cloyne publifhed his treatife entitled "The Analyft," in which he attempted to overfet the doctrine of "Fluxions," and to charge mathematicians with infidelity in matters of religion. This work was the occafion of Mr. Maclaurin's elaborate Treatife on Fluxions, which was publifhed at Edinburgh in 1742, and which is reckoned the moft complete treatife on that fcience that has even yet appeared. He became a very active and diftinguifhed member of the fociety which had exifted fome years at Edinburgh for the improvement of medical knowledge, but which he contrived to extend more generally to the interefts of fcience in all its branches. In conjunction with Dr. Plummer, profeffor of chemiftry, he was appointed joint fecretary, and generally at the monthly meetings either read fome paper of his own, or communicated the contents of letters received from foreign parts, by which means the fociety was informed of all the new difcoveries and improvements in the fciences. He fhewed his zeal for promoting the interefts of fcience, by projecting the building of an "Aftronomical Obfervatory," and a theatre for experiments in the univerfity, of which he drew an excellent plan, and would probably have carried it into execution by the munificence of private perfons, had not the unhappy diforders of the country intervened. In the year 1739, he was confulted by the earl of Morton with regard to the fettling of the geography of the Orkney and Shetland iflands, which had been laid down in the maps without attention to real facts deduced from aftronomical obfervations. He drew up a memorial of what was neceffary to be done, furnifhed the proper inftruments, and recommended Mr. Short, the celebrated optician, as a fit perfon for managing the affair. From the account which he received of this vifit to thofe iflands, he was made more fenfible than before of the errors in their geographical fituation, which have proved the occafion of numerous fhipwrecks, and he engaged feveral of his old pupils, who were then fettled in the northern counties, to furvey the coafts, expecting, as the refult of their obfervations, to obtain a good map of Scotland. He had at this time another fcheme for the improvement of geography and navigation, which was the difcovery of a paffage from Greenland to the South-fea by the north pole: he was fatisfied that fuch a paffage exifted, and would, if his fituation could have admitted of it, have undertaken the voyage at his own expence. A premium was afterwards offered by government for the difcovery of a north-weft paffage, which did not accord with his views, as he was convinced, from all his reading on the fubject, that it muft lie near the pole. In the year 1745, he took a moft active part in favour of his majefty's government, in oppofition to the rebels who were marching to the fouth. By the fatigue and anxiety to which he was expofed by his exertions in this caufe, he laid the foundation of the difeafe which in a few months put a period to his life. When, however, the rebel army got poffeffion of the city, he thought it advifable to make his efcape into England, well knowing that he could not expect mercy if he fell into the hands of the enemy. As foon as he arrived in the neighbourhood of York, he was invited by the archbifhop to refide with him during his ftay, with which he gladly complied, and on account of which he was impreffed with the deepeft fentiments of gratitude. Upon the march of the rebels into England, he ventured to return to Edinburgh, when it was found his conftitution was completely undermined: and that his diforder had already advanced beyond the reach of medicine. His complaint being the dropfy, he was three times tapped, but the operations proved inefficacious, and he died on the 14th of June 1746, having exhibited, through the progrefs of his difeafe, a difpofition worthy of a philofopher and a Chriftian.

Mr. Maclaurin was not only diftinguifhed by his genius and learning, but by the qualities of the heart: by his fincere love to God and his fellow creatures, and by his univerfal benevolence and unaffected piety. His favourite ftudies were the mathematics, which he cultivated with extraordinary fuccefs. His peculiar merit as a philofopher was, that all his ftudies were accommodated to general utility, and in many parts of his works, there is evidently an application of his moft abftrufe theories to the perfecting of mechanical arts. He had refolved, for the fame purpofe, to compofe a courfe of practical mathematics, and to refcue feveral ufeful branches of the fcience from the treatment which they too frequently meet with in lefs fkilful hands. Thefe defigns were prevented by his death: in his life-time, however, he frequently had the pleafure to ferve his friends and country by his fuperior attainments. If any difficulty occurred concerning the conftruction or perfecting of machines, the working of mines, the improvement of manufactures, &c. Mr. Maclaurin was ever ready to refolve them. He was likewife employed to terminate fome difputes which had arifen at Glafgow concerning the gauging of veffels; and prefented to the commiffioners of excife two elaborate memorials, containing rules by which the officers acted, with

with their demonstrations. He made calculations relative to the fund for the widows of the Scotch clergy, and of the professors in the universities, and contributed very much to perfect the scheme which has been found of eminent utility to a vast number of persons who would otherwise have been left destitute of the means of support. But what seems to have endeared his studies to him, was the use they are of in demonstrating the existence and attributes of the Creator, and establishing the principles of natural religion on a solid foundation. To this use Mr. Maclaurin frequently applied them: and he was equally zealous in the defence of revealed religion, which he would warmly vindicate, whenever he found it attacked either in conversation or writing. Besides the works already mentioned, Mr. Maclaurin was author of many papers in the Philosophical Transactions; "On the Construction and Measures of Curves;" "On Equations with impossible Roots;" "On the Description of Curves," &c. He gave an "Account of the Annular Eclipse of the Sun at Edinburgh in January 1742—3." After his death were published his "Treatise on Algebra," and his "Account of sir Isaac Newton's philosophical Discoveries." The first of these is a capital introduction to the science of which it treats. The author's design with regard to the second seems to have been to explain only those parts of sir Isaac's philosophy which have been, and which were, for some time, controverted, which was probably the reason that his discoveries concerning light and colours were scarcely touched on.

Such was the life of this eminent person, spent in a course of laborious study; in continually endeavouring to be useful; in improving curious and useful arts, and propagating truth, virtue, and religion amongst mankind. "He was," says his biographer, "taken from us at an age when he was capable of doing much more, but has left an example, which will be long admired and imitated, till the revolution of human affairs puts an end to learning in these parts of the world; or the fickleness of men, and their satiety of the best things, have substituted for this philosophy some empty form of false science, and by the one or the other means, we are brought back to our original state of barbarity." Account of the Life, &c. of the Author prefixed to the work last-mentioned.

Maclaurin, John, *Lord* Dreghorn, son of the above, born at Edinburgh in December, 1734, was educated at the grammar-school of Edinburgh, and afterwards went through an academical course at the university of that city. He was admitted a member of the faculty of advocates at Edinburgh in 1756. In 1782, a Royal Society was established in Edinburgh, of which Mr. Maclaurin was one of the original constituent members, and at an early period of the institution he read an Essay to prove that Troy was not taken by the Greeks. In 1787 he was raised from the Scottish bar, at which he had practised long and successfully, to the bench, by the title of lord Dreghorn. He died in 1796. As an author we have "An Essay on Literary Property;" "A Collection of Criminal Cases;" "An Essay on Patronage;" and some poetical pieces: besides which we have in the dramatic line ascribed to him, "Hampden;" "The Public;" and "The Philosopher's Opera." During the years 1792, 3, 4, and 5, lord Dreghorn kept a journal, or diary, in which he recorded the various events that happened in Europe during those years. From this journal he made a selection for publication: and in 1799 a selection of his lordship's works was printed in two vols. 8vo. Biog. Dram.

MACLE, in *Mineralogy*. *Macle basaltique, ou schorl en prism quadrangulaires rhomboidaux*, Romé de l'Isle; *Chiastolit*, Karsten; *Hohlspath*, Werner; *Hollow-spar*, Jameson; *Crucite*, Delameth; *Argilla chiastolithus*, Lat. (not of Forster.)

This remarkable mineral has hitherto been found only crystallized; but its forms are very different from those of all other mineral substances we are acquainted with, and not easily determinable.

It is generally found in long, slightly rhomboidal prisms of a yellowish, reddish or greenish colour; each prism is apparently produced by four tabular or prismatic crystals, externally straight and more or less exactly joined, internally more or less separated from one another: the space thus left in the centre of the prism, and varying both in form and extent, is filled up with a black or bluish-black substance; whence a transverse section of the complete prismatic crystal represents a black nucleus, generally of a slightly rhombic figure, from each angle of which a black line runs towards the opposite angle of the external substance, producing a kind of cross, more or less dilated in the centre, (*Macle tétragramme* of Haüy, pl. 51. f. 219.) and generally equally dilated at its four extremities (Macle *pentarhombique*, Haüy, ib. fig. 220.) Sometimes the same black diagonal lines branch out into other lines, (Macle *polygramme*, Haüy, ib. fig. 221.) In the narrow prismatic variety the black substance forms by far the principal part, appearing in the form of a prism, enclosed in a thin case of the same form, and of a yellowish-white colour.

The black rhombic figure in the centre of the horizontal section of the crystals appears at first sight to belong to a prism; but it is generally the section of a pyramid, as is manifested by the increasing or diminishing size of the rhombic spot, according as the transversal sections are made nearer to one or to the other extremity of the crystal.

The crystals are generally middle-sized, sometimes very narrow and acicular; they sometimes adopt a cylindrical form.

Fracture more or less foliated, with a double cleavage; the principal one parallel to the lateral planes of the prism.

It is translucent on the edges, at least in those crystals that have the appearance of feldspar; those that approach to the nature of steatite are opaque.

Hardness variable, according as the substance exhibits the appearances just mentioned.

Specific gravity 2.9444, Haüy; 2.927, Karsten.

Before the blowpipe it is converted into a whitish scoria; the internal black substance melts into a blackish glass.

This substance has not been subjected to chemical analysis.

Macle occurs imbedded in clay-slate. Mr. Buch suspects that the streaked and spotted appearance of some of the varieties of primitive clay-slate, called *frucht* or *kukuk-schiefer*, is produced, not by hornblende, but by minute crystals of macle or hollow spar.

It is found at Gefrees, in the margraviate of Bayreuth; in ci-devant Brittany, in France; and near St. Jago di Compostella, in Galicia. Those of Brittany are more exactly quadrangular. Some of them have about four and a half lines in diameter, and upwards of three and a half inches in length. Those of Spain are generally much thicker, and of a rounded form. According to Haüy, the external surface both of the Spanish and French macles frequently exhibits something of a pearly lustre.

It has also been observed by Lelièvre and Dolomieu in the valley of Bareges, in the Pyrenees; and by Ramond on the plateau de Troumouse, in the High Pyrenees. This substance has also been found by Mr. Davy in the clay-slate of Cumberland, and in the county of Wicklow in Ireland, where it has likewise been observed by Dr. Fitton. Professor feffor Link has found it in the mica flate of the Serra de Marao in Portugal.

The macle has been mentioned by Boëtius de Boot under the name of *lapis cruciger*. It was applied at his time as an amulet for ftopping hemorrhages, &c ; and even at the prefent day it is ufed for feveral fuperftitious purpofes.

Werner confiders this fubftance as nearly related to feldfpar. Dr. Fitton and Mr. Stephens, in their very interefting "Notes on the Mineralogy of Part of the Vicinity of Dublin," fufpect that a connection exifts between the macle and the andalufite (*Feldfpar apyre* of Haüy); the former gentleman, in particular, has convinced himfelf that colour, fracture, luftre, and other characters obfervable in the cryftalline part of the former fubftance, completely agree with thofe of the andalufite.

Macle, *Criftaux maclés*, *Macled cryftals*, are the names by which feveral mineralogifts, and principally Romé de l'Ifle, have diftinguifhed the cryftals with re-entering angles, formed by the union of two diftinct cryftals, producing the appearance of two halves of one fymmetrical cryftal, which in the act of uniting have turned on each other in fuch a manner, that the planes of the upper part of the one correfpond to thofe of the lower part of the other, or nearly fo. Such cryftals are denominated *criftaux tranfpofés* and *hémitropes* by Haüy; and *Zwillings-kryftalle* by Werner.

MACLIN, Charles, in *Biography*, a native of Ireland, probably born in the county of Weft Meath, of a family named M'Laughlin, which was anglicifed to that by which he was ever afterwards known. He was born about the 1ft of May 1690, and in 1708 abfconding from his mother, then a widow, he came over to England. For fome mifconduct with regard to a female connection he was fent back to Ireland. Here he formed an acquaintance with certain undergraduates of Trinity college, Dublin, and took up the employment of bargeman in that college, read much for the improvement of his mind, and remained in that degraded ftate till he had attained the age of twenty-one. He then came to London, made a connection with a ftrolling company of players, and acted the part of harlequin. After leading an extraordinary courfe of life, he was again reftored to his mother, and returned a penitent to his former ftation in Trinity college. In 1716 he arrived in England for the third time, joined a company of players at Briftol, then attached himfelf to feveral ftrolling companies, and afterwards made his entrè at the theatre in Lincoln's-inn-Fields, where his merit was firft difcovered in a trifling character in Fielding's "Coffee-houfe Politician," which, it is faid, would in any other hands have gone unnoticed. He now for feveral fucceffive feafons performed comic characters, and on the tenth of May 1735, had the misfortune to kill Mr. Hallam, an actor in the fame theatre with himfelf, in a private quarrel. He was brought to trial in confequence; but no malicious intent appearing in evidence he was acquitted. In 1741 he eftablifhed his fame as an actor, in the character of Shylock in "The Merchant of Venice," and by his fine and impreffive manner reftored to the ftage a play which had been forty years fupplanted by lord Lanfdown's "Jew of Venice." The manager and performers having about this time difagreed, Maclin, and feveral of the moft eminent of the company, among whom was Garrick, revolted, and figned a formal agreement, by which they were bound not to accede to any terms which might be propofed to them by the patentee, without confent of the fubfcribers. The feceders applied, but without effect, for the grant of a new patent, of courfe they found themfelves under the hard neceffity of agreeing to the terms offered by the manager, who afcribed the revolt of the players to the influence and fuggeftion of Maclin, and refolved to punifh him for his ingratitude. To the others he was reconciled, but the fentence of eternal banifhment from his theatre was pronounced againft the man who had been once his friend and adviser. A change in the management, by which Mr. James Lacey fucceeded Fleetwood, reftored Maclin to his ufual employment. This was in 1747, and in the following fpring he accepted an invitation from the manager of the Dublin theatre, by which he engaged his fervices for two years, but fcarcely had he gone through the duties of his ftation a fingle month, when he took offence at fome inftances of fuppofed neglect, which ended in a feparation from that concern. After various incidents, he, in 1753, obtained from Mr. Garrick the ufe of his theatre for a fingle night, and took a formal leave of the ftage, in a prologue written for the occafion, in which he introduced his daughter as an actrefs to the protection of the public. He now projected the eftablifhment of a tavern and coffee-houfe which was to make his fortune: this he foon after converted into a debating and fpouting club, under the name of "The Britifh Inquifition:" but Maclin was wholly unfit for the bufinefs of a tavern-keeper, became a prey to every needy and unprincipled villain, and, in Feb. 1755, was feen in the lift of bankrupts. On his examination before the commiffioners every thing turned to his character, except that he had been miferably deficient in prudence, and in the end he paid twenty-fhillings in the pound. He next joined Mr. Barry in founding a new theatre in Dublin, where, however, he did not remain more than two or three years, and in 1759 he returned to London and made an engagement at Drury-lane, at a very confiderable falary, and brought out his farce of Love a-la-Mode, which, though oppofed at firft, was received in London and at Dublin with unbounded applaufe. Maclin in a fhort time transferred himfelf from Drury-lane to Covent Garden theatre, to which he continued uniformly attached. He obtained great and almoft univerfal and unbounded applaufe as an actor in comedy, but in 1773 he was determined to attempt the character of Macbeth in tragedy; in this new line he gave full fatisfaction to his friends, but the public, headed by a few violent fpirits, probably his perfonal enemies, were fo much enraged at his attempting tragedy, that for a long time they would not admit him in his own comic parts, and he was formally difmiffed from the theatre. In 1775 he brought his action againft his opponents, and having obtained a verdict in his favour, he willingly relinquifhed the damages awarded in his favour upon the moft liberal terms, a circumftance which drew from lord chief juftice Mansfield the following handfome and well-turned compliment; "You have met with great applaufe to-day: you never acted your part better." From this period Maclin occafionally performed and paid a vifit to Dublin during Mr. Daly's management. In 1788, and again in 1789, while acting his favourite characters, he fuddenly loft his memory, and in the fecond inftance he refolved to make no other effort; but by the advice of his friends he publifhed by fubfcription his two pieces "The Man of the World;" and "Love a-la-Mode:" by the exertions of Mr. Murphy, who fuperintended the printing, and his other friends, 1500*l.* was raifed, with which an annuity of 200*l.* was fettled on himfelf, and 75*l. per ann.* on his wife, if fhe furvived him.

Mr. Maclin died on the 11th of July 1797, at the age of 107, if he were born at the period before-mentioned, but of this the reader fhould be apprized there were fome ferious doubts entertained. His remains were interred under the chancel of Covent Garden church. Mr. Maclin, fays his biographer, was in his private character a tender hufband, a good father, and a fteady friend. To his firmnefs and refolution

lution in supporting the rights of his theatrical brethren, it was owing that they have been relieved from a species of oppression to which they had been ignominiously subjected for many years, whenever the caprice or malice of their enemies chose to exert itself. We allude to the prosecution which he carried on against a set of insignificant beings, who, calling themselves "The Town," used frequently to disturb the entertainments of the theatre, to the terror of the actors, as well as to the annoyance and disgrace of the public. As a comedian his principal and most important parts were sir Gilbert Wrangle in "The Refusal;" sir Archy M'Sarcasm in his own farce of "Love a-la-Mode;" and sir Pertinax Mac Sycophant in "The Man of the World," written also by himself, and first brought forward in 1781. Maclin also made a fine figure in the character of Shakspeare's Iago; but the part in which he was allowed to shine without a competitor was that of Shylock. Besides the dramatic works already referred to, Maclin wrote a tragedy of "King Henry VII. or the Popish Impostor;" "A Will or no Will;" "The suspicious Husband criticised; or the Plague of Envy;" "The Fortune Hunters;" and some other pieces. Biog. Dram.

MACNEN-ABAD, in *Geography*, a town of Persia, in Segestan; 111 miles S.S.E. of Zareng.

MACOGUA, a fort on the W. coast of Africa, at the mouth of the St. Domingo river. N. lat. 12° 20′.

MACOKETH, or MACOKETCH, *Great*, a river of America, which runs into the Mississippi from the north-west, in N. lat. 42° 23′. *Little Macoketch* falls through the E. bank of the Mississippi about 45 miles above the mouth of the former.

MACOLOE, one of the Querimba islands, in the Indian sea. S. lat. 11° 10′.

MACOMER, a town of the island of Sardinia; 16 miles W. of Bosa.

MACON, a town of France, principal place of a district, and capital of the department of the Saône and Loire, near the Saône; before the revolution the metropolis of a small country called the "Mâconnois," which was formerly a county and the see of a bishop. It contained four churches, a commandery of Malta, seven convents, a college, and an hospital. Its trade is considerable. The place contains in two cantons 5807, and the cantons 20,252 inhabitants, on a territory of $177\frac{1}{2}$ kiliometres, in 28 communes. N. lat. 46° 18′. E. long. 4° 55′.

MACONDEGAY ISLANDS, three small islands in the bay of Gunong-Tellu, on the E. coast of the island of Celebes. S. lat. 0° 30′. E. long 120° 25′.

MACONIA, a town of Pegu; 20 miles S. of Pegu.

MACOPIN, a small river of America, which runs from the S.E. into the Illinois, 18 miles from the Mississippi, 20 yards wide and navigable nine miles in the hills: the shore, which is low, is covered with maple, ash, button-wood, &c.: the land abounds with timber, and is overrun with high weeds.

MACORIZ, a small river on the S. side of the island of St. Domingo; 16 leagues E. of the city of St. Domingo.

MACOTERA, a town of Spain, in the province of Leon; 18 miles E. of Salamanca.

MACOTTO, a town on the S. coast of the island of Luçon. N. lat. 13° 12′. E. long. 123° 8′.

MACOU, a town of Persian Armenia; 75 miles S. of Erivan.

MACOUBA ST. ANN, LE, a town of the island of Martinico. N. lat. 14° 54′. W. long. 61° 17′.

MACOUBEA, in *Botany*, occurs only in Jussieu and Aublet, the former having taken it from the Supplement of the latter author's work on the Plants of Guiana, where it is figured in t. 378.—The only parts of fructification with which they were acquainted, are *Peric.* Capsule orbicular, slightly compressed, sometimes obtusely triangular, of one cell; hollow within-side; rough, reddish and marked with grey spots on the outside. *Seeds* numerous, oblong, incurved, obtuse, convex above, furrowed below, inclosed in a white membrane, and attached to the internal coat of the pericarp. —*M. guianensis* is a *tree* rising to the height of forty feet. Its *wood* is of a greenish-yellow, and in drying has a disagreeable smell. *Leaves* opposite, on footstalks, ovate, acute, entire. *Fruit* as big as oranges, in clusters, at the divarications of the branches. The whole tree abounds with a milky juice.—Aublet found it in the woods of Guiana, bearing fruit in February. Jussieu places *Macoubea* in the natural order of *Guttiferæ* on the authority of Aublet's description.

MACOUCOUA, is the Caribbean name of the plant in question, as we learn from Aublet.—It is noticed by Jussieu as nearly allied to *Ilex*, but figured by Lamarck under its vernacular and generic name.—Aubl. Guian. 88. Lamarck Dict. v. 3. 669. Illustr. t. 75. Juss. 379.—Class and order, *Tetrandria Monogynia*. Nat. Ord. *Rhamni*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, cloven into four, short, acute segments. *Cor.* of one petal, tubular, standing upon the receptacle; tube very short; limb divided into four, roundish lobes. *Stam.* Filaments four, within the divisions of the corolla; anthers roundish, of two cells. *Pist.* Germen superior, very small, roundish; style none; stigma obtuse. *Peric* and *Seeds* unknown.

1. M. *guianensis*. Aubl Guian. t. 34. Lamarck Illustr. t. 75. The only species known. A native of woods in Guiana and Cayenne, flowering in February.—The *trunk* of this tree is thirty or forty feet in height, much branched. *Bark* thick, hard, brittle, white externally. *Leaves* alternate, nearly sessile, polished, oval, obtuse and sometimes ending in a sort of jagged point. *Flowers* corymbose, axillary, on footstalks, white. Fruit unknown.—The natives use the bark of this tree merely for fuel.

MACOURIA, in *Geography*, a river of Guiana, which runs into the Atlantic, N. lat. 5°. W. long. 53° 46′.

MACOWAL, a town of Hindoostan, in the circar of Sirhind; 50 miles N. of Sirhind.

MACOYAQUI, a town of New Mexico, in the province of Mayo; 70 miles E.N.E. of Santa Cruz.

MACPHERSON, JAMES, in *Biography*, a modern writer of some celebrity, was born, in 1738, at Ruthven, in the county of Invernefs. He studied at the universities of Aberdeen and Edinburgh, and while he was a resident at the latter, he published a poem, entitled "The Highlands," which displayed some genius, though undisciplined by good taste. He was intended for the church, but never entered upon its duties. In 1760 he was living as private tutor in the family of Mr. Graham, of Balgowan, and about this time he published "Fragments of Ancient Poetry, collected in the Highlands of Scotland, and translated from the Gaelic and Erse Languages." The singularity of these pieces, the novelty of their style and imagery, and the idea that they were the product of a remote age and rude people, caused them to be received with great interest by many lovers of poetry; and as hopes were given that other works of the same kind might be recovered, a subscription was set on foot to enable Macpherson to leave his employment, and visit the Highlands for that purpose. The result of this mission, or of his own leisure, was the epic poem of "Fingal," and several other pieces, which were said to be composed compofed by Offian, the fon of Fingal, king of the Highlands. An animated controverfy was foon kindled relative to their authenticity: the Scotch were, in general, on the fide favourable to the national honour; but many learned and able writers in the fouthern part of the ifland rejected their claims to the antiquity affumed. The arguments urged againft their authenticity, were drawn from the improbability of the exiftence and prefervation of regular epic poems among an uncivilized people who had not the ufe of letters; the abundance of poetic ornament, and the elevation and delicacy of moral fentiment, together with the freedom from all mixture of puerility and extravagance. Whatever was their origin, they met with a number of enthufiaftic admirers, and were tranflated into feveral languages: they were commented upon by critics, and admitted as evidence of manners, habits, and cuftoms by hiftorians and antiquarians. The blind Offian was placed in company with the blind Homer, and the wild mountains and heaths of the Highlands were converted into claffic ground. The originals were now loudly called for, and indirect promifes made that they fhould appear, till at length the fuppofed tranflator, inftead of convincing or conciliating the fceptical, attempted to filence them by a tone of infolent affumption. The controverfy, however, continued during the life of Macpherfon, and is not, indeed, at this moment completely terminated, there being ftill advocates who juftify the claims of Offian as the real author of the works publifhed under his name. Dr. Aikin, in the General Biography, obferves, that the late mafterly difcuffion of the topic by Mr. Lairy feems to have produced a general opinion, that at leaft the great mafs of the poems is modern fiction; and curiofity is now moftly limited to the enquiry how far it may have had a foundation in the traditionary ftories ftill current in the Highlands. In 1764, Mr. Macpherfon was taken by governor Johnftone to Penfacola, in Florida, as his fecretary. After executing his office in fettling the government of that colony, he vifited feveral of the Weft India iflands, and fome of the North American provinces, and returned in 1766. Refuming his literary purfuits, he publifhed, in 1771, "An Introduction to the Hiftory of Great Britain and Ireland," which is elegantly written, and contains much valuable matter. He next publifhed a fort of profe tranflation of Homer, which obtained for him neither fame nor profit, and was foon difmiffed to total oblivion. He now devoted himfelf wholly to hiftorical and political compofition, and in 1775 publifhed "The Hiftory of Great Britain from the Reftoration to the Acceffion of the Houfe of Hanover," in two volumes, quarto. This was at the fame time accompanied with two other volumes of original papers, ferving as documents and authorities for the hiftory. Although the author difcovered a confiderable predilection for the Stuart family, and appeared to place too much confidence in the reprefentations of facts made by James II. in the manufcript memoirs of his own life, yet it certainly made a valuable addition to the knowledge of that period of Englifh hiftory. Mr. Macpherfon next engaged in political warfare, and when the refiftance of the Americans called forth the pen, as well as the fword of authority, he was engaged as one of the ableft. He publifhed a pamphlet, entitled "The Rights of Great Britain afferted againft the Claims of the Colonies," for which he obtained great credit, on account of the ftyle and argument: it was very induftrioufly circulated by the agents and adherents of government. This was printed in 1776, and in 1779 he wrote "A Short Hiftory of the Oppofition during the laft Seffion of Parliament," which was highly commended. His fervices were not neglected, and he received from thofe, whofe caufe he vindicated, the lucrative poft of agent to the nabob of Arcot, whofe concerns with the Eaft India company were, at that period, very perplexed. Mr. Macpherfon did not receive the emoluments without performing the duties of his office, and wrote feveral appeals to the public in behalf of this potentate; and it being judged neceffary that the nabob fhould have a reprefentative in the houfe of commons, he was returned, in 1780, to ferve in parliament for the borough of Camelford, and was re-elected in 1784 and 1790. After this we find that his health was in a declining ftate, he retired to a feat which he had built, called Bellevue, near Invernefs, where he died, in February 1796. His remains were depofited in Weftminfter Abbey: he bequeathed 300*l.* to be laid out in a monument of him, to be erected at Bellevue; and 1000*l.* to defray the expence of printing and publifhing the original Offian. Gen. Biog.

MACPHERSON'S *Strait*, in *Geography*, a channel in the Mergui Archipelago, between Banks's ifland and St. Sufanna. N lat. 10° 37'.

MACQUER, JOSEPH, in *Biography*, a phyfician and eminent chemift, was born at Paris in 1710, and became a doctor of the faculty of medicine in the univerfity of that metropolis, profeffor of pharmacy, and cenfor-royal. He was, likewife, a member of the Academies of Sciences of Turin, Stockholm, and Paris, and conducted the medical and chemical departments of the Journal des Sçavans. He had the merit of purfuing chemiftry, not fo much with a view of multiplying the preparations of pharmacy, which had conftituted the leading enquiries of experimentalifts before his time; but engaged in it as a department of natural philofophy, and gained a confiderable reputation by the publication of feveral ufeful and popular works on the fubject. In fact, he was one of the moft fuccefsful cultivators of the fcience, upon rational principles, previous to the new modelling which it has received within the laft twenty-five years. He died in 1784. The following is a lift of his publications: 1. "Elemens de Chymie Theorique," 1749—1753, 12mo. 2. "Elemens de Chymie Pratique," two volumes, 12mo. 3. "Plan d'un Cours de Chymie experimentale et raifonnée," 12mo., 1757. This was compofed in conjunction with M. Baumé, who was affociated with him in his lectures. 4. "Dictionnaire de Chymie," two volumes, 8vo., 1766. Thefe works have all been tranflated into Englifh and German; the Dictionary particularly by Mr. Keir, with great additions and improvements. 5. "Formulæ Medicamentorum Magiftralium," 1763; and he had alfo a fhare in the compofition of the "Pharmacopeia Parifienfis," of 1758. Eloy Dict. Hift. de la Méd. Gen. Biog.

MACQUER, PHILIP, an hiftorical writer, was born at Paris in 1720. He was brought up to the bar, but the weaknefs of his conftitution prevented him from taking an active part in his profeffion, and he accordingly devoted himfelf to literary occupations. His principal works were "Abregè Chronologique de l'Hiftoire Ecclefiaftique," three volumes, 8vo., compofed after the manner of Hefnault's Chronological Hiftory of France; "Les Annales Romains;" and "Abregè Chronologique de l'Hiftoire d'Efpagne et de Portugal," two volumes, 8vo. He had a fhare in the "Dictionnaire des Arts et Metiers," and other confiderable works. He died in 1770, leaving behind him an excellent character for fimplicity and unaffected integrity.

MACREUSE, in *Ornithology*, the *Anas Nigra*, Scoter or Black Diver. See DUCK.

MACRI, or MACARI, in *Geography*, a town of Afiatic Turkey, in Natolia, in a bay of the Mediterranean, called the gulf of Macri, anciently "Glaucus Sinus;" 70 miles S.W. of Satalia. N. lat. 36° 58'. E. long. 29° 30'.

 MACRIANUS,

MACRIANUS, Titus Fulvius Julius, in *Biography*, an Egyptian of obfcure birth, who, from a private foldier, rofe to the higheft command in the army, and proclaimed himfelf emperor when Valerian had been made prifoner by the Perfians, A.D. 260. He maintained his ufurped power by the influence of his liberality: his two fons, Macrianus and Quietus, were invefted with the imperial purple, and during a fhort period the enemies of Rome were feverally defeated either by the emperors or their generals. When he had fupported his dignity for a year in the Eaftern parts of the world, Macrianus marched towards Rome to crufh Gallienus, who had been proclaimed emperor. He was defeated in Illyricum by the lieutenant of Gallienus, and put to death, with his fon, at his own defire.

MACRINUS Opilius, a native of Cæfarea, in Africa, who from the loweft origin rofe to the high dignity of emperor of the world. He is faid to have been a flave, and to have exhibited in public fhows in the character of a gladiator, which facts have been doubted, as he raifed himfelf to reputation as a pleader in the courts. He became the fteward of Plautianus, the minifter of Severus, and on his difgrace and fall he narrowly efcaped with his life, and was banifhed to Africa, where he maintained himfelf by the united profeffions of rhetorician, pleader, and counfellor. After fome abfence he was recalled from his exile by Severus, who made him poft-mafter on the Flaminian way. Caracalla afterwards created him a Roman knight, and he rofe through the different employments to the high office of pretorian-prefect, an office which he filled with honour and integrity. He at length became an object of the emperor's fufpicions, and faw, or imagined that he faw, his own fafety entirely depended upon ftriking the firft blow, and accordingly engaged a difcontented foldier to ftab the tyrant, which he effected. He immediately fucceeded to the vacant throne by an election of the foldiers in the year 217, and the fenate confirmed the choice of the military. Macrinus was not deftitute of qualities and principles worthy of his high ftation, and by the punifhment of informers, and the refpect which he himfelf paid, and which he caufed others to pay to the laws, he reftored tranquillity to his country. Thefe promifing appearances did not long continue, and the timidity which Macrinus betrayed in buying a peace of Artabanus, the Parthian, by a large fum of money, rendered him odius to his fubjects, and while he affected to imitate the virtuous Aurelius, without poffeffing the good qualities of his heart, he became contemptible and infignificant. The army, who had raifed Macrinus to the purple, now took a decided part againft him; the whole army mutinied, and their tumult was increafed by the confcioufnefs of their power and numbers. At this time the young Bafianus was produced as the natural fon of Caracalla, and was declared emperor by the army. Macrinus, at firft, was refolved to oppofe his competitor: the two armies met, and a bloody battle enfued: the fortune of the day remained fome time very dubious, when Macrinus, who might probably have been victorious had he been firm and fteady, fhamefully fled, leaving his enemies in poffeffion of the field, and eventually of the crown. He paffed through Antioch, croffed Leffer Afia in difguife, and arrived at Chalcedonia with the intention of paffing over into Europe; but being there recognifed, he was feized and conveyed towards Cappadocia. On the road news was brought him that his fon had been taken prifoner and put to death, which fo enraged him, that he leaped from the chariot, and in the fall broke his arm; the guards, dreading the lofs of their captive, inftantly difpatched him, and carried his head to his rival. This circumftance happened in the month of June 218, after a reign of fourteen months. Hiftorians mention, to the honour of this emperor, that he meditated a great reform in jurifprudence, by abolifhing all thofe imperial refcripts which had obtained the authority of laws, though often iffued on particular occafions, and dictated by the caprice of the prince on the throne; but the fhortnefs of his reign prevented the execution of this and other plans which he had devifed for the public good. Gibbon. Crevier.

Macrinus, Salmoneus, a modern Latin poet, whofe proper name was John Salmon, was born at Loudun, and flourifhed in the fixteenth century. He obtained fo high a reputation as a poet, efpecially in the clafs of Lyrics, that he was called the Horace of his time. He was appointed preceptor of the two fons of René, of Savoy, and acquitted himfelf fo well in this employment, that he was received at court, and acquired the friendfhip of feveral of the principal perfons who frequented it. He wrote a great number of verfes, of which fome of the beft are thofe to his wife. He died in the year 1557. Several of his poems are contained in the fecond volume of the "Deliciæ Poetarum Gallicorum:" and a collection of his felect hymns was printed by R. Stephanus. He had a fon Charles, who is faid to have furpaffed his father in his knowledge of the Greek language, and to have equalled him in his Latin poetry. He was appointed preceptor to Catharine of Navarre, fifter of Henry IV., and unfortunately perifhed in the bloody maffacre of St. Bartholomew. Moreri.

MACROBIUS, Aurelius Theodosius, a Latin writer and eminent critic, who flourifhed towards the clofe of the fourth century, is fuppofed to have been a Greek, but the place of his birth is unknown. He is, indeed, claimed by the people of Parma, who fhew his tomb, but he refers his birth-place to a country in which the Latin language was not vernacular. He undoubtedly lived at Rome, but it is not known whether he was the fame Macrobius who was great chamberlain under Honorius and Theodofius II. It has likewife been difputed whether he was with regard to his religion a Chriftian or Pagan. The fuppofition that he held the office of chamberlain under the Chriftian emperors has been the chief, or, perhaps, the only ground for imagining him to have been a Chriftian, fince the language of his writings and the interlocutors in his dialogue are entirely heathen. He wrote a Commentary on Cicero's "Dream of Scipio," from which it appears he was a Platonift: and a dialogue, entitled "Saturnalia," or Mifcellanies, which was fuppofed to have been written at a feftival of Saturn, by a company of learned perfons, whofe names are thofe of fome of the moft learned fcholars of that time. The queftions treated of related to topics of antiquity, mythology, hiftory, and poetry, difcuffed in a pleafing way, and with references to the works of ancient authors, and to the laws and cuftoms of the Romans; and although the ftyle is not pure, and the arrangement cannot be commended, yet it is a work of confiderable merit, and of much utility as a help to claffical erudition, and as containing fome curious obfervations on the two greateft epic poems of antiquity. The beft editions of this author are thofe of the Variorum; and Gronovius in 1670, and Leipfic in 1777. Macrobius has been regarded and cenfured as a plagiarift, but without juft reafon, as he exprefsly mentions, in his preface, an intention of borrowing from any exifting authors whatever might fuit his purpofe.

Many of the works of Macrobius are ftill preferved, among others, his Commentary on Cicero's *Somnium Scipionis*, and his Saturnalia, in feven books. In this laft work there are many interefting paffages concerning ancient mufic.

MACROCE-

MACROCEPHALUS, in *Natural Hiſtory*, a genus of inſects of the order Hemiptera. The generic character is, that it has an inflected ſnout; the ſheath is one-valved, three-jointed, and furniſhed with three briſtles; it has neither jaws, feelers, nor lip; the antennæ are projecting, very ſhort, ſubmoniliform, clavate; the head is oblong, cylindrical above; the ſcutel, which is as long as the abdomen, is depreſſed and membranaceous. There is but a ſingle

Species.

Cimicoides, which is found in North America, and is rather leſs than the Cimex eroſus: the body is of a ferruginous grey; the ſcutel is of a pale aſh colour with a yellow ſpot; the under wings are purpliſh-violet, and the foreſhanks are thickened

Macrocephalus, Μακροκεφαλος, compounded of μακρος, *great*, and κεφαλη, *head*, denotes a perſon with a head larger or longer than the common ſize.

Macrocephali, or *long-heads*, is a name given to a certain people, who, according to the account of authors, were famous for the unſeemly length of their heads; yet cuſtom ſo far habituated them to it, that inſtead of looking on it as a deformity, they eſteemed it a beauty, and as ſoon as the child was born, moulded and faſhioned its head in their hands to as great a length as poſſible, and afterwards uſed all ſuch rollers and bandages as might ſeem moſt likely to determine its growing long.

MACROCERCI, the name eſtabliſhed by Dr. Hill for a large genus of animalcules, diſtinguiſhed from all others by having tails longer than their bodies. See Animalcule and Vorticella.

MACROCNEMUM, in *Botany*, from μακρος, *long*, and κνημη, *a leg*, alluding, as it ſeems, to the long ſtalks by which its cluſters of flowers are ſupported. Browne Jam. 165. Linn. Gen. 90. Schreb. 120. Willd. Sp. Pl. v. 1. 933. Mart. Mill. Dict. v. 3. Juſſ. 200.—Claſs and order, *Pentandria Monogynia*. Nat. Ord. *Rubiaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth ſuperior, of one leaf, turbinate, five-toothed, permanent; often bearing a foliaceous, ſtalked, internal appendage. *Cor.* of one petal, tubular; its limb ſmall, in five ovate, ſlightly ſpreading ſegments. *Stam.* Filaments five, awl-ſhaped, villoſe, ſhorter than the corolla; anthers ovate, compreſſed, in the mouth of the flower. *Piſt.* Germen inferior, conical; ſtyle ſimple, the length of the ſtamens; ſtigma thickiſh, two-lobed. *Peric.* Capſule oblong, ſomewhat turbinate, two-celled, and two-valved, burſting lengthwiſe, the partitions from the middle of each valve. *Seeds* numerous, imbricated, on a ſeparate linear receptacle in each cell.

Eſſ. Ch. Corolla tubular, five-cleft. Capſule inferior, oblong, of two cells; the valves burſting longitudinally, with partitions from their centre. Seeds imbricated.

Obſ. This genus is allied to *Cinchona*, but differs eſſentially in the ſtructure of its capſule. Its great peculiarity conſiſts in the large, leaf-like, coloured, ſtalked, ſolitary appendages, placed within the calyx, and according to Jacquin, in his *Hortus Schoenbrunenſis*, originating from the very baſe of the germen, between two teeth of the calyx; but theſe, which might eaſily be miſtaken for bracteas, are not found in every ſpecies, nor in every flower of any one. The original ſpecies is deſtitute of them.

1. M. *jamaicenſe*. Linn. Sp. Pl. 244. Swartz. Obſ. 68. t. 3. f. 1.—Corymbs on long axillary ſtalks. Calyx without an appendage. Native of ſhady places, about the banks of rivers, in the ſouthern part of Jamaica. A branched ſmooth ſhrub, with long, lax, round ſcarred *branches*. *Leaves* oppoſite, ſtalked, a ſpan long, elliptic-oblong, pointed, entire, ſmooth, crowded about the ends of the branches; paler beneath. *Flowers* yellowiſh-green, in long-ſtalked corymboſe panicles. *Fruit* near an inch in length.

2. M. *ſpecioſum*. Jacq. Hort. Schonbr. v. 1. 19. t. 43.—Corymbs ſhorter than the leaves, hairy. Calycine bractea roundiſh-ovate, its ſtalk ſhorter than the corolla.—Native of the Caraccas. Jacquin had it flowering in his ſtove in December. This is a moſt beautiful ſhrub, five feet high, its *infloreſcence*, and even the *calyx* and *corolla*, downy or hairy, as well as the margins of the *leaves*. The axillary and terminal corymboſe *panicles* compoſe a large tuft of *flowers* at the end of each branch, very conſpicuous for the long purple-mouthed *corolla*, and the large roſe-coloured, veiny, ſmooth or downy, appendage to the *calyx* of moſt of them, more ſplendid than the flowers themſelves.

3. M. *candidiſſimum*. Vahl. Symb. v. 2. 38. t. 30.—Corymbs ſhorter than the leaves, ſmooth. Calycine bractea roundiſh-ovate, its ſtalk longer than the corolla.—Found by Von Rohr in the neighbourhood of St. Martha.—This differs from the laſt in its ſmaller ſize, and white calycine *bractea*, whoſe ſtalk exceeds the *flower* in length. The *corolla* is alſo of a ſhorter figure. *Capſule* elliptic-oblong, compreſſed.

4. M. *coccineum*. Vahl. Symb. v. 2. 38. t. 29.—Corymbs denſe, the length of the footſtalks, in long cluſters. Calycine bractea elliptical, its ſtalk much longer than the corolla.—Native of Trinidad. *Von Rohr.* A *tree* with hairy *branches*. The *leaves* are from one to two feet long, elliptic-obovate. *Corymbs* ſhort and denſe, diſpoſed in very long cluſters. One *flower* in each corymb is furniſhed with a very large, elliptical, long-ſtalked, ſcarlet calycine appendage, looking, at firſt ſight, like a *bractea* to each. The *corolla* is ſmooth, its limb nearly as long as its tube. *Germen* hairy.

5. M. *ſtrictum*. Roxb. MSS.—Flowers in little denſe, round, axillary heads, ſhorter than the footſtalks.—Native of Bengal. *Herb. Banks.* The *branches* are ſmooth and angular. *Leaves* only two or three inches long, elliptical, pointed. *Flowers* ſmall, without calycine bracteas.

Some ſpecies of this curious genus ſtill, we believe, remain unſettled.

MACROCOLUM, or Macrocollum, formed of μακρος, *large*, and κολλαω, *I join*, among the Romans, the largeſt kind of paper then in uſe. It meaſured ſixteen inches, and frequently two feet.

MACROCOSM, Μακροκοσμος, compounded of μακρος, *long*, *large*, and κοσμος, *world*, denotes the great world, that is, the univerſe.

In which ſenſe it ſtands contradiſtinguiſhed from microcoſm, a term uſed to expreſs man.

MACRODESPOUR, in *Geography*, a town of Bengal; 20 miles E.S.E. of Kiſhenagur.

MACROLOBIUM, in *Botany*, was ſo named, as Profeſſor Martyn ſuggeſts, from having one of the petals very long in proportion to the others, but we are rather inclined to conſider it as derived from μακρος, *large*, and λοβος, *a pod*; the large ſeed-veſſel moſt evidently warranting ſuch an application of the name, which was given by Schreber with Aublet's plates before him. Schreb. 30. Willd. Sp. Pl. v. 1. 186. Vahl. Enum. v. 2. 37. Mart. Mill. Dict. v. 3. (Outea; Aubl. Guian. 28. Juſſ. 347. Lamarck Illuſtr. t. 26.—Vouapa; Aubl. Guian. 25. Juſſ. 350. Lamarck Illuſtr. t. 26.)—Claſs and order, *Triandria Monogynia*. Nat. Ord. *Lomentaceæ*, Linn. *Leguminoſæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, double; the outer of two, oppoſite, ovate-oblong leaves, adhering to the baſe of the

the inner, which is of one leaf, turbinate, ſhort, with an oblique, five-toothed margin. *Cor.* Petals five, unequal; the upper one large, erect, unguiculate, oblong, obtuſe, concave, undulated, inſerted into the inner perianth; lower petals four, ſmall, ovate, ſpreading, attached to the upper part of the inner perianth. *Stam.* Filaments four, one of them ſhort, barren, ſtanding under the large petal; the reſt very long, thread-ſhaped; anthers ſquare. *Piſt.* Germen ſuperior, ſtalked, ovate; ſtyle thread-ſhaped; ſtigma obtuſe. *Peric.* Legume ovate, compreſſed, coriaceous, of one cell. *Seed* ſolitary, roundiſh, compreſſed.

Eſſ. Ch. Calyx double: the outer of two leaves; the inner turbinate and obliquely five-toothed. Corolla of five petals, unequal. Legume ſingle-ſeeded.

Obſ. Schreber remarks that *Outea* and *Vouapa* of Aublet do not ſeem to be diſtinct genera, as the corolla, fertile ſtamens and the piſtil agree in number, form, and ſituation in both. In the former indeed, *Outea*, Aublet had never ſeen the ripe fruit, and in the latter he appears not to have diſtinguiſhed the leſſer petals from the calyx. Vahl, however, has kept theſe genera diſtinct, on the authority of Richard.

1. M. *pinnatum*. Willd. (Outea guianenſis; Aubl. Guian. t. 9.)—Leaves pinnate, obtuſe.—Native of woods and foreſts in Guiana, flowering in May. - The *trunk* of this tree riſes to the height of fifty feet, and is about a foot in diameter. *Bark* ſmooth and greyiſh. *Wood* whitiſh towards the ſurface, but red at the heart. *Branches* ſpreading, inclining, the upper ones erect. *Leaves* abruptly pinnate, alternate; leaflets four, ovate, obtuſe. *Stipulas* two, acute, ſmall, deciduous, at the baſe of the common ſtalk. *Flowers* in ſpikes, axillary, of a violet colour. Some eminent botaniſts have ſuſpected that this may be a *Tamarindus*, and the following a *Hymenæa*.

2. M. *hymenæoides*. Willd. Vahl. (Vouapa bifolia; Aubl. Guian. t. 7.)—Leaves binate, pointed, oblique at the baſe. Legume oblong. Found in the woods of Guiana and Cayenne, near the ſhores of lakes and rivers, flowering in November and bearing fruit in January. - A *tree* ſixty feet high, much branched at the top. *Leaves* alternate, of two green, ſtrong, and thick, oval, long-pointed leaflets. *Flowers* in ſolitary, terminal cluſters from the boſom of the leaves, of a pale violet colour.

3. M. *ſphærocarpum*. Willd. Vahl. (Vouapa Simira; Aubl. Guian. t. 8.)—Leaves binate, pointed, ovate. Legume roundiſh compreſſed.—Native of woods at Courou, in Guiana, bearing fruit in June. The height of this *tree* is eighty feet. *Trunk* thick, much branched at the top. *Leaves* alternate of two ovate, entire leaflets, reticulated with veins. The *flowers* have not been ſeen, but the *fruit* grows in axillary cluſters, and is a thick, roundiſh, leathery, ferrugineous legume, of one cell and two valves, containing a ſolitary, roundiſh, depreſſed, ſmooth *ſeed*. The *wood* is violet-coloured.

MACROLOGY, Μακρολογια, formed of μακρος, *long*, and λογος, *diſcourſe*, in *Rhetoric*, a redundant, or too copious ſtyle; an example of which we have in Livy, lib. viii. "Legati non impetrata pace, retro domum, unde venerant abierunt."

The too copious is equally ſubject to obſcurity with the too conciſe ſtyle, and conſequently ought to be avoided. See BRACHYOLOGY, DICTION, and STYLE.

MACRONISI, in *Geography*, a ſmall iſland in the Turkiſh Archipelago, near the coaſt of Livadia; formerly called Helena, becauſe it is ſaid to have afforded an aſylum to that princeſs. It was anciently very populous, but is now deſerted, and only occupied by lizards or other reptiles. In the interior parts are found many rare plants; 6 miles N.E. of cape Calonni. N. lat. 37° 38'. E. long. 24° 17'.

MACROPEDIUM, the *long-legs*, a name given by ſome writers in natural hiſtory to the common tipula.

MACROPIPER, a name given by authors to the *piper longum*, or long pepper.

MACROPNUS, formed of μακρος, *long*, and πνοη, *breath*, a word uſed by Hippocrates, and other old writers in medicine, to ſignify a perſon who fetches his breath at long intervals. It is uſed in oppoſition to *brachypnus*, or ſhort-breathed.

MACROPTERA, derived from μακρος, *long*, and πτερον, *a wing*, in *Ornithology*. The hawks of this genus have their wings ſo long, that when cloſed they reach to the end of the tail, or nearly ſo. Of this genus are the bald-buzzard, the kite, the hen-harrier, the honey-buzzard, and the common buzzard, the ſacre, the jerfalcon, &c.

MACROPUS, KANGUROO, in *Natural Hiſtory*, a genus of the claſs and order Mammalia-feræ. The fore-teeth in the upper jaw ſix, and emarginated; but in the young animal they are eight; there are only two in the lower jaw, very large, long, ſharp, and pointing forwards: there are five grinders on each ſide, both in the upper and lower jaw, diſtant from the other teeth; the fore-legs are very ſhort; and the hind ones very long; the female has an abdominal pouch. There are two ſpecies, *viz.* the major, or M. *giganteus*, anſwering to the Didelphis gigantea of Linnæus; and the M. *minor*, or the kanguroo rat.

This genus, as it appears from what has been ſaid, has hitherto been generally confounded with the *Didelphis*, which ſee: it is, however, found eſſentially to diſagree with that genus in reſpect to the teeth and other particulars: hence Dr. Shaw, and other later naturaliſts, have ſeparated it from the Didelphis tribe.

Of all the animals which the continent of Auſtralaſia has preſented to our view, the *Platypus* excepted, (which ſee) the kanguroo muſt be conſidered as the moſt extraordinary: "its ſize, conformation, teeth, and other particulars, conſpiring to render it a moſt intereſting object to every naturaliſt."

Species.

MAJOR; Great kanguroo. Browniſh, with ſharp ears and pentadactylous fore feet. This animal was firſt diſcovered by captain Cook's people, while at Botany Bay, in New Holland, in the year 1770, an intereſting account of which is given in the captain's firſt voyage. It is thus deſcribed by Dr. Shaw: "The general ſize of the kanguroo is at leaſt equal to that of a full-grown ſheep: the upper parts of the animal are ſmall, while the lower are remarkably large in proportion; yet ſuch is the elegance of gradation in this reſpect, that the kanguroo may juſtly be conſidered as one of the moſt pictureſque of quadrupeds. The head bears ſome reſemblance to that of a deer, and the viſage is mild and placid; the ears are moderately large, of a ſharpened form, and upright; the eyes large; and the mouth rather ſmall; the neck is thin and finely proportioned; the fore-legs are extremely ſhort, with the feet divided into five toes, each of which is furniſhed with a ſharp and ſomewhat crooked claw. From the breaſt downwards the body gradually enlarges, and again decreaſes a little towards the tail; the thighs and hind-legs are extremely ſtout and long; and the feet are ſo conſtructed as to appear, at firſt ſight, to conſiſt of but three toes, of which the middle one is by far the largeſt, and is furniſhed with a claw of great ſize and ſtrength; the exterior toe is alſo furniſhed with a very ſtrong claw, but far ſmaller than that of the middle; and the interior conſiſts of two ſmall toes united under a common ſkin, with their reſpective claws placed ſo cloſe to each other

other as to appear like a split or double claw: the whole appearance of the foot bears a distant resemblance to that of a bird. The great kanguroo rests on the whole length of the foot, which is callous, blackish, and granulated beneath. The colour of the animal is an elegant pale brown, lighter, or more inclining to whiteness on the abdomen; the ventral pouch, or receptacle for the young, is situated as in the didelphis tribes, and is extremely large and deep." The dimensions of a full-grown kanguroo are these: eight feet from the tip of the nose to that of the tail; length of the tail three feet one inch; of the head eleven inches; of the fore-legs two feet; of the hind three feet seven inches; circumference of the fore-part of the animal, near the legs, three feet nine inches; of the lower part, near the legs, four feet five inches; round the thickest end of the tail thirteen inches. The weight of the largest specimens is said to be 150lbs., but it is thought to attain a still larger size. "Though the general position of the kanguroo, when at rest, is standing on its hind-feet, yet it frequently places its fore-feet on the ground also, and thus feeds in the manner of other quadrupeds. It drinks by lapping. In its natural state it is extremely timid, and springs from the sight of mankind by vast bounds of many feet in height, and to a surprising distance. The female kanguroo has two mammæ, situated in the abdominal pouch, and on each side are seated two teats; yet, so far as has hitherto been observed, the animal produces but one young at a birth, and so exceedingly diminutive is the young, when first found in the pouch, as scarcely to exceed an inch in length. The young continues in the pouch till it is grown to a large size, and takes occasional refuge in it long after it has been accustomed to come abroad. It feeds on vegetable substances, and chiefly on grass. In their native state, kanguroos are said to feed in herds of thirty and forty together, and one is usually stationed, as if apparently on the watch, at a distance from the rest. One of the most remarkable peculiarities of this animal is its power of separating at pleasure, to a considerable distance, the two long fore-teeth in the lower jaw. The *Mus maritimus*, it must be observed, does the same. It is thought that there are several varieties of the great kanguroos; some being of a much darker colour than the common kanguroo described, and have a coarser fur. This animal may now be considered as, in a great degree, naturalized in England; several having been kept some years in Richmond park, where they have bred. The flesh of the kanguroo is coarse, and will not be eaten as a luxury; but will serve in case of scarcity to persons in their foreign travels.

Minor, Lesser, or brown kanguroo. Ash-coloured beneath, with rounded ears, and tetradactylous fore-feet. This species of animal has, from its colour and general aspect, obtained the title of kanguroo-rat; it is about the size of a rabbit; the tail is long, tapering, hairy; hind-legs long, three-toed; ears rounded; eight upper fore-teeth, the two middle ones sharper; the lower two long and pointed; three grinders on each side, the fore-most channelled; fur smooth, dark-brown. The structure of the hind-feet in this species perfectly resembles that of the great kanguroo. The female is furnished with an abdominal pouch for the reception of the young. Some of this species were imported in a living state from New Holland.

MACRORYNCHÆ, *long-beaked*, derived from μακρος, *long*, and ῥυγχος, *a beak*, in *Ornithology*, the character of a large order of the bird kind.

The birds of this order have all of them beaks many times longer than their heads, with oblong nostrils, and a furrow running from them towards the apex of the beak.

MACROTELOSTYLA, in *Natural History*, the name of a genus of crystals, which are composed of two pyramids, joined to the end of a column; both the pyramids, as also the column, being hexangular, and the whole body consequently composed of eighteen planes.

The word is derived from the Greek μακρος, *long*, τελειος, *perfect*, and στυλος, *a column*; expressing a perfect crystal with a long column.

There are only three known species of this genus. Either of the sorts found with us, are called by the common name of *Cornish diamonds*.

MACROULE, in *Ornithology*, the name given by many to the largest species of coot. It is of a deeper black than the common kind, and has a large bald spot on its head. It is also called by some *diable de mer*. It is found in Lancashire and Scotland. See Fulica *Aterrima*.

MACROURUS, in *Natural History*, a genus of fishes of the order Thoracici. There is but a single species, which is reckoned by Gmelin as belonging to the genus Coryphæna. We have, however, in that article, given reasons why it cannot be admitted in that tribe; instead, therefore, of denominating the fish under consideration the Coryphæna *Rupestris*, we follow Dr. Shaw, and others, in naming it the

Macrourus *Rupestris*, or Long-tailed Imminset, of which the generic character is, head large, eyes large; body at the hind part attenuated into the tail.

The head of this remarkable fish is large and thick: the upper jaw projecting above into the form of an obtuse snout; the eyes are very large, the mouth wide, with five rows of small curved teeth in the upper jaw, and two rows in the lower; the tongue is white, thick, short, and cartilaginous; beneath the tip of the lower jaw hangs a beard or cirrus; the body tapers from the middle part, and at length is continued into a very long, slender, and pointed tail; the whole fish is covered with moderately large rounded scales, each of which is furnished with a strong toothed carina, ending in a pointed tip, which causes a remarkable roughness of surface; so that the hand is wounded by drawing it over the fish from the tail towards the head. The first dorsal fin is situated near the middle of the back, and is furnished with nine or ten rays. The second dorsal fin commences at a small distance from the first, and running to the tip of the tail is united with the vent fin, which is likewise continued from the tip of the tail to the vent, near the middle of the body. The colour of this fish is a silvery-grey, deepest on the upper parts; its usual length is about three feet, but is occasionally seen of a larger size. It is a native of the Northern seas, and is mostly found about the coasts of Greenland and Iceland, and is numbered among the edible fishes of the Greenlanders. It swims swiftly, and when first taken, it struggles with great violence, endeavouring to defend itself by lashing with its tail; its large eyes projecting, at the same time, to a surprising degree. It is known in some places by the name of Berg-lax, or Mountain Salmon; and the Greenlanders call it "Ingminniset," from which the English generic name has been taken. Shaw's Zoology.

MACSOUD-BEGUI, in *Geography*, a town of Persia, in the province of Irak; 54 miles E.S.E. of Ispahan.

MACSWINE's Bay, a bay of Ireland, in the N. part of Donegal bay; 11 miles W. of Donegal. N. lat. 54° 36′. W. long. 8° 17′.

MACTEN, one of the smaller Philippine islands, in which, as some say, Magellan was killed. N. lat. 10° 30′. E. long. 123° 48′.

MACTRA, in *Natural History*, a genus of the class Vermes, and order Testacea, is thus described: the animal is

 a *Tethys*,

a *Tethys*, which fee; fhell bivalve, unequal-fided, equivalve; middle tooth of the hinge complicated, with a fmall hollow on each fide, lateral ones remote, and inferted into each other. There are twenty-feven fpecies inhabiting the coafts of all quarters of the world, and four of them, as will be noticed by afterifks in the article, are found on our own coafts. They are of different fizes, from that of a man's hand, downwards, fo that fome of them are fcarcely an inch broad. The fhells are likewife exceedingly different, fome being fmooth, others wrinkled; fome are wedge-fhaped, others ovate; they are alfo diaphanous, pellucid, and femi-tranfparent; fome are ftriate, banded, white or fawn-coloured, and fome refemble a *tellina*, others a *mya*. The following is a brief enumeration of the feveral

Species.

Spengleri. The fhell of this is fmooth, with a flat anterior margin, on which is a lunate gape; it is found at the Cape of Good Hope, nearly as large as a man's hand, and is a little gaping, pale, fub-diaphanous, fub-triangular. The gape, before the hinge, is lunate, acute, and reaching to the hollow of the hinge; the beaks are incurved, and the teeth of the hinge triangular.

Plicatoria. Shell with tranfverfe wrinkled plaits, diaphanous; the anterior margin is flattifh; behind the beaks is a compreffed oblong gape. It is found in the Indian ocean, and is from one to two inches long, and two inches and a half broad. The fhell of this fpecies is thin as paper, with fmooth lanceolate depreffions on each fide the hinge; the anterior one flattifh, with a ridge near the beaks; the pofterior impreffed, and more ovate; beaks incurved; lateral teeth of the hinge compofed of two parallel membranes.

Papyracea. Shell very thin, pellucid, and white; it is convex, the fore-part a little gaping, very finely ftriate, and ribbed. It is found in the Nicobar iflands, but is extremely rare; it refembles the laft, but is more convex and unequal-fided; except in the hinge, it is very like a tellina.

Striatula. The fhell is fmooth and diaphanous; the beaks are fubftriate, with a fmooth marginal impreffion before them, furrounded with a rim. It inhabits the Coromandel coafts, and is found alfo in the Mediterranean, is about two inches and a half long, and three inches broad; it is white, fub-triangular, rather convex, a little gaping on the fore-margin.

Striata. The fhell is thick and triangular, with ftrong, thick, crowded, fmooth, arched ftriæ; it is white, and glabrous within at the beaks. Is found in the Mediterranean, and is about the fize of the laft.

Glabrata. This fpecies has a fmooth, diaphanous, and ftriate fhell; the beaks are very fmooth; and the margins on each fide are ftriate. It is found in the African and Indian oceans; is about the fize of the *Striata;* the colour is white; beaks fmooth, and ftriate on the border.

Rotundata. Shell obtufely triangular, whitifh, with milk-white bands on the beaks; the margins, on each fide the beaks, are violet. It inhabits the Mediterranean, and is of the fame fize as the laft.

Nitida. The fhell is fnowy and diaphanous; the depreffions on each fide the beaks are ftriate; the anterior ones marked with a ridge. The fhell is triangular, and the beaks retroverted and diftant.

Corallina. This is an inhabitant of the Mediterranean and Guinea feas; the fhell is fmooth, fub-diaphanous, and white with paler bands; it is about two inches broad, and an inch and a half long, triangular, with obtufe depreffions on each fide the beaks.

Lactea. The fhell is thin, pellucid, white, and the fore-part very finely ftriate, with paler bands. It is found in the Indian ocean: it refembles the laft, but is thinner, and more convex; the anterior part is flattifh, with an obtufe margin.

* Stultorum. The fhell is femi-tranfparent, fmooth, and gloffy; it is obfoletely radiate, white without; and purplifh within. This is found on the fhores of our own country, and alfo in the American feas; and is only the fize of a hazel-nut; the fhell is convex, fomewhat triangular, brown, teftaceous or cinereous, with or without faint rays.

Grandis. Shell femi-tranfparent, fmooth, fawn-colour, with pale rays; the beak and hinge placed beyond the middle. This is very like the laft; is more than three inches broad; and two broad, gaping at the extreme angle; the anterior fide more produced.

* Solida. Shell opaque, and fmoothifh; found very commonly on the European fhores; the fhell is thick, ftrong; colour white, to a yellowifh-brown, frequently marked with blue or pale orange belts; while alive it is fmooth, and when dead it has a few high tranfverfe ftriæ, like ribs; the lateral teeth are fmall, elongated with a large hollow; the middle tooth is fmall.

* Lutraria. The fhell is oval-oblong and fmooth, without lateral teeth. It inhabits the European coafts, near the mouths of rivers; it refembles a mya gaping at both ends; in colour it is of a dirty-white, or yellowifh tinged with orange, and irregularly clouded with brown; hinge with a fmall and large triangular cavity in one valve, and a fimilar cavity with an elevated triangular tooth in the other.

Cygnus. Shell fnowy, thick, and three-fided, very finely ftriate tranfverfely; the fore-part is flattifh, and flightly wrinkled; behind the beaks a broad, heart-fhaped, thinly ftriate impreffion. It is found on the coafts of Tranquebar; an inch long, and rather more than an inch broad.

Maculata. Shell obtufely triangular, fmooth, thin, with pellucid chefnut fpots; within white, and very finely ftriate.

Turgida. The fhell of this fpecies is inflated, faintly ftriate, of an ochre colour, but white within; the beaks are diftant purplifh; the hinge has a fupernumerary triangular double tooth. It inhabits Tranquebar, and is nearly three inches long, and more than that broad; it is thin, pellucid, finely ftriate, and wrinkled before and behind.

Violacea. Shell thin, obfoletely radiate, finely ftriate tranfverfely; margins on each fide the beaks whitifh; hinge with a fupernumerary double triangular tooth. This is found on the coafts of Tranquebar, and is about two inches long, and three broad. The fhell is thin brittle, gaping here and there, the anterior margin oblong, elevated, and wrinkled.

Cuneata. Shell wedge-fhaped, blue, finely ftriate tranfverfely; the margin crenulate within; it refembles in many refpects the laft, but is only an inch long, and not fo much as that broad; it is fometimes white.

Glauca. The fhell of this is ovate, dirty-white, with glaucous rays, very finely ftriate tranfverfely; the anterior part wrinkled. It inhabits the Mediterranean; the fame fize as the Turgida: the beaks are turned backwards, with a narrow gape between them.

Pellucida. Shell ovate, thin, and of a pellucid white, with unequal tranfverfe ftriæ. It inhabits Guinea; is not two inches long, but rather more than this broad; the fhell is brittle, a little produced forwards, and gaping.

Fragilis. In this the fhell is ovate, thin, fmooth, pellucid, flattifh; the anterior gape tranfverfely ftriate, and wrinkled. It inhabits the Nicobar iflands, and refembles the laft; the fhell is gaping, and flightly plaited on the fore-

fore-part; the margin is acute, subangular before and rounded behind.

Rugosa. Shell ovate, dirty-white, with elevated longitudinal striæ crossing the transverse ones, which are a little more raised. It is thick and white within, and is about two and a half inches long, and the same in breadth.

Nicobarica. Shell ovate, thin, and pellucid on the fore-part; the hind-part with cancellate striæ. Found in and about the Nicobar islands.

Complanata. In this the shell is ovate, thin, with arched plaits; the plaits transversely striate. It inhabits India, and is of a blueish colour, but sometimes white, is an inch long, and two and a half broad.

* Listeri. Shell very thin, nearly round, whitish; hinge with a triangular tooth, and large pyriform hollow. Found at the mouth of the river Tees; rather larger than the last.

Piperita. Shell ovate, compressed, transversely striate; teeth of the hinge very minute, with a large oblique hollow. Inhabits the Mediterranean; about two inches long and one and a half broad.

MACUCAGUA, in *Ornithology*, the name of a Brasilian bird of the gallinaceous kind, called also by some the *gallina sylvestris*, or wild hen. It has no tail: but is a very well tasted fowl, and has twice as much flesh as the European hen; its eggs are somewhat larger than the common hen eggs, and of a blueish-green colour; it feeds on fruit that falls off the trees, &c. and runs well, but cannot fly high or far, and never is seen in the trees. Marcgrave. See Tetrao *Major*.

MACUIH-YU, in *Geography*, a small Chinese island, belonging to the province of Quang-tong. N. lat. 23° 10′. E. long. 116° 32′.

MACUL, a town of Chili; 15 miles S.E. of St. Yago de la Nouvelle Estramadura.

MACULA, a sea-port of Arabia, in the province of Hadramaut; 150 miles N.E. of Aden.

Macula, in *Medicine*, a *spot*, is a term principally used to denote those detached efflorescences of the skin, or discoloured patches, of various dimensions and figures, which appear without any considerable elevation or protuberance above the rest of the surface, and with large interstices of the natural colour. The term includes, therefore, those congenital discolourations, which are called *mother-spots*, or technically *nævi materni*, and which are commonly attributed, without any foundation, to frights or other affections of the mind or imagination of the mother; as well as *moles*, *petechiæ*, *freckles*, &c. See Imagination.

The *maculæ hepaticæ*, or *liver-spots* of the older authors on medicine, are little else than large freckles; consisting of patches of various sizes, affecting chiefly the breast, shoulders, and groins, of a brown colour, and accompanied with a slight roughness of the surface, in consequence of the formation of minute branny scales, in which the cuticle partially exfoliates. In the arrangement of cutaneous affections adopted by Dr. Willan, these spots are comprehended in the order of *scaly* diseases, under the title of Pityriasis; which see.

The *maculæ volaticæ* of authors, which occur in infants during dentition, are varieties of the eruption, popularly denominated the *red-gum*, the Strophulus of Dr. Willan. See that article; also Dentition, and Infants, *Diseases of.*

The last mentioned author has constituted an order of *maculæ* in his arrangement, which includes those chronic affections of the skin, that are unaccompanied by scales, pimples, rashes, vesicles, pustules, or tubercles, which characterise the other orders. It comprehends principally, therefore, the *ephelides* and freckles, *nævi*, moles, and other original marks. The removal of these spots is sometimes accomplished by surgical means; but they are merely local, and beyond the controul of medicine. See Nævus, &c.

Macula *Oculi*, a word used by many authors to signify a cataract or suffusion.

Maculæ, in *Astronomy*, dark spots appearing on the luminary faces of the sun, moon, and even some of the planets.

In which sense *maculæ* stand contradistinguished from *faculæ*.

The *solar maculæ* are dark spots of an irregular, changeable figure, observed in the face of the sun, first taken notice of by Galileo, 1610, soon after he had finished his telescope, and afterwards accurately observed by Scheiner, Hevelius, Mr. Flamsteed, Cassini, Kirch, &c. Phil. Trans. vol. i. p. 274. vol. lxiv. p. i. p. 194.

Many of these maculæ appear to consist of heterogeneous parts; of which the darker and more dense are called by Hevelius nuclei, and are encompassed, as it were, with atmospheres somewhat rarer, and less obscure; but the figure both of the nuclei and entire maculæ is variable. In 1644, Hevelius observed a small thin macula, which, in two days time, grew to ten times its bulk; appearing withal much darker and with a larger nucleus, and such sudden mutations are frequent. The nucleus, he observed, began to fail sensibly before the spot disappeared; and that, before it quite vanished, it broke into four, which, in two days, again re-united. Some maculæ have lasted two, three, ten, fifteen, twenty, thirty, but seldom forty days; though Kirchius observed one in 1681, which remained from April 26th to the 17th of July. The spots move over the sun's disk with a motion somewhat slacker near the limb than the centre: that observed by Kirchius was twelve days visible on the sun's disk; for fifteen days more it lay behind it, it being the usual rule to return to the limb whence they departed in twenty-seven, sometimes in twenty-eight days.

Lastly, it must be observed, that the maculæ contract themselves nearer the limb, and in the middle of the disk appear much larger; those often running into one in the disk, which in the limb were separate: that many of them arise in the middle of the disk, and many disappear in the same: and that none of them are observed to deviate from their path near the horizon; whereas Hevelius, observing Mercury in the sun near the horizon, found him too low, being thrust twenty-seven seconds beneath his former path.

From these phenomena we collect, 1. That since Mercury's depression below his path arises from his parallax, the maculæ, having no parallax from the sun, are nearer him than that planet.

2. That, since they arise and disappear in the middle of the sun's disk, and undergo various alterations with regard both to bulk, figure, and density, they must be formed *de novo*, and again dissolved about the sun; and hence some have inferred, that they are a kind of solar clouds, formed out of its exhalations.

3. If they are of this nature, as they rise over his body and are suspended at a certain height from it, it appears, from the laws of hydrostatics, that the sun must be encompassed with some fluid to drive those exhalations upwards; which fluid must be denser as it is lower, and rarer as higher, like our atmosphere: and, since the maculæ dissolve and disappear in the very middle of the sun's disk, the matter thereof, supposing them to be solar exhalations, must fall back again to the sun: whence there must arise changes in the sun's atmosphere; and consequently in the sun itself.

4. Since

4. Since the revolution of the maculæ round the sun is very regular, and since their distance from the sun is very small, it is not properly the maculæ that move round the sun, but it is himself, together with his atmosphere, wherein the maculæ swim, that in the space of twenty-seven days, twelve hours, twenty minutes, moves round his own axis; and to the same fixed star in twenty-five days, fifteen hours, fixteen minutes (see SUN); and hence it is, that the maculæ, being viewed obliquely near the limb, appear narrow and oblong.

5. Since the sun appears with a circular disk in every situation, his figure, as to sense, must be spherical.

The magnitude of the surface of the spot may be estimated by the time of its transit over a hair in a fixed telescope. Galileo reckons some spots to be larger than all Asia and Africa put together: but if he had known the sun's parallax and distance as exactly as we do, he would have found them much larger than the whole surface of the earth. For, in 1612, he observed a spot so large as to be plainly visible to the naked eye; it, therefore, subtended an angle at the eye of about a minute. The diameter of the earth, if removed to the sun, would subtend an angle of but about seventeen seconds. Therefore, the diameter of the spot was to the diameter of the earth as sixty to seventeen, or three one half to one, nearly; and consequently, the surface of the spot, if circular, to a great circle of the earth as twelve one-fourth to one, and to the whole surface of the earth as twelve one-fourth to four, or nearly three to one. Gassendus observed a spot whose diameter was $\frac{1}{20}$th of the sun's, and, therefore, subtended an angle at the eye of above a minute and a half. Its surface was, therefore, above six times larger than the whole surface of the earth. He tells us, that he saw above forty spots at once, but did not perceive that the light of the sun was sensibly diminished: nevertheless, the paleness of the sun mentioned by historians, after the death of Julius Cæsar, might have been caused in this manner, if we admit the fact.

The opinions that have been formed concerning the nature, origin, and situation of the solar spots, have been various: Dr. Wilson, professor of practical astronomy in the university of Glasgow, by attending particularly to the different phases presented by the umbra, or shady zone, of a spot of an extraordinary size that appeared upon the sun, in the month of November, 1769, during its progress over the solar disk, was led to form a new and singular conjecture concerning the nature of these appearances; which he seems to have afterwards confirmed by repeated observations. The results of these observations are, that the solar maculæ are cavities in the body of the sun; that the nucleus, as the middle or dark part has been usually called, is the bottom of the excavation; and that the umbra, or shady zone usually surrounding it, is the shelving sides of the cavity. Dr. Wilson appears not only to have very satisfactorily ascertained the reality of these immense excavations in the sun's body, but has pointed out a method of measuring the depth of them. He estimates, in particular, that the nucleus, or bottom of the large spot above mentioned, was not less than a semidiameter of the earth, or about four thousand miles, below the level of the sun's surface; while its other dimensions were of a much larger extent. He observed, that when a spot in the middle of the sun's disk, where it is surrounded equally on all sides with its umbra, comes near the western limb of the sun; that part of the umbra, which is next to the sun's centre, gradually diminishes in breadth, and at length, when the spot reaches within about a minute of the limb, totally disappears; while the umbra, on the other side of it, continues nearly of its former dimensions. If, after the period of half a revolution, the spot appears again on the opposite side of the disk, that part of the umbra, which had before disappeared, and which is now on the left hand side of the nucleus, is now plainly to be seen: but the umbra on the other side of the spot, or that which is next to the sun's centre, seems to have vanished in its turn; being hid from the view by the upper edge of the excavation, or by the oblique position of its sloping sides, with respect to the eye. As the spot, however, advances on the sun's surface, this umbra, or side of the cavity, comes in sight; it first appearing narrow, but afterwards gradually increasing in breadth, in proportion as the spot moves toward the middle of the disk. These appearances, in particular the gradual diminution and disappearance, as well as the re-appearance and gradual enlargement of the umbra, on the one side or the other of a spot, according as it advances near the western limb, or proceeds onwards from the eastern edge of the sun, are naturally accounted for by Dr. Wilson's supposition, that the umbræ are the sloping sides of a cavity, which will appear under different angles, or of different breadths, or totally disappear, according to their position with respect to the eye of the spectator. These appearances, at least, perfectly resemble the phases that would be exhibited by an excavation in a spherical body, made to revolve on its axis; the bottom of the cavity being painted black, and the sides lightly shaded. From these and other observations it may be inferred, that the body of the sun, at the depth of the nucleus, either emits no light, or emits so little as to appear dark, when seen at the same time, and compared with that resplendent, and probably, in some degree, fluid substance that covers his surface. This manner of considering these phenomena naturally gives rise to many curious speculations and inquiries. It is natural, for instance, to inquire by what great commotion this refulgent matter is thrown up on all sides, so as to expose to our view the darker part of the sun's body, which was before covered by it? What is the nature of the shining matter? and why, when an excavation is formed in it, is the lustre of this shining substance, which forms the shelving sides of the cavity, so far diminished as to give the whole the appearance of the shady zone, or darkish atmosphere surrounding the denuded part of the sun's body? On these and many other subjects, Dr. Wilson has advanced some ingenious conjectures; for which we must refer the curious to the Phil. Trans. vol. lxiv. part i. art. 1. See also some remarks on Dr. Wilson's Theory, by Mr. Woolaston, in the Phil. Trans. vol. lxiv. part ii. art. 1. p. 337, &c.

M. de la Lande, in the Memoirs of the French Academy for 1776, contends, that the spots of the sun are owing to dark bodies like rocks, which by an alternate flux and reflux of the liquid igneous matter of the sun, sometimes raise their heads above the general surface: and that that part of the opaque rock, which at any time thus stands above, gives the appearance of the nucleus, while those parts which in each lie only a little under the igenous matter, appear to us as the surrounding umbra. See this opinion examined, and Dr. Wilson's vindicated by himself, in Phil. Trans. vol. lxxii. pt. i. art. 10.

Dr. Herschel thinks that the sun is an opaque body, possibly inhabited, covered with an atmosphere in which clouds of a luminous nature are floating, and that the spots are interruptions of these clouds. Of these clouds, as he conceives, there are two strata, the upper of which only is luminous, and the lower stratum, as he supposes, protects the body of the sun from their heat. Phil. Trans. for 1795, vol. lxxxv. p. 46, &c.; and in Phil. Trans. for 1801, p. 265. 354, he endeavoured to shew that the variations of heat of different years is owing to the more or lefs copious fupply of fuel in the fun, which conftitutes his fpots. See FACULÆ, SPOTS, and SUN.

MACULPA, in *Geography*, a town of Mocaumpour; 20 miles S. of Batgan.

MACUMBA, a country of Africa, forming the fouthern province of Mocaranga.

MACUNA, in *Botany*. See DOLICHOS.

MACUNA, in *Geography*, one of the Navigator's iflands, in the South Pacific ocean, where feveral of M. de la Peroufe's crew were maffacred by the inhabitants. S. lat. 14° 19'. W. long. 169°.

MACUNGY, a townfhip of America, in Northampton county, Pennfylvania, containing 1844 inhabitants.

MACUPA, a town of Africa, in the country of Mambaça, near the coaft; five miles N.W. of Mambaça.

MACURITAS, a town of the ifland of Cuba; 115 miles W.S.W. of Havanna.

MACUTA, in *Commerce*, a money of account in Guinea, on the coaft of Africa, equal in value to 2000 fmall fhells, called cowries, or zimbis. The Sierra Leone Company ufe pieces of 10, 5, 2, and 1 macutas. The firft weighs 16 dwt. 21 gr. contains, in pure filver, 330.8 gr. and is worth 3*s.* 10¾*d.* fterling. The fecond weighs 8 dwt. 13 gr. contains, in pure filver, 167.6 gr. and its value is 1*s.* 1¼*d.* fterling. The third weighs 3 dwt. 7½ gr. contains, in pure filver, 65 gr. and is worth 9*d.* The fourth weighs 1 dwt. 16 gr. contains, in pure filver, 32.5 gr. and its value is 4½*d.* fterling. The 10 macuta piece, or dollar, has on one fide two joined hands, with the figures 100 both above and under them, and the infcription "one-dollar piece;" on the reverfe, a lion; legend over the lion, SIERRA LEONA COMPANY, and under it, AFRICA. The half-dollar is marked 50; the ⅕ dollar, 20; and the 1/10 dollar, 10; with the infcriptions, HALF-DOLLAR PIECE, TWENTY-CENT PIECE, and TEN-CENT PIECE: the reft as on the dollar.

MAD, in *Geography*, a town of Hungary; five miles N. of Tokay.

MAD, a river of America, called alfo "Pickawa Fork," which is a rapid branch of the Great Miami, that paffes in a beautiful ftream with a S.W. courfe through a pleafant level country of very great fertility.

MAD-*Apple*, or *Melongena*, in *Botany*. See SOLANUM.

This plant is propagated in the gardens of the curious with us; and in Spain, Italy, and Barbary, common in the kitchen-gardens, the fruit of them being frequently eaten there, boiled with fat flefh, putting thereto fome fcraped cheefe, and preferving it through the winter with vinegar, honey, or falt pickle. This they efteem of great efficacy to provoke venery. In fummer alfo, when the fruit is juft ripe, they eat it frefh dreffed, with fpices, and other ingredients.

The apples being much like thofe of the mandrake, have induced fome moderns to fufpect this plant to be the male mandrake of Theophraftus; and fuppofing them to be deadly to call them mad-apples; whereas in reality they excite no fymptoms of madnefs, but are ufed by the Italians and Spaniards in their fauces and fweatmeats. They have the tafte of the citron.

MAD-*Dog*. See DOG and HYDROPHOBIA.

MAD-*Water*, among *Miners*, is water that has been drawn from a fhaft, or any part of the mine, and returns back again to the fame place from whence it was drawn.

MAD-*Wort*, in *Botany*. See ALYSSUM.

MAD-*Wort*, *German*. See ASPERUGO.

MADABLOTA. See GÆRTNERA.

MADAGASCAR, in *Geography*, an ifland in the Indian fea, feparated from the coaft of Africa by the channel of Mozambique. Its length is ftated by De Pagés to be about 900 miles and its breadth 100; but others affign to it 840 geographical miles in length, and about 220 in medial breadth. De Pagés fays, that next to Borneo, it is the moft extenfive in the world. He might alfo have excepted Papua and New Holland, if the latter may be claffed in the number of iflands. As it extends from N.N.E. to S.S.E. from the 12th to the 26th degree of fouth latitude, its climate is mild and agreeable. Of its firft difcovery, nothing certain is known. The ancients, even as late as Ptolemy, feem to have been unacquainted with it. The firft mention of it, upon which we can depend, is by Marco Polo, in the 13th century, who having derived his knowledge of it from the Arabs, defcribes it by its prefent name. It efcaped the notice of Gama, who coafted along the African fhore; and though it is faid to have been known to the Arabs and Perfians from time immemorial, under the name of "Sarandib," its firft difcovery is afcribed to Lorenzo, or Lawrence Almeyda, in the year 1506. Hence the Portuguefe gave it the name of St. Lawrence; the French, in the reign of Henry IV., called it Ifle Dauphiné: its real name, however, is Madecaffa, though it is now generally known by that of Madagafcar. It is divided into 28 provinces; and its furface, according to Rochon, may be eftimated at 200 millions of acres of good and arable ground, celebrated for fertility and for the variety of its productions. All its different parts are watered by torrents and large rivers, and more efpecially by a number of fmaller rivulets, which flow from the vaft ridge of mountains that feparates the eaftern from the weftern coaft. Vigagora is the higheft mountain in the N., and Botiftmena in the S. Thefe mountains contain in their bowels precious minerals and curious foffils, and their fummits are crowned with lofty trees, of long duration. The fcenery which the ifland prefents is very picturefque and interefting, as it is diverfified with precipices, cataracts, and immenfe forefts. The vegetation of its hills and plains experiences no obftruction from the viciffitude of the feafons, nor does it derive much affiftance from the labour of the inhabitants. The fpacious commons afford pafture to numerous droves of oxen and flocks of fheep: and the foil evinces its fertility, with little aid of culture, by yielding a crop of rice in the proportion of 100 grains to one that is fown. The woods afford a prodigious variety of trees, fuch as all kinds of palm trees, woods ufed in dyeing, ebony, bamboos of an enormous thicknefs, as well as orange and lemon trees. They alfo fupply timber for building fhips and houfes. Flacourt fays, that in the year 1650 he fent to France 52,000 aloe trees of the firft quality; and he has given the names of two or three hundred different plants. Of late there have been obtained from this ifland the Mauritanian mulberry with green fruit, and the Gummiphera Madagafcarienfis, the juice of which, called by the iflanders "finguiera," concretes into an elaftic gum, fimilar to the caoutchouc of Cayenne. Of efculent plants this ifland furnifhes not only rice in abundance, but the banana, yam, nymphæa lotos, feveral fruits of dolichos or kidney beans, gourds, water melons, and cocoa nuts. The fruits are pine apples, tamarinds, oranges, and pomegranates. The fpices and other condiments are common and betel pepper, ginger, turmeric, cinnamon, and fugar. The Indian fig grows, as well as cotton and indigo. Many quadrupeds are peculiar to this ifland, whence fome naturalifts have, perhaps, too haftily inferred, that it never joined the African continent. Here are no lions, tigers, elephants, nor horfes. Many of the moft valuable minerals might be fupplied from hence; fuch as the pureft rock cryftal, beds of which occur, gold ore, topazes, fapphires, emeralds, and

 fpotted

ſpotted jaſper, or blond ſtones. Here are found numerous black tourmalins of Haüy, which the ancient mineralogiſts conſidered as the ſchorl of Madagaſcar. The inhabitants of Madagaſcar, who call themſelves "Malegaſhes," or "Madecaſſes," are in general well-ſhaped, and above the middling ſize: the colour of their ſkin is various; ſome tribes being of a deep black, others tawny; ſome having a copper complexion, but the greateſt number being of an olive colour. All thoſe that are black have woolly hair, like the negroes of the coaſt of Africa. The hair of thoſe who have the complexion of Indians or Mulattoes, does not frizzle more than that of the Europeans; their noſe is not flat; their forehead is broad and open, their lips not pouting, and every feature of their face is regular and pleaſant. Their phyſiognomy bears, in general, the marks of a character replete with frankneſs and amenity. Rochon compares them, with regard to their diſpoſition and général character, to the ſavage, whoſe condition he abſurdly extols, becauſe, like the brute animal, he is deſtitute of all reflection on the paſt, and forethought with regard to the future. From the hair, complexion, and make of the natives of Madagaſcar, M. de Pagés conceived them to be deſcended from different races of men. Some who are ſhort, with lank and ſmooth hair, of an olive complexion, have a ſtrong reſemblance to the Malay Indians, and do not ſeem to have originally ſprung from the aborigines of the iſland. Others, tall and well-proportioned, with criſped locks, large and beautiful eyes, an eaſy carriage, and an open, unreſerved countenance, appear to be the true poſterity of the primitive inhabitants; their colour is nearly black, and differs but little from that of the natives on the Malabar coaſt. In their diſpoſition they are lively and obliging, but wholly deſtitute of genius; vain, whimſical, and intereſted; dextrous in the uſe and application of their bodily faculties; but without the powers of combination, and in the general conduct of life, light, precipitate, and incapable of preſerving a ſteady conduct, or of acquiring a decided character. With weak minds, they poſſeſs a conſiderable portion of wit and vivacity, and they blend a variety of good and bad qualities. They wear an apron at the girdle, and ſomething of the ſame kind on the ſhoulders, with a bonnet conſtructed like an umbrella; the hair is combed into ſmall treſſes, and the beard is permitted to grow only on the chin. The men are little addicted to agriculture, but more inclined to look after their cattle, which roam in the woods. They conſtruct war canoes, as well as canoes for their ordinary occupations. The latter are ſmall, and navigated only with the oar; but the former, which are the property of the chief, are much larger, and have a ſort of rigging. Some of them carry 100 men, and are in condition to ſail round the iſland. The women are generally of the middle ſize, with expreſſive faces, and though not entitled to be claſſed with the handſome part of the ſex, few of them are ugly. Round the waiſt they have a long apron, with a kind of under waiſtcoat, which barely covers the breaſts. They frequently wear, by way of ornament, a large circular plate of ſilver; and round the neck, falling down upon the boſom, a number of ſmall ſilver chains. Their hair appears in a multitude of little treſſes, dangling over the forehead, or on the corner of the eye, or turned up in the form of a creſcent. The women, beſides cultivating fields of corn, rice, and other ſorts of grain, are employed in planting trees and roots, particularly the caſſava, batatas, and the banana or plantain. The leaves of the tree, named raſia, are made to ſupply them with thread; and with theſe materials, dyed of various colours, they manufacture a kind of cloth, which is woolly, and affords a very handſome article of dreſs. They prefer, however, the cotton ſtuffs imported by Europeans from the continent. Every family is provided with a loom, and carries on a manufacture equal to its own conſumption. From the leaves of a tree, named vacoua, they procure materials for mats, bonnets, bags, and other uſeful articles. Their common food conſiſts of rice, bananas, and dried fiſh; they conſume little fleſh meat or freſh fiſh; their drink is water, or the juice of the ſugar cane, fermented with pimento and muſtard. Their houſes are ſmall and awkwardly conſtructed. The walls are formed of bull-ruſhes, and the roof covered with plantain leaves. The chief part of the timber work conſiſts of maſſy pieces of wood, the reſt being bamboo, very rudely executed. The floor is laid with the pith of the palm, or ſome other tree, and is often raiſed far above the level of the ground, to avoid the exhalations of the ſoil, and alſo to guard them from the annoyance of ſerpents and inſects during the rainy months. Although the natives have no regular form of worſhip, they nevertheleſs adore one ſupreme being, as the patron of juſtice and goodneſs, who will judge men after death, and reward or puniſh them according to the merit or demerit of their actions. The rite of circumciſion is performed upon males between the 7th and 8th year of their age; and the day of circumciſion is obſerved with feſtivity, and cloſed with the ſingular cuſtom of firing from a muſket the fore-ſkin of the patient. They believe alſo in a devil, or evil being; and upon this article is founded the craft of the Panſaret or Magician, who, being ſuppoſed to defeat or controul the machinations of the inviſible enemy, practiſes a thouſand tricks on the credulity of the multitude. Amulets of a ſpecies of wood, ſuſpended round the neck, or preſerved in a little bag, are ſuppoſed to ſecure the poſſeſſor againſt wounds and the diſaſters of war. A ſhrimp or toad, applied with words of incantation to the head of a perſon affected by diſeaſe, is expected to reſtore him to health. Expoſing the ſick in a hut of a certain elevation, open towards the eaſt, from which is let fly an aſſemblage of party-coloured threads, is a ſovereign remedy in the moſt deſperate caſes. Perfumes are introduced in abundance in all the arts and enchantments of the magicians. All theſe abſurd obſervances ſeem to be the barbarous veſtiges of religious notions, indiſtinctly tranſmitted to the people from their Aſiatic neighbours. The rite of circumciſion, the common uſe of perfumes, and a profound veneration for the quarter of the eaſt, are evidently the remains of religious ſyſtems of the higheſt antiquity. But the moſt horrid part of their ſuperſtition remains ſtill to be related. When an infant has the misfortune to drop into the world on a day eſteemed unlucky, or of bad omen, by the Panſaret, he is expoſed or ſuffered to die of want, or to be devoured by wild beaſts. The natives are accuſtomed to hunt the whale along their coaſt; and when he is ſtruck with the harpoon, they wait till his ſtrength is nearly exhauſted, and then lead him towards the ſhore. The women aſſemble on the beach, and vociferate ſongs of praiſe in honour of him who gave the firſt wound. The whale is then near the land, and ſurrounded by all the men in the village, when the public orator advances, and having pronounced a long oration on the pre-eminent qualities of the fiſh, the whale is cut up, and affords a rich repaſt to the company. When any ſubject of diſpute occurs between the natives of Madagaſcar and the Europeans, or between Indians of different tribes, it is formally diſcuſſed in the "palaver," or council of the tribe; and the deciſion is the reſult of long deliberation.

Property in this iſland conſiſts of cattle, grain, and ſlaves of the ſame nation with their maſter. Every perſon who has the misfortune to be made a priſoner of war, man, woman, or or child, is reduced to the condition of ſlavery, and from that moment is regarded by his own kindred as an object of contempt. Their arms conſiſt of a ſhield, and the "ſagay," a kind of lance, which they throw with peculiar addreſs. They are alſo tolerably well provided with muſquets, purchaſed from the French; and they have alſo ſome ſwivel guns and cannon, obtained from the ſame quarter. The reſidence of the chief is within a fort or ſtockade, conſiſting of three rows of large trees, fixed in the ground ſo cloſe as almoſt to exclude the light; and faſtened together at the top by a croſs beam. Their forts in general are mere ſimple paliſades, conſtructed in the form of an oblong ſquare; though ſome of them have baſtions and galleries, with openings for the purpoſe of reconnoitring. On the eve of war, the women, children, and cattle, retreat to the woods, and there conceal themſelves, waiting the iſſue of the campaign. The village is then occupied only by the men, who, previouſly to any act of hoſtility, ſacrifice an ox. An Indian, of diſtinguiſhed eloquence, harangues on the injuſtice of the enemy; and his countrymen, in the mean while, dip their ſagays in the blood of the victim. Their operations in the field are of a very deſultory deſcription, conſiſting chiefly in teazing and haraſſing the enemy, or attempting to ſurpriſe him in the night. They ſeldom come to a regular engagement. The natives of Madagaſcar are ſuſceptible of very violent enmities, and ſometimes execute on their devoted objects the moſt deliberate cruelties. The cuſtomary uſe of preſents is the ſame here as in India. It is the buſineſs of the inferior to make the firſt advance, as well as the firſt preſent; but he always receives another in return. The natives indulge in all the offices of hoſpitality; but not to the exceſs which ſome travellers have aſcribed to them, who have ſaid that it is cuſtomary for parents to proſtitute their children to the embraces of ſtrangers. This M. de Pages abſolutely denies. He acknowledges, however, that chaſtity in the intercourſe of the ſexes is little regarded. The young ladies of Madagaſcar, habituated to intrigue, prompted by the political and pecuniary views of their parents, and captivated by the charm of ſome new ornament for their perſons, ceaſe to be reluctant to the wiſhes of their admirers. Married women are very little addicted to violate the nuptial engagement. When a woman happens to conceive by a foreigner, ſhe recurs to various drugs, known to the natives, in order to procure abortion. In the language of Madagaſcar, which is by no means harſh or diſagreeable to the ear, M. de Pages perceived ſome inflexions of voice which occur in that of the Philippine iſles. It ſeems to be a compound of different languages, and contains many words borrowed from the Arabic and Portugueſe.

The iſland of Madagaſcar is divided into a great number of tribes. Its population, ſays M. Rochon, may be reckoned at 4,000,000 inhabitants; but no preciſe calculation is poſſible; as the iſland is divided into diſtinct ſocieties, each of which inhabits the canton which it likes beſt, and is governed by its own uſages. A tribe conſiſts of ſeveral villages, who all have a particular chief. This chief is ſometimes elective, but more frequently hereditary. The land is never parcelled out, but belongs to thoſe who take the trouble of cultivating it. Theſe iſlanders have neither locks nor bolts, and live in a frugal manner. The French ſettlement of Fort Dauphin is in the ſouth-eaſt extremity of the iſland. For an account of it, ſee *Fort* DAUPHIN. The chiefs never go out without their gun, and a ſtick tipped with iron, ornamented at its end with a tuft of cow-hair. They wear a cap of red wool, by the colour of which they are diſtinguiſhed from their ſubjects. In the province of Carcanoſſy, in which Fort Dauphin is ſituated, the territories are deemed to belong to the chiefs, who diſtribute them among their ſubjects for cultivation, for which they expect a ſmall return. The people of this province are not quite ignorant of the art of writing. They have ſome hiſtorical books written in the Malegaſh language; but their men of letters, called "Ombiaſſes," uſe the Arabic character. They have treatiſes on phyſic, geomancy, and judicial aſtrology. The moſt famous of them come from Mantatara, and profeſs geomancy and aſtrology in the public ſchools. The art of writing has doubtleſs been brought to this iſland by the Arabs, who conquered it between three and four centuries ago. The paper is manufactured in the valley of Amboul, and is wrought from the papyrus nilotica. The pens uſed by the iſlanders are made of bamboo. Their ink is prepared of a decoction in boiling water of the bark of a tree, called "Arandrato." The Arabic has made ſome progreſs in the north-weſt of Madagaſcar; and the Arabians have a ſtaple on the river Bombetoque in the iſland, where they carry on commerce; and thus they have ſucceeded in introducing, with their language and learning among the natives, ſome traces of Mahometaniſm. The contiguity of Madagaſcar to the coaſt of Africa makes it natural to aſcribe its population to that vaſt continent; and the different races of inhabitants are now ſo much confounded, as to render it a vain attempt to enumerate them. For an account of the *Kimoſſes* of Madagaſcar, ſee that article. The north-eaſtern part of the iſland of Madagaſcar is the rich ſtaple of the colonies of the iſles of France and Bourbon. The moſt frequented harbours are "Foule Pointe," "St. Mary's," and the "bay of Antongil." In theſe three places the French have endeavoured to form colonies; but the incurſions of pirates and the prevalence of the ſlave-trade have, according to Rochon's ſtatement, by their conſequences deſolated the northern part of Madagaſcar. S. lat. 12° 30′ to 25° 30′. E. long. 44° to 51°. Rochon's Voyage to Madagaſcar. De Pages' Travels round the World, vol. iii. See BENYOWSKY.

MADAGH, a town of Algiers, near the coaſt; 20 miles W.S.W. of Oran.

MADAH, a town of Perſia, in the province of Segeſtan; 24 miles S. of Zareng.

MADALENA, or MAGDALENA, a majeſtic navigable river of South America, in New Grenada, reckoned the Danube of this province, which riſes about 30 miles E. of Popayan, and after a northerly courſe of 100 miles, in which it is augmented by other rivers, runs into the Caribbean ſea. The courſes of this river, and alſo of the Cauca, are conſiderable ſtreams, perhaps the iſſues of ſubterranean waters, from the vaſt cavity under the Table land, where the volcanoes often pour out deſtructive torrents of water and mud. N. lat. 11°. W. long. 74 40′.—Alſo, a ſmall iſland in the Pacific ocean, near the ſouth coaſt of Chiloe. S. lat. 44° 15′.

MADALENA, *La*, a town of Canada, on the river St. Lawrence. N. lat. 46° 25′. W. long. 72 25′.—Alſo, a ſmall iſland near the coaſt of Sardinia. N. lat. 41° 15′. E. long. 9 35′.

MADALENA, *La*, *Bay of*, a bay on the weſt coaſt of California. N. lat 24° 53′. E. long. 247° 56′.

MADALENA, *St.*, a town of New Navarre; 150 miles S.W. of Caſa Grande.

MADAMAT, in *Hindoo Mythology*, the ſon of Kriſhna and Rukmeni, and a name of Kama, the god of love; he having been incarnated in the perſon of Madamat, otherwiſe Madana, or Makadama. See KAMA.

MADAME ISLE, in *Geography*, forms the north-eaſt ſide of the gut of Canſo, as you enter from the ſouth-eaſt, and

and is oppoſite to the eaſtern extremity of Nova Scotia. The north point of the iſland lies 14 miles S. of St. Peter's harbour, in Cape Breton iſland; on which iſland the iſles de Madame are dependent.

MADAMPAR, a ſea-port town of the iſland of Ceylon, on the weſt coaſt, at the mouth of a river.

MADAMUT, a town of Egypt, on the eaſt ſide of the Nile; 20 miles S.S.W. of Kous.

MADAN, MARTIN, in *Biography*, an Engliſh divine of the eſtabliſhed church, was born about the year 1726, and was brought up to the profeſſion of the bar, which he quitted for the church, though without preferment. The chapel at the Lock-hoſpital was built chiefly by his exertions; and he officiated many years as the chaplain, without any emolument. He is chiefly known as an author by a work entitled, "Thelyphthora, or a Treatiſe on Female Ruin," in 3 vols., 8vo., publiſhed in 1781, which occaſioned a long and very violent controverſy. The author maintained the lawfulneſs, or even the duty of polygamy. Mr. Madan was a good claſſical ſcholar, and publiſhed a tranſlation of Juveral and Perſius: he alſo wrote a treatiſe on "Capital Puniſhments." He died in 1790, having attained to much popularity as a preacher; and as a man, his moral character was unimpeachable.

MADAN's *Point*, in *Geography*, a cape on the north-eaſt coaſt of the iſland of St. Chriſtopher. N. lat. 17° 28'. W. long. 62° 38'.

MADANA, in *Hindoo Mythology*, a name of Kama, the Hindoo god of love, otherwiſe *Madamat;* which ſee.

MADAPASSA, in *Geography*, a town of Bengal; 60 miles S. of Dacca.

MADAPOUR, a town of Bengal; 10 miles S.E. of Rajemal.

MADARAVAN, a town of Fez, in the vicinity of iron-mines, not far from mount Atlas.

MADARGUNGE, a town of Bengal; 82 miles N.N.W. of Dacca.

MADAROSIS, from μαδος, *bald*, in *Surgery*, a loſs of the eye-laſhes.

MADBAH, in *Geography*, a town of Kemaoun; 23 miles S.E. of Kerigur.

MADBAN, a town of Hindooſtan, in Bahar; 37 miles S.E. of Bettiah. N. lat. 26° 25'. E. long. 85° 21'.

MADBURY, a townſhip of America, in Strafford county, New Hampſhire, between Dover and Durham, about 10 miles N.W. of Portſmouth; incorporated in 1755, containing 544 inhabitants.

MADDAPOUR, a town of Bengal; 34 miles E. of Mauldah.

MADDEN, *Dr.* SAMUEL, in *Biography*, was born in Ireland about the year 1686, and educated at Dublin, where he reſided the greater part of his life. In 1729 he was in England, and wrote a tragedy, entitled "Themiſtocles;" and was, as he ſays of himſelf, tempted to let it come out, by the offer of a noble ſtudy of books from the profits of it. In 1732 he publiſhed "Memoirs of the twentieth Century," a work which, for ſome reaſon not now known, was in a few days totally ſuppreſſed. In 1740 we find him in his native country, and ſetting apart the ſum of one hundred pounds to be diſtributed in premiums for the encouragement of arts, manufactures and ſcience; and the ſame ſum he continued to beſtow annually for the like purpoſe, ſo long as he lived. The good effects of theſe well-directed benefactions were not only felt in Ireland, but their influence was extended to the ſiſter country, and, it is thought, gave riſe to the "Society for the Encouragement of Arts, Manufactures, &c. in London," of which his grace the duke of Norfolk is now the preſident. Dr. Madden obtained church preferment in Ireland, and he died in December 1765. He left behind him another tragedy, as a legacy to Mr. Sheridan. Biog. Dram.

MADDER, in *Agriculture*, the common name of a plant, ſometimes cultivated in the field, as an ingredient in the dyeing of a ſcarlet colour. The ſorts commonly cultivated for this uſe is, the *rubia tinctoria*, which is a plant of the thick fleſhy tap-rooted kind.

It is ſtated by a late writer, that this plant "was formerly much more cultivated in particular diſtricts in this country than it is at preſent, the importations from Holland having leſſened the demands, and reduced the price of it, ſo much as to render its culture incapable of being conducted with profit to the farmer."

Soil.—The ſoils which are the moſt ſuited to the cultivation of this plant, according to the ſame writer, are thoſe of the deep fertile ſandy loams that are not retentive of moiſture, and which have a conſiderable portion of vegetable matter in their compoſition. It may alſo be grown on the more light deſcriptions of ſoil that have ſufficient depth, and which are in a proper ſtate of fertility to admit of its being grown upon them.

Preparation, and Plants or Sets.—In the preparation of the land for the reception of this crop, "it will be neceſſary to plough it up deeply before the winter into high ridges, in order that it may be expoſed to the action and influence of the froſts, and the atmoſphere. Early in the ſpring theſe ridges ſhould be well harrowed down by a heavy long-tined harrow, and then ploughed again in the contrary direction to a good depth. And when after this the land is not perfectly clean from weeds, or not rendered ſufficiently fine and mellow, another ploughing and harrowing ſhould be given. In the laſt operations the ground ſhould always be left in as level and even a ſtate as poſſible. It is then ready for the reception of the plants. The ſets or plants may then be obtained either by ſowing the ſeed upon a bed of earth which is rich, and made perfectly fine by digging and raking in the ſpring, and then lightly covered in, or from offſets or ſuckers from the old plants. In the firſt method, on the plants appearing they ſhould be made perfectly clean by weeding, and be ſet out to the diſtance of three inches in the beds by the hoe. In this way, by keeping the ground quite clean and well ſtirred about the plants, they will be ready to ſet out in the ſecond autumn, though it will moſtly be better to defer the buſineſs till the ſpring, in this climate, if the ſets can be procured, as the plants ſeldom ripen their ſeed perfectly, or afford it in a ſtate to vegetate well. It requires about twenty thouſand plants for ſetting an acre of land. The moſt ſuitable time of taking the ſets is ſhewn by the plants having attained the height of ten or twelve inches from the ground, and the ſuckers having thrown out fibrous roots at their bottoms. This may be ſeen by drawing up a few of the plants, and uſually about the latter end of May or beginning of June." Beſides "it is neceſſary that the ſets have formed root-fibres at the bottoms, before they are removed, as where that is not the caſe, they never ſucceed well."

The land being prepared in the manner directed above, and the plants thus provided, "a ſufficient number of labourers are to be provided, that the work may be performed as expeditiouſly as poſſible. In taking off the ſets, much care is neceſſary not to injure them. Some perform it by means of a dibble with a flat edge, and which is ſhod with iron; this tool, on being thruſt into the ground on the ſide of the ſhoots, divides and ſeparates them by depreſſing the handle without hurting the fine fibrous roots. The number of plants

plants that can be fet in a fhort fpace of time fhould only be taken up at once. They fhould be prepared by having about a third of their top parts cut off. A fort of thin batter fhould likewife be made, by mixing good vegetable mould and water well together, into which the roots of the fets fhould be dipped before they are placed into the earth, as by this means the neceffity of watering the plants afterwards is prevented. This work is executed by a perfon before the planting commences. Two others are employed afterwards in diftributing the plants fo as to be convenient for putting them into the ground."

There are different methods employed in fetting the plants; in fome cafes they are put in the furrow by means of the plough, while in others they are fet in beds by a dibble. The former is probably the better method, and as being the moft expeditious, is beft adapted to the culture of the plant on an extenfive fcale. In this the planter begins by drawing a ftraight furrow on one fide of the plantation to a good depth; a row of plants is then laid in it by a perfon for the purpofe, at the diftance of five, fix, or more inches from each other, according to the circumftances of the land, in fuch a manner as to lean off from the plough; another furrow is then formed, by the mould of which they are covered. In this manner the work proceeds until the whole is finifhed.

In the other method, it is obferved, the fets, after the land has been formed into beds, five feet in breadth, with two feet between each for intervals, are put in by means of a line and a dibble, beginning at the diftance of fix inches from the outfides, and fetting a row of plants at fuitable diftances from each other, as juft mentioned; then removing the line two feet farther on them, and putting in another row; after which it is again removed two feet, and a third row of plants fet in, which finifhes the bed; the work proceeding in this manner till the whole of the plantation is completed. In this way each bed contains three rows of plants, at two feet diftance each, three feet being left between the rows on the different beds."

But "in Holland, where the culture of this root is extenfive, their method is, it is obferved, a little different from the above. The plants, after being taken from the older plantations about the month of May, are immediately fet in rows at the diftance of three or four inches from plant to plant, and about fifteen inches from row to row, the beds being ten or twelve feet in width, with intervals of only about two feet."

It is fuggefted that, "as in whatever manner the plants are fet, fome of them, even in the moft favourable feafons, are liable to die foon after the work has been performed, it is neceffary, in the courfe of a fortnight or three weeks, to look over the ground and put frefh vigorous plants in the places where the others have been deftroyed. By this means the plantations may be rendered more perfect and productive."

But whatever method of planting may be practifed, it is of the greateft importance to the fuccefs of the crop, "that it be kept perfectly clean from weeds, and that the mould be occafionally ftirred about the roots of the plants." The firft of thefe is accomplifhed, according to the furvey of Kent, by means of hand-weeding and hoeing during the fummer feafon, and the latter either by the ufe of a hand-hoe, or a light plough; this laft is the moft eafy and expeditious. In this manner, or by digging the intervals of the rows, the mould is alfo laid up to the plants once each year after the ftems have been removed in the autumn feafon. Where the bed practice is followed, they are fometimes earthed up in the autumn after the ftems have been cut down, by paring the intervals fomewhat in the manner of thofe of the afparagus kind. This method is, however, in general too expenfive and troublefome where the crops are cultivated on an extenfive fcale.

According to Mr. Young, the beft way of performing this culture is "to ufe the fhim, not for turning a ridge againft the rows, as the plants will yet be too weak for that operation, but merely to loofen the earth of the intervals, thereby to kill the weeds, and prepare the foil for being thrown up againft the rows by a fucceeding operation. Hand-hoeing and weeding fhould depend on the number of the weeds that arife among the plants. Let the cultivator of madder, through the whole procefs of the crop, remember, fays he, that he muft be to the full as accurate as a gardener; his foil muft be rendered little inferior to a dunghill; all weeds muft be for ever eradicated; not one muft injure the plants; his land muft always be kept perfectly loofe and well pulverized; for a crop that depends merely on the quantity of the roots, can never thrive to profit in land that is bound or in an adhefive ftate."

Whatever practice is adopted, "the crops are to be managed in this manner until the third autumn after planting, when the plants will be in a ftate to be taken up; this is known by their ftalks beginning to wither, and is generally about October. This bufinefs is performed either by trenching the land over with a fpade, or by means of the plough. The firft is the more certain, though much lefs expeditious method. In executing it, the workmen dig along the rows to the depth of about two feet, breaking and reducing every fpit of earth as perfectly as poffible, each being attended by two perfons, who pick out the roots of the madder. But when the planting has been done in narrow beds, it is fometimes the practice to take the roots up by turning the earth into the intervals by a *fpud*, or broad three-tined fork. In this way it is fuppofed that the roots are taken up more perfectly, and with lefs danger of being injured. But the moft ready method is by means of the plough, which after having the earth-board and coulter removed, is paffed along each fide of the rows, fo as to fully loofen the mould; perfons being employed to pick out the roots, loofening fuch parts of the earth as may have efcaped the action of the plough by their fpades." And "when the roots have been taken up, they fhould be expofed fome time to the air, in order that they may be rendered fo dry as to be cleared from dirt. They are then to be conveyed to a kiln, fuch as is employed for the purpofe of drying malt, or hops, when they are to be brought into fuch a ftate of drynefs as to be perfectly brittle. This is to prevent the danger of their being injured by becoming mouldy, or from running into a ftate of fermentation; but much caution is neceffary in conducting the procefs. After this they are packed up in bags, in order to be difpofed of to the dyer, who reduces them into a powder by a mill before they are made ufe of as a colouring ingredient." Mr. Young, however, obferves, that he is "informed, that at prefent (1803) the largeft quantity of madder ufed in our manufactures, is ufed without being powdered as formerly, and that it is faleable with common drying, without ftove-work; but that, that common degree is open to much uncertainty, fo that the preceding remarks are not done away. The price of 4*l. per* hundred weight, marks a confiderable deficcation in his opinion."

It is hinted, that in order to judge of this root, the beft is that which, on being broken in two, has a brightifh red or purplifh appearance, without any yellow caft being exhibited.

It is ftated, "in order to collect the feed of the madder plant, it is neceffary to let the plants remain in the field till the feed is almoft wholly ripe, which is generally in the month of September. The heads are then to be feparated from

from the stems, and exposed in a cloth in the sun, till the seed can be easily forced out by slightly beating them. It is then to be rendered perfectly clean, and afterwards placed in a sunny situation, until it become quite dry; for if the least dampness remain, it will grow mouldy, and its vegetative power be either greatly impaired or wholly destroyed. When thus properly dried, it should be put in small bags, and hung up to the ceiling of a room where a fire is constantly kept."

The produce from the root of this plant is different, according to the difference of the soil; but mostly from ten to fifteen or twenty hundred weight, where they are suitable to its cultivation.

It seems not improbable, a late writer says, "that the cultivation of madder might be rendered a profitable article of field-husbandry in different districts, if the importation of the root from Holland was prohibited; as the event of different trials has shewn that full crops of good madder are capable of being raised." And it is supposed by the intelligent writer of the Survey of Kent, "that if the price was never lower than 3*l.* the hundred weight, it might be grown not only with profit by the farmer, but without injury to the consumer." As it is supposed, "from the high degree of culture which land under this sort of crop must necessarily undergo, and its not being so much exhausted as in many other cases, that it must be an excellent preparation for wheat, or any other crop that requires a clean and fine pulverized condition of the mould or soil."

But the author of the Farmer's Calendar "recommends the young farmer to remember that the culture of these plants, applicable only to the use of manufactures, and which are also largely imported from abroad, is rarely advisable. He was a madder planter once, and lost by every acre he planted. A man may plant at the moment of a high price, and take up his crop three years after at a low one. All such speculations are too hazardous; nor was there even a fair open competition among the purchasers. Those who have cultivated madder with the success boasted by the writers of husbandry, should not hold these observations in contempt. There appears to him almost as much use in mentioning trials that were unsuccessful, as in those that are ever so profitable; for it is certainly of as much consequence to tell one man that his soil *will not do* for madder, as to assure another that his *will do.* Instead of an acre or two, he might possibly have launched (like many others) into ten or fifteen acres; in which case, the loss would have been no trifle. And it is surely highly incumbent on every one to make known to the world such of his experience as will probably be of any use to it. Bad success of several persons in a culture is too apt to prejudice others in general against it. However irrational, still it is so; and it ought to be a caution not to recommend any thing in general, under the extravagant notion, that because an article of culture is profitable on one soil, it must be the same on very different ones. But the grand obstacle to the culture of madder is the difficulty of sale: for while a man has not a fair market for his unmanufactured madder, none can with any prudence engage in it, unless on so large a scale as to admit the whole apparatus of reducing it to such a state as to be absolutely a marketable commodity. In answer to this it may be said, that madder really dry is a *marketable commodity.* But this matters not, if the purchaser has it in his power to be a knave: he has a pretence, a screen always at hand that will cloak the greatest knavery, and to a degree known in no other branch of agriculture. Among the gentlemen of trade who have a mutual understanding and confidence, such objections appear trivial; but to the cultivator at a distance from the market, it is a different affair. He writes to a madder-merchant to know the price. The answer is, *4l. an hundred weight.* Up he sends his madder, and instead of 4*l.* he receives but 3*l.*, not from a variation in *price,* but in *weight.* It may be said, that the correspondent in London may be right. Very true; but will the countryman believe it? He thinks himself right, and has no other proof that he is not so but the interested assertion of the man who buys it. Is it not evident that, in such a case, the cultivator will be disgusted, and throw aside a business in which he knows neither the market-weight nor the market-price? If encouragement is designed to this culture from any quarter, it should not be exclusive of this circumstance. Manufactures should be erected and established, in which the madder could be prepared for any one, at so much an hundred weight, and that by persons not the least concerned in purchasing. Then the cultivator would have a commodity in his hands, which he could sell in as simple and fair a way as any other. If nothing of this sort can be effected, all encouragement should be for such a number of acres (and no less) as will answer the expence of a private manufacture; which would prevent persons being unguardedly drawn in, by premiums apparently considerable, to cultivate a root which, when raised, is in its sale absolutely at the mercy of the purchaser."

Kilns are often necessary in the culture of this root; but for small crops, a common oven may serve, though it is very tedious, and would require large ovens to supply the place of kilns. However, to save the expence of building such kilns, a place may be made over the roof of the oven, to put the roots in, that they may begin to dry. Where much madder is grown, it is, notwithstanding, absolutely necessary to have a kiln proportioned to the quantity that is to be dried. These may be made of different forms, being attentive that it may contain a large quantity of roots; that it be worked with ease, and the smallest proportion of fuel; and that it may be so contrived as to retain an equal moderate heat.

Those made use of in the Low Countries differ very little from that used here in drying malt. There is a large furnace, in which a great fire is made: this furnace is made under an arch; the hot air and smoke pass through a funnel over the furnace, and spread themselves in a space in form of an inverted pyramid, the bottom of which is covered with a perforated floor, on which the madder-roots are spread. See KILN.

And where the manufacture of the article is carried on, a mill for the purpose of pulverizing the dried madder is likewise necessary. See MILL.

Expences of Culture per Acre.—This is on land worth forty shillings *per* acre, in the digging mode, and before the great rise in the price of farm labour.

	£	s.	d.
Rent for three years	6	0	0
Digging ditto at two-pence *per* perch	1	6	8
Dividing ditto into beds, two men one day, at one shilling each	0	2	0
Raking ditto, two men one day, at one shilling each	0	2	0
Planting ditto with two thousand plants, one day, at one shilling and sixpence each	0	3	0
Six women to take up two thousand ditto, at sixpence each, one day	0	3	0
Hoeing the first summer five times	0	15	0
Covering ditto in autumn the first year	0	6	0
Carried over	8	17	8

Brought

Produce of an acre of madder	52	12	2
Expences	15	18	2
Profit	36	14	0

In this eſtimate, which is much below the preſent price, nothing is allowed for plants; as, though expenſive at firſt, when once done, a ſupply from the plantation will conſtantly be had for a long time.

Madder, in *Botany* and *Gardening*. See Rubia.

Madder, in *Law*. See Larceny.

Madder, in the *Materia Medica*. The roots of madder were employed by the Greek writers with the ſame medicinal intentions for which they are recommended by moſt modern writers on the materia medica. Madder differs from ſome other ſubſtances uſed in dyeing, by its property of tinging with a florid red colour, not only the milk, urine, &c. but the bones of thoſe animals which have fed upon it. This circumſtance was firſt noticed by Antonius Mizaldus, (Memorab. ut. ac jucunda Cent. 7. Aph. 91. Lutet. 1566.) but not known in England till Mr. Belchier publiſhed an account of a pig and a cock, whoſe bones became red by eating madder mixed with their food. (Phil. Tranſ. vol. xxxix. vol. xli.) Since that time various experiments have been made, by M. Hamel du Monceau and others, from which it appears that the colouring matter of madder affects the bones in a very ſhort time, and that the moſt ſolid or hardeſt part of the bones firſt receives the red colour, which gradually extends, *ab externo*, through the whole oſſeous ſubſtance, while the animal continues to take the madder; and if the root be alternately intermitted and employed for a ſufficient length of time, and at proper intervals, the bones are found to be coloured in a correſpondent number of concentric circles. Mem. de l'Acad. des Scienc. 1739. Med. Eſſ. Edinb. abr. vol. ii.

According to Lewis (Mat. Med.), the roots of madder have a bitteriſh, ſomewhat auſtere taſte, and a ſlight ſmell not of the agreeable kind. They impart to water a dark red tincture, to rectified ſpirit and to diſtilled oils a bright red: both the watery and ſpirituous tinctures taſte ſtrongly of the madder.

By medical writers, madder has been conſidered as a deobſtruent, detergent, and diuretic, and is chiefly uſed in the jaundice, dropſy, and other diſeaſes, ſuppoſed to proceed from viſceral obſtructions, particularly thoſe of the liver and kidnies; and ſome modern authors have recommended it as an emmenagogue (Home's Clin. Exp.), and in rickety affections. (Levret ſur les Accouchemens.) With regard to its diuretic quality, for which there are ſeveral reſpectable authorities, Dr. Cullen aſſerts, that in many trials, both for this and other purpoſes, ſuch an effect is not conſtant, as it never occurred to him. As a remedy for the jaundice, it has the authority of Sydenham, and was formerly an ingredient in the icteric decoction, which the college of Edinburgh directed to be prepared by boiling an ounce of madder, the ſame quantity of turmeric, and the ſame quantity of the roots and leaves of celandine, in three pints of water to a quart; to which, when ſtrained and cooled, the juice of 200 millepedes are added; and a quarter of a pint of this liquor was ordered to be taken twice a day, or oftener. But as this decoction ſeemed to be more adapted to the "fæces albidæ," than to the diſeaſe itſelf, it was expunged from the Pharmacopeia. That ſome French writers ſhould preſcribe madder in a rickety ſtate of the bones, appears a little ſurpriſing, ſays Dr. Woodville, as the brute animals to which it was given, eſpecially the younger, ſuffered conſiderable emaciation and proſtration of ſtrength from its effects. Its virtues, as an emmenagogue, reſt principally on the authority of Dr. Home, who gave from a ſcruple to half a dram of the powder, or two ounces of the decoction, three or four times a day. But this medicine failed with Dr. Cullen, who alſo ſays, (Mat. Med. vol. ii.) "I know of other practitioners in this country, who, after ſeveral ineffectual trials made with it, have now entirely deſerted its uſe." Woodv. Med. Bot.

Madder, *Rubia Tinctorum*, in the *Arts and Manufactures*, grows wild in many parts of the Levant, as well as in the ſouth of Europe, and has been very largely cultivated in Holland, particularly in Zealand, and alſo in the northern parts of Europe, for the uſe of the dyers and calico printers. (See Dyeing.) The method of cultivating it in Holland is this: in autumn they new plough the land, where the madder is to be planted, if it is ſtrong and heavy, laying it up in high ridges, that it may be mellowed by the winter's froſts. In March they plough it again, working it very deep, and laying it in ridges at eighteen inches aſunder, and about a foot deep. Then, in the beginning of April, when the madder begins to ſhoot out of the ground, they open the earth about the old roots, and take off all the ſide ſhoots, which extend themſelves horizontally juſt under the ſurface of the ground, preſerving as much of the root as may be with them. Theſe they plant immediately on the tops of the new ridges, at about a foot diſtance from each other; and this they uſually do in ſhowery weather, when the plants immediately take root and require no more water. In theſe ridges they let the plants remain two ſeaſons, keeping them clear of weeds; and at Michaelmas time, when the leaves are fallen off, they take up the roots, and dry them for the market. See Rubia.

The madder-plant grows to about three feet in height, but it is the long-ſpreading fibrous root that is uſed in dyeing. The madder of the Levant, called "Lizari," or "Azala," has a ſomewhat higher and finer colour than that of the Dutch; but that of Holland is more carefully prepared. The Dutch method is as follows: the roots, as ſoon as they are gathered, are put under a ſhed, or in a granary, or other ſheltered place, and there remain, expoſed to a current of air, for ten or twelve days, till they are quite pliable, and till no juice can be preſſed out by ſqueezing them. They are then farther dried, either in a common oven of ſlack heat, if the quantity be ſmall, or in large ſtoved rooms, conſtructed for this purpoſe, and heated with turf, a large opening being left for the eſcape of all the internal vapours. This proceſs requires particular attention and management. When the roots are quite hard and brittle, they are laid on a threſhing-floor, and beaten with a flail, in order to ſeparate the dirt and outer thin ſkin; they are afterwards ground in a mill, and the powder, being ſifted and ſorted, is carefully

fully packed in large barrels: it is thus exported, and in this ftate ufed by the dyers. For the method of cultivating and preparing madder in England, fee the article RUBIA. The method practifed in Turkey and Perfia for preparing the madder ufed in the beautiful Adrianople red, is ftated by an eye-witnefs, cited in Aikin's Dictionary, to be as follows: For every 100lb. weight of the frefh root, a fteeping liquor is prepared of 2lbs. of bran, and 1lb. of honey and alum, in four gallons of water. The roots, having been previoufly wafhed clean, are foaked in this liquor for two or three days, and then dried, firft under cover, and laftly in the fun. They are afterwards ground and fifted, the powder laft produced in the mill being of the beft quality.

The powder of madder fhould not be dry and harfh, but feel fomewhat greafy, and adhere together under the fingers. Madder-root confifts of three parts, *viz.* the fkin or cuticle which is rubbed off under the flail, and is of no ufe; a thicker bark or cortical part, and within this a woody portion. Thefe two latter parts are of a high red, and both are intermixed with many yellowifh particles, which injure the red colour, but cannot be feparated in grinding the root. When the colour is extracted in the dyeing vat, the red part is lefs foluble in water than the yellow, and is not fo readily extracted; and, therefore, the beauty of the red colour is deteriorated by long boiling, and by ufing too large a quantity of the root. In the ftate of madder, when ufed by the dyers, it is an orange brown powder, liable to become damp, and to be fpoiled in a moift place. As to the chemical properties of madder, we fhall detail the following experiments by Mr. Wali, from Berthollet Elem. de Teinture, vol. ii. Zealand madder of the beft quality, was of an orange-brown colour, and in moderately fine powder. This powder, with water, gave an orange-red infufion, by maceration with or without heat, but in the latter cafe the colour was finer. By flow evaporation of the infufion, or decoction in a fhallow veffel, a pellicle is gradually formed, and finks to the bottom, and is fucceffively replaced by others. The extract, when nearly dry, is of a dingy brown, and is only in part again foluble in water. Alum added to the infufion gives a precipitate of a very deep brown-red, and the fupernatant liquor affumes a brownifh-yellow tinge. If the alkaline carbonats be added to this liquor, they give a blood-red lake, mifcible with oils, but very inferior in beauty to the cochineal lake. With an excefs of alkali, the precipitate is re-diffolved, and the liquor becomes red. The colour given by foda is not fo fine as that by pot-afh. Lime precipitates a brown-red lake, having no beauty. The acids added to all infufions of madder turn it yellow, but form no precipitate. The natural colour is again reftored by alkalis. Carbonat of magnefia, added to the water in which madder is infufed, turns it of a clear blood red colour, which, when fpread upon paper, becomes yellow by the fun's rays. The following effects are produced by different metallic folutions: acetate of lead, added to the aqueous infufion of madder, gives a brownifh-red precipitate; nitrat of mercury a purple-brown; fulphat of iron a beautiful clear brown; and fulphat of manganefe alfo a purplifh-brown. The folutions of tin, as Berthollet obferves, produce a lake void of brilliancy and beauty, owing, as he conjectures, to the precipitation of the yellow as well as the red particles of madder, fo that this metal, which ferves to heighten the beauty of cochineal, can hardly be ufed with any advantage for madder. Sir Henry Englefield has invented a method of extracting the red of madder of lakes, for which he obtained the gold medal from the Society of Arts. (See Tranf. of the Society, vol. ii.) His method is founded on the difcovery that the red colouring part is fcarcely foluble in cold water, but in the ufual method of extraction is chiefly fufpended by means of the mucilage of the root. His principal procefs is as follows: Inclofe two ounces (troy weight) of the fineft Dutch madder, known in commerce by the name of "crop madder," in a bag capable of containing three or four times that quantity, made of ftrong and fine calico. Put it into a large marble mortar, and pour on it a pint of foft river water, preffing the bag in every direction, and rubbing it as much as poffible without danger of burfting; the water will foon become quite opaque, and loaded with colouring matter. Pour off the water, and add another frefh pint of water, triturating it with the madder as before; and repeat the operation, till the water, the laft added, comes away but flightly tinged. About five pints will be required to exhauft the colour, after which the root, if taken out dried, will be found to have loft $\frac{1}{16}$ths of its weight, and alfo its peculiar fmell; and the colour will be a light nankeen or cinnamon. The water loaded with the colouring matter muft then be put into an earthen or well-tinned copper veffel (not iron) and heated till it juft boils. Then pour it into a large bafon, and add an ounce of alum diffolved in a pint of hot foft water, carefully ftirring the mixture. Afterwards add about $1\frac{1}{2}$oz. of a faturated folution of carbonat of potafh, which will immediately excite an effervefcence, and a fubfequent precipitation of a coloured lake. When it has ftood till cold the lake is to be collected, well wafhed with repeated quantities of warm water, and gently dried. It will then be found to weigh about half an ounce, or a fourth part of the madder employed. This madder lake, which is very beautiful, is found by analyfis to confift of more than 40 *per cent.* of alumine, the remainder is the colouring matter of the madder. If the alum folution and the madder infufion, without the alkali, be fuffered to ftand for a while, a dull red lake will equally precipitate, and the clear liquor will afterwards yield a beautiful ooze-red lake by alkali, but wanting a fufficient body of colour. A lake equally good with the firft mentioned, but of a lighter colour, will be afforded by previoufly allowing the madder and cold water to ftand for a few days in a moderately warm place, by which a flight fermentation will be induced, and a portion of the mucilage of the root deftroyed. The procefs is then to be continued as before. The fame ingenious experiments alfo fucceeded very perfectly in obtaining a ftill more beautiful and equally durable lake, from the frefh madder-root imported from Holland, packed up in mofs. Aikin's Dict.

Wool, previoufly boiled in a folution of alum and tartar, receives from a hot decoction of madder and tartar, a very durable, but not a very beautiful red colour. M. Margraaf (Berlin Mem. 1771) fhews how a very durable lake, of a fine red colour, fit for the purpofes of painting, may be obtained from madder. The procefs is as follows: take two ounces of the pureft Roman alum, and diffolve it in three (French) quarts of diftilled water that has boiled, and in a clean glazed pot. Set the pot on the fire, and when the water begins to boil, withdraw it, and add to it two ounces of the beft Dutch madder. Boil the mixture once or twice, then remove it from the fire, and filtrate it through a double filtre of paper not coloured. Let the filtrated liquor ftand for a night to fettle; and pour off the clear liquor into the glazed pot, well cleaned. Make the liquor hot, and add to it gradually a clear folution of falt of tartar in water, till all the madder is precipitated; filtrate the mixture, and upon the red precipitate which remains upon the filtre, pour boiling diftilled water, till the water no longer acquires a faline tafte; the red

red lake is then to be gently dried. The colour of this precipitate is deep; but if two parts of madder be ufed to one part of alum, the colour will be ftill deeper: one part of madder, and four parts of alum, produce a beautiful rofe-colour.

MADDIGUBA, in *Geography*, a town of Hindooftan, in the circar of Gooty; 10 miles from Anantpour.

MADDIGUER, a town of Hindooftan; 12 miles N.W. of Gooty.

MADDORPETTA, a town of Hindooftan, in Myfore; 19 miles N.E. of Seringapatam.

MADDOX, Isaac, in *Biography*, who arrived at the higheft honours of the church, was defcended from parents of rather mean rank in London. Of thofe parents he was deprived while very young, and he was placed in a charity-fchool, where he imbibed a tafte for ufeful knowledge. An attempt was made to put him apprentice to a paftry-cook, but his love of reading, and his defire after learning, feem to have unfitted him for that employment, and he was, by the intereft of his friends, allowed to purfue his ftudies at one of the Scotch univerfities. It has been faid, but the fact feems at leaft doubtful, that he became a preacher among the diffenters for a fhort time. It is certain that he refufed to take orders in the church of Scotland, and, probably by his talents, obtained the patronage of bifhop Gibfon. He was, by the intereft of the learned prelate, admitted of Queen's college, Cambridge, and foon after received epifcopal ordination. He was firft appointed curate of St. Bride's, and then domeftic chaplain to Dr. Waddington, bifhop of Chichefter, whofe niece he married, and was afterwards promoted to the rectory of St. Vedaft, Fofter-lane, London. In the year 1729 he was appointed clerk of the clofet to queen Caroline, about which time he was created a doctor by a diploma from Lambeth. In 1733, he was made dean of Wells, and in the fame year he publifhed "A Vindication of the Government, Doctrine, and Worfhip of the Church of England, eftablifhed in the Reign of Queen Elizabeth." The work was a fort of anfwer to, or attack on, Neal's Hiftory of the Puritans. This defence of the church, together with his intereft by marriage and otherwife, paved the way for his preferment, and he was in 1736 confecrated bifhop of St. Afaph, from which fee he was tranflated to that of St. Afaph in 1743, and from thence to Worcefter. Excepting the volume already referred to, the bifhop publifhed only fourteen fingle fermons, preached on public occafions, between the years 1734 and 1752. The bifhop died in 1759, about the age of fixty-two. As a prelate, he difcharged the duties of his ftation with fidelity and much diligence: in the government of the clergy he acted the part of a prudent and affectionate father. He was always liberal, and in many inftances munificent: during his life, he gave two hundred pounds a-year towards the augmentation of the fmaller benefices of his diocefe. He was a zealous encourager of public and benevolent inftitutions. To the London hofpitals he was a great benefactor, and was among the firft promoters of the Worcefter infirmary. In his manners he was diftinguifhed for cheerfulnefs, affability, and good nature, and was at all times above the falfe pride of concealing his humble origin. At one of his entertainments he preffed the company to tafte his paftry, faying he believed it was good, but he could affure them that it was not of his own manufacture. Gen. Biog.

MADE Streams, in *Agriculture*, fuch as are formed by art, as in the cafe of irrigation, &c.

MADEE, in *Geography*, a town of Hindooftan, in Tellingana; 38 miles of Warangole.

MADEIRA, a well-known ifland in the Atlantic, of which Funchal, fituated near the eaftern extremity of the fouth coaft, is the capital and bifhop's fee. The firft fight of the ifland is peculiarly magnificent to thofe who have never travelled beyond the Britifh channel. The entrance to the bay affords a moft beautiful profpect of the city of Funchal and of the furrounding country, which from every part of the coaft rifes fo fteep as to bring very diftant objects into a fore-ground, like a Chinefe landfcape. As high as the temperature will admit the hills are clothed with vines, in the midft of which a white manfion, at agreeable diftances, is difcovered, and on the higheft habitable part of the hill is an elegant chapel, dedicated to Noffa Senhora de Monte. To the left of this is a beautiful country feat, with a fine hanging wood, erected by the late conful, Mr. Ch. Murray, and fince purchafed by a Portuguefe nobleman. Above this the mountain is covered with woods or verdure, as high as the fight can diftinguifh, and indeed in every part, excepting thofe columnar peaks, the foil of which has been wafhed away by the violent rains to which thofe latitudes, and particularly fuch elevated parts, are liable. The whole ifland is faid to be about 40 miles in length, and 11 in its greateft breadth. The altitude of Pico Ruivo, its higheft land, taken by the barometer and thermometer according to M. de la Luc, is eftimated at 5068½ London feet. To Mr. Johnfon, called by the Portuguefe the accomplifhed Englifhman, we are indebted for an accurate map of Madeira, and many other very valuable remarks. Though partner in a confiderable mercantile houfe, he was a well-educated man, and always turned his acquirements to the benefit of others. His obfervations, confirmed, we believe, by the quadrant, eftimated the peak fomewhat higher. This is, however, nearly an Englifh mile, elevated on a furface of about five miles on each fide, which is enough to give an idea of the prodigious fteepnefs of every part of the ifland. From Pico Ruivo, fituated nearly at the eaftern extremity of the mountainous part, there is a kind of table land, running weftward for more than twenty miles, in fome parts extremely narrow, and from its elevated fituation fo tempeftuous during the winter, that no habitations are found in its whole extent. This is called Paulo da Serra, and is faid to be level ground, a comparative term in an ifland, the furface of which is fo univerfally uneven. The following account of the geology of Madeira is offered as the moft recent, though in many refpects imperfect, from the fhort ftay of the honourable H. G. Bennet, to whom we are indebted for it.

"It confifts," fays that gentleman, "of a fucceffion of lofty hills rifing rapidly from the fea, particularly on the eaftern and northern extremities. The fummits of many of thefe ranges prefent the appearance of what has been called a table land; yet occafionally the forms are conical, and furmounted by a peak, which in fome inftances I found to be of columnar bafalt. Deep ravines or vallies defcend from the hills or *ferras* (fo called from the interfections the eye meets with in viewing from below the different chains of mountains) to the fea, and in the hollow of moft of them flows a fmall river, which in general is rapid and fhallow. The foil of the ifland is clay on the furface, and large maffes of it as hard as brick are found underneath. Though there are not at prefent any exifting volcanoes in the ifland, yet the remains of two craters are to be feen, one on the eaftern, the other on the weftern fide, the largeft being about a Portuguefe league, or four Englifh miles, in circumference. Every thing around wears marks of having

 fuffered

ſuffered the action of fire; yet I was unable to diſcover any depoſit of ſulphur, and was told that none had hitherto been found in the iſland.

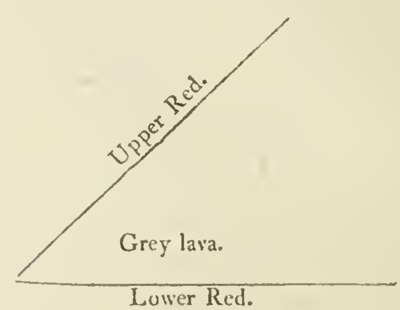
"The varieties of ſtrata, which I ſhall term generally lava, are not numerous. I myſelf ſaw but four, and I was informed there were no more to be met with Three of them were invariably alternating in the ſame order. The firſt or loweſt lava is of a compact ſpecies, containing few, if any, extraneous ſubſtances, is of a blue colour, and of a remarkably fine grain. Upon that, the ſecond, which is a red earthy friable lava, reſts; ſometimes ſeparated by beds of clay mixed with pumice, and layers of black aſhes and pumice. This red lava contains minute pieces of olivine; ſometimes it aſſumes a priſmatic form, and in one place was of a moderate degree of hardneſs: the principal ſprings of water in the iſland iſſue from this ſtratum. On the top is the third, a greyiſh lava, generally compact, though at times near the ſurface very cellular, and containing much olivine. This lava takes principally the priſmatic form of baſalt. I have ſeen it in the moſt perfect priſms from 30 to 40 feet or more in height, the ſurface being covered with ſcoria, aſh, and pumice. Theſe maſſes of lava contain more or leſs of what I conſider to be olivine, occaſionally carbonate of lime and zeolite, which laſt aſſumes either a cryſtallized or globular form, or is diffuſed in a thin coating between the different layers.

"The fourth ſpecies of lava is of a coarſe grain, is uſed for the making of walls, and the commoneſt and pooreſt houſes are built of it, the blue and grey lavas being uſed for the copings, &c. It works eaſier than the two other kinds above mentioned, is more friable and ſoft, and its colour is a mixture of brown and red. I obſerved it in a ſtratum by itſelf, and it did not ſeem to have any connection with the other three kinds.

"Theſe are the principal ſtratified lavas that the iſland affords; but in the beds of the rivers, particularly in that which flows in the valley of the Corral, ſeveral varieties occur in iſolated maſſes, containing olivine and zeolite in greater or leſs quantity, and exhibiting detached portions of ſtrata, ſimilar to thoſe that are found in the Foſſa Grande on the ſide of Veſuvius.

"I alſo examined the coaſt to the weſtward of the town of Funchal. From the beach before the town to Illhoo Caſtle, and beyond it to the land called the *Punta de la Cruz*, the general character of the coaſt is as follows: The red ſtone is the apparent baſe upon which reſts a bed of grey priſmatic lava, the ſtratum being ſometimes from 40 to 100 feet in depth. At times this grey lava reſts upon a deep bed of aſhes and pumice, agglutinated together like the *peperino* and *puzzolano* in the vicinity of Naples. The ſcoria at the ſurface is remarkably thick, and all the upper parts of the lava appear to be cellular. The general dip of the lava on the coaſt near Funchal is to the north, but near the fort of Illhoo it forms with a maſs of pumice that is interſected with ſlight veins of carbonate of lime and zeolite, a rapid angle or curve of declination to the eaſt. To the weſtward of the fort, the lava is not found for a little diſtance, and there is nothing but deep beds of pumice and the agglutinated maſs above mentioned. Theſe beds of pumice are of various thickneſs, the deepeſt appearing to be about four feet, and alternating with that ſtratum which I have called *peperino*. In different cavities of the pumice bed, there are large depoſits of black aſhes. Towards the extremity of the ſtrata the red ſtone appears on the ſurface in a more ſolid ſtate, and lies in priſmatic maſſes, the priſms being ſmall, and not exceeding a few inches in diameter. Their ſubſtance is brittle, and crumbles with eaſe. This ſtratum of red lava is of a ſhort continuance. Paſſing a ſmall brook, it dips rapidly to the weſtward, and in its place the grey lava is found in a confuſed though ſometimes priſmatic form, and riſes from the beach, while the red lava ſtill runs along the ſurface to the height of near 100 feet, the top being covered with a thick ſcoria.

"There is alſo in the vicinity of Funchal, to the eaſtward of the town, a fall of water, which, independent of the romantic beauty of the ſituation, merits being viſited on account of the expoſure of the two ſtrata of lava in their relative poſition. The hills are compoſed wholly of lava, ſometimes of a confuſed, ſometimes of a priſmatic formation, the red and grey lavas being viſible on both ſides of the valley. Near the head of it, a ſhort diſtance from the caſcade, the red ſtratum is at the bottom, and about 60 feet higher it re-appears, and again, about 200 feet higher, alternating with the grey lava. The upper red lava dips rapidly to the ſouth, and the ſtrata are diſpoſed in the following manner:



"The rock, down which the caſcade falls, is alſo interſected with a red ſtratum of about three feet wide, that traverſes it, and dips to the weſtward, and is broken off by a broad dyke of grey lava. It appears about 30 feet higher, and dips again to the weſtward. The ſubſtance of the red rock in this place is hard, and it breaks into a columnar form, being by far the moſt compact of the red ſtrata I met with in the iſland. I ſaw this red lava alſo in the iſland of Teneriffe, to the eaſtward of Santa Cruz, as well as in the neighbourhood of Orotava."

From the ſides of Pico Ruivo ariſe three principal rivers, which traverſe the iſland in different directions. Beſides theſe are two very conſiderable fountains on the table land, and various other tributary ſtreams. This command of water at ſuch a height is a moſt munificent bleſſing of providence in a country uſually free from rain for more than ſix months of the year, the ſteepneſs of which renders the rivers in their natural forms little better than cataracts. By diverting the water to the ſides of the mountains by regulations long eſtabliſhed among the coloniſts, tracts of land are fertilized, which muſt otherwiſe remain for ever unproductive, or exhibit only trees and prickly pears (cactus mamillaris) whoſe roots would often become bare by the torrents of the rainy ſeaſons.

The following is the popular tradition of the diſcovery of Madeira. One Machin, an Engliſhman of obſcure birth, had fallen in love with a young damſel, called Anne d'Arſet, of exquiſite beauty, and of a noble family, which diſdaining ſo low an alliance, though Machin had gained her affections, obtained a warrant from the king to keep him in priſon, until the lady was perſuaded to marry a nobleman, who took her immediately to his ſeat near Briſtol. Machin, being ſome time afterwards releaſed, found means to convey the lady on board a veſſel provided to carry them to France.

France. When they were far at fea, a ftorm arofe, and they were toffed for thirteen days on the waves out of fight of land. At length they perceived fomething that appeared like an ifland, overgrown with wood. The fhip foon came to anchor, and Machin and the lady, with a few attendants, went on fhore. In the courfe of the night a tempeft drove the veffel from her anchor, and carried her to the coaft of Barbary, where fhe was wrecked, and the feamen made captives by the Moors. The lady, affected by this difafter, died in a fhort time, and Machin, through grief, foon followed her. Their attendants, rendered defperate by the lofs of their conductor, quitted the ifland, and betaking themfelves to their open boat, put out to fea, without knowing what courfe to fteer. After a feries of adventures, they fell in with a Spaniard, who, delighted with their ftory, communicated it to Gonçalves Zargo, fent out by the king of Portugal on a voyage of difcovery, and prevailed upon him to fail in fearch of the ifland, who in a little time found it.

This ftory, though unnoticed by De Barros, the Livy of the Portuguefe, is not only authenticated by a contemporary hiftorian, but, after a very minute inquiry of the late Rev. Mr. Roberts, we are affured, ftands on as fair a foundation as any other hiftorical fact. The gentleman we allude to, being a clergyman of the Roman Catholic perfuafion, and a native of Oporto, had the moft favourable opportunities of afcertaining the fact, which diligence, knowledge of the languages, and accefs to every library, could afford him, and expreffed his firm perfuafion that the legend of Machin was, if not in all, at leaft in moft, refpects true. At Mecheco, a town in the eaftern extremity of the ifland, a fmall chapel was fhewn, of which the following was the hiftory given by the inhabitants. That the Englifhman (Machin), on the demife of his wife, had erected a crofs, with an infcription, requefting that fhould hereafter any Chriftian by chance refort to the ifland, a chapel might be built, in which maffes fhould be performed for the foul of his Anne: that the above chapel was erected on the fpot, and the crofs, made of cedar, was preferved near the altar. This crofs was always exhibited. It was, however, much diminifhed, on account of fmall pieces given gratuitoufly to different vifitors, infomuch that it was at laft nailed to another and larger wooden crofs, to preferve its form, and keep it together. This chapel had certainly greater marks of antiquity than any other building in that town. It was unfortunately wafhed away in that memorable flood which occurred in October 1803; fo that, at this time, nothing remains to commemorate the event but the picture above alluded to, in the caftle hall.

De Barros, who confiders the ifland as difcovered by Gonçalves Zargo, informs us, that as foon as it was divided into captainfhips (Mecheco and Funchal), the firft ftep taken by the new fettlers was to fet fire to the trees, the foreft being every where impenetrable. Nothing can be better confirmed by every fpecies of evidence than thefe facts, and that the ifland derived its name from the quantity of its wood. The word Madeira has the fame fignification as the Latin *materia*, from which it is only vernacularifed, the Portuguefe frequently fubftituting *d* for the Latin *t*, and tranfpofing the *r* from its fituation with its connecting vowel; of which we need give no more familiar inftances than *padre* and *fradre* for *pater* and *frater*, when ufed in a fpiritual fenfe. That *materia* is the claffical term for foreft trees, we have the authority of Cæfar in his Commentaries, who remarks of Britain, " *Materia* cujufque generis, ut in Gallia, eft; præter fagum et abietem." At this time the trunks of immenfe cedars are often difcovered, but all the original trees themfelves feem extinct, and, in the inhabited part of the ifland, to have given place to chefnut trees. The land is fuppofed to have derived its great fertility from this conflagration, which is faid, and with much probability, to have continued in different parts for feven years. But it is well known that no land could be fertilized by fuch an event for three centuries; and the account we have given of the nature and quantity of the vegetable ftratum, joined to the abundance of water, and a favourable temperature, is fufficient to explain all the fertility it really poffeffes. Though the vines grow luxuriantly, and produce abundantly, wherever they have a fufficient depth of foil, plenty of water, and a favourable afpect, yet the corn-lands require all the cultivation and occafional fallows of other lefs favoured countries. At the fame time, it is no fmall boaft of the iflanders that their country produces the beft wheat, the pureft fugar, and the fineft wines in the world, befides being bleft with the cleareft water, the moft falubrious air, the mildeft climate, and a freedom from all noxious reptiles. Their wheat and fugar are fuch as are produced in the Mediterranean iflands; but their wine, though originally brought from that fource, infinitely furpaffes all other in ftrength, delicacy of flavour, and drynefs, befides the advantage of improving by being kept for any length of time, and even in fouthernmoft latitudes.

The mode of producing a good crop of wheat, at a diftance from the town, is by a previous cultivation of the common broom. This is cut for fuel, and, after a time, grubbed up, and burnt on the foil. By thefe means, a crop of wheat is infured for a fucceffion of years, more or lefs, according to the foil; after which the fame procefs is again reforted to. For this purpofe, the feeds of the broom are collected, and generally bear the fame price by meafure as wheat. With all thefe affiftances, the quantity of wheat produced is faid not to equal a third of what is confumed, though maize is the principal food of the peafantry. Sugar is no longer cultivated as an object of traffic. Thofe fidalgos, who have plantations, ftill keep them up chiefly for their own ufe, and prefents for their friends. Immediately after the fugar harveft, a fmall trade is carried on by manufacturing fomething like barley-fugar, called *rapaduras*, (probably *rafpaduras*, meaning the rafpings or fcrapings of the frefh fugar,) with which moft of the natives are accuftomed to regale themfelves and children at this feafon; but for common ufe, the ifland is fupplied with fugar from the Portuguefe fettlements in the Brazils.

The wealth of the country confifts in its wines, which are cultivated with a degree of induftry proportioned to their value. To preferve the foil, it is found neceffary to erect walls along the fides of the hills, at diftances regulated by the declivity. Thefe walls are, in fome places, erected with prodigious labour. In afpects favourable for the growth of vines, if the foil has been previoufly wafhed away, fo as to leave the bare rock, even here different ftages have been erected, to which earth has been brought up, fo as to form an artificial foil for this valuable production.

It will eafily be conceived that fuch works as thefe cannot be accomplifhed without immenfe labour. When to this are added the difficulties of the roads, the vaft expence and danger with which they are made, which, from the nature of the country, will in very few places admit of wheel carriages, and the confequent inconveniences of conveying every article from the town to remote parts of the country, and alfo of conveying the wine and other productions of the country to Funchal: when all this is taken into account, it will be readily underftood that the cultivators of Madeira cannot be a flothful race. Yet becaufe men, who have been hard at work from before fun-rife, are feen refrefhing themfelves

felves with fleep in the open air, and even on the beach, during the interval allowed for reft at noon-tide, they are often confidered as indolent by ftrangers, who firft view them after fix hours' labour. Nor are the women lefs induftrious. Thofe who are young enough climb the mountains to procure broom and brufh-wood, which they bring to town, and fell for fuel. Others bring the produce of their gardens; whilft the elder ones are conftantly employed at home in fpinning or domeftic concerns.

It is true, that the increafed demand for labour in Funchal has produced a race, fomewhat fimilar to our *long-fhore* and *water-fide* men in England, who labour much too hard, and fupport themfelves under it with ardent fpirits or wine. But this is far from the character of the people.

The country is cultivated by what are called by the French *metayers*, that is, by a peafantry who divide the produce with the land-owner. Confidering the labour required for firft preparing the land, and that the produce of the wine is reckoned as nothing till the third year, fuch a return to the cultivator is very unequal. He is ufually allowed a fmall fpace for yams, or rather eddoes, *arum efculentum*, fweet potatoes, *convolvulus batata*, or other efculents. Thefe he is expected to fhare with the landlord. In this there is faid to be great collufion; but in the wine this can hardly be the cafe, on account of the tythes. The cultivators have, however, one very great intereft in the land, and confequently a great inducement to engage in thefe operofe undertakings. Whatever neceffary improvements they make, become their own: hence the walls, the vines, and even their cottage, as far as is confidered neceffary, is their own property; and though, in entailed eftates, a leafe cannot be granted for more than nine years, yet the tenant cannot be difpoffeffed till he is paid the full value of his improvements. In proportion as the increafe of commerce has rendered money of lefs value, the money-price of thefe improvements is advanced; and even the vines are eftimated, not by number, but by their age and fuppofed fertility. Hence the tenant not only furveys the property he has acquired by his own labour or expence, but fees that property yearly improving by the common operations of nature.

The tythes of this, in common with the other Portuguefe colonies, were given by the pope to the king of Portugal, as fovereign of the order of Chrift. Out of them the clergy are paid, and for the moft part very poorly. They formerly received all their revenue in kine; but, unfortunately for themfelves, petitioned to have a moiety in money. In confequence of this, by the gradual diminution of the value of money, and increafed value of every production, they are confiderable lofers. Some of them make a traffic of wine; and, on the whole, they are much lefs fuperftitious than in moft Catholic countries. Their number, both fecular and regular, is much lefs than is generally fuppofed. By fome it is faid not to exceed 300, including the monks and nuns. Of the former there is only one order in the ifland: the number of nuns is uncertain. There is a feminary in Funchal for the education of the clergy of the ifland, with fomething like an academic eftablifhment, originally, we believe, formed by the Jefuits, who erected other fchools in various parts of the country. The bifhop retains his original number of pipes of wine, befides other emoluments, which render his fituation more lucrative than the governor's. He is expected, indeed, to divide his revenue with the poor; and an inftance is often mentioned of one whofe benefactions exceeded his implied obligations.

The natives of Madeira are a very mixed race. Among the labouring clafs in the town we often recognife faces truly Englifh, and even Englifh complexions. This is faid to arife from the frequent intermixture of the two nations, not only by the Englifh fettlers, but by the conftant arrival of Englifh failors. The other inhabitants, excepting the fuperior claffes in fome parts of the ifland, are a mixed race. Befides the coloniftls from the mother country, Moors in great number were at one time imported. Spaniards alfo reforted hither during the union of the two countries; and negroes have been purchafed for this, as well as the other European fettlements. The laft were, however, few in number; their intermarriages with the natives fewer, fo that but little veftige remains of their characteriftic marks. On the whole, the male inhabitants may be called a comely race: they are, for the moft part, about the middle fize, well enough formed, with ftrong mafculine features, hair, and complexions. The women are almoft univerfally fhorter than the comparative difference would lead us to expect. Such as are engaged in the laborious employments foon lofe the few charms which youth might otherwife fupply.

The animals, natives of the country, are, as in moft mountainous parts, univerfally fmall. To an Englifhman, their beef and mutton is alfo lean and taftelefs; but thofe who are accuftomed to warm climates fpeak of them in better terms. Of poultry, the common domeftic fowls are fmall; but this is amply made up by their ducks and turkies, the latter of which are not inferior to thofe of Norfolk. Pork is peculiarly fine; but the expence of feeding, or the warmth of the feafons, makes it fuch a rarity, that it is rarely produced excepting at Chriftmas feftivals. It is true, hogs are found rambling about the towns, but very few are reared for porkers. Fifh, particularly rock-fifh, is plentiful and good of the kind; but the nature of the coaft prevents the refidence of many fhell-fifh.

The uneven form of the country renders the ifland productive of the European as well as more fouthern fruits; but it is a miftake that the true tropical fruits are readily produced. In the vallies are found guavas, bananas, and oranges. A fingle allegator pair tree has grown for feveral years, but rarely produces fruit. Pine apples are reared with great difficulty; and the *granadilla quadrangularis*, after fpreading to a great extent, and flowering moft luxuriantly, has not yet, we believe, produced ripened fruit.

The ftaple commodity of the ifland is wine, of which the average quantity made about ten years ago was reckoned between 30 and 40,000 pipes. More than half this is exported, principally to the Britifh fettlements in the Eaft and Weft Indies. A quantity, comparatively very fmall, finds its way to London. Speculations in trade have lately increafed this quantity: but there is reafon to fear that the quality is not improved by it, as there is faid to be conftantly a difference between *barter-wine* and *bill-wine*; that is between wine exchanged for marketable articles, and wine which is paid for by bills drawn at a fhort credit. The beft wine grows on the fouth fide of the ifland, and the beft of that for the moft part in the inferior parts, and on that fide of the hill which points to the eaft. This advantage feems entirely attributable to warmth; the weft being always cooled by the breeze or inbah, which by noon conftantly blows from that quarter. The north wine was formerly much undervalued, and principally confumed in the ifland, either as a beverage of the natives, or diftilled into brandy. But the increafed demand for the article has encouraged many of the merchants to mix a portion of north wine with the fouth; and the improvement of its price has given additional encouragement to improving it by cultivation. That the quality of the wine, however, depends principally on the afpect and foil, is pretty clearly proved by the fuperiority of the cercial. This, though originally produced from the Rhenifh grape, is confidered the ftrongeft and richeft of all the dry wines in the ifland. The beft wine is almoft always mixed with a portion of the *vinho tinto*. This is at firft nearly the colour of red port, but from year to year grows paler. Hence, could we always afcertain the genuinenefs of the wine, the colour would be a confiderable means of afcertaining its age. But the addition of the north wine will at any time lower the colour, and to the eye give the appearance of age. Certain it is that the vaft demand of late years has nearly exhaufted the ifland of old wine, fo that thofe who wifh for fuch a luxury, will do well to keep it themfelves. This fhould be done, not in a cold underground cellar, but in the warmeft part of a dwelling-houfe, and, if fuch can be procured, in an apartment open to the fouth.

The quantity of genuine Malmfey produced annually is very fmall, and in truth very uncertain, becaufe a good deal is manufactured with refined fugar, and though greatly inferior to the genuine, is, if well managed, truly delicious. We have reafon to believe thefe are the only fophiftications of Madeira wine. The ftories of the importation from Teneriffe and other places are certainly unfounded ; at leaft fuch is the univerfal anxiety to preferve the credit of the ifland, that no quantity can be imported which would pay for the danger and expence.

The other exports from Madeira are trifling ; they confift principally of chefnuts, walnuts, preferved citrons, and thofe occafional fupplies of frefh provifions for veffels touching at the port, which are purchafed here much dearer than in England. The imports confift of the greateft part of the provifion of the ifland, excepting frefh meat, and even living fheep and oxen are imported with advantage from Barbary, and the Azores, or Weftern iflands. From America they derive principally their wheat, Indian corn, and, in common with other Catholic countries, vaft quantities of falt fifh. From England they receive moft of their wearing apparel, the quantity and value of which increafe rapidly every year.

The crown of Portugal derives its revenue in part from a duty of 20 *per cent.* on the invoice value of all articles imported excepting provifions. But its principal revenue is from the wines. Befides the tythes, the farming of which is difpofed of by auction every year, and which is every year purchafed at a higher rate, a duty is impofed on all the wine as it is exported, and a fort of excife on what is confumed in the ifland. A revenue is alfo derived from the monopoly of fnuff, cards, and foap. The aggregate is enough to pay all the expences of the civil, military, and ecclefiaftical eftablifhments, and to remit confiderable fums to the crown. But there is always much uncertainty in the laft. We have heard it ftated as 5000 and 50,000 ; the latter we fhould conceive muft be neareft the truth, when we reflect that a confiderable part of the merchants' capital confifted at one time in the manner in which the revenue was remitted to Lifbon.

Of all the complicated mercantile queftions, nothing is for the moft part equal to that of the money in Madeira. From their intercourfe with the Englifh Weft Indies, or from fome other caufe, fcarcely any thing is feen but Spanifh filver coins, and by fome unaccountable incidents, thefe have got the name of Portuguefe coins. Thus the peftreen is called two teftoons, and five of them are called a milrea, and though five peftreens are as exactly equal to a dollar as 5*s.* are to a crown, yet the Portuguefe having no coin correfponding to dollars, for a long time the five peftreens were more valuable than the dollar, which laft was hardly confidered current in the ifland. Though this laft abfurdity is now done away, yet it has made no other difference in the names of their currency, excepting that the dollar has now the name of milrea, in common with its reprefentative five peftreens. But the coins in Portugal, whofe names are thus ufurped by the Spanifh pieces, are intrinfically worth nearly 20 *per cent.* more than the latter. Hence, when an ignorant captain fells his cargo for fo many thoufand milreas, he ufually finds his bills produce him about 20 *per cent.* lefs than he calculated upon. The currency and ufe of the dollar are gradually remedying this inconvenience.

The mode of government remittance to Lifbon was by giving Madeira milreas, for which the merchants gave their bills on Lifbon for the fame number of milreas, payable at two years. By thefe means they paid about ten *per cent. per ann.* for the ufe of money for two years, at the expiration of which they often paid their bills as they became due, by iffuing frefh ones. Thefe tranfactions, though very convenient to the government, and ftill more fo to the merchant, have often been productive of ferious injuries, by inducing inconfiderate people to overtrade their capital, and on the leaft fufpicion of their folvency, the crown has feized their whole ; laying, as in England, violent hands on landed property, which has been fold by the government-debtor after the debt was contracted.

Befides the above duties on wine, the Britifh conful and factory receive a certain fum on every pipe exported to any part of the Britifh dominions, for the expences attending their eftablifhment ; for the relief of failors left on the ifland ; and of decayed merchants entitled to fuch a benefit. This fund fhould alfo fupport a clergyman and Proteftant chapel, the erection of which would probably increafe the reputation of the Britifh nation among the natives, and might even fupport itfelf by voluntary contributions.

We have been thus particular in our account of this ifland, becaufe, however inconfiderable in extent, it cannot be confidered fo in importance. Its climate productions, its fituation by its proximity to Europe, and in the courfe to the Eaft or Weft Indies, all render it interefting, but moft of all, the prefent condition of the European continent, and the intereft which England feels in whatever may facilitate her connection with her diftant fettlements. On this account it may not be amifs to add a few words on the advantage which England might derive from fuch a poffeffion, and the confequences to the ifland of fuch a change.

Madeira is already fo much connected with England, and the inhabitants of Funchal are fo much anglicifed, that in many of the Portuguefe fettlements it is humouroufly called *pichena Londres*, or little London. It is not only the quantity of Englifh goods confumed in the ifland that benefits Great Britain, but the quantity exported from hence to the other Portuguefe fettlements. It is difficult to fay whether England or Madeira is moft benefited by this traffic. The only exchange that can be made for every article of luxury is wine, and the neceffity of this commodity induces an increafe of induftry. Should the ifland become altogether Englifh, it is probable that another fource of wealth would be derived from Englifh capital, which, expended in cultivating or improving frefh lands, might prove a profitable, though at firft an uncertain, fpeculation. But whatever might be the confequences to England, the ifland could not but be benefited by all that is expended on its cultivation. This muft however be accomplifhed by the manual labour of the natives, whofe knowledge of their land enables them to turn to good account their induftry, mufcular ftrength, and great patience under meagre fare. But thefe are no longer fufficient without capital, fince the price of labour is fo much increafed, and the parts eafieft cultivated and moft profitable to the labourer, are more generally occupied.

The prefent government is fimilar to that in the mother country,

country, to which all appeals are made, and to which any alteration in the exifting laws are referred for decrees from the prince. It would not be fafe fuddenly to alter this fyftem; but great pains are wanted to purify the fountains of juftice. A people, accuftomed only to obey by mandate, and to protect each other from the oppreffions of government, could not at once fall into a legiflation of which they are themfelves a part. They muft gradually be taught the bleffings of liberty, by the certainty with which their property and perfons are fecured, and by the reftoration of thofe privileges they once enjoyed; but which now exift only in name. Thefe fhould be well underftood and defined, and the utmoft attempted at firft fhould be a careful appointment of enlightened magiftrates, or judges, as they are moftly termed, with a proper augmentation of their falaries, and the fuperintendance of a governor acquainted with the languages, laws, and cuftoms.

From the heavy duties impofed by government, many expences are fupported, which, according to the freedom of our conftitution, are defrayed by the public, and regulated by commiffioners of their own choice. We refer chiefly to the public works, *viz.* the building and repairing of churches, the improvement of the ports, and the conftruction and repair of roads and bridges. Thefe laft are paid only in part by the crown, the male inhabitants being obliged to perform certain labours in their different diftricts. If the work is confiderable, a certain pay is allowed, but not at all adequate to the ufual price of labour.

If the average amount expended on roads and bridges by government were lodged in the hands of commiffioners chofen by the inhabitants; and if, in aid of this, a tax of two guineas *per annum* were laid on every horfe; if the produce of this were added to the former fund, and the commiffioners were authorized, as in England, to borrow money on annuities: by thefe means, the whole ifland might foon be interfected with roads, and united by bridges, fo as to render every part acceffible with eafe. Hence the produce of the country would readily be brought to the towns, and from thence, by water, to different parts of the coafts; the gentry would have greater encouragement to remain a confiderable part of the year at their country eftates; the manfions on which be rendered univerfally convenient and elegant, and this example would foon extend to the wealthier cottagers, and even to the merchants and tradefmen, who would, as in England, be all ambitious of country refidences. That all this may be accomplifhed, we have a ftriking example in the pavilion which M. de Carvalhal has erected for himfelf, at the diftance of about three miles eaft of Funchal. On a fpot, at one time fcarcely acceffible, with only a fingle clump of trees, and almoft without water, he now exhibits large fheets of water, extenfive avenues of flowering fhrubs, roads in every direction, and the profpect of an Englifh *ferme ornée*.

In conftructing roads in Madeira, the firft object fhould, of courfe, be to preferve as level ground as is confiftent with the nature of the country, by winding round the hills. But great care fhould be taken that the afcent is never interrupted: becaufe, by fuch a provifion, whatever is brought from the country can be conveyed without difficulty or labour; the back carriage muft always be laborious, but mules with packs may be kept at different paffes, and hired on the fpot, like fome additional horfes in particularly fteep roads in England.

One moft ferious evil muft be immediately remedied whenever the ifland is allowed to ufe thofe bleffings with which providence has indulged it. We have remarked the advantages derived from the height at which the rivers rife. This not only gives the command of water before alluded to, but furnifhes a power by which mills might be multiplied to any extent, or for any purpofe. At prefent, the privilege of erecting water-mills is confined to a grandee, who never faw the ifland. Hence the mills, excepting near the town, are diftant, nor is there any inducement to multiply them, as all muft refort to them, however inconvenient. Nor is this all, in order to feed the mills near the town, a confiderable quantity of water is loft, which, if expended on the higher grounds, would, in fome feafons, add greatly to their fertility.

Thefe are only a few of the benefits which England as a nation, and Madeira as a fettlement, might mutually confer on each other. Befides this, a port might be conftructed at Funchal, the bay of which, though invariably calm in the fummer, is, during the winter, always uncertain, and fometimes dangerous. But the advantages to the individuals of both nations would be incalculable. The eafy diftance might induce many in delicate health to pafs the winter in Funchal, where the thermometer is rarely lower than 60°, nor above 65°, and often ftationary within doors for twenty-four hours. In the fummer about 10° higher, and the air gradually cooler as you afcend the mountains. This city already, we are informed, has its theatres, its coffee-houfes, and would foon have its library, its printing-preffes, and its own gazettes. Though the expences of the table are perhaps equal to thofe of London, yet wine may be procured without an exorbitant duty; there are few other taxes, and the equipages of London will never be neceffary in fuch a climate, nor perhaps manageable in fuch a country.

If ever the population of Madeira fhould be fo confiderable as to render labour cheap, or that employment fhould be wanted for many fuperfluous hands, the filk worm feems, of all others, the moft promifing article. For fix, often for feven or eight months, they could feed on the trees in the open air without the danger of rain, and the defcription given of the rivers would at any time furnifh ftreamlets which might turn mills fufficient for winding off the web. It is true, the attempts formerly made to introduce the white mulberry have hitherto failed, but this has been rather from a want of general concurrence in the cottagers, than from any difficulty in the foil.

The inhabitants of Madeira were reckoned at the laft cenfus about 100,000; of thefe nearly a tenth part are faid to refide in or near the capital. Funchal has been well fortified fince the Englifh have arrived there, which was eafily done on account of the barriers provided by nature. The regular force of the Portuguefe government was 200 infantry, ill dreffed and ill trained. The fame number of artillery, whofe appearance and difcipline are highly refpectable. There are three regiments of militia commanded by colonels of diftricts. Thefe are dreft in uniform at their own expence. The reft of the inhabitants, from the age of twelve years and upwards, are expected to furnifh themfelves with pikes or guns according to their abilities. In fhort, the whole government may be called military, a ftriking proof how little danger there is putting arms in the hands of citizens who are not oppreffed, for in Madeira affaffinations are few, and thofe few rarely among the lower clafs; and civil commotions have feldom exifted for years paft, and never proved fanguinary.

The other iflands, included under the government of Funchal, are fcarcely inhabited, excepting Porto Santo. This has its own governor, but is amenable to the governor at Funchal. Its produce is fimilar to Madeira, excepting that the wine is inferior. A good deal of barley is grown on this and the fmall iflands, called *defertas*. Porto Santo alfo produces the water-melon in abundance, and much

much fuperior in flavour to thofe which have been attempted in the larger ifland. Its foffilology is faid to be very curious and valuable, but hitherto it has not been fufficiently explored. There is a tradition that it is inhabited by the offspring of degraded fidalgos from the mother country. It is certain that the natives have a different caft of features, being fairer, but by no means handfomer, nor fo well formed. We have never heard their numbers afcertained. The falvages contain lime-ftone, which is not to be met with in the other iflands.

MADEIRA, or *Madera*, a river which rifes in the government of Charcas in Peru, near Cochabamba, in S. lat. 18°, firft called "Conderillo:" having received fome fmaller rivers, it changes its name into "Parapite." Hitherto its courfe is S.E., till it enters a lake fituated in S. lat. 19° 50′, after which it takes a northerly direction, with the name of "St. Miguel," afterwards "Sara;" about S. lat. 14°, it is called "Mamore;" and in S. lat. 10°, it leaves Peru, and enters Brazil, from which time it is called Madeira, till it difcharges itfelf into the river of the Amazons in S. lat. 3° 15′. W. long. 60° 40′. Its whole courfe is about 1200 miles.

MADELA, a town of Afia, in Paleftine; 192 miles S.E. of Jerufalem.

MADELAN, a town of Hindooftan, in the Subah of Agra; 10 miles S.E. of Kerowly.

MADELEY MARKET, a market town and parifh fituated in the hundred of Wenloch, and county of Salop, England. It is finely feated in a winding glen, through which the river Severn flows, at the diftance of 147 miles from London, and $5\frac{1}{2}$ from Shifnal. According to the parliamentary returns in 1801, this town then contained 291 houfes, and 4758 inhabitants, being 2432 males, and 2326 females, of whom 1594 were found to be employed in various branches of trade. A navigable canal to the Ketley iron-works, which are among the moft extenfive in England, and alfo to a work for the extracting of foffil tar or petroleum from the condenfed fmoke of pit-coal, paffes clofe to the houfes. Over the Severn, in this parifh, is thrown a noble bridge of caft iron, which was erected in 1779, and confifts only of a fingle arch, 100 feet 6 inches in fpan, and 40 feet in height at the centre above the level of the bafe line. The road over this bridge is compofed of clay and iron flag, 24 feet wide, and one foot deep. Iron top plates project from each fide, and ferve to fupport a very noble baluftrade of caft metal. The weight of iron, in the whole, is 378 tons 10 cwt. This bridge contributes not a little to enhance the natural beauty of the romantic dale in which it is placed. (See BRIDGE, *Iron*, in vol. v. of this work.) At the foot of this bridge is the market-place, which is nearly two miles diftant from its original fituation. The market, fince its revival in 1763, previous to which period it had been long difcontinued, has been regularly held on Friday, and is, for the moft part, well fupplied with all the articles requifite for the fuftenance of man. This parifh includes the populous hamlets of Colebrook-dale, and Madeley-wood, which are remarkable for their extenfive coal works.

MADENALLY, a town of Hindooftan, in the circar of Sollapour; 36 miles N. of Sollapour.

MADER, a town of Perfia, in the province of Farfiftan; 20 miles N.E. of Eftakar.

MADERAM-PULLI, in *Botany*, a name ufed by fome authors for the tree whofe fruit is the tamarind of the fhops.

MADERNO, CHARLES, in *Biography*, an eminent Italian architect, was born at Biffona, in Lombardy, in the year 1556. He went at a very early age to Rome, where his uncle, Domirico Fontana, was, at that time in full employ as an architect. His genius for fculpture became manifeft, and he was placed with an artift in that branch of the fine arts. His progrefs in modelling was fuch as led his uncle to confide to him the management of fome buildings then in hand, which he executed with fo much fkill, that he was advifed to devote himfelf entirely to architecture. At the death of Sixtus V. Maderno was appointed to defign and execute the magnificent tomb for his interment. The public works which were carried on under Clement VIII. were chiefly committed to the care of this artift, and fo high was his reputation in the fucceeding pontificate, that, on the fucceffion of Paul V. in 1605, he was appointed to finifh the building of St. Peter's; his plans being preferred to thofe of eight competitors, and the work was placed under his direction. He was afterwards employed upon the pontifical palace on the Quirinal mount. Another work, for which he is celebrated, was the raifing a fine fluted column found in the ruins of the temple of Peace, and placing it on a marble pedeftal in the fquare of St. Maria Maggiore. His genius was by no means confined to architecture, he was fent by the pope on a commiffion to examine the ports of the ecclefiaftical ftates, and afterwards furveyed the lake of Perugia, and furrounding country, in order to divert the inundations of the river Chiana. He was confulted upon moft of the great edifices undertaken in his time in France and Spain, as well as in the principal towns of Italy. His laft work of confequence was the Barberini palace of Urban VIII., which he did not live to complete. He died of the ftone in 1629, when he had attained to the age of feventy-three. He had feen ten popes, by moft of whom he had been regarded with favour. Gen. Biog.

MADERNO, in *Geography*, a town of Italy, on the S.W. coaft of lake Garda; four miles N.E. of Salo.

MADETZ, a town of Walachia, on the Danube; 30 miles W.S.W. of Giorgiev.

MAD-HOUSE. By 14 Geo. III. c. 49. enacted to be in force for five years, and by 19 Geo. III. c. 15. which continued it for feven years farther, and by 26 Geo. III. c. 91. made perpetual, no perfon, on pain of 500*l.* fhall entertain or confine, in any houfe kept for the reception of lunatics, more than one lunatic at a time, except fuch lunatics as are committed by the lord chancellor, &c. without a licence to be granted yearly by the college of phyficians, within London and Weftminfter, and feven miles thereof, and within the county of Middlefex, and elfewhere by the juftices in feffions. The licences are to be ftamped with a 5*s.* ftamp: every one who keeps a number of lunatics, not exceeding ten, fhall pay the fum of 10*l.* and above ten the fum of 15*l.* and 6*s.* 8*d.* on every licence, as a fee to the fecretary of the commiffioners. No licence can authorife any perfon to keep more than one houfe. The commiffioners, confifting of two juftices and a phyfician, may vifit licenfed houfes, and infpect their ftate as often as they think fit: on application to the commiffioners for information concerning any confined perfon, the fecretary is to fearch his books, and acquaint the perfons applying with the name of the keeper in whofe houfe the lunatic is confined. The keeper is required to give notice to the fecretary, within fourteen days after receiving a patient, who is to file fuch notice; and every keeper admitting a perfon as lunatic, without an order under the hand of fome phyfician or furgeon that fuch perfon is proper to be received, fhall pay the fum of 100*l.*

No licence fhall be granted unlefs the keeper enter into a recognizance in 100*l.* with two fureties in 50*l.* each, or one

one furety in 100*l.*; on the ufual conditions, for the good behaviour of the keeper. This act doth not extend to any of the public hofpitals. This act contains various diftinct regulations for fuch houfes in London, Weftminfter, and within feven miles of the town, and in the county of Middlefex. By 48 Geo III. c. 96. feveral provifions are made for the better care and maintenance of lunatics, being paupers or criminals in England. The firft feventeen fections, and fome others, relate to the building and endowing of lunatic afylums. As foon as fuch an afylum is ready, juftices are, by warrant, to remove lunatics to it, and the parifh is chargeable with an allowance. If the overfeer neglects to inform the juftices, and to apply for fuch warrant, he fhall forfeit for every offence, not exceeding 10*l.* nor lefs than 40*s.* When lunatics are committed by juftices under the 17 Geo. II. c. 5. the faid juftices fhall order in their warrant that fuch lunatic, or mad perfon, fhall be confined in fuch lunatic afylum, and not elfewhere; but if no lunatic afylum be eftablifhed, they may order that fuch perfon be confined in any houfe duly licenfed under the 14 Geo. III. c. 49. Where the lunatic's legal fettlement cannot be afcertained, the juftices may order fuch perfon to be confined in the lunatic afylum for the county or diftrict within which fuch perfon fhall have been apprehended, if there be any fuch, and not elfewhere; if there be none, in fome houfe dulylicenfed under 14Geo.III. c. 49, or in fome other fecure place, as directed by the 17 Geo. II. c. 5. And if fuch perfon have not an eftate to pay and fatisfy the reafonable charges of removing, and of keeping and maintaining and curing fuch perfon under 17 Geo. II. c. 5. then thofe charges fhall be paid by the treafurer of the county within which fuch perfon fhall be apprehended, out of the county rates, by order of two juftices directed to him for that purpofe. All lunatics, &c. fhall be fafely kept, nor be fuffered to quit the faid afylum, until the vifiting juftices fhall order their difcharge, and fignify the fame in writing under their own hands and feals: and if any fervant or officer in fuch afylum fhall, by neglect or connivance, permit fuch perfon to efcape and to be at large, without fuch order, he fhall, for every fuch offence, forfeit not exceeding 10*l.* nor lefs than 40*s.* In all cafes, where by virtue of the 39 and 40 Geo. III. c. 94. any perfon fhall be kept in cuftody, it fhall be lawful for any two juftices of the county where fuch perfon fhall be fo kept, to afcertain, by the beft legal evidence that can be procured under the circumftances of perfonal legal difability of fuch lunatic, the place of the laft legal fettlement, and the circumftances of fuch perfon; and if fuch perfon is not poffeffed of fufficient property for his maintenance, to make order upon the parifh where they fhall adjudge him to be legally fettled to pay fuch weekly fum for his maintenance in fuch place of cuftody as fuch court or his majefty fhall appoint, as fhall be from time to time directed and fixed upon by one of his majefty's principal fecretaries of ftate; and where fuch place of fettlement cannot be afcertained, fuch allowance fhall be paid by the treafurer of the county where fuch perfon fhall have been apprehended; but if it fhall appear that fuch perfon is poffeffed of fufficient property as aforefaid, then fuch juftices fhall order the fame to be applied to fatisfy the expence and maintenance of fuch perfon in the manner directed by 17 Geo. II. c. 5.

MADIA, in *Botany*, was fo named by Molina, in his Natural Hiftory of Chili. We are unable to conjecture, with precifion, concerning the derivation of this word; it cannot furely be traced from μαδος, *fmooth*, or *without hair*, becaufe one fpecies at leaft, if not the whole genus, is remarkably hairy. Molin. Chil. 113. Willd. Sp. Pl. v. 3. 1951. Cavan. Ic. v. 3. 50. Juff. 450.—Clafs and order, *Syngenefia Polygamia Superflua*. Nat. Ord. *Compofitæ difcoideæ*, Linn. *Corymbiferæ*, Juff.

Gen. Ch. *Common calyx* globofe, of many leaves arranged in a double row, carinated; the eight exterior ones acute, and longer, approximating into a globe. *Cor.* compound, radiated; florets of the difk all perfect, numerous, tubular, five-cleft; thofe of the radius female, eight in number, ligulate, three-toothed. *Stam.* (in the tubular florets) Filaments five, capillary, very fhort; anthers cylindrical. *Pift.* (in the tubular florets) Germen ovate-compreffed, moft acute at the bafe, incurved; ftyle fimple; ftigmas two. *Peric.* none, except the permanent calyx. *Seeds* folitary, the fhape of the germen. *Recept.* naked. *Down* none.

Eff. Ch. Receptacle naked. Down none. Calyx double, the outer one of eight or ten equal leaves, longer than the inner one, which is compofed of many leaves.

1. M. *vifcofa.* Cavan. Ic. t. 298. (M. mellofa; Jacq. Hort. Schoenb. t. 302.)—Leaves feffile, almoft lanceolate, hairy. Flowers axillary.—A native of Chili. It flowered in the Royal Gardens of the Efcurial in Auguft and September 1795.—*Stem* round, fomewhat corymbofe, branched, more than two feet high, covered with glandular hairs. *Leaves* fcattered, feffile, but not embracing the ftem, obtufe at the point, broader at the bafe, fingle-ribbed. *Flowers* yellow, ftrong-fcented, on fhort footftalks, at the fummits of the branches. *Seeds* black and fhining.

2. M. *fativa.* Willd. n. 1.—Leaves linear-lanceolate, on footftalks.—A native of Chili.—*Stem* hollow, erect, round. *Flowers* on ftalks, terminal.

3. M. *mellofa.* Willd. n. 2.—Leaves embracing the ftem, lanceolate, hairy.—A native alfo of Chili. These two fpecies are adopted by Willdenow from Molina without any further defcription than is now given.—Cavanilles alfo mentions them, but merely to fay that *vifcofa* differs from them both in having fhort roots, and feffile leaves, never embracing the ftem.

MADIAN, or MIDIAN, in *Ancient Geography*, a town of Arabia, in the province of Hedsjas, which owes its name to one of the fons of Keturah, and was deftroyed in the time of Abulfeda. It is feated at a fmall diftance from the Red fea, which at this place is not more than 100 paces wide. The Arabs call it "Megar el Schuaid," or the Grotto of Schuaid, or Jethro; and they fuppofe that this is the place where Mofes tended his father-in-law's flocks. Ptolemy calls it *Modiana*. N. lat. 28° 20′. E. long. 38° 10′. See MIDIAN.

MADINGA, in *Geography*, a river of America, in the ifthmus of Darien, which runs into the Spanifh Main, N. lat. 9° 22′. E. long. 78° 48′.

MADISON, a county of Virginia, bounded north-eaft by Culpepper, fouth by Orange, and weft by Shenandoah county; about 30 miles fquare, watered by the Rapid Ann and Robfon rivers, and containing 4886 free inhabitants, and 3436 flaves.—Alfo, a county of Kentucky, adjoining Fayette, Clarke, Lincoln, and Mercer counties. It contains 10.380 inhabitants, of whom 1688 are flaves. The chief town is Milford.—Alfo, a fmall poft-town of Amherft county, Virginia, on the north fide of James's river, oppofite to Lynchburg; 150 miles W. by N. of Richmond.

MADISON'S *Cave*, the largeft and moft celebrated cave in Virginia, fituated on the north fide of the Blue Ridge. The cave extends into the earth about 300 feet, branching into fubordinate caverns, which terminate, after afcents and defcents, in two different places, or bafons of water of unknown

known extent, nearly on a level with the water of the river.

MADISTERIUM, Μαδιστήριον, a name given by the Greeks to an inftrument intended to keep the fkin fmooth, by eradicating the hairs.

MADMAR, in *Geography*, a town of Perfia, in Khorafan; 12 miles W. of Herat.

MADMEN. See LUNATICS.

MADNESS. See MENTAL *Derangement*.

MADNESS *from the Bite of rabid Animals*, the *Rabies canina*, and *Hydrophobia* of medical writers, will be found defcribed at length under the latter title. The term *madnefs*, as applied either to the difeafe in the dog, or other rabid animal, or to that of the human fpecies, when bitten, is an abfolute mifnomer, and has led to fome important popular errors both of opinion and practice, and ought therefore to be difcarded. There is neither the violence in the rabid animal, which the term implies; nor the derangement of intellect, or violence in the hydrophobic patient, which has been inferred from the appellation. Yet thefe miftaken notions have led to the practice of permitting dogs, actually rabid, to go loofe, and inflict mifchief on the public, as well as to that of murdering fick men by fuffocation, from an apprehenfion of the ungovernable fury which it has been fuppofed would enfue. See DOG and HYDROPHOBIA.

MADNETI, in *Geography*, a town of Hindooftan, in Myfore; 18 miles E. of Bangalore.

MADNING-MONEY; old Roman coins, found about Dunftable, are fo called by the country people; and have their name from *magintum*, ufed by the emperor Antoninus in his Itinerary, for Dunftable.

MADODENQUIK, in *Geography*, a river of New Brunfwick, which runs into the St. John, N. lat. 46° 19'. W. long. 67° 34'.

MADOLAND, a town of Kemaoon; 5 miles N.W. of Kerigar.

MADOMGUNGE, a town of Hindooftan, in Bahar; 7 miles S. of Bahar.

MADONA, a fmall ifland in the Mediterranean. N. lat. 36° 31'. E. long. 26° 49'.

MADONA *di Scopia*, a town on the eaft coaft of the ifland of Zante; 2 miles S.E. of Zante.

MADONIA, a mountain of Sicily, in the valley of Mazara; 35 miles S.E. of Palermo.

MADONNINA, in *Commerce*, a filver coin of Genoa, of which there are the double, fingle, and half, at 40, 20, and 10 foldi. The double Madonnina (the fingle and half piece being in proportion) weighs 5 dwt. $19\frac{1}{2}$ gr., contains, in pure filver, 116.2 grains, and its value is 1*s.* $4\frac{1}{4}$*d.* fterling. The impreffion is a whole length figure of the Virgin ftanding, with her head encircled by ftars: legend, SUB TUUM PRÆSIDIUM (under thy protection), with the date; and round the figure, NE DERELINQ. NOS (do not forfake us): reverfe, arms of Genoa; legend, DUX ET GUB. REIP. GENU. (doge and governor of the republic of Genoa).

MADOO, in *Geography*, a fmall ifland in the Eaft Indian fea. S. lat. 7° 31'. E. long. 122° 18'.

MADOOCARRY, or MADOOGARY, a town of Hindooftan, in Coimbetore; 6 miles S.S.W. of Coimbetore.

MADOOR, a river of Hindooftan, which rifes in the Myfore, about 20 miles N.N.W. of Sera, and runs into the Cauvery, 36 miles below Seringapatam.

MADOOSAND, a town of Hindooftan, in Rohilcund.

MADORE, a town of Hindooftan, in Myfore; 8 miles N. of Seringapatam.

MADRAPOUR, a town of Bengal; 20 miles S.E. of Boglipour.

MADRAS, FORT ST. GEORGE, or, as it is called by the natives, *China-patam*, a town of Hindooftan, on the coaft of Coromandel, and clofe on the margin of the fea. It was about the year 1620 that the Englifh Eaft India company obtained leave of the king of Golconda to fettle at Madras-patan, where they were permitted to build the fort called St. George; which place has ever fince been the company's general factory for their trade to all parts eaft of Cape Comorin. (And. Hift. Com. vol. ii. p. 6. folio.) Others fay, that Madras was fettled by the Englifh about the year 1640; and it is alfo faid, that the town was built in the reign of Charles II. by order of the Eaft India company, under the fuperintendance of fir William Langhorne. As he placed it in the midft of a fandy defert, altogether dry, and where there was no water fit for drinking, except what was fetched from the diftance of more than a mile, people were curious to know what reafons could have induced him to make fo bad a choice. His friends pretended that his view was to draw thither all the trade of St. Thomas, which has actually been the confequence; while his enemies imputed it to a defire of continuing in the neighbourhood of a miftrefs he had in that Portuguefe colony. In the rainy feafon, the fea threatens deftruction on one fide, while the river, menacing an inundation, is no lefs terrifying on the other. From April to September the fun's heat is fcorching; and if it were not mitigated by the fea-breezes, the place would not be habitable. In the vicinity of the city the foil is fo dry and fandy, that it does not produce fo much as a blade of grafs fpontaneoufly, nor any corn without great labour of culture. The roots, herbage, and vegetables, confumed in this place, are brought from a confiderable diftance. It is ftill a more unfavourable circumftance, regarding the place in a commercial view, that, in common with all the other European fettlements on this coaft, Madras has no port for fhipping; the coaft forming nearly a ftraight line; and it is alfo incommoded with a high and dangerous furf that breaks upon it, and induces the neceffity of ufing the boats of the country for the purpofe of landing. Thefe are of a fingular conftruction, being formed without ribs or keel, with flat bottoms, and having their planks fewed together; iron being totally excluded throughout the whole fabric. By this conftruction they are rendered flexible enough to elude the effects of the violent fhocks which they receive by the dafhing of the waves, or furf on the beach; and which either overfets or breaks to pieces a boat of European conftruction. No port for large veffels occurs between Trinkamaly and the Ganges, that is, in an extent of 15 degrees; fo that the comparative proximity of the former to Madras and Pondicherry renders it a capital object, both to the Englifh and French. Neverthelefs, Madras has been reckoned among the richeft ports in India. Notwithftanding local difadvantages, the company find it convenient in other refpects, efpecially as to their trade in calicoes, chintzes, and muflins, diamonds, &c., and in putting off their European wares moft fought after there, *viz.* ftockings, haberdafhery, gold and filver lace, looking-glaffes, drinking-glaffes, lead, wines, cyder, cheefe, hats, ftuffs, ribbons, &c.

Madras is divided into the White Town and the Black Town. The firft of thefe, known in Europe by the name of Fort St. George, is inhabited only by the Englifh. The fort lies N.N.E. and S.S.W. in the middle of the White or Englifh Town. It is a regular fquare, about 100 yards on each fide. The White Town is about a quarter of a mile in

length,

length, and half as much in breadth. North of the fort are three ſtraight ſtreets, and on the ſouth an equal number. The houſes are flat-roofed, built with brick, and covered with a plaiſter made of ſea-ſhells, which no rain can penetrate. The walls are thick, and rooms lofty; but few of them exceed one floor, though ſome are raiſed a floor above the ground. Oppoſite to the weſt gate of the fort is a barrack, for lodging the company's ſoldiers when off guard; and adjoining to this, a very convenient hoſpital. At the other end of the barrack is a mint, where the company coin gold and ſilver. There is a town-houſe, where the magiſtrates aſſemble, and in which courts of juſtice are held. The whole is encompaſſed with a ſtrong wall of the ſame ſtone with that uſed for building the fort. This is defended by batteries, baſtions, half-moons, and flankers; the whole being mounted with about 200 pieces of cannon, and three mortars, including the guns on the outworks, beſides field-pieces. Round it, on the weſt ſide, is the river, by which and a battery it is defended. South of the White Town is a little ſuburb, the reſidence of the black watermen, who are its ſole occupants. This conſiſts of little low thatched cottages; and beyond it is an outguard of blacks, to give notice of any danger. Indeed it cannot be well attacked, except on the ſouth and north ſides; for towards the ſea, the ſwell and ſurges are a perfect ſecurity. Madras is now, perhaps, ſays major Rennell, one of the beſt fortreſſes in the poſſeſſion of the Britiſh nation; and although not ſo regular a deſign as Fort William, in Bengal, yet from the greater facility of relieving it by ſea, and the natural advantages of ground, which leave the enemy leſs choice in the manner of conducting his attacks, it may, upon the whole, be deemed at leaſt equal to it.

The Black Town, called *Madras*, and ſometimes *Chinapatam*, was formerly quite open, but, ſince the year 1767, it has been ſurrounded with a ſtrong wall, and a ditch full of water. The wall is of brick, 17 feet thick, with baſtions at proper diſtances. On the weſt is a river, and on the eaſt the ſea; north is a canal cut from the river to the ſea, which anſwers the purpoſe of a moat on that ſide. The town is a mile and a half in circumference, and might be reckoned a ſtrong place, with a garriſon proportioned to it; and attention has lately been given to this circumſtance, ſo that it neither wants men, nor ſtores and proviſions for its ſecurity and defence. This town is inhabited by Gentoos, Mahometans, and Indian Chriſtians, *i. e.* Armenians and Portugueſe, and alſo a number of Jews. The ſtreets of the Black Town are wide, and ſheltered with trees from the ſun's heat. Some of the houſes are of brick; the others are mean cottages. The abbè Raynal reckons the whole number of inhabitants of Madras at 300,000.

The town is in general very populous, each of the cottages containing a family of ſeven, eight, or nine perſons; and yet, numerous as they are, and mean in their appearance, the place abounds with wealth. The bazar or market is every day crowded, and exchanges of property are made to a great amount, which they transfer with as much facility as it is done on the Exchange of London. In the Black Town is an Armenian church, with ſeveral little pagodas or Indian temples, to which belong a number of prieſts and female choriſters. From the beginning of March 1777 to the end of February 1778, the temperature of this coaſt was upon a mean 81°.4; that of the ſtandard is 81°.3; the greateſt heat was 102°, the leaſt 64°. Kirwan. N. lat. 13° 5'. E. long. 80° 25'.

The company's lands, or Jaghire, extend from Madras to the Pallicate lake, northward; and to Alemparvé, ſouthwards; and weſtward, beyond Conjeveram; that is, about 108 Britiſh miles along ſhore, and 47 inland, in the wideſt part. This Jaghire is underſtood to be held in perpetuity. It contains about 2440 ſquare miles, and its revenue is reckoned at about 150,000*l. per annum.* Rennell's Mem.

MADRE DE DIOS, an iſland in the South Pacific ocean, near the coaſt of Patagonia, 180 miles in circumference. S. lat. 51°. W. long. 77° 46'. See alſo RESOLUTION.

MADRE *de Popa*, a town with a convent, in South America, in the province of New Grenada, ſituated on the river Grande, or Magdalena. The pilgrims in South America reſort in great numbers to the convent in this place, regarding it with a veneration ſimilar to that with which Santa Caſa is reſpected in Europe. Many miracles are reported to have been wrought here by the holy virgin, in favour of the Spaniſh fleets and their ſailors, who are therefore very liberal in their donations at her ſhrine; 34 miles E. of Carthagena. N. lat. 10° 51'. W. long. 76° 15'.

MADREBOMBO. See SCHERBRO.

MADREPORA, MADREPORE, in *Natural Hiſtory*, a genus of the claſs Vermes, and order Zoophyta; animal reſembling a meduſa; coral with lamellate ſtar-ſhaped cavities. There are about 120 ſpecies ſcattered through the different ſeas on the globe, ſome of which, as will be noted, are common to our coaſts. Theſe are uſually diſtributed into five ſubdiviſions, as follow:

A. *Compoſed of a ſingle Star.*

Species.

*VERRUCARIA. Star orbicular, flattiſh, ſeſſile, with a convex diſk full of tubular pores and a radiate border. This ſpecies is found in the Red, Mediterranean, and Northern ſeas, adhering to marine vegetables, and the ſofter zoophytes. It is the ſize of a ſplit pea, and appears an intermediate ſpecies between the madrepore, tubipore, and millepore; white or yellowiſh, with aggregate tubes on the diſk, like florets of a compoſite flower, and a flattened ſtriate border, like the rays of theſe flowers.

TURBINATA. This is deſcribed as turbinate, ſeſſile, ſmooth, with an hemiſpherical concave ſtar. It is found in Gothland and Campania.

*PORPITA. Without a ſtem; the ſtar is convex, orbicular, with a depreſſed centre, beneath flat, margined, ſmooth.

FUNGITES. Orbicular, convex, with ſimple longitudinal laminæ or gills, beneath concave and papillous. It is found in the Indian and Red ſeas; ſometimes with and ſometimes without footſtalks; is from one to ſix inches in diameter; white, with a concave centre, and rough beneath; the gills are acute, alternately ſhorter and irregularly ſerrate.

PATELLA. Without ſtem; gills granulate at the ſides, denticulate at the margin, and placed in a triple order; the third reaching from the centre to the margin. Inhabits the Mediterranean, and is about an inch and a half in diameter. All the gills are denticulate at the margin, and very rough at the ſides: the younger ſpecimens are flat, but the full-grown ones convex.

CYATHUS. Clavate, turbinate, with a tapering baſe; ſtar rather conic, with a double, prominent, jagged centre. It inhabits the ſouthern coaſts of Europe; it is about two inches long, and three quarters of an inch in diameter. In ſubſtance it is white and hard; it has about forty gills, with as many intermediate ſmaller ones, the latter reaching to the margin, but not extending to the centre like the larger ones.

B. *With*

B. *With numerous ſeparate Stars, and continued Gills.*

Species.

Pileus. Without ſtem, oblong, convex, beneath concave, with longitudinal rows of concatenate ſtars; gills crowded, abbreviated. This ſpecies inhabits the Indian ocean. In the furrow along the middle is a line of ſtars with their gills diſpoſed on each ſide in a radiate form; under theſe on each ſide are two rows of ſtars, as it were linked together, with their rays nearly parallel and pointing upwards and downwards; margin all round terminated by ſharp erect laminæ, or gills.

Cristata. Foliaceous, creſted, with rows of ſtars impreſſed in the centre; the foliations broad and flattiſh. It inhabits the Indian and South ſeas.

Lactuca. Seſſile, with large, crowded, frondeſcent ſtars, the fronds perpendicular, waved, jagged. This is a rare ſpecies, but is occaſionally found in the American ocean.

Ficoides. This ſpecies is foliaceous, creſted, with ſcattered ſtars; the lateral foliations flattiſh, marginal ones carinate; gills foliaceous. It inhabits the South ſea.

Acerosa. Foliaceous, creſted, with ſcattered ſtars; lateral foliations flat, terminal ones ſubcarinate; gills needle-ſhaped.

Lichen. Foliaceous, creſted, with obconic rounded rows of ſtars, and very acute, carinate, ſubflexuous, obliquely placed foliations. Found in the South ſea.

Agaricites. This is without ſtem; with carinate grooves and concatenate ſtars. Found in the American iſlands; is about five or ſix inches in diameter; cinereous in colour, conſiſting of various divergent ſemiorbicular gills, with numerous ſerpentine grooves, in the bottom of which are placed the ſtars.

Elephantotus. Somewhat turbinate, with granulous parallel gills, and ſcattered prominulent ſtars within. Inhabits the Indian ocean, and is an intermediate ſpecies between the *Lactuca* and *Agaricites*; it reſembles a thin, ſeſſile, undulately curled lamina, with ſtars diſpoſed nearly in the form of a quincunx.

Crustacea. Cruſtaceous, with a flat ſtellate ſurface, compoſed of thick-toothed concatenate rays. Inhabits the American ocean; obtuſely conic, with the ſtars diſpoſed in a quincunx form.

Incrustum. This is unequal, with prominent, conic, truncate, hollow ſtars, which are diſtant at the tip and lamellate within. It inhabits the Red ſea. Stars about the ſize of a pea at the baſe, and half the ſize at the tip.

Exesa. Cruſtaceous, with reticulate, concatenate ſtars, and abrupt, conic, acute interſtices. Inhabits the Pacific ocean. It is white, with conic warts, ſmooth at the tip; gills rough, unequal.

Filograna. This is without ſtem, ſimple, with a very thin, ſerpentine, labyrinthic ſtar, with an acute ſuture, and flat perforated ſpaces. Found in the Indian ocean.

Natans. Simple, without ſtalk; ſtar ſerpentine, labyrinthic, with the diſks of the undulations very broad; ſuture obtuſe, coral porous. Inhabits the Indian and American ſeas.

Anthophyllum. Simple, with an ovate ſtalk; ſtar terminal, hemiſpherical, concave, with radiate thicker gills at the bottom. It inhabits the Mediterranean.

C. *With numerous united Stars.*

Species.

Labyrinthica. Without ſtalk; ſtar with ſerpentine undulations, and obtuſe ſuture. Found in India, and likewiſe in South America; very variable in form, and frequently many feet in diameter. In the Caribbee iſlands it is often burnt into lime; gills denticulate, and jagged at the ends.

Sinuosa. This has ſpreading, ſhort, flexuous undulations, and unequal jagged diſſepiments, the prominent undulations moſtly doubled; gills denticulate. Inhabits South America.

Meandrites. Without ſtalk; ſtar with ſerpentine undulations and acute ſuture. Inhabits South America and the Mediterranean. The undulations are larger and looſer than in the *Labyrinthica*, and the ſubſtance is more ſolid, and nearly ſtony; the centres of the ſtars radiate with thick gills.

Areola. Without ſtalk; the undulations are dilated, and in ſome places doubled, with narrow truncate margin; gills crenate. This is found in India and South America; is of a roſy colour, and ſmooth beneath.

Abdita. Subglomerate, with ſtar-ſhaped, angular, obconic foliations and ſimple undulations; gills narrow, with crenulate teeth. This is thought to be a variety of the *Favoſa*, to be hereafter deſcribed.

Phrygia. With long narrow undulations, and perpendicular prominent ones, the diſſepiments ſimple, lamellate, lobulate; gills rather remote. Found in the Southern ocean. The undulations are ſometimes ſtraight, and ſometimes flexuous.

Repanda. This has prominent undulations thickened; the diſſepiments ſimple and hardly united; gills numerous, moſt of them thickened within.

Ambigua. The undulations of this ſpecies are ſtar-ſhaped and flexuous, the prominent ones are thickened, diſſepiments ſimple and thickiſh; the gills are diſtant.

Dædalea. This has deep, ſhort undulations, and perpendicular prominent ones; the diſſepiments jagged-gills ſerrate. Found in the Eaſt Indian ocean.

Gyrosa. This ſpecies is cellular, with doubled foliaceous, prominent undulations, and ſimple diſſepiments; the gills are foliaceous and equal. This is one of the ſmootheſt of the genera, and covered with numerous cells.

Clivosa. The undulations in this are narrow at the baſe with equal diſſepiments, the prominent ones are ſimple and thickiſh; the gills are alternately abbreviated. It inhabits South America; is rounded and nodulous.

Cerebrum. This is known as the *Brain-ſtone*; it is nearly globular, with very long tortuous undulations, and ending with flattiſh prominent ones. It differs in ſize from two inches to two feet in diameter.

Involuta. The undulations in this are dilated at the baſe, and are ſhort with nearly equal diſſepiments; the prominent ones are ſimple.

Implicata. Undulations rounded, and nearly perpendicular with equal and broad diſſepiments; the prominent ones are doubled and broad.

Cochlea. In this the undulations are ſpiral; the ſtar is ſimple or double, with a punctured centre; the rays are ſerrulate. It inhabits Tranquebar, and is a ſpecies that is between the Teſtacea and the Zoophyta.

D. *Aggregate, undivided, with diſtinct Stars, and porulous, tuberculous, prominent Undulations.*

Species.

Favosa. The ſtars, in this ſpecies, of the fourth diviſion, are angular, concave, connected. It inhabits the Indian ocean. It is white and ſtriate at the ſides; when divided tranſverſely it appears reticulate, with unequal pores and ſpots; gills toothed.

Cavata.

Cavata. This is fubglomerate, with ftar-fhaped, angular undulations, and fimple narrow divifions; the gills are denticulate.

Bulliens. In this the ftars are diftant, round or oblong, unequal and elevated at the margin, the interftices are formed with fomewhat concave, radiate wrinkles.

Ananas. With annular convex ftars, which are concave on the difk. It inhabits the Mediterranean and South American feas, and is frequently found in a foffile ftate. It is gibbous, and when diffected tranfverfely, refembling a white net with hexangular fpots, including a white ring, and ftriate between the net and the ring.

Hyades. With crowded, obconic, rounded, and fomewhat angular ftars, and thick porous divifions; the centres are flattifh and convex.

Siderea. With crowded, rounded, and angular ftars, and thick, rather convex, divifions; alternate gills nearly united at the margin; centres fimple.

Galaxea. This has rather crowded impreffed ftars, and thick, flattifh, nearly diftinct divifions; the gills are very thin, and the centres a little worn. The gills are formed by fours, reaching to the centre; the three intermediate ones are connivent at the bafe.

Pleiades. The ftars are roundifh with acute, elevated margins; the interftices are concave, fmoothifh, and in fome parts a little cavernous.

Papillosa. This is fomewhat aggregate; the ftars are cylindraceo-papillous, with thickened, rounded, oblique margins. It refembles the *Muricata*, of which it may probably be the embryo, but the papillæ are contiguous, and difpofed in a fingle row.

Radiata. Stars cylindraceous, with elevated margins, the interftices broad, concave, and radiate with grooves.

Latebrosa. Stars roundifh, with many rays and elevated margins; the interftices are radiate with grooves, a little narrowed and unequal. It is found in the Weft India iflands.

Polygona. With minute crowded ftars, intermixed with larger perforated ones, the bottom concave, cylindrical. It inhabits the Indian fea, and refembles a white cruft about two inches thick; the fmaller ftars are minute, rather obtufe, and twelve-rayed, the larger ones as big as the end of a finger, more gibbous, with an empty cavity between them.

Arenosa. This, which has contiguous, flattifh, ochraceous ftars, is found in Algira; is white, with large ftars, fometimes a little elevated and verrucofe.

Interstincta. With round, diftant, immerfed cylindraceous ftars; the interftices are porous. It inhabits India, America, and Norway.

Spongiosa. This is fomewhat dilated, with craggy foliations, obtufe above and flat beneath; the ftars are funnel-formed, deep, and unequal.

Foliosa. This is likewife dilated, with foliations fomewhat craggy and verrucofe above, beneath flattifh; ftars unequal and fmall. It is found in the Indian ocean. It is large and rofy.

Porcelata. The ftars of this fpecies are obconic, with acute margins, and in fome places remote; the interftices are fmooth, and the gills every where granulous. It is very rare, and is of a greyifh-white.

Stellulata. With round, diftant, equal cylinders of ftars elevated at the margins; the interftices are rather flat and rough.

Astroites. This is fub-globular, with very numerous immerfed ftars, the interftices are porous. It inhabits South America, in large maffes, and is whitifh.

Stellata. Solid, rough outwardly, with fcattered convex ftars impreffed in the middle; it inhabits the Indian ocean, is grey with rough minute points.

Nodulosa. This has crowded obconic ftars; the interftices and gills are rather fharp and roughifh; the coral is a little nodulous.

Acropora. Hemifpherical, with crowded, annular, prominent, crenate ftars, which are fmall, elevated with a deeper centre.

Cavernosa. The ftars in this fpecies are immerfed, falver-fhaped with a ftriate border, and feparated by an elevated future; it is found in South America and the Mediterranean; the ftars are elevated, and the future forms a pentagonal net-work.

Punctata. This has crowded ftar-like points compofed of ten dots; inhabits the European ocean, and alfo the Mediterranean; it is rounded, white, friable, with fmall unequal ftar-like dots.

Calycularis. In this the cylinders are united; the ftars are concave, with a rather prominent centre; it inhabits the Mediterranean; is roundifh and brown, with diftinct lateral cylinders, tranfverfely wrinkled outwardly; the inhabitant is an actinia, and is a large and very fluggifh animal.

Truncata. Joints turbinate, proliferous, coalefcing at the extreme margin; ftars truncate, with a concave cylindrical difk. It is found in a foffile ftate; a little rugged, with joints of equal length and breadth.

Stellaris. Joints proliferous, central, folitary; ftars connected by a dilated margin; found foffile on the fhores of Gothland; ftems fimple, parallel, erect, as thick as a finger, and four or five inches long; bark obfoletely ftriate, with cup-fhaped joints an inch long.

Organum. Corals cylindrical, fmooth, diftant, combined, with deflected membranes. It inhabits the Red fea, but is more frequently foffile; the cylinders are parallel, and as thick as an oat-ftraw.

Divergens. Sub-globular, with divergent cylinders ftanding out beyond the furface twice their diameter; this is alfo found in a foffile ftate.

* Musicalis. Corals cylindrical, ftriate, diftant, united by numerous tranfverfe diffepiments; it inhabits the Indian ocean, and is fometimes caft on the Irifh coafts, and often found petrified; coral white, and often very large.

Denticulata. Stars unequal, the gills have an elevated margin, the larger ones acute with a procefs at the bafe; the interftices are grooved.

Faveolata. The ftars of this fpecies are fomewhat angular, many-rayed, and here and there doubled when cut longitudinally.

Retepora. The ftars are rather angular with filamentous gills, and reticulate when cut longitudinally.

Rotulosa. Stars cylindraceous, with few rays; the gills erect and acute towards the margin, with an erect fpine at the bafe.

Cespitosa. Corals round, flightly branched, ftriate, approximate, with turbinate concave reticulate ftars; the coral is white, ftony, very large, and often foft; it is frequently found in a foffile ftate.

Flexuosa. Corals cylindrical, rough, flexuous, approximate, with concave ftriate ftars. Found caft on the fhores of the Baltic.

Fascicularis. The corals are ftraight, cylindrical, glabrous, and divergent. It is found in the Indian ocean; white, ftony, folid, unequal; frequently found foffile in different parts of Europe.

Pectinata. The ftars of this fpecies are orbicular, with a tumid, dilated, radiate margin, the interftices are dotted.

dotted. It is found in Silesia; the stars are flat, with about 30 unequal denticulate gills.

ROTULARIS. The coral of this species is of many shapes, with solitary, orbicular, flat, unequally radiate stars, with a smooth, flat, and hardly prominent margin. This is found in the Red sea, frequently growing to other marine substances, white, solid, sub-globular, or flattened, the stars about a line in diameter.

TUBULARIS. In this the tubes are cylindrical, very entire, a little prominent and expanded into an unequally radiate star. This is frequently found fossile; the tubes are about the size of a crow-quill; the stars have six thicker gills, between each of which are three lesser ones.

MAMILLARIS. Stars orbicular, prominent, wart-like, excavated. Found near Frankfort in a fossile state; the stars are without a border.

PATELLOIDES. Glabrous, stars large and many-rayed, being a little elevated with a minute centre. This is found fossile; the stars have from 30 to 40 thick equal rays.

GLOBULARIS. Stars large, rounded, equally rayed, with a large perforated centre.

FILUM. The stars in this species are rounded, large and somewhat crowded, with a very minute and partly excavated centre. This is found in a fossile state near Basle.

PERFORATA. Stars crowded, minute, excavated, with perforated gills. The coral is sometimes hemispherical, and nearly a foot in diameter; the stars are twelve-rayed.

VERMICULARIS. Stars with unequal, undulate, smooth rays; it is found fossile; the stars have about eight principal rays, some of them are forked.

*ARACHNOIDES. Stars crowded, minute, flattened, with subundulate, short, equal rays. It is found fossile; coral hemispherical; the stars have twelve contingent rays.

UNDULATA. Stars large, elevated, with elongated curved rays; found fossile; stars about half an inch wide, with 24 rays.

SOLIDA. Stars every where contiguous, with united membranaceous margins. It inhabits the Red sea, where it forms vast rocks, and is used in building, and burnt into lime; the stars are concave, with a very thin brittle margin; the centre is orbicular and rough, with a row of small tubercles.

* MONILE. Stars funnel-formed, without disk, covered with gills and divisions; gills equal, radiant, denticulate, and continued into the next star. Found in a fossile state in Arabia; stars as large as a pea; the centre less than a mustard-seed.

DÆDALICA. The stars of this species are somewhat hexagonal, with united reticulate divisions toothed internally, and at the margin. Inhabits the Red sea; the stars are snowy, very thin, and toothed within.

MONOSTRIATA. Divisions between the old stars elevated into rough lanceolate tongue-shaped processes; this is found in the Red sea; is spongy, tough, snowy.

CONTIGNATIO. This is flattish and orbicular, with linear stars at the circumference tending to the centre, the middle ones ovate, divaricate, and nearly contiguous. An inhabitant of the Red sea; is sometimes found a foot in diameter.

CRISTATA. Corals ventricose-conic, smooth, but rough towards the tip; stars angular-rounded, labyrinthic, and furnished with alternately shorter rows of gills. Is found on the shores of China.

RUS. Unequal, with spongy papillæ, and superficial flattish distant stars. It inhabits the Red sea.

CUSPIDATA. Corals conic, grooved; stars turbinate, with straight, elongated, acute gills. It is found in China.

E. *Branched, with distinct Stars and tuberculous porulous Undulations.*

Species.

PORITES. Slightly branched, composite, rough, with substellate crowded pores. Inhabits India and South America; is of a clear white, outwardly often grey; the branches are patulous, obtuse, and rough, with eminent dots.

DIGITATA. Branches clavate, flattened; stars scattered, six-rayed, with a projecting, vaulting, upper margin. Inhabits the Indian ocean; resembles the last; the coral is white, outwardly yellowish-grey.

DAMICORNIS. This species is very much branched; the branches are tapering and subdivided; stars crowded, blind, and ciliate. It inhabits Africa and India.

VERRUCOSA. This also is very much branched, and the branches are obtuse, and furnished with numerous simpler wart-like sub-divisions; the stars are scattered, and also crowded and ciliate.

MURICATA. This is a composite and sub-imbricate species, with obliquely truncate prominent ascending stars; there are six varieties of this species, *viz.* 1. With long pointed branches, and without smaller sub-divisions. 2. With divaricate branches, and short divergent pointed subdivisions. 3. With ascending straight branches and subdivisions. 4. With decumbent lower branches, and ascending, short, acute sub-divisions. 5. In this variety the branches are united into a palm at the base, with divergent sub-divisions. 6. This has numerous divergent branches and sub-divisions; the cylinders of stars are turbinate, with thickend rounded margins. Inhabits India and South America.

FASTIGIATA. In this the stars are decorticated outwardly. Inhabits South America; is white and nearly a foot high.

RAMEA. The branches are striate, cylindrical, truncate, with terminal stars; it is found in the Indian, Mediterranean, and Atlantic seas, is about two feet high; stony, ferruginous, and marked with fine longitudinal striæ, some of which are undulate.

OCULATA. This is tubular, glabrous, flexuous, obliquely striate, with alternate branches and concave stars pointing two ways. Inhabits the Indian ocean, and is found in European countries in a fossile state; the coral is white, perforated within.

VIRGINEA. This is sub-dichotomous, straight, solid, with alternate eminent stars. It inhabits the Mediterranean, American, and Norway seas; it is milk-white, and about the thickness of one's finger.

ROSEA. This species is, according to its name, of a rose colour, much branching, with numerous prominent margined stars; it inhabits the Indian ocean, and is about four inches high; the coral is of a beautiful rose-colour when recent, and afterwards fading to a paler tinge; the branches taper towards the base.

HIRTELLA. Stars every where alternate, prominent, with exserted acute gills. It inhabits the Indian ocean, and is white.

LIMITATA. Branches a little flattened, with scattered six-rayed stars, equal at the margin.

BOTRYOIDES. With thick, fastigiate, obtuse, clustered branches, and reticulate craggy undulations.

GRANOSA. This species is a little branching, crested, and somewhat fingered; with the branches obtuse; all the undulations are acutely carinate; the stars are linear and irregular.

PROLIFERA.

PROLIFERA. This is ſub-dichotomous, coaleſcing, with ſtars at the ſide proliferous, terminal, concave. This is an inhabitant of the Norway ſea; it is white and very ſolid; the ſtars are funnel-formed with about eight gills.

SERIATA. This ſpecies is branching, with ſubulate ſubdiviſions and ſtar-like pores in longitudinal rows. Inhabits the Eaſtern ocean; it is white, ſtony, about the ſize of a large quill, and nearly a foot high.

CACTUS. This has compreſſed, divergent, dichotomous branches, carinate at the edge; the ſides with contiguous ſtars. It is found foſſile in Arabia; is about a foot high; the branches are a little erect, and in tranſverſe rows.

CORYMBOSA. The branches of the corymb are thicker at the tip and marked with prickly ſtriæ; the ſtars are terminal, and ſolitary; the branches are as thick as a finger; the ſtars are an inch wide.

GEMMASCENS. This ſpecies has prominent, obconic, bud-like ſtars. It inhabits the Indian ocean, and is ſnow-white.

PROBLEMATICA. With oblique, minute, immerſed, diſtant ſtars, and broad punctured margin. Is found about the Antilles iſlands; it is ſtony, rough, ſea-green, ſometimes as thick as a man's arm, and full five feet high; the interſtices of the ſtars are marked with lines.

SPURIA. This is ſlightly branched and dichotomous, with cylindrical tubes filled with ſmall, irregularly diſpoſed, longitudinal diviſions.

INFUNDIBULIFORMIS. This is turbinate, ſtriate, funnel-formed, with ſlightly prominent ſtars within. It inhabits the Indian ocean; and is white and ſolid.

ANGULOSA. Dichotomous, faſtigiate, with terminal, turbinate, angular ſtars, and toothed gills. It inhabits the American ſeas; is ſhort, thick, cellular, ſmooth, and white.

DISCOIDES. This ſpecies is diſk-ſhaped, ſomewhat pedunculate, and roughiſh, with marginal faſciculate ſtars. It is found in the Indian ocean.

CHALCIDICUM. This is known by its prominent, remote, cylindrical tubes of ſtars, lamellate without and within. It is found in the Red ſea.

CONCAMERATA. This is flat, with remote ſtars, a little prominent at the margin; the interſtices are lamellate. It is found in a foſſile ſtate.

ROSACEA. Furniſhed with a ſtem, and branched; the leſſer branches are cylindrical, aſcending; ſtars terminal; it is ſometimes roſy, ſometimes white, and ſometimes grey.

We ſhall conclude this article with ſome general obſervations, taken chiefly from the 47th volume of the Philoſophical Tranſactions. In ſpeaking of the animal that fills the cavities of the madrepore, it is ſaid its feet are numerous, and terminate externally in two conical productions, which, being placed on each ſide of every one of the lamellæ that give the ſtellular form to the cavity of the coral, ſerve to affix the animal to the circumference of its cell, and may, with propriety, be conſidered as the inſtruments by which the little animal forms the lamellæ themſelves. The baſes of theſe conical productions unite and form round bodies, which poſſeſs ſomewhat of the figure, and of the properties of muſcles; they ſerving to lengthen or to ſhorten the feet, and alſo moſt probably to regulate the force with which they claſp the lamellæ, on which they exert their plaſtic powers. The other ends of theſe round bodies terminate in ſmall cylindric tubes, which are attached to the ſhell of the animal, in the centre of which is ſeen its head, capable of moving with great quickneſs, and ornamented with ſeveral rays, which are moſt probably the arms or claws with which it ſeizes and ſecures the animalcules on which it feeds. Admitting that the formation of theſe corals is the work of the madreporean polype, it may be thus traced through its wonderful labours. It is found that each of the legs of the polype is provided with two proceſſes, which are applied to each ſide of one of the perpendicular laminæ, while a muſcular pyriform body, attached to the other end of the leg, gives to it the power of employing that motion which is neceſſary for the accompliſhment of its taſk. The young polype may be conſidered as completing its operation by two diſtinct proceſſes; the ſecretion and ſeparation of carbonate of lime from ſea-water conveyed through the pyriform body; and its diſpoſition, at the moment of ſecretion, by the two ſmall proceſſes, where the economy of the animal directs. Proportioned to the number of legs poſſeſſed by the infant animal, is probably the number of perpendicular laminæ, or pillars, converging in the centre, which it begins to erect; theſe, when raiſed to a certain height, appear to be connected together by a horizontal plate of the ſame ſubſtance; on theſe the animal erects ſimilar pillars, and places on them a covering, ſimilar to that with which he has completed the firſt compartment. Thus ſeem to proceed the labours of this minute artiſt; and as the number of its legs or inſtruments increaſe, and as they extend in length, ſo much the number of the perpendicular laminæ, and the circumference of the horizontal plates, augment.

MADREPORE STONE; *Madrepor ſtein*, Moll. Karſten; *Chaux carbonatée madréporite*, Brongn.

This rare ſubſtance, which was diſcovered by baron Moll in the valley of Rufsbach, in the territory of Saltzburg, is conſidered by ſome mineralogiſts as a variety of lime-ſtone, while Klaproth and others conſider it as a diſtinct ſpecies of the calcareous genus.

Externally, and on its longitudinal fracture, its colour is greyiſh-black; on the croſs-fracture, it is of a pitchy black colour.

Has been found hitherto only in maſſive, blunt-cornered, rounded, and oblong, ſometimes flattened pieces, of from three inches to one foot in diameter.

Its ſurface is more or leſs finely furrowed, and ſometimes ſmall ſhallow holes are ſeen in it; furrows often radiating, and marked with tranſverſe minute ſtriæ.

Externally this ſubſtance is glimmering, paſſing into dull; internally, on the longitudinal fracture, partly glimmering, partly gliſtening; but on the tranſverſal planes of fracture it ſhews a pitchy luſtre, ſometimes approaching to metallic. It gives a grey ſtreak.

It is not particularly hard; it is brittle, and eaſily frangible. Fragments opaque, indeterminately angular, not very ſharp-edged, always of a ſtraight or divergingly columnar ſtructure. They often contain copper pyrites, finely diſſeminated, and in pellicles.

It is not particularly heavy; leſs ſo than compact lime-ſtone.

Before the blowpipe, the black colour of the madrepore ſtone is converted into greyiſh-white.

According to the analyſis of Meſſrs. Schrol and Heim, the conſtituent parts of this ſubſtance are, lime $63\frac{4}{16}$, alumine $10\frac{2}{16}$, ſilex $12\frac{5}{16}$, iron $15\frac{15}{16}$; and the ſame conſtituents, and their proportion, are quoted in the French ſyſtems of mineralogy, as the reſults of an analyſis of madreporite made in the *Ecole des Mines*. But Klaproth, who analyſed a ſpecimen ſent by baron Moll himſelf, obtained the following reſults:

Carbonate

Carbonate of lime	93.
Carbonate of magnefia	0.50
Carbonate of iron	1.25
Carbon (radical)	0.50
Arenaceous filex	4.50
Oxyd of manganefe, a trace	
	99.75

Klapr. Beytr. iii. p. 276.

The ftructure of the feparate pieces of this mineral, refembling the aggregation of madrepores, has given rife to its name. Some mineralogifts have, indeed, fuppofed that the fubftance derives its origin from a fpecies of madrepores; but Klaproth obferves, that this opinion is not fupported by any certain mark indicative of preceding organic ftructure.

Patrin confiders the madrepore ftone as a fafcicular variety of arragonite.

The geognoftic fituation of this mineral is not known.

MADRET, in *Geography*, a town of Arabia, in the province of Yemen; 10 miles N.E. of Chamir.

MADRID, a city of Spain, in the province of New Caftile, and capital of the kingdom; feated on the river Manzanares. The accefs to its feveral gates is by ftreets and avenues, planted with trees; of thefe, the gate of Alcala is the moft grand, being conftructed in the form of a triumphal arch, and the entrance to the city by this gate is the moft interefting. As foon as you pafs this gate, you are prefented with an avenue, having on one fide a row of low but uniform houfes, and on the other railings, through which are feen extenfive gardens; the end of it is croffed by the promenade of the Prado; and the view terminates in the extended ftreet of Alcala. The origin of this city is not fatisfactorily afcertained. Some pretend that it was founded by the Greeks, who never penetrated fo far into Spain: others fay that it was the ancient Mantua Carpetanorum. It was at firft known, however, by the palace, or pleafure-houfe, poffeffed here by the kings of Caftile; and the foundation of the town is faid to have been laid by Alphonfo, the 6th of Leon and 1ft of Caftile, who reigned at the end of the 11th century. We find that it was facked by the Moors in 1169, and that it was overthrown by an earthquake towards the middle of the 14th century, under the reign of Peter the Cruel, and rebuilt by Henry II., the fucceffor of that prince. Charles I. felected it for the place of his refidence, which occafioned its increafe from fmall beginnings, and his fon, Philip II., transferred the feat of government to it in 1563. Its firft limits were very narrow, and not extended beyond the vicinity of the king's palace; but in procefs of time it was enlarged by the addition of feveral fuburbs.

Madrid is fituated on feveral low hills near each other, in the midft of an extenfive plain, bounded, on the fide of old Caftile, by the mountains of Guadariama, and undefined by any fixed boundaries on any other fide. The plain is dry, parched up, and naked, without trees, and uneven; and the city is fituated at a confiderable height above the level of the fea. Its fituation for the government of the kingdom is convenient, as it lies in the centre of the kingdom, and equally within reach of the diftant provinces. Its prefent extent is 41,333 feet, or two leagues in circumference; its figure is a fquare; and it has 15 gates of granite, 506 ftreets, 42 fquares, large and fmall, 7398 houfes, 133 churches, convents, colleges, feminaries, or hofpitals, 65 public edifices, 17 fountains, and feveral promenades. It is divided into eight diftricts, each diftrict into eight wards, to each of which an alcade is attached, a fort of commiffary of police, chofen annually from among the inhabitants. The population, according to the account of 1788, amounted to 156,272 perfons; and if the garrifon be included, which confifts of from 8 to 10,000 foreigners, and Spaniards from the provinces, the population may be reckoned at 200,000. Townfend reckons 13 parifhes, 7398 houfes, 32,745 families, amounting to a population of 147,543. The number of deaths in 1788 was 5915, and that of the births 4897. In 1797, the deaths were reckoned to be 4441, and the births 4911. The Plaza Mayor, which is near the centre of the city, and from which feveral ftreets branch out, is the moft populous and beft frequented place in Madrid, the centre of commerce, and particularly of retail trade. It is likewife the place where public fêtes are given, and at that time acquires, from its decorations, illuminations, and crowds of fpectators, a grand appearance. Madrid is well laid out; and though it has many narrow and crooked ftreets, the greater number are handfome, and there are fome which would do honour to the fineft cities in Europe. That of Alcala is the moft diftinguifhed, as it extends in a ftraight line from the Prado to the Puerta del Pol, and is broad enough to admit ten carriages abreaft; but the houfes are not lofty in proportion to the breadth of the ftreet. The ftreets, though roughly paved, are kept very clean, and well lighted by lamps placed on both fides over the houfes, oppofite to each other, at equal and fhort diftances. Many of the private edifices, efpecially in the large ftreets, though difplaying no magnificence of architecture, exhibit an agreeable appearance. The interior of the houfes of perfons of fuperior rank is handfomely and magnificently furnifhed; fome of them being adorned with chef-d'œuvres of the fine arts.

The city of Madrid is in the diocefe of Toledo; and the fpiritual adminiftration is directed by the grand vicar of that city; a bifhop *in partibus infidelium*, auxiliary to the archbifhop, alfo refides there, with the powers of that prelate. In Madrid they reckon 15, or, as Townfend fays, 13 parifhes and fix chapels of eafe; and a number of monafteries, convents, &c. which it is needlefs for us to fpecify. The fecular clergy are 395 in number; and the regular clergy, including thofe of the monks and nuns, amount to 2718; amounting in the whole to 3113. The eftablifhments, under the name of hofpitals, and benevolent affociations for the relief of indigence and diftrefs in this city, are very numerous. The head of the civil adminiftration of Madrid is a military governor, who bears the honours of captain-general of a province; and the police is under the fuperintendance of different magiftrates. Since the expulfion of the Jefuits, Charles III., in 1770, eftablifhed an enlarged plan for the inftruction of youth, the execution of which is committed to a number of fecular priefts, who, in one of the houfes formerly occupied by the Jefuits, fuperintend the college of St. Ifidore. This eftablifhment includes fixteen mafters, or profeffors, for the languages and fciences, and a good library. There is another college appropriated to the inftruction of the young nobility. The academies are numerous: amongft thefe we may reckon four for jurifprudence, and another for medicine; a Spanifh academy, founded in 1714, by Philip V., for the improvement of the Spanifh language; an academy for hiftory, inftituted in 1735, by the fame prince, for the elucidation of hiftorical fubjects, in connection with geography and chronology: the academy St. Fernando, devoted to painting, fculpture, and architecture, which originated in the munificence of Philip V. Among the libraries, we may enumerate the royal library, formed in 1712, and containing a great number of printed volumes, a large collection of MSS., a variety of modern medals, and a selection of antiques: the cabinet of natural history was formed by Charles III., and is receiving continual accessions. To the class of curious and useful edifices in Madrid, we may refer several of its churches, its gates, the custom-house, erected in 1769, the house of the academy of St. Fernando, and of the cabinet of natural history, the Casa de Carreos, or post-house, the Caract de Corse, or state-prison, erected under Philip IV., the Casa del Ayuntamiento, or town-house, the Palacio de los Consajos, or council-house, which is the seat of a supreme tribunal, the Armeria Real, or royal magazine, and the king's palace. The latter stands on an eminence at one of the extremities of Madrid, commanding a distant view of the beautiful country, which is watered by the Manzanares: founded by Alphon. VI. in the 11th century, sacked by the Moors in 1109; afterwards destroyed by an earthquake, but repaired by Henry II. and completed by Henry IV.; much enlarged by Charles V., and his successors; totally consumed by fire in 1734; and, in 1737, rebuilt on its present plan by Philip V. and Ferdinand VI. This new palace presents four fronts, 470 feet in length, and 100 in height, enriched with numerous pillars and pilasters. The interior of this palace is ornamented by several productions of the arts. Its walls and cielings are covered with allegorical paintings by the best masters; and the apartments are filled with pictures by the most eminent artists, among which we may select an Adoration of the Magi by Rubens, and a Bearing of the Cross by Raphael. Among the paintings we may also select a piece by Titian, of Venus binding the Eyes of Cupid, an Apotheosis of Hercules by Mengs, and an Adoration of the Shepherds by the same master. There is also a group of nymphs dancing round the statue of Priapus by Poussin. One of the most magnificent apartments in the palace is the king's hall, in which his majesty gives public audience to foreign ambassadors; it is a double cube of 90 feet, hung with crimson velvet, and adorned with a sumptuous canopy and painted cieling; it is embellished with mirrors of an extraordinary size, with several antique heads, and a small equestrian statue of Philip II., in gilded bronze. The palace is the depository of the crown jewels and regalia; among which we may mention a superb throne, with its canopy, constructed for Philip II. The Buen-Retiro is another royal mansion, situated in another extremity of Madrid, opening on the promenade of the Prado, and extending to the country that borders on the road from Alcala to Madrid; erected by Philip IV. This palace is environed by beautiful gardens, which occupy an immense area, in one of which is placed an equestrian statue of Philip II. in bronze. Madrid has several promenades, but their distance renders them inconvenient of access. Of these the Prado is that which is most frequented.

Madrid does not possess one manufacture, from which it can derive any advantage. It has, indeed, three for hats, and another for stained paper, but they are barely sufficient to answer the demands of the capital. There are also three others of greater note, for inlaid work in stone, for tapestry, and for porcelain; but as they are appropriated to the king, they are wholly unproductive to commerce. A considerable manufacture of salt-petre was also established in 1779, and in 1785 it occupied 4000 men, the number of which has since been increasing. Madrid is so destitute of commerce, that it is absolutely dependent for support on remote provinces or foreign countries for every article of use or ornament, for clothes and corn, for all the luxuries and necessaries of life. This city has no discriminating character with regard to manners or customs. Its amusements are numerous; but that which most interests the inhabitants is the bull-fight. In Madrid are three theatres, which scarcely receive from those who attend them sufficient encouragement for their support. On Corpus Christi day there is a grand procession, composed of the secular and regular clergy of Madrid, followed by the king, his ministers and court, each bearing in his hand a wax taper. As to the climate of Madrid, we observe that the sky is almost always serene and free from clouds; the air is dry, pure, and bracing, especially in the winter season, but it is highly injurious to hectic subjects. The air is so piercing, as to give rise to the proverb, that the air of Madrid destroys a man, when it does not extinguish a candle. The winds most prevalent are, the north in winter, the south and west in spring. In summer the heat is intense, and during the months of July and August almost insupportable. The usual heat in summer is said to be from 75° to 85°; at night the thermometer seldom falls below 70°; the mean height of the barometer is 27°.96. It seems to be about 1900 feet above the level of the sea. Upon the whole, Madrid may be considered as a healthy residence. The various articles of food consumed in this capital are supplied by different parts of Spain. Its bread is excellent, and its water is pure and good. For the supply of the capital, schemes have been adopted for rendering the small stream of Manzanares the channel of communication with the provinces. With this view it has been proposed to form a junction between the Manzanares and the Xarama; and at length under the auspices of Charles III. a canal was formed from the bridge of Toledo near Madrid to the Xarama, near the village of Manzanares, which includes a distance of four leagues. N. lat. 40° 25′ 18″. W. long. 3° 12′. Laborde's View of Spain, vol. iii. Townsend's Travels in Spain, vols. i. and ii.

Madrid, a town of America, in the northern part of Louisiana, seated on the W. bank of the Mississippi, settled some years ago by Col. Morgan, of New Jersey, under the patronage of the Spanish king, and called by the name of the capital of his European dominions. The spot on which it was proposed by the settlers to found a great city, is situated in N. lat. 36° 30′, and 45 miles below the mouth of the Ohio river. Its limits were proposed to extend four miles S. and two W. from the river, so as to cross a beautiful deep lake of clear spring water, called St. Anne's, 100 yards wide, and several miles in length, emptying itself by a constant and rapid narrow stream through the centre of the city. On each side of this lake it was proposed to lay out streets, 100 feet wide, and to continue a road round it of the same breadth. A street, 120 feet wide, was to be formed on the bank of the Mississippi; 12 acres of land were to be preserved in the central part of the city, to be laid out and ornamented for public walks; and other lots of land were destined for other public uses. For the completion of this plan, the country round this spot presents several inducements. It is singularly fertile and productive. The natural growth consists of mulberry, locust, sassafras, walnut, hickory, oak, ash, logwood, &c. besides grape vines in great abundance. The meadows are fertile in grass, flowering plants, strawberries, and with culture produce good crops of wheat, barley, Indian corn, flax, hemp, and tobacco, and are easily tilled. The climate is favourable to health, and to the production of various kinds of fruits and vegetables. Iron and lead mines and salt springs are plentiful; and the banks of the Mississippi, for many leagues, commencing about 20 miles above the mouth of the Ohio, are a continued chain of lime-stone. A fine tract of high, rich, level land S.W., W., and N.W. of New Madrid, about 25 miles wide, extends quite to the river St. Francis. The situation of New Madrid is excellently ly adapted to its being rendered the great emporium of the weftern country.

MADRIDEJOS, a town of Spain, in New Caftile; 30 miles S.E. of Toledo.

MADRIER, in the *Military Art*, a thick plank, about 18 inches fquare, ftrengthened on one fide with a ftrong band of iron, and a ftrong iron hook, and having, on the other fide, a cavity fufficient to receive the mouth of a petard when charged; with which it is applied againft a gate, or other body defigned to be broken down. See PETARD.

MADRIER alfo denotes a long and broad plank, ufed for fupporting the earth in mining, carrying on faps, making caponiers, galleries, and the like.

There are alfo madriers lined with tin, and covered with earth; ferving as defences againft artificial fires, in lodgments, &c. where there is need of being covered over head.

MADRIGAL, in the modern Italian, Spanifh, and French poetry, denotes a little amorous piece, containing a certain number of free unequal verfes, not tied either to the fcrupulous regularity of a fonnet, or the fubtlety of an epigram, but confifting of fome tender and delicate, yet fimple thought, fuitably expreffed.

Menage derives the word from *mandra*, which, in Latin and Greek, fignifies a fheepfold; imagining it to have been originally a kind of paftoral, or fhepherd's fong; whence the Italians formed their *madrigale*, and we *madrigal*. Others rather choofe to derive the word from *madrugar;* which, in the Spanifh, fignifies to rife in the morning; the *madrigals* being formerly fung early in the morning, by thofe who had a mind to ferenade their miftreffes.

Huet fuppofes it to be a corruption of *martegeaux*, a name given to the inhabitants of a diftrict of Provence, who either invented or excelled in this fpecies of compofition. If the origin is deduced from the Spaniards, it may have taken its name from a town in Spain, called *Madrigal*. Others, fuppofing that its firft application was to religious poems addreffed to the Virgin, *alla Madre*, derive from thence *madrialle*, and *madrigale*.

The madrigal, according to M. le Brun, is an epigram without any thing very brifk and fprightly in its fall, or clofe: fomething very tender and gallant is ufually the fubject of it: and a certain beautiful, noble, yet chafte fimplicity, forms its character.

The madrigal is ufually looked on as the fhorteft of all the leffer kinds of poems, except the epigram: it may confift of fewer verfes than either the fonnet, or roundelay. There is no other rule regarded in mingling the rhymes and verfes of different kinds, but the fancy and convenience of the author. This poem, however, really allows of lefs licence than many others; whether we regard the rhyme, the meafures, or the purity of expreffion. The term is alfo applied to a mufical compofition of three or more parts for different voices, adapted to the words of fuch poems.

MADRIGAL is likewife a mufical term for a vocal compofition, feldom in lefs than four parts. The etymology of this word has been much difputed. But it feems as if its firft application had been to fhort religious lyric poems, or hymns, addreffed to the virgin, *alla Madre*; whence *madriale* and *madrigale*; but being afterwards applied to poems on love and gallantry, by the Italians, French, and Spaniards, the original import has been forgotten. Indeed, the words of all the madrigals which we have feen of the 16th century, when they were moft in favour, feem to belong to the mother of love and gallantry; *alla madre, della gaia, madre galante, mater lætitiæ*, than to the Virgin, or religious fubjects. It never can have meant a morning fong, as fome have imagined; the Italians having been long in poffeffion of the term *matinata*, a lover's matins under the windows of his miftrefs; as they have of *fenerata*, an evening fong. This fpecies of mufic feems to have been brought to its higheft degree of perfection in Italy, by Luca Marenzio, at the latter end of the 16th century, after which time it foon declined, and loft the favour of the public.

Few Italian compofers of eminence produced madrigals after Luca Marenzio, except Stradella, and Aleffandro Scarlatti, which are admirable.

MADRIGAL, in *Geography*, a town of Spain, in Old Caftile, 27 miles N. of Avila.—Alfo, a town of Spain, in Old Caftile, near Olmedo, on the Adaja; 30 miles S. of Valladolid.—Alfo, a town of Popayan, in South America; 110 miles S. of Popayan. N. lat. 0° 50′. W. long. 75° 45′.

MADRIGOLO, a town of the duchy of Parma; fix miles W. of Parma.

MADRISIO, a town of Italy, in Friuli; 30 miles N. of Venice.

MADROGAN, or BANANATAPA, a town of Africa, in the kingdom of Mocaranga, in which is a palace of the king. S. lat. 18°. E. long. 29° 30′.

MADROV, a town of Hindooftan, in Myfore; 18 miles E.N.E. of Seringapatam.

MADRUSAVA, a town of Japan, in the ifland of Niphon; 36 miles S.E. of Xenday.

MADRUZZO, a town of the Tyrolefe; 4 miles W.S.W. of Trent.

MADS, in *Agriculture*, a provincial term applied to earth-worms.

MADSJAS, in *Geography*, a town of Arabia, in the province of Oman; 20 miles S.E. of Sohár.

MADUE SEE, a large lake of Hinder Pomerania, drained in 1770, and now inhabited.

MADUGAR, a town of Hindooftan, in the circar of Jyenagur; 10 miles S. of Jyepour.

MADURA, a province of Hindooftan, about 180 miles in length, and 80 in breadth, annexed in 1742 to the dominions of the nabob of Arcot.—Alfo, the capital of the above-named province, fortified with fquare towers and parapets, and well furnifhed with cannon. In 1757, this town was purchafed by the Britifh troops for 170,000 rupees. The pagoda of this place is one of the moft fuperb in Hindooftan; 80 miles S.S.W. of Tanjore. N. lat. 9° 52′. E. long. 78° 11′.

MADURA, an ifland and principality in the Eaft Indian fea, reckoned the fixth empire of Java, though not properly belonging to it, as it is a feparate ifland, divided from Java by a narrow ftrait. It is about 75 miles in length, and from nine to fifteen in breadth. It is very fertile in rice, for which it is one of the granaries of India; and while Java was in poffeffion of the Dutch (now, *i. e.* 1811, furrendered to the Englifh) it was under the government of a prince, who was the vaffal of the Dutch company. Its capital of the fame name lies on the S. coaft. S. lat. 6° 44′ to 7° 15′. E. long. 112° 14′.

MADZAR, a town of Ruffia, in the government of Caucafus; 56 miles E.N.E. of Ekaterinograd.

MÆCENAS, CAIUS CILNIUS, in *Biography*, an illuftrious Roman knight, defcended from the kings of Etruria, has rendered himfelf immortal by his liberal patronage of learned men and of letters, and to his prudence and advice Auguftus acknowledged himfelf indebted for the fecurity which he enjoyed. His love of pleafure removed him from the reach of ambition, and he preferred to die, as he had been born, a Roman knight, to all the honours and dignities which either the friendfhip of Auguftus or his own popularity could heap upon him. He attended the emperor through his various fortunes, and in some military actions he is said to have displayed both valour and skill. He, however, chiefly served his master in a civil capacity, and was one of the three intimates, who were delegated by him to effect an accommodation with Antony when he had laid siege to Brundusium. During a long period he held the important post of prefect of Rome, to which his political talents were peculiarly adapted, and with perfect fidelity to the emperor, and vigilance to maintain his interests, he was not chargeable with any acts of cruelty and oppression. It is to the honour of Augustus that he received the private admonitions of Mæcenas in the same friendly manner in which they were given, and he was not displeased with the liberty which he once took of sending to him a paper with these words written upon it, "surge carnifex," "rise butcher," while he was sitting on his judgment seat, and betraying revenge and impatience in his countenance. He was struck with the admonition, and left the tribunal without passing sentence of death on the criminals. No minister was more the personal friend of his sovereign than Mæcenas; for this it is thought he was partly indebted to the attachment of the emperor to his wife Terentia, at which the favourite disgracefully connived. It is said that a coolness took place in his latter years between him and the emperor, but at his death, which happened about the eighth year before the birth of Christ, he instituted him his general heir. Though a zealous patron of learning and learned men, he was a man addicted to the pursuit of pleasure. "Where vigilance was required," says Velleius Paterculus, "he was sleepless, provident, and active, but as soon as a relaxation from business could be permitted, he dissolved in a more than feminine indolence and delicacy." The style of his own compositions was infected with the same effeminacy which characterized his manners, but the soundness of his judgment with respect to the writings of others, seems apparent from the merit of those on whom he bestowed his patronage. His name is perpetuated by the two great Roman poets, Virgil and Horace: with the latter he lived upon a footing of freedom and familiarity, which does equal honour to both, and no name appears with so much distinction in his works as that of Mæcenas. Virgil dedicated to him his Georgics, which appear to have been composed at his request. So signal were his good offices towards literary genius, that the name of Mæcenas has ever since been applied to its liberal patrons. Of his own writings a single specimen only has come down to our times, the sense of which is, that he would be contented to live, though oppressed by almost any bodily sufferings and infirmities that could be accumulated, a sentiment which a Roman philosopher would despise, but which has been avowed by persons of our day, whose names will be perpetuated to distant ages by the works which they have left behind them: among these may be mentioned the celebrated Dr. Johnson, and the author of the Επεα πτεροεντα; the one from a dread of death, the other from an attachment to life: the latter, indeed, enduring much bodily pain, and very great infirmities for many years, in the midst of them all, never ceased to wish for a prolongation of life, nor to express a lively sense of the obligations he was under for a large balance of happiness in his favour; and on the tomb, intended by himself for his lifeless body, he inscribed, while living, the expressive epitaph, "Contented and Grateful." The historian Dio has attributed to Mæcenas the introduction of warm baths at Rome, and also the invention of a species of short-hand writing, by the aid of which orations could be taken down from the mouth of the speaker: other writers, however, ascribe this to Cicero's freedman Tiro. He is supposed to have been the author of a history of animals; a journal of the life of Augustus; a treatise on the different natures and kinds of precious stones, besides the two tragedies of Octavia and Prometheus, and other things that are lost. Univer. Hist.

MAEGOA, or Fremona, in *Geography*, a town of Abyssinia; 9 miles from Axum.

MAEL-Carhaix, a town of France, in the department of the Northern Coasts, and chief place of a canton, in the district of Guingamp. The place contains 1767, and the canton 7395 inhabitants, on a territory of 225 kiliometres, in eight communes.

Mael *Coronde*, in the *Language of the Celonese*, the flowering cinnamon-tree. This is a name given to a peculiar species of the cinnamon-tree, which is all the year round found full of flowers. The flowers are not easily to be distinguished from the very finest cinnamon-flowers, but they produce no fruit, which the flowers of the fine cinnamon always do. The bark is much like that of the best cinnamon, in external appearance; but it has very little taste or smell. The tree grows very large, and the inhabitants sometimes tap it, by boring a hole in the trunk, at which it bleeds a thin watery juice, in the manner of our birch-tree.

MÆANDER, in *Geography*, a river of Turkey, in Asia, which rises N. of the ancient city of Apamea, and runs in a winding stream, about 250 British miles, and not far from its mouth, is about 190 feet broad. It is called by the Turks Boone Minder, or Great Mæander, to distinguish it from another little stream, which resembles it in its course.

MÆATÆ, in *Ancient Geography*, a general name, which comprehended the following five British nations, *viz.* the Otodeni, Gadeni, Selgovæ, Nevantæ, and Dumnii, who possessed the country between the walls of Severus and Antoninus Pius. This name, used by the Greek and Roman writers, was probably not unknown to the Britons themselves; and is supposed by some to have been derived from two British words, *moi*, a plain, and *aitich*, inhabitants, and by others from *mean*, middle, and *aitich*, as being situated in the middle, between the provincial and unconquered Britons. We have sufficient evidence, that the Roman armies, under Julius Agricola and the emperor Severus, penetrated a considerable way into that part of Britain which lies to the N. of the wall of Antoninus Pius, between the firths of Forth and Clyde. Tacitus (Vit. Agric. c. 21 to 39.) gives a very distinct account of the first of these famous expeditions in Caledonia, and Dio Nicæus of the second. (Xiphilin. e Dione in Sever.) Many Roman coins have been found in several parts of that country, and there are still remaining in it very distinct vestiges of several Roman camps. But it is no less evident, that the Romans never formed any solid or permanent establishment beyond the wall of Antoninus, which was always considered as the utmost limit of the Roman empire in Britain.

MÆLER, in *Geography*, a very beautiful lake of Sweden, containing several islands rich in wood and pasture, with hilly shores, diversified with trees, villas, and farm-houses. It is usually frozen in winter, and opens an easy communication, by means of sledges, with Stockholm. See Arboga, Canal, and Trolhætta.

MAELLA, a town of Spain, in Aragon; 15 miles E. of Alcaniz.

MAELSTROM, a whirlpool in the North sea, near the island of Moskoe. Its noise is heard at the distance of several leagues, and it is so violent, that a vessel which comes near it is drawn irresistibly into the vortex, and carried immediately to the bottom, where it is dashed to pieces against the rocks. At flood tide the stream runs up into the country with a boisterous rapidity; and at ebb, it returns to the sea

 with

with a violence and noife not equalled by the loudeft cataracts. Whatever it carries down, it inftantly abforbs; but at the turn of ebb and flood, when the water becomes ftill, the fcattered fragments rife to the furface. When this whirlpool has been agitated by a ftorm, it reaches veffels to the diftance of five or fix Englifh miles, at a time when the crews have thought themfelves perfectly fecure. N. lat. 67° 40'. E. long. 11° 44'.

MÆMACTERION, Μαιμακτηριων, in *Chronology*, the fourth month of the Athenian year. It contained twenty-nine days, and anfwered to the latter part of our September and beginning of October. The Bœotians called it *alalcomenius*.

It took its name from the feftival Memacteria, facred to Jupiter, kept at this time.

MÆMACYLON, in the *Materia Medica*, a name given by Diofcorides, and the ancients in general, to the fruit of the *arbutus*, or ftrawberry-tree.

MÆNA, in *Ichthyology*, the name of a fmall fifh, caught in vaft abundance about the fhores of the Mediterranean, and common in the markets of Italy, where they are accounted but a poor fort of fifh, and fold at a very cheap rate. It is fomewhat of the figure of the perch, but broader and thinner, and is feldom above four or five inches in length.

MÆNA *Candida*, a name given by many authors to the fmaris. It is not very improper, for they are both of the fame genus of the fparus, and are very nearly allied to one another; the principal difference confifting in the tail and belly fins of the fmaris being red. See SPARUS.

MÆNALUS, in *Ancient Geography*, a mountain of the Peloponnefus, in Arcadia, mentioned by Strabo, Pliny, and Virgil. This mountain was particularly confecrated to Pan. Several towns were fituated on the extent of this, which were deftroyed, and whofe inhabitants affembled at Megalopolis,

MÆONIA, a country of Afia Minor, formerly comprehending that part of Lydia which lay eaftward towards mount Tmolus, and which was the fource of the Pactolus.—Alfo, a town of this province, fituated at the foot of mount Tmolus.

MÆOTÆ, a Scythian people who inhabited the banks of the Palus Mæotis, and who gave their name to this lake.

MÆOTIS, or MÆOTIS *Palus*. See *Sea of* AZOF.

MAERHUET, in *Geography*, a town of Sweden, in Smaland; 31 miles N.W. of Calmar.

MAERNA, a town of the Tyrol; 23 miles W.S.W. of Trent.

MAERSE, a town of Holland, in the department of Utrecht; 5 miles N.W. of Utrecht.

MÆRUA, in *Botany*, fo called by Forfkäll from its Arabic name *Meru*, is one of his genera, adopted by Juffieu, Vahl and Willdenow.—Vahl Symb. p. 1. 36. Willd. v. 2. 1168. Juff. 440. Clafs and order, *Polyandria Monogynia*. Nat. Ord. *Plantæ incertæ fedis*, Juff.

Gen. Ch. *Cal.* Perianth of one leaf, tubular, coriaceous, four-cleft; tube fquare, fhort, broader upwards; fegments of the limb oblong, obtufe, reflexed, a little longer than the tube. *Cor.* none. *Nectary* at the mouth of the tube of the calyx, entire or divided, fhorter than the calyx, conniving, covering the ftalk of the germen. *Stam.* Filaments numerous, at the bafe of the germen, thread-fhaped, twice as long as the calyx; anthers oblong, incumbent. *Pift.* Germen cylindrical, fhorter than the filaments, fmooth, on a thread-fhaped, fquare ftalk, the length of the tube, fwelling upwards; ftyle none; ftigma obtufe. *Peric.* and *Seeds* unknown.

Eff. Ch. Calyx four-cleft, with the nectary in its tube. Corolla none. Stigma feffile.

Obf. This genus is clofely akin to *Grewia*, as Vahl obferves, but differs fufficiently from that in having a four-cleft calyx, a nectary crowning the mouth of the tube, and a feffile ftigma.

1. M. *uniflora*. Vahl and Willd. (M. craffifolia; Forfk. Defcr. 104.)—Stalks fingle-flowered. Nectary many-cleft. A native of Arabia Felix.—This *fhrub* is furnifhed with round, fpreading, very fmooth *branches*, and a purplifh *bark*: *Leaves* alternate, on footftalks, fcattered, often many from the fame bud, oval, entire, pointed, thick. *Flowers* axillary, each placed on a folitary, thread-fhaped ftalk, twice as long as the leaves. *Nectary* divided into many thread-fhaped fegments.

2. M. *racemofa*. Vahl and Willd.—Flowers racemofe. Nectary undivided.—Alfo a native of Arabia Felix.—*Branches* round and fmooth. *Leaves* on footftalks, remote, pendent, oval, pointed, retufe, entire, fmooth, half an inch long; footftalk fhorter than the leaf. *Clufters* of flowers terminal, drooping. *Nectary* undivided.

MAES, GODFREY, in *Biography*. Amidft thofe who practifed the art of painting in the Flemifh fchool, after the aftonifhing powers of Rubens were developed, this artift held a confiderable rank. He was born at Antwerp in 1660, and having received early inftructions from his father, he improved and perfected himfelf by ftudying and copying the fine pictures placed in the great churches and cabinets of his native city.

His works, when he began to practife upon his own invention, were highly approved; and he was much employed both publicly and privately, till at laft he was appointed to the diftinguifhed ftation of director of the academy at Antwerp.

MÆSA, in *Botany*, fo called by Forfkäll, and by him alone; all fucceeding authors having agreed that the plant in queftion is not generically diftinct from BÆOBOTRYS, (fee that article)—Willdenow, Vahl and Martyn call the *Mæfa* of Forfkäll *B. lanceolata*.—Juffieu fuggefts the affinity of this genus to Thunberg's *Aucuba*.

MAESEYK, in *Geography*, a town of France, in the department of the Lower Meufe, feated on the Meufe; 30 miles N.N.E. of Liege. N. lat. 51° 4'. E. long. 5° 47'.

MAESLAND, or MAESLAND SLUYS, a town of Holland, on a canal that forms a communication between Delft and the Meufe; the inhabitants of which are principally occupied in the herring and whale fifhery; 7 miles S. of Delft.

MÆSTLINUS, MICHAEL, in *Biography*, a German aftronomer, was born in the duchy of Wirtemberg, and became mathematical profeffor at Tubingen, where he died in 1590, at the age of forty-eight, leaving behind him feveral works on mathematics and aftronomy. In early youth he made a fpeech in favour of Copernicus's fyftem, which is faid to have brought the afterwards celebrated Galileo over from the philofophy of Ariftotle and Ptolemy, to whofe fyftems he had been previoufly devoted. Kepler was one of the pupils of Mæftlinus, and has, in his own work entitled "Aftronomia Optica," commended feveral of his inventions. Martin. Biog. Phil.

MAESTOSO, in the *Italian Mufic*, majeftic, fpirited, but not quick.

MAESTRICHT, in *Geography*, a town of France, and principal place of a diftrict, in the department of the Lower Meufe;

Meuse; formerly one of the largest, as well as the most ancient towns in the Netherlands, and belonging to the duchy of Lorrain. The possession of it was secured by Charles V. in 1530, at the diet of Augsburg; and he united it to the duchy of Brabant. Its magistracy is composed of two burgomasters, one a Catholic, the other a Protestant, and 20 echevins, half Catholics and half Protestants. It was formerly a bishop's see; but the see was removed in 710, by St. Hubert to Liege. It has two collegiate, and several parish churches, and before the revolution it had several religious houses: its town-house is handsome, and it has a good library. It has been fortified at different times by the Spaniards, Dutch, to whom it was ceded by the peace of Nimeguen in 1678, and French, when they had respectively possession of it.

The ramparts of Maestricht consist of the old inclosure, flanked with small towers and ancient bastions. But the principal strength of the place lies in several detached bastions, some great, some small, in several horn-works, and a covert-place, in some places double, and in others treble, the whole supported by a vast number of mines. They can form two inundations round the town, to prevent its being approached, one above, the other below the city; besides, on the south side of the town, towards Liege, there is a very strong entrenchment on the declivity of a hill, called fort St. Pierre, able to hold 13 or 14,000 men, which, with the help of several redoubts well planted with artillery, are capable of being a great obstruction to an army that would undertake the siege of the town. This fort consists of a large bastion with a very good casemate, a counterscarp, and two covert-ways; the whole supported with entrenchments which extend right and left to the inundation formed by the little river Jeker. The suburb of Wyck has a rampart a quarter of a league in circumference, flanked with three large bastions, joining to the body of the place. It has likewise another inclosure of earth, flanked with several bastions, ravelins, and a good covert-way. There are likewise two isles, one above, and the other below the bridge, which are strongly entrenched and defended with redoubts and other works. In short, Maestricht is justly looked upon as one of the strongest places in Europe. Near it are large stone quarries, in which are subterraneous passages of great extent, where the farmers frequently store hay, corn, and other articles.

On the 23d of February 1793, it was bombarded by the French, under general Miranda; but being attacked by general Clairfayt on the 1st of March, the republicans lost 2000 men, and nine pieces of artillery, and were compelled to raise the siege. On the fourth of November, the city was taken by the French, the garrison, consisting of between seven and eight thousand men, surrendering themselves prisoners of war. The town contains 17,963, and its two cantons 29,245 inhabitants, on a territory of 120 kiliometres, in 22 communes; 15 miles N. of Liege. N lat. 50° 48'. E. long. 5° 43'.

MAESTRO, a town of Italy, in the Paduan territory; 8 miles N.W. of Venice.

Maestro, a master; as *Maestro di cappella*, the master of a choir, or the composer in a cathedral. It is likewise a title given, by courtesy, to the composer of an opera, the master who presides at a harpsichord in a concert, and sometimes to a mere music master.

MAESWINES Bay, in *Geography*, a harbour of Ireland, in the county of Donegal, being one of the many inlets in the bay of Donegal. It lies W. of St. John's Point and E. of the harbour of Killybegs.

MAEVA, a town of Russia, in the government of Irkutsk, on the Lena; 20 miles N.N.W. of Vercholensk.

MAFAMEDE, a small island in the Indian sea, near the coast of Africa. S. lat. 16° 20'.

MAFARECK, a town of Egypt; 30 miles N.E. of Kous.

MAFFÆUS, Vegio, in *Biography*, a Latin poet, was born at Lodi, in the Milanese, in the year 1407. He was educated for the law, but soon shewed an attachment to the belles lettres, and in future life had the happy art of blending the charms of poetry with the gravity of jurisprudence. He obtained the professorship of the law at Pavia, from whence he was called to Rome, where he held some considerable offices at the church of St. John de Lateran. He died in 1458: his chief works are, 1st, "De Educatione Liberorum," and, 2dly, "Poetical Pieces," of which the most remarkable was a poem called a continuation of the Æneid of Virgil, which has been translated into English burlesque by Mr. John Ellis.

Maffæus, Bernardin, a learned cardinal, who died at Rome, at the age of 40, about the year 1553. He is known as the commentator on Cicero's epistles, and as the author of a treatise on medals and inscriptions. Moreri.

Maffæus, or Maffei, John Peter, was born at Bergamo in 1536, and was instructed by his uncles Basil and Chrysostom Zanchi, nobles of that city, in the ancient languages, and in philosophy and theology. In 1563 he was appointed professor of eloquence at Genoa, with an ample salary. During the two years which he continued in that office he acquired great applause, and was chosen to the office of secretary of state; in 1565, he returned to Rome, where he entered into the society of Jesuits. He spent six years as professor of eloquence in the Roman college, during which he translated, into the Latin language, the history of the Indies by Acosta, which was published in 1570; after this he was invited to Lisbon by cardinal Henry, to draw up, from papers and other documents with which he was to be furnished, a complete history of the Portuguese conquests in the Indies, and of the progress of the Christian religion in those countries. He returned to Italy in 1581, and spent several years, partly at Rome and partly at Sienna, in learned labours, and at length was placed, by Clement VIII. in the Vatican, for the purpose of continuing, in the Latin language, the annals of Gregory XIII. begun by him in the Italian. He died at Tivoli in October 1603. He wrote the life of Ignatius Loyola, but his principal work is entitled "Historiarum Indicarum, Lib. xvi." which has been frequently reprinted. The best edition is in two volumes 4to. printed at Bergamo in 1747. His works are chiefly to be regarded on account of the purity of the style in which they are written. Moreri.

Maffæus, Francis-Scipio, an Italian marquis, and elegant writer in his native language, was born at Verona in 1675. His early education was entirely conducted by his mother, a woman of very superior accomplishments, but as soon as he was of a proper age, he was sent to the Jesuits' college at Parma, where he distinguished himself by his attachment to poetry. Having completed his studies, he visited Milan, Genoa, and Rome, and at the last named city he was admitted into the Academy degli Arcadi. He now devoted himself to the pursuits of polite literature. Uniting the spirit of philosophy with that of gallantry, he maintained, before an assembly of both sexes in the academy of Verona, certain "Conclusioni d'Amore," in which the elegance of his language and the vivacity of his sentiments were equally admired. For a short time he quitted the arts of peace and joined

joined the army, in which he ferved as a volunteer at the battle of Donawert in 1704, under the command of his fecond brother, who was general of the Bavarian troops in alliance with France: during the campaign he had an opportunity of faving his brother's life, by difarming an officer whofe piftol was pointed at him. At the conclufion of the campaign he returned to Verona, and refumed thofe literary occupations which he never after forfook. He fet himfelf to reform the ftage, and produced, by way of model, his tragedy of "Merope." About the fame time he undertook the more important tafk of reforming the moral principles of his countrymen, efpecially with regard to the practice of duelling, to which his brother had nearly fallen a facrifice. On this fubject he publifhed two works, of which the latter, entitled "Della fcienza chiamata cavallerefca," he dedicated to pope Clement XI. This was a performance of much learned refearch and folid argument, and fo well written in every refpect, that it acquired general applaufe, and paffed through feveral editions. His "Merope," already noticed, was exceedingly popular, and was tranflated into moft of the modern languages. By fome of his contemporaries it was feverely criticifed and violently cenfured: among thefe was Voltaire, who afterwards attempted to rival it by a tragedy of the fame name, which is reckoned one of his beft pieces. Maffæus foon after wrote a comedy, entitled "Commedia delle Cerimonie;" and a drama, called "La Fida Ninfa." He was indefatigable in his ftudies of antiquity and theology, with the view of promoting the honour of his native country, and the fpreading of the Roman Catholic religion. One of his moft ufeful works on the fubject of antiquities was his "Iftoria Diplomatica," being an introduction to the critical knowledge of pieces diftinguifhed under the name of diplomas, with a collection of feveral documents hitherto inedited. In 1732 he raifed a durable monument to the fame of his native city, by a learned work, entitled "Verona Illuftrata." This piece is comprifed in four parts, and is replete with curious information relative to the hiftory and antiquities of the north of Italy, and ranks among the ableft and moft interefting of topographical works. His principal object in a tour undertaken through foreign countries, was the collection of ancient infcriptions, with the defign of uniting them with thofe collected by Gruter, and other writers on the fame fubject. In his journey he vifited every place where the relics of antiquity and the cabinets of the curious were to be found. On his arrival at Paris, he printed an account of what he had feen under the title of "Galliæ Antiquitates quædam felectæ." Here he was elected a foreign member of the Academy of Infcriptions, and was a frequent attendant on its meetings. The difputes concerning the bull Unigenitus interefted him fo warmly, that he ftudied the fubjects in difpute with the utmoft zeal, and in a fhort time produced an elaborate folio volume, the refult of his theological reading. In this he appeared as the champion of the Moliniſts againſt the Janfenifts, and the defender of the bull Unigenitus. This was not publifhed till the year 1742, and previoufly to it he paffed from Paris to London, where he was diftinguifhed by the notice of the royal family, feveral of the nobility, and by the moft eminent men of letters. He vifited both univerfities, and received at Oxford, in compliment to his literary merit, the degree of doctor of laws. From England he went to Holland and Flanders, and proceeded through Germany to Vienna, where he had a moft gracious reception from the emperor Charles VI. He returned to Verona in 1736, and immediately began to publifh the "Offervazioni Letterarie," intended as a continuation of the Italian literary journal. Several original pieces of Maffæus, relative to his hiftory and antiquities, appeared in the fucceffive tomes of his works. The true members of the church of Rome having maintained, in oppofition to the Jefuits, that taking intereft of money to any degree was the crime of ufury, Maffæus oppofed this doctrine in a work entitled "Dell' Impiego del Danaro," which was a learned and rational differtation on the employment of money in ancient times, and the true principles of morality and policy on this head. For this treatife he incurred the charge of herefy, and was banifhed the city: the ftorm at length paffed over, and he returned in triumph. After this he publifhed many other pieces on various topics; among thefe was a metrical verfion of the two books of the Iliad; fome Hebrew poetry; and enquiries into the generation of lightning and other phyfical phenomena in nature. Ever actuated by a defire of advancing the glory of his native city, in which he had already promoted the liberal ftudies, by tranfplanting a colony of learned teachers from the Arcadi at Rome, and eftablifhing a literary affembly in his own houfe, he exerted himfelf in laying the foundation of a mufeum of antiquities and curiofities, which became confiderable, and was announced to the public by a catalogue entitled "Mufeo Veronefe." In 1749 he endeavoured to correct the popular notions concerning magic and witchcraft, by a treatife, "Arte magica dileguata," which brought upon him a hoft of enemies, of whom fourteen replied to his reafonings. He was not, however, to be intimidated, and juftified himfelf by the publication of two other pamphlets on the fame fubject. His next work was entitled "De' Teatri Antichi e Moderni," in which he attempted a vindication of theatrical fpectacles, in oppofition to thofe who maintained that they were all unlawful. He continued to devife new plans, to augment and confirm his literary reputation till the year 1754, when the effects of old age and the feverity of winter threatened him with immediate diffolution. As foon as his danger was known in the city, the council ordered public prayers to be put up for him during three days. His valuable life was protracted a few weeks only, and on the 11th of February 1755, he expired, in the 79th year of his age. He was interred amidft a vaft concourfe of mourning fellow citizens, and a ftatue was erected to his memory in the principal fquare, by the fide of thofe of Fracaftoro, and others who had conferred honour on Verona. Gen. Biog.

MAFFAH, *Old* and *New*, in *Geography*, two towns of the ifland of Madagafcar; the firft fituated on the N.W. coaft, in S. lat. 15° 22′. E. long. 51°; and the fecond, 25 miles S.E. of the other.

MAFFERSDORF, a town of Bohemia, in the circle of Boleflaw; 10 miles N. of Turnau.

MAFFRA, a town of Portugal, in the province of Eftramadura, containing about 1040 inhabitants; near which king John V. erected a magnificent building; in confequence of a vow, made in a dangerous fit of illnefs, to found a convent for the ufe of the pooreft priory in the kingdom, which was found to be that of Maffra. The building was defigned to exceed even the Efcurial; it is conftructed of white marble, contains 37 windows in front, and is nearly a fquare of 728 feet; in the centre is the church, with the palace on one fide and the convent on the other. This ftructure was commenced by order of king John V. in 1717, and finifhed in 1742, the architect being a German, named John Frederic. In the whole building, it is faid, there are 870 rooms, and 520 windows; five miles N.W. of Lifbon.

MAFMALA, a fmall ifland in the Indian fea, near the coaft of Africa. S. lat. 16° 20′.

MAFORTIUM, among the *Romans*, a veil or head-drefs worn by the married women.

MAFRAGG, in *Geography*, a river of Africa, in Algiers, which

which runs into the Mediterranean, near Cape Roſa; anciently called "Rubricalus."

MAFUMO, or English River, a river of Africa, which runs into Delagoa bay, navigable for large veſſels; its channel is about a mile wide; and ſhips lie commonly about two miles up the river, where, in good depth of water, they are ſafe from all winds and ſupplied plentifully with proviſions, ſuch as beef, goats, fowls, fiſh, lemons, oranges, ſweet potatoes, and other vegetables, with good water on both ſides of the river. S. lat. 26°.

MAGACELA, a town of Spain, in Eſtramadura; 18 miles E.S.E. of Merida.

MAGADA, in *Mythology*, a title under which Venus was known and worſhipped in Lower Saxony; where this goddeſs had a famous temple, which was treated with reſpect even by the Huns and Vandals, when they ravaged the country. It is ſaid to have been deſtroyed by Charlemagne.

MAGADINO, in *Geography*, a town of Italy, in the bailiwick of Locarno, on the lake of that name; five miles S. of Belinzona.

MAGADIS, Magas, from μαγαδίζειν, *to ſing*, or *play in uniſon* or *octave*, the name of a muſical inſtrument in uſe among the ancients.

There were two kinds of magades, the one a ſtringed inſtrument, formed of twenty chords, arranged in pairs, and tuned to uniſon or octave, ſo that they yielded ten ſounds; the invention of which is aſcribed by ſome to Sappho; by others to the Lydians; and by ſome to Timotheus of Miletus.

The other was a kind of flute, which, at the ſame time, yielded very high and very low notes. The former kind was, at leaſt, much improved by Timotheus of Miletus, who is ſaid to have been impeached of a crime, becauſe, by increaſing the number of chords, he ſpoiled and diſcredited the ancient muſic.

Among all obſcure terms in the ancient Greek muſic, which have bewildered modern inquirers, few have perplexed them more than this, and its meaning is ſtill ſo far from ſettled, that we have yet to learn whether it was a wind or a ſtringed inſtrument; or, indeed, whether it was any inſtrument at all, or any thing more than a monochord, or the bridge of an inſtrument. Rouſſeau aſſures us, that the verb, *to magadire*, in the Greek muſic, implied to ſing in the octaves, as a man and a woman, or a boy, naturally do; and adds, that as the word comes from *magas*, the bridge of an inſtrument, by extenſion it was applied to an inſtrument with double ſtrings tuned octaves to each other, like the uniſons and octave in our old double harpſichord.

MAGADOXO, Magadosho, or *Maldoſcho*, in *Geography*, a kingdom of Africa, ſituated along the coaſt of the Indian ſea, from the river Jubo, near the equinoctial line, to beyond the fifth degree of north latitude. Its name is derived from its capital, which is ſituated in a large bay, formed by the mouth of a river of the ſame name, called by the Arabs, "the Nile of Magadoxo," on account of its annual overflowing. The ſource of this river is not aſcertained, but its courſe is concluded to be long, from its conſiderable channel and large bay, and alſo from its extenſive inundations, which ſupply various canals, and fertilize the country through which it runs, ſo that it produces in abundance wheat and barley, and a variety of fruits, and ſupplies food for numbers of horſes, oxen, ſheep, and other animals which are bred near its banks. The city of Magadoxo is a place of great commerce, and vaſt reſort from Aden and other parts; whence their merchants bring cotton, ſilk, and other cloths, ſpices, and drugs, which they exchange with the inhabitants for gold, ivory, wax, and other commodities. The inhabitants are chiefly Mahometans, among whom are many Bedouin Arabs, who retain their ancient ſuperſtitions, and farther inland there is a greater number of Abyſſinian Chriſtians, ſubject or tributary to that empire. The king and his court are Mahometans; his ſubjects, of whom ſome are white, others tawny and olive, and others black, all ſpeak the Arabic tongue. They are ſtout and warlike, and uſe, among others, poiſoned arrows and lances. The town is ſituated in N. lat. 2° 6'. E. long. 45° 50'.

MAGALAWAUK, a town of Hindooſtan, in Myſore; 10 miles W.S.W. of Punganore.

MAGALHAENS, Ferdinand de, in *Biography*, commonly known by the name of Magellan, an eminent navigator, was by birth a Portugueſe. He ſerved with much reputation during five years under Albuquerque, in the Eaſt Indies, and particularly diſtinguiſhed himſelf at the conqueſt of Malacca in the year 1510. After this, thinking his ſervices had been but miſerably requited by his own court, he entered into the employment of Charles V. king of Spain, who gave him the command of a fleet, with which, in 1519, he diſcovered the ſtraits called after himſelf at the extremity of South America. Soon after this he took poſſeſſion of the Ladrone and Philippine iſlands in the name of the monarch in whoſe ſervice he was engaged. At one of the latter, named Zebu, Magalhaens obtained the converſion of the king, having aſſured him that by becoming a Chriſtian he would be rendered ſuperior to his enemies. Under the farther condition of his becoming a vaſſal to Spain, the Portugueſe aſſiſted him in his attempts to reduce to ſubjection the neighbouring chieftains, and the holy croſs was erected over the ſmoking aſhes of ſome villages that had been plundered and deſtroyed. In one inſtance his authority was ſet at nought, and he determined to inflict a ſummary vengeance on the rebellious chief: he accordingly landed with about fifty of his men upon the iſland of Matan, and was met by the chief and his people, who though rudely armed, and ſubject to no regular diſcipline, made a formidable reſiſtance during the greateſt part of a day. At length the fire of the Spaniards ſlackened from want of ammunition, and the iſlanders preſſing on, a retreat became neceſſary. Magalhaens received a wound from an arrow in the leg, and being ill ſupported by his men, he was beaten down and ſlain by a lance. This happened in 1521, and by this act of imprudence he loſt the honour of being the firſt circumnavigator of the globe. He has, however, ſecured to himſelf a high reputation among maritime diſcoverers, by the commencement of this great enterprize. Barney's Diſcovery in the South Sea.

MAGALOTTI, *Count* Lawrence, a celebrated philoſopher and mathematician, was born at Rome in 1637. Having been initiated in the elements of learning, he was ſent to the univerſity of Piſa, for the purpoſe of ſtudying juriſprudence, in which he made a great and very rapid progreſs, but the bent of his genius led him to devote his main attention to the ſtudy of mathematics and natural philoſophy. He cultivated theſe branches of ſcience at Florence, during three years, under the celebrated Vincent Viviani, and was, by his recommendation, and that of Borelli, made ſecretary to the Academy del Cimento, which had been eſtabliſhed, in 1656, by prince Leopold of Tuſcany, for the expreſs purpoſe of elucidating philoſophical ſcience by a ſeries of experiments. The duties of this appointment Magalotti diſcharged with the utmoſt aſſiduity and care, and being directed by the prince to draw up an account of the experiments made there, he aimed at rendering his work popular, as well from its elegance as from

from the perſpicuity of its ſtyle. The work was accordingly publiſhed in the year 1666, and was received with univerſal applauſe by men of ſcience. The ſubjects which it embraces are the preſſure of the air; natural and artificial freezing; the various effects of heat and cold; the compreſſion of water; magnetiſm; the nature of colours; of ſounds; the projection of bodies, &c. While the ſecretary was engaged in drawing up his account of the experiments of the academy, he obtained leave from Leopold to pay a viſit to his father at Rome, where he wiſhed to conſult the learned Angelo Rici on the ſubject of that work; but the chief object of his journey was to obtain ſome eccleſiaſtical promotion. Having failed in this object, he determined to return to Florence, and to apply for a place at the court of the grand duke Ferdinand II. In this he was ſucceſsful; and ſhortly after a penſion was given him by pope Alexander VII., to whom prince Leopold had preſented a conſiderable part of the inſtruments uſed in making the experiments at the academy. He attempted a work on electricity, but the ſcience was too much in its infancy, and the facts known reſpecting it were too ſcanty to admit of much being done in it. While engaged in theſe purſuits he did not neglect his favourite ſtudy aſtronomy, and at the ſame time paid ſome attention to theology, particularly to the writings of the fathers. About the year 1666, he drew up and publiſhed a ſmall volume relative to the hiſtory and peculiarities of China, which was received with great applauſe; and at the ſame time he publiſhed a ſmall, but elegant Compendium of the Moral Doctrine of Confucius. He was a good poet, and the firſt perſon who publiſhed a good tranſlation of the Odes of Anacreon in Italian verſe. He was very converſant in many of the modern languages, and could write and ſpeak French, Spaniſh, and Engliſh, with the correctneſs and eaſe of the natives of thoſe countries. Of this he gave abundant evidence in different viſits which he paid to them either in a private or official character. In England he was the intimate friend and boſom companion of the illuſtrious Mr. Robert Boyle, whom he attempted to convert from the errors of the Proteſtant faith, but the Engliſh philoſopher was too well grounded in the evidences of his religion to be moved by the eloquence of his Catholic friend. He was employed in ſeveral miſſions to foreign princes, and at length, in 1674, he was appointed ambaſſador to the imperial court. At Vienna he was received in the moſt honourable manner by perſons of all ranks, and acquired the particular favour of the emperor. Here he formed an intimate connection with the men moſt eminent for ſcience and literature, and ſpent his time agreeably in learned leiſure, till he was embarraſſed by the delay of the neceſſary pecuniary remittances from his court. He now determined to return to Florence without waiting the permiſſion of the duke. Shortly after, that prince ſuperſeded him in his embaſſy to Vienna, and gave him apartments in his palace, with a conſiderable penſion. This was not exactly the thing which he wiſhed, and which his ſervices ſeem to have claimed; he therefore withdrew into retirement, and gave himſelf up entirely to his ſtudies. In 1684, he compoſed fifteen Italian odes, in which he has drawn the picture of a woman of noble birth, and exquiſite beauty, diſtinguiſhed not only by every perſonal, but by every mental charm, and yet rendering herſelf chiefly the object of admiration and delight by her manners and conduct. Not believing that ſuch an original exiſted in nature, he gave this piece the title of "The Imaginary Lady." His next work conſiſted of Letters againſt Atheiſts, in which his learning and philoſophy appear to great advantage. In the year 1689, he was appointed a counſellor of ſtate to the grand duke, who ſent him his ambaſſador into Spain to negotiate a marriage between one of his daughters and king Charles II. Soon after he had accompliſhed the object of this miſſion he ſunk into a temporary melancholy, which led him to exclude himſelf from all intercourſe with the world for nearly a year, till by the intreaties of the grand duke he was induced to return to his poſt at court. He now reſumed very ſucceſsfully his literary labours, and publiſhed works upon various ſubjects, and left others which were given to the world after his deceaſe, which happened in the year 1712, when he had attained the age of 75. Magalotti was as eminent for his piety as he was for his literary talents; unimpeachable in his morals, liberal, beneficent, friendly, polite, and a lively and cheerful, as well as very inſtructive companion. His houſe was the conſtant reſort of men of letters from all countries, whom he treated with elegant hoſpitality. He was deeply converſant with the writings of the ancient philoſophers, and was a follower of the Platonic doctrine in his poems. In his natural and philoſophical inveſtigations he diſcarded all authority, and ſubmitted to no other guide but experiment. Among the moderns he was particularly attached to Galileo. After his death a medal was ſtruck in honour of his memory, with the figure of Apollo raiſed on the reverſe, and the inſcription OMNIA LUSTRAT. In the General Biography is given a long liſt of his various publications, taken from the third vol. of the well known work entitled "Fabronii Vit. Italorum doct. excell."

MAGAME, in *Geography*, a town of the iſland of Ceylon, near the E. coaſt; 96 miles S.E. of Candy.

MAGAN, a town of Spain, in New Caſtile; 8 miles N.N.E. of Toledo.

MAGANJA, a river of Africa, which runs into the Zambeze, S. lat. 16° 20′. E. long. 33° 40′.

MAGAPERAM, a town of Hindooſtan, in the circar of Cuddapa; 14 miles N.N.E. of Combam.

MAGARABA, a mountain of Africa, in Algiers, extending about 30 miles along the coaſt of the Mediterranean, inhabited by a people called "Magarabas," deſcended from the Berberes, who live in tents, feed large flocks, and pay a tribute to the dey of Algiers.

MAGARZAN, an iſland in the Red ſea, near the coaſt of Nubia; it is high, and the largeſt of three forming a triangle, about five miles in length. N. lat. 21° 10′.

MAGAS, in the *Ancient Muſic*, is uſed to denote the bridge of any inſtrument. See MAGADIS.

MAGASSA, in *Geography*, a town of Tyrol; 24 miles W.S.W. of Trent.

MAGATTI, CÆSAR, in *Biography*, (or, as he was called in his Latin writings, *Magatus*,) an eminent ſurgeon, was the ſon of a reſpectable citizen of Scandiano, in the duchy of Reggio, where he was born in 1579. He diſtinguiſhed himſelf by his early proficiency in philoſophy and medicine at Bologna, at which univerſity he received the degree of doctor in both theſe ſciences, in March 1597, in the 18th year of his age. He ſtill remained at that place, however, attending the public hoſpitals, under the direction of the moſt eminent phyſicians, for ſome time; and afterwards went to Rome, where he united the ſtudy of anatomy and ſurgery, with that of medicine. Returning to his native country, he commenced the practice of his profeſſion, where he ſoon acquired ſo much reputation, that the marquis of Bentivoglio induced him to ſettle at Ferrara, as profeſſor of ſurgery in the univerſity of that city. Here, however, he met with conſiderable oppoſition and enmity from the eſtabliſhed practitioners, who interdicted him from practising, unless he would submit to their examinations; with which he at length complied, and gave abundant proofs of superior talents and acquirements. He soon attained the highest professional reputation at Ferrara, and gained the greatest applause from numerous classes of students by his able conduct in the chair, until he was seized with a severe illness, under the impression of which he was induced to enter into the fraternity of Capuchins, and afterwards assumed the habit of the order. He still continued, however, to practise medicine and surgery, in his new condition, with a success that acquired him the confidence of persons of the first rank, especially of Francis I. duke of Modena. But the severity of his sufferings from the stone induced him, in 1647, to repair to Bologna, for the purpose of relieving himself by undergoing the operation of lithotomy; but he survived it a very short time, and died at the age of sixty-eight.

Magatus was the author of a considerable improvement in the art of surgery, by his work entitled "De rara Medicatione Vulnerum, seu, de Vulneribus raro tractandis," Venice, 1616, which he also strenuously inculcated in his lectures, and the good effects of which he had often witnessed during his attendance at Rome. This was the rejection of tents in the treatment of wounds, and the recommendation of a simple easy method of dressing, without the irritation of frequently cleansing and rubbing the tender granulations; a practice which he supported at great length by sound and rational arguments, tinctured a little, however, by the Galenical theories. His work contains also a number of valuable observations respecting particular wounds; and it has an appendix, relating to gun-shot wounds, in which he refutes the notion of their being envenomed, or attended with cauterization. Sennertus published a criticism on his work, containing a defence of the use of tents; to which Magatus, now a monk, replied, in the name of his brother John Baptist, (if that was not his own conventual name) by publishing a pamphlet, with the title of "Tractatus, quo rara Vulnerum deligatio defenditur contra Sennertum," 1627, which is to be found in the Venice edition of the former work, published in 1676. Eloy Dict. Hist. de la Méd. Gen. Biog.

MAGAZINE, Literary, a miscellaneous, periodical pamphlet, containing a variety of essays, in prose and verse. The term, as applied to literature, is modern, but is now become of extensive and popular import. In England it was first employed in "The Gentleman's Magazine," the first number of which was published January 1, 1731; and this has been regularly continued every month from that time to the present. This was not the earliest periodical publication in monthly numbers, as one had appeared in the year 1681, under the title of "The Monthly Recorder of all true Occurrences both Foreign and Domestic." Soon after "The Gentleman's Magazine," a rival work, under the title of "The London Magazine," was published, but this was discontinued in the year 1785.

"The invention of this new species of publication," observes Dr. Kippis, in his memoir of Edward Cave, in the Biographia Britannica, "may be considered as something of an epocha in the literary history of the country. The periodical publications before that time, (*i. e.* 1731) were almost wholly confined to political transactions and to foreign and domestic occurrences: but the magazines have opened a way for every kind of inquiry. The intelligence and discussion contained in them are very extensive and various; and they have been the means of diffusing a general habit of reading through the nation; which in a certain degree hath enlarged the public understanding. Many young authors, who have risen to considerable eminence in the literary world, have here made their first attempts in composition. If it were not an invidious task, the history of them would be no incurious or unentertaining subject." In a former part of this dictionary, we have given a brief history of Newspapers, Magazines under the term "Journal," but if the reader be desirous of obtaining an ample account of periodical literature, he will find it fully narrated in "Nichols's Literary Anecdotes of the eighteenth Century," 6 vols. 8vo.

Magazine, in the *Military Art*, a place in fortified towns, where all sorts of stores are kept; and where carpenters, wheelwrights, smiths, &c. are employed in making things needful to furnish out the train of artillery.

Magazine, *Powder*, is a building constructed for keeping large quantities of powder. These magazines were formerly towers erected in the town walls; but many inconveniences attending this situation of them, they are now placed in different parts of the town. They were at first constructed with Gothic arches; but M. Vauban, finding these too weak, constructed them in a semicircular form, of the following dimensions, *viz.* sixty feet long within, and twenty-five broad; the foundation eight or nine feet thick; and eight feet high from the foundation to the spring of the arch; the floor about two feet from the ground, to prevent damp; and consequently six feet for the height of the story.

The thinnest part or hanches of the arch is three feet thick, and the arch made of four lesser ones one over the other, and the outside of the whole terminated in a slope to form the roof; from the highest part of the arch to the ridges is eight feet, which makes the angle somewhat greater than ninety degrees; the two wings, or gable ends, are four feet thick, raised somewhat higher than the roof, as is customary in other buildings; as to their foundations they are five feet thick, and as deep as the nature of the ground required.

The piers or long sides are supported by four counterforts, each six feet broad, and four feet long, and their interval twelve feet; between the intervals of the counterforts, are air-holes, in order to keep the magazine dry and free from dampness; the dices of these air-holes are commonly a foot and a half every way, and the vacant space round them three inches, made so, as the in and outsides be in the same direction. The dices serve to prevent an enemy from throwing fire in to burn the magazine, and for a farther precaution, it is necessary to stop these holes with several iron plates, that have small holes in them like a skimmer, otherwise fire might be tied to the tail of some small animal, and so drive it in that way; this would be no hard matter to do, since, where this precaution had been neglected, egg-shells have been found within, that have been carried there by weasles.

To keep the floor from dampness, beams are laid long ways, and to prevent these beams from being soon rotten, large stones are laid under them; these beams are eight or nine inches square, or rather ten high and eight broad, which is better, and eighteen inches distant from each other; their interval is filled with dry sea coals, or chips of dry stones, then over these beams are others laid cross-ways, four inches broad, and five high, which are covered with two-inch planks.

M. Belidor would have brick walls made under the floor, instead of beams, and a double floor laid on the cross-beams: which does not appear to be so well as the manner proposed here; the reader is, however, at liberty to choose the method he likes best.

To

To give light to the magazine, a window is made in each wing, which is ſhut up by two ſhutters of two or three inches thick, one within and the other without it; that which is on the outſide is covered with an iron plate, and is faſtened with bolts, as well as that on the inſide. Theſe windows are made very high, for fear of accidents, and are opened by means of a ladder, to give air to the magazine in fine dry weather.

There is likewiſe a double door made of ſtrong planks, the one opens on the outſide, and the other within; the outſide one is alſo covered with an iron plate, and both are locked by a ſtrong double lock; the ſtore-keeper has the key of the outſide, and the governor that of the inſide: the door ought to face the ſouth nearly, if poſſible; in order to render the magazine as light as can be, and that the wind blowing in may be dry and warm. Sometimes a wall of ten feet high is built round the magazine about twelve diſtant from it, to prevent any thing from approaching it without being ſeen. Mr. Muller has propoſed ſome alterations by way of improvement, in M. Vauban's conſtruction, for which ſee his Practical Fortification, p. 219, &c.

If large magazines are required, the piers or ſide-walls which ſupport the arch ſhould be ten feet thick, ſeventy-two feet long, and twenty-five feet high; the middle wall, which ſupports the two ſmall arches of the ground floor, eight feet high, and eighteen inches thick, and likewiſe the arches: the thickneſs of the great arch ſhould be three feet ſix inches, and the counterforts, as well as the air-holes, the ſame as before. Magazines of this kind ſhould not be erected in fortified towns, but in ſome inland part of the country near the capital, where no enemy is expected. It has been obſerved, that after the centres of ſemicircular arches are ſtruck, they ſettle at the crown and riſe up at the hanches; now as this ſhrinking of the arches muſt be attended with ill conſequences, by breaking the texture of the cement after it has been partly dried, and alſo by opening the joints of the vouſſoirs at one end; Dr. Hutton, in his Treatiſe on Bridges, has propoſed to remedy this inconvenience, with regard to bridges, by the arch of equilibration; and as the ill effect is much greater in powder magazines, he has alſo propoſed to find an arch of equilibration for them alſo; and to conſtruct it when the ſpan is twenty feet, the pitch or height ten, which are the ſame dimenſions as thoſe of the ſemicircle, the inclined exterior walls, at top, forming an angle of 113°, and the height of their angular point above the top of the arch equal to ſeven feet; this curious queſtion was anſwered in 1775, by the Rev. Mr. Wildbore, and the ſolution of it may be found in Hutton's Miſcellanea Mathematica.

Magazine, *Artillery*, or the magazine to a field battery, is uſually made about fifty or ſixty yards behind the platform. This is a cavity dug in the ground about four feet deep, and the earth thrown between the pit and the platform; the ſides of the pit are ſometimes planked round to keep it dry and to prevent the earth from crumbling in; and the powder-barrels placed here are covered with hurdles and earth, or tanned hides, to preſerve the powder from wet or fire. The communication to the magazine is by a ſloping trench beginning to deſcend about five or ſix yards behind the platform; and the earth is thrown on that ſide where it will moſt conveniently cover the perſons who remove the barrels of powder from the great magazine to the battery or ſmall magazine. When there are many cannons in the battery, and the ſervice is quick, it is cuſtomary to have, for every two pieces, a ſmall magazine to hold twenty or thirty barrels of powder; this is placed about fifteen or twenty yards behind the platform, and againſt the merlon between the cannon; and as theſe barrels are uſed, they are replaced by others from the great magazine. At each magazine a centinel is placed to prevent accidents; and in order to prevent perſons from coming into the battery and magazines who have no buſineſs there, a trench is ſometimes dug behind the magazine and carried into the trenches, which communicate between the magazine and battery.

Magazine, the apartment uſed to keep the powder in; which in large ſhips is ſituated forwards, and in ſmall ſhips abaft. It ſhould always be ſituated as low down as poſſible.

MAGBOTE, or Mægbote, formed of the Saxon *mæg*, *i. e. cognatus*, and *bote*, *compenſatio*, in our *Old Writers*, a compenſation for the ſlaying or murder of one's kinſman, in ancient times, when corporal puniſhments for murder, &c. were ſometimes commuted into pecuniary fines, if the friends and relations of the party were ſo ſatisfied.

MAGDALA, in *Ancient Geography*, a town of Paleſtine, on the weſtern bank of the lake Tiberias.

MAGDALEINE, in *Geography*, the name of an iſland ſituated at the bottom of Falſe bay, near the Cape of Good Hope, in which is a great reſort of ſea wolves, and of penguins, named "Manchots."

MAGDALEN. *Religious of St. Magdalen*, is a denomination given to divers communities of nuns, conſiſting, generally, of penitent courtezans; ſometimes, alſo, called *Magdalanettes*.

Such are thoſe at Metz, eſtabliſhed in 1452; thoſe at Paris, in 1492; thoſe at Naples, firſt eſtabliſhed in 1324; and endowed by queen Sancha, to ſerve as a retreat for public courtezans, who ſhould betake themſelves to repentance; and thoſe of Rouen and Bourdeaux, which had their original among thoſe of Paris in 1618.

In each of theſe monaſteries there are three kinds of perſons and congregations; the firſt conſiſt of thoſe who are admitted to make vows, and theſe bear the name of St. Magdalen; the congregation of St. Martha is the ſecond, and is compoſed of thoſe who it is not judged proper to admit to vows; finally, the congregation of St. Lazarus is compoſed of ſuch as are detained there by force.

The religious of St. Magdalen at Rome were eſtabliſhed by pope Leo X. Clement VIII. ſettled a revenue on them, and farther appointed that the effects of all public proſtitutes, dying inteſtate, ſhould fall to them; and that the teſtament of the reſt ſhould be invalid, unleſs they bequeathed a portion of their effects, which was to be at leaſt a fifth part, to them.

Magdalen *Hoſpital*. See Hospital.

Magdalen *Iſlands*, in *Geography*, a cluſter of iſlands in the gulf of St. Lawrence, N.E. of the iſle of St. John's, and N.W. of that of Cape Breton. They are inhabited by a few fiſhermen, and are dangerous to ſhips ſailing near them in foggy weather. The largeſt, which gives name to the cluſter, is ſituated in N. lat. 47° 25′. W. long. 61° 20′.

Magdalen *River*, a river of Canada, which runs into the river St. Lawrence. N. lat. 49° 12′. W. long. 65° 5′.

MAGDALENA, a ſmall iſland in the South Pacific ocean, being one of the *Marqueſas*; ſituated nearly in S. lat. 10° 29′. W. long. 138° 50′. See Marquesas.

Magdalena, a town of the iſland of Cuba; 30 miles S. of Havanna.

Magdalena *River*. See Madalena.

Magdalena, *Cape of*, a promontory in the centre of Canada, which has an iron mine abounding with ore and yielding excellent metal.

MAGDALEO, a word uſed by diſpenſatory writers, to expreſs any thing made up into a cylindrical form. The common rolls of plaſters which the apothecaries make up to be ready for ſpreading upon occaſion, are thus called, as alſo the rolls of ſulphur or common brimſtone.

MAGDALGAD, in *Ancient Geography*, a town of Paleſtine, in the tribe of Judah. Joſh. c. xv.

MAGDALLÆ, or MAGDALIDES, the ſame as Magdaleones, rolls of ſulphur, plaſter, &c.

MAGDALUM, in *Ancient Geography*, a place of Egypt, on the coaſt of the Red ſea, between Baal-Zephen and Phi-hahiroth.

MAGDEBURG, in *Geography*, a duchy ſurrounded by the Mark of Brandenburg, the duchy of Brunſwick, the principalities of Halberſtadt and Anholt, the county of Mansfeld, and the electorate of Saxony. The country belonging to this duchy is, in general, level. Although fuel is ſcarce, it has ſeveral mines of pit-coal, and by means of its rivers, particularly the Elbe, which pervades the duchy, obtains wood from the neighbouring provinces. Its ſalt ſprings afford a ſupply of ſalt ſufficient for the demands of all Germany. In 1703, the whole duchy contained 35 towns and 431 villages. From the years 1750 to 1756, the number of inhabitants, eſtimated by the burials, amounted to 330,000. According to Hoeck's account in 1801, the number is ſtated at 275,262. The ſtates of the country conſiſted of prelates, the nobility, and the cities. The Reformation was introduced into this duchy in the ſixteenth century, and about the middle of the ſucceeding century Lutheraniſm was the only religion that was tolerated; but ſince that time French and German Calviniſt refugees have been received, and under king Frederick-William, the private exerciſe of the Roman Catholic worſhip was tolerated both at Magdeburg and Halle. The biſhopric of Magdeburg was formed out of a Benedictine convent, founded by the emperor Otho I. in 937, and converted into an archbiſhopric in 967. By the peace of Weſtphalia, in 1648, the houſe of Brandenburg obtained, under certain ſtipulations, the reverſion of this archbiſhopric, and in 1680 the actual poſſeſſion of it. The duchy had its own regency, which, in 1714, was removed from Halle to Magdeburg, and conſiſted of two ſenates; but the cathedral chapter was afterwards excluded from any part in the government. The annual revenues amounted to above 800,000 rix-dollars. By the peace of Tilſit in 1807, that part of the duchy, which lies on the left ſide of the Elbe, was ceded by the king of Pruſſia to the new kingdom of Weſtphalia.

MAGDEBURG, a city of Weſtphalia, the capital of the above-mentioned province, in the circle of Lower Saxony, on the left bank of the Elbe. This was formerly one of the principal trading towns in Germany. It is ſtrongly fortified, and has a citadel on an iſland in the river Elbe. It is well built, and the cathedral ſquare is ornamented with large and elegant houſes. Among the principal edifices may be reckoned the king's palace, formerly the epiſcopal reſidence, the armoury, the governor's houſe, and the guildhall, to which we may add the Lutheran cathedral, which is a ſuperb ſtructure, in the antique taſte. The Lutherans have alſo three collegiate, and ſix parochial churches, and a convent. The manufactures, which are numerous, conſiſt of woollen cloths and ſtuffs, ſilk ſtuffs, cottons, linen, ſtockings, hats, leathern gloves, tobacco, ſnuff, &c. The ſituation of the Elbe, and the road connecting High and Low Germany, render it convenient for trade. Magdeburg, as early as the time of Charles the Great, was a place of ſome note; and it attained a conſiderable degree of proſperity in later times, and became one of the Hanſe towns. In the year 1807, it was taken by the French. The number of inhabitants, in 1798, is ſtated by Haſſel at 30,611, and in 1802, by Krug, at 32,000; 52 miles E.S.E. of Potzdam. N. lat. 52° 8′. E. long. 11° 50′.

MAGDELA, a town of Germany, in the principality of Weimar; 7 miles S.E. of Weimar.

MAGDELAINE, a cluſter of ſmall iſlands in the Mediterranean, near the N. coaſt of Sardinia. N. lat. 41° 11′. E. long. 9° 36′.

MAGDOLUS, or MAGDOL, in *Ancient Geography*, a town ſituated towards the middle of the frontiers of Lower Egypt, mentioned Jer. c. lxvi. v. 14. Exod. c. xiv. v. 2. and alſo by Herodotus l. xi. c. 49. It was not far from the ſea. The Itinerary of Antonine places it in the vicinity of the Delta, E. of it, about 12 miles from Peluſium, near the moſt eaſterly mouth of the Nile.

MAGEDAN, a town of Judea, ſituated E. of the lake of Genneſareth.

MAGEDO. See MEGIDDO.

MAGEE, in *Geography*, a town of Hindooſtan; 25 miles E. of Benares.

MAGEEYONCOLLA, a town of Burmah; 42 miles N. of Prome.

MAGEGODEVICK, or EASTERN RIVER, a river of America, which falls into the bay of Paſſamaquoddy, and ſuppoſed to be the true St. Croix, which forms part of the eaſt boundary line between the United States and New Brunſwick.

MAGEGOWN, a town of Hindooſtan, in Concan; 25 miles S. of Severndroog.

MAGELHOLM, a ſmall iſland of Denmark, in the Baltic, near the S. coaſt of the iſland of Zealand. N. lat. 54° 43′. E. long. 11° 17′.

MAGELLAN, STRAITS *of*, a paſſage between the Atlantic and Pacific oceans, at the ſouthern extremity of the continent of America; eſtimated by Bougainville at 342 miles from Cape Virgin Mary, in the Atlantic, S. lat. 52° 24′. W. long. 68° 22′, to Cape Pillar, in the Pacific, S. lat. 52° 45′. W. long. 75° 10′. The breadth of it is various in different parts; and it has many capes and bays, affording places of anchorage and ſecurity to ſhips that paſs through it. On the north it is bounded by Patagonia, and on the ſouth by Terra del Fuego. Theſe ſtraits were firſt diſcovered by Ferdinando Magellan, or Magalhaens, in the ſervice of the crown of Spain, who, in the year 1520, found a paſſage through them from the Atlantic to the Pacific ocean, (ſee his biographical article.) Admiral Drake alſo paſſed theſe ſtraits in his voyage round the world; and they have been ſince paſſed by ſeveral other navigators, *viz.* commodore Byron in 1764, Wallis in 1766, and Carteret in 1767, Bougainville in 1768, &c. They have been carefully examined by the navigators juſt mentioned, with regard to their bays, harbours, and headlands; the numerous iſlands which they contain, and the coaſts on both ſides, that incloſe them; and the tides, currents, and ſoundings that occur in them, through their whole extent. Of the tranſactions of Byron, Wallis, and Carteret in theſe ſtraits, we have details in the accounts of their reſpective voyages, and theſe, together with the chart, founded on their obſervations and diſcoveries, are a very valuable acceſſion to geography. Commodore Byron cloſes his account of the voyage through theſe ſtraits, with the following general remarks. "It is probable, that whoever ſhall read this account, of the difficulties and dangers which attended our paſſage through the ſtrait of Magellan, will conclude, that it ought never to be attempted again; but that all ſhips which ſhall hereafter ſail a weſtern courſe from Europe

Europe into the South seas, ought to go round Cape Horn. I, however, who have been twice round Cape Horn, am of a different opinion. I think that at a proper season of the year, not only a single vessel, but a large squadron might pass the strait in less than three weeks; and I think, to take the proper season, they should be at the eastern entrance some time in the month of December. One great advantage of this passage is, the facility with which fish is almost every where to be procured, with wild celery, scurvy grass, berries, and many other vegetables in great abundance; for to this I impute the healthiness of my ship's company, not a single man being affected with the scurvy in the slightest degree, nor upon the sick list for any other disorder, notwithstanding the hardship and labour which they endured in the passage, which cost us seven weeks and two days, as we entered the strait on Sunday the 17th of February, and quitted it on Tuesday the 9th of April. Wood and water are also to be procured almost at every anchoring place beyond Fresh-water bay. Our sufferings I impute wholly to our passing the strait just as the sun approached the equinox, when, in this high latitude, the worst weather was to be expected; and indeed the weather we had was dreadful, beyond all description." (Hawkesworth's Voyages, vol. i.) Capt. Wallis's account of his passage through this strait terminates with this reflection: "Thus we quitted a dreary and inhospitable region, where we were in almost perpetual danger of shipwreck for near four months, having entered the strait on the 17th of December 1766, and quitted it on the 11th of April 1767; a region where, in the midst of summer, the weather was cold, gloomy, and tempestuous, where the prospects had more the appearance of a chaos than of nature, and where, for the most part, the vallies were without herbage, and the hills without wood." To the account of captain Wallis's voyage is annexed, a table of the courses and distances from point to point, in this strait, as by compass.

MAGELLANIC Clouds, in *Astronomy*, whitish appearances like clouds, seen in the heavens towards the south pole, and having the same apparent motion as the stars.

They are three in number, two of them near each other. The largest lies far from the south pole, but the other two are not many degrees more remote from it than the nearest conspicuous star, that is, about eleven degrees. Mr. Boyle conjectures, that if these clouds were seen through a good telescope, they would appear to be multitudes of small stars like the milky way. Boyle's Works abr. vol. i. p. 295.

Magellanic *Goose*, *Anser magellanicus*, in *Ornithology*. See Duck.

MAGELLANICA Terra, in *Geography*. See Patagonia.

MAGERGONG, a town of Hindoostan, in Candeish; 54 miles S. of Indore.

MAGGERI, a town of Hindoostan, in Mysore; 21 miles W. of Bangalore.

MAGGEROE, a large island near the coast of Lapland, separated from it by a strait of the North sea, called "Magger Sund." This island is said to be the most northern land in Europe. N. lat. 71°. E. long. 24° 55'.

MAGGI, Jerome, in *Biography*, a lawyer, philologist, and engineer, was born at Anghiari, in Tuscany, in the earlier part of the sixteenth century; he studied at the principal Italian universities, and while young acquired an intimate acquaintance with antiquities and polite literature. He had scarcely attained to the age of manhood, when he was selected by his townsmen as their embassador at the court of Florence. In 1558, he was appointed judge at Amatrica, in the kingdom of Naples, but his usual residence was in the city of Venice, where he wrote the greater part of his learned works. Of his legal studies, the fruit was "A Commentary on the four Books of Justinian's Institutes." In general literature, his principal work was "Variarum Lectionum seu Miscellaneorum," which was elegantly written, and which proves him to have been thoroughly acquainted with the best ancient and modern authors. He appeared as a theologian, in a treatise "De Mundi exustione, et de Die Judicii," commended by Dupin for its learning and elegance. He gave signal proofs of his talents as a poet, but the work by which he acquired the greatest reputation, was relative to the subject of military engineering, entitled "Della Fortificazione delle Citta," which contains a description of many ingenious machines and instruments of his own invention. On account of his skill in this department of science, he was sent to Cyprus, when threatened with invasion by the Turks, and his services as an engineer were of great use in the celebrated siege of that place, and enabled it to hold out a long time, and with vast destruction to the enemy. At length it fell, and Maggi was carried by the Turks as a slave to Constantinople, where he underwent much hardship. In the gloomy solitude of a dungeon, he wrote two pieces, entitled "De Tintinnabulis," and "De Equuleo," the latter, "On the Rack," was probably suggested to him by the reflection on the tortures to which he was daily liable. He was at length, and at the moment when negociations were carrying on for his deliverance, strangled in his prison, in the year 1572. Bayle.

Maggi, Charles Maria, an Italian poet of the 17th century, and one of the restorers of good taste in Italy, after the barbarous ravages of the school of Marini. He was born at Milan in 1630, and was secretary to the senate of that city. He died in 1690, and his works were published in the following year by Muratori, at Milan, in four vols 12mo.

Maggi, in *Geography*, a town of Tunis; 40 miles S.W. of Gabbs.

MAGGIA Val, an Italian bailiwick, belonging to the Swiss cantons, containing 22 parishes, and 24,000 inhabitants of the Catholic religion. It is partly bounded by the duchy of Milan, and the bailiwicks of Livenen and Locarno, and terminated by mountains of eternal snow.—Also, a town of Italy, in the bailiwick of Bellinzona; seven miles W.S.W. from Bellinzona.—Also, a river of Italy, which runs into lake Maggiore, at Locarno.

MAGGIORA, Lago. See Lake.

MAGGIORE, an Italian adjective, from *major*, Lat. a word now naturalized in the English language, and synonymous with *greater*, as a *major* 3d implies a greater or sharp 3d, as a *minor* does a less or a flat 3d. These degrees of comparison are of very frequent use in music, the variable intervals amounting to five; as the semitone, the tone, the 3d, the 6th, and the 7th. With regard to the tone and the semitone, their difference of *major* and *minor* can only be expressed in numbers, as we have no notes to express them in our system. The semitone major is the interval of a second minor, as from B to C, or E to F, and its ratio is 15 to 16. The major is the difference between the 4th and 5th, and its ratio 8 to 9. The three other intervals, namely, the 3d, 6th, and 7th, differ constantly from each other by a semitone from the major to the minor. Thus, the 3d minor consists of a tone and a half, and the 3d major of two tones. There are some still smaller intervals, which are called major and minor in theory, as the quarter tone, and the comma; but as these intervals can only

only be expreffed in numbers, they are imaginary diftinctions, and ufelefs in practice.

A mode or key is alfo faid to be major, when the 3d above the key note is major; that is, confifting of four femitones above the bafe. To modulate from a major key to a minor, and *e contra*, are common mufical expreffions.

MAGGOT, the common name of the fly-worm, bred in flefh, from the egg of the great blue flefh-fly. Notwithftanding the diftafte for this animal, its figure and ftructure of parts are greatly worth attending to, and may ferve as a general hiftory of the clafs of worms produced from the eggs of flies.

This animal is white and flefhy; its body is compofed of a number of rings, like the bodies of caterpillars, and other the like infects, and is capable, at the pleafure of the animal, of affuming different figures, being at times more or lefs extended in length, and confequently more or lefs thick.

Notwithftanding that this creature has no legs, it is able to move itfelf very fwiftly, and, in its firft attempt to move its body, is extended to its greateft length, and affumes fomething of the figure of a pointed cone. The pointed part of this cone is the head of the animal, and is not feparated from the next ring by any deeper furrow than the reft of the rings are from one another. In fome ftates of the animal one may fee two fhort horns thruft out from the head; but what are more conftantly obfervable, are two brown fcaly hooks; thefe are, however, fometimes hid, and have each of them a fheath, or cafe, into which the animal can retract them at pleafure. Thefe hooks are bent into an arch, the concavity of which is toward the place on which the creature is placed, and they are thickeft at their infertion in the head, and thence diminifh gradually, till they terminate in a fine fharp point.

Thefe two hooks are placed in a parallel direction, and can never come together, and therefore cannot ferve in the place of teeth to grind the food between, but merely to pull and fever it to pieces, that it may be of a proper fize for the mouth of the creature.

The creature has, befides thefe two hooks, a kind of dart, which is of about a third part of their length, and is placed at an equal diftance between them. This alfo is brown like them, and fcaly; it is quite ftraight, and terminates in a fine point. The hooks have, as it were, two fcaly thorns at their points, and this dart feems intended, by reiterated ftrokes, to divide and break the pieces of flefh thefe have feparated from the reft, into fmaller parts.

Immediately below the apertures for the egrefs of the hooks, is placed the mouth of the animal; the creature does not fhew this little opening unlefs preffed; but if the preffure be properly managed, it will fufficiently open it, and there may be difcovered within it a fmall protuberance, which may very naturally be fuppofed either the tongue, or the fucker of the animal.

The hooks in this creature not only fupply the place of teeth but alfo of legs; fince it is by faftening thefe hooks into the fubftance it is placed on, and then drawing up its body to it, that it pulls itfelf along.

The back of the creature lowers itfelf by degrees as it approaches the extremity of the belly; and near the place where the back begins to lower itfelf, are placed the creature's two principal organs of refpiration. One may perceive there two fmall roundifh brown fpots: thefe are very eafily diftinguifhable by the naked eye; becaufe the reft of the body of the creature is white: but if we take in the affiftance of glaffes, each of thefe fpots appears to be a brown circular eminence raifed a little above the reft of the body. On each of thefe fpots one may alfo difcover three oblong oval cavities, fomething in the fhape of button-holes; thefe are fituated in a parallel direction to one another, and their length nearly in a perpendicular direction to that of the body of the animal.

Thefe apertures are fo many ftigmata or air-holes, openings deftined to admit the air neceffary to the life of the animal. The creature has fix of thefe ftigmata, three in each fide of its body.

The great tranfparence of the body of this infect, gives us an opportunity alfo to diftinguifh that it has on each fide a large white veffel running the whole length of the body. It is eafy to follow the courfe of thefe veffels through their whole length, but they are moft diftinct of all toward its hinder part, and they are always feen to terminate each in the brown fpot before defcribed; this leaves us no room to doubt but that they are the two principal tracheæ.

Thefe pofterior tracheæ have been well known to the later naturalifts; but there are two others befides thefe which they feem not to have diftinguifhed. Thefe are fituated in the anterior part of the animal, and are eafily difcovered by following the courfe of the tracheæ on each fide; for though thefe all the way diminifh in their diameters as they approach the head of the animal, yet it may be eafily enough feen where they terminate, which is (taking the head for one ring) in the junction of the fecond and third ring. In this place the naked eye eafily difcovers a fmall fpot at the extremity of each, which viewed with a good microfcope appears to be a plain ftigma, of the figure of a funnel with half of it cut off, and very elegantly indented, and as it were fringed at the edges.

Thefe ftigmata in the anterior part of the body, are as conftant in this creature as the pofterior ones, but it feems to have none of thofe which the caterpillar clafs are furnifhed with along their fides; though it feems from the ftructure of the fly it afterwards transforms itfelf into, that it ought to have them, fince that has ftigmata in their places.

The ramifications of the two great tracheæ are very beautifully feen in this creature, efpecially on his belly; and it is remarkable that no veffel analogous to the great artery in the caterpillar clafs can be difcovered in thefe; though, if there were any fuch, their great tranfparence muft needs make them very eafily diftinguifhable; nor could its dilatations and contractions, if fo confiderable as in that clafs of animals, be lefs fo. Malpighi imagined that artery, in the caterpillar clafs, a feries of hearts; in its place, however, there may be feen in thefe animals a true heart. It is eafy to obferve in thefe creatures, about the fourth ring of the body, a fmall flefhy part, which has alternate contractions and dilatations, and is not only difcoverable in the body by means of the creature's tranfparence; but, on making a proper fection of them in the fecond, third, and fourth rings, will be thrown out of the body of the creature, and will afterwards continue its beats for fome minutes. Reaumur's Hift. of Infects, vol. iv. p. 166, feq. See LARVA, PUPA, &c. under the article ENTOMOLOGY.

MAGHERA, in *Geography*, a poft-town of the county of Londonderry, Ireland; 96 miles N. from Dublin.

MAGHERAFELT a poft-town of the county of Londonderry, Ireland, near Lough Neagh; 88 miles N. from Dublin.

MAGHEREE, a clufter of iflands on the coaft of the county of Kerry, not far from Tralee bay.

MAGI, or MAGIANS, a title which the ancient Perfians gave to their wife men or philofophers.

The learned are in great perplexity about the original of the word *Magus*, μαγος. Plato, Xenophon, Herodotus, Strabo, &c. derived it from the Perfian language, in which it it ſignified a *prieſt*, or perſon appointed to officiate in holy things; as *Druid*, among the Gauls; *Gymnoſophiſt*, among the Indians; and *Levite*, among the Hebrews. Others derive it from the Greek μεγας, *great;* which they ſay, being borrowed of the Greeks by the Perſians, was returned in the form of μαγος; but Voſſius, with more probability, brings it from the Hebrew חגה, *haga, to meditate;* whence מחגים, *maaghim*, in Latin *meditabundi*, q. d. people addicted to meditation. See the ſequel of this article.

Magi, among the Perſians, anſwers to σοφοι, or φιλοσοφοι, among the Greeks; *ſapientes*, among the Latins; *Druids*, among the Gauls; *Gymnoſophiſts*, among the Indians; and *prophets, prieſts*, among the Egyptians.

The ancient Magi, according to Ariſtotle and Laertius, were the ſole authors and conſervators of the Perſian philoſophy; and the philoſophy principally cultivated among them, was theology and politics; they being always eſteemed as the interpreters of all law, both divine and human; on which account they were wonderfully revered by the people. Hence, Cicero obſerves, that none were admitted to the crown of Perſia, but ſuch as were well inſtructed in the diſcipline of the Magi; who taught τα βασιλικα, and ſhewed princes how to govern.

Plato, Apuleius, Laertius, and others, agree, that the philoſophy of the Magi related principally to the worſhip of the gods; they were the perſons who were to offer prayers, ſupplications, and ſacrifices, as if the gods would be heard by them alone.

They teach their doctrine concerning the nature and origin of the gods, ſays Laertius, whom they think to be fire, earth, and water; they reject the uſe of pictures and images, and reprobate the opinion, that the gods are male and female; they diſcourſe to the people concerning juſtice; they think it impious to conſume dead bodies with fire: they allow of marriage between mother and ſon; they practiſe divination and prophecy, pretending that the gods appear to them; they forbid the uſe of ornaments in dreſs; they clothe themſelves in a white robe; they make uſe of the ground as their bed, of herbs, cheeſe, and bread for food, and of a reed for their ſtaff. Strabo alſo relates, that there were in Cappadocia a great number of Magi, who were called "Pyrethi," or worſhippers of fire, and many temples of the Perſian gods, in the midſt of which were altars attended by prieſts, who daily renewed the ſacred fire, accompanying the ceremony with muſic.

But according to Lucian, Suidas, &c. this theology or worſhip of the gods, as it is called, about which the Magi were employed, was little more than the diabolical art of divination; ſo that μαγεια, ſtrictly taken, was the art of divination. Theſe people were held in ſuch veneration among the Perſians, that Darius, the ſon of Hyſtaſpes, among other things, had it engraven on his monument, that he was the maſter of the Magi.

Philo Judæus deſcribes the Magi to be diligent inquirers into nature, out of the love they bear to truth; and who, ſetting themſelves apart from other things, contemplate the divine virtues the more clearly, and initiate others in the ſame myſteries.

The Magi, or Magians, formed one of the two grand ſects into which the idolatry of the world was divided between 5 and 600 years before Chriſt. Theſe abominated all thoſe images which were worſhipped by the other ſect, denominated Sabians, and paid their worſhip to the Deity under the emblem of fire. Their chief doctrine was, that there were two principles, one of which was the cauſe of all good, and the other the cauſe of all evil. The former was repreſented by light, and the latter by darkneſs, as their trueſt ſymbols; and of the compoſition of theſe two, they ſuppoſed, that all things in the world were made. The good god they called Yazdan, denominated by the Greeks Oromaſdes; and the evil god Ahraman, whom the Greeks called Arimanius. (See ARIMANIUS.) Concerning theſe two gods, there was this difference of opinion among them; that whereas ſome held both of them to have been from all eternity, there were others who contended, that the good god only was eternal, and that the other was created. But they both agreed in this, that there will be a continual oppoſition between theſe two, till the end of the world; when the former ſhall overcome the latter; and that from thenceforth each of them ſhall have his world to himſelf; that is, the good god ſhall have his world with all good men with him; and the evil god his world, with all evil men with him. The good god they always worſhipped before fire, as being the cauſe of light, and eſpecially before the ſun, as being, in their opinion, the moſt perfect fire, and cauſing the moſt perfect light; and for this reaſon they had in all their temples fire continually burning on altars, erected in them for that purpoſe. Before theſe ſacred fires they performed all their public acts of devotion, as they likewiſe practiſed their private devotions before their private fires in their own houſes. Such were the tenets of this ſect, when Smerdis, who was the principal leader of it, having uſurped the crown after the death of Cambyſes, was ſlain by ſeven princes of Perſia; and many of the Magians, who adhered to him, ſhared likewiſe the ſame fate. In conſequence of this event, thoſe who adopted the ſentiments of this ſect, were called, by way of deriſion, Magians, from *mige-guſh*, which ſignified, in the language of the country then in uſe, *one that had his ears cropped*. The whole ſect of the Magians would ſoon have ſunk into utter extinction, if it had not, in a few years after this period, been revived and reformed by Zoroaſter. This celebrated philoſopher, called by the Perſians Zerduſht, or Zaratuſh, began about the thirty-ſixth year of the reign of Darius to reſtore and reform the Magian ſyſtem of religion. He was not only excellently ſkilled in all the learning of the Eaſt that prevailed in his time; but likewiſe thoroughly verſed in the Jewiſh religion, and in all the ſacred writings of the Old Teſtament that were then extant, whence ſome have inferred, that he was a native Jew both by birth and profeſſion; and that he had been ſervant to one of the prophets, probably Ezekiel or Daniel. (See ZOROASTER.) He made his firſt appearance in Media, in the city of Xiz, now called Aderbijan, as ſome ſay; or according to others, in Ecbatana, now called Tauris. Inſtead of admitting the exiſtence of two firſt cauſes, with the Magians, he introduced a principle ſuperior to them both, one ſupreme God, who created both theſe, and out of theſe two produced, according to his ſovereign pleaſure, every thing elſe. See Iſaiah, v. 5, 6, 7.

In order to avoid making God the author of all evil, he taught that God originally created only light or good, and that darkneſs or evil followed it by conſequence, as the ſhadow doth the perſon. According to his doctrine, there was one ſupreme being independently, and ſelf-exiſting from all eternity: under him there were two angels, one the angel of light, the author and director of all good; and the other the angel of darkneſs, who is the author and director of all evil: theſe two, out of the mixture of light and darkneſs, made all things that are; and they are in a ſtate of perpetual conflict; ſo that where the angel of light prevails, there the moſt is good; and where the angel of darkneſs darknefs prevails, there the moft is evil: this ftruggle fhall continue to the end of the world; and then there fhall be a general refurrection, and a day of judgment; after which, the angel of darknefs and his difciples fhall go into a world of their own, where they fhall fuffer in everlafting darknefs the punifhment of their evil deeds; and the angel of light and his difciples fhall go into a world of their own, where they fhall receive in everlafting light, the reward due unto their good deeds: and henceforward they fhall for ever remain feparate. See EMANATION.

Plutarch, fpeaking of the improvement of the religious fyftem of the Magi by Zoroafter, fays, (Ifis et Ofiris, tom. ii. p. 155) "fome maintain, that, neither is the world governed by blind chance without intelligence, nor is there one mind alone at the head of the univerfe; but, fince good and evil are blended, and nature produces nothing unmixed, we are to conceive, not that there is one ftore-keeper, who, after the manner of an hoft, difpenfes adulterated liquors to his guefts; but that there are in nature two oppofite powers, counteracting each other's operations, the one accomplifhing good defigns, the other evil. To the better power Zoroafter gave the name of Oromaldes, to the worfe that of Arimanius; and affirmed, that, of fenfible objects, the former moft refembled light, the latter darknefs. He alfo taught, that Mithras was a divinity, who acted as moderator between them, whence he was called by the Perfians the Mediator." After relating feveral fabulous tales concerning the contefts between the good and evil dæmons, Plutarch, ftill reciting the doctrines of Zoroafter, proceeds, "The fated time is approaching, in which Arimanius himfelf fhall be utterly deftroyed; in which the furface of the earth fhall become a perfect plain, and all men fhall fpeak one language, and live happily together in one fociety." He adds, on the authority of Theopompus, "It is the opinion of the Magi, that each of thefe gods fhall fubdue and be fubdued by turns for 6000 years, but that, at laft, the evil principle fhall perifh, and men fhall live in happinefs; neither needing food, nor yielding a fhadow; the God who directs thefe things taking his repofe for a time, which, though it may feem long to man, is but fhort." Diogenes Laertius, after Hecateus, gives it as the doctrine of Zoroafter, that the gods (meaning, doubtlefs, thofe of whom he laft fpeaks, Oromafdes and Arimanius) were derived beings.

Thofe who remain of this fect in Perfia and India, in the prefent day, retain the fame doctrines. Zoroafter alfo caufed fire temples to be erected wherever he came: for having feigned that he was taken up into heaven, and there inftructed in the doctrines he taught by God himfelf, out of the midft of a great and moft bright flame of fire, he taught his followers, that fire was the trueft fhechinah of the divine prefence; that the fun being the moft perfect fire, God had there the throne of his glory, and the refidence of his divine prefence in a peculiar manner; and next to this in our elementary fire: and, therefore, he ordered them to direct all their worfhip to God, firft towards the fun, which they called Mithra, and next towards their facred fires: and when they came before thefe fires to worfhip, they always approached them on the weft fide, that having their faces towards them, and alfo towards the rifing fun at the fame time, they might direct their worfhip towards both. And in this pofture they always performed every act of their worfhip. Zoroafter alfo pretended, that he brought fome of the heavenly fire with him on his return, and placed it on the altar of the firft fire-temple, which he erected at Xiz, in Media, whence it was propagated to all the reft. And on this account, their priefts carefully watch it, and never fuffer it to be extinguifhed.

Zoroafter, having affumed the character of a divine prophet and reformer of religion, retired into a cave, devoting himfelf to prayer and meditation, where he compofed the book called the *Zend*, in which his pretended revelations were contained. From Media he removed into Bactria; and he went alfo into India among the Brachmans, and having acquired all their knowledge in mathematics, philofophy, and aftronomy, returned and communicated the knowledge he had acquired to his Magians; and thus they became famous for their fkill in thefe fciences; fo that a learned man and a Magian were equivalent terms. The vulgar conceived of them as perfons actuated and infpired by fupernatural powers; and hence thofe, who pretended to wicked and diabolical acts, affumed the name of Magians; and the term magician acquired its evil meaning. However, this diftinguifhed knowledge was confined to thofe, who were by way of eminence, the Magi, or the priefts; who, like thofe of the Jews, being of the fame tribe, appropriated their learning to their own families. Thefe priefts were diftributed into three orders, *viz.* the inferior priefts, who conducted the ordinary ceremonies of religion; the fuperintendants, who governed them, and prefided over the facred fire; and the archimagus, or high-prieft, who poffeffed fupreme authority over the whole order; and their churches or temples were alfo of three forts, parochial or oratories, in which the people performed their devotions, and where the facred fire was kept only in lamps; fire-temples, in which fire was kept continually burning on a facred altar, where the higher order of the Magi directed the public devotions, and the people affembled to perform magical incantations, hear interpretations of dreams, and practife other fuperftitions; and laftly, the fire-temple in which the archimagus refided, which was vifited by the people at certain feafons with peculiar folemnity, and to which it was deemed an indifpenfible duty for every one to repair, at leaft once in his life. Zoroafter at length carried his religious fyftem to the royal court of Sufa, and made Darius a profelyte, together with moft of the great men of the kingdom. Darius was fo attached to the Magian fyftem, that he became an archimagus, and ordered, that, among other titles, it fhould be engraven on his monument, that he was *mafter of the Magians*. Hence the kings of Perfia were confidered as pertaining to the facerdotal tribe, and were always initiated in the facred order of the Magians, before they took on them the crown, or were inaugurated into the kingdom.

No images or ftatues were permitted in the Perfian worfhip. Hence, when Xerxes found idols in the Grecian temples, he, by the advice of the Magi, fet them on fire, faying, that the gods, to whom all things are open, are not to be confined within the walls of a temple.

Zoroafter, after this fuccefs, returned to Balch, in Bactria, where, according to his own inftitution, he was obliged to refide, as archimagus or head of the fect, and there he reigned in fpirituals, with the fame authority, over the whole empire, as the king did in temporals; and from hence probably arofe the miftake of making him king of Bactria. The principal temple erected at Balch by Zoroafter remained till the 7th century, when his followers being driven by the Mahometans into Carmenia, another building of the fame kind was raifed, to which thofe who adhered to the ancient Perfian religion reforted. Zoroafter, at length, fell a facrifice to his zeal; for having concerted an enterprize againft Argafp, king of of the oriental Scythians, who was a zealous Sabian, to draw him over to his religion; the Scythian prince invaded Bactria with an army, and slew Zoroaster, with all the priests of this patriarchal church, to the number of eighty persons, and demolished all the fire-temples in that province. This is said to have happened in the 35th year of Darius. Pythagoras derived a great part of his knowledge from Zoroaster, and his disciples the Magians. Prideaux's Conn. vol. i.

Their descendants, the modern Magi, or fire-worshippers, are divided into three classes; of which the first and most learned neither eat nor kill animals; but adhere to the old institution of abstaining from all living creatures. The Magi of the second class refrain only from tame animals; nor do the last kill all indifferently, it being the firm and distinguishing settled notion of them all, την μετεμψυχωσιν ειναι, *that there is a transmigration of souls*. See METEMPSYCHOSIS and GABRES.

The ancient Arabians, like the neighbouring Chaldæans and Persians, seem to have had their wise men, by whom their knowledge, such as they had, was taught, and their religious ceremonies and superstitious arts were practised. Pliny (Hist. Nat. l. xxx. c. 1.) mentions the Arabian Magi, and speaks of Hippocus, an Arabian, as belonging to this order. One of the most ancient sects of the Magi, as the Mosaic history informs us (Exod. iv.), was among the Egyptians. These Magi made use of small images, of various forms, with which they pretended to perform many wonders, and particularly to cure diseases.

MAGIC, MAGIA, Μαγεια, in its ancient sense, the science, or discipline and doctrine, of the Magi, or wise men of Persia.

The magic which Zoroaster invented was probably nothing more than the performance of certain religious ceremonies, by means of which, good dæmons were supposed to be prevailed upon to communicate supernatural properties and powers to herbs, stones, and other natural bodies, or to afford assistance in other miraculous ways to those who invoked them. In war, it was supposed, that, by the help of magic, the forces of an enemy might be routed, or an army struck with a general panic, as is said to have happened to Ninus, in his war with the Bactrians. In this art the kings of Chaldæa and Persia were instructed, as one of the most useful instruments of government, among a people, whose ignorance and credulity rendered them proper subjects of imposture. For it is justly observed by Plutarch (in Sertorio), that "barbarous nations are naturally prone to superstition; and a weak, illiterate, and fickle multitude, when they are once brought under its dominion, will be more obedient to their priests than to their civil or military leaders." We have given some account of it under the article CHALDÆANS.

The Chaldæans, as we are informed by Diodorus Siculus (lib. i.) learned the art of astrology and magic from the Egyptians, who were, from the earliest times, adepts in these fictitious sciences, and by the cultivation of these arts, their priests acquired an irresistible sway over an ignorant and superstitious populace. See the preceding article.

MAGIC, in a more modern sense, is a science which teaches to perform wonderful and surprising effects.

The word magic originally carried with it a very innocent, nay, a very laudable, meaning; being used purely to signify the study of wisdom, and the more sublime parts of knowledge; but in regard the ancient Magi engaged themselves in astrology, divination, sorcery, &c. the term magic, in time, became odious, and was only used to signify an unlawful and diabolical kind of science, depending, as it was pretended, on the assistance of the devil, and departed souls.

If any wonder how so vain and deceitful a science should gain so much credit and authority over men's minds, Pliny gives the reason of it. It is, says he, because it has possessed itself of three sciences of the most esteem among men, taking from each all that is great and marvellous in it. Nobody doubts but it had its origin in medicine, and that it insinuated itself into the minds of the people, under pretence of affording extraordinary remedies. To these fine promises is added every thing in religion that is pompous and splendid, and that appears calculated to blind and captivate mankind. And, lastly, it mingled judicial astrology with the rest, persuading people, curious of futurity, that it saw every thing to come in the heavens. Agrippa divides magic into three kinds, *natural*, *celestial*, and *ceremonial* or *superstitious*.

MAGIC, *Natural*, is no more than the application of natural active causes to passive things or subjects; by means of which many surprising, but yet natural, effects are produced.

MAGIC, *Celestial*, borders nearly on judiciary astrology; it attributes to spirits a kind of rule, or dominion, over the planets: and to the planets a dominion over men; and on those principles, builds a ridiculous kind of system.

MAGIC, *Superstitious*, or *Geotic*, consists in the invocation of devils, or dæmons: its effects are usually evil and wicked, though very strange, and seemingly surpassing the powers of nature: they are supposed to be produced by virtue of some compact, either tacit or express, with evil spirits; but the truth is, these supposed compacts have not the power that is usually imagined; nor do they produce half those effects ordinarily ascribed to them.

MAGIC *Lantern*, an optic machine contrived by Kircher, (see his Ars Magna Lucis et Umbræ, p. 768, 769.), by means of which little coloured images are represented on an opposite wall of a dark room, magnified to any bigness at pleasure, and exhibited in their natural and vivid colours.

MAGIC *Lantern*, *Construction of the*. Suppose A B C D (*Plate* X. *Optics*, *fig.* 1.) a common tin lantern, to which is added a tube to draw out, F G. In H is fixed a metallic concave speculum, of a foot diameter at most, or four inches at least: or, in lieu thereof, near the extremity of the tube, there must be placed a convex lens, consisting of a segment of a small sphere, its diameter not exceeding a few inches. The use of this lens is to throw a strong light upon the image; and sometimes a concave speculum is used with the lens, in order to make the image still more vivid. In the focus of the concave speculum, or lens, is placed a lamp L; within the tube where it is soldered to the side of the lantern, is placed a small lens, convex on both sides, being a portion of a small sphere, having its focus about the distance of three inches. The extreme part of the tube, F M, is square, and has an aperture quite through, so as to receive an oblong frame, N O, passed into it; in this frame are round holes, an inch or two in diameter. According to the bigness of these holes are drawn circles, on a plain thin glass; and in these circles are painted any figures or images, at pleasure, with transparent water colours. These images, fitted into the frame, and placed invertedly, at a little distance from the focus of the lens I, will be projected on an opposite white wall of a dark room, prodigiously magnified in all their colours, and in an erect situation. By having the instrument so contrived, as that the lens, I, may move in a slide, the focus may be made, and consequently the image appear distinct, at almost any distance.

Or thus:—Every thing being managed as in the former, into the sliding tube, F G, insert another convex lens K, the segment of a sphere somewhat larger than I. Now, if the picture be brought nearer to I than the distance of the focus, diverging rays will be propagated, as if they proceeded from the object; wherefore, if the lens, K, be so placed,

placed, as that the object is very near its focus, the image will be exhibited on the wall, exceedingly magnified.

MAGIC *Lantern, Theory of the.* The lamp being placed in the focus of the concave ſpeculum, or any convex glaſs, the rays will be propagated parallel to each other, and the image will be ſtrongly illumined, and will therefore emit a great number of rays upon the lens I. But, being ſuppoſed to be placed near the lens I, the inverted image of the picture inverted muſt be formed on the oppoſite wall, exceedingly magnified, after its refraction through the lens; and it will be ſtill the more magnified, as the lens is a ſegment of a leſs ſphere, and as the picture is placed nearer the focus of the lens; in a dark place, therefore, the picture will be repreſented prodigiouſly large and extremely vivid.

To heighten the light, ſpecula are preferred to lenſes; the focus of a ſpeculum being nearer than that of a lens. De Chales orders the diameter of the lens, I, to be two, four, or five digits, and in a ſubduple proportion to the other K; *i. e.* if I be five digits, K muſt be ten; and the diameter of the ſpeculum, according to the ſame, is to be two digits. Zahnius chooſes to have the diameter of I $\frac{9}{10}$ of a foot; and that of K one foot and a half, &c.

Little animals being included in the magic lantern, in the manner obſerved in ſpeaking of the microſcope, or any little tranſparent objects faſtened to a ſlice of talc or glaſs, and ſubſtituted inſtead of images, the magic lantern will become a microſcope.

A view of the inſtrument itſelf may be ſeen in *fig.* 2, in which *b h c* is the lens that throws the light of the candle or lamp, *a*, on the object *d e*, and *k l* is the lens that magnifies the image, *f g*, on the white wall, F H, in a dark room. It is plain, that if the tube, *b n k l m c*, be contracted, and the glaſs, *k l*, be brought nearer the object *d e*, the image, *f g*, will be enlarged; and hence, this lantern has been called the *lanterna megalographica*. On the contrary, if the tube be protracted, the image of the object will be diminiſhed. In ſome magic lanterns, inſtead of the ſingle lens *k l*, two lenſes are uſed of leſs curvature, and ſet at a little diſtance from each other; and theſe produce a ſomewhat better effect than a ſingle lens. Between them is placed a perforated diaphragm.

M. Euler propoſed a ſcheme to introduce viſion by reflected light into the magic lantern, as well as the ſolar microſcope, by which many inconveniences to which thoſe inſtruments are ſubject, might be avoided. For this purpoſe, he ſays, that nothing is neceſſary but a large concave mirror, perforated as for a teleſcope, and that the light be ſo ſituated, that none of it may paſs directly through the perforation, ſo as to fall on the images of the objects upon the ſcreen. He propoſes to have four different machines for objects of different ſizes; the firſt for thoſe of ſix feet long, the ſecond for thoſe of one foot, the third for thoſe of two inches, and the fourth for thoſe of two lines. An idea of this contrivance is given in *fig.* 3, in which O D repreſents the concave mirror, E the object, *l, l*, the lights, and A the lens, through which the rays are tranſmitted to the ſcreen. Nov. Com. Petrop. vol. iii. p. 363.

MAGIC *Square*, a ſquare figure, formed of a ſeries of numbers, in mathematical proportion, ſo diſpoſed in parallel and equal ranks, as that the ſums of each row, taken either perpendicularly, horizontally, or diagonally, are equal.

The ſeveral numbers which compoſe any ſquare number (for inſtance, 1, 2, 3, 4, 5, &c. to 25 incluſive, which compoſe the ſquare number 25), being diſpoſed after each other, in a ſquare figure of 25 cells, each in its cell; if then you change the order of theſe numbers, and diſpoſe them in the cells in ſuch a manner, as that the five numbers which fill an horizontal rank of cells, being added together, ſhall make the ſame ſum with the five numbers in any other rank of cells, whether horizontal or vertical, and even the ſame number with the five in each of the two diagonal ranks: this diſpoſition of numbers is called a *magic* ſquare; in oppoſition to the former diſpoſition, which is called a *natural* ſquare. See the figure following.

Natural Square.

One would imagine, that theſe magic ſquares had that name given them, becauſe this property of all their ranks, which, taken any way, make always the ſame ſum, appeared extremely ſurpriſing, eſpecially in certain ignorant ages, when mathematics paſſed for magic; but there is a great deal of reaſon to ſuſpect, that theſe ſquares merited their name ſtill farther, by the ſuperſtitious operations they were employed in, as the conſtruction of taliſmans, &c. for, according to the childiſh philoſophy of thoſe days, which attributed virtues to numbers, what virtues might not be expected from numbers ſo wonderful?

However, what was at firſt the vain practice of makers of taliſmans and conjurers, has ſince become the ſubject of ſerious reſearch among mathematicians; not that they imagine it will lead them to any thing of ſolid uſe or advantage. Magic ſquares favour too much of their original to be of much uſe; but only as it is a kind of play, where the difficulty makes the merit, and it may chance to produce ſome new views of numbers, which mathematicians will not loſe the occaſion of.

Eman. Moſchopulus, a Greek author of no great antiquity, is the firſt that appears to have ſpoken of magic ſquares: and, by the age in which he lived, there is reaſon to imagine he did not look on them merely as a mathematician. However, he has left us ſome rules for their conſtruction. In the treatiſe of Corn. Agrippa, ſo much accuſed of magic, we find the ſquares of ſeven numbers, *viz.* from three to nine incluſive, diſpoſed magically; and it muſt not be ſuppoſed that thoſe ſeven numbers were preferred to all the other without ſome very good reaſon: in effect, it is becauſe their ſquares, according to the ſyſtem of Agrippa and his followers, are planetary. The ſquare of 3, for inſtance, belongs to Saturn; that of 4, to Jupiter; that of 5, to Mars; that of 6, to the Sun; that of 7, to Venus; that of 8, to Mercury; and that of 9, to the Moon. M. Bachet applied himſelf to the ſtudy of magic ſquares, on the hint he had taken from the planetary ſquares of Agrippa, as being unacquainted with the work of Moſchopulus, which is only in manuſcript in the French king's library; and, without the aſſiſtance of any author, he found out a new method for thoſe ſquares whoſe root is uneven; for inſtance, 25, 49, &c. but he could not make any thing of thoſe whoſe root is even.

After him came M. Frenicle, who took the ſame ſubject in hand. A certain great algebraiſt was of opinion, that whereas the ſixteen numbers which compoſe the ſquare might

 be

be disposed 20922789888000 different ways in a natural square (as from the rules of combination it is certain they may), they could not be disposed in a magic square above sixteen different ways; but M. Frenicle shewed, that they might be thus disposed 878 different ways: whence it appears how much his method exceeds the former, which only yielded the 55th part of magic squares of that of M. Frenicle.

To this inquiry he thought fit to add a difficulty, that had not yet been considered; the magic square of 7, for instance, being constructed, and its 49 cells filled, if the two horizontal ranks of cells, and, at the same time, the two vertical ones, the most remote from the middle, be retrenched, that is, if the whole border or circumference of the square be taken away, there will remain a square, whose root will be 5, and which will only consist of 25 cells. Now, it is not at all surprising, that the square should be no longer magical, because the ranks of the large ones were not intended to make the same sum, excepting when taken entire with all the seven numbers that fill their seven cells; so that being mutilated each of two cells, and having lost two of their numbers, it may be well expected, that their remainders will not any longer make the same sum. But M. Frenicle would not be satisfied unless when the circumference or border of the magic square was taken away, and even any circumference at pleasure, or, in fine, several circumferences at once, the remaining squares were still magical: which last condition, no doubt, made these squares vastly more magical than ever.

Again, he inverted that condition, and required that any circumference taken at pleasure, or even several circumferences, should be inseparable from the square; that is, that it should cease to be magical when they were removed, and yet continue magical after the removal of any of the rest. M. Frenicle, however, gives no general demonstration of his methods, and frequently seems to have no other guide but chance. It is true, his book was not published by himself, nor did it appear till after his death, *viz.* in 1693.

In 1703, M. Poignard, canon of Brussels, published a treatise of sublime magic squares. Before him there had been no magic squares made but for serieses of natural numbers that formed a square; but M. Poignard made two very considerable improvements. 1°. Instead of taking all the numbers that fill a square, for instance, the thirty-six successive numbers, which would fill all the cells of a natural square, whose side is six, he only takes as many successive numbers as there are units in the side of the square, which, in this case, are six; and these six numbers alone he disposes in such manner in the thirty-six cells, that none of them are repeated twice in the same rank, whether it be horizontal, vertical, or diagonal; whence it follows, that all the ranks, taken all the ways possible, must always make the same sum, which M. Poignard calls repeated progression. 2°. Instead of being confined to take these numbers according to the series and succession of the natural numbers, that is, in an arithmetical progression, he takes them likewise in a geometrical progression, and even in an harmonical progression. But with these two last progressions the magic must necessarily be different to what it was: in the squares filled with numbers in geometrical progression, it consists in this, that the products of all the ranks are equal; and, in the harmonical progression, the numbers of all the ranks continually follow that progression: he makes squares of each of these three progressions repeated.

This book of M. Poignard gave occasion to Mr. de la Hire to turn his thoughts the same way, which he did with such success, that he seems to have well-nigh completed the theory of magic squares. He first considers uneven squares; all his predecessors on the subject having found the construction of even ones by much the most difficult; for which reason M. de la Hire reserves those for the last. This excess of difficulty may arise partly from hence, that the numbers are taken in arithmetical progression. Now in that progression, if the number of terms be uneven, that in the middle has some properties which may be of service; for instance, being multiplied by the number of terms in the progression, the product is equal to the sum of all the terms.

M. de la Hire proposes a general method for uneven squares, which has some similitude with the theory of compound motions, so useful and fertile in mechanics. As that consists in decompounding motions, and resolving them into others more simple; so does M. de la Hire's method consist in resolving the square that is to be constructed into two simple and primitive squares. It must be owned, however, it is not quite so easy to conceive those two simple and primitive squares in the compound or perfect square, as in an oblique motion to imagine a parallel and perpendicular one.

Suppose a square of cells, whose root is uneven, for instance 7; and that its forty-nine cells are to be filled magically with numbers, for instance, the first 7. M. de la Hire, on the one side, takes the first seven numbers, beginning with unity, and ending with the root 7; and on the other 7, and all its multiples to 49, exclusively; and as these only make six numbers, he adds 0, which makes this an arithmetical progression of seven terms, as well as the other; 0, 7, 14, 21, 28, 35, 42. This done, with the first progression repeated, he fills the square of the root 7 magically: in order to this, he writes in the first seven cells of the first horizontal rank, the seven numbers proposed, in what order he pleases, for that is absolutely indifferent; and it is proper to observe here, that those seven numbers may be ranged in 5040 different manners in the same rank. The order in which they are placed in the first horizontal rank, be it what it will, is that which determines their order in all the rest. For the second horizontal rank, he places in its first cell, either the third, the fourth, the fifth, or the sixth number, from the first number of the first rank; and after that writes the six others in order as they follow. For the third horizontal rank, he observes the same method with regard to the second, that he observed in the second with regard to the first, and so of the rest. For instance, suppose the first horizontal rank filled with the seven numbers in their natural order, 1, 2, 3, 4, 5, 6, 7; the second horizontal rank may either commence with 3, with 4, with 5, or with 6; but in this instance it commences with 3; the third rank therefore must commence with 5, the fourth with 7, the fifth with 2, the sixth with 4, and the seventh with 6. The commencement of the ranks which follow the first being thus determined, the other numbers, as we have already observed, must be written down in the order wherein they stand in the first, going on to 5, 6, and 7, and returning to 1, 2, &c. till every

1	2	3	4	5	6	7
3	4	5	6	7	1	2
5	6	7	1	2	3	4
7	1	2	3	4	5	6
2	3	4	5	6	7	2
4	5	6	7	1	2	3
6	7	1	2	3	4	5

every number in the firſt rank be found in every rank underneath, according to the order arbitrarily pitched upon at firſt. By this means it is evident, that no number whatever can be repeated twice in the ſame rank; and by conſequence, that the ſeven numbers 1, 2, 3, 4, 5, 6, 7, being in each rank, muſt of neceſſity make the ſame ſum.

It appears, from this example, that the arrangement of the numbers in the firſt rank being choſen at pleaſure, the other ranks may be continued in four different manners: and ſince the firſt rank may have 5040 different arrangements, there are no leſs than 20,160 different manners of conſtructing the magic ſquare of ſeven numbers repeated.

1	2	3	4	5	6	7
2	3	4	5	6	7	1
3	4	5	6	7	1	2
4	5	6	7	1	2	3

7	1	2	3	4	5	6
6	7	1	2	3	4	5
5	6	7	1	2	3	4
4	5	6	7	1	2	3
3	4	5	6	7	1	2
2	3	4	5	6	7	1

The order of the numbers in the firſt rank being determined; if in beginning with the ſecond rank, the ſecond number 2, or the laſt number 7, ſhould be pitched upon, in one of thoſe caſes and repeated; and, in the other caſe, the other diagonal would be falſe, unleſs the number repeated ſeven times ſhould happen to be 4; for four times ſeven is equal to the ſum of 1, 2, 3, 4, 5, 6, 7: and, in general, in every ſquare conſiſting of an unequal number of terms, in arithmetical progreſſion, one of the diagonals would be falſe according to thoſe two conſtructions, unleſs the term always repeated in that diagonal were the middle term of the progreſſion. It is not, however, at all neceſſary to take the terms in an arithmetical progreſſion; for, according to this method, one may conſtruct a magic ſquare of any numbers at pleaſure, whether they be according to any certain progreſſion, or not. If they be in an arithmetical progreſſion, it will be proper, out of the general method, to except thoſe two conſtructions, which produce a continual repetition of the ſame term, in one of the two diagonals; and only to take in the caſe, wherein that repetition would prevent the diagonal from being juſt: which caſe being abſolutely diſregarded, when we computed, that the ſquare of 7 might have 20,160 different conſtructions; it is evident, that by taking that caſe in, it muſt have vaſtly more.

To begin the ſecond rank with any other number beſides the ſecond and the laſt, muſt not, however, be looked on as an univerſal rule: it holds good for the ſquare of 7; but if the ſquare of 9, for inſtance, were to be conſtructed, and the fourth figure of the firſt horizontal rank were pitched on for the firſt of the ſecond, the conſequence would be, that the fifth and eighth horizontal ranks would likewiſe commence with the ſame number, which would therefore be repeated three times in the ſame vertical rank, and occaſion other repetitions in all the reſt. The general rule, therefore, muſt be conceived thus: let the number in the firſt rank pitched on, for the commencement of the ſecond, have ſuch an exponent of its quota, that is, let the order of its place be ſuch, as that if an unit be taken from it, the remainder will not be any juſt quota part of the root of the ſquare; that is, cannot divide it equally. If, for example, in the ſquare of 7, the third number of the firſt horizontal rank be pitched on for the firſt of the ſecond, ſuch conſtruction will be juſt; becauſe the exponent of the place of that number, *viz.* 3, ſubtracting 1, that is, 2 cannot divide 7. Thus alſo might the fourth number of the ſame firſt rank be choſen, becauſe 4 — 1, *viz.* 3, cannot divide 7; and, for the ſame reaſon, the fifth or ſixth number might be taken: but in the ſquare of 9, the fourth number of the firſt rank muſt not be taken, becauſe 4 — 1, *viz.* 3, does divide 9. The reaſon of this rule will appear very evidently, by conſidering in what manner the returns of the ſame numbers do or do not happen, taking them always in the ſame manner in any given ſeries. And hence it follows, that the fewer diviſions the root of any ſquare to be conſtructed has, the more different manners of conſtructing it there are; and that the prime numbers, *i. e.* thoſe which have no diviſions, as 5, 7, 11, 13, &c. are thoſe whoſe ſquares will admit of the moſt variations in proportion to their quantities.

The ſquares conſtructed, according to this method, have ſome particular properties not required in the problem; for the numbers that compoſe any rank parallel to one of the two diagonals, are ranged in the ſame order with the numbers that compoſe the diagonal to which they are parallel. And as any rank parallel to a diagonal muſt neceſſarily be ſhorter, and have fewer cells, than the diagonal itſelf, by adding to it the correſpondent parallel, which has the number of cells by which the other falls ſhort of the diagonal, the numbers of thoſe two parallels, placed, as it were, end to end, ſtill follow the ſame order with thoſe of the diagonal: beſides, that their ſums are likewiſe equal; ſo that they are magical on another account. Inſtead of the ſquares, which we have hitherto formed by horizontal ranks, one might alſo form them by vertical ones; the caſe is the ſame in both.

First Primitive.

1	2	3	4	5	6	7
3	4	5	6	7	1	2
5	6	7	1	2	3	4
7	1	2	3	4	5	6
2	3	4	5	6	7	1
4	5	6	7	1	2	3
6	7	1	2	3	4	5

All we have hitherto ſaid regards only the firſt primitive ſquare, whoſe numbers, in the propoſed example, were 1, 2, 3, 4, 5, 6, 7; here ſtill remains the ſecond primitive, whoſe numbers are

Second Primitive.

0	7	14	21	28	35	42
21	28	35	42	0	7	14
42	0	7	14	21	28	35
14	21	28	35	42	0	7
35	42	0	7	14	21	28
7	14	21	28	35	42	0
28	35	42	0	7	14	21

are 0, 7, 14, 21, 28, 35, 42. M. de la Hire proceeds in the same manner here as in the former; and this may likewise be constructed in 20,160 different manners, as containing the same number of terms with the first. Its construction being made, and of consequence all its ranks making the same sum, it is evident, that if we bring the two into one, by adding together the numbers of the two corresponding cells of the two squares, that is, the two numbers of the first of each, the two numbers of the second, of the third, &c. and dispose them in the forty-nine corresponding cells of a third square; it will likewise be magical, in regard to its rank, formed by the addition of equal sums to equal sums, which must of necessity be equal among themselves. All that remains in doubt is, whether or not, by the addition of the corresponding cells of the two first squares, all the cells of the third will be filled in such manner, as that each not only contains one of the numbers of the progression from 1 to 49, but also that this number be different from any of the rest, which is the end and design of the whole operation.

As to this it must be observed, that if in the construction of the second primitive square, care has been taken in the commencement of the second horizontal rank, to observe an order with regard to the first, different from what was observed in the construction of the first square; for instance, if the second rank of the first square began with the third term of the first rank, and the second rank of the second square commence with the fourth of the first rank, as in the example it actually does; each number of the first square may be combined once, and only once, by addition with all the numbers of the second. And as the numbers of the first are here 1, 2, 3, 4, 5, 6, 7, and those of the second 0, 7, 14, 21, 28, 35, 42, by combining them in this manner, we have all the numbers in the progression from 1 to 49, without having any of them repeated; which is the *perfect* magic square proposed.

Perfect Square.

The necessity of constructing the two *primitive* squares in a different manner, does not at all hinder but that each of the 20,160 constructions of the one may be combined with all the 20,160 constructions of the other: of consequence, therefore, 20,160 multiplied by itself, which makes 406425600, is the number of different constructions that may be made of the perfect square, which here consists of the 49 numbers of the natural progression. But as we have already observed, that a primitive square of seven numbers repeated may have above 20,160 several constructions, the number 406425600 must come vastly short of expressing all the possible constructions of a perfect magic square of the 49 first numbers.

As to the *even* squares, he constructs them like the *uneven* ones, by two primitive squares; but the construction of *primitives* is different in general, and may be so a great number of ways: and those general differences admit of a great number of particular variations, which give as many different constructions of the same even square. It scarcely seems possible to determine exactly, either how many general differences there may be between the construction of the primitive squares of an even square, and an uneven one; nor how many particular variations each general difference may admit of; and, of consequence, we are still far from being able to determine the number of different constructions of all those that may be made by the primitive squares.

See the Memoirs of the Royal Academy of Sciences, for 1705 and 1710, where this subject is almost exhausted by M. de la Hire and M. Sauveur. See also Saunderson's Algebra, vol. i. p. 354, &c.

The ingenious Dr. Franklin seems to have carried this curious speculation farther than any of his predecessors in the same way. He has constructed not only a magic square of squares, but likewise a magic circle of squares, of which we shall give some account for the amusement of our readers. The magic square of squares is formed by dividing the great square, as *Plate* XI. *Analysis*, *fig.* 6. The great square is divided into 256 small squares, in which all the numbers from 1 to 256 are placed in 16 columns, which may be taken either horizontally or vertically. The properties are as follow:

1. The sum of the sixteen numbers in each column, vertical and horizontal, is 2056.

2. Every half column, vertical and horizontal, makes 1028, or half of 2056.

3. Half a diagonal ascending, added to half a diagonal descending, makes 2056; taking these half diagonals from the ends of any side of the square to the middle thereof; and so reckoning them either upward, or downward; or sidewise from left to right hand, or from right to left.

4. The same with all the parallels to the half diagonals, as many as can be drawn in the great square: for any two of them being directed upward and downward, from the place where they begin to that where they end, their sums will make 2056. The same downward and upward in like manner: or all the same if taken sideways to the middle, and back to the same side again. N. B. One set of these half diagonals and their parallels are drawn in the same square upward and downward. Another such set may be drawn from any of the other three sides.

5. The four corner numbers in the great square added to the four central numbers therein, make 1028; equal to the half sum of any vertical or horizontal column, which contains 16 numbers; and equal to half a diagonal or its parallel.

6. If a square hole (equal in breadth to four of the little squares) be cut in a paper, through which any of the sixteen little squares in the great square may be seen, and the paper be laid on the great square; the sum of all the sixteen numbers, seen through the hole, is equal to the sum of the sixteen numbers in any horizontal or vertical column, *viz.* to 2056.

The magic circle of circles (*fig.* 7.), is composed of a series of numbers, from 12 to 75 inclusive, divided into eight concentric circular spaces, and ranged in eight radii of numbers, with the number 12 in the centre; which number, like

like the centre, is common to all theſe circular ſpaces, and to all the radii.

The numbers are ſo placed, that the ſum of all thoſe in either of the concentric circular ſpaces above mentioned, together with the central number 12, make 360; equal to the number of degrees in a circle.

The numbers in each radius alſo, together with the central number 12, make juſt 360.

The numbers in half of any of the above circular ſpaces, taken either above or below the double or horizontal line, with half the central number 12, make 180: equal to the number of degrees in a ſemicircle.

If any four adjoining numbers be taken, as if in a ſquare, in the radial diviſions of theſe circular ſpaces; the ſum of theſe, with half the central number, make 180.

There are, moreover, included four ſets of other circular ſpaces, bounded by circles which are excentric with reſpect to the common centre; each of theſe ſets containing five ſpaces. The centres of the circles which bound them are at A, B, C, and D. The ſet, whoſe centre is at A, is bounded by dotted lines; the ſet whoſe centre is at C is bounded by lines of ſhort unconnected ſtrokes, and the ſet round D is bounded by lines of unconnected longer ſtrokes, to diſtinguiſh them from one another. In drawing this figure by hand, the ſet of concentric circles ſhould be drawn with black ink; and the four different ſets of excentric circles with four kinds of ink of different colours; as blue, red, yellow, and green, for diſtinguiſhing them readily from one another.

Theſe ſets of excentric circular ſpaces interſect thoſe of the concentric, and each other; and yet, the numbers contained in each of the excentric ſpaces, taken all around through any of the 20, which are excentric, make the ſame ſum as thoſe of the concentric; namely, 360, when the central number 12 is added. Their halves alſo, taken above or below the double or horizontal line, with half the central number, make 180.

Obſerve, that there is not one of the numbers but what belongs at leaſt to two of the circular ſpaces; ſome to three, ſome to four, ſome to five: and yet they are all ſo placed as never to break the required number 360, in any of the twenty-eight circular ſpaces within the primitive circle.

To bring theſe matters in view, all the numbers as abovementioned are taken out, and placed in ſeparate columns, as they ſtand around both the concentric and excentric circular ſpaces, always beginning with the outermoſt and ending with the innermoſt of each ſet; and alſo the numbers as they ſtand in the eight radii, from the circumference to the centre; the common central number 12 being placed the loweſt in each column.

If now we take any four numbers as in a ſquare form, either from No. 1. No. 2. (as ſuppoſe from No. 1.) as in the margin; and add half the central

14 72
25 63
6

number

number 12 to them, the sum will be 180; equal to half the numbers in any circular space, taken above or below the double horizontal line: and equal to the number of degrees in a semicircle. Thus, 14, 72, 25, 63, and 6, make 180. See Franklin's Exp. and Obs. p. 350, &c. edit. 4to. 1769; or Ferguson's Tables and Tracts, 1771, p. 318, &c.

MAGICAL *Picture*, in *Electricity*, was first contrived by Mr. Kinnersley, and is thus made: having a large mezzotinto with a frame and glass, *e. gr.* of the king, take out the print, and cut a pannel out of it, near two inches distant from the frame all round; with thin paste or gum-water, fix the border that is cut off on the inside of the glass, pressing it smooth and close; then fill up the vacancy by gilding the glass well with leaf-gold, or brass. Gild likewise the inner edge of the back of the frame all round, except the top part, and form a communication between that gilding and the gilding behind the glass; then put in the board, and that side is finished. Turn up the glass, and gild the fore-side exactly over the back gilding, and when it is dry, cover it, by pasting on the pannel of the picture that hath been cut out, observing to bring the correspondent parts of the border and picture together, by which means the picture will appear of a piece, as at first, only part behind the glass and part before. Hold the picture horizontally by the top, and place a little moveable gilt crown on the king's head. If now the picture be moderately electrified, and another person takes hold of the frame with one hand, so that his fingers touch its inside gilding, and with the other hand endeavour to take off the crown, he will receive a terrible blow, and fail in the attempt. If the picture were highly charged, the consequence might be as fatal as that of high treason. The operator, who holds the picture by the upper end, where the inside of the frame is not gilt, to prevent its falling, feels nothing of the shock, and may touch the face of the picture without danger. If a ring of persons take the shock among them, the experiment is called the conspirators. Franklin's Exp. and Obs. p. 30.

MAGICIAN, one who practises the art of magic. See DIVINATION, MAGIC, and SORCERY.

The ancient magicians pretended to extraordinary powers of interpreting dreams, foretelling future events, and accomplishing many wonderful things, by their superior knowledge of the secret powers of nature, of the virtues of plants and minerals, and of the motions and influences of the stars. And as the art of magic among the Pagan nations was founded in their system of theology, and the Magi who first exercised it were the priests of the gods, they pretended to derive these extraordinary powers from the assistance of the gods; which assistance they sought by a great variety of rites and sacrifices, adapted to their respective natures, by the use of charms and superstitious words, and also by ceremonies and supplications: they pretended likewise, in the proper use of their art, to a power of compelling the gods to execute their desires and commands. An excellent writer has shewn, that the scripture brands all these powers as a shameless imposture, and reproaches those who assumed them with an utter inability of discovering or accomplishing any thing supernatural. (See Isaiah, xlvii. 11, 12, 13. chap. viii. 18, 19. chap. xli. 23, 24. chap. xliv. 25. Jerem. x. 2, 3. 8. 14. chap. xiv. 14. chap. xxvii. 9, 10. chap. l. 36. Ps. xxi. 6. Jonah, ii. 8.) Nevertheless, many of the Christian fathers, as well as some of the heathen philosophers, ascribed the efficacy of magic to evil dæmons: and it was a very prevailing opinion in the primitive church, that magicians and necromancers, both among the Gentiles and heretical Christians, had each their particular dæmons perpetually attending on their persons, and obsequious to their commands, by whose help they could call up the souls of the dead, foretel future events, and perform miracles. In support of this opinion, it has been alleged, that the names by which the several sorts of diviners are described in scripture, imply a communication with spiritual beings; that the laws of Moses (Exod. xxii. 18. Lev. xix. 26. 31. chap. xx. 27. Deut. xviii. 10, 11.) against divination and witchcraft, prove the efficacy of these arts, though in reality they prove nothing more than their execrable wickedness and impiety; and that pretensions to divination could not have supported their credit in all the heathen nations and through all ages, if some instances of true divination had not occurred. But the strongest argument is derived from the scripture history of the Egyptian magicians who opposed Moses. With regard to the works performed by these magicians, some have supposed that God himself empowered them to perform true miracles, and gave them an unexpected success; but the history expressly ascribes the effects they produced, not to God, but to their own inchantments. Others imagine, that the devil assisted the magicians not in performing true miracles, but in deceiving the senses of the spectators, or in presenting before them delusive appearances of true miracles: against which opinion it has been urged, that it tends to disparage the credit of the works of Moses. The most common opinion since the time of St. Austin, has been, that they were not only performed by the power of the devil, but were genuine miracles, and real imitations of those of Moses. In a late elaborate inquiry into the true sense and design of this part of scripture history, it has been shewn, that the names given to the magicians seem to express their profession, their affectation of superior knowledge, and their pretences both to explain and effect signs and wonders, by observing the rules of their art; and therefore, that they are the persons, whose ability of discovering or effecting any thing supernatural the scripture expressly denies. The learned author farther investigates the design, for which Pharaoh employed them on this occasion: which, he apprehends, was to learn from them, whether the sign given by Moses was truly supernatural, or only such as their art was able to accomplish. Accordingly it is observed, that they did not undertake to outdo Moses, or to controul him, by superior or opposite arts of power, but merely to imitate him, or to do the same works with his, with a view of invalidating the argument which he drew from his miracles, in support of the sole divinity of Jehovah, and of his own mission. The question on this occasion was not, are the gods of Egypt superior to the God of Israel, or can any evil spirits perform greater miracles than those which Moses performed by the assistance of Jehovah? but the question was, are the works of Moses proper proofs, that the God of Israel is Jehovah, the only sovereign of nature, and consequently that Moses acts by his commission; or, are they merely the wonders of nature, and the effects of magic? In this light Philo, (de Vita Mosis, lib. i. p. 616.) and Josephus, (Antiq. Jud. lib. ii. cap. 13.) place the subject. Moreover, it appears from the principles and conduct of Moses, that he could not allow the magicians to have performed real miracles: because the scripture represents the whole body of magicians as impostors; the sacred writers, Moses in particular, describe all the heathen deities, in the belief of whose existence and influence the magic art was founded, as unsupported by any invisible spirits, and utterly impotent and senseless: the religion of Moses was built on the unity and sole dominion of God, and the sole divinity of Jehovah was the point which Moses was now about to establish, in direct opposition to the

the principles of idolatry; ſo that if he had allowed that the heathen idols, or any evil ſpirits ſupporting their cauſe, enabled the magicians to turn rods into ſerpents, and water into blood, and to create frogs, he would have contradicted the great deſign of his miſſion, and overthrown the whole fabric of his religion; beſides, Moſes appropriates all miracles to God, and urges his own, both in general and ſeparately, as an abſolute and authentic proof, both of the ſole divinity of Jehovah, and of his own miſſion; which he could not juſtly have done, if his oppoſers performed miracles, and even the ſame with his. On the other hand, it has been urged, that Moſes deſcribes the works of the magicians in the very ſame language as he does his own, (Exod. vii. 11, 12. chap. v. 22. chap. viii. 7.) and hence it is concluded, that they were equally miraculous. To this objection it is replied, that it is common to ſpeak of profeſſed jugglers, as doing what they pretend and appear to do; but that Moſes does not affirm, that there was a perfect conformity between his works and thoſe of the magicians, but they did *ſo*, or in like manner, uſing a word which expreſſes merely a general ſimilitude; and he expreſsly refers all they did, or attempted in imitation of himſelf, not to the invocation or power of dæmons, or of any ſuperior beings, but to human artifice and impoſture. The original words, tranſlated *inchantments*, (Exod. vii. 11, 22. and chap. viii. 7, 18) import deception and concealment, and ought to have been rendered, *ſecret ſlights* or *jugglings*. Our learned writer farther ſhews, that the works performed by the magicians did not exceed the cauſe, or human artifice, to which they are aſcribed. Farmer's Diſſ. on Miracles, 1771, chap. 3. § 3. chap. 4. § 1.

MAGIEROW, in *Geography*, a town of Poland, in the palatinate of Belcz; 22 miles S.S.W. of Belcz.

MAGILLICUDDY's Reeks, high mountains in the county of Kerry, Ireland, lying near Killarney. They are ſuppoſed to be higher than Mangerton, which is 2500 feet above the level of the ſea.

MAGILLIGAN Point, a cape of Ireland, in the county of Londonderry, at the entrance of Lough Feyle. N. lat. 55° 12′. W. long. 6° 50′.

MAGINI, John Anthony, in *Biography*, an Italian mathematician and aſtronomer, was born at Padua in the year 1556. He acquired an early reputation for acquaintance with the ſciences, and was appointed profeſſor of mathematics in the univerſity of Bologna. He was decidedly in favour of the Copernican ſyſtem, but had not courage openly to avow his opinions; and to prevent any diſputes that might occur, and to avoid the penalties of hereſy, he taught the doctrine of Ptolemy. He was a practical philoſopher, and made the inſtruments which he uſed with his own hands, among theſe were large concave mirrors, full five feet in diameter. He died in 1617, in the ſixty-ſecond year of his age, leaving behind him many works that reflect much credit on his memory: among theſe the moſt important were his "Ephemerides," in three volumes, from 1580 to 1630: "Theoria Planetarum juxta Copernicas Obſervationes:" "Problemata Aſtronomica, Gnomonica, et Geographica:" "Italiæ Deſcriptio Chorographica," illuſtrated with ſixty maps. Bayle.

MAGISI, in *Geography*, a town of Brazil, in the government of St. Paul; 36 miles N.E. of St. Paul.

MAGISTER, Master, a title frequently found in old writings; noting the perſon who bore it to have attained ſome degree of eminence *in ſcientia aliqua, præſertim in literaria*.

In old times, thoſe we now call *doctors*, were called *magiſtri*, or *maſters*.

MAGISTERY, in *Chemiſtry*, a term formerly uſed to ſignify a *precipitate*. Since the new nomenclature of chemiſtry has been introduced, it has become obſolete.

Magistery *of Biſmuth*. See Bismuth.

Magistery *of Lead*. See Lead.

Magistery *of Sulphur*. See Sulphur.

MAGISTRATE is the name of any public officer, or ruler, to whom the executive power of the law is committed, either wholly or in part. Of magiſtrates ſome are ſupreme, in whom the ſovereign power of the ſtate reſides; others are ſubordinate, deriving all their authority from the ſupreme magiſtrates, accountable to him for their conduct, and acting in an inferior ſecondary ſphere. In all tyrannical governments, the ſupreme magiſtracy, or the right both of *making* and of *enforcing* the laws, is veſted in one and the ſame man, or one and the ſame body of men; and whenever theſe two powers are united together, there can be no public liberty. The magiſtrate may enact tyrannical laws, and execute them in a tyrannical manner, ſince he is poſſeſſed, in quality of diſpenſer of juſtice, with all the power which he, as legiſlator, thinks proper to give himſelf. But when the legiſlative and executive authority are in diſtinct hands, the former will take care not to entruſt the latter with ſo large a power as may tend to the ſubverſion of its own independence, and therewith of the liberty of the ſubject. With us in England, therefore, the ſupreme power is divided into two branches; the one legiſlative, *viz.* the parliament, conſiſting of king, lords, and commons; the other executive, conſiſting of the king alone. See King, Parliament, Sheriff, Justice, &c.

MAGIUS, Al, in *Geography*, a town of Perſia, in the province of Farſiſtan; 45 miles S.W. of Yezd.

MAGLASAN, a town of Perſia, in the province of Adirbeitzan; 66 miles W. of Tauris.

MAGLEBIE, a town of Denmark, in the iſland of Zealand; four miles S. of Copenhagen.

MAGLIA, a town of the iſland of Candia; 16 miles E.S.E. of Candia.

MAGLIABECCHI, Anthony, in *Biography*, a perſon remarkable for his knowledge of books, was born at Florence in 1633. Having attained the elements of the Latin language, he was apprenticed to the buſineſs of a goldſmith and jeweller, but his paſſion for reading induced him to employ every leiſure moment in improving his mind, and in laying in large ſtores of uſeful knowledge; and at the death of his parents in 1673, he entirely abandoned trade, and devoted himſelf wholly to the purſuits of literature. By means of an aſtoniſhing memory, and almoſt inceſſant application, he became more converſant with literary hiſtory than any man of his time, and was appointed librarian to the grand duke of Tuſcany. He kept up a correſpondence with the moſt learned men in Europe, from many of whom, even in the very higheſt ranks of life, he received tokens of reſpect and eſteem. Lewis XIV. always commiſſioned the French literati who viſited Italy to ſalute Magliabecchi in his name. To thoſe who viſited him through motives of mere curioſity, he was diſtant and reſerved; but to the truly learned, no man was more communicative of his knowledge, and many of the moſt eminent ſcholars of the time have expreſſed their obligations to him. He could moſt readily direct an author to all the works which treated upon the ſubject on which he was writing. So expert and accurate was he in this reſpect, that he has been called a living library. He was taken ſeriouſly ill in 1708, and upon his recovery Ferdinand wiſhed him to lodge in the palace, and prepared for him a commodious apartment, and a large room for his books. Here he reſided a few months, and then returned to his own cottage, where he died, at the age

age of eighty-one, in the year 1714. Magliabecchi was a man of a most forbidding and savage aspect, and exceedingly negligent of his person. His habits were solitary and cynical, never indulging in the pleasures of society, or the gratifications of sense. He refused to be waited upon, and rarely took off his clothes to go to bed. In the midst of the coldest winter he made the same cloak a covering for the day and the night. His dinner was commonly three hard boiled eggs, with a draught of water. He spent some hours in each day at the palace library, but is said never in his life to have gone farther from Florence than to Pratz, whither he once accompanied cardinal Norris to see a manuscript. He had a small window in his door, through which he could see all those who approached him, and if he did not wish their company he would not admit them.

MAGLIANO, in *Geography*, a town of Italy, in the Sabina, a bishop's see; 28 miles N. of Rome. N. lat. 42° 20'. E. long. 12° 28'.—Also, a town of Etruria; 12 miles N.E. of Orbitello.

MAGLOI, a town of Bosnia, on the Bosna; 21 miles N. of Serajo.

MAGMA, Μαγμα, among *Chemists*, &c. the dregs or recrements of a composition remaining after all the more fluid parts are expressed.

It is a word used by medical writers on many occasions, sometimes in a very lax, and sometimes in a more appropriated sense. Some writers use it to express a mass of any thing; others for a thick ointment made up with very little fluid matter to prevent its running; and others for the remains of an ointment after expression from its ingredients. Galen restrains the word *magma* to express only the fæces of myrobalans.

MAGNA Arteria, in *Anatomy*. See Aorta and Artery.

Magna *Assiza Eligenda*, a writ directed to the sheriff to summon four lawful knights before the justice of assize, there, upon their oaths, to choose twelve knights of the vicinage, &c. to pass upon the *great assize* between A. B. plaintiff, and C. D. defendant, &c. See Assises.

Magna *Charta*, the *great charter* of liberties of England, signed and sealed by king John in a conference between the king and barons at Runnemede, between Windsor and Staines, June 19th, A.D. 1215, and confirmed by Hen. III. and Edward I.

The reason of its being termed *Magna*, or *great*, is either because of the excellency of the laws and liberties therein contained, or because there was another charter, called *Charta de Foresta*, established with it, which was the lesser of the two; or else because it contained more than any other charters; or in regard of the wars and troubles in the obtaining of it; or of a great and remarkable solemnity in the denouncing excommunications against the infringers of it.

Magna Charta may be said to derive its origin from king Edward the Confessor, who granted divers liberties and privileges, both civil and ecclesiastical, by charter: the same, with some others, were also granted and confirmed by king Henry I., soon after his coronation and agreeably to an oath by which he had bound himself before he was crowned, by a celebrated great charter.

By this charter he restored the Saxon laws which were in use under Edward the Confessor, but with such alterations, or (as he styled them) "emendations, as had been made in them by his father, with the advice of his parliament," at the same time annulling "all evil customs and illegal exactions, by which the realm had been unjustly oppressed." Some of these grievances were specified in the charter, and the redress of them was there expressly enacted. It also contained very considerable mitigations of those feudal rights claimed by the king over his tenants, and by them over their's, which either were the most burthensome in their own nature, or had been made so by an abusive extension. In short, all the liberty, that could well be consistent with the safety and interest of the lord in his fief, was allowed to the vassal by this charter, and the profits due to the former were settled according to a determined and moderate rule of law. According to the words of one of our greatest antiquaries, sir Henry Spelman, "it was the original of king John's Magna Charta, containing most of the articles of it, either particularly expressed, or in general, under the confirmation it gives to the laws of Edward the Confessor." So mistaken are they, says lord Lyttelton, who have supposed that all the privileges granted in Magna Charta were "innovations" extorted by the arms of rebels from king John!—a notion which seems to have been first taken up, not so much out of ignorance, as from a base motive of adulation to some of our princes in later times, who, endeavouring to grasp at absolute power, were desirous of any pretence to consider those laws, which stood in their way, as violent encroachments made by the barons on the ancient right of the crown; whereas they were in reality restitutions and sanctions of ancient rights, enjoyed by the nobility and people of England in former reigns; or limitations of powers which the king had illegally and arbitrarily stretched beyond their due bounds. In some respects, says our author, this charter of Henry I. was more advantageous to liberty than *Magna Charta* itself. (See Henry I.) In confirmation of sir Henry Spelman's opinion above-mentioned, we may allege the testimony of an ancient historian. Matthew Paris tells us, that, in the year 1215, the barons came in arms to king John at London, and demanded of him that certain liberties and laws of king Edward, with other liberties granted to them, and to the kingdom and church of England, should be confirmed, "as they were contained and set down in the charter of king Henry I. and in the laws above-mentioned." And the same historian, where he mentions the "capitula," or rough draught of the great charter, delivered to John by the barons, says, that the articles thereof "were partly written before, in the charter of king Henry I. and partly taken out of the ancient laws of king Edward." These passages, and also what he says before, of the barons having sworn at St. Edmund's Bury, to make war on the king, till he should confirm to them, by a charter under his seal, the laws and liberties granted in the charter of Henry I., sufficiently shew, that they understood and intended this charter to be the original and foundation of that which they demanded and obtained from John. With regard to another passage that occurs in Matthew Paris, relating to the charter of Henry I. and connected with his account of a convention or synod held in London under Stephen Langton, archbishop of Canterbury, in the year 1213, it imports that the charter of king Henry was then a "novelty" to the barons, and that they expressed a surprise of joy at hearing a copy of it read, which the archbishop told them was "just found." But from the same historian we learn that, after the charter was given, the king ordered as many transcripts of it to be made as there were counties in England, and to be laid up, as records, in the abbies of every county. Besides, the first charter of Stephen "confirms the liberties and good laws, which his uncle king Henry gave and granted, and all good laws and good customs, which the nation had enjoyed in the time of Edward the Confessor," words which evidently refer to the charter. It was also confirmed more expressly by king Henry II. "How is it possible then," says lord Lyttelton,

Lyttelton, "that in the reign of his fon it fhould be fo difficult to produce a fingle tranfcript of it, and that even the remembrance of what it contained fhould be fo totally loft among the principal nobles? The ftrong objections to fo ftrange a ftory did not efcape the penetration of the learned and judicious Dr. Blackftone. In his accurate edition of the charters, he takes notice of the great improbability of it; and further obferves, that it is mentioned by no other contemporary hiftorian; but that, on the contrary, all of them affign quite different reafons for the confederacy of the barons." Our noble author adds, "that the credit of this ftory is ftill more weakened, by its being only delivered *upon common fame* (*ut fama refert*), though it is faid to have paft *in fecret*."—"How can one fuppofe that the particular words of a fpeech *made in fecret*, could be accurately reported by *common fame*?"—"That the archbifhop fhould produce to the barons a tranfcript of the charter, as a proper foundation for their confederacy, and for the demands, or claim of rights, they were to make to the king, I think (fays lord Lyttelton) is very probable. But that there could be any difficulty in finding fuch a tranfcript, or that it fhould be regarded by them as a novelty, appears to me quite incredible." "How far Matthew Paris, or rather Roger de Wendover, (from whom the former has tranfcribed this part of his hiftory), is from being exact in his account of thefe affairs, we need no better evidence, than the copy he gives us of the charter of king John, which is effentially different from the originals in the Britifh Mufeum and at Salifbury, and from the entry in the Red Book of the Exchequer. No hypothefis, therefore, can reafonably be built on this paffage in that writer; though fome have been induced to infer from it, that the charter of Henry I. became obfolete almoft as foon as it was given, and was fo totally neglected, as to be in a manner forgotten." But to return from this digreffion, the fucceffors of Henry I. king Stephen, king Henry II. and king John, confirmed or re-enacted the fame; but the laft prince violating his charter, the barons took up arms, and his reign ended in blood. Henry III who fucceeded him, after having procured an inquifition to be made by twelve men in each county, what the liberties of England were in the time of Henry I., confirmed, with fome alterations, the charter, obtained fword in hand from king John, in 1215, being the prefent Magna Charta; which he feveral times confirmed and as often broke again; till in the thirty-feventh year of his reign, he came to Weftminfter-hall, where, in the prefence of the nobility and bifhops, with lighted candles in their hands, Magna Charta was read, the king all the while laying his hand on his breaft, and at laft folemnly fwearing faithfully and inviolably to obferve all the things therein contained, as he was a man, a Chriftian, a foldier, and a king. Then the bifhops extinguifhed their candles, throwing them on the ground, crying, "Thus let him be extinguifhed and ftink in hell who violates this charter."

Neverthelefs, king Henry in the next year invaded the rights of his people, till the barons levied war againft him; and, after various fuccefs, he confirmed this charter and the charter of the forefts, in the parliament of Marlbridge, and in the fifty-fecond year of his reign. Afterwards, by ftatute 25 Edw. I. called *Confirmatio chartarum*, whereby the great charter is directed to be allowed as the common law, all judgments contrary to it are declared void; copies of it are ordered to be fent to all cathedral churches, and read twice a year to the people; and fentence of excommunication is directed to be as conftantly denounced againft all thofe that by word, deed, or counfel, act contrary thereto, or in any degree infringe it. Sir Edward Coke obferves, that it was confirmed no lefs than thirty-two times, from the firft Edward to Henry IV. Then, after a long interval, by the Petition of Right, by many falutary laws, particularly the Habeas Corpus act of Charles II. by the Bill of Rights, and laftly by the Act of Settlement.

The Magna Charta is the bafis of the Englifh laws and liberties: befides thofe provifions, which redreffed many grievances incident to feodal tenures, care was alfo taken therein to protect the fubject againft other oppreffions, frequently arifing from unreafonable amercements, from illegal diftrefs, or other procefs for debts or fervices due to the crown, and from the tyrannical abufe of the prerogative of purveyance, and pre-emption. It fixed the forfeiture of lands for felony in the fame manner as it ftill remains; prohibited for the future the grants of exclufive fifheries, and the erection of new bridges, fo as to opprefs the neighbourhood. With refpect to private right, it eftablifhed the teftamentary power of the fubject over part of his perfonal eftate, the reft being diftributed among his wife and children: it laid down the law of dower, as it continued ever fince; and prohibited the appeals of women, unlefs for the death of their hufbands. In matters of public police and national concern, it enjoined an uniformity of weights and meafures; gave new encouragement to commerce, by the protection of merchant-ftrangers; and forbad the alienation of lands in mortmain. With regard to the adminiftration of juftice; befides prohibiting all denials or delays of it, it fixed the court of common pleas at Weftminfter, that the fuitors might no longer be haraffed with following the king's perfon in all his progreffes; and at the fame time brought the trials of iffues home to the very doors of the freeholders, by directing affizes to be taken in the proper counties, and eftablifhing annual circuits; it alfo corrected fome abufes then incident to the trials by wager of law and of battle: directed the regular awarding of inqueft for life or member; prohibited the king's inferior minifters from holding pleas of the crown, or trying any criminal charge, whereby many forfeitures might otherwife have unjuftly accrued to the exchequer; and regulated the time and place of holding the inferior tribunals of juftice, the county-court, fheriff's torn, and court-leet. It confirmed and eftablifhed the liberties of the city of London, and all other cities, boroughs, towns, and ports of the kingdom. And laftly, (which alone would have merited the title that it bears of the *Great Charter*) it protected every individual of the nation in the free enjoyment of his life, his liberty, and his property, unlefs declared to be forfeited by the judgment of his peers or the law of the land. Blackft. Comm. vol. iv.

MAGNAL-LAVAL, in *Geography*, a town of France, in the department of the Upper Vienne, and chief place of a canton, in the diftrict of Bellac; 24 miles N. of Limoges. The place contains 2654, and the canton 6759 inhabitants, on a territory of 162½ kiliometres, in five communes.

MAGNANINA, in *Ornithology*, the name of a fmall bird defcribed by Aldrovand, Gefner, and fome other authors, and feeming to be the fame with our hedge-fparrow, commonly known among authors by the name of *curruca*. See MOTACILLA *modularis*.

MAGNANO, in *Geography*, a town of the duchy of Piacenza; 13 miles S.S.E. of Piacenza.

MAGNENTIUS, MAGNUS, in *Biography*, a German by birth, but who, from being a private foldier, rofe to the chief employments in the Roman empire. He owed his diftinguifhed ftation to the circumftance of his having been made a prifoner of war. To free himfelf from chains he joined the Roman troops, and became diftinguifhed for valour. He was commander of the Jovian and Herculean bands, ftationed to guard the banks of the Rhine, at the time

time when Conftans I. emperor of the Weft, had incurred the contempt of the army on account of his indolence and voluptuoufnefs. In 350, he afcended the throne, and on the murder of Conftans, he was left without a rival in the Gallic and Italian præfectures. At Rome, Magnentius acted with great tyranny, and by his various extortions, he was enabled to levy a very powerful army to maintain his ufurped authority. So formidable did he appear, that Conftantius, emperor of the Eaft, and brother of the deceafed Conftans, fought a peace, on the terms of leaving him in poffeffion of Gaul, Spain, and Britain, but his propofals were rejected. Conftantius now determined to attack him; a bloody battle enfued, which terminated in the total defeat of Magnentius. He fled to the foot of the Julian alps, and collected the fcattered remains of his army, pofted them advantageoufly to defend the paffes, and fpent the winter in Aquileia. After this he went to Gaul, and obtained a victory over the van of the purfuing enemy at Pavia. His troops, however, foon fuftained another defeat, after which he took refuge in Lyons, where he difpatched himfelf with his own fword. This event took place in the year 353, after a reign of nearly four years. The example of fuicide was imitated by Decentius, who ftrangled himfelf on the news of his brother's death. A fevere inquifition was extended over all who, either from choice or compulfion, had been involved in the caufe of Magnentius. The moft innocent people were expofed to exile and confifcation, to death and torture, and, fays Gibbon, "as the timid are always cruel, the mind of Conftantius was inacceffible to mercy." Gibbon.

MAGNES, in *Geography*, a town of the ifland of Candia, on the N. coaft, fuppofed by Dr. Pocock to be the ancient Dictamnum, or Dictynna; 12 miles N.W. of Canea.

MAGNES *Carneus*, in *Natural Hiftory*, a name given by Cardan and fome other authors to a white earth dug in Italy and fome other places, and called alfo by many calamita alba. It is an indurated earthy fubftance of the hardnefs of ofteocolla, and is of a white colour variegated with black lines. It adheres very firmly to the tongue, and is hence faid to attract flefh in the fame manner as the magnet does iron. It is even pretended, that if an iron ftylus be rubbed over with this ftony earth, and then plunged into the flefh, the virtue of the earth will heal the wound as foon as made, and when the weapon is taken forth, there will remain no appearance of hurt. Cardan affirms that he faw this tried with fuccefs, but fufpects witchcraft in the cafe.

MAGNESIA, in *Agriculture*, a fubftance which has not yet been found in a pure ftate in nature; it is conftantly combined either with acids in the form of earthy falts, or mixed with other earths, as *ferpentine*, *fteatites*, *talc*, *afbeftos*, &c. With a view to moft purpofes, it is commonly prepared by the decompofition of bitter falt, by the fixed mild alkalies, and fubfequent feparation of the carbonic acid by calcination.

But the experiments of Mr. Tennant feem to fhew, that this fubftance, when in combination with calcareous matters, fuch as that of lime, &c. is unfriendly to vegetation. It is, however, obferved by lord Dundonald, that it is found "in a variety of earths and ftones, and that it combines with acids, forming neutral falts, all of which are very foluble, and the greater part of them promotes, in a very confiderable degree, the growth of plants. Magnefian earths, he conceives, may be applied with peculiar advantage to foils generally, and not improperly, called four foils, containing green vitriol, arifing from the decompofition of pyrites. It will decompofe the metallic falt by fuperior affinity, and form with the acid Epfom falt, known in a high degree to promote vegetation; while the earth of iron will be feparated in the ftate of an ochre, or iron combined with fixable air."

In has been fuggefted by a writer, in the Farmer's Magazine, likewife, that he tried the vegetative power of this fubftance, by fowing oats in a pot containing one-tenth part of magnefia, and the reft common earth, in which they grew and throve extremely well; but in another pot containing magnefia alone, they would not vegetate at all, which might, he thinks, be expected. It is likewife fuppofed to extirpate forrel, when applied on lands that abound with it, probably by neutralizing the acid, which is the cafe with lime. This writer has, however, applied it to lands overgrown with forrel, without its producing fuch beneficial effects.

MAGNESIA, in *Chemiftry*, one of thofe fubftances that pafs under the general name of earths. It is lefs abundant in nature than lime, alumina, or filex, but more abundant than any of the other earths. It forms a confiderable part of the lime-ftone, commonly called magnefian, from which it may be obtained by diffolving the ftone in muriatic acid, and precipitating the magnefia with pure ammonia.

This earth was little known before its nature was inveftigated by the experiments of Dr. Black. It was before frequently confounded with lime.

It exifts, in combination with muriatic and fulphuric acids, in fea water. The latter falt is found in fome mineral waters, particularly the waters in the vicinity of Epfom, known by the name of Epfom falt.

It is from this falt that the magnefia of commerce is generally procured. The falt is firft diffolved in water; then to the clear folution a quantity of common carbonat of potafh is added. The magnefia is precipitated in the ftate of carbonat, which, when wafhed and dried, conftitutes the magnefia commonly ufed in medicine. It is fometimes expofed to a ftrong red heat, in crucibles, by which the carbonic acid is expelled. In this ftate it is called calcined magnefia.

If the precipitation be made with pure ammonia inftead of potafh, the earth will be obtained in a ftate of tolerable purity.

Magnefia, in a pure ftate, appears in the form of powder, foft to the feel, and perfectly white. It has no tafte, but when taken into the mouth it excites a peculiar fenfation, arifing from the rapid abforption of the faliva. It is deftitute of fmell, but emits a peculiar odour when moifture is applied to it. Its fpecific gravity, according to Kirwan, is 2.3. Like the alkalies, and the alkaline earths, it changes the blue colour of fome vegetables to that of green.

It does not undergo any rapid change by expofure to the air. It flowly combines with water and carbonic acid; the former may be detected by diftillation, and the latter by its effervefcence with an acid.

It is nearly infoluble in water; fince, according to Kirwan, it requires 7900 parts of water to diffolve one of magnefia.

Like the other earths, when ftrictly pure, it is not fufible at any known degree of heat, although it is capable of fufion when mixed with other earths. Lime and magnefia, in the proportion of four to one, runs through the crucible at 150° Wedgewood. But one of lime to four of magnefia did not melt at 165°. In the proportion of one of the latter to three of the former; they melted into a greenifh-yellow glafs. For thefe facts we are indebted to Kirwan.

Magnefia has long been fufpected to be a compound body, but not with much ground of probability, till the late interefting experiments by Mr. (fir Humphrey) Davy, in which the alkalies and fome of the earths appear to be compounds. Berzelius is faid to have fucceeded in decompofing magnefia by

 the

the agency of the Galvanic battery. The earth was placed in contact with mercury, and he supposed that the base of the magnesia, which was thought to be metallic, combined with the mercury, forming a peculiar alloy. Mr. Davy has repeated this experiment, with the sulphat of this earth, with a similar result. Attempts have since been made to decompose magnesia in various ways, by Guy Lussac and Thenard, but without any satisfactory result.

In the experiments of Mr. Davy, although he did not succeed in obtaining the metal from the alloy with mercury, he found that magnesia was produced by throwing the alloy into water. It is highly probable, therefore, that this earth, like lime and barytes, is a compound, a peculiar metal united with oxygen, between which the affinity may be so great as not to be obtained, but with great difficulty. It is, therefore, to future experiments that we must look for the final establishment of the compound nature of this earth.

It is an useful medicine for taking up acidity in the stomach; and has lately been recommended by Mr. Brandt as a solvent for the urinary calculus constituted by the uric acid.

Magnesia combines with sulphur, but very imperfectly: if two of the earth with one of sulphur be exposed to heat in a crucible, the mass becomes yellow. It affords a small quantity of sulphuretted hydrogen when thrown into water. If the heat at which it is formed be a little increased, the sulphur is expelled, leaving the earth pure. It does not combine with phosphorus, carbon, nitrogen, nor the metals, nor with any of the metallic oxyds.

There is no action between magnesia and the alkalies. The solubility of magnesia by the carbonats of the alkalies, is occasioned by the carbonic acid which leaves the alkali and combines with the earth.

Salts of Magnesia.—The greater proportion of the magnesian salts are of no known use, and have in consequence been little examined. The sulphat is the only one with which we are much acquainted, from its well known virtues as a purgative.

Sulphat of Magnesia.—This salt is found native in sea water; in the waters of Epsom, from which it has been called Epsom salt, and in many mineral waters. That used in medicine is obtained from the above sources. Several schistose stones contain sulphur and magnesia, which being exposed to air with moisture, the sulphur is converted into sulphuric acid, and, combining with the magnesia, forms this salt, which is separated from the heterogeneous matter by crystallization.

The efflorescence formed on brick walls is principally found to be sulphat of magnesia, sometimes mixed with nitre.

Sulphat of magnesia dissolves in its own weight of water at 60°. On evaporation and slow cooling, this salt crystallizes in the form of four-sided prisms; it has a bitter and disagreeable taste. The crystals have the property of double refraction. When exposed to the air they soon lose their water of crystallization, and appear in the form of white powder. When exposed to a strong heat, it first fuses in its water of crystallization, which soon escapes. If the heat be continued and raised to high temperature, it melts into a vitreous mass. It is composed, according to the analysis of Bergman, of 33 acid, 19 magnesia, and 48 water; according to Wenzel, 30.64 acid, 16.86 magnesia, and 52.5 water. Dalton makes the atom of magnesia to be 17, that of sulphuric acid 34. Then $\frac{34 + 17}{34} = \frac{100}{67.8}$, which gives 67.8 acid, and 32.2 magnesia. If we take the acid and base only, in the analysis of Wenzel we shall have $\frac{30.64 + 16.86}{30.64} = \frac{100}{64.5}$, or 64.5 acid, and 35.5 magnesia.

This salt has the property of combining with some other of the sulphats which form compounds, having peculiar properties. These, like the rest of the compounds called triple salts, perhaps in all cases, owe their existence to the circumstance of their crystallizing together, from the analogous form of their crystals, and ought not to be considered as distinct species, since on analysis they are found to consist of certain proportions of the two salts, rather than of two bases united to one common quantity of acid. There is little doubt but that these salts, when in solution, would possess the individual properties of the two salts, being in this situation a mere mixture.

The sulphat of magnesia and potash is said to be composed of three parts of sulphat of potash, and four of sulphat of magnesia. The crystals are of a rhomboidal form.

The sulphat of magnesia and soda is composed of six of sulphat of magnesia, and five of sulphat of potash. Its crystals are prismatic.

Sulphat of Magnesia and Ammonia is in the form of octahedrons, and consists of 68 of sulphat of magnesia, and 32 of sulphat of ammonia.

Nitrat of Magnesia.—This salt is formed by saturating the nitric acid with magnesia. On evaporating the solution to a certain extent, and suffering it to cool, the salt crystallizes in the form of rhomboidal prisms, which, when small, have the appearance of needles. The taste of this salt is unpleasantly bitter, like most other of the magnesian salts. It dissolves in its own weight of water at 60°; it is also soluble in nine times its weight of alcohol of the specific gravity of .84. When evaporated to dryness, and exposed to the air, it speedily becomes liquid, by attracting moisture from the air.

When exposed to a strong heat, it affords oxygen and nitrous oxyd, the acid being decomposed, leaving the earth behind in a state of purity.

Its composition by the analysis of Bergman is 43 acid, 27 magnesia, and 30 water; by Richter's, 69.6 acid, and 30.4 base; by Kirwan's, 46 acid, 22 base, and 32 water; and by Wenzel, 72 acid, and 28 base.

The weight of the atom of acid is 19, that of the base 17. Then, since the nitrats are super salts, we have $\frac{17 + 19 \times 2}{19 \times 2} = \frac{100}{69}$, or 69 acid, and 31 magnesia, nearly.

Muriat of Magnesia.—This salt abounds in sea water, and in some mineral waters. It may also be formed by adding carbonat of magnesia to muriatic acid, till the effervescence ceases. When the solution is evaporated to the consistence of syrup, and exposed to a temperature of 32°, crystals of a needle shape are formed, although in small quantity and with difficulty.

It has a pungent bitter taste. It is soluble in one-half its weight of cold water, and in almost any proportion of boiling water. It is also very soluble in pure alcohol.

This salt is very deliquescent from its great attraction for moisture. In consequence of the same property, a portion of it is evaporated with the water in which it is dissolved, when exposed to a boiling heat. It is decomposable by heat, the acid being expelled.

By the analysis of Kirwan, its composition is 34.59 acid, 31.7 base, and 34.34 water. By Wenzel's, 57 acid, and 43 base. The atom of muriatic acid being 22, we have

$\frac{22 + 17}{22} = \frac{100}{56.4}$, the acid is therefore 56.4, and 43.6 baſe. The acid and baſe of Kirwan's analyſis, reduced to the 100, will be 52 acid, and 48 baſe.

Hyperoxymuriat of Magneſia.—When the oxymuriatic acid gas is paſſed through a mixture of water and magneſia, we do not obtain an oxymuriat, but the common muriat mixed with the hyperoxymuriat. This ſalt has ſimilar properties to thoſe of the hyperoxymuriat of lime, the ſubſtance at preſent in uſe for bleaching.

Phoſphat of Magneſia.—This ſalt may be formed by directly adding the baſe to the acid, as in the muriat of magneſia; or it may be formed more perfectly, by adding a ſolution of ſulphat of magneſia to a ſolution of an equal weight of phoſphat of ſoda. In a few hours, the ſalt in queſtion will appear in beautiful tranſparent cryſtals.

Theſe cryſtals are in the ſhape of hexagonal priſms, ſoluble in 15 parts of water at 60. It has but little taſte. When expoſed to dry air, it ſoon loſes its water of cryſtallization, and aſſumes the ſtate of white powder. It is not decompoſed by heat, but melts and becomes vitreous.

A compound ſalt, denominated the *phoſphat of magneſia* and *ammonia*, has been found by Fourcroy in the calculous concretions found in the colon of the horſe.

It may be prepared by mixing ſolutions of the two ſalts together. A ſalt of difficult ſolubility is precipitated. This ſalt is found to be an ingredient of urine, and will appear in cryſtals, when that fluid is expoſed in cloſe veſſels for ſome time. It is partly from this ſalt that phoſphorus is obtained by the diſtillation of urine. The ammonia is given out, leaving the phoſphoric acid, which is deprived of its oxygen by the carbonaceous matter of the urine.

According to the analyſes of Fourcroy and Vauquelin, it is compoſed of 33 phoſphat of ammonia, 33 phoſphat of magneſia, and 33 water.

Fluat of Magneſia.—When magneſia is added to the fluoric acid, by a little at once, it is for ſome time diſſolved, but as it approaches ſaturation, it falls down in the ſtate of white powder. This ſhews that the ſalt is ſoluble in exceſs of acid. In its neutral ſtate, it is inſoluble in water. No analyſis has been given of this ſalt. It ought, however, to be compoſed in the neutral ſtate, of 15 acid to 17 acid, or by the 100 it will be $\frac{15 + 17}{15} = \frac{100}{47}$, or 47 acid and 53 baſe.

Borat of Magneſia.—This ſalt may be formed by diſſolving magneſia in boracic acid. It affords cryſtals by evaporation. It diſſolves ſparingly in water, and is ſoluble in acetic acid. Alcohol is ſaid to diſſolve the boracic acid from it, while the earth falls down. This ſalt is found native in Germany. It has the property of becoming electrical by heat; the truncated angles being plus, and the oppoſite ones minus.

Carbonat of Magneſia.—This ſalt may be formed by adding a ſolution of carbonat of potaſh to ſulphat of magneſia. A white powder is precipitated, which, when waſhed and dried, conſtitutes the magneſia uſed in medicine. (See Carbonat *of Magneſia.*) It is ſlightly ſoluble in water, at leaſt more ſo than the earth itſelf. If, however, the ſupercarbonat of potaſh be added to the ſolution of ſulphat of magneſia, a ſupercarbonat of magneſia will be formed, which is more ſoluble and capable of cryſtallization by evaporation, their form being that of hexagonal priſms. It is ſaid to be ſoluble in 48 parts of cold water, but leſs ſoluble in hot water. It is, however, in all likelihood much more ſoluble when it is firſt formed, or when the decompoſition of the ſulphat takes place by the ſupercarbonat of potaſh. There appears much inconſiſtency in the analyſis by different chemiſts. The carbonat by theory ſhould conſiſt of 19.4 acid, to 17 baſe, or in the 100, 53.3 acid, and 46.7 baſe. The ſupercarbonat conſiſts of 2 × 19.4 acid, and 17 baſe. In the 100, 69.5 acid, and 30.5 magneſia.

Acetat of Magneſia.—This ſalt may be directly formed, by diſſolving magneſia in the acetic acid. It does not cryſtallize when evaporated to dryneſs, it ſoon attracts moiſture from the air. It is very ſoluble both in water and alcohol.

Its component parts, according to Richter, are 70.65 acid, and 29.35 baſe.

Oxalat of Magneſia.—This ſalt is nearly inſoluble in water as well as alcohol.

Tartrat of Magneſia.—The tartaric acid diſſolves magneſia, forming a ſalt which cryſtallizes in needles.

Citrat of Magneſia.—This ſalt may be formed like the laſt, by adding the baſe to the acid. It does not afford cryſtals. It is compoſed of 66.66 acid, and 33.34 baſe.

Malat of Magneſia is a deliqueſcent ſalt.

Camphorat of Magneſia.—When magneſia is boiled with cryſtals of camphoric acid in water, they unite, forming a ſalt, which, on evaporation and cooling, falls down in ſmall ſcales. The reſt of the magneſian ſalts are not known to be of any importance.

Magnesia *Alba*, P. L. 1787, *Magneſiæ Carbonas*, or *Carbonate of Magneſia*, in the *Materia Medica*, a fine white powder, which formerly at Rome bore the name of the Count of Palma; though many are of opinion, that the preparation was carried from Germany into Italy. It was, however, for ſeveral years, a celebrated ſecret, in poſſeſſion of ſome particular perſons, till the method of preparing it was made public by Lanciſi in the year 1717, and afterwards by Hoffman in 1722. It was then extracted from the mother-ley, or the liquor which remains after the cryſtallization of rough nitre; either by precipitation with a ſolution of fixed alkaline ſalt, or by evaporating the liquor, and calcining the dry reſiduum, ſo as to diſſipate the acids by which the earth had been made diſſoluble. As quick-lime is commonly much employed in moſt of the German, French, and other European nitre-works, the ſubſtance obtained from the mother-leys of thoſe works is rather a calcareous earth than magneſia, and appears to be ſuch by its burning into quick-lime, and forming a ſelenites with the vitriolic acid. Magneſia was called the *miraculum chemicum*, becauſe from two pellucid liquors a coagulum is formed, which contains this ſubſtance.

From the experiments of Dr. Black, related in the Edinburgh Phyſ. and Lit. Eſſ. vol. ii. art. 8. we learn, that magneſia is ſoluble, with effervеſcence, in vitriolic, nitrous, marine, and acetous acids; forming, with the vitriolic acid, cryſtals ſimilar to thoſe of the Epſom ſalt, and with the nitrous acids, cryſtals which deliquated in a moiſt air: with marine acid it formed no cryſtals; but the ſaline matter being evaporated to dryneſs, ſoon deliquated by expoſure to air: with diſtilled vinegar it formed no cryſtals by evaporation, but a ſaline maſs, viſcid when warm, reſembling glue in colour and conſiſtence, and brittle when cold. Magneſia was found to loſe, by calcination, ſeven-twelfths of its weight, and was thus deprived of the power of effervеſcing with acids; whence the ſubſtance loſt by calcination was gas, or fixable air: nevertheleſs this gas, and almoſt the whole weight loſt by calcination, were reſtored to it by ſolution in vitriolic acid, and precipitation from them by a mild fixed alkali, the gas of which it abſorbed: in this laſt re-

ſpect

fpect it feemed analogous to the calcareous earths, but differed from them in other properties; particularly in thefe, that when calcined, it was not foluble in water, nor communicated any fenfible impregnation to it, and that it did not, like them, when calcined, become cauftic or acrid.

Dr. Black alfo found, that magnefia was precipitated from acids by volatile alkali; that, when uncalcined, it precipitated calcareous earth from acids; but when calcined, or in any other way deprived of its gas, it did not precipitate thefe earths: when uncalcined or united with gas, it precipitated lime from lime-water; which fhews that the calcareous earth had a ftronger power to combine with the gas, than the magnefia had, fince the former earth took this gas from the latter; by which means the former was rendered mild and unfoluble in water, and therefore was precipitated. This property fuggefted to Dr. Allton a method of procuring fweet water at fea, by adding magnefia to water, the putrefaction of which has been prevented by the previous addition of quick-lime. M. Monnet obferves, that magnefia, combined with fulphur, generally invelopes ftrata of coal: M. Margraaf has difcovered that the ferpentine earths in Saxony contain magnefia: and M. Monnet adds, that the marly and alfo the alum earths contain it.

The directions for preparing it, given in the laft London Pharmacopeia, are as follow: Take of fulphat of magnefia, fubcarbonat of potafs, of each a pound, and water three gallons. Diffolve the fubcarbonat of potafs in three pints of the water, and ftrain; diffolve alfo the fulphat of magnefia feparately in five pints of the water, and ftrain: then add the reft of the water to the latter folution; apply heat, and when it boils, pour in the former folution, ftirring them well together; next ftrain through a linen cloth; laftly, wafh the powder repeatedly with boiling water, and dry it upon bibulous paper in a heat of 200°. The double decompofition of the falts ufed in this procefs yields carbonat of magnefia and fulphat of potafs, the firft of which it is the object to collect as free as poffible from the laft. Hence, as the newly formed fulphat of potafs requires a large proportion of water for its folution, fuch a proportion is directed in the firft inftance, and it is afterwards well wafhed with more. If water be impregnated with carbonic acid gas, it will diffolve carbonat of magnefia; and hence the liquor is made to boil, for the purpofe of detaching it. If the two folutions be mixed cold, and the precipitate left for fome days upon the filter without artificial drying, many large and perfect cryftals of carbonat of magnefia will be formed in it. The fubfequent heat, by which the powder is dried, fhould not be great enough to detach any of the carbonic acid. The prefent procefs will yield a pure and elegant preparation: its form is that of a white powder, eafily friable, and, according to Fourcroy, if the bafe be fully faturated with carbonic acid, as in the cryftals, (for in its ordinary form it is a fubcarbonat,) 100 parts contain of carbonic acid 50, of magnefia 25, of water 25; and if not fo faturated, but in its ftate of fub-falt, of carbonic acid 48, of magnefia 40, and of water 12. In commerce, the muriat of magnefia contained in the refiduary liquor, after the cryftallization of muriat of foda from fea-water, is decompofed by a fimilar procefs, and yields a large proportion of the ordinary magnefia of the markets. The dofe of carbonat of magnefia to adults is from ʒß to ʒii, and of fulphat from ʒi to ℥i. See CARBONAT *of Magnefia*, and the preceding article.

Mr. Henry, an ingenious apothecary at Manchefter, has communicated the following procefs for making the magnefia. Diffolve any quantity of fal catharticus amarus in its own weight of water; filter and add to it by degrees a filtered folution of pearl or pot-afhes, in an equal quantity of water, ftirring them gently, until the mixed liquors have acquired the appearance of a complete coagulum; then defift from adding any more of the alkaline lixivium, and immediately throw the mixture into a large veffel of boiling water; keep it boiling for a quarter of an hour, then take it out, and put it into glazed earthen veffels; as foon as the powder hath fubfided, and before the water is quite cold, pour it off, and add a frefh quantity of boiling water: repeat thefe ablutions with hot water feveral times, till the liquor hath entirely loft its faline tafte: then let it be fo agitated as to fufpend the finer parts of the powder, in which ftate decant it into other veffels, and having feparated the water from the magnefia, by inclination, put it on large chalk-ftones, till a confiderable part of the humidity is abforbed; then wrap it up in fheets of white paper, and dry it before the fire. Pour hot water upon the remaining powder, ftir and decant it in its turbid ftate, and feparate the magnefia from the water as before: thus the whole, or moft of it, will be reduced to an equal degree of finenefs. The larger the quantity of water into which the precipitated powder is caft, the more fpeedily and perfectly will the vitriolated tartar, which is formed by the union of the alkali with the acid of the fal. cath. be wafhed off. The neutral falt fhould be wafhed off as quickly as poffible; otherwife, by allowing the mixture to ftand for fome time, the powder concretes into minute grains, which, when viewed with a microfcope, appear to be affemblages of needles diverging from a point. Thefe concretions cannot be re-diffolved by any wafhing, however long continued. Dr. Black orders four times the quantity of water to that of the folution for throwing the coagulum into; but Mr. Henry obferves, that this quantity is much too little. The water fhould be pure, and diftilled water is the beft, provided it be kept till its empyreuma is gone off. Hard or impure water makes magnefia coarfe and difagreeable. The chalk-ftones on which the magnefia is dried fhould be expofed to a moderate heat, that the moifture may evaporate quickly: and cleanlinefs fhould be particularly attended to through the whole procefs.

The magnefia is recommended by Hoffman, as an ufeful antacid, a fafe and inoffenfive laxative in dofes of a dram or two, and a diaphoretic and diuretic, when given in fmaller dofes of fifteen or twenty grains. It is now much in ufe, particularly in heart-burns, for correcting acidities in the primæ viæ, and for preventing or removing the many diforders to which children are fubject on this account. It is preferred to all common abforbents, on account of its laxative quality, which it manifefts when it meets with an acid in the ftomach and bowels. If it is mixed with rhubarb, it prevents the rhubarb from leaving a coftivenefs behind. If the magnefia is neither accompanied, nor met with by an acid, it is not purgative, but fimply abforbent.

Objection has been made to the ufe of magnefia by Hoffman and others, that it frequently produced flatulencies, gripings, and other uneafy fenfations, particularly in weak bowels. It is now well known, that thefe fymptoms muft have been produced by the great quantity of fixed air contained in it, and difcharged from it in confequence of its meeting and effervefcing with an acid in the ftomach or inteftines. Dr. Percival, therefore, fuggefted to Mr. Henry the idea of depriving it of its air, with a view of obviating thefe troublefome fymptoms occafionally attending the ufe of it. For this purpofe the magnefia fhould be calcined by putting it in a common crucible, placing it in a glowing fire, and keeping it red-hot for the fpace of two hours. The magnefia thus treated was found to be equally purgative,

tive, when given in half its former dofe, and is deprived, by this procefs, of the difagreeable qualities above mentioned, and acquires likewife new properties, which render it likely to anfwer fome other important practical purpofe. By calcination it is not only rendered incapable of generating air in the ftomach and bowels, but it is qualified to abforb, or render fixed, that which it finds there, and which is produced, fometimes in too great quantities, in the procefs of digeftion; and it is confequently adapted to relieve thofe colics or other diforders, which are commonly called flatulent. In this refpect it promifes, as Mr. Henry obferves, to be much more efficacious than the whole tribe of carminatives, from which it effentially differs with regard to its mode of operation and effects. It appears likewife to be the moft proper cathartic for patients afflicted with the ftone, who are under a courfe of the foap-ley; as it cannot, like the vegetable purgatives, counteract the lixivium, by throwing air into it; but, on the contrary, muft abforb a part of that air, which is already in the primæ viæ, and which would otherwife be attracted by the cauftic alkali, and render it lefs capable of acting on the calculus. In order to produce thefe effects, it is of great importance that the magnefia, intended for calcination, fhould be perfectly free from any admixture of calcareous earth; as in that procefs, this laft mentioned fubftance muft neceffarily be deprived of its air, or rendered cauftic; and the magnefia which contains it will accordingly impregnate the water in which it is infufed with the tafte and qualities of lime-water. Mr. Glafs's magnefia, which has been fo highly extolled, appears, by Mr. Henry's experiments, to contain no inconfiderable portion of calcareous earth. Lond. Med. Tranf. vol. ii. art. 16. Henry's Exp. and Obf. 1773.

Magnesia *Nigra*, in *Chemiftry*. See Manganese.

Magnesia, *Opalina*, *Opalin*, or ruby-coloured magnefia of antimony, is made, according to the directions of Lemery, of equal parts of antimony, nitre, and decrepitated fea-falt. It is a much weaker emetic than the liver of antimony.

Magnesia *Ufta*, P. L. 1787. *Magnefia*, in the *Materia Medica*, is prepared by burning four ounces of carbonat of magnefia in a very ftrong fire, for two hours, or until acetic acid, being dropped in, extricates no bubbles of gas. Here it may be noted that a definite quantity has been prefcribed merely for the fake of precifion, and not as influencing the quality of the product. This preparation was the "magnefia ufta" of the former Pharmacopeia; but as the term "magnefia" is correctly ufed to exprefs only the pure earth, fo it has been thought proper to apply it decidedly in the prefent inftance, although in common language, the fame term may be moft generally applied to the carbonat, and the epithet *calcined* added to exprefs the prefent preparation. The procefs depends upon the expulfion of the carbonic acid of the carbonat by heat, and in the form of gas, and hence the carbonat yields about half its weight, or rather 7,ths of the pure magnefia. It may be confidered as infoluble in water; for Kirwan ftates 7900 times its weight to be neceffary for this purpofe at 60. The dofe of magnefia for adults is from ʒß to ʒj.

Magnesia, in *Ancient Geography*, a province fituated on a peninfula E. of Theffaly, and S.E. of Macedonia; which fome geographers have annexed to the former country, and others have defcribed as part of the latter. Strabo and Pliny place this province in Macedonia, and in their time the Romans had annexed it to this country: but before the kings of Macedonia had extended their conquefts beyond mount Olympus, Magnefia was reckoned a portion of Theffaly. It had been denominated Æneonia and alfo Magnes campus. The peninfula on which it was fituated bounded on the S.W. the Sinus Pelafgiacus, the entrance of which formed a ftrait, having on the N.E. the Æantium promontorium in Magnefia, and to the S.W. the Antron in Phthiotis. Magnefia extended as far as mount Offa, and as fome fay, to the valley of Tempé; and M. d'Anville places to the N.W. of it, the country called Pelafgiotis. In Magnefia were found the following towns, *viz.* Magnefia, Phera now Sidero, Jerufat or Fanifar, Melibœa parva, Ileos, Demetrias now Demetriada, Pagafæ, and Tempe Theffala. Its mountains were Offa now Coffovo, and Pelion, and its promontories were thofe of Magnefia and Sepias.

Magnesia, the capital of the above province, fituated on the eaftern coaft, at the bottom of a fmall gulf.

Magnesia *ad Mæandrum*, a town of Afia Minor, in Ionia, on the northern bank of the Mæander; 15 miles S.E. of Ephefus. This, according to Diodorus Siculus, was one of thofe towns given by Artaxerxes to Themiftocles. According to Pliny, this town was a colony of Magnefians of Theffaly, united with the Cretans. The Turks call it "Guzel-Hifar," or the beautiful caftle.

Magnesia *ad Sipylum*, or *Magnefia Sipyli*, a town of Afia Minor, in Lydia, at the foot of mount Sipylus, S. of the confluence of the rivers Hyllus or Phrygius, and the Hæmus. The victory obtained by the Romans over Antiochus, near this city, rendered it famous. Strabo fays, that under the reign of Tiberius, it was deftroyed by an earthquake. Near it was a beautiful plain of the fame name, at the foot of mount Sipylus.

MAGNESITE. *Native Magnefia; Native Talc Earth*, Jam.; *Reine* or *Natürliche Talk-erde*, Wern.; *Magnefit*, Karften; *Magnéfie native*, Broch.; *Magnéfite de Mitchell*, Brongn.; *Magnefie carbonatée*, Haüy.

The following defcription is derived from the original native magnefia of Dr. Mitchell, and that of Piemont defcribed by Giobert. All the others we find mentioned by authors are dubious.

Colour yellowifh-grey, or a dirty-yellowifh white, that of Piemont blueifh-white before it has been much expofed to the air; that of Moravia is marked with blackifh-brown ftains, penetrating from the furface into the interior, as alfo marbled with grey and blueifh grey fpots.

It is always found maffive, generally in rounded pieces, fometimes of the fize of a man's head, and of earthy afpect: thefe pieces are fometimes found with fiffures, but not with rounded cells.

Its hardnefs variable; in its more compact ftate the Moravian variety fcratches calcareous fpar, but is fcratched by fluor fpar; the moft compact Piedmontefe varieties are ftill harder. It is alfo found in a friable ftate, when it foils the fingers.

Fracture flat conchoidal, approaching to even; dull.

Its tenacity is inconfiderable, efpecially in thofe varieties that contain no filica.

Fragments indeterminately angular, more or lefs fharp-edged.

It is generally perfectly opaque; fometimes very thin fragments are tranflucent at the edges.

It is fcarcely at all unctuous to the feel. It adheres to the tongue.

Specific gravity of the whitifh variety from Moravia, when penetrated by water, 2.881, and when not thoroughly faturated with it, 2.456; Haberle.

Magnefite is perfectly infufible before the blowpipe. In a ftrong heat it lofes its carbonic acid, contracts and acquires a fufficient a fufficient degree of hardnefs to fcratch glafs. It diffolves with effervefcence in concentrated acids; but Giobert informs us that the variety of Caftellamonte contains no carbonic acid when in the bofom of the earth; whence, as in all other refpects it is like the magnefia from Baudiffero, he is of opinion that alfo the latter is originally deftitute of carbonic acid, and that it only contains it, when, after a long expofure to contact with the air, it can abforb it from the atmofphere.

The following are the refults of the analyfes that have been lately given of the different varieties of this fubftance. Thofe of Hrubfchitz, in Moravia, according to the experiments of the accurate Bucholz, contain

Variety I.

Magnefia	-	0.48
Carbonic acid		0.52
		100

Variety II.

Magnefia	-	46.59
Carbonic acid		51.
Alumine	-	1.
Oxyd of iron and manganefe		0.25
Lime	-	0.16
Water	-	1.
		100.

Variety III.

Magnefia	-	45.42
Carbonic acid		47.
Silica	-	4.50
Water	-	2.
Alumine	-	0.50
Oxyd of iron and manganefe		0.50
Lime	-	0.08
		100. Ann. de Chem. tome 74.

The analyfes that were firft given by Mitchell, Lampadius, and Klaproth, of the Moravian magnefite, agree pretty exactly with thofe of Bucholz, but they all differ confiderably from that publifhed by Wondrafcheck, who obtained magnefia 33, carbonic acid 30, filica 8, lime 0.5, manganefe and iron 1 5, water 20, lofs 7.

Giobert and Guyton's analyfes of the Piemontefe magnefite again offer different refults. That of Baudiffero contained in hundred parts

Magnefia	-	68.
Carbonic acid		12.
Silica	-	15.6
Sulphate of lime		1.6
Water	-	3.
		100.2 Giobert.

And that of Caftellamonte

Magnefia	-	26.5
Carbonic acid		46.
Silica	-	14.2
Water	-	12.
Lofs	-	1.5
		100. Guyton.

The two known localities of magnefite are Hrubfhitz diftrict of Gromau, in Moravia; and Baudiffero and Caftellamonte, villages in the vicinity of Turin. The Moravian variety was brought by Dr. Mitchell from Vienna, and prefented to Werner, who gave it its prefent place in the fyftem. The Piemontefe varieties paffed a long time for pure alumine, till Giobert difcovered their true nature.

The geognoftic fituation of this foffil in either of the above countries, is nearly the fame. At Hrubfhitz it is found in a bed of decompofing ferpentine; accompanied with common and earthy talc, meerfchaum, and magnefian limeftone. That of Turin occurs in a fimilar ferpentine rock, accompanied, according to Giobert, by hornftone in decompofition, to which latter this chemift is inclined to afcribe the origin of the magnefite.

According to Giobert, the magnefite of Baudiffero forms an excellent porcelain with filex. He alfo made crucibles and capfules of it, having added fome of the argillaceous earth of Caftellamonte, fufficient to unite it into a pafte. The crucibles were expofed for 48 hours in the furnace of a glafs houfe; the earths did not appear to have formed a fufficient union; neverthelefs, the hardnefs of the crucibles was fuch that they could not be affected by the file.

It may alfo be employed with advantage for producing fulphat of magnefia by means of fulphat of iron, which likewife abounds in the fame places of Piemont.

MAGNET, Magnes, the *Loadftone;* a fort of ferruginous ftone, in weight and colour refembling iron ore, hard, fo as juft to afford fparks when ftruck with fteel, and heavy; endued with divers extraordinary properties, attractive, directive, inclinatory, &c.

The magnet is alfo called *lapis Heracleus*, from Heraclea, a city of Magnefia, a part of the ancient Lydia, where it is faid to have been firft found, and from which it is ufually fuppofed to have taken its name. Though others derive the word from a fhepherd named *Magnes*, who firft difcovered it with the iron of his crook on mount Ida. It is alfo called *lapis nauticus*, by reafon of its ufe in navigation; and *fiderites*, from its attracting iron, which the Greeks called σιδηρος.

The magnet is indeed a true iron ore, from which a confiderable portion of iron may be extracted, and is ufually found in iron mines, and fometimes in very large pieces, half magnet, half common ore. This fpecies of iron ore contains a greater quantity of iron, either in the metallic ftate, or not much oxygenated, than moft other ores. Neverthelefs, though every magnet feems to contain fome iron in a metallic ftate, it does not follow that every kind of ore, which contains iron in that ftate, is magnetic: many iron ores having been found, which had the appearance of being good magnets, and yet were not poffeffed of the magnetic properties. The natural magnets often contain, befides particles of iron, a portion of quartz and argil, and probably fome fulphur; whence they have, when made red hot, a fulphureous fmell; and alfo fome other fubftances. Magnets differ with regard to their fpecific gravity, according to the nature and proportion of the other ingredients which are

 mixed

mixed with the iron or martial part; but they are generally about seven times heavier than distilled water. The colour of the magnet is different, white, blue, red, black, but mostly ferruginous, or a dull brownish-black, according to the different countries it is brought from, the admixture of heterogeneous substances, and the state of the iron contained in them. Norman observes, that the best are those brought from China and Bengal, which are of an irony or sanguine colour; those of Arabia are reddish; those of Macedonia blackish; and those of Hungary, Germany, England, &c. of the colour of unwrought iron. Neither its figure nor bulk is determined, but it is found of all forms and sizes.

It has been observed, that, in general, those magnets which have a fine close grain, are more powerfully magnetic, and retain the virtue much longer than those that are of a coarser grain; and even longer than the artificial magnets which are made of steel.

The ancients reckoned five kinds of magnets, different in colour and virtue; the Ethiopic, Magnesian, Bœotic, Alexandrian, and Natolian. They also took it to be of two kinds, male and female; but the chief use they made of it was in medicine; especially for the cure of burns, and defluxions on the eyes. The moderns, more enlightened and happy, take it to conduct them in their voyages.

As the properties possessed by the natural magnet may be communicated to iron, steel, and other ferruginous substances, these bodies, after having acquired the magnetical properties, are called *Artificial* MAGNETS; which see.

The most distinguishing properties of the magnet, whether natural or artificial, are, that it attracts iron, and other ferruginous substances, thus serving the purposes of the chemist in discovering or separating small particles of iron, mixed with other matters; and that it points towards the poles of the world; that it is endued in certain cases with attractive and repelling powers; and in other circumstances, also dips or inclines to a point beneath the horizon, directly under the pole; and that it communicates these properties, by proper methods, to iron, steel, and other ferruginous substances. On which foundation are formed the mariner's needles; both the horizontal, and the inclinatory, or dipping-needles.

MAGNET, *the attractive Power of the* was known to the ancients, and is mentioned even by Homer, Pythagoras, Aristotle, and by Plato and Euripides, who call it the *Herculean stone*; because it commands iron, which subdues every thing else. The Jews were acquainted with it. This property is finely described by Pliny: "Quid lapidis rigore pigrius? Ecce sensus manusque tribuit illi. Quid ferri duritia pugnacius? Sed cedit, et patitur mores: trahitur namque a magnete lapide, domitrixque illa rerum omnium materia ad inane nescio quid currit; atque ut propius venit, assilit teneturque, complexuque hæret." Lib. xxxvi. cap. 16.

The ancients seem also to have been acquainted with the communicative virtue of the magnet. Plato has described a chain of iron rings suspended by one another, the first of which is sustained by the load-stone: Lucretius, Philo, Pliny, Galen, and Nemesius, have likewise described the same phenomenon; but the knowledge of its directive power, whereby it disposes its poles along the meridian of every place, and occasions needles, pieces of iron, &c. touched with it, to point nearly north and south, is of a much later date; though the exact time of its discovery, and the discoverer himself, are yet in the dark. The first tidings we hear of it are erroneously referred to the year 1260, when Marco Polo, the Venetian, is said by some to have introduced the mariner's compass (see COMPASS); though not as an invention of his own, but as derived from the Chinese, who are said to have had the use of it long before; though some imagine that the Chinese before that had borrowed it from the Europeans. Flavio de Gioia, a Neapolitan, and a citizen of Amalfi, is the person usually supposed to have the best title to the discovery, about the year 1302, and he, if not the inventor, was the first who used it for the guidance of vessels in the Mediterranean; and yet sir G. Wheeler mentions that he had seen a book of astronomy much older, which spoke of the use of the needle: though not as applied to the uses of navigation, but of astronomy. And in Guyot de Provins, an old French poet, who wrote about the year 1180, there is express mention made of the load-stone and the compass, and their use in navigation is obliquely hinted at. The Spanish Jesuit Pineda and Kircher affirm, that Solomon knew the use of the compass, and that his subjects did actually use it in their navigation. See COMPASS, *Mariner's*.

It appears from a Latin letter, written by Peter Adsiger, on the description of the nature of a magnet, and dated in 1269, from which Mr. Cavallo has made copious extracts in his "Treatise on Magnetism," 1800, that most of the properties of the magnet, with which we are now acquainted, were known in his time; though they were not applied to the same useful purposes. From these extracts we learn that the laws of magnetic attraction, and of the communication of that power to iron, the directive property of the natural magnet, as well as of the iron that has been touched by it, and even the declination of the magnetic needle, were particularly described by Adsiger with a view to the instruction of a friend. See *Mariner's* COMPASS.

MAGNET, *Variation of the*, or its declination from the pole, is said to have been first discovered by Seb. Cabot, a Venetian, in 1500, who first served our king Henry VII. then the king of Spain, and lastly returning to England, was constituted grand pilot by king Edward VI. with an annual salary of above 160*l.*; though Ferdinand, the son of Columbus, asserts that his father observed it on the 14th of September, 1492: and the variation of that variation by Mr. Gellibrand, an Englishman, who published his discovery in a small quarto pamphlet, intitled "A Discourse Mathematical on the Variation of the Magnetic Needle," printed in 1635. See the preceding article, and DECLINATION.

Lastly, the dip or inclination of the needle, when at liberty to play vertically, to a point beneath the horizon, was first discovered by another of our countrymen, Mr. R. Norman, who, in 1581, published the discovery he had long before made, in a small pamphlet, called the "New Attractive," where he shews how to determine its quantity. See DIPPING and DIPPING-*needle*.

MAGNET, *Phenomena of the*. 1. In every magnet there are at least two poles, one whereof points northward, the other southward; one of these is called the north pole, and the other the south, and that is called the north pole, which, if the magnet was put into a little boat of wood, or other materials large enough to support it, and set afloat in water, or so suspended by a thread, &c. as to be at liberty to move itself easily, would turn itself towards the north pole of the earth, or towards a point not much distant from it; and that is called the south pole which would turn, in similar circumstances, towards the south. The property itself is called the magnet's "directive power," or "magnetic polarity;" and when a magnetic body places itself in that direction, it is said to "traverse." A plane perpendicular to the horizon, and passing through the poles of a magnet when standing in their natural direction, is called the "magnetic meridian;" and the angle made by the magnetic meridian and the plane of the meridian of the place where the magnet stands, is called the "declination of the magnet," or more commonly the "declination

"declination of the magnetic needle;" becaufe the artificial magnets, commonly ufed for obferving this property, are generally made flender, and fomewhat in the fhape of a needle, or becaufe real fewing needles have been often ufed for this purpofe. The north pole of one magnet always attracts the fouth pole, when placed oppofite to one another, and repels the north-pole of another, and *vice verfà*. In fhort, magnetic poles of the fame name repel one another, whereas thofe of a different name attract one another. It is obferved that the poles of magnets are not at their extremities, but at a little diftance from thence; and if the magnet be divided into ever fo many pieces, the two poles will be found in each piece, and fometimes more than two; though each of the parts has not always the fame number of poles. The poles of the fragments generally, but not always, anfwer to the poles which were neareft to them in the original magnet. We may add, that in fome natural magnets there are more than two poles, inftances having occurred of fome in which there are eight, nine, and even ten. M. Mufchenbroek fays that he has feen a cube, each fide of which was polar. The figure, and alfo the heterogeneous nature of the magnets, are the principal caufes of their having often more than two poles. In order to determine the number and fituation of the poles in a magnet, let the various parts of its furface be prefented to one of the poles of another magnet that is freely fufpended; then thofe parts of the magnet which repel the other that is fufpended, have the fame polarity, and thofe which attract it have a different polarity. *E. G.* If the magnet be prefented to the north pole of the other fufpended magnet, then thofe parts of the former which repel the latter are poffeffed of a north polarity, and thofe which attract it are poffeffed of a fouth polarity.

By the following method alfo, the fituation of the poles, and the direction of the (fuppofed) magnetic effluvia in paffing out of the ftone, may be exhibited to the fight: let A B, C D, (*Plate* VI. *Magnetifm*, *fig.* 1.) be the poles of the ftone; about every fide gently ftrew fome iron or fteel-filings on a fheet of white paper; thefe fmall particles will be affected by the effluvia of the ftone, and fo difpofed as to fhew the courfe and direction of the magnetic particles in every part. Thus, in the middle of each pole between A B and D C, it appears to go nearly ftraight on; towards the fides it proceeds in lines more and more curved, till at laft the curve lines from both poles exactly meeting and coinciding form numberlefs curves on each fide, nearly of a circular figure, as reprefented in the diagram.

A fmall artificial magnet may be ufed in this experiment inftead of the real magnet, with a fimilar effect. If the table on which the paper refts receives a few gentle knocks, fo as to fhake the filings a little, they will the more readily difpofe themfelves round the magnetic bar; otherwife, the action of the magnet will not have power fufficient to difpofe properly thofe particles which lie at a confiderable diftance. This phenomenon, which has been obferved from time immemorial, has led various perfons to believe, that a certain fluid circulates from one of the poles of every magnet to the other, in confequence of which the iron or fteel-filings are thus arranged round the magnet. A little confideration will evince the abfurdity of this fuppofed circulation, becaufe if the fluid, of whatever nature it may be, did really circulate from one pole to the other, and had any action on the filings, thefe would be all driven toward that pole to which the moving fluid directed its courfe. The true caufe of the arrangement of the filings is, their becoming actually magnetic, and their two extremities being poffeffed of different polarities. Suppofe, firft, that only one oblong particle of iron be affixed to the various parts of the furface of the magnet, it is evident, from what has been already faid, that on the poles this particle of iron, A B, (*Plate* VI. *Magnetifm*, *fig.* 2.) would ftand perpendicular to the furface, becaufe its farther extremity B, having the fame polarity as the extremity, C, of the magnet, is equally repelled by it on every fide, and is far from the influence of the other extremity D; on the fides near to the poles the faid particle will ftand inclined, becaufe the fartheft pole of the magnet begins now to act upon it; and on the middle of the magnet the wire will lie quite clofe to it, or, if it be kept at fome diftance, will lie parallel to the magnet, becaufe the two poles of the magnet, being equidiftant from the extremities of the iron particle, have an equal action upon it. Now, when there are many particles of iron, *viz.* the filings, near the magnet, thofe particles which touch its furface are rendered magnetic, confequently they attract other particles, and thefe being made alfo magnetic, attract others, and fo on; forming ftrings of fmall magnets, which gradually decreafe in power as they recede from the magnet. As each of thefe particles has two magnetic poles, by a little confideration it will appear, that the fartheft ends of thofe ftrings or lines which proceed from the parts adjacent to one of the poles of the magnet, for inftance, the north, are likewife poffeffed of the north polarity, and the fartheft extremities of thofe ftrings which proceed from the parts adjacent to the fouth pole of the magnet, are poffeffed of the fouth polarity; hence, when they come fufficiently near, they attract the extremities of the former ftrings, and confequently form the curves delineated on the figure.

The fituation of the poles may be alfo determined by placing over the magnet a very fine needle, which will ftand perpendicular over each pole, being more ftrongly attracted by it, and no where elfe.

When a magnet that is freely fufpended, has only two poles, it will place itfelf very readily in the magnetic meridian, or in that place in which other good magnets are wont to place themfelves; but when it has more than two poles, it may happen that thefe poles are fo fituated, as that the magnet will not traverfe; that is, it will have no directive power, and yet it will attract, repel, &c.

Two circumftances deferve to be noticed with refpect to magnets that have more than two poles. One is, that the parts adjacent to one pole are poffeffed of a contrary polarity; and the other is, that the number of poles of one denomination in a magnet is either equal to, or differs from, the number of poles of the other denomination by one; thus, if the magnet has four fouth poles, then it will have either four, three, or five north poles. It is obferved, that good magnets of an uniform texture and proper form, have only two poles, and they lie in oppofite parts of their furfaces, fo that a line drawn from the one to the other paffes through the centre of the magnet. The polarity of a magnet, however, muft not be underftood to refide only in two points of it; for, in reality, it is the half, or a great part of the magnet that is poffeffed of one polarity, *i. e.* has the property of repelling the contrary pole of another magnet; and the reft of the magnet is poffeffed of the other polarity; the poles being, therefore, thofe points in which that power is the ftrongeft.

In magnets, fuch as we have juft defcribed, the line between the two poles is called the "axis;" and a line formed all round the furface of the magnet by a plane, which divides the axis into two equal parts, and is perpendicular to it, is called the "equator of the magnet." Hence it appears, that philofophers have appropriated to the magnet the poles, the equator, the meridian, in imitation of the terraqueous globe; and to complete the fimilarity, magnets have been often

often made of a spherical shape, with the poles and the equator marked on their surfaces. When so shaped, they have been called "terrellas," *i. e.* small earths.

The poles. of any given magnetic body may be ascertained by presenting the various parts of its surface successively to one of the poles of a magnetic needle, and you will soon discover which parts of the given body are possessed of a contrary polarity, by the needle's standing perpendicularly towards them. Then present the various parts of the surface of the same body to the other pole of the needle, &c. The magnetic body, in this operation, should not be brought too near the needle, for fear of changing its polarity. The distance is various for producing such an effect, according to the strength of the magnetic body; so that it is impossible to state it; but the operator needs never mistake, if he keeps the magnetic body so far from the needle, as just to affect it sensibly.

2. These poles, in different parts of the globe, are differently inclined towards a point under the horizon. Thus, when a magnet is placed so as to be at liberty to move itself very easily, it generally inclines one of its poles towards the horizon, and of course it elevates the other above it. This property is called the "inclination" or "dipping" of the magnet, or more commonly of the "magnetic needle." See DIPPING.

3. These poles, though contrary to one another, do help mutually towards the magnet's attraction and suspension of iron.

4. If two magnets be spherical, one will turn or conform itself to the other, so as either of them would do to the earth; and after they have so conformed or turned themselves, they will endeavour to approach or join each other; but if placed in a contrary position, they will avoid each other. This property may be illustrated by placing two magnets on small pieces of wood, formed in the shape of boats, and swimming freely on stagnated water, undisturbed by wind, and at such a distance as to be within the sphere of each other's activity: both the boats will swim towards each other with an accelerated motion, and meet exactly in the middle of the distance between them, provided that the boats and magnets were exactly of the same weight and bulk: but if either boat be turned, so that its magnet may present a contrary end to that by which it was attracted by the other magnet, they will both recede from each other with an equal velocity. The same phenomenon may likewise be exhibited by suspending a magnet, C, from the end, B, of a balance (*Plate* VI. *Magnetism, fig.* 3), and forming an equilibrium with a weight in the scale A, place another magnet, D, under C, and C will be found to rush towards D, and to lift the weight in the scale A: but if the opposite end of D be presented to C, C will be repelled by it, ascend, and the scale, A, will descend: if D be placed above C, as in E, the effects will be just the contrary.

M. Muschenbroeck has found by a variety of experiments, that two magnets attract one another with different forces at different distances; that they act most strongly in mutual contact, in which case their force has been equal to the weight of three hundred and forty grains, but at the distance of twelve inches, equal only to twenty-three grains: nevertheless, they observe no regular proportion in their decrease, but the ratio is less than the inverse of their distances; and different in different magnets and at different times. There are some whose sphere of activity reaches even to fourteen feet, and others in which it is not sensible at the distance of eight or nine inches. He has also found, that the sphere of repulsion varies in different magnets, and at different distances; and that the repulsive force is much less than that of attraction; the latter in contact being equal to three hundred and forty grains, whereas the former is equal only to forty-four grains. It appears also from another experiment of the same author, that the repelling forces of both poles of the same magnet, are very considerable at the distance of twelve lines, being equal to thirty grains, that they increase to the distance only of seven lines, where they are equal to thirty-six, but that in immediate contact they are equal only to thirteen grains. Mr. Michell, however, differs much in his deductions from those abovementioned: he maintains, that each pole acts, attracts, or repels exactly equally, at equal distances in every direction; and that the magnetical attraction and repulsion are exactly equal to each other. He adds, that the mistake of those who think otherwise, arose from their not attending to the different degrees of strength, which magnets have in different circumstances: for two magnets that are placed with their attracting poles towards each other, will have their power, by that means, increased: and on the contrary, if their repelling poles be placed towards each other, their power will thereby be diminished: and this increase or diminution of power will be in a greater or less degree, according as the magnets are nearer to, or farther from, each other; whence in all the experiments made on this subject, the attraction and repulsion come perpetually nearer to an equality, the greater the distance of the two magnets is, with which the experiments are made, and *vice versâ.*

And so great is the effect of magnets on each other, that when the repellent poles of a large magnet and a small one are brought into contact, the small one shall sometimes have its repellency changed into attraction. Mr. Michell also infers from other experiments, that the attraction and repulsion of magnets decrease as the squares of the distances from the respective poles increase. The differences of opinion in this respect are ascribed by him to the want of making proper allowances for that property of magnets, in consequence of which they attract or repel equally at equal distances, together with the increase and diminution of power in the magnets with which the experiments were tried.

We shall here subjoin a few more observations on magnetic attraction and repulsion. If a piece of iron, or steel, or other ferruginous substance, be brought within a certain distance of one of the poles of a magnet, it is attracted by it so as to adhere to it with a considerable degree of force; and this attraction is mutual, the iron attracting the magnet as much as it is attracted by it; so that if they were placed on pieces of cork or wood and made to swim on water, the iron would be found to advance towards the magnet as well as the magnet towards the iron; and if the iron were kept steady, the magnet would move towards it. A smaller degree of attraction than that which is observed by means of water may be discovered by placing the given body to swim upon quicksilver, and by presenting the magnet to it; in which case it will move with surprising velocity. In this method the following particulars must be minded, *viz.* the aperture of the vessel, in which the quicksilver is kept, must be at least six inches in diameter; otherwise, as the surface of the quicksilver descends near the sides of the vessel, and that curvature is proportionably greater in narrow vessels than in larger ones, the floating body, when the quicksilver is kept in a vessel of three or four inches, will be perpetually running towards the sides. The quicksilver must be very pure; but, as it is very difficult to find it, or to preserve it pure, it must be frequently passed through a funnel of paper, *viz.* a piece of writing paper rolled up conically, and having a small aperture of about a fortieth of an inch in diameter; for, if the quickfilver be impure, the floating body will move with lefs facility upon it than upon water. The air about it muft not be difturbed much, in order to keep the body without motion; in which ftate one of the poles of a ftrong magnet is to be prefented on one fide of it, in the fame manner as when the experiment is tried on water, following the fame precautions. The force of magnetic attraction varies according to the ftrength of the magnet, the weight and fhape of the body prefented to it, the magnetic or unmagnetic virtue of that body, the diftance betweeen it and the magnet, and fome other circumftances. A piece of foft and clean iron is more powerfully attracted by a magnet than any other ferruginous body of fimilar fhape and weight. The iron ores are attracted more or lefs forcibly, as they contain a greater or lefs quantity of metallic particles, as that quantity is in a more or lefs perfect metallic ftate, and as it is of a fofter or harder nature; but all thefe, as well as hard iron and fteel, are lefs forcibly attracted than foft iron. By prefenting a piece of iron fucceffively to the different parts of the furface of a magnet, the attraction will be found ftrongeft at the poles of the magnet, or thofe points that are directed, when the magnet is freely fufpended, towards the north and fouth; it will be found to decreafe as the part towards which the iron is prefented recedes from the poles, and it will be very little, or not at all, perceptible about thofe parts of the furface which are equidiftant from the poles. The attraction, as we have already obferved, is moft powerful near the furface of the magnet, and is diminifhed in receding from it, fo that if a piece of iron be placed in contact with one of the poles of a magnet, it will require a certain degree of force to feparate them; at the diftance of an inch from the pole, the attractive power, though much diminifhed, will be perceptible; and at a greater diftance, it will be ftill weaker. However, the law of this diminution has not been fatisfactorily afcertained; fo that it is not known, whether it is twice, thrice, or any other number of times greater than at double that diftance. In fome cafes, the attraction has feemed to decreafe in the inverfe ratio of the diftances; but in others it has decreafed much fafter, or in different proportions at different diftances; and the only general conclufion that has been deduced from a variety of experiments is, that the decreafe of magnetic attraction is not flower than the inverfe ratio of the diftances, fo that at double the diftance it is half as ftrong, &c. In fome other experiments with magnetic needles, the attraction appeared to decreafe in the ratio of the cubes of the diftances. Mr. Whifton ftates, that the abfolute attractive power of different armed load-ftones is, *cæteris paribus*, according to the quantity, not of their diameters or folidities, but of their furfaces, or in a duplicate proportion of their diameters. Whereas, the power of good magnets unarmed, not fenfibly different in ftrength, fimilar in figure and pofition, but unequal in magnitude, is fometimes a little greater, fometimes a little lefs, than in the proportion of their fimilar diameters. He fays, that the load-ftone attracts needles that have been touched, and others that have not been touched, with equal force at unequal diftances; *viz.* where the diftances are to one another as five to two. According to his account, the attractive power of load-ftones, in their fimilar pofition to, but different diftances from, magnetic needles, is in the fefquiduplicate proportion of the diftances of their furfaces from their needles reciprocally; or as the mean proportionals between the fquares and the cubes of thofe diftances reciprocally; or as the fquare roots of the fifth powers of thofe diftances reciprocally. Thus the magnetic power of attraction, at twice the diftance from the furface of the load-ftone, is between a fifth and fixth part of that power at the firft diftance; at thrice the diftance, the power is between the fifteenth and fixteenth parts at four times the diftance, the power is thirty-two times as fmall; and at fix times the diftance, eighty-eight times as fmall. Where it is to be noted, that the diftances are not taken, as in the laws of gravity, from the centre; but from the furface: all experience affuring us, that the magnetic power refides chiefly, if not wholly, in the furfaces of the load-ftones and iron; without any particular relation to any centre at all. The proportion here laid down was determined by Mr. Whifton, from a great number of experiments of Mr. Haufkbee, Dr. Brook Taylor, and himfelf. The force they meafured by the chords of thofe arcs, by which the magnet, at feveral diftances, draws the needle out of its natural direction, to which chords (as he has demonftrated) it is ever proportional. The numbers in fome of their moft accurate trials he gives us in the following table; fetting down half the chords, or the fines of half thofe arcs of declination, as the true meafures of the power of magnetifm.

Diftance in Inches.	Degrees of Inclination.	Sines of half Arcs.	Rat. fefquidupl.
20	2	175	466
$14\frac{3}{5}$	4	349	216
13[illegible]	6	523	172
$12\frac{5}{6}$	8	697	138
$11\frac{1}{8}$	10	871	105
$10\frac{1}{4}$	12	1045	87
$9\frac{1}{4}$	14	1219	70

Sir Ifaac Newton fuppofes magnetic attraction to decreafe nearly in the triplicate ratio of the diftance. Mr. Martin obferves, that the power of his load-ftone decreafes in the fefquiduplicate ratio of the diftances inverfely. Dr. Helfham found it to be as the fquares of the diftances inverfely, which ratio agrees with that of the ingenious Mr. Michell; others, as Dr. Brook Taylor and Mr. Mufchenbroeck, are of opinion, that this power follows no certain ratio at all, but that it is much quicker at greater diftances than at fmall ones, and that it is different in different ftones. Mufchenbroeck has made the following experiments in relation to this fubject, and as they were accurately made, we fhall here annex them. Introd. Nat. Phil. c 19.

Exp. 1.—A cylindrical magnet, two inches long, and weighing 16 drams, was fufpended to one fcale of an accurate balance, and under it there was placed, upon a table, a cylinder of iron, which was exactly of the fame bulk and fhape. Things being thus prepared, the cylinder of iron was fucceffively placed at different diftances from the magnet, and at each diftance the degree of attraction between the iron and the magnet was afcertained by weights put in the oppofite fcale of the balance. The refults were as follows, *viz.*

Diftance in Inches.	Attractions in Grains.
6	3
5	$3\frac{1}{2}$
4	$4\frac{1}{2}$
3	6
2	9
1	18
0	57

Exp. 2.—A fpherical magnet, of the fame diameter as the cylindrical one ufed before, but of greater ftrength, was affixed to one of the fcales of the balance; and the cylindrical magnet, ufed in the preceding experiment, was placed upon the table, with its fouth pole upwards, and facing the north

north pole of the ſpherical magnet. In this diſpoſition of the apparatus, the attractions were found to be as follow:

Diſtance in Inches.	Attractions in Grains.
6	21
5	27
4	34
3	44
2	64
1	100
0	260

Exp. 3.—Inſtead of the cylindrical magnet, the cylinder of iron was placed upon the table, and under the globular magnet. The reſult was as follows:

Diſtance in Inches.	Attractions in Grains.
6	7
5	9½
4	15
3	25
2	45
1	92
0	340

Exp. 4.—Inſtead of the iron cylinder, a globe of iron of the ſame diameter as the ſpherical magnet was placed upon the table, and the attractions were found to be as follow:

Diſtance in Inches.	Attractions in Grains.
8	1
7	2
6	3½
5	6
4	9
3	16
2	30
1	64
0	290

From the ſecond and third experiments it appears, that, when in contact, a magnet attracts another magnet with leſs force than a piece of iron. This has been confirmed by many other experiments. But the attraction between two magnets begins from a greater diſtance than between the magnet and iron; hence it muſt follow a different law of decrement.

The attraction between a given magnet and a piece of iron, is ſubject to a variation ariſing from the weight and ſhape of the iron; there being a limit, in the weight and ſhape of the iron, in which the magnet will attract it more forcibly than either a greater or a ſmaller one: but this moſt advantageous weight and extenſion of the piece of iron can only be determined by actual experiment, it being various according to the various nature, ſtrength, and ſhape of the magnet, as well as of the iron.

Magnetic attraction takes place between the magnet and ſuch ferruginous bodies as were not magnetic before, or between the contrary poles of two magnets: but when two magnets are placed with their poles of the ſame name toward each other, then, inſtead of attracting, they repel each other. However, it often happens, that though the north pole of one magnet be placed near the north pole of another magnet, or the ſouth pole of the one be placed near the ſouth pole of the other, yet they attract each other: and ſometimes they ſhew no attraction nor repulſion.

In order to reconcile this apparent contradiction, it is neceſſary to mention firſt another phenomenon, which takes place whenever a piece of ferruginous ſubſtance is brought near a magnet; and which indeed is the foundation of, and ſerves to explain a great many, other appearances, otherwiſe unintelligible, in the ſcience of magnetiſm.

The phenomenon, in ſhort, is thus: when a piece of iron, or any other ſubſtance that contains iron, is brought within a certain diſtance of a magnet, it becomes itſelf a magnet, having the poles, the attractive power, and in ſhort every property of a real magnet. That part of it which is neareſt to the magnet acquires a contrary polarity: thus, if an oblong piece of iron, A B, be brought within a proper diſtance of a magnet, ſo that the extremity, A, of the iron may be oppoſite the north pole of the magnet, then this ſame extremity, A, will become a ſouth pole, and the other extremity, B, will become a north pole.

The magnetiſm acquired by being placed within the influence or the ſphere of activity of a magnet, in ſoft iron laſts only whilſt the iron continues in that ſituation, and when removed from the vicinity of the magnet, its magnetiſm vaniſhes immediately; but with hard iron, and eſpecially with ſteel, the caſe is quite different; for the harder the iron or the ſteel is, the more permanent is the magnetiſm which it acquires from the influence of a magnet; but it will be in the ſame proportion difficult to render it magnetic. If, for inſtance, a ſoft piece of iron and a piece of hard ſteel, both of the ſame ſhape and ſize, be brought within the influence of a magnet at the ſame diſtance, it will be found that the iron will appear much more magnetic than the ſteel; but if the magnet be removed, the ſoft iron will inſtantly loſe its magnetiſm, whereas the hard ſteel will preſerve it for a long time.

From theſe obſervations two conſequences are evidently deduced, *viz.* firſt, that there is no magnetic attraction but between the contrary poles of two magnets; for the iron, or other ferruginous body, that is preſented to the magnet, muſt become itſelf a magnet before it be attracted: and ſecondly, it appears why a magnet muſt attract a piece of ſoft iron more forcibly than hard iron, and much more than hard ſteel, *viz.* becauſe the hard iron, and more eſpecially the hard ſteel, does not become ſo ſtrongly magnetical as ſoft iron, when preſented to a magnet.

We may now reſume the ſubject of magnetic repulſion, and ſhew why the magnetic poles of the ſame name may repel, attract, or not act at all, upon one another.

Indeed, the law of repulſion being always exerted between magnetic poles of the ſame name, nearly as ſtrong as the attraction between thoſe of different name, remains certain and immutable; but it often happens, that one of the magnets, being more powerful than the other, will change the pole of that other magnet, in the ſame manner as it gives magnetiſm to any other piece of iron which is expoſed to its influence, and then an attraction will take place apparently between magnetic poles of the ſame names; though in fact it is an attraction between poles of different names, becauſe one of them has been actually changed. Thus, ſuppoſe that a powerful magnet be placed with its north pole very near the north pole of a weak magnet; it will be found, that inſtead of repelling, they will attract each other, becauſe that part of the weak magnet, which before was a north pole, has been changed into a ſouth pole by the action of the ſtrong magnet.

As thoſe bodies which are poſſeſſed of any magnetiſm cannot be very readily affected by the influence of another magnet, for the very ſame cauſe which renders them capable of retaining any magnetiſm at all, namely, the hardneſs; and, as the power of a magnet diminiſhes in proportion to the diſtances from its ſurface, it follows, that when the north or ſouth pole of a weak magnet is from a conſiderable diſtance, gradually brought near the like pole of a powerful

magnet,

magnet, the pole of the weak magnet cannot be changed very eaſily; hence, beyond a certain diſtance, *viz.* before the ſaid pole be changed, the two magnets muſt exert a repulſion againſt each other; but when the ſmall magnet has been brought ſo near the powerful one, as that its pole may begin to be changed, then neither an attraction nor a repulſion will take place; and when the two magnets are approached nearer than that limit, then, the pole of the weak one being changed, an attraction will enſue.

After theſe obſervations, the ingenious reader may eaſily imagine that the decreaſe of repulſion between homogeneous magnetic poles muſt be at leaſt as much, if not more irregular than the decreaſe of the attraction at different diſtances. It is likewiſe evident, that many objects muſt be had in view, in attempting to inveſtigate the law of that decreaſe.

5. If a magnet be cut through the axis, the parts or ſegments of the ſtone, which before were joined, will now avoid and fly each other. 6. If the magnet be cut by a ſection perpendicular to its axis, the two points which before were conjoined, will become contrary poles; one in one, the other in the other ſegment. 7. Iron is not only attracted by a magnet, even more than another magnet, and equally attracts it, but alſo receives virtue from the magnet by application to it, or barely from an approach near it, though it do not touch it; and the iron receives this virtue variouſly, according to the parts of the ſtone it is made to touch, or even but to approach to; the part of the iron or ſteel which is neareſt to the magnet acquiring the contrary polarity, &c. In order to communicate the magnetic virtue more effectually, the following methods are made uſe of: *viz.* it has been diſcovered, that iron rubbed upon one of the poles of the magnet acquires much greater virtue than from any other part of it; and this is more conſiderable from an armed magnet than from a naked one. Farther, the more gently the iron is preſſed, and the more it is preſſed againſt the pole, the more magnetical it becomes. Again, it is more convenient to impregnate iron on one pole, than on both ſides ſucceſſively; becauſe the iron receives magnetic virtue from each pole, in contrary directions, which deſtroy each other's effects. Moreover, the iron is much better impregnated by preſſing it uniformly and in the ſame direction, according to its length, than by rubbing it by the middle; and the extremity which touches the pole laſt, retains the greateſt virtue: it is alſo of importance, that the length of the iron be conſiderable. Beſides, a piece of poliſhed ſteel, or of pointed iron, receives more virtue than mere iron, or iron of the ſame figure: and, *cæteris paribus*, a piece of iron that is long, ſmall, and pointed, is more ſtrongly impregnated than that of any other form. 8. If an oblong piece of iron be any way applied to the ſtone, it receives virtue from it, only as to its length. 9. The magnet loſes none of its own virtue by communicating any to the iron, but has it rather improved; though this is doubted by Mr. Savery; and this virtue it can communicate to the iron very ſpeedily; though the longer the iron touches or joins the ſtone, the longer will its communicated virtue remain in it; and a better magnet will communicate more of it, and ſooner, than one not ſo good.

It is obvious that when the iron, ſteel, or any ferruginous body is applied in contact with the magnet, it acquires a ſtronger power than if it be placed at ſome diſtance from its ſurface. A magnet can never communicate a greater power than itſelf poſſeſſes, or even an equal degree of it; but ſeveral magnets, of nearly an equal degree of magnetiſm, when joined together, have a ſtronger power than one of them ſingly: hence, in order to impart a ſtrong magnetic power to a given body A, by means of a weak magnet B, we muſt firſt render ſeveral bodies, C, D, E, F, &c. weakly magnetic; and then, by properly joining C, D, E, F, &c. together, we may communicate to another body, or ſeveral other bodies, a ſtronger magnetiſm, till, at laſt, we ſhall be able to communicate to A the required degree of magnetic power.

The late Dr. Gowin Knight practiſed a method, which he never publiſhed, of communicating to iron a very conſiderable magnetic virtue, and alſo of increaſing that of feeble magnets. From a report delivered to the Royal Society in 1744, it appears that he had prepared a ſmall eight-corned bar of ſteel, three inches and almoſt $\frac{7}{10}$ths long, and about half an ounce troy in weight, which lifted by one of its ends about eleven of the ſame ounces; that another plain bar of ſteel, of a parallelopiped form, $5\frac{9}{10}$ inches long, $\frac{4}{10}$ths of an inch broad, and $\frac{2}{10}$ths of an inch thick, weighing 2 ounces $8\frac{1}{2}$ penny-weights, lifted, in like manner, by one of its ends, twenty troy ounces; that a ſteel bar, almoſt of the ſame form as the laſt, but only four inches in length, capped or armed with iron at each end, cramped with ſilver, and weighing all together one ounce fourteen penny-weights, lifted by the feet of the armour full four pounds troy; and that a ſingle block of ſteel, of a parallelopiped form, almoſt four inches long, $1\frac{2}{10}$ high, and $\frac{4}{10}$ths of an inch thick, armed with iron, cramped with braſs, and ſuſpended by a ring of the ſame, and weighing all together fourteen ounces one penny-weight, lifted by the feet of the armour 14 pounds $2\frac{1}{2}$ ounces troy weight. He alſo exhibited a compound artificial magnet, conſiſting of twelve bars of ſteel armed, which lifted by the feet of the armour, as the laſt, 23 troy pounds $2\frac{1}{2}$ ounces. At the ſame time he preſented before the Society a ſmall armed load-ſtone, which, with its armour, weighed ſeven penny-weights fourteen grains, and which could ſcarcely lift two ounces; but improved by his method, it ſuſtained ſix ounces eighteen penny-weights and three grains. See *Armed* MAGNET, and *Artificial* MAGNET.

10. Iron will receive magnetiſm more eaſily than ſteel; the ſoft ſteel receives it much more eaſily than the ſpring-tempered, and the ſpring-tempered much more eaſily than the hard: but a piece of ſpring-tempered ſteel will not retain near ſo much magnetiſm, and is therefore incapable of being excited to the ſame degree as hard ſteel; ſoft ſteel will retain it ſtill leſs; and iron, which is the ſofteſt of all, and in which the acquired magnetiſm is the ſtrongeſt, ſcarcely retains any, when it is removed from the influence of the magnet. Other ferruginous bodies preſerve it for a longer or ſhorter time, according as they participate more of the nature of hard ſteel, or of that of ſoft iron. Mr. Michell has evinced the truth of theſe obſervations both by reaſoning and experiment. There are other bodies, beſides iron and ſteel, which are ſuſceptible of magnetiſm; theſe are probably no other than iron in ſome ſhape or other, or bodies that have a mixture of them: ſuch are all ſorts of iron ore after ignition, and ſome before. It is obſervable, that ſeveral of the hard ores of iron, which are not affected in the leaſt by the magnet in their natural ſtate, are vigorouſly attracted by it when moderately roaſted; that the calces of iron, by ſlight roaſting with inflammable additions, are made to obey the load-ſtone, and revived into their metallic form, each particle appearing now to be perfect iron; whilſt the calces of other metals are in no degree revived, without being brought into fuſion.

The ores of iron are attracted more or leſs readily, according as they contain a greater or a ſmaller quantity of metal, and as that metal is in a more or leſs perfect metallic ſtate. By the action of fire, iron ores are generally put into a ſtate

a ſtate

a ftate of being much more readily attracted. The fcales which are feparated from the furface of red-hot iron when hammered, and the particles of burnt fteel that are produced from the collifion of a flint and fteel, are attracted by the magnet nearly as well as pieces of good iron that equal them in bulk. The black calx of iron is attracted very weakly. The red calx, or ruft, whether it be produced by the action of acids, of fire, or by expofure to the atmofphere, is attracted very little; but it never becomes quite infenfible of the magnet's action, though it be repeatedly wafhed and purified. It is obfervable, that a quantity of iron is attracted with the leaft force, when reduced into the fmalleft bits, or fineft powder. The ores of other metals are generally, though weakly, attracted by the magnet, thus indicating that they contain fome iron: fuch are the ores of lead, of tin, and of copper. Native cinnabar is likewife attracted; but the factitious cinnabar is not. The pure metals are not attracted. Of the pure metals, zinc, bifmuth, and particularly cobalt, as well as their ores, are almoft always attracted by the magnet. Antimony, unlefs it be firft expofed to a gentle fire, is not attracted. Arfenia is not attracted at all. A certain fort of bifmuth poffeffes a fingular property of being repelled on every fide by the magnet. The other minerals, befides the metallic, are almoft all attracted by the magnet, at leaft after having been expofed to the action of fire. Of the pure earths, the calcareous is leaft, or not at all, and the filiceous the moft frequently, attracted.

There are alfo feveral forts of heavy, fhining, opaque, black, or dark chocolate-coloured fand, moft of which, if not all, are iron ores, which are fufceptible of magnetifm. Of this kind is the dark-brown fand in emery: we may alfo refer to this clafs moft brafs, and feveral other metals; and bricks that have been much burnt in the fire. The magnetifm of thefe is probably owing to a fmall quantity of iron mixed with them. What is in the brafs, Mr. Michell conjectures, may come from the lapis calaminaris, which is faid to have often a fmall mixture of iron in it; but Mr. Arderon, who has fucceeded in giving magnetifm and polarity to brafs, has doubts as to the mixture of iron with brafs: particularly, becaufe brafs fluxes with a much lefs degree of heat than iron, and iron naturally fwims in fluid brafs. Phil. Tranf. vol. l. p. 774.

Mr. Cavallo made feveral experiments, with a view of afcertaining the magnetifm of brafs, and inveftigating the caufe of it. The refult is as follows: It appears, he fays, "1ft. That moft brafs becomes magnetic by hammering, and lofes the magnetifm by annealing or foftening in the fire, or at leaft its magnetifm is fo far weakened by it, as afterwards to be only difcoverable when fet afloat on quickfilver.

"2dly. That the acquired magnetifm is not owing to particles of iron or fteel imparted to the brafs by the tools employed, or naturally mixed with the brafs.

"3dly. Thofe pieces of brafs which have that property, retain it without any diminution after a great number of repeated trials, *viz.* after having been repeatedly hardened and foftened. But I have not found any means of giving that property to fuch brafs as had it not naturally.

"4thly. A large piece of brafs has generally a magnetic power fomewhat ftronger than a fmaller piece; and the flat furface of the piece draws the needle more forcibly than the edge or corner of it.

"5thly. If only one end of a large piece of brafs be hammered, then that end alone will difturb the magnetic needle, and not the reft.

"6thly. The magnetic power which brafs acquires by hammering has a certain limit, beyond which it cannot be increafed by farther hammering. This limit is various in pieces of brafs of different thicknefs, and likewife of different quality.

"7thly. Though there are fome pieces of brafs which have not the property of being rendered magnetic by hammering, yet all the pieces of magnetic brafs, that I have tried, lofe their magnetifm, fo as no longer to affect the needle, by being made red-hot; excepting indeed when fome pieces of iron are concealed in them, which fometimes occurs: but in this cafe, the piece of brafs, after having been made red-hot and cooled, will attract the needle more forcibly with one part of its furface than with the reft of it; and hence, by turning the piece of brafs about, and prefenting every part of it fucceffively to the fufpended magnetic needle, one may eafily difcover in what part of it the iron is lodged.

"8thly. In the courfe of my experiments on the magnetifm of brafs, I have twice obferved the following remarkable circumftance:—A piece of brafs, which had the property of becoming magnetic by hammering, and of lofing the magnetifm by foftening, having been left in the fire till it was partially melted, I found, upon trial, that it had loft the property of becoming magnetic by hammering; but having been afterwards fairly fufed in a crucible, it thereby acquired the property it had originally, *viz.* that of becoming magnetic by hammering.

"9thly. I have likewife often obferved, that a long continuance in a fire fo ftrong as to be little fhort of melting-hot, generally diminifhes, and fometimes quite deftroys, the property of becoming magnetic in brafs. At the fame time, the texture of the metal is confiderably altered, becoming what fome workmen call *rotten*. From this it appears, that the property of becoming magnetic in brafs by hammering, is rather owing to fome particular configuration of its parts, than to the admixture of any iron; which is confirmed ftill farther by obferving, that Dutch plate brafs, which is made not by melting the copper, but by keeping it in a ftrong degree of heat whilft furrounded by lapis calaminaris, alfo poffeffes that property; at leaft, all the pieces of it, which I have tried, have that property.

"From thefe obfervations it follows, that when brafs is to be ufed for the conftruction of inftruments wherein a magnetic needle is concerned, as dipping needles, variation compaffes, &c. the brafs fhould be either left quite foft, or it fhould be chofen of fuch a fort as will not be made magnetic by hammering; which fort, however, does not occur very frequently."

For the remarks of Mr. Bennett on Cavallo's experiments, and the reply of the latter, we refer to the Phil. Tranf. for 1792, and the appendix to Cavallo's Magnetifm. This author examined other metallic fubftances, *viz.* copper, zinc, and platina. The two former manifefted no figns of being magnetic: and of various pieces of platina, fome did not acquire any magnetifm by hammering, and others were rendered evidently attractable by the magnet by three or four ftrokes, and about ten ftrokes gave them the full power of which they were fufceptible. But when the grains of platina that were made capable of being attracted by the magnet under the operation of hammering were put upon a charcoal fire, and made red-hot by means of a blowpipe, and were afterwards prefented firft to the magnet and alfo to the fufpended needle, they fhewed not the leaft fign of attraction. Heat, therefore, deprives them, as well as brafs, of the property acquired by hammering. Mr. Cavallo concludes upon the whole from experiments of this kind, that the power of being attracted by the magnet may exift, or may belong to other fubftances, independent of iron; and therefore that the attraction of a few a few particles of any unknown substance by the magnet is not a sure sign of the presence of iron. Although it be true, that iron is always attractable by the magnet, yet it does not hence follow, that whatever is attracted by the magnet must be iron.

Amber, and other combustible minerals, are generally attracted by the magnet, especially after burning. Of the precious stones, those that are pellucid, as the diamonds and crystals, are not attracted. The amethyst, topaz, chalcedony, and generally those which are deprived of their colour by fire, are not attracted. The other precious stones are all attracted, *viz.* the ruby, especially the oriental, the chrysolite, and the tourmalins. The emerald, and particularly the garnet, are not only attracted, but frequently acquire an evident polarity from the influence of a strong magnet, so that afterwards they are attracted from one side and repelled from the other. The opal is but weakly attracted. Almost every part of animal or vegetable bodies, after combustion, is in great measure attracted by the magnet. The flesh, and especially the blood, after burning, are attracted most, but the bones are attracted less powerfully. The vegetables, after burning, are almost all, though not with equal force, attracted by the magnet. But unburned and most animal or vegetable substances very seldom, if ever, shew any perceptible attraction towards the magnet. Even soot, and the dust which usually falls upon whatever is left exposed to the atmosphere, are sensibly attracted by the magnet. Hence it appears that iron, though divided into exceedingly small particles, is in some state or other mixed with every substance: that it is to be found in animals, in vegetables, in minerals, and even in the air; that in every state of existence it always shews some attraction towards the magnet; and that its existence in several substances can be discovered by no other known method besides the magnet. But we have already observed, that there is reason for presuming, that some bodies independent of iron, are attracted by the magnet.

11. A needle touched by a magnet will turn its ends the same way towards the poles of the world, as the magnet itself does. 12. Neither the load stone nor needles touched by it do conform their poles exactly to those of the world, but have usually some variation from them; and this variation is different in divers places, and at divers times in the same place. (See DECLINATION, DIPPING, and VARIATION.) 13. A load-stone will take up much more iron when armed or capped, than it can when naked. See ARMS and *Armed* MAGNET.

It has also been observed, that amongst the natural magnets, the smallest generally possess a greater attractive power, in proportion to their size, than those which are larger. There have been often seen natural magnets not exceeding the weight of 20 or 30 grains, which could lift a piece of iron that weighed 40 or 50 times more than themselves. Mention is made of a small magnet wore in a ring, which weighed about three grains, and was capable of taking up 746 grains, or nearly 250 times its own weight; and we have seen one which could not weigh more than six or seven grains, and was capable of lifting a weight of about 300 grains. But magnets of above two pounds weight seldom lift up ten times their own weight of iron.

It often happens, that a natural magnet, cut off from a larger load-stone, will itself be capable of lifting a greater weight of iron than the original large load-stone from which it was cut off. This must be imputed to the heterogeneous nature of the large load-stone; for, suppose that one part of it contains a good quantity of pure metal strongly magnetical, the rest of it being impure or mixed with other substances, it is plain that the impure part can only obstruct the action of the purer part; hence this latter, being separated from the rest, must act more powerfully than the whole together did.

14. The force of a magnet may be variously increased or lessened by the various application of iron, or another magnet, to it. Thus, the holding of a piece of iron of some magnitude to one pole of a magnet, increases the attraction of the other pole, so as to enable it to lift a greater weight. Also, the attractive power of a magnet may be increased considerably by gradually adding more and more weight to it; for by this means it will be found that the magnet will keep suspended on one day a little more weight than it did the preceding day; which additional weight being added to it on the following day, or some time after, it will be found that the magnet can keep suspended a weight still greater, and so on as far as a certain limit.

On the contrary, by an improper situation, or by putting a very small weight of iron into it, the magnet may gradually lose much of its strength.

Heat weakens the power of a magnet; and a white heat destroys it entirely, or at least in a great measure. Hence it appears, that from this cause alone, besides others which may concur, the power of a magnet must be continually varying.

15. A strong magnet at the least distance from a lesser, or a weaker, cannot draw to it a piece of iron adhering actually to such lesser or weaker stone; but if it come to touch it, it can draw it from the other: but a weaker magnet, or even a little piece of iron, can draw away or separate a piece of iron contiguous to a greater or stronger load-stone.

16. In these northern parts of the world, as various authors have said, the north pole of a magnet generally has an attractive power somewhat stronger than the south pole; but in the southern parts of the earth, the south pole of the magnet is said to possess the greatest attractive power. However, this law has not yet been properly ascertained.

17. Neither the attraction nor the repulsion of magnetism is sensibly affected by the interposition of bodies of any sort, except iron or ferruginous bodies in general. Thus, suppose that when a magnet is placed at an inch distance from a piece of iron, there is required an ounce of force to remove it; or, which is the same thing, suppose that the attraction towards each other is equal to one ounce; it will be found that the same degree of attraction remains constantly unaltered, *viz.* always equal to one ounce, though a plate of other metal, or of glass, or paper, or other body, be interposed between the magnet and the iron; or though they be inclosed in separate boxes of glass or other matter. Neither the absence or presence of air has any effect upon them. In short, no other substance besides iron, or those bodies which contain that metal in any of its metallic states, does sensibly affect the attraction or repulsion of magnetism. Accordingly, Mr. Boyle found this true in glasses sealed hermetically; and glass is a body as impervious, as most are, to any effluvia. The magnetic virtue is sensibly continued through the substance of several contiguous bodies or pieces of iron, as keys, &c. It pervades the pores of the hardest bodies; and equally attracts the iron in vacuo, as in open air.

18. It has frequently been observed, that bars, and other pieces of iron, by having remained a long time in one situation, have become magnetic. Sometimes iron bars, which were not capable of a permanent magnetism on account of their softness, have in time, and by being left exposed to the atmosphere in a due situation, acquired a considerable degree of magnetism; but it has been also remarked,

marked, that thofe bars have, at the fame time, become harder; which is, perhaps, owing to a partial calcination, or to fome other hitherto unafcertained change in the nature of the iron.

The polarity thus communicated by the earth to iron bars, is more or lefs permanent, in proportion to the degree of hardnefs of the iron, the time of their remaining in one fituation (the moft proper being that of the dipping-needle), and laftly, the fhape of the iron, or the proportion between the thicknefs and length of the pieces.

An oblong piece of iron made red-hot, and then left to cool in the magnetical line, acquires thereby a degree of magnetifm, which is more or lefs permanent, according to the nature of the iron. The reafon of which is, becaufe, whilft red-hot, the iron is foft, and therefore the earth can render it magnetic more eafily; but, when cooled, it becomes harder, and confequently more tenacious of the acquired power.

In drilling, filing, hammering, and, in fhort, in all thofe cafes in which iron, fteel, &c. is put into violent action, fome of the pieces concerned frequently acquire a confiderable degree of magnetifm; the origin of which muft be derived from the earth, and from the changeable nature of the metal, or the viciffitudes of heat, cold, and vibratory motion, in which it is accidentally put.

Profeffor Robifon found, that when a good magnet was ftruck for ¾ths of an hour, and allowed in the mean time to ring, its efficacy was deftroyed; although the fame operation had little effect when the ringing was impeded; fo that the continued exertion of the cohefive and repulfive powers appears to favour the tranfmiffion of the magnetic as well as the electric fluid.

It feems that, for the fame reafons, magnetifm is in certain cafes produced by means of electricity; the particulars obferved concerning which are the following, and they were afcertained by means of the moft powerful electrical machine that has been yet made. They in a great meafure coincide with thofe made with other machines.

When the bar or needle is laid horizontally in the magnetic meridian, whichever way the fhock of an electric jar or battery enters, the end of the bar that ftands towards the north will acquire the north polarity, *viz.* the power of turning towards the north when freely fufpended; the other end acquiring the fouth polarity. If the bar, before it receives the fhock, has fome polarity, and is placed with its poles contrary to the ufual direction, then its original polarity is always diminifhed, and often reverfed.

When the bar or needle is ftruck ftanding perpendicularly in thefe parts of the world, its loweft end becomes the north pole, even when the bar had fome magnetifm before, and receives the fhock whilft ftanding with its fouth pole downwards. When all the other circumftances are alike, the bars feem to acquire an equal degree of magnetic power, whether they are ftruck whilft ftanding horizontally in the magnetic meridian, or perpendicular to the horizon.

When a bar or needle is placed in the magnetic equator, the fhock fent through its length very feldom, if ever, renders it magnetic; but if the fhock be paffed through its width, then the needle becomes magnetic, the extremity of it which was laid towards the weft, generally becoming the north pole.

If a needle or bar ftrongly magnetic, or a natural magnet, be ftruck by the electric fhock, its power is thereby diminifhed.

When the fhock is too ftrong, with refpect to the fize of the fteel needle, fo as to render it confiderably hot, then it acquires either none at all, or a very fmall degree of magnetifm.

For thefe experiments, the bars or needles muft be proportioned to the degree of electric power; otherwife they will not fucceed. See Van Marum's account of a very powerful electrical machine, conftructed for the Mufeum of Teyler at Haerlem; and Cavallo's Treatife on Electricity, vol. i. p. 66, and vol. ii. p. 282.

Hence, a ftroke of lightning, which is an electrical phenomenon, often renders magnetic pieces of iron, or fteel, or thofe bodies which contain iron, as certain bricks, &c.

If one pole of a magnet, for inftance the north, be applied to one end, C, of an oblong piece of iron or fteel, like C D, (*fig.* 4.) that end, C, will become a fouth pole; and if the bar, C D, be very long, there will be found a part of it, not far diftant from C, which is poffeffed of the north polarity; and this is followed by another part poffeffed of the fouth polarity; and fo on alternately, till the power becomes imperceptible; the number of thofe fucceffive poles depending upon the ftrength, and principally upon the length of the bar; but if the bar be of a proper length and thicknefs, which muft be likewife proportioned to the ftrength of the magnet employed, then the bar will have only two poles, its other extremity, D, acquiring the north polarity.

In the latter cafe, if the pole of the magnet be gradually moved along the furface of the bar from C as far as D, it will afterwards be found, that the polarity of the bar is entirely changed, the extremity, C, being now poffeffed of the north, and the extremity, D, of the fouth polarity.

It is evident, that, whilft the magnet is advancing along the furface of the bar, the fouth polarity of the end C, before it changes into a north polarity, muft decreafe in ftrength; and that when the magnet is at a certain point M, the end, C, has no polarity at all; its fouth polarity being juft vanifhed, and the north polarity juft beginning. With refpect to the extremity D, it muft be obferved, that its north polarity, by the approach of the magnet, is increafed as far as a certain limit H; after which, as the magnet comes ftill nearer to D, the north polarity of this extremity decreafes, till it vanifhes when the magnet is arrived at a certain point N; after which its north polarity begins to be changed into a fouth one.

The points, M and N, have been called the *points of indifference*; becaufe, when the magnet is at M, the extremity, C, of the bar has neither the fouth nor the north polarity; and when the magnet is at N, the end, D, has no polarity. The point, H, has been called the *culminating point*, becaufe, when the magnet is at that point, the polarity firft acquired by the end, D, of the bar is the ftrongeft.

As the determination of thefe points, in bars of different forts of iron, of different lengths, &c. not only fhews more evidently the action of the magnet, and points out the advantages and difadvantages attending the practical methods of making artificial magnets, but is befides likely to open the way to farther difcoveries; there have been no pains fpared to inveftigate the particulars on which their fituation depends, and a vaft number of accurate experiments have been made for that purpofe; but, notwithftanding thofe endeavours, fuch is the various nature of magnets, of iron, &c. that the prefent knowledge of the fubject does not allow thefe points to be determined in a given bar, without actual experiments. The general laws which may be deduced from the various experiments made for this purpofe, are the following:

1. The points M, H, and N, do not come always in the order fhewn by the figure; but though their order is not always the fame, yet it is evident that the point, H, can never

never coincide with, or come after N, *viz.* nearer to the end D, than the point N.

2. When the bars differ in length only, every thing elſe being the ſame, the longer the bar is, (as far as a certain limit, which depends on the ſtrength of the magnet employed,) the greater is the diſtance C M.

3. The ſtronger the magnet is which is employed, the greater is the diſtance C M, as far as a certain limit, which depends upon the proportion between the power of the magnet and the length of the bar; and beyond which limit C M will be ſhorter than if a weaker magnet had been uſed.

4. When the bars differ in length only, every thing elſe being the ſame, the diſtance, C H, is greater in a longer than in a ſhorter bar, as far as a certain limit, which depends as has been mentioned above.

5. The ſtronger the magnet is which is uſed, the greater is the diſtance C H, as far as a certain limit, which depends as above.

6. In a longer bar, every thing elſe being the ſame, the diſtance, C N, is greater than in a ſhorter one, as far as a certain limit, &c.

7. The diſtance C N, in bars of equal length, is greater when a ſtronger than when a weaker magnet is uſed, as far as a certain limit, &c.

8. When the bars differ only in thickneſs, every thing elſe being the ſame, the diſtance, C M, is greater in thicker than in thinner bars; but the diſtance, C N, is nearly the ſame in them all, as far as a limit, which depends as before-mentioned.

9. Laſtly, when the bars differ only in hardneſs, the diſtances C M, C H, C N, are ſometimes equal, ſometimes greater, and ſometimes ſhorter, in the harder than in the ſofter bars.

Beſides the points of indifference and culmination, there is another point to be conſidered, namely, the magnetic centre, which is the point or part between the two poles, where the magnet has no attraction nor repulſion. With reſpect to this point, we ſhall briefly obſerve, that it does not always lie midway between the two poles; and that, when one pole of a magnet is drawn over the ſurface of an oblong piece of iron, as in the before-mentioned experiment, the magnetic centre moves forwards in proportion as the magnet is advanced; but at a certain limit, both the magnet and the ſaid centre are in the ſame place, or rather in oppoſite ſides of the thickneſs of the bar. The motion and place of the magnetic centre are ſubject to a great deal of variety, ariſing from the nature, length, and thickneſs of the bar, as well as from the ſtrength of the magnet, and from the manner of drawing it along the ſurface of the iron or other ferruginous body.

When any magnet, but eſpecially an oblong one, having two poles, is broke in two, the magnetic centre of each part is at firſt generally much nearer that end of the piece which is contiguous to the fracture; but in time it advances nearer the centre of the piece.

What has been obſerved concerning oblong pieces of iron or ſteel, may ſerve to explain the phenomena which take place in pieces of an irregular form; the particular enumeration of all which caſes would be endleſs, and of little, if at all of any uſe.

Every piece of iron or ferruginous body is capable of retaining only a certain degree of magnetic power; ſo that if a ſtrong magnet be applied to a comparatively ſmall piece of ſteel, that piece, whilſt it remains within the influence of the magnet, will appear to be very powerfully magnetic; but, as ſoon as it is removed from the vicinity of the magnet, its power begins to decreaſe, and in a ſhort time comes down to that degree which the piece of ſteel is capable of, and which may be called *its point of ſaturation*. Hence it follows, that if a certain magnet is juſt ſufficient to communicate to a piece of iron or ſteel the full power of magnetiſm of which that piece is capable, a ſtronger magnet will not increaſe it in the leaſt.

19. The power or virtue of a magnet, and of iron or ſteel impregnated with the magnetic virtue, may be impaired by long lying in a wrong poſition, with regard to the earth or with reſpect to each other. Thus, if two magnets be placed ſo, that their contrary poles may be contiguous to each other, they will preſerve one another's power; but if the north pole of one be placed near the north pole of the other, and the ſouth near the ſouth, then they will entirely deſtroy or diminiſh each other's magnetiſm; and if their original powers were very unequal, the polarity of the weaker magnet will be changed by the action of the ſtronger one.

In general, the ſame means which facilitate the communication of magnetiſm, when pieces of iron, &c. are properly ſituated with reſpect to the poles of the earth, or of other magnets, will likewiſe facilitate the loſs of magnetiſm, when the magnets are improperly ſituated; thus, a red heat deſtroys in a great meaſure, or entirely, the power of a magnet. A ſteel bar, ſtrongly magnetic, will have its power much diminiſhed by being repeatedly ſtruck between two ſtones, eſpecially if it be ſtruck ſtanding in a direction perpendicular to the magnetic meridian. A bar of pretty hard iron, which has acquired ſome degree of permanent magnetiſm, by being made red-hot, and then cooled in the direction of the magnetical line, will have that power deſtroyed, or much diminiſhed, by a few ſmart blows on its middle.

20. Some have ſaid that iron or ſteel has been rendered heavier or lighter by being magnetic; but Gaſſendus, Merſennus, and Gilbert maintain the contrary; and it ſeems to be allowed, upon the whole, that its weight is not thus affected. Mr. Whiſton ſays that he found, by accurate experiments with large needles, that after the touch they weighed leſs than before. One of $4584\frac{1}{2}$ grains loſt $2\frac{5}{8}$ grains by the touch; and another of 65,726 grains loſt no leſs than 14 grains. Cavallo ſuggeſts, that the vicinity of iron, or of ſome other ferruginous body, might have had ſome action on the magnetic ſteel when it was weighed.

21. A piece of iron wire, well touched, will, upon being bent round in a ring, or coiled round on a ſtick, &c. generally quite loſe its directive virtue; but it will always have it much diminiſhed: and yet if the whole length of the wire was not entirely bent, ſo that the ends of it, though but for the length of one-tenth of an inch, were left ſtraight, the virtue will not be deſtroyed in thoſe parts: though it will in all the reſt. This was firſt obſerved by Meſſrs. Grimaldi and De la Hire; and is confirmed by the experiments of Dr. Derham; who adds farther, that though coiling or bending the wire as above would always deſtroy its virtue by day, yet it would not do it in the evening. In order to weaken or deſtroy the magnetiſm of a wire by bending, let the magnetic power be communicated to an iron or ſoft ſteel wire, of about four or five inches in length, and about $\frac{1}{50}$th of an inch in diameter; then roll it round a ſmall ſtick, ſo as to make four or five revolutions round the ſtick; after which, on ſtraightening the wire again, its magnetiſm will be generally found to be quite deſtroyed by the bending, or conſiderably weakened.

The effect is the ſame with ſhorter or longer wires; for, if they make one revolution round the ſtick, the effect will take place; which is evidently owing to the ſtreſs or derangement of the particles of the wire, as is rendered more evident by the following obſervation; *viz.* that if the wire be of ſuch ſpringy nature, as to recover its ſtraight ſituation, if left to itſelf, after coiling it round the ſtick, then its magnetiſm is either not at all, or little diminiſhed: ſo that, in order to produce the above-mentioned effect, a ſtraining of the parts of the wire is abſolutely neceſſary.

When only the middle of the wire is bent, and its extremities remain ſtraight, then the magnetiſm is ſeldom deſtroyed, or even diminiſhed.

If a piece of magnetic wire be cleft or ſplit lengthwiſe, the parts will have ſometimes contrary, and ſometimes the ſame poles as they had when in one piece. When one part is much thinner than the other, then this ſlender part will generally have its poles reverſed.

22. The ſphere of the activity of magnets is greater and leſs at different times: in particular that preſerved in the repoſitory of the Royal Society will keep a key or other body ſuſpended to another, ſometimes at the height of eight or ten feet; and at others, not above four feet. (See 4 above.) To which we may add, that the variation of the magnetical needle from the meridian varies at various times of the day; as appears from ſome experiments of Mr. Graham. See Declination and Variation.

23. The directive power of a magnet is extended to a greater diſtance than its attractive power; for inſtance, if a magnet be freely ſuſpended, another magnet properly ſituated within a certain diſtance of the former, will turn it out of its wonted direction; yet the degree of attraction exerted by theſe magnets againſt each other, is not ſenſible at that diſtance; which may be eaſily tried, by fixing one of the magnets to the ſcale of a balance. The reaſon of this property is, that the directive power depends both upon the attraction of the poles of different names, and on the repulſion of thoſe of the ſame name; whereas, the attraction takes place only between poles of different names. In order to render this explanation more intelligible, imagine that a magnetic needle is freely ſuſpended, and is placed within the influence, or ſphere of action of a magnet. In this diſpoſition, ſuppoſe that the north pole of a magnet attracts the ſouth pole of a magnetic needle with a force equal to ten grains; and, as the attraction between poles of different names is nearly equal to the repulſion between poles of the ſame name, it follows, that the ſame north pole of the magnet repels the north pole of the magnetic needle with a force equal to ten grains: but theſe two forces both concur in altering the direction of the needle; therefore, the endeavour of the magnet to turn the needle's direction is equal to 20 grains; whereas the attraction, or the force by which the needle is drawn towards the magnet, is only equal to the difference between the two above-mentioned oppoſite forces, which difference ariſes from the pole of the magnet being nearer to one than to the other of the poles of the needle. The ſame reaſoning may be applied to the action between the ſouth pole of the magnet and the ſuſpended needle.

24. By twiſting a piece of wire touched with a magnet, its virtue is exceedingly diminiſhed, and ſometimes ſo diſordered and confuſed, that in ſome parts it will attract, and in others repel; and even in ſome places, one ſide of the wire ſeems to be attracted, and the other ſide repelled by one and the ſame pole of the ſtone. The effect of magnets on a crooked wire may be ſhewn in the following manner. Let an iron wire of about a quarter of an inch in diameter, and four or five inches long, be bent ſomewhat like a Gothic arch, *viz.* with a ſharp corner in the middle, A B C, *fig.* 5, and tie it faſt to a croſs bar, or let an aſſiſtant hold it with the corner downwards; then apply either pole of the magnet, D E, to one of its extremities A, and whilſt the magnet remains in that ſituation, apply a piece of iron, H, of no great ſize, to the corner C, and you will find that the iron remains ſuſpended. Now, if another magnet be applied to the other extremity, B, of the crooked wire, ſo that the pole, G, may be contrary to the pole E, the iron, H, will immediately fall off; but if the pole, G, be analogous to the pole E, *viz.* be both ſouth, or both north, then the iron, H, not only will remain adhering to C, but the ſaid corner will be capable of ſupporting a weight ſtill greater than H. The reaſon of which is, that in the former caſe, the extremities, A, B, of the bent wire being poſſeſſed of different polarities, the corner, C, was the magnetic centre, where there is no attraction nor repulſion; whereas, in the ſecond caſe, both extremities of the bent wire being poſſeſſed of the ſame polarity, the corner, C, was neceſſitated to acquire the contrary polarity; and in this caſe, the bent wire muſt have two magnetic centres, *viz.* one on each ſide. 25. A piece of wire that has been touched, being ſplit or cleft lengthwiſe, in two, the poles are ſometimes changed; as in a cleft magnet; the north becoming the ſouth, and the ſouth the north: and yet ſometimes one-half of the wire will retain its former poles, and the other half will have them changed. When one part is much thinner than the other, then the ſlender part will generally have its poles reverſed. (See No. 21 *ſupra.*) To which it may be added, that laying one or other ſide of the half uppermoſt, cauſes a great alteration in its tendency or averſion to the poles of the magnet. 26. A wire being touched from end to end with the ſame pole of the magnet, the end at which you begin will always turn contrary to the pole which touched it: if it be again touched the ſame way with the other pole of the magnet, it will then be turned the contrary way. 27. If a piece of wire be touched in the middle with only one pole of the magnet, without moving it backwards or forwards; in that place will be the pole of the wire, and the two ends will be the other pole. 28. If a magnet be heated red-hot, and again cooled either with its ſouth pole towards the north in a horizontal poſition, or with its ſouth pole downwards, in a perpendicular poſition, its poles will be changed. 29. Mr. Boyle (to whom we are indebted for the following magnetical phenomena) found he could preſently change the poles of a ſmall fragment of a load-ſtone, by applying them to the oppoſite vigorous ones of a large magnet. Dr. Knight diſcovered a method of changing the direction of the poles in natural magnets, multiplying and variouſly placing them at pleaſure. In the firſt inſtance, recorded in the Philoſophical Tranſactions, he inverted the poles of a magnet by a proceſs which required only a minute's time; ſo that the ſame end, which before attracted the ſouth end of the needle, now attracted the north and repelled the ſouth, and *vice verſâ:* in the ſame time he again turned the direction of the polarity of the ſtone at right angles, to its former direction; and afterwards inverted this laſt direction of the poles. In the ſecond ſeries of experiments, he cut a piece of natural load-ſtone into the ſhape of a parallelopiped $\frac{8}{10}$ths of an inch long, $\frac{4}{10}$ths of an inch broad, and $\frac{2}{10}$ths of an inch in thickneſs: its weight was three drams and ten grains. In this ſtone he placed the magnetical virtue in ſuch a manner, that the two oppoſite ends became, both of them, ſouth poles, and the middle was quite round a north pole. The two oppoſite ends of another ſtone were made both north poles, and the two oppoſite ſides ſouth poles. At one end of another ſtone he placed a north pole, ſurrounded by a ſouth; and at the other end a ſouth, ſurrounded by a north pole; ſo that the edges of

each ſurface had a pole of a different denomination from that which occupied the middle. On another occaſion, he inverted the poles at the ends of a piece of magnet, and then transferred them to the ſides of the ſtone. All theſe changes of the poles are eaſily produced by ſteel bars, A B, C D, (*Plate* VI. *Magnetiſm, fig.* 6.) impregnated with a ſtrong magnetic virtue, by which the piece of magnet, E F, placed between them is ſo affected, that the poles may be changed at pleaſure, and excited in places that are touched by the ends of the bars. Mr. Michell has ſhewn the method of doing this both in ſmall and large magnets. If a ſmall and ſhort magnet is to have its poles changed, lay the ſupporters deſcribed under *Armed* MAGNETS ſo, that the centre of their force ſhall, at each end, lie at the end of the line deſigned to be the axis of the magnet, and touch it double in the manner explained under *Artificial* MAGNET, as near as may be in that direction. If the poles are to be converted, and the magnet be long enough, touch it double, according to the directions for converting the poles of an artificial magnet; then ſupport it, and touch it over again with freſh touches: or if the magnet is ſhort, apply bars as ſupporters only, and change them two or three times: or elſe make uſe of the following method, applicable to large magnets. If the poles of ſuch are to be changed, the middle of the end of the piece of iron placed at each end of the magnet (ſee *Armed* MAGNET) is to be placed againſt the end of the line deſigned to be the axis. If the poles are to be converted, it ſhould be done firſt by touching double, if a ſufficient force of magnetical bars can be applied for this purpoſe: but if, by touching double, the poles will not be converted, place the magnet between two pieces of iron, then keeping them ſteady at their diſtance, remove the magnet, and connecting the pieces of iron by wedges of iron, that may not ſtand in the way of it, when it is to be put in its place again, apply the ſupporters as before, and putting the magnet in its place, take off the iron wedges. This may be done two or three times, if it be found neceſſary, re-touching the ſupporters every time. (See *Artificial* MAGNET.) It is well known, that lightning not only deſtroys, but reverſes, in ſome caſes, the poles of magnetic needles. 30. Hard iron tools, well tempered, when heated by a briſk attrition, as filing, turning, &c. will, while warm, attract thin filings, or chips of iron, ſteel, &c. though not when cold; though there are not wanting ſome inſtances of their retaining the virtue when quite cold. 31. The iron bars of windows, &c. which have ſtood a long time in an erect poſition, grow permanently magnetical; the lower end of ſuch bars being the north pole, and the upper end the ſouthern. 32. A ſtraight bar of ſoft iron (*e. g.* one of two or three feet in length, and about ½ths of an inch in diameter), that has not ſtood long in an erect poſture, if it be only held, in theſe parts of the world, in a vertical poſition, will become magnetical; and its lower end the north pole; as appears from its attracting the ſouth pole of a needle; and the upper end the ſouth pole, being capable of repelling the ſouth pole: but then this virtue is tranſient, and by inverting the bar, the poles will ſhift their places. An iron bar of four or five feet in length, and above an inch thick, in this ſituation, will be capable of attracting a ſmall bit of iron, or a common ſewing-needle. The explanation of this curious phenomenon is as follows: ſince, in theſe northern parts, the earth is poſſeſſed of a ſouth magnetic polarity, the loweſt part of the iron bar, by being neareſt to it, muſt acquire the contrary, *viz.* the north polarity; the other extremity of the bar becoming a ſouth pole. It follows, likewiſe, (and it is confirmed by actual experiment), that in the ſouthern parts of the earth, the loweſt part of the bar acquires the ſouth polarity; that on the equator the bar muſt be kept horizontal, in order to let it acquire any magnetiſm from the earth; and that, even in theſe parts of the earth, the moſt advantageous ſituation of the bar is not the perpendicular, but that a little inclined to the horizon. In ſhort, in every part of the world, it muſt be placed in the magnetical line, *viz.* in the direction of the dipping-needle. If the iron bar, inſtead of being kept in the magnetical line, be placed in a direction perpendicular to it, then it will acquire no magnetiſm, becauſe, in that ſituation, the actions of both poles of the earth upon each extremity of the bar are equal. If, inſtead of the abovementioned two directions, the bar be placed in any other poſition, then it will acquire more or leſs magnetic power, according as it approaches nearer to the former or to the latter of the ſaid two directions.

A bar of hard ſteel, or of hard iron, does not acquire any magnetiſm from the earth, like the bar of ſoft iron, becauſe the magnetic power of the earth is weak, in proportion to that which is required, in order to render a ſteel bar magnetic. In order, therefore, to render the quality permanent in an iron bar, it muſt continue a long time in a proper poſition. But the fire will produce the effect in a ſhort time: for as it will immediately deprive a load-ſtone of its attracting virtue, ſo it ſoon gives a verticity to a bar of iron, if, being heated red-hot, it be cooled in an erect poſture, or directly north and ſouth. Nay, tongs and pokers, by being often heated and ſet to cool again in a poſture nearly erect, have frequently gained this magnetical property. It is a well-known propoſition, that ſoft iron, or ſoft ſteel, acquires magnetiſm very eaſily, and loſes it with equal facility; but that hard ſteel acquires that power with difficulty, and afterwards retains it obſtinately. From the conſideration of theſe properties, Mr. Cavallo was led to imagine, that if a piece of ſteel, whilſt red-hot, were placed between magnetic bars, and whilſt ſtanding in that ſituation, cold water were to be ſuddenly poured upon it, ſo as to harden it, there might, perhaps, be obtained an artificial magnet much more powerful than what can be produced in the ordinary way; becauſe the magnetic bars employed for ſuch purpoſe would communicate a great degree of magnetic power to the ſteel when red-hot, and conſequently ſoft, which power would be fixed upon the ſteel by the hardening.

In order to put this project to the trial, ſix magnetic bars were ſo diſpoſed, in an oblong earthen veſſel, as that the north poles of three of them might be oppoſite the ſouth poles of the three others, forming two parcels of bars, lying in the ſame direction, and about three inches aſunder, which was nearly the length of the ſteel bar which was intended to be rendered magnetic. Things being thus diſpoſed, the ſteel bar was made quite red-hot, and in that ſtate was placed between the magnetic bars; after which, cold water was immediately poured upon it, which rendered it ſo hard as not to admit being filed: its magnetiſm was found to be conſiderably ſtrong, but by no means extraordinary. From repeated trials with ſteel bars of different ſizes, and by uſing a greater or leſs number of magnetic bars, Mr. Cavallo found that ſhort ſteel bars acquire a proportionally greater degree of magnetiſm, by this method, than thoſe which were longer; that the magnetiſm in the longer bars is not proportionally as ſtrong, principally becauſe the artificial magnets, being placed at their extremities, have very little power on thoſe parts of the pieces of ſteel which are near its centre; and, laſtly, that when, in order to remedy the juſt-mentioned inconvenience, more magnets are placed nearer the middle of the ſteel bar, then this piece of ſteel generally acquires many ſucceſſive magnetic poles.

Upon the whole, it ſeems that though this method alone be be not sufficient to communicate to steel bars an extraordinary degree of magnetism, yet it may be of great use in constructing large artificial magnets; for, if these bars, instead of being hardened in the usual way, by plunging them, when red-hot, in water, be hardened whilst standing between powerful magnets, they will thereby acquire a considerable degree of magnetic power, without any additional trouble to the workman. They may then be polished, after which they may be rendered more strongly magnetic by the usual method of touching them with other magnetic bars; whereas it is a very laborious operation to render magnetic large bars of hardened steel from the very beginning, *viz.* when they have none of that power.

In the course of performing these trials, Mr. Cavallo frequently observed that the pieces of steel, whilst they were red-hot, seemed not to be attracted by the magnets; so that the least shock, and even the pouring of the water, could remove them from the proper situation, which rather surprised him; because it has been asserted by some authors, that the magnet attracts red-hot iron as well as cold. Kircher especially says, that he tried the experiment, (De Magnete, lib. i. p. 2, theorem xxxi.) and found that the piece of iron, heated so as to be hardly discernible from a burning coal, was attracted by the magnet as easily as when cold; and he even assigns a reason why the power of a magnet is destroyed by a great degree of heat; whereas the red heating of the iron will not prevent its being attracted by the magnet. The reason he gives is, that the fire corrupts and calcines the magnet, but purifies the iron. The following experiments were made in order to ascertain this matter:

"I kept (says Mr. Cavallo) a piece of steel in the fire till it was quite red-hot, and in that state presented the magnet to it, so as to touch it repeatedly in various places; but no sign of attraction could be perceived before the redness disappeared. I mean, however, such redness as may be evidently seen in the clear day light; for, as was shewn by other experiments, when the magnet begins to attract the heated iron, the redness of the latter can still be seen in the dark.

"Having repeated the experiment with different pieces of iron and of steel, the result was constantly the same, *viz.* whilst the iron or steel remained quite red-hot, or white-hot, the magnet did not attract it; but the attraction began when the degree of redness which is clearly perceivable in the day-light began to disappear; and it was as strong as ever when the iron was cooled a little more than when the redness quite disappeared in the dark. In regard to this limit, or maximum of attraction, I think I have observed, as well as the nature of the experiment would permit, a difference between steel and iron; which is, that in the steel the maximum of attraction follows the disappearance of the red heat sooner than in iron.

"This experiment is subject to two sources of mistake, which, perhaps, misled father Kircher, and which it is necessary to mention, for the sake of others who wish to repeat it. The first is, that when a piece of iron, of no great extent, is red-hot, or even white-hot, in one place, and below a red heat in other parts, the magnet will frequently attract it, though the red-hot side be presented to it. The second cause of mistake is, that when a small piece of iron or steel, as a common sewing-needle, is made red-hot, and is then presented to the magnet, if the magnet touch it, the contact cools it instantly below the necessary degree of heat, and of course the attraction takes place. It is owing to this last cause, that I have not yet been able to ascertain, whether the attraction between the magnet and the iron be quite annihilated, or only diminished to a great degree, by rendering the iron red, or white-hot; so that I can only say with certainty, that a magnet will not attract a certain piece of iron red-hot, or white-hot; whereas it will attract another piece of iron, at least fifty times bigger, if it be cold, or below a red heat.

"To try this experiment in a different and more convincing manner, I heated a large iron nail till it was white-hot, and in that state placed it upon an earthen support, near one pole of the magnetic needle, so as to lie, not in the same direction, but on one side of it. Then, looking attentively on the graduated circle of the compass, I observed, that the needle was not in the least moved from its natural situation, whilst the nail remained red-hot; but, as soon as the redness began to disappear, the needle advanced towards the nail, and a few seconds after the needle pointed directly towards it.

"I tried whether, in this experiment, any difference was occasioned by the magnet's being natural or artificial; but, as it might be expected, there was none.

"In pursuance of those magnetic experiments wherein heat is concerned, I tried the effects which took place when the magnet was heated; but, as the diminution of its power by heating, and an increase of it by cooling, were observed and described by the late Mr. Canton, (Phil. Transf. vol. li.) I shall only add a circumstance, which may perhaps be new. It is, that an artificial magnet, after having had its power diminished by heating, does not recover it entirely again by cooling; having constantly found, that the magnets which had been heated, after cooling would never hold so great a weight of iron as they did before. The heat to which those magnets were exposed never exceeded that of boiling water. This was rendered more evident by the following experiment.

"A magnetic bar was placed in an earthen vessel, at some distance from the south pole of the needle of a very good compass; by the action of which magnet, that end of the needle was drawn several degrees from the magnetic meridian, or from the direction in which it stood before. In this situation of the apparatus, boiling water was poured into the vessel wherein the magnet stood, in consequence of which the needle went back two degrees and a half. Some time after, when the water was quite cold, the needle was found nearer to the magnet, but not so near as it stood before the hot water was poured into the vessel."

33. Mr. Boyle found, that by heating a piece of English ochre red-hot, and placing it to cool in a proper posture, it manifestly acquired a magnetic virtue. And an excellent magnet of the same ingenious gentleman's having lain near a year in an inconvenient posture, had its virtue surprisingly impaired; as if it had been injured by fire. 34. A needle well touched, it is well known, will point north and south: if it have one contrary touch of the same stone, it will be deprived of its faculty; and by another such touch, it will have its poles quite changed. 35. If a bar of iron have gained a verticity by being heated red-hot, and cooled again, north and south, and then hammered at the two ends; its virtues will be destroyed by two or three smart blows on the middle. Mr. Martin says, that by a smart stroke of a hammer on the untouched end of the dipping-needle, he has often caused the whole magnetic virtue to come to that end from the other, so as to make it dip on that side as much as it did on the other before: on the contrary, by such a stroke he has sometimes made it dip much more on the touched end than before. Sometimes, by striking it, the needle, which dipped before, will be restored to its equilibrium, as if the virtue had

had made its eſcape, or were uniformly diffuſed all over the needle. 36. By drawing the back of a knife, or long piece of ſteel wire, &c. leiſurely over the pole of a load-ſtone, carrying the motion from the middle of the ſtone to the pole; the knife or wire will accordingly attract one end of the needle: but if the knife or wire be paſſed from the ſaid pole to the middle of the ſtone, it will repel that end of the needle which in the other caſe it attracts. 37. Either a magnet or a piece of iron being laid on a piece of cork, ſo as to ſwim freely in water; it will be found, that whichſoever of the two is held in the hand, the other will be drawn to it: ſo that iron attracts the magnet as much as it is attracted by it; action and re-action being always equal. In this experiment, if the magnet be ſet afloat, it will direct its two poles to the poles of the world. 38. A knife, &c. touched with a magnet, acquires a greater or leſs degree of virtue, according to the part it is touched on. It receives the ſtrongeſt touch, when it is drawn leiſurely from the handle towards the point over one of the poles: and if the ſame knife thus touched, and thus in poſſeſſion of a ſtrong attractive power, be retouched in a contrary direction, *viz.* by drawing it from the point towards the handle over the ſame pole, it immediately loſes all its virtue. 39. The attraction of iron towards the magnetic needle, or magnet, is increaſed to a certain degree by the action of vitriolic acid. The experiment, aſcertaining this fact, is ſtated by Mr. Cavallo, who made the diſcovery of it, as follows: ſome pieces of iron, as filings, nails, &c. are put into an earthen pot, and the pot is placed laterally near one end of a ſenſible magnetic needle; in conſequence of which, that end of the needle will be drawn away from its natural direction, and will approach the pot more or leſs, according to the quantity of iron and vicinity of the pot. In this ſituation, if diluted vitriolic acid be poured upon the iron in the pot, ſo as to occaſion a briſk effervеſcence, the needle will be found to come nearer to the pot during ſome minutes, after which it will gradually recede. This increaſed attraction is more or leſs, according to the quantity, ſurface, and vicinity of the iron, according to the briſkneſs of the effervеſcence, &c. but with two or three ounces of iron filings, or with about ſix ounces of nails, and a ſuitable quantity of diluted vitriolic acid, the needle may be expected to make a movement from about 15′ to half a degree.

"When I firſt obſerved this phenomenon, I naturally ſuſpected (ſays Mr. Cavallo) that the increaſed attraction might have been cauſed by a quantity of iron filings being brought by the violence of the effervеſcence nearer to that ſide of the pot which ſtood towards the needle; and to avoid this ſource of miſtake, I tried the experiment with a ſingle piece of wire inſtead of filings, and twiſted the wire in various directions, ſo as to be admitted into the pot. This experiment was ſeveral times repeated then, and alſo very lately, and the iron was uſed in various forms, *viz.* nails, turnings, pieces of wire, &c. but the reſult has been invariably the ſame, namely, an increaſed attraction." Mr. Bennett has queſtioned the fact. See Phil. Tranſ. for 1792, p. 93.

40. Natural magnets may be imitated in the following manner: Take ſome martial æthiops, or, which is more eaſily procured, reduce into very fine powder the ſcales of iron, which fall from red-hot iron when hammered, and which are found abundantly in ſmith's ſhops. Mix this powder with drying linſeed oil, ſo as to form it into a very ſtiff paſte, and ſhape it in a mould ſo as to give it any form you require, whether of a terrella, a human head, or any other. This done, place it in a warm place for ſome weeks, and it will dry ſo as to become very hard. Then render it magnetic, by the proper application of powerful magnets, and it will acquire a conſiderable power.

We ſhall here ſubjoin ſome additional obſervations on the ſubject, extracted from the laws of magnetiſm, propoſed by Mr. Whiſton. An inclinatory, or dipping-needle, of ſix inches radius, and of a priſmatic, or cylindric figure, when it oſcillates along the magnetic meridian, performs, according to Mr. W. every mean vibration in about 6′ or 360‴; and every ſmall oſcillation in about 5½″, or 330″; and the ſame kind of needle, four feet long, makes every mean oſcillation in about 24″, and every ſmall one in about 22″.

The entire power of magnetiſm in this country, as it affects needles a foot long, is, as he ſays, to that of gravity nearly as 1 to 300; and as it affects needles four feet long, as 1 to 600. And the quantity of magnetic power accelerating the ſame dipping needle, as it oſcillates in different vertical planes, is ever as the coſines of the angles made by thoſe planes, and the magnetic meridian, taken on the horizon.

Thus, if we would eſtimate the quantity of forces in the horizontal and vertical ſituations of needles in London, we ſhall find that the latter, in needles a foot long, is to the entire force along the magnetic meridian, as 96 to 100; and in needles four feet long, as 9667 to 10000: whereas in the former, the entire force in needles a foot long is as 28 to 100; and in thoſe four feet long, as 2569 to 10000. Whence it follows, that the power by which horizontal needles are governed in theſe parts of the world, is but one quarter of the power by which the dipping needle is moved.

Hence, alſo, ſince the horizontal needle is moved only by a part of the power which moves the dipping-needle; and that it only points to a certain place in the horizon, becauſe that place is the neareſt its original tendency of any its ſituation will allow it to tend to; whenever the dipping-needle ſtands exactly perpendicular to the horizon, the horizontal needle will not reſpect one point of the compaſs more than another, but will wheel about every way uncertainly.

The time of oſcillation and vibration, both in dipping and horizontal needles equally good, is as their length directly; and the actual velocity of their points along their arcs is always equal.

Hence magnetic needles are, *cæteris paribus*, ſtill better, the longer they are; and that in the ſame proportion with their length.

Magnet, in *Medicine.* Some writers of the middle ages have, from a miſtaken tranſlation of Theophraſtus, been induced to account the load-ſtone poiſonous, which the ancients were ſo far from doing, that they gave it inwardly. Galen aſcribes a purgative quality to it, and recommends it in dropſies; and Dioſcorides preſcribes it as a good medicine to evacuate groſs melancholic humours. It is doubtleſs poſſeſſed of the ſame virtues with the other ores of iron, though in modern times never uſed inwardly, having been only made an ingredient in ſome plaſters. To theſe plaſters very extraordinary virtues have been aſcribed; ſuch as that, when applied to wounds, they would extract iron, or even a knife, from the human body. See ſeveral ſimilar ſtories in Kircher's "De Magnete," who was too wiſe to give them any credit. The chemiſts are ſaid to have been able to extract an oil of wonderful efficacy from the magnet, and to have made with it ſeveral preparations.

It has been ſaid, that the application of the artificial magnet, or of a magnetical bar, to the teeth, will effectually cure the tooth-ache, that it will eaſe the pains of parturient women, that it will diſperſe white ſwellings, &c.; and, on on the contrary, that the wounds made with a knife, or other steel instrument, which has been previously rubbed with a magnet, are mortal. It is hardly necessary to add, that none of these pretended medicinal or poisonous qualities in the magnet are warranted by authentic facts: and as magnetism does not affect the smell, the taste, or any other sense of the body, it is improbable, to the greatest degree, that it should have any effect upon animal bodies. For though there are, without doubt, particles of iron in almost every part of an animal body, yet these particles are so subdivided and calcined, and bear so small a proportion to the other elements, that, in a natural state, the magnet has no action upon them.

Magnet, in *Metallurgy* and *Chemistry*. Iron ores may generally be discovered to be such by the magnet; for almost all of them will be attracted by it either before or after ignition. A strong artificial magnet, well hung, and used as a needle, will best serve for this purpose. It will also readily find, and separate any little bits of iron or steel from other things, and particularly iron or steel from those of other metals. It will likewise discover whether tools, &c. are made of steel, or whether they are iron case-hardened; for the steel will receive a strong touch, when the other will hardly receive any. For the use of the magnetic needle, in *Mining*, see Needle. According to Neumann, the magnet is almost totally soluble in spirit of nitre, and partially in the vitriolic and marine acids. See Iron, *Ores of*.

Magnet, *Armed*, denotes one that is capped, cased, or set in iron or steel, in order to make it take up a greater weight, and also more readily to distinguish its poles. As both magnetic poles together attract a much greater weight than a single one, and as the two poles of a magnet are generally in opposite parts of its surface, in which situation it is almost impossible to adapt the same piece of iron to them both at the same time; therefore it has been commonly practised to adapt two broad pieces of soft iron to the poles of a load-stone, and to let them project on one side of the magnet, because in that case, the pieces of iron being rendered themselves magnetic, another piece of iron could be conveniently adapted to their projections, so as to let both poles act at the same time. Those pieces of iron are generally held fast upon the magnet by means of a brass or silver box. The magnet in this case is said to be *armed*, and the pieces of iron are called the *armature*.

In *fig.* 7. *Plate* VI. A B represents the magnet; C D, C D, represent the armature or pieces of iron, the projections of which are D, D, and to which the piece of iron, F, is made to adhere. The dots E C D C D represent the brass box, having a ring, E, at its upper part, by which the armed magnet may be suspended. Thus the two poles of the magnet, which are at A and B, are made to act at D D, where the straight piece of iron, F, may be conveniently applied.

For this purpose, and to avoid the armature, artificial magnets have been made in the shape of a horse-shoe, having their poles in the truncated extremities; for which reason they have more power than the straight magnetic bars.

When a piece of natural magnet is required to be armed, the first operation is to find out its poles; then let the magnet be properly shaped, *viz.* either in the form of a terrella, or in the more usual one of a parallelopipedon, in which latter case care must be had to let the poles fall about the middle of two opposite surfaces, in which direction the magnet ought to have the greatest length possible; it having been often observed, that a natural magnet is weakened in power much more by cutting off a part of its length, in the direction of the poles, *viz.* so as to make the magnetic axis shorter, than in any other direction.

After having shaped the magnet properly, let two plates of soft iron be made, equal in breadth to those surfaces where the poles stand, and to project a little way on one side of the stone, as shewn in the figure. Those projections D, D, must be much narrower than the breadth of the plates. For magnets smaller than one ounce, the lower surfaces of the projections, to which the iron, F, is to be applied, need not be larger than about one-tenth of an inch; and from a quarter to half an inch is sufficient for larger magnets.

The thickness of the plates C D, C D, must be proportioned to the power of the magnet; there being a certain size which is the properest for any magnet, a larger or smaller thickness than which being not so advantageous. This thickness cannot be easily determined without actual trial; hence the best way is to make them very thick at first: then filing a little off, and examining the power of the magnet alternately: for the power increases gradually till a certain degree, at which limit the filing ought to be discontinued.

It is indifferent whether the armature be kept on by tying, or by a box; whether of metal or of wood; but as the box is the most permanent, this ought to be preferred: and it may be made of any metal excepting iron or steel.

When the magnet is spherical, the armature, or pieces of iron, must be adapted to that surface, and each to cover about a quarter of it.

What has been here said about the natural magnet, is equally applicable to the artificial ones; so that many magnetic bars may be joined together, and may be armed so as to form a very powerful *compound magnet*.

The armature rather strengthens the power of the magnet, for the same reason for which a piece of iron affixed to a magnet tends to render it more powerful.

If the artificial magnets be made in the shape of a horse-shoe, or of a semicircle, then there is no need of the armature, it being sufficient to join them together, either by rivetting or by a box; and, indeed, even with straight bars, the compound magnet may be made without the armature; but then, as the two magnetic poles cannot act in the same plane, it is proper to have two of those compound magnets, for the purpose of giving more conveniently magnetism to other bodies.

By this means the late Dr. Gowin Knight constructed two very powerful artificial magnets, or magazines of magnetic bars, which are now in the repository of the Royal Society. Each of these magazines consists of 240 bars, disposed in four lengths, so as to form a parallelopipedon, every length containing 64 bars. All these bars are kept together by means of iron braces, and the whole is suspended upon pivots and a proper wooden pedestal or carriage, so as to be easily placed in any required position. For a farther description of those magnetic magazines, see the Phil. Trans. vol. lxvi. p. 591.

Mr. Michell directs to increase the power of a natural magnet, if it be small and short, by laying a great number of iron bars at its ends, after the manner of supporters, care being taken to apply the proper poles: if it be pretty long, so as to allow room for it, by touching it also double with several bars, according to its bulk, applying them to all sides at once. To increase the power of a large magnet, instead of placing supporters, he advises to put a large piece of iron, of the thickness and breadth of the magnet, at each end of it. This piece of iron should be either three or four times as long as it is thick, or else short, and three or four

four times as large at the end not touching the magnet, as at the other: in the former of these ways, there are to be placed on one side, in the other case at the broad end, as many supporters as can conveniently stand there. This, if the magnet be very short, may be sufficient; if it be long, it should besides be touched double. If the magnets to be thus improved be very susceptible of magnetism, they should have much thicker armour than is generally used, because they will thus retain more magnetism; and the armour should be so fastened, that the hoops, &c. used for that purpose may not stand in the way of applying any thing to the ends, or the sides; for it is much the best way to make any short magnets magnetical in their armour, because they will retain more power by this means. But Mr. Michell apprehends, that the best way of managing very large magnets, would be to slit them, in a direction parallel to the axis, into several long bars of the length of the stone, and having made them magnetical singly, to put them into their armour, in the manner directed for compound artificial magnets. The steel bars used for artificial magnets may be armed and made magnetical, like the natural magnets. Armed compound artificial magnets may be made of several bars exactly of a length, with armour nicely fitted to them. The bars should have the same proportions as those of single unarmed magnets; they should be touched singly, and put into their armour, as they are touched, with the poles of the same denomination the same way. The armour should be pretty thick, and should have a wedge of iron applied to it, whilst the bars are putting in, and till the whole is bound together and finished; for which reason the case, that keeps the armour together at bottom, should be put on before any of the bars are in. The iron wedge should always continue applied to the magnet, but when it is used; for this will be a great preservation to it; though with all this precaution, it will lose a great deal of its first strength, in a very little time. Mr. Michell directs an occasional magnet of this kind to be made in the following manner: let there be a small box, about an inch deep, six inches long, and three or four wide; in the bottom of this box fix two bars of iron, at each end one, about $\frac{3}{8}$ths of an inch square, reaching quite across the ends and through holes in one side, and projecting a little way beyond; these projecting ends serve as feet to lift with, like those of the common armed natural magnet: the faces of these feet should lie in the same plane with each other, and they may be reduced, by taking off the edges, to about half the breadth of the bar, in the flat way of the box. When the magnet is wanted, apply a wedge of iron to the two feet that come through the side of the box; and having made any number of the six-inch bars as magnetical as may be, place them one by one with their edges against the two iron bars in the box, and with their poles of the same denomination the same way, pushing them close against the side of the box, which will keep them from turning over and lying flat-ways. Having placed as many of the six-inch bars as are required in this manner, lay two or three doubles of flannel, or something else that is soft and spungy, over them, and press them against the two iron bars with the lid of the box, and fasten it down. Such a magnet as this may be easily taken to pieces and retouched, and set together again, as occasion shall serve. A magnet of this kind, consisting of three dozen of six-inch bars, will lift fifty pounds avoirdupois.

The following experiment will shew in what circumstances a magnet can lift the greatest weight. Take a magnetic bar, and find by trial an oblong piece of iron, about four inches long, and of a weight little greater than the magnet will support. It is plain, that if you affix this iron to one pole of the magnet, the moment you remove your hand, the iron will drop; but if, before you remove the hand, you present another larger piece of iron just under the lower extremity of the former, and within half or three-quarters of an inch from it, you will find that the magnet will then support that piece of iron which it could not support before, when a secondary piece of iron was not under it. In short, a magnet can lift a greater weight of iron from over another piece of iron, as an anvil, or the like, than from over a table.

The reason of which property is, that in the former case, the iron basis, or inferior piece of iron, becoming itself in some measure magnetic, helps to increase the magnetism of the first piece of iron, and consequently tends to increase the attraction between it and the magnet; which does not take place when the iron is lifted from over a table, or something else which is incapable of acquiring any magnetism.

In order to render this property more intelligible, suppose that a piece of iron be affixed to the north pole of a magnet; it is plain, that by the action of the magnet the part of it that stands next to the magnet has acquired a south polarity, and its other, or inferior extremity, has acquired a north polarity, the attraction being a consequence of this acquired magnetism, and being greater or smaller in proportion as that acquired magnetism is more or less powerful; consequently, whatever tends to increase that magnetism in the piece of iron, must likewise increase the attraction. Now, when another piece of iron is under the former, that other piece of iron, being within the sphere of action of the magnetic bar, becomes magnetic, and the part of it which is contiguous to the north pole of the magnet acquires the south polarity; but this is contiguous to the lower end, which is the north pole, of the first piece of iron, therefore it must increase that north polarity, and, of course, the south polarity of the upper end of the first piece of iron, which stands next to the magnet.

In fact, if, instead of the secondary piece of iron, you put the south pole of another magnet at a little distance below the lower extremity of the suspended iron, you will produce the same effect, *viz.* will increase the attraction between it and the north pole of the first magnet; but if you present the north pole of the second magnet under it, then you will produce the contrary effect, *viz.* will weaken its magnetic power, and, of course, diminish the attraction.

The variable power of a magnet may be shewn by suspending iron to it, in the following manner. Suspend a magnet in a place that is not much shook, and apply to it as much weight of iron as it will just support. For this purpose, the magnet, either natural or artificial, ought to be armed, or made in the shape of a horse-shoe, *viz.* so as to have the poles in one plane; in this form the effect being more conspicuous. Let a hook or a scale, like those used for a balance, be fastened to this iron. On the day following, you may put a little more weight into the scale, which the magnet will support. One or two days after, a little more weight may be added; and so on; the power of the magnet increasing daily: and, though this increase of power is neither unlimited nor very regular, being affected in some measure by the vicissitudes of heat and cold, &c.; yet, upon the whole, the power of a magnet will be considerably increased by this artifice.

It is very remarkable, that if, in the course of the operation, the iron were to drop from the magnet, on replacing it, you will find that the magnet will no longer support as much

much weight as it did a moment before, fo that now you muft diminifh the weight, though in the courfe of the following days you may increafe it gradually again: hence, in placing the weights into the fcale, or upon the hook, care muft be taken not to give it any jerk, fo as to caufe the iron to fall off; otherwife a great deal of the work will be loft.

The reafon of this experiment is, that the iron being rendered magnetic, tends to ftrengthen the magnetifm of the magnet, in the fame manner as any other magnet endeavours to render magnetic any ferruginous fubftance that is placed within its fphere of action. When the iron falls off, the magnet lofes part of the acquired power, efpecially if the magnet had acquired more than its point of faturation, there having been removed the caufe which kept it up; and when the iron is replaced, the magnet will not recover the loft power very readily, becaufe there is required a confiderable time to communicate a certain degree of magnetic power to a hard ferruginous fubftance, as the magnet is, efpecially when that magnetifm muft be communicated by the action of a proportionably weak magnet, like the iron weight.

According to Æpinus's hypothefis of the magnetic fluid, this experiment is explained thus: The magnetic fluid in a magnet is not equally difperfed through its fubftance; but one pole, or half of it, is overcharged, and the other undercharged. There is a ftrong attraction between the undercharged part and the fuperfluous quantity of magnetic fluid in the overcharged part, and the reftoration of the balance is in great meafure prevented by the hardnefs or fome other quality of the magnet. Now, when the iron is affixed to the magnet, it becomes magnetic, *viz.* that part of it which is contiguous to the overcharged pole of the magnet, becomes undercharged, and the oppofite one becomes overcharged. In this fituation, the undercharged part of the iron, endeavouring to draw the magnetic fluid of the magnet towards itfelf, accumulates or draws it ftill nearer to that overcharged pole of the magnet; and, on the other fide, the overcharged part of the iron being contiguous to the undercharged pole of the magnet, tends continually to drive the magnetic fluid away from that undercharged pole of the magnet; but the power of the magnet, according to the hypothefis, depends on the unequal diftribution of the magnetic fluid, therefore the action of the iron, by endeavouring continually to increafe that unequal diftribution, muft increafe the power of the magnet.

It follows from this experiment, that a magnet is apt to lofe much of its power when kept without any iron affixed to it.

Magnet, *Arfenical, Magnes Arfenicalis*, in *Chemiftry*, denotes a mixture of equal parts of arfenic, fulphur, and antimony, melted together over the fire, and condenfed in manner of a ftone.

It is a very gentle cauftic, and was firft invented by Angelus Sala. It fucceeds very well in taking down fungous flefh in wounds. It has its name magnet, becaufe, being worn during malignant difeafes, it is fuppofed to preferve the wearer from infection, by a magnetical power.

Magnet, *Artificial*, is a fteel or iron bar, impregnated with the magnetic virtue, fo as to poffefs all the properties, and be ufed inftead of the natural load-ftone.

Before we proceed to give a particular account of the various methods that have been practifed for making artificial magnets, it may not be improper to premife fome general obfervations on the communication of magnetifm. We have already more than once had occafion to remark, that when a piece of iron or fteel, or, in fhort, of any ferruginous body, is prefented to a magnet, within a proper diftance of one of its poles, it becomes inftantly magnetic the part of it which is neareft to the magnet acquiring the contrary polarity, &c.

This acquired magnetifm is ftrongeft with foft iron, and weakeft with hardened fteel, or with the brittle fort of caft iron; the other forts of iron or ferruginous bodies acquiring a ftronger or weaker power, according as they approach the hardnefs of the latter, or the foftnefs of the former. But the permanency of the acquired magnetifm follows juft the reverfe of this rule; fo that the hardeft fteel retains it for many years with little or no diminution; whereas very foft iron lofes it entirely the moment it is removed from the influence of the magnet; the other ferruginous bodies preferving it for a longer or fhorter time, according as they participate more of the nature of hard fteel, or of that of foft iron. Hence it may be deduced, that, in general, the beft method of making artificial magnets confifts in applying one or more powerful magnets to pieces of the hardeft fteel, becaufe thofe pieces will thereby acquire a confiderable power, and will retain it for a long time; taking care, in this operation, that the north pole of the magnet or magnets be applied to that extremity of the piece of fteel which is required to be made the fouth pole, and that the fouth pole of the magnet be applied to the oppofite extremity. In the fame manner as a piece of fteel or iron is rendered magnetic, a weak magnet may be rendered more powerful, or its power may be reftored when loft.

It is evident, that in this method the operator fhould have one or more magnets, by the application of which the fteel, or other ferruginous body, may be rendered magnetical; therefore it may be afked, by what means is magnetifm originally given to fuch artificial magnets, as are faid to have that power imparted without the interference of any magnet? The anfwer to this queftion is, that no magnetifm at all can be communicated to any ferruginous body whatever, without the action of another magnet; and that, in the method vulgarly called, of giving magnetifm to fteel, &c. without the aid of a magnet, the beginning of the magnetic power is communicated from the earth, which is a real magnet; and, therefore, there is no magnetifm communicated but by the action of another magnet. See art. 32, *fupra*.

There are fome particular circumftances which demand attention, in order to enable us to afcertain the beft method of conftructing artificial magnets.

1. The nature of the body muft be adapted to the power which is to render it magnetic; remembering, that the foft ferruginous bodies both acquire and lofe magnetifm eafier than thofe which are harder.

2. The fhape of the bodies is to be confidered next, experience fhewing that an oblong one is in general preferable to any other. In cafe of fteel bars, they ought to be quite hard, in order to acquire the greateft poffible power, provided one has magnets fufficiently ftrong for the purpofe; and if cylindrical, their diameters ought to be about one-fifteenth of their length; or, if not cylindrical, their thickneffes ought to be fuch as nearly to equal the weight of the cylindrical bars of the fame length, and the diameter of which may be about one-fifteenth of their lengths.

3. Several magnets are much preferable to a fingle one, for the purpofe of communicating magnetifm; in the application of which, it muft be remembered, that the fouth pole of the magnet produces a north pole in the part of the ferruginous body to which it is applied, and that the north pole of the magnet produces a fouth pole in the part, &c.

4. If it were required to conftruct a ftrong magnet, when the operator has either no magnet at all, or a very weak one, he muft proceed gradually. It being impoffible for a hard and

and large steel bar to receive any sensible degree of magnetism from the action of the earth, or of any other weak magnet, the operator must begin with giving magnetism to several small and soft steel bars, impregnating one at a time by means of the weak magnet, or, if he have no magnet, by means of one or more iron rods properly situated, which in that case are real, though weak magnets. Then, by joining in a proper manner the small steel bars already made magnetic, he may communicate a stronger power to larger and harder steel bars; which will be capable of impregnating bars still larger; and so on.

It has been asserted by various authors, that if a short bar of soft steel be repeatedly stroked from end to end, in any situation, by a sufficiently long iron bar, likewise kept in any situation, the steel bar will thereby acquire a considerable degree of magnetism: from which it might perhaps be inferred, that there is no necessity of deriving the origin of magnetism from the earth. But an accurate investigation of this pretended fact has shewn, that the steel bar will not acquire magnetism in every situation. Indeed, as the bar of iron is rendered more or less magnetic by the earth in every situation, except that which is perpendicular to the magnetical line; in a random way of making the experiment, it is almost impossible to keep the bar so near that direction as to acquire no magnetism at all from the earth; but if, in rubbing the steel bar, the iron one be kept in a situation nearly perpendicular to that of the magnetical line, then the steel will acquire no magnetism at all. Besides, when the iron bar is kept in any situation, the degree of magnetism which is communicated to the bar, is greater or less in proportion as the direction of the bar is nearer to or farther from that of the magnetical line; which proves, beyond a doubt, that the communicated magnetism is originally derived from the earth.

In order to make a piece of iron acquire magnetism from the earth, let the following process be pursued: Take a bar of soft iron, about two or three feet long, and between one-half of an inch and two inches thick, (such are some kitchen pokers,) and place it in the magnetical line, *i. e.* in the direction of the dipping needle, if this be at hand, or straight up in higher latitudes N. or S. than 40°, but horizontally when nearer to the equator than the above-mentioned degree of latitude. Then place a magnetic needle on a pin, and holding the pin in your hand, present the needle to the various parts of the bar from top to bottom, and you will find, that in this island the lower half of the bar is possessed of the north polarity, capable of repelling the north and of attracting the south pole of the needle, and the upper half is possessed of the south polarity, capable of repelling the south and of attracting the north pole of the needle. The attraction is strongest at the very extremities of the bar; it diminishes as it recedes from them, and vanishes about its middle, where no one pole of the needle is attracted in preference to the other. In short, in that situation, the iron bar is as much a magnet as any piece of iron that stands within the influence of a magnet.

If you turn the bar top-side down, the extremity of it, which was south pole when it stood uppermost, will now become north pole, and the other extremity will become south pole.

In the southern parts of the world, the lower part of the bar is a south pole; or, to be more explicit, when in any part of the world the bar is situated in the magnetic line, the extremities of the bar will acquire the polarities corresponding to the nearest poles of the earth.

In order to fix in an iron bar the magnetism which the earth has communicated to it, the following circumstances should be regarded. The very soft iron acquires the greatest degree of magnetic power in the shortest time, but loses it with the same quickness; so that, if the preceding experiment be performed with a bar of that sort of iron, the magnetism communicated to it by the earth will not be permanent; but if it be made red-hot, and be left to cool in the magnetic line, or if it be repeatedly struck with a hammer, whilst standing in the magnetic line, it will thereby acquire a small degree of permanent magnetism; which power, however, either by leaving the bar for some time in an improper situation, or by inverting and striking it again, will be soon destroyed.

When the iron is somewhat harder, the acquired magnetism lasts much longer; though a longer time, or longer operation, be required in order to render it magnetic.

As the constant action of a weak magnet or a ferruginous body continually tends to increase the magnetism of that body, so the iron bars, which are left in the direction of the magnetic line for a considerable time, become continually more strongly magnetic, and the acquired power becomes more permanent.

The reason why iron, by long standing, by hammering, &c. acquires a permanent magnetism from the earth, whereas by the mere position, in a short time, the power is not at all permanent, seems to be the unequal texture of the iron: suppose, for instance, that a piece of iron is composed of hard and soft particles, or of some, through which the magnetic power moves very easily, and others, through which it moves very slowly. The former then of those particles acquire the magnetism at first from the earth, and lose it very easily; but by continuing in the same position, or by being softened, &c. the hard particles gradually acquire magnetism from the former, and having once acquired it, retain that power for a long time. It is, besides, very probable, and in certain circumstances actually proved, that some sort of iron becomes harder by being kept long exposed to the atmosphere.

The method of making magnets of this kind, by means of a natural magnet, and even without the assistance of any magnet, was suggested many years ago by Mr. Servington Savery, and particularly described in the Phil. Transf. N° 414. See also Abridgment, vol. vi. part ii. p. 260, &c. But as his method was tedious and operose, though capable of communicating a very considerable virtue, it was little practised. A more simple method was proposed by Mr. Arnold Marcel, nephew to Mr. Leeuwenhoeck, and is described in the Phil. Transf. (See Martyn's Abr. vol. vi. part ii. p. 278.) It is as follows: "In the year 1776," says he, "making several further observations about the magnetical force which I found in great pieces of iron, I made use of a large iron vice, about 90lbs. weight, in which I fixed a small anvil of about 12lbs. Upon the bright surface of this anvil I laid the steel, to which I would give the virtue, in a position of north and south, which happened to be in a diagonal of the square surface of the anvil; then I took a piece of iron, one inch square, and 33 inches long, of about 8lbs. weight, having at one end the figure here represented (*fig.* 8.) brightly polished at A, and taper at the other end. Then I held fast down the piece of steel upon the anvil with one hand, and with the other I held the iron bar aforesaid perpendicular, with its point, A, upon the steel, and, pressing hard, I rubbed the steel with the iron bar towards me, from north to south, several strokes, always carrying the bar far enough round about, to begin again at the north, to prevent the drawing back of the magnetical force. Having thus given ten or twelve strokes, I turned the steel upside down, leaving it in the same position as to north and south, and,

after

after rubbing it and turning it, till I rubbed it about 400 times, it received by degrees more and more ſtrength, and at laſt had as much as if it had been touched by a ſtrong load-ſtone. The place where I began to rub, was always that which pointed to the north when the needle was hung, the end where I had ended the ſtroke turning to the ſouth. Sometimes it has happened, that in a few ſtrokes I gave the ſteel its virtue; nay, even in the very firſt ſtroke, one may give a great deal to a ſmall needle. This way I have given the magnetical virtue to needles of ſea compaſſes, made of one piece of ſteel, ſo ſtrongly, that one of the poles would take up three quarters, and the other a whole ounce of iron. Although theſe needles were anointed with linſeed oil, which made a hard coat, to keep them from ruſting, yet they kept the virtue; but in ſtrengthening theſe ſorts of needles, I rubbed by turns firſt to the right and then to the left ſide.

"The ſame way I brought the virtue into the point of a knife, ſo that it would ſuſtain $1\frac{3}{4}$ ounce.

"I brought the ſaid virtue into four ſmall pieces of ſteel, each one inch long, and $\frac{1}{4}$th of an inch broad, as thin as the ſpring of a watch. Theſe four pieces I joined together, as into an artificial load-ſtone, weighing 18 grains troy, and then it did draw up and ſuſtain an iron nail, which weighed 144 grains troy. This artificial load-ſtone has now theſe ſix years been tumbled about, and been lying among iron and ſteel, and in any poſition, and yet it has rather got more than loſt any of its virtue.

"The magnetical virtue being thus brought into iron or ſteel, I have farther obſerved, that that end where the ſtroke was begun, would draw to the north, and where the ſtroke ended, to the ſouth, in whatever ſituation the ſteel had been laid upon the anvil to give it the virtue. I took a piece of ſteel, and rubbed it from one end to the middle, and then from the other end to the middle, and found it had two north poles, one at each end, and the middle a ſouth pole.

"Further, beginning to rub from the middle towards each end of another piece of ſteel, I found it to have at each end a ſouth pole, and in the middle a north pole."

A very eaſy way of giving magnetiſm to a ſmall piece of ſoft ſteel, is the following: Take two pokers of ſoft iron, or two iron bars, of about an inch ſquare, and more than three feet in length, keep them in the magnetical line, or if in this iſland, perpendicularly, as ſhewn in *fig.* 9. Then let the piece of ſteel, C B, be either faſtened to the edge of a table, or be held by an aſſiſtant; and placing the lower extremity of the bar A B, and the upper extremity of the bar C D, both on the ſame ſide, and in the middle of the ſteel, ſtroke the ſteel from the middle towards its extremities, moving the end of the bar, C D, from the middle of the piece of ſteel towards its end C, at the ſame time that the end of the bar, A B, is moving from the middle of the piece of ſteel to its other extremity B; and when the bars are arrived to the ſaid extremities, remove them from the ſteel, and apply them again to the middle, and ſo on; thus ſtroking the piece of ſteel about forty or fifty times on every ſide, will give it a conſiderable degree of magnetiſm.

It is evident, that if in this experiment, when the iron bars are arrived to the extremities of the ſteel, you bring them back to the middle of it, by drawing them along the ſurface of the ſteel, the experiment will not ſucceed, becauſe the magnetic power communicated by their rubbing the ſteel in one direction, will be deſtroyed by their contrary motion.

Dr. Gowin Knight was the firſt who brought this kind of magnets to their preſent ſtate of perfection, ſo as to be of much greater efficacy than the natural ones. The reſult of his method, though the proceſs itſelf was kept ſecret, was firſt publiſhed in the Phil. Tranſ. for 1744, vol. xliii. art. 8, and Phil. Tranſ. for 1745, art. 3. See alſo vol. xliv. for 1747, art. 2. Mr. Wilſon has communicated to the public Dr. Knight's method; who informs us, that having provided himſelf with a large quantity of clean filings of iron, he put them into a large tub, that was more than one-third filled with clean water: he then, with great labour, worked the tub to and fro for many hours together, that the friction between the grains of iron by this treatment, might break off ſuch ſmaller parts as would remain ſuſpended in the water for ſome time. The obtaining of theſe very ſmall particles in ſufficient quantity, ſeemed to him to be one of the principal deſiderata in the experiment. The water being thus rendered very muddy, he poured the ſame into a clean earthen veſſel, leaving the filings behind; and when the water had ſtood long enough to become clear, he poured it out carefully, without diſturbing ſuch of the iron ſediment as ſtill remained, which now appeared reduced almoſt to impalpable powder. This powder was afterwards removed into another veſſel in order to dry it; and this proceſs was ſeveral times repeated. When a ſufficient quantity of this fine powder was procured, he made a paſte of it with linſeed oil; preferring this vehicle, becauſe it contained a conſiderable quantity of the phlogiſtic principle. With theſe two ingredients he made a ſtiff paſte, which he well kneaded, before he formed it into convenient ſhapes, and then upon wood, and ſometimes on tiles, in order to bake or dry it before a moderate fire, at about a foot diſtance from it. In about five or ſix hours it generally attained a ſufficient degree of hardneſs. When theſe baked pieces were become old, he gave them their magnetic virtue in any direction he pleaſed, by placing them between the extreme ends of his large magazine of artificial magnets for a few ſeconds or more, as he ſaw occaſion. By this method, the virtue they acquired was ſuch, that when any one of thoſe pieces was held between two of his beſt ten-guinea bars, with its poles purpoſely inverted, it immediately of itſelf turned about to recover its natural direction, which the force of thoſe very powerful bars was not ſufficient to counteract. (Phil. Tranſ. vol. lxix. part i. for 1779, art. 5.) However, the method of making artificial magnets was diſcovered and publiſhed by Mr. John Michell, in a Treatiſe of Artificial Magnets, printed in 1750, and by Mr. John Canton, in the Phil. Tranſ. for 1751, vol. xlvii. art. 6, p. 31. The proceſs for this purpoſe was alſo found out by others, particularly by Marul Uitgelezze Natuurkund. Verhand, tom. ii. p. 261, and Du Hamel, Hiſt. Acad Roy. 1745 and 1750.

Mr. Michell's method of making magnets is as follows: prepare a dozen bars of ſteel, of about $1\frac{1}{4}$ ounce weight each, ſix inches long, and half an inch broad: let theſe be hardened with a full, but not too great heat: let one end be nicked all round with a chiſſel, to diſtinguiſh it from the other; and the ends of the bars ſhould be cleaned after hardening, either upon a ſmooth ſtone, or razor-grinder's wheel: the ſize and ſhape of the bars may be varied at pleaſure, provided that the length be proportioned to the thickneſs. The beſt ſort of ſteel is that which has no veins of iron in it, and Mr. Michell has found the common bliſtered ſteel at leaſt equal to any other. When any magnet does not anſwer expectation, it will be proper to harden it over again, with a greater or leſs degree of heat, till it proves better. In order to preſerve theſe bars, contrive a box, that ſhall have two pieces of iron, about an inch long

each

each, fixed upright in the middle of each end, over againſt each other, at the diſtance of ſix inches from outſide to outſide. Theſe pieces of iron may be about a quarter of an inch ſquare, and ſhould be filed pretty ſmooth on the ſides. Againſt theſe are to be placed, with their edges towards them, the twelve magnetical bars, ſix on one ſide, with their ſouth, or north poles one way, and ſix on the other ſide with the ſame poles the contrary way. It is neceſſary to obſerve that theſe bars muſt neither be taken out, nor put in, all, or too many on a ſide at once; for if two only be left, with their poles of the ſame denomination the ſame way, without one or more on the other ſide to counter-balance their effects, they will damage each other: and if two of the ſame ſide be taken out together, or laid with their poles of the ſame denomination together, after they are taken out they will alſo damage one another: and if this be the caſe it will be proper to reſtore them before they are uſed, after the manner preſcribed for making of magnets. In order to make the marked ends of theſe bars ſouth poles, and the other ends north poles, place ſix of them in a line north and ſouth, bringing the unmarked end of one, to touch the marked end of the next throughout; the marked ends lying towards the north, which will be ſome advantage to them. Then take an armed magnet, and placing it with both poles upon one of the bars, the north pole towards the marked end, which is to be a ſouth pole, and the ſouth pole towards the unmarked end, which is to be a north pole, ſlide it backwards and forwards from end to end of the whole line of bars three or four times, taking care that they all touch. Then taking it off, remove the two endmoſt bars into the middle, and paſs over them again three or four times. Having thus touched the bars, it will not be improper to turn them with the other ſide uppermoſt, and to touch them over again on that ſide as before, omitting the endmoſt bars, till they are removed into the middle, where they alſo are to be touched.

If an unarmed magnet, either natural or artificial, be uſed, lay the bars in a line as before; place the ſouth pole of the magnet upon the marked end of the endmoſt bar, and ſlide it over the whole line to the end: then taking that pole off, place the north pole upon the ſame bar in its room, not at the extremity of the bar, but towards the middle, and ſlide it back again; then change the poles again, obſerving to ſet the magnet on at the middle of the bar, and ſlide it to the other end, as at firſt. Having done this four or five times, remove the two endmoſt bars into the middle, and placing the ſouth pole of the magnet upon the marked end of them, ſlide it to the unmarked end; and then, placing the north pole upon the unmarked end, ſlide it to the marked end. Let this be repeated three or four times; and turning the bars with the other ſide upward, repeat the ſame proceſs again. When the magnets are weak, it may be neceſſary to touch the bars, according to the preceding direction, before they are hardened, when they will receive the magnetic virtue more eaſily; then, making the whole dozen magnetical, in the manner hereafter preſcribed, till they are as ſtrongly ſo as they will be in their ſoft ſtate, harden one half; and having made theſe again magnetical with the remaining half that are ſoft, harden thoſe alſo, and proceed. But if the magnets are too weak to perform properly, even in this caſe, recourſe muſt be had to ſmaller bars of ſteel, which ſhould alſo be ſoft; and if theſe fail, bars of iron muſt be uſed. Having communicated a ſmall degree of magnetiſm to ſix of the bars, let the other ſix, which are unmagnetical, be laid in a line, in the ſame manner as the former: and let A B, (*Plate* VI. *Magnetiſm, fig.* 10.) repreſent this line, conſiſting of ſix bars, though three only are delineated. The line drawn acroſs at the end of each bar, repreſents the mark diſtinguiſhing that end which is to be made the ſouth pole, from the other. Let C D, E F repreſent the ſix bars already made magnetical: theſe lean againſt each other at the top, and are ſeparated by a piece of wood, or other matter except iron, about the tenth of an inch at the bottom. The three magnets in C D have all their ſouth poles downward, and are placed towards the unmarked ends of the bars in the line which are to be north poles; and the three magnets in E F have all their north poles downward, and are placed towards the marked ends of the bars which are to be ſouth poles. Slide theſe ſix magnetical bars thus placed, backward and forward three or four times over the whole length of the line. Then taking them off, having firſt brought them to touch at the bottom, remove the two endmoſt bars of the line into the middle, and replacing the magnetical bars upon them, as before, paſs over thoſe again. Then taking them off, and turning the bars in the line with the other ſide upward, go over them again in the ſame manner, excepting the endmoſt bars; which, when thoſe in the middle are touched, are to be removed thither, to be touched in their turn. Thus the bars in the line will give a ſtronger power to that of the other ſix, by which they were touched; and, therefore, theſe latter may now be laid down in a line, and retouched, after the ſame manner, with the latter: when this is done, lay thoſe down again, and retouch them with the others: repeat this operation a few times, firſt touching one ſet, and then the other, till they have acquired as much magnetiſm as they will retain; or till they will receive no additional force by any farther repetition. The ſix-inch bars, made magnetical after this manner, when properly hardened, will ſingly lift, by one pole, a piece of iron, weighing a pound or better, if it be of a proper form; and ſix ſuch bars will touch a line of freſh bars of the ſame ſize, to their full perfection, by three or four times ſliding over them; except the endmoſt, which muſt always be removed into the middle. As ſeveral magnets laid together with their poles of the ſame denomination the ſame way, will greatly injure one another, unleſs they have ſomething to counteract them, it is abſolutely neceſſary not to place two of them, of a ſide, or together; but ſingly, one on one ſide, and one on the other, making them to lean together, that they may reſt againſt one another at the top: at the bottom they are preſerved from injuring one another, by being placed upon the bar which is to be made magnetical. In like manner, they muſt not be taken off two of a ſide together, but ſingly, firſt on one ſide, and then on the other. But the readieſt way of taking them off is firſt to bring them to touch one another at the bottom, in the ſame manner as they do at the top, and then they may be removed at once, and upon occaſion ſet on again; only obſerving not to ſeparate them again at the bottom, till they are placed upon the bar which they are to touch. The reaſon of removing the two bars at the ends of the line, in order to their receiving a greater virtue, ſeems to be, that the ſix magnets, employed in touching, are endeavouring to make that part of the bar which is not included between them magnetical, in a contrary direction from that which is included between them. As this laſt is the direction of magnetiſm deſigned, the former endeavour would be injurious; and it is prevented by two cauſes: one of which is the power, whereby the ſteel reſiſts in a degree every endeavour, either to make it magnetical, or to deſtroy its magnetiſm; and the other is the power of the bars already in ſome meaſure magnetical, which lie at both ends of the bar that is touched. Now this laſt power is wanting at one extremity of thoſe bars that are placed at the ends; and conſequently not having a ſufficient force fully to reſiſt the contrary endeavour

vour of the magnets employed in touching them, they become lefs magnetical than the others, which have a fufficient force. Though in the line of bars, when making magnetical, each bar has only one at each end to fupport it (thofe magnets that are planted at the ends of the others to preferve them being called fupporters) againft the contrary endeavour of the fix, made ufe of to touch it; and this does very well; yet fome will receive an additional force by being fupported with larger magnets; or inftead of thefe, two or three of their own fize, at each end; thofe at the marked end all with their north poles touching it, and thofe at the unmarked end all with their fouth pole touching it. And becaufe there will be two or three north poles, and as many fouth poles together amongft the fupporters, at the other end from the bar to be touched, that have nothing to counteract them, it will be proper to place the fouth pole of another magnet among the north poles, and the north pole of another among the fouth poles, that they may not hurt one another, which they otherwife will do.

The manner above defcribed is called the *double touch*: and Mr. Michell obferves, that two magnets will give more ftrength to a bar of their own fize, when ufed after this manner, than a fingle magnet equal to five of the former in ftrength, when applied after the manner of the fimple touch. This ingenious writer has defcribed a frame, contrived for holding feveral of the fix-inch bars, when they are ufed in touching large bars, and when they cannot be conveniently held in the hand; for an account of which we muft refer to his excellent pamphlet, already cited, p. 45, &c. ed. 2. He obferves, that the form of magnets is of very little confequence with regard to their receiving the magnetic virtue, provided that they have a fufficient length in proportion to their bulk. The ftraight bars may be made fquare, round, or flat: though the flat are moft convenient for touching; and probably fomewhat ftronger. Thefe may alfo be pointed at the ends, as in *fig.* 11, in order to render them lighter, and to increafe their power of lifting; though pointed bars are not fo proper for touching. The magnet may be made in the form of a horfe-fhoe, as in *fig.* 12, where a wedge of iron is fuppofed to be applied to the poles of it; and it will thus lie in a narrower compafs, a wedge of iron may be applied to its two poles, and it will lift by both poles at once. The magnet may be alfo made annular, which is a plain flat bar, bent flatways inftead of edgeways; and a femicircular magnet may be bent flatways, like the annular, or edgeways, like the horfe-fhoe; and two magnets of this kind may be conveniently placed together, in order to preferve each other.

The poles of a magnet may be converted by placing the bars which are to retouch it, with their north poles towards its north pole, and the fouth poles towards its fouth pole. In doing this, they fhould be placed on at the middle, and flid once or twice backwards and forwards, before it is fupported; and then that which was the north pole muft be fupported as a fouth pole by north poles: and that which was the fouth pole, as a north pole by fouth poles. In order to make a bar magnetical, fo that it fhall have feveral poles, fupport it at the places where the poles are defigned to be, with poles of a contrary denomination from thofe defigned; and if any place is fupported with fouth poles, the next places on either fide muft be fupported with north poles, and *vice verfâ*. Having done this, confider each piece included between any two fets of fupporters, as a feparate bar, to be made magnetical, with its fouth pole towards the north fet of fupporters, and its north pole towards the fouth fet, and touch it accordingly. Magnets of this fort will not do well, unlefs they are very long; and at beft they are always weak, and will very foon be injured; fo that they fhould only be made occafionally.

Mr. Michell has alfo publifhed a method of obtaining magnetifm by means of three iron bars, without the affiftance of a natural load-ftone, for which we fhall refer to his pamphlet, p. 60, &c. and proceed to defcribe the method defcribed by the ingenious Mr. Canton.

This gentleman bas fucceeded fo well in his attempts to convey a confiderable magnetic virtue to bars of hardened fteel, as to be able to impregnate fuch bars with this virtue to as high a degree, at leaft, as any bars of the fame weight and dimenfions, which he had feen or heard of; and to as high a degree, as he apprehends, the fame bars, in their prefent ftate, are capable of being impregnated. Mr. Canton was able, in about half an hour's time, to communicate to fix bars of hardened fteel, at firft entirely deftitute of any magnetic virtue, the utmoft virtue they were capable of receiving; and that without the mediation or affiftance of any natural load-ftone, or of any artificial magnet. Mr. Canton has publifhed the defcription of his procefs with fuch directions, that any perfon may readily perform the fame. For this purpofe procure a dozen bars; fix of foft fteel, each three inches long, $\frac{1}{4}$ inch broad, and $\frac{1}{20}$th of an inch thick, with two pieces of iron, each half the length of one of the bars, but of the fame breadth and thicknefs: and fix of the hard fteel, each $5\frac{1}{2}$ inches long, $\frac{1}{2}$ an inch broad, and $\frac{3}{20}$ths of an inch thick, with two pieces of iron of half the length, but the whole breadth and thicknefs of one of the hard bars; and let all the bars be marked with a line quite round them at one end. Then take an iron poker and tongs, or two bars of iron, (*Plate* VII. *Magnetifm*, *fig.* 1.) the larger they are, and the longer they have been ufed, the better; and fixing the poker upright between the knees, hold to it near the top one of the foft bars, having its marked end downward, by a piece of fewing filk, which muft be pulled tight with the left hand, that the bar may not flide; then grafping the tongs with the right hand a little below the middle, and laying them nearly in a vertical pofition, let the bar be ftroked by the lower end, from the bottom to the top, about ten times on each fide, which will give it a magnetic power fufficient to lift a fmall key at the marked end; which end, if the bar was fufpended on a point, would turn towards the north, and is, therefore, called the north pole, and the unmarked end is, for the fame reafon, called the fouth pole of the bar. Four of the foft bars being impregnated after this manner, lay the other two (*fig.* 2.) parallel to each other, at the diftance of about one-fourth of an inch between the two pieces of iron belonging to them, with a north and a fouth pole againft each piece of iron; then take two of the four bars already made magnetical, and place them together, fo as to make a double bar in thicknefs, the north pole of one being even with the fouth pole of the other; and the remaining two being put to thefe, one on each fide, fo as to have two north and two fouth poles together, feparate the north from the fouth poles at one end by a large pin, and place them perpendicularly with that end downward, on the middle of one of the parallel bars, the two north poles towards its fouth, and the two fouth poles towards its north end; flide them backward and forward three or four times over the whole length of the bar, and removing them from the middle of this, place them on the middle of the other bar as before directed, and go over that in the fame manner; then turn both the bars with the other fide upward, and repeat the former operation: this being done, take the two from between the pieces of iron, and placing the two outermoft of the touching bars in their room, let the other two be the outermoft of the four to touch these with; and this process being repeated till each pair of bars has been touched three or four times over, which will give them a considerable magnetic power, put the half dozen together after the manner of the four (*fig* 3.), and touch with them two pair of the hard bars, placed between the irons at the distance of about half an inch from each other; then lay the soft bars aside; and with the four hard ones let the other two be impregnated (*fig*. 4.), holding the touching-bars apart at the lower end near two-tenths of an inch, to which distance let them be separated after they are set on the parallel bar, and brought together again after they are taken off; this being observed, proceed according to the method already described, till each pair has been touched two or three times over. But as this vertical way of touching a bar will not give it quite so much of the magnetic virtue as it will receive, let each pair be now touched once or twice over, in their parallel position between the irons (*fig*. 5.), with two of the bars held horizontally, or nearly so, by drawing at the same time the north of one from the middle over the south end, and the south of the other from the middle over the north end of a parallel bar: then bringing them to the middle again without touching the parallel bar, give three or four of these horizontal strokes to each side. The horizontal touch, after the vertical, will make the bars as strong as they can possibly be made; as appears by their not receiving any additional strength, when the vertical touch is given by a greater number of bars, and the horizontal by those of a superior magnetic power. This whole process may be gone through in about half an hour, and each of the larger bars, if well hardened, may be made to lift twenty-eight troy ounces, and sometimes more. And when these bars are thus impregnated, they will give to a hard bar of the same size its full virtue in less than two minutes; and will, therefore, answer all the purposes of magnetism in navigation and experimental philosophy, much better than the load-stone, which is well known not to have sufficient power to impregnate hard bars. The half dozen being put into a case (*fig*. 6.), in such a manner as that two poles of the same denomination may not be together, and their irons with them as one bar, they will retain the virtue they have received; but if their power should, by making experiments, be ever so far impaired, it may be restored without any foreign assistance in a few minutes. And if, out of curiosity, a much larger set of bars should be required, these will communicate to them a sufficient power to proceed with, and they may in a short time, by the same method, be brought to their full strength. Mr. Canton, by the same process, communicated magnetic virtue to two large bars, each half an inch square, 10½ inches in length, and weighing nearly ten ounces and twelve pennyweights, to such a degree, that one of them lifted by one of its ends seventy-nine ounces and nine pennyweights: and a flat semicircular magnet, weighing an ounce and thirteen pennyweights, was made to lift, by applying its two ends together to an iron wedge, ninety troy ounces. The same ingenious gentleman could also readily deprive his bars of their virtue; and change the poles of a natural load-stone, by placing it in an inverted direction, between the contrary poles of his larger bars, laid down at some distance from each other, in the same straight line continued at the distance of about a quarter of an inch from either of the poles, without touching the stone with either of the bars.

The method in which the steel he made use of was hardened is as follows: having cut a sufficient quantity of the leather of old shoes into very small pieces, an iron pan is provided, which a little exceeds the length of a bar, is wide enough to admit of two bars side by side without touching each other on the pan, and at least an inch deep. This pan is nearly half filled with the bits of leather, upon which are laid the two bars, having fastened to the end of each a small wire for taking them out: the pan is then quite filled with the leather, and placed on a gentle flat fire, being covered and surrounded with charcoal. The pan, being brought to somewhat more than a red heat, is kept about half an hour, and the bars are suddenly quenched in a large quantity of cold water. Mr. Horne, in his Essays on Iron and Steel, p. 147, claims the merit of directing this process for hardening Mr. Canton's bars.

In order to communicate the magnetic virtue to a steel bar, to the needle of a compass, &c. by means of two magnetic bars, place the bar or needle, A B (*fig*. 7.), upon a table, then place the two magnetic bars C D, E F, straight up upon A B, at a little and equal distance from the middle of the bar A B, and in such manner, as the south pole, D, of one of the bars may be nearest to that end of the bar, A B, which is required to become the north pole, &c. then these two bars must be slid gradually towards one extremity of the bar, keeping them constantly at the same distance from each other; and when one of the magnetic bars, for instance C D, is arrived at A, then they must be slid the contrary way, till E F arrives at B; and thus the bar, A B, must be rubbed a greater or smaller number of times, till it will be found by trial to have acquired a considerable power. When the magnetic bars are powerful, and the bar, A B, is of very good steel, and not very large, a dozen of strokes are fully sufficient. When the magnetic bars are to be removed from the bar A B, care must be had to bring them to the same situation where they were first placed, *viz*. at a little and equal distance from the middle of the bar A B, and then they may be lifted up.

In this operation, the effect of the bars may be improved several ways, which will be found necessary when the bar, A B, is proportionably large, and it is required to give it the greatest possible power. This may be effected, first, by joining the magnetic bars at top, interposing a piece of wood or other substance, except iron, to keep them apart, as shewn in *fig*. 8; for in this manner, the upper poles of the bars being contiguous, will tend to strengthen each other, and, of course, their lower poles will also be strengthened. Secondly, by placing the bar, to be rendered magnetic, between two bars of soft iron, or two other magnets, as shewn in *fig*. 9, or in the manner before directed. Thirdly, the magnetic bars may be inclined the contrary way, after the manner used by Mr. Æpinus (*fig*. 10.); so that the magnets C D, E F, may make an angle of about fifteen degrees with the bar A B.

The bar, A B, may, in the same manner, be rendered magnetic by means of an armed magnet, as shewn in *fig*. 11; or by a horse-shoe magnet, as shewn in *fig*. 12, placing both the poles of the magnet in contact with the bar, &c.

In all these methods, the bar to be rendered magnetic must be stroked on every side; and, in order to let the magnetic centre fall just in its middle, care must be had to stroke one-half of the bar just as often as the other half.

Whenever a steel bar, or in general a piece of ferruginous substance, is rendered magnetic by applying two bars, or whenever two magnetic poles are applied to it at the same time, as used in this and the preceding experiment, the operation is usually called the *double touch*, in distinction from the *single touch*, which is when only one magnetic pole is applied to it.

As artificial magnets are frequently made in the shape of a semicircle, or like a horse-shoe, for the sake of bringing both poles in the same plane, the crooked steel bars of which they are constructed are made magnetic in the same manner as the straight bars, excepting only, that the magnetic bars which are used for it must follow the curvature of the steel bar; thus, if it be required to render magnetic the piece of steel A B C (*fig.* 13.), place it flat upon a table, and to its extremities apply the magnets D F, E G; joining their extremities F, G, with the conductor or piece of soft iron F G. Then apply the magnetic bars H, I, to the middle of the piece A B C, and stroke it with them, from end to end, following the direction of the bent steel, so that on one side of it the magnetic bars may stand in the direction indicated by the dotted representation L K. In this manner, when the piece of steel has been rubbed a sufficient number of times on one side, turn the other side upwards, and repeat the operation till it has acquired a sufficient degree of magnetism.

In this operation, the same precautions must be followed as were recommended for the method of communicating the magnetism to straight bars, *viz.* the magnets D F, E G, as well as the magnets H, I, must be placed so that their south poles must be towards that extremity of the bent steel which is required to be made the north pole, and their north poles towards the other extremity. The magnets, I, H, must be first placed on the middle of the bent steel; and after having drawn them over one leg of it as often as over the other, in order to let the magnetic centre fall just in the middle of the bent steel, they are removed, &c.

If a person have only one magnetic bar, or a terrella, with which he wishes to give magnetism to a needle or other bar, the only way of effecting it is, to apply one pole of the terrella, or magnetic bar, A B (*fig.* 14.), to one extremity, C, of the needle, and to draw it all along the surface of it till it reaches the other extremity D; then the magnet being removed, must be applied again to the extremity C, and must be drawn over the needle as before. Thus the needle must be rubbed several times, by which means it will acquire a considerable degree of magnetism.

It must be observed, that the extremity of the needle which the pole of the magnet touched last, acquires the contrary polarity. Thus, in the present instance, if B be the north pole of the magnet, the extremity, D, of the needle will afterwards be found to have acquired the south polarity, and the other extremity, C, the north.

In this operation it is evident, that, after the first stroke, when the magnet is applied again to C, this extremity, having acquired the north polarity, will have that power destroyed by the vicinity of the north pole, B, of the magnet; so that it seems that every stroke undoes what was done in the preceding. However, the fact is, that by repeating the strokes the power is increased; but, in general, this method will never be so advantageous as when more than one magnetic pole is used: hence it ought not to be used, excepting in case of necessity, *viz.* when one has only one magnetic bar or terrella.

Artificial magnets are preferable to the natural ones in a variety of respects. Mr. Michell mentions particularly, that they may be had at much less expence and trouble, and in greater plenty; that they are much superior to natural magnets in strength, and better able to communicate the magnetic virtue in proportion to their strength; that they are more easily restored to their former strength when they are at any time damaged; that they furnish several poles; and that they may be had in every form. Cavallo's Magnetism. Cavallo's Philosophy, vol. iii.

MAGNETICAL AMPLITUDE, *Azimuth*, and *Declination*, see the several substantives.

MAGNETICAL *Island*, in *Geography*, an island in the South Pacific ocean, near the N.E. coast of New Holland, discovered by Capt. Cook in the year 1770, and so named from its seeming to have some effect on the compass. S. lat. 19° 8'. W. long. 213° 22'.

MAGNETICAL *Line*, is that line in which a needle would place itself, if left at entire liberty to turn itself as well vertically, as horizontally. See DIPPING.

MAGNETICAL *Meridian*. See MERIDIAN.

MAGNETICAL *Needle*. See NEEDLE. See also *Mariner's* COMPASS, DIPPING, and the article MAGNET.

MAGNETICAL *Paradox*. Upon the table A B (*Plate* VI. *Magnetism*, *fig.* 15.) place a piece of iron wire, not above a tenth of an inch long. Let the magnetic bar, E F, be held at about four or five inches above the table, with either pole downwards, and in such a place, as that the perpendicular let fall from it to the table may touch the table at G, *viz.* two or three inches distance from the iron wire: these distances, however, are subject to a good deal of variety, arising from the power of the magnet.

By the action of the magnet the iron wire will elevate one of its ends, as represented by C D, forming with the table an angle, which is larger the nearer the wire comes to the point G, where it stands quite erect.

In this situation, if you give gentle knocks to the table, the wire, C D, will gradually proceed towards G, every knock making it jump up and advance a little way. The reason of which a superficial observer would immediately attribute to the attraction between the magnet and the iron wire, which, being not sufficiently strong to raise the wire from the table, has just power enough to draw it a little nearer to the point G, when the motion of the table lifts it up.

Thus far the experiment shews nothing extraordinary; but if it be repeated with only this variation, *viz.* that the magnet, instead of being held above the table, be placed below it, *viz.* at H I, the event will be, that the wire, which will now make an obtuse angle towards G, as represented by K L, on knocking the table, will gradually recede from the point G, shewing as if the magnet repelled it; which has given to this experiment the name of *magnetical paradox*; for, in fact, the magnet attracts the wire.

This phenomenon results from the directive property of the magnet acting at a greater distance than the attractive.

In order to explain the immediate cause of this phenomenon, it must be considered, that the wire K L, (*fig.* 16.) being rendered magnetic by the action of the magnet H, is inclined to it according to the above-mentioned laws of the dipping needle; but, on account of its weight, and because it is supported not in its centre, but by one end, namely K, which stands upon the table, it does not incline so much as it ought to do, if it were freely suspended by its centre, the end, K, now being a little higher than its proper situation. Let M N be the perpendicular, which passes through the centre of the wire. Now, when by the motion given to the table, the wire is made to jump; this, whilst remaining in the air, will take its proper inclination, as shewn by *r* Q, its centre remaining in the same perpendicular M N; for the directive power of the magnet, H, acts at a greater distance than its attraction. In this situation it is evident, that a perpendicular P O, let fall from the lower extremity, *r*, of the wire, touches the table in a point farther from G than the point K; and as the wire after the jump comes down to the table again with the proper inclination, *viz.* parallel to *r* Q, it follows, that now its lower end must touch the table at O: and thus every knock will

will force it to recede a little more from the point G, which lies just over the magnet H.

The same explanation applied to the first part of the experiment, will shew that the wire must in that case, *viz.* when the magnet is held above the table, approach continually the point G.

This experiment may be diversified by using iron filings, instead of the iron wire; for, in the first case, the filings dispersed over the table will be gradually collected about the point G; and in the latter case, the filings placed about the point, G, will be gradually forced to recede from that point. Cavallo's Magnetism, chap. vii.

MAGNETICAL *Variation.* See VARIATION and DECLINATION.

MAGNETIS LAPIS, in the *Natural History of the Ancients*, the name given in different ages to two very different substances. The earliest Greek authors expressed by it the load-stone, which became afterwards called *Heraclius lapis*, (see IRON, *Ores of*, and MAGNET); and then the word *magnes* was applied to a very different stone brought from the same place, the neighbourhood of Magnesia in Lydia.

This was a fine beautiful and bright substance, of a pure white, and so very bright and glossy, as to bear a resemblance to polished silver. It was dug in large masses, and was of a texture capable of being wrought into any figure. Accordingly it was in great esteem among the ancients, who had it wrought into vessels for the use of the table.

It seems to be wholly unknown at present among the nations we have commerce with. Hill's Theophrast. p. 79.

MAGNETISM, MAGNETISMUS, that quality or constitution of a body, and its pores, whereby it is rendered *magnetical*, or a *magnet*.

Magnetism is found to be a transient power, capable of being produced and destroyed again.

MAGNETISM *of the Earth* is that property of the terrestrial globe, from which the magnetism of the ordinary magnets, the direction of the magnetic needle, and other phenomena are derived, and upon which they necessarily depend. This hypothesis is evinced by so many observations, that no philosopher can be sceptical enough to dispute its truth. The principal reasons, says Mr. Cavallo, which prove it, almost to a demonstration, are, first, that almost all the phenomena which may be exhibited with a usual magnet, may be also exhibited with the earth, as far as it may be tried; and secondly, that vast masses of iron, or ferruginous substance, actually magnetic, are dug out of the earth almost in every part of it.

"The phenomena of the compass and of the dipping needle, in different parts of the world, and the magnetism naturally acquired by soft iron when properly situated, are exactly imitated by a common magnet, or a terrella; but the only phenomenon, which has not been observed with respect to the earth, and which is the principal property of the usual magnets, is the attraction of a piece of iron, or other ferruginous substance. For instance, if a piece of iron be presented to either of the poles of a common magnet, it will be powerfully attracted by it; but if it be presented to the middle of the magnet, the attraction will be found to be hardly perceivable, or at least incomparably weaker than at the poles; in conformity to which, it might be expected, that a piece of iron should be attracted more powerfully downwards, when near the poles of the earth than when near the equator; which attraction, being combined with the attraction of gravitation, ought to be known by the difference of the weights of the same piece of iron, when weighed near the poles, and when weighed near the equator; for, if the magnetic attraction of the earth upon it be at all sensible, it ought to weigh more in the former case than in the latter. But this difference of weights has not yet been ascertained; however, if it were to be tried with all the accuracy necessary for so nice an experiment, I am inclined to think that it would be found to answer; *viz.* that the same piece of iron would be found to weigh somewhat more in places nearer to the poles, than it does nearer to the equator: but, even in case no such difference of weights were observed, it would be improper to infer that the earth does not exert any magnetic attraction towards the iron on its surface, and that this attraction is not stronger near the poles than near the equator; because, first, the magnetism of the earth being very weak, the difference of the attraction in different places must be likewise very small, notwithstanding the directive power is considerably strong; for, as was explained under the article MAGNET, the latter of those powers extends to a much greater distance than the former. And, secondly, it must be considered, that the equatorial diameter of the earth is longer than its polar diameter, and that the attraction of gravitation, or the weight of bodies, decreases in proportion to the squares of the distances from the centre of the earth; in consequence of which, if we abstract the magnetic attraction, and consider only the attraction of gravitation, it will appear that the piece of iron must weigh more when weighed near the poles than when weighed near the equator; namely, because when near the poles, it stands actually nearer the centre of the earth than when near the equator.

"If the magnetic needle pointed always due north and south, or always within a certain distance of those points, it would shew that the earth has two fixed magnetic poles, either coinciding with its astronomical poles, or at some distance from the same; but the continual variation of the magnetic needle shews, that those magnetic poles of the earth move with respect to the surface of the earth, and, on this account, many suppositions have been offered to the public by divers ingenious persons. It was imagined, that there was a large magnet inclosed within the body of the earth, which being not fixed to the external part, moved with respect to it, and, consequently, occasioned the variation of the needle." To this purpose, Mr. Whiston alleges that the earth on which we live, includes within it a vast spherical magnet, concentrical thereto, having its own poles, meridians, equator, and parallels; and all much of the same general nature of those with small terrellæ, or spherical load-stones, in the possession of the curious among us.

The power of a good terrella, or a spherical load-stone, says this author, as it affects a needle a foot long, is equal to the magnetic power of that internal load-stone about two and a half, or three diameters of such load-stone. From which consideration, the quantity of magnetic attraction at all distances from the internal load-stone, for needles a foot long, may be determined; and from the same consideration it appears, that the diameter of this internal load-stone is about eleven hundred and fifty miles. To which we add, that, in regard sir Isaac Newton has demonstrated, that the power of gravity diminishes within the earth, and is less there than at its surface, nearly in the proportion of its greater nearness to the centre, the magnetic power, at two thousand nine hundred miles distance from us, and nearly one thousand and sixty from the earth's centre, which is $\frac{10}{24}$ of the power of gravity here, will be somewhat greater than the power of gravity there; which limit is worthy our attention, gravity being stronger than magnetism on the one side of it, and weaker on the other; we mean, as it affects needles of one foot diameter. At that limit, therefore, at least

leaſt near the magnetic poles, iron a foot long will be twice as heavy, and fall twice as faſt, as any other natural body, *viz.* by the union of thoſe two equal powers, gravity and magnetiſm; and of conſequence, above that limit, ſuch an iron will be leſs than twice as heavy, below it more than twice as heavy, as any other natural body.

The earth's internal load-ſtone, he ſays, is not fixed to our upper parts, but is moveable with reſpect to them, and actually revolves on the earth's axis, from eaſt to weſt, in a certain long period of time; as appears beyond contradiction, from the conſtant variation of the horizontal needle weſtward; as well as the regular increaſe of inclination of the dipping needle.

The only way to render this motion, *i. e.* the variation, poſſible and intelligible (to uſe Dr. Halley's words), is to ſuppoſe it to turn about the centre of a globe, having its centre of gravity fixed and immoveable in the ſame common centre of the earth. This moveable internal ſurface muſt likewiſe be looſe, and detached from the external part of the globe, which may be reckoned the ſhell, and the other the nucleus or inner globe, included within it, with a fluid medium between. Now, from the variation's moving weſtward, it is plain, that the foreſaid nucleus has not preciſely attained the ſame degree of velocity with the exterior parts in their diurnal revolution: but ſo nearly equals it, that in three hundred and ſixty-five revolutions, the difference is ſcarcely ſenſible; and muſt probably have ariſen from hence, that the impulſe, whereby the diurnal motion was impreſſed on the earth, was given to the external parts, and thence communicated to the internal.

This internal magnet has one central pole northward, in the nature of the poles of our common load-ſtones; but its ſouthern pole appears not to be central, but rather circular, and that at a great diſtance from the ſouthern pole of the earth.

The northern magnetic pole is *now* ſituate, ſays Mr. Whiſton, about the latitude of $76\frac{1}{2}$ degrees; *i. e.* $13\frac{1}{2}$ degrees from the north pole of the earth, and about 30 degrees eaſtward from the meridian of London.

The ſouthern magnetic circular pole has its centre, or central pole, nearly in the parallel of 60 degrees; and, in a meridian paſſing along the eaſt coaſt of Borneo, about 117 degrees eaſtward of London. Its radius is alſo an arc of a great circle of about 44 degrees.

The reſpective motion of the internal magnet, or the velocity, *v. g.* of its north pole, appears to be 27 deg. 0 min. in 144 years, *i. e.* upwards of one degree in five years; ſo that it makes an entire revolution in 1920 years. Hence, as the number of degrees in the upper earth's diurnal revolution is to the number of days in the revolution of the internal magnet, *i. e.* as 1 is to 700,000, ſo is the reſpective motion of this magnet from eaſt to weſt to the real motion of the upper earth from weſt to eaſt; or, to ſpeak ſtrictly, ſo is the difference of their motions from weſt to eaſt to the entire motion of the upper earth the ſame way. This external fixed earth has therefore communicated almoſt all its motion already to the internal magnet; and can communicate no more than this difference of their motion, and that only in an infinite term of years; or, in other words, this real internal motion can never be the ſeven hundred thouſandth part ſwifter than it is at preſent. This internal motion, therefore, began with the commencement of the diurnal motion of the upper earth; and has gone on ſtill faſter and faſter by the communication of that motion through the intermediate fluid. Since, therefore, action and re-action are equal, and tend to contrary parts, this internal load-ſtone, thus accelerated by the upper part, muſt have all along retarded that upper earth, and made the diurnal rotation ſtill ſlower and ſlower. This acceleration on one ſide, and retardation on the other, muſt have been very great at the firſt beginning of the diurnal motion, when the difference of their motion was equal to the entire motion itſelf, and muſt have been diminiſhing ever ſince. To which cauſe is probably owing that acceleration of the moon's motion with reſpect to that of the earth, ſince the time of the old aſtronomers, firſt taken notice of by Dr. Halley, and embraced by ſir Iſaac Newton. And the ſame conſideration ſeems to ſuggeſt a method for determining the age of the world; for, were the proportions of the quantity of matter in the upper earth to the internal magnet, with the tenacity of the intermediate fluid, &c. known, one might go back from the known difference of their velocity now, and find thoſe differences and quantities of motion themſelves, *à priori*, in all paſt ages; or, were the velocity of the firſt diurnal rotation of the upper earth known, we might geometrically determine, *à priori*, how long ago that rotation began, or how ancient our earth is.

The variation of magnetic needles from the azimuth of the meridians of the internal magnet is derived, ſays Mr. Whiſton, from the difference of the ſtrength of the ſeveral parts of the internal magnet's ſurface; which as it is only to be known by experience, that variation cannot be determined before-hand, unleſs where there are good accounts how much it had formerly been; it being probable, that it returns round, and will be the ſame in any year of the next revolution of the internal magnet, that it has been in the like year of any former revolution, or will itſelf have a revolution in about 1920 years. Mr. Whiſton adds, that the two fixed magnetic poles in our upper earth firſt introduced by Dr. Halley, as neceſſary to ſolve the irregularity of the variation of the horizontal needle from the meridians of the moveable internal magnet, ſeem not to have any juſt foundation in nature, the like irregularities being found in the common terrellæ, or ſpherical load-ſtones, and being beſt accounted for from the compoſition of the magnets, which are found to have parts of different degrees of purity, ſtrength, and perfection; ſo that where the parts are weaker than ordinary, the ſtronger neighbouring parts prevail, and draw the needle that way: not but Dr. Gilbert's notion of prominent and depreſſed parts on magnets may have ſome room, and be allowed to contribute ſomewhat, to ſuch variations. See VARIATION.

On the ſuppoſition above ſtated, the variation ought to be regular; that is, it ought to move in all parts of the world, ſo as to anſwer to the two points of the large internal magnet; which, however, is not the caſe.

In order to ſupply the deficiency of this hypotheſis, it was farther imagined, that there were four magnetic poles within the earth, which were moveable with reſpect to each other, and that, therefore, the variation of the needle ought to be derived from all their actions conjointly; which would render the theory of the variation exceedingly intricate: but, notwithſtanding this difficulty, a regularity, within certain laws and limits, ought to be ſtill obſervable reſpecting the variation; but no ſuch regularity has been yet proved. In ſhort, without detaining our readers any longer on this point, it will ſuffice to ſay, that no theory yet offered has been ſufficient to foretel, with certainty, the variation of the needle for any future period of time, or for any place diſtant from thoſe in which obſervations have been frequently made. See DECLINATION, COMPASS, and VARIATION.

Mr. Cavallo is of opinion, that the magnetiſm of the earth ariſes from the magnetiſm of all the magnetic ſub-

ſtances

ftances therein contained, and intermixed with other bodies; that the magnetic poles of the earth may be confidered as the centres of the polarities of all the particular aggregates of the magnetic fubftances: and that thefe principal poles muft change place, relatively to the furface of the earth, according as the particular aggregates of magnetic fubftances within the earth are in fome manner or other altered, fo as to have their power diminifhed, increafed, approached, or removed from the principal poles.

Although no regularity has been eftablifhed with refpect to the variation of the needle, yet as the different fituation of the magnetic poles within the earth occafions a great variety of appearances, and as the right underftanding of thefe varieties may be of great ufe to thofe who wifh to inveftigate this intricate fubject, the developement of which will be of vaft ufe to mankind; we fhall here fubjoin the principal cafes, as they are drawn up by Mr. Lorimer, which feem to be poffible, relating to the pofition of the magnetic poles; conceiving, agreeably to the moft natural and moft generally received fuppofition, that they are two, and that they lie on the furface of the earth. Thefe cafes are no more than four, *viz.*

Cafe 1.—If the magnetic poles of the earth had coincided with the true poles thereof, there could have been no declination or variation of the mariner's compafs in any part of the world, that is, if the earth be uniformly magnetical; for, in that cafe, the needle, in pointing to the magnetic poles, would always have pointed to the true poles alfo; this needle would therefore be neceffarily directed along the courfe of the meridian, or, in other words, it would have no declination or variation either to the eaft or weft thereof.

Cafe 2.—If the magnetic poles were fituated in the fame meridian, and in oppofite parallels; upon that meridian which paffes through the magnetic and true poles, from the one of the magnetic poles to the other, and upon the oppofite meridian all along, there could be no declination, for the reafon mentioned in the former cafe. Likewife, upon the equator, there would be no declination; for though if one of the magnetic poles were only to act upon the needle, in paffing along the equator to the diftance of 90 degrees in longitude eaft or weft, the declination would increafe, fo that at 90 degrees diftance from the line of no declination it would be equal to the angle contained between the magnetic and true poles; yet, as the other magnetic pole, in this cafe, is always within the fame diftance of the needle, it will act upon the oppofite end of it with equal force, and confequently, will keep it parallel to itfelf all round the equator. But in going from the equator north or fouth, the declination would increafe fo as to be 180 degrees on the little arches or fpaces of the meridian contained between the true and the magnetic poles, which is the greateft poffible declination in all cafes whatfoever. It muft be farther obferved on this cafe, that the lines of no declination, including thofe arches of 180°, form two great circles of the globe along the meridian and the equator, croffing one another at right angles, and dividing the furface of this globe into four quarters, two in each hemifphere; the one hemifphere having weft declination in the north, and eaft declination in the fouth half thereof, and in the oppofite hemifphere it would be juft the reverfe; fo that each of the arches or femicircles of no declination would have eaft declination on the one fide of them, and weft declination on the other. The fmall arches of 180° declination, which are between the true and magnetic poles, may be reckoned in all cafes as a part of the lines of no declination; for there indeed the needle conforms itfelf to the meridian as well as in the other parts of the circle, though its ends are reverfed. In fhort, as all the lines of declination do coincide and terminate in the magnetic and true poles, fo thefe arches of 180° are a kind of limit, making with each of thofe lines, as in the prefent cafe, a curve line or figure returning into itfelf; which figures, from 180° between the poles, to 0 declination upon the equator, do each of them include a fpace larger than the other, till at laft they fill up the whole quarter of the furface of the globe, and conform themfelves, as nearly as poffible, to the fhape and figure thereof.

As a variety of this cafe, it may be added, that the magnetic poles may be fituated in the fame meridian, but in parallels which are not oppofite. In that cafe, the only alteration which could happen is, that in the hemifphere in which the magnetic and true poles are neareft to each other, the figures formed by the lines of declination become fmaller, and the correfponding figures in the oppofite hemifphere, larger. The line of no declination, which, in this cafe, reprefents the equator, would alfo be proportionably nearer to thofe poles which are neareft to one another.

Cafe 3.—If the magnetic poles were fituated in oppofite meridians, and in oppofite parallels; upon thofe meridians which pafs through the magnetic and true poles there could be no declinations, for the reafons mentioned in the former cafes. But upon the equator, eaftward or weftward, to the diftance of 90° in longitude, the declination would actually increafe, fo as there to be equal to the angle which meafures the diftance between the true and the magnetic poles; and from thence it would, in the fame manner, decreafe for the other 90° to the oppofite meridian. The declination lines of 10°, 20°, &c. as far as the greateft declination upon the equator, in this cafe, become arches or curves, which conform themfelves, as nearly as may be, to the courfe and direction of the lines of no declination, and are called lines of the firft order. But the lines of the greateft equatorial declination crofs one another at the diftance of 90° in longitude from the meridian or circle of no declination, fomething in form like the letter X, or like two Gothic arches joined at the vertex. They are called lines of the fecond order, and may very properly be confidered as the boundary between the lines of the firft and third order, as the lines of no declination are always boundaries between the lines of eaft and weft declination. In this cafe, thofe lines of no declination, including the arches of 180°, form only one great circle along the meridian, dividing the furface of this globe into two hemifpheres, in the one of which there is eaft declination, and in the other weft declination.

From the greateft equatorial declination to the arches of 180°, the declination lines of the third order are curves returning into themfelves, and in fhape nearly refembling parabolas erected upon thofe arches of 180°.

As a variety of this cafe, it may be added, that if the magnetic poles were fituated in oppofite meridians, but in parallels which are not oppofite, then, in that hemifphere in which the true and the magnetic poles approached neareft to one another, the figure formed by the lines of declination would be fmaller, and in the oppofite hemifphere the correfponding figures would be larger in proportion.

Cafe 4.—This cafe is a very extenfive one, *viz.* when the magnetic poles are fituated neither in the fame nor in oppofite meridians; and this feems to have been the real pofition of thofe poles ever fince any obfervations of the declination of the magnetic needle have been made.

In this cafe, then, the lines of no declination cannot be either in the direction of a meridian or along the equator, as in the former cafe, but in a kind of curves, which are varioufly inclined to both; and they divide the furface of the globe into two parts, but thefe parts are not hemifpheres, as in the laft cafe, for they may be of a very different extent. If the magnetic poles be fituated in meridians nearly oppofite, the curvature of thofe lines will not be fo great, that is, they become more like to Cafe 3. But as the magnetic poles approach nearer to the fame meridian, the curvature of the lines of no declination becomes greater, till they almoft touch one another, fomething in form like the figure of the number 8, and at laft they complete the two great circles, as in Cafe 2. The lines of the fecond order, which correfpond to the greateft equatorial declination, if the magnetic poles be fituated in meridians nearly oppofite, have a declination nearly equal to the angle formed between the magnetic and true poles, as in Cafe 3; but as the magnetic poles approach towards the fame meridian, this declination decreafes, till at laft it entirely vanifhes, as in Cafe 2. The other declination lines in this cafe are fo fimilar to the former, that they require only to be referred to it. Laftly, it muft be obferved, that whether the magnetic poles be fituated in oppofite parallels or not, makes as little difference in this as in the former cafe.

Hitherto the magnetic poles have been confidered to lie on the furface of the globe; but if we attentively confider the fituation which they may more likely have, it will appear, that in all probability they are not fituated near the furface of this globe, but at fome depth below it; at leaft this muft be the cafe with the fouth pole; for, fince the water of the fea is incapable of magnetifm, and the fouthern hemifphere, efpecially about the fouth pole, contains a vaft deal more fea than land; it is plain that the fouth magnetic pole muft be fituated at leaft near the bottom of the fea; in confequence of which, the variation of the needle in that hemifphere muft be different from what it would be if the magnetic pole were fituated on the furface of the terraqueous globe. The fame may be obferved with refpect to the fituation of the north magnetic pole. Befides this, we muft alfo confider the irregularities arifing from the unequal and irregular fituation of land and fea; it being natural to conceive, that large tracts of land on one fide of the magnetic needle will draw it away from the real meridian, whereas a large ocean can produce no fuch effect. This, however, is fubject to a great deal of variety, arifing from the nature of the land, the depth of the fea, the nature of the ground at the bottom of the fea, &c. It appears, therefore, that a great many caufes combine to act upon the magnetic needle, occafioning it to decline from the true meridian, and that it is almoft impoffible to form a ufeful theory upon it.

Magnetism, *Theory of.* As for the caufes of magnetifm, or the manner in which attraction, repulfion, and other magnetic phenomena are produced, we have yet no hypothefis, that will fatisfactorily account for them. Plutarch tells us, the magnet attracts iron, by emitting fome fpiritual effluvia, whereby the contiguous air being opened and driven on either fide, does again drive that contiguous to it; and thus the action being communicated round, the iron is thereby protruded; but this is contradicted by the equally vigorous action of the load-ftone in vacuo, and in the open air. Others of the ancients afcribe the action of a magnet to a foul that animates it; and others to an unknown fympathy between the effluvia of the iron and thofe of the magnet.

An opinion, that has much prevailed among the moderns is that of Des Cartes, maintained by Malebranche, Rohault, Regis, &c. and even admitted and confirmed by Mr. Boyle, &c. In this it is fuppofed, that there is continually flowing, from the poles of the world, a fubtle, impalpable, and invifible matter, channelled or ftriated; which matter, circulating round the earth, in the planes of the meridians, re-enters at the pole, oppofite to that from which it iffued, and paffes again through the poles parallel to its axis: that the magnet has two poles anfwerable to thofe of the earth; and that out of thefe there iffues a matter like that juft mentioned; and that this matter, entering at one of the poles, gives the impulfe, whereby iron tends to the magnet, and produces what we call attraction. Now, befides the magnetical matter re-entering the poles of the magnet, there is always a certain quantity thereof circulating round the magnet, compofing a kind of vortex about it. The fpace wherein this matter moves, is the fphere of activity of the magnet, within which its attractive faculty is confined.

Dr. Gilbert, in his work "De Magnete," folio, printed 1600, concludes, from fome experiments which he made, that the needle is not attracted by the magnet, but turned into its pofition, by what he calls a difponent virtue; which he fuppofed to furround the ftone, fomewhat in form of an atmofphere.

As to its directive faculty, or the inclination of a needle touched with it to the poles of the world, and its dip to a point beneath the horizon, they follow from the fame principle; fince, were the magnet or needle to have any other fituation, the magnetic matter would ftrike on its other furface in vain; and, not being able to get admiffion, would, by degrees, change its fituation, till fuch time as its pores correfponded to the courfe of the magnetical matter; which fituation having once acquired, it would ceafe to move, the magnetical matter then ceafing to difturb it.

The form or effence of a magnet, therefore, is fuppofed to confift in its being perforated by an infinite number of parallel pores; fome of which are difpofed to admit the ftriated matter from the north pole of the world, others that of the fouth: hence the north and fouth poles of the magnet.

Mr. Hartfoeker maintains, that the magnet is no more than a common ftone, full of an infinite number of hollow prifms; which, by the diurnal motion of the earth, are ranged parallel to each other, and nearly parallel to the axis of the earth. Thefe prifms have their cavities filled with an extremely fubtle matter, which, by the diurnal motion of the earth, is paffed from prifm to prifm; thus making a circulation, and returning into the prifms, where it firft began. From thefe principles he deduces all the phenomena of the magnet; and M. Andry does the fame, from the doctrine of alkali and acid.

As to the directive power of the magnet, Mr. Whifton inclines to think it mechanical; and afcribes it to magnetic effluvia circulating continually round the load-ftone; of which circulations, he thinks, there are evident indications in magnetic experiments; as Mr. Boyle thinks there are of the magnetifm, or magnetic effluvia of the earth; though thefe effluvia are never yet rendered fenfible, as electric effluvia began to be in his time. But the attractive power Mr. Whifton thinks entirely immechanical, as the power of gravity is; not being able to devife any fuch motion of a fubtle fluid belonging to the load-ftone, as will account for the attractive power in the fefquiduplicate proportion of the diftances reciprocally; though if he could, yet would that be no more than to remove the immediate power of the Supreme Being one ftep farther; the laft refort of all mechanical principles whatever being in the immechanical power and efficacy of the Deity.

Dr. Knight deduces from feveral experiments the following propofitions, which he offers, not fo much to explain the nature of the caufe of magnetifm, as the manner in which it acts: the magnetic matter of a load-ftone, he fays,

 moves

moves in a ſtream from one pole to the other internally, and is then carried back in a curve line externally, till it arrive again at the pole where it firſt entered, to be again admitted; the immediate cauſe why two or more magnetical bodies attract each other, is the flux of one and the ſame ſtream of magnetical matter through them: and the immediate cauſe of magnetic repulſion is the conflux and accumulation of the magnetic matter. His opinion was, that this earth had originally received its magnetiſm, or rather that its magnetical powers had been brought into action, by a ſhock, which entered at about the ſouthern, and paſſed out at the northern tropic. This, according to his ſtatement, was the courſe of the magnetic fluid, and he ſuppoſed, that the magnetic poles were at firſt diametrically oppoſite to each other. But if this was the caſe at firſt, we are led to conclude from Mr. Canton's doctrine, that they would not long have continued ſo; for, on account of the intenſe heat of the ſun in the torrid zone, according to the principles ſtated under the article DECLINATION, the north pole muſt ſoon have retired to the north-eaſtward, and the ſouth pole to the ſouth-eaſtward. (Phil. Tranſ. vol. xliv. p. 665, &c.) Mr Michell rejects the notion of a ſubtle fluid; but though he propoſed to publiſh a theory of magnetiſm eſtabliſhed by experiments, no ſuch theory has appeared. Signior Beccaria, from obſerving that a ſudden ſtroke of lightning gives polarity to magnets, conjectures, that a regular and conſtant circulation of the whole maſs of the electric fluid from north to ſouth may be the original cauſe of magnetiſm in general. This current he would not ſuppoſe to ariſe from one ſource, but from ſeveral, in the northern hemiſphere of the earth: the aberration of the common centre of all the currents from the north point, may be the cauſe of the variation of the needle, the period of this declination of the centre of the currents may be the period of the variation, and the obliquity with which the currents ſtrike into the earth may be the cauſe of the dipping of the needle, and alſo why bars of iron more eaſily receive the magnetic virtue in one particular direction. Lettre dell' Elettriciſmo, p. 269, or Prieſtley's Hiſt. Elec. vol. i. p. 409, &c.

Similar to the laſt hypotheſis is that propoſed by the ingenious Æpinus, (Tentamen Theoriæ Electricitatis et Magnetiſmi, cap. i. § 3.) which, though labouring under ſeveral objections, ſeems however to be the moſt plauſible.

From the analogy of the eſtabliſhed or more common hypotheſis of electricity, which goes under the name of Dr. Franklin's, Mr. Æpinus is led to imagine, that there exiſts a fluid productive of all the magnetic phenomena, and conſequently to be called the *magnetic fluid;* that this fluid is ſo very ſubtle as to penetrate the pores of all bodies; and that it is of an elaſtic nature, *viz.* that its particles are repulſive of each other.

He farther ſuppoſes, that there is a mutual attraction between the magnetic fluid and iron, or other ferruginous bodies; but that all other ſubſtances have no action on this fluid; they neither attracting nor repelling each other.

He then obſerves, that there is a great deal of reſemblance between ferruginous bodies and electrics, or non-conductors of electricity; for the magnetic fluid paſſes with difficulty through the pores of the former, as well as the electric fluid paſſes with difficulty through the pores of the latter. However, there is not a body that has any action on the magnetic fluid, and is, at the ſame time, analogous to non-electrics; for inſtance, there is no body, the particles of which attract the magnetic fluid; and yet this fluid can pervade its pores without any obſtruction. In iron, indeed, a kind of gradation of this ſort ſeems to take place; for, the ſofter the iron is, the more freely does the magnetic fluid pervade its pores; and, on the contrary, the harder it is, the greater oppoſition it offers to the free paſſage of that fluid; ſo that the iron, when ſoft, ſeems to be more analogous to non-electrics than when hard.

According to this hypotheſis, iron, and all ferruginous ſubſtances, contain a quantity of magnetic fluid, which is equably diſperſed through their ſubſtance, when thoſe bodies are not magnetic; in which ſtate they ſhew no attraction nor repulſion againſt each other, becauſe the repulſion between the particles of the magnetic fluid is balanced by the attraction between the matter of thoſe bodies and the ſaid fluid, in which caſe thoſe bodies are ſaid to be in a natural ſtate; but, when in a ferruginous body, the quantity of magnetic fluid belonging to it is driven to one end, then the body becomes magnetic, one extremity of it being now overcharged with magnetic fluid, and the other extremity undercharged. Bodies thus conſtituted, *viz.* rendered magnetic, exert a repulſion between their overcharged extremities, in virtue of the repulſion between the particles of that exceſs of magnetic fluid; which is more than overbalanced by the attraction of their matter. There is an attraction exerted between the overcharged extremity of one magnetic body, and the undercharged extremity of the other, on account of the attraction between that fluid and the matter of the body; but to explain the repulſion, which takes place between their undercharged extremities, we muſt either imagine that the matter of ferruginous bodies, which deprived of its magnetic fluid, muſt be repulſive of its own particles, or that the undercharged extremities appear to repel each other, only becauſe either of them attracts the oppoſite overcharged extremities; both which ſuppoſitions are embarraſſed with difficulties.

A ferruginous body, therefore, is rendered magnetic by having the equable diffuſion of magnetic fluid throughout its ſubſtance diſturbed, ſo as to have an overplus of it in one or more parts, and a deficiency of it in one or more other parts; and it remains magnetic as long as its impermeability prevents the reſtoration of the balance between the overcharged and undercharged parts. Moreover, the piece of iron is rendered magnetic by the vicinity of a magnet; becauſe, when the overcharged part or pole of the magnet is preſented to it, the overplus of magnetic fluid in that pole repels the magnetic fluid away from the neareſt extremity of the iron, which, therefore, becomes undercharged, or poſſeſſed of the contrary polarity, to the moſt remote part of the iron, which conſequently becomes overcharged, or poſſeſſed of the ſame polarity as the preſented pole of the magnet. When the piece of iron is rendered magnetic by preſenting to it the undercharged extremity or pole of the magnet, then the part of the iron which is neareſt to it, becomes overcharged, &c. becauſe that part of the magnet, being deprived of its magnetic fluid, attracts the magnetic fluid of the iron to that extremity of the iron which lies neareſt to itſelf.

In conſequence of which it appears, that, in order to give magnetiſm to a body, as a piece of ſteel, the ſtrength of the magnet employed muſt be ſuch as to overcome the reſiſtance, which the ſubſtance of the ſteel makes againſt the free paſſage of the magnetic fluid; hence, a piece of ſoft ſteel is rendered magnetic more eaſily than a hard one; hence, a ſtronger magnet will render magnetic ſuch ferruginous bodies, as other ſmaller magnets have no power upon.

The action of two magnets upon each other is likewiſe eaſily explained by this hypotheſis. When two equal magnets

nets oppofe their contrary poles to each other, they thereby preferve and ftrengthen their power; but when the homologous poles of two magnets are placed near, then, if the ftrength and quality of thofe magnets be equal, they will only diminifh each other's magnetic power; but, if they be unequal in power or other quality, as the hardnefs, fhape, &c. then the weakeft will have its power diminifhed, deftroyed, or changed, in proportion to its foftnefs, weaknefs of magnetifm, and other circumftances, which will eafily occur to the intelligent reader.

Our venerable countryman, Mr. Cavendifh, had invented a fimilar theory, and had entered in many refpects more minutely into the detail of its confequences without being acquainted with the abovecited work of Æpinus; although the publication of his paper on the fubject was 12 years later. Lambert, Meyer, Coulomb, and Robifon have alfo purfued inquiries of a fimilar nature, both theoretically and experimentally, with great fuccefs. See Young's Philofophy, vol. i. lect. 55.

Magnetism, *Laws of*. See Magnet, *fupra*.

Magnetism *and Electricity*, *Analogy between*. The well-known property of amber, by which, after being rubbed, it attracts fmall bodies, was, in an early period of the fcience of electricity, defcribed under the appellation of the magnetifm of amber; fo that thefe two powers, the electrical and the magnetic, were confidered as the fame, or at leaft not fufficiently diftinguifhed. At a later period thefe two powers have been regarded as quite diftinct from each other, but in feveral refpects exhibiting a mutual refemblance. We fhall, therefore, here ftate fome particulars in which they refemble one another, and others in which they differ. The power denominated by philofophers *electricity* (fee that article) is of two forts, *viz.* the *pofitive*, and the *negative* electricity. In the fcience of electricity, it is an invariable law, that bodies poffeffed of the fame fort of electricity repel each other, whereas thofe which are poffeffed of different electricities attract each other.

Thus, in magnetics, there is a north and a fouth pole; thofe parts of magnetic bodies which are poffeffed of the fame polarity, repel each other; but thofe which are poffeffed of different polarities attract each other.

In electricity, whenever a body in a natural ftate is brought within the fphere of action of an electrified body, it becomes itfelf electrified, and poffeffed of the contrary electricity, after which an attraction takes place; fo that in truth there is no electric attraction but between bodies poffeffed of different electricities: for inftance, if a piece of paper be brought fufficiently near a glafs tube, electrified pofitively, the paper will acquire the negative electricity, and will then be attracted by the tube; but if the paper be fo circumftanced as not to have it in its power to acquire the negative electricity, then no attraction will take place.

Thus, a ferruginous fubftance, which is brought within the fphere of action of a magnet, cannot be attracted by either pole of the magnet, unlefs it acquires firft a contrary polarity.

One fort of electricity cannot be produced by itfelf, but is always accompanied by the other; thus, if a glafs tube be electrified pofitively on its external furface, a negative electricity muft exift, either on its internal furface, or on the air contiguous to the tube.

In the fame manner, the two magnetic poles are always together; nor was there a piece of ferruginous fubftance ever produced, which had one polarity, and not the other.

The electric virtue can be retained and confined by certain bodies, like glafs, amber, refins, and others, called *electrics*; but it eafily pervades other fubftances, called *conductors*, or *non-electrics*.

The magnetic virtue is retained by ferruginous fubftances, efpecially thofe of a hard nature, like hard fteel, and the magnet: but it pervades eafily, and without the leaft perceivable impediment, all other forts of fubftances.

On the other hand, the magnetic power differs fom the electric, firft, in its not affecting our fenfes with any light, fmell, tafte, or noife; whereas, the electric fpark, fhock, fmell, and tafte, are known to every one converfant in electric experiments. Secondly, magnetifm attracts only iron, or thofe bodies which contain that metal in fome ftate or other; whereas, the electric power attracts bodies of every fort. Thirdly, the electric virtue refides on the furface of electrified bodies, whereas the magnetic is quite internal. Laftly, a magnet lofes nothing of its power by magnetifing other fubftances; but an electrified body lofes part of its electricity by electrifying other fubftances. Here, however, muft be remarked, that an electrified body lofes part of its power, when in electrifying another body touches it, and that body acquires then the fame fort of electricity; but when that other body is electrified by being only brought within the fphere of action of the former, in which cafe it acquires the contrary electricity, then the former body lofes nothing of its power; for inftance, fuppofe that a body, A, poffeffes a certain quantity of pofitive electricity, and that another body B, in a natural ftate, be gradually brought near A; then the body B, when it comes within a certain diftance of the electrified body A, acquires a negative electricity, which negative electricity takes away nothing of the power of the body A; but if the two bodies come very near, fo as to touch, or as that the electricity of the body, A, may leap from it to the other, then the body, B, will become electrified pofitively, and A lofes thereby part of its power. Indeed, if it be duly confidered, this laft cafe does not feem ever to take place with magnetifm; for bodies appear to be rendered magnetic merely by the action of their fpheres of activity, or by that power which enables magnets to act at fome diftance from their own bodies; and therefore we may juftly fay, that electrified and magnetic bodies agree in this, *viz.* that they lofe nothing of their power, when other bodies are electrified or rendered magnetic in virtue of their fpheres of activity.

When the *aurora borealis*, which has been thought to be an electrical phenomenon, forms a luminous arch towards the northern part of the horizon, the moft elevated part, or middle of that arch, is generally in the magnetic meridian.

Several other points of analogy, or of difference between magnetifm and electricity, will, perhaps, occur to thofe perfons who examine both fubjects; but if they be attentively confidered, we think they will be found to be comprehended in thofe which have been enumerated above. Cavallo's Magnetifm, and Prieftley's Electricity, *ubi fupra*.

Magnetism, *Animal*, an appellation given by fome defigning or felf-deceived operators upon the credulity and purfes of mankind, to certain practices, by which, under the pretence of curing difeafes, various effects were produced on the animal economy, fuch as faintings, partial and even general convulfions &c. Thefe practices were principally carried on in France, by a perfon of the name of Mefmer, and his difciples, and were believed to influence the human body through the medium of the magnetic principle. In confequence, however, of the appointment of a committee of philofophers for the inveftigation of the matter by the French king, the true nature of the operation was proved, in the moft unequivocal manner, and the effects of it traced, by by the cleareſt experiments, ſolely to the mind or *imagination* of the perſons *magnetiſed*. An ample detail of this able inveſtigation, as well as of ſeveral other facts and practices referrible to the ſame ſource, will be found under the article IMAGINATION.

MAGNETISM is alſo uſed, by ſome *Chemiſts*, to ſignify a certain virtue, whereby one thing becomes affected at the ſame time with another, either in the ſame or in a different manner. This amounts to the ſame with what they otherwiſe call *ſympathy*.

It has been obſerved, that much confuſion in the ſcience of magnetiſm has been occaſioned by the application of the term *magnetiſm* to other things which had no relation to it. Thus, the chemical affinity between metals has been called the magnetiſm of metals by ſome old authors. The vibration occaſioned by the ſound of muſical ſtrings or pipes upon others which were tuned in concord with them has been alſo called the magnetiſm of muſic. Some writers alſo ſpeak of the magnetiſm of aſtronomy, the magnetiſm of water, &c.

MAGNICOURT, in *Geography*, a town of France, in the department of the ſtraits of Calais, and chief place of a canton, in the diſtrict of St. Pol; two leagues S.E. of St. Pol.

MAGNIFYING, among *Philoſophers*, is chiefly uſed in ſpeaking of microſcopes, which are ſaid to magnify objects, that is, to make them appear bigger than they really are, though in reality they do not, nor can, magnify any object, but only ſhew it nearer, and diſcover more of its parts than before were taken notice of.

The magnifying power of denſe mediums of certain figures was known to the ancients, though they were far from underſtanding the cauſe of this effect. Seneca ſays, that ſmall and obſcure letters appear larger and brighter through a glaſs globe filled with water; and he abſurdly accounts for it by ſaying, that the eye ſlides in the water, and cannot lay hold of its object. Nat. Queſt. lib. i. c. 6.

Alexander Aphrodiſienſis, the great commentator upon Ariſtotle, who flouriſhed near two centuries after Seneca, ſays, that the reaſon why apples appear large when they are immerſed in water is, that the water which is contiguous to any body is affected with the ſame quality and colour; ſo that the eye is deceived in imagining the body itſelf to be larger. But the firſt diſtinct account we have of the magnifying power of glaſſes is in the writings of Alhazen, who flouriſhed in the twelfth century; and he was preceded by our countryman Roger Bacon, who, in his Opus Majus, demonſtrates, that if a tranſparent body, interpoſed between the eye and an object, be convex towards the eye, the object will appear magnified; nor is it improbable, that from the obſervations of Alhazen and Bacon the conſtruction of ſpectacles was derived. See SPECTACLES.

MAGNIFYING *Glaſs*, in *Optics*, denotes a little ſpherical convex lens; which, in tranſmitting the rays of light, inflects them, ſo as that the parallel ones become converging, and thoſe which were diverging become parallel; by means whereof, objects viewed through them appear larger than when viewed by the naked eye. See MICROSCOPE.

MAGNIN, in *Geography*, a town of Egypt, on the left bank of the Nile; 12 miles S. of Shabur.

MAGNISA, anciently MAGNESIA, a town of Aſiatic Turkey, in the province of Natolia, ſituated near a mountain, whoſe top is always covered with ſnow. The town is large and populous, but has few Chriſtians; 20 leagues N.N.E. of Smyrna. N. lat. 38° 44′. E. long. 27° 18′.

MAGNISI DEGLI, a peninſula of Sicily, on the E. coaſt, in the valley of Noto; ſix miles N. of Siracuſa or Syracuſe; formerly the peninſula of Tapſus. Oppoſite to this peninſula are the ruins of a monument, ſaid to have been erected in memory of the victory of Marcellus.

MAGNISSA, in *Mineralogy*, a name given by ſome of the ancients to the white pyrites, called by others *leucolithos* and *argytholithos*. See MARCASITE.

MAGNITUDE, any thing that has parts without (or *extra* to) parts connected together by ſome common term.

Magnitude is any thing locally extended, or continued; or that has ſeveral dimenſions.

The origin of all magnitude is a point, which, though void of parts itſelf, yet its flux forms a line, the flux of that a ſurface, and of that a body.

Magnitude amounts to much the ſame with what is otherwiſe called *quantity*.

MAGNITUDE, *Geometrical*, may be uſually conſidered as generated or produced by motion. Thus lines may be conceived as generated by the motion of points; ſurfaces, by the motion of lines; ſolids, by the motion of ſurfaces; angles may be ſuppoſed to be generated by the rotation of their ſides.

Geometrical magnitude is always underſtood to conſiſt of parts; and to have no parts, or to have no magnitude, are conſidered as equivalent in this ſcience. There is, however, no neceſſity for conſidering magnitude as made up of an infinite number of ſmall parts; it is ſufficient that no quantity can be ſuppoſed to be ſo ſmall, but it may be conceived to be farther diminiſhed; and it is obvious, that we are not to eſtimate the number of parts that may be conceived in a given magnitude, by thoſe which in particular determinate circumſtances may be actually perceived in it by ſenſe, ſince a greater number of parts become ſenſible, by varying the circumſtances in which it is perceived. See Maclaurin's Fluxions, art. 290, &c.

Many of late have ſuppoſed geometrical magnitude to be compoſed of infinitely ſmall parts, and infinite in number; and hence have raiſed many paradoxes and myſteries in a ſcience in which there ought to be none. Nay, infinitely ſmall parts of infinitely ſmall parts, &c. *ad infinitum*, have been introduced without the leaſt neceſſity. See Maclaurin's Fluxions, in the Introduction, where he makes ſeveral remarks on Monſieur de Fontenelle's Geometrie de l'Infini. See EXTENSION.

MAGNITUDE, *Literal*, denotes a magnitude expreſſed by letters.

MAGNITUDE, *Numerical*, is that expreſſed by numbers.

MAGNITUDE, *Broken*, denotes a fraction.

MAGNITUDE, *Complex*, is that formed by multiplication.

MAGNITUDE, *Incommenſurable*, is that which has no proportion to unity.

MAGNITUDE, *Apparent*, of a body, in *Optics*, is that meaſured by the optic or viſual angle intercepted between rays drawn from its extremes to the centre of the pupil of the eye. It is one of the fundamental maxims in this ſcience, that whatever things are ſeen under the ſame or equal angles, appear equal; and *vice verſâ*.

The apparent magnitudes of an object at different diſtances, are in a ratio leſs than that of their diſtances reciprocally.

The apparent magnitudes of the two great luminaries, the ſun and moon, at riſing and ſetting, are phenomena that have extremely embarraſſed the modern philoſophers. According to the ordinary laws of viſion they ſhould appear the leaſt when neareſt the horizon, as being then fartheſt diſtant from the eye; and yet we find the contrary to be true in fact.

Thus it is well known, that the mean apparent magnitude of of the moon is 30′ 30″, in round numbers 30′, at a full moon in the midſt of winter, and when ſhe is in the meridian, and at her greateſt northern latitude, and conſequently at her utmoſt elevation above our horizon: it is alſo as well known that when ſhe is in this ſituation, being looked upon by the naked eye, ſhe appears to be, accommodating her magnitude to our ſenſible meaſures, about a foot broad. But when ſhe is looked upon as ſhe riſes, ſhe appears to be three or four feet broad. and yet if we take her diameter with an inſtrument, both in the one ſituation and the other, we ſhall find that ſhe is only 30′.

Ptolemy, in his Almageſt, lib. i. cap. 3, has aſcribed this appearance to a refraction of the rays by vapours, which actually enlarge the angle under which the moon appears; juſt as the angle is enlarged by which an object is ſeen placed under water; and his commentator Theon explains diſtinctly how the dilatation of the angle in the object immerſed in water is cauſed. But it was afterwards diſcovered, that there is no alteration in the angle: upon which another ſolution was ſtarted by the Arab Alhazen; and followed and improved by Vitellio, Kepler, Peckham, Roger Bacon, and others. According to Alhazen, the ſight apprehends the ſurface of the heavens as flat, and judges of the ſtars as it would of ordinary viſible objects extended upon a wide plain; the eye ſees them under equal angles, but at the ſame time perceives a difference in their diſtances, and (on account of the ſemidiameter of the earth, which is interpoſed in one caſe and not in the other) it is hence induced to judge thoſe which appear more remote to be greater. Some farther improvement was made in this explanation by Mr. Hobbs, though he fell into ſome miſtakes in his application of geometry to this ſubject. For he obſerves, that this deception operates gradually from the zenith to the horizon; and that if the apparent arch of the ſky be divided into any number of equal parts, thoſe parts, in deſcending towards the horizon, will gradually ſubtend a leſs and leſs angle; and he was the firſt who expreſsly conſidered the vaulted appearance of the ſky as a real portion of a circle. Des Cartes, and from him Dr. Wallis, and moſt other authors, account for the appearance of a different diſtance under the ſame angle, from the long ſeries of objects interpoſed between the eye and the extremity of the ſenſible horizon; which makes us imagine it more remote than when in the meridian, where the eye ſees nothing in the way between the object and itſelf. This idea of a great diſtance makes us imagine the luminary the bigger; for any object being ſeen under any certain angle, and believed at the ſame time very remote, we naturally judge it muſt be very large, to appear under ſuch an angle, at ſuch a diſtance. And thus a pure judgment of the mind makes us ſee the ſun, or moon, bigger in the horizon than in the meridian; notwithſtanding their images painted on the retina are leſs in the former ſituation than the latter.

James Gregory, Geom. Par. Univerſ. p. 141, ſubſcribes to this opinion: Father Malebranche alſo, in the firſt book of his "Récherches de la Verité," printed in 1673, has explained this phenomenon almoſt in the expreſſion of Des Cartes: and Huygens, in his treatiſe on the Parhelia, tranſlated by Dr. Smith, Optics, art. 536, has approved, and very clearly illuſtrated the received opinion. The cauſe of this fallacy, ſays he, in ſhort is this; that we think the ſun or any thing elſe in the heavens to be remoter from us, when it is near the horizon, than when it approaches towards the vertex, becauſe we imagine every thing in the air that appears near the vertex to be no farther from us than the clouds that fly over our heads; whereas, on the other hand, we are uſed to obſerve a large extent of land lying between us and the objects near the horizon, at the farther end of which the convexity of the ſky begins to appear; which, therefore, with the objects that appear in it, is uſually imagined to be much farther from us. Now when two objects of equal magnitudes appear under the ſame angle, we always judge that object to be larger which we think is remoter. And this is the true cauſe of the deception we have been ſpeaking of. It is a wonder that an hypotheſis ſo rational as this ſhould ever loſe its credit, after having been maintained by writers of reputation, and for a great number of years. But it was generally imagined, that the actual perception of thoſe objects which divide the ſpace that is intercepted betwixt the eye and the horizon was neceſſary, in order to its ſuggeſting the idea of its extraordinary diſtance: and thus philoſophers were led to form much more objectionable ſolutions of the phenomenon. Accordingly Gaſſendus was of opinion, that the pupil of the eye, which is always more open as the place is more dark; being more ſo in the morning and evening than at other times, becauſe the earth is covered with groſs vapours; and beſides, being obliged to paſs through a longer column or ſeries of vapours to reach the horizon; the image of the luminary enters the eye at a greater angle, and is really painted there larger at the former times than the latter. In anſwer to which it may be ſaid, that, notwithſtanding this dilatation of the pupil, occaſioned by the obſcurity, if the moon be viewed through a little pin-hole made in a paper, ſhe appears leſs when in the horizon than in the meridian. Nor can any thing be more abſurd than the poſition of Gaſſendus, who aſſerts, that a dilated pupil magnifies an object for the ſame reaſon as a convex glaſs does.

F. Gouye advances another hypotheſis, which is, that when the luminaries are in the horizon, the neighbourhood of the earth, and the groſs vapours wherewith they then appear enveloped, have the ſame effect with regard to us, as a wall, or other denſe body, placed behind a column; which, in that caſe, appears bigger than when inſulate, and encompaſſed on all ſides with an illumined air. Farther, it is obſerved, that a column, when fluted, appears bigger than before, when it was plain; the flutes being ſo many particular objects, which, by their multitude, occaſion the mind to imagine the whole object, whereof they are compoſed, of a larger extent. The ſame thing may be ſaid of the ſeveral objects ſeen towards the horizon, to which the ſun or moon correſpond at their riſing and ſetting. And hence it is, that they appear larger ſtill, when they riſe or ſet between trees; the narrow, yet diſtinct, intervals whereof have the ſame effect with regard to the apparent diameter of the luminary, as a greater number of flutes with regard to the ſhaft of a column.

Biſhop Berkeley ſuppoſed, that the moon appears larger near the horizon, becauſe her appearance is then fainter, and her beams affect the eye leſs; but this hypotheſis is refuted by Dr. Smith. Mr. Robins has recited ſome other opinions on this ſubject, Math. Tracts, vol. ii. p. 242. The commonly received opinion has been diſputed not only by F. Gouye, who obſerves, Acad. Par. 1700, p. 11, that the horizontal moon appears equally large acroſs the ſea, where there are no objects to produce the effect aſcribed to them; but alſo by Mr. Molyneux, who ſays, Phil. Tranſ. abr. vol. i. p. 221, that if this hypotheſis be true, we may at any time increaſe the apparent magnitude of the moon, even in the meridian; for, in order to divide the ſpace between it and the eye, we need only to look at it behind a cluſter of chimnies, the ridge of a hill, or the top of a houſe. He alſo makes the ſame obſervation with F. Gouye, above-mentioned, and farther obſerves,

ſerves. that when the height of all the intermediate objects is cut off, by looking through a tube, the imagination is not helped, the moon being ſtill conceived to be as large as before. However, Mr. Molyneux advances no hypotheſis of his own. Dr. Deſaguliers has well illuſtrated the doctrine of the horizontal moon, Phil. Tranſ. abr. vol. viii. p. 130, upon the ſuppoſition of our imagining the viſible heavens to be only a ſmall portion of a ſpherical ſurface, and conſequently ſuppoſing the moon to be farther from us in the horizon than near the zenith, and by ſeveral ingenious contrivances he demonſtrated how liable we are to ſuch deceptions. But the moſt complete illuſtration of this curious ſubject is given us by Dr. Smith. The cavity of the heavens, he ſays, appears to the eye, which is the only judge of an apparent figure, to be a leſs portion of a ſpherical ſurface than a hemiſphere. In other words, the centre of the concavity is much below the eye, and by taking a medium among ſeveral obſervations, he found that the apparent diſtance of its parts at the horizon was generally between three or four times greater than the apparent diſtance of its parts over head. This he determined by meaſuring the actual height of ſome of the heavenly bodies, when, to his eye, they ſeemed to be half way between the horizon and the zenith. In this caſe their real altitude was only twenty-three degrees. When the ſun was but 30 high, the upper arch always appeared leſs than the under, and he thought that it was always greater when the ſun was about 18 or 20° high. Mr. Robins, in his Tracts, vol. ii. p. 245. ſhews how to determine the apparent concavity of the ſky in a more accurate and geometrical manner; by which it appears, that if the altitude of any of the heavenly bodies be 20 at the time when it ſeems to be half way between the horizon and the zenith, the horizontal diſtance will be hardly leſs than four times the perpendicular diſtance; but if that altitude be 28, it will be little more than two and a half. Dr Smith having determined the apparent figure of the ſky, is able to give a ſatisfactory explanation of the phenomenon of the horizontal moon, and other ſimilar appearances in the heavens. For ſuppoſing the arc A B C, (*Plate* X. *Optics*, *fig.* 4.) to repreſent that apparent concavity, he found that the diameter of the ſun and moon would ſeem to be greater in the horizon than at any propoſed altitude, meaſured by the angle A O B, in the proportion of its apparent diſtances O A, O B. The numbers that expreſs theſe proportions he reduced into the following table, anſwering to the correſponding altitudes of the ſun or moon, which are alſo exactly repreſented to the eye in the figure, in which the figures of the moon, placed in the quadrantal arc F G, deſcribed about the centre O, are all equal to each other, and repreſent the body of the moon in the heights here noted, and the unequal moons in the concavity A B C are terminated by the viſual rays that come from the circumference of the real moon, at thoſe heights, to the eye, at O. The diameters of theſe unequal moons at A and B do, therefore, bear the ſame proportion to each other, as their apparent diſtances O A, O B; and they muſt appear in the ſame proportion that they really have in this concave, becauſe we judge all objects in the heavens to be in this ſurface: ſo that the appearance to the eye is exactly the ſame, as if ſeveral moons were painted upon a real ſurface, A B C, in the proportions here aſſigned; in which caſe we ſhould certainly judge the real magnitudes of the larger paintings of the lower moon to be really larger, though the viſible magnitudes of them all, anſwering to their equal images upon the retina, were exactly equal. For the ſame reaſon Dr. Smith obſerves, that all the objects and diſtances of ſtars in the heavens, as well as the ſun and moon, muſt ſeem to be greater in the horizon than in higher ſituations; which is known to be the caſe. He alſo obſerves, that the apparent concave of the ſky being leſs than an hemiſphere, is the cauſe that the breadths of the colours in the inward and outward rainbows, and the interval between the bows appear leaſt at the top, and greater at the bottom; and by an eſtimate of the apparent breadths of the inward rainbow, at two different heights, made by a friend, he determined the apparent concavity of the ſky to be much the ſame as by the former methods. (See HALO.) This theory of the horizontal moon is alſo confirmed by the appearances of the tails of comets, which, whatever be their real figure, magnitude, and ſituation in abſolute ſpace, do always appear to be an arc of the concave ſky; and in farther confirmation of it, he gives us Mr. Cotes's explanation of the optical appearance of a remarkable meteor ſeen in the year 1716. Beſides the general cauſe above ſtated of the appearance of the horizontal moon, Dr. Smith acknowledges, that, at different times, the moon appears of different magnitudes even in the ſame horizon, and occaſionally of an extraordinary large ſize. This, he is inclined to believe, is chiefly owing to an extraordinary largeneſs of her picture upon the retina, which, in the preceding general theory, was ſuppoſed to be invariable. This, he ſays, might beſt be examined by taking the diameter of the moon with a micrometer, or by noting the year and day of the month, together with the heights of the barometer and thermometer. For if it ſhould appear, by many ſuch obſervations, that the largeſt horizontal moons generally happen at her perigee, in the warmeſt ſummer evenings, the barometer being low, and the thermometer high; ſince theſe cauſes are independent of one another, and all conſpire to enlarge the picture of the moon, we may reaſonably conclude that theſe extraordinary moons are chiefly owing to the concurrence of theſe circumſtances. But ſince the difference in the apparent magnitude of the moon is not increaſed $\frac{1}{16}$th part of the whole in conſequence of her being in her perigee, and the enlargement of the image in all the other caſes here mentioned is very inconſiderable, it is probable that when the moon is imagined to be ſo much larger than uſual, the imagination is farther impoſed upon by ſome circumſtances which have not been attended to. Smith's Optics, vol i. p. 63, &c. Remarks, p. 53.

MAGNOL, PETER, in *Biography*, a celebrated botaniſt of Montpellier, was born in 1638. He was bred to phyſic, but, being a Proteſtant, could not take his degree there. He was therefore obliged to have recourſe to ſome more ſenſible and more Chriſtian univerſity, where ſuch excluſive laws were unknown. Such are not the reproach of popery only. A few years ago ſome members of the univerſity of Oxford propoſed that one of their honorary degrees ſhould be conferred on Mr. Kirwan of Dublin; a propoſal intended at leaſt as much for their own honour as for his. But this was found to be impracticable, becauſe forſooth that illuſtrious philoſopher and diſtinguiſhed character was a diſſenter! Wherever Magnol graduated, he practiſed phyſic at Montpellier for a long courſe of years, and at the ſame time very aſſiduouſly cultivated Botany, not only as an auxiliary to medicine, but with the moſt enlarged views to its advancement as a ſcience of itſelf. He was beloved for his urbanity, and eſteemed for his knowledge. Numerous botaniſts flocked at this time to Montpellier, that neighbourhood being famous for its vegetable riches; and thefe were all eager to enjoy the fociety, and to benefit by the guidance and inftructions of fo able a man. Hence the herborizations around Montpellier have become celebrated in fo many books; and the fituations of the *hortus Dei* at l'Efperou, the *Mons Ceti*, Caftelnau, wood of Gramont, &c. have become claffic fpots. Among the pupils of Magnol were Fagon and the illuftrious Tournefort, who regularly ftudied under him, and on many fubfequent occafions gratefully acknowledged their obligations to him. He was not chofen public profeffor till long after the years 1679 and 1681, when Tournefort was at Montpellier. He had indeed been one of four perfons, nominated, and recommended to the king for the vacant profefforfhip, in 1667; but his religion was an infuperable obftacle to his appointment, as that of king Solomon himfelf would, in the fame cafe, have been. This difficulty was removed, by his affuming the guife at leaft of Catholicifm, before the year 1694, when he at length obtained the profefforial chair.

In 1676, our author publifhed at Lyons his firft work, the *Botanicum Monfpelienfe*, an octavo volume of 287 pages, with 22 plates. This fame edition was republifhed at Montpellier in 1688, with a new title-page, and 20 pages of appendix. In this book Linnæus reckons that 1366 plants are enumerated; Haller fays 1354; all found wild about Montpellier, and almoft entirely gathered there by the author himfelf. Among thefe, very few of the clafs *Cryptogamia* are included, but fome of them are now acknowledged varieties, and the laft four of the appendix are exotics, inferted merely on account of their novelty. The arrangement of the work is alphabetical. The choice of the names is very felect, and various criticifms or defcriptions are fubjoined, with the particular places of growth and medical virtues of each plant. The plates are rude, but original and characteriftic. This is in fact one of the moft original and authentic works of its kind, being to the Montpellier botanifts what Ray's *Synopfis* is to thofe of Britain, the bafis of all their knowledge. They are neceffarily fuppofed to be able to give an account of every plant which it contains; but their ideas are by no means as yet correct refpecting every one, and an accurate Linnæan *Flora Monfpelienfis* is ftill a defideratum.

In 1689, Magnol publifhed an octavo volume, entitled *Prodromus Hiftoriæ Generalis Plantarum*, in which he undertook a fcheme of natural arrangement. We have not feen this performance. Haller fays the method is that of Ray, deduced from all the parts of a plant; and that the vegetable kingdom is difpofed in 76 families, fubdivided into genera. The author confiders the flowers and fruits as of primary importance, but has recourfe alfo to the roots and habit occafionally. Haller indicates a few miftakes. If they are the worft he could difcover, the work muft rank very high, even at the prefent day.

In 1697 appeared the *Hortus Regius Monfpelienfis*, an 8vo. volume of 209 pages, with 21 elegant plates. This is an alphabetical catalogue of the garden, in which feveral new or rare fpecies are defcribed as well as figured. In their generic diftribution the author conforms to Tournefort principally, and his preface fhews how much he had contemplated this fubject and its difficulties. When we confider that Magnol had had the care of the garden only three years previous to the publication of this rich catalogue, and that he found the collection in a very poor ftate, the book is an honourable monument of his induftry as well as knowledge. The *Garidella*, *Saxifraga hirfuta* and *umbrofa*, *Lathyrus Niffolia*, and fome others, here appear for the firft time.

In 1708, Magnol was admitted a member of the *Academie des Sciences* of Paris, in the place of his diftinguifhed friend Tournefort, who died that year. He continued to profecute his favourite ftudies, having prepared fome obfervations upon the *Pinax* of Cafpar Bauhin, which however he did not live to complete. He communicated to the *Academie des Sciences* fome objections to the opinion of a circulating fap in vegetables, and fome remarks on the importance of their *medulla* or pith. He alfo gave an account of an eafy method of tinging the flowers of the Tuberofe with a folution of fome kind of lake.

Magnol died in 1715, at the age of 77. He left a fon, named Anthony, who was profeffor of phyfic at Montpellier, but not of Botany. To this fon we are indebted for the publication of the *Novus Character Plantarum*, on which the fame of Magnol as a fyftematic botanift chiefly refts. This pofthumous work appeared in 1720, making a quarto volume, of 341 pages. The fyftem therein taught is much celebrated by Linnæus, who in his *Claffes Plantarum*, 375—403, gives a general view of it, expreffing his wonder that fo new and fingular a fyftem had not made more profelytes. It profeffes to be founded on the calyx; but that term is taken in a very wide, and, at this time of day, unauthorized fenfe; for it comprehends the pericarp as well as perianth, the former being denominated the internal calyx, the latter the external. It is neceffary to obferve that Linnæus, in the work above-mentioned, p. 376, fect. 2, α and β, by an erroneous tranfpofition of the words *perianthium* and *pericarpium*, has rendered his account totally unintelligible.—According to this fyftem, every plant is fuppofed to have either an external calyx (enfolding or fuftaining the flower); or an internal one, which is the pericarp; or both. It is more natural than moft early fyftems in its detail, but paradoxical in fome of its primary characters. That fort of fuppofed external calyx, which merely fuftains the flower, is often fcarcely more than the receptacle of Linnæus, the real perianth being either paffed over, or taken for a corolla. The claffes devoted to trees and fhrubs are, as Haller obferves, very imperfect; but we can hardly fubfcribe to his decifion, that the work ought, for the fake of its author, to have been configned to oblivion. It is undoubtedly worthy the confideration of thofe who ftudy natural affinities, and is not the lefs eftimable for being hoftile to the popular methods of its time, founded on the corolla; though that circumftance has probably contributed, more than any thing elfe, to its neglect. The corolla in this method of Magnol affords fubordinate diftinctions only, entering into none of thofe obfcure and evanefcent *minutiæ*, on which fome of the primary characters in the method of Tournefort depend.—Works of Magnol. Hall. Bib. Bot. Dryandr. Bibl. Banks. Dorthes Recherches fur la Vie et les Ouvrages de Belleval. V. Brouffonet Corona Fl. Monfp. S.

MAGNOLIA, in *Botany*, a noble genus of trees or fhrubs, named by Plumier in honour of Peter Magnol, Botanical Profeffor at Montpellier; fee the laft article. Linn. Gen. 278. Schreb. 373. Willd. Sp. Pl. v. 2 1255 Mart. Mill. Dict. v 3. Ait. Hort. Kew. ed. 2. v 3. 329. Juff. 281. Plum. Gen. 38 t. 7. Lamarck Illuftr. t. 490. Gærtn. t. 70.—Clafs and order, *Polyandria Polygynia*. Nat. Ord. *Coadunatæ*, Linn. *Magnoliæ*, Juff.

Gen. Ch. *Cal.* Perianth inferior, of three ovate, equal, concave, petal like, deciduous leaves. *Cor.* of fix, nine, or more oblong, concave, obtufe petals, narrower at the bafe. *Stam.* Filaments numerous, fhort, incurved, pointed, compreffed and two-edged, inferted into the common receptacle of the piftils below the germens; anthers terminal, linear, of two cells, burfting longitudinally at the inner fide. *Pift.* Germens numerous, ovate-oblong, imbricated upon a cylindrical

drical or ovate receptacle; ſtyles recurved, very ſhort; ſtigmas longitudinal, downy. *Peric.* Capſules numerous, ſeſſile, crowded, coriaceous, compreſſed, wedge-ſhaped, of one cell and two valves burſting outwards, permanent. *Seeds* one or two in each cell, roundiſh-oblong, pulpy, coloured, at length hanging by a thread-like ſtalk, out of the capſule.

Eſſ. Ch. Calyx of three leaves. Petals ſix to twelve. Anthers burſting inwardly. Capſules of two valves, crowded into the form of a cone. Seeds pulpy, pendulous.

Obſ. For the diſtinctions between this genus and *Liriodendrum*, ſee that article.

1. M. *grandiflora.* Laurel-leaved Magnolia. Andr. Repoſ. t. 518. (M. maximo flore, foliis ſubtùs ferrugineis; Trew Ehret. t. 33.)—Leaves perennial, coriaceous, oblong. Petals obovate.—Native of North America, from the northern limits of Carolina to the Miſſiſſippi. *Michaux.* It ſeems by the Hort. Kew. not to have been cultivated in this country before the year 1734. This is a very noble evergreen tree, ſufficiently hardy, at leaſt in the ſouthern parts of England, or near the ſea, only requiring plenty of water to bloſſom freely. The *leaves* are ſcattered, on ſhort thick ſtalks, elliptic-oblong, more or leſs pointed at each end, from four to ten inches long, and two or three broad, veiny, very rigid and coriaceous; ſmooth, ſhining, and of a full bright green, above; opaque, and ſometimes clothed with ruſty down, beneath; their margin entire, thickened and ſomewhat wavy. *Stipulas* ſolitary, convolute, ſheathing, downy, ſoon deciduous. *Flowers* terminal, ſolitary, on thick downy ſtalks, each as large as a pint baſon, white, deliciouſly fragrant like the flavour of cold lemonade. The *petals* have the texture and aſpect of delicate white leather, and ſhrink very much in drying. Theſe *flowers* come out in July. The variety with ruſty leaves bloſſoms at an early age, and is therefore moſt popular; but the great ſmooth-leaved kind, firſt brought to this country, of which fine ſpecimens may be ſeen at Chelſea, Sion houſe, and other old gardens, is vaſtly preferable in itſelf, when it arrives at a ſufficient age to produce its much larger flowers.

2. M. *Plumieri.* Weſt Indian Magnolia. Swartz. Prodr. 87. Fl. Ind. Occ. 997. Plum. Gen. as above. (Talauma; Juſſ. 281.)—Leaves perennial, coriaceous, roundiſh-ovate, ſmooth on both ſides. Flower-ſtalks ſmooth. Petals ten or twelve.—Native of the Weſt Indies, obſerved by Dr. Swartz in St. Lucia, Martinico, and Guadaloupe, where the French call it either *Bois pin*, or *Bois Cachiman.* This author deſcribes it as one of the largeſt of trees, often 80 feet high. "*Branches* round, annulated, ſcarred where the leaves have ſtood, their bark of a greyiſh-brown. *Leaves* alternate, ſtalked, large, roundiſh inclining to ovate, coriaceous, reticulated with veins, ſmooth on both ſides. *Footſtalks* thick, round, flattiſh above, ſmooth and naked. *Flowers* terminal, ſolitary, very large, white and fragrant, on thick ſmooth ſtalks, marked with whitiſh rings. *Calyx* of three large, ovate, concave, coriaceous, petal-like, veiny, deciduous leaves, externally glaucous. *Petals* from 10 to 12, rather longer than the calyx, oblong, obtuſe, concave, thick, contracted at the baſe." Dr. Swartz never met with the fruit. Plumier deſcribes and figures the latter as hard and knobby, of a blue colour, lodging in its ſubſtance ſeveral oblong nuts, each of which contains a kernel of the ſame ſhape. Juſſieu, who found a ſpecimen in Surian's collection, with the name of *Talauma*, deſcribes it as "large and ovate, reſembling a *ſtrobilus* or cone, compoſed externally of thick, granulated, corky, permanent ſcales; while the inner part is woody, hard, hollowed out in its circumference into numerous ſingle-ſeeded cells, apparently not burſting, ſome of them abortive." Theſe are all the materials we have to judge by. Burman's ignorance and miſplaced economy induced him to omit publiſhing a figure of the plant in his *Icones* of Plumier; ſee p. 161 of that book. Swartz ſeems to have had no ſuſpicion that it could be any thing but a *Magnolia*, though his character and deſcription prove it ſpecifically diſtinct from the *grandiflora*; to which however it appears to be ſo very nearly related, that we think it highly improbable there can be any real generic diſtinctions in the ſeed-veſſel. We find nothing in Plumier or Juſſieu, but what may be referred to a not quite ripe, or an ill-underſtood, fruit of a genuine *Magnolia.* If it ſhould prove otherwiſe, we have already (ſee Lobelia) hinted the propriety of not diſturbing the name by which the bulk of the ſpecies are ſo well known, and would rather retain for this, if a ſeparate genus, the appellation it has in Juſſieu, though of barbarous origin. As the point in diſpute is one of the moſt intereſting botanical problems, we wiſh it may excite the attention of ſome Weſt Indian traveller.

3. M. *glauca.* Swamp Magnolia. Linn. Sp. Pl. 755. (M. lauri folio ſubtùs albicante; Trew Ehret. t. 9. Dill. Elth. 207. t. 168.)—Leaves elliptic-oblong, obtuſe, glaucous beneath. Petals obovate.—Native of ſwampy ground in North America. "From New Jerſey to Florida." *Michaux.* It appears to have been the firſt of its genus introduced into the gardens of England, having been cultivated by Biſhop Compton, at Fulham, in 1688. This is a ſmall tree, very deſirable on account of its *flowers*, which come forth, at the ends of the branches, in July, and are cream-coloured, concave, about two inches wide, with a peculiarly rich vinous fragrance, to ſome people rather oppreſſive. The *leaves* alſo are beautiful, about three inches long, varying in breadth, veiny; bright green above; glaucous and ſomewhat ſilky beneath. In the variety ſeen in our gardens they are deciduous; in another, of which we have ſpecimens from Carolina, they are evergreen, and of a longer narrower figure.

4. M. *conſpicua.* Lily-flowered Magnolia, or Youlan. Ait. n. 3. Saliſ. Parad. t. 38. (Mokkwuren 1; Banks Ic. Kæmpf. t. 43.)—Leaves obovate, obtuſe with a point, appearing after the flowers are over.—Preſumed to be a native of China, where it has been cultivated for ages, forming a *tree* 30 or 40 feet high, with zigzag much divided *branches*, at the end of each of which, in the early ſpring, before any leaves appear, ſtands an elegant white lily-like *flower*, four inches wide, with ſome of the cool lemon ſcent of the firſt ſpecies, at leaſt when brought into a warm room. The *leaves* expand in May, and are flexible, on ſlender ſtalks, of a broad obovate or wedge-like figure, with a ſmall tip, each three or four inches, or more, in length. Sir Joſeph Banks procured this fine plant from China in 1789. It is hardy in our climate, and is at an early age covered with flowers from February to April, though the ſevere eaſt winds of the ſeaſon often injure its beauty, unleſs it be protected by a frame, or planted in a conſervatory.

5. M. *obovata.* Purple Magnolia. Thunb. Tr. of Linn. Soc. v. 2. 336. (M. purpurea; Curt. Mag. t. 390. Andr. Repoſ. t. 324. M. diſcolor; Venten. Malmais. t. 24. M. glauca β; Thunb. Jap. 236. Mokkwuren; Kæmpf. Amoen. 845. Banks Ic. Kæmpf. t. 44.)—Leaves obovate, pointed, appearing with the flowers. Petals oblong, bluntiſh.—Native of China, from whence the late duke of Portland is ſaid to have obtained it in 1790. It is tolerably hardy, flowering in May and June, but appears to moſt advantage in a conſervatory. In the ſhape and habit of its *leaves* this agrees much with the laſt, but the *flowers* are larger, of a

fine

fine purple, darkeſt at the outſide, and do not appear till the foliage is fully expanded; they have little or no ſcent. Willdenow and Thunberg erroneouſly conſider Kæmpfer's Ic. t. 43 and 44 as one and the ſame plant, nor has any one corrected their miſtake till now. It is lamentable that Curtis's appropriate name, *purpurea*, has not been preferred to that of Thunberg, whoſe confounding the preſent plant with *M. glauca*, rather ſhakes our confidence in his botanical obſervations and opinions. It muſt be preſumed that his white-flowered variety is our *M. conſpicua*; but in neither of theſe plants are the leaves glaucous beneath. They are in both, eſpecially their ribs and veins, more or leſs clothed with ſhort brown hairs.

6. M. *tomentoſa*. Slender Woolly Magnolia. Thunb. Tr. of Linn. Soc. v. 2. 336. Willd. n. 5. Ait. n. 5. (M. gracilis; Saliſ. Parad. t. 87. Kobus; Kæmpf. Amoen. 845. Ic. t. 42.)—Leaves obovate, pointed, downy beneath, appearing after the flowers. Petals ſix, oblong, obtuſe.—Native of Japan and China, from which laſt country the late Mr. Greville is ſaid to have received a plant, which bloſſomed with him in the ſpring. Mr. Saliſbury aſcertained the ſynonym of Kæmpfer, from his herbarium and papers in the Britiſh Muſeum, and has well aſſerted this to be a diſtinct ſpecies from the laſt.

7. M. *pumila*. Dwarf Magnolia. Ait. n. 6. Andr. Repoſ. t. 226. Sims in Curt. Mag. t. 977. (Gwillimia indica; Rottler MSS. Sampa Saláca, or Milk Flower, of the Malays.)—Leaves elliptic-lanceolate, pointed, ſmooth. Petals ſix, obovate, very blunt, concave. Flower-ſtalk and calyx ſmooth, incurved.—Native of China, or rather, as we ſuſpect, of ſome of the Eaſt Indian iſlands. It is cultivated in China, (from whence the late lady Amelia Hume received a plant about 1786,) as well as at Batavia and Madras, but is never known to produce fruit in any ſituation in which it has come under the examination of botaniſts, ſo that the genus is by no means certain. See what we have already mentioned on this ſubject under LIRIODENDRUM *liliifera*. The preſent is a humble, ſmooth, deciduous *ſhrub*, kept in the greenhouſe, where it blooms at various periods during ſummer. The *foliage* has a glaucous tinge, and is wavy, and finely reticulated with veins. *Flowers* terminal, drooping, globoſe, cream-coloured, ſhort-lived, very fragrant at night, moſt like thoſe of M. *glauca* in ſhape, but ſmaller, and with more of a greeniſh caſt. The cells of the *anthers* are cloſe together, at the inner ſide, and the whole anther is club-ſhaped and obtuſe, very unlike that of the other ſpecies. Mr. Andrews alone has expreſſed theſe moſt important characters.

8. M. *fuſcata*. Brown-ſtalked Magnolia. Andr. Repoſ. t. 229. Sims in Curt. Mag. t. 1008. Ait. n. 7. (M. annonæfolia; Saliſ. Parad. t. 5.)—Leaves elliptic-lanceolate, ſmooth. Petals ſix, elliptical, concave. Flower-ſtalk erect, hairy, as well as the calyx.—Native of China, from whence it was procured by ſir J. Banks, for Kew garden, in 1789. We ſaw and deſcribed the plant about the ſame time in lady A. Hume's collection. It flowers in the greenhouſe from April to July. The *ſtem* is of humble growth, with brown hairy branches. *Leaves* elliptic-lanceolate, ſometimes inclining to obovate, about three inches long, ſmooth, veiny, deciduous except when kept in the ſtove. *Flowers* on lateral or axillary hairy ruſty ſtalks, of a dark dull purple, ſmelling ſtrongly like apples, much ſmaller than thoſe of M. *pumila*. *Anthers* with nearly marginal linear cells, opening inwards, as in true *Magnoliæ*.

9. M. *acuminata*. Blue Magnolia. Linn. Sp. Pl. 756. Ait. n. 8. (M. flore albo, folio majore acuminato, haud albicante; Cateſb. Carol. v. 3. 15; with a plate.)—Leaves ovate-oblong, pointed, downy beneath. Petals more than ſix, channelled, glaucous.—Native of North America from Pennſylvania to Carolina, upon the loftieſt mountains. *Michaux*. Mr. Collinſon firſt introduced it alive into England, in 1736. His original tree was lately in fine perfection at Mill Hill, and we hope ſtill exiſts there, having eſcaped the devaſtation which that intereſting ſpot underwent on its firſt ſale, when ignorance and bad taſte contended which ſhould do the moſt miſchief there. The place is now become a ſchool, and its few remaining treaſures muſt be preſumed to be in great jeopardy. (See COLLINSON, PETER.) The preſent ſpecies forms a large, umbrageous, deciduous *tree*, whoſe wood is yellow. *Leaves* cluſtered at the end of each branch, but on its ſubſequent elongation becoming alternate, ſtalked, pointed at each end, ſeveral inches long, and nearly half as broad; green and ſmooth above; paler, and at firſt downy, beneath. The *flowers* appear among the young leaves early in June, ſtanding ſolitary, each on a ſhort ſmooth ſtalk, at the end of the branches. They are neither fragrant nor beautiful, though remarkable for their pea-green very glaucous *petals*, which vary in ſhape, but are always concave, or channelled, and uſually about two inches long. The *capſule*, with its red *ſeeds*, hanging by long threads out of their cells, is ſometimes ripened in England. We have ſeen it at Kew.

10. M. *tripetala*. Umbrella Magnolia. Linn. Sp. Pl. 756. Ait. n. 10. (M. foliis ovato-oblongis ad baſin et apicem anguſtis, utrinque virentibus; Trew Ehret. t. 62, 63.)—Leaves lanceolate. Petals nine; the three outermoſt reflexed and dependent.—Native of Carolina; more rarely of Virginia. Miller appears to have had this tree at Chelſea in 1752, nor is it now uncommon in curious collections. It loves a moiſt ſtrong ſoil. The *leaves* are deciduous, oblong, ſmooth, light green, tapering at each end, of a very large ſize, uſually 18 inches long at an early period, and finally above two feet, ſpreading in the form of an umbrella at the end of each branch. Among them, early in June, ſtands an upright, very large, white *flower*, remarkable for the three pendulous outer petals, and for its peculiar ſcent, which Munchauſen commends, but moſt people find inſufferable, from its ſtarch-like overwhelming faint ſweetneſs. Ehret compares it to a vaſt quantity of white lilies. The *fruit* is not known to have been ripened here.

11. M. *auriculata*. Ear-leaved Magnolia. Michaux Boreal-Amer. v. 1. 328. Willd. n. 8. Ait. n. 12. Andr. Repoſ. t. 573. Sims in Curt. Mag. t. 1206. (M. Fraſeri; Walt. Carol. 159. t. 1. M auricularis; Saliſ. Parad. t. 43.)—Leaves ſpatulate-ovate, acute; heart-ſhaped at the baſe; ſmooth beneath. Petals obovate.—Native of lofty mountains in Carolina, from whence it was firſt brought to England alive by the late Mr. Fraſer in 1786. This, like the laſt, is a tree that flowers at an early age, and their habits are ſimilar. The prominent rounded lobes at the baſe of the *leaves* mark the preſent ſpecies. The *flowers* appear in July, and are *large*, of a yellowiſh-white, and delightfully fragrant. Willdenow ſeems to have taken from the figure in Mr. Walter's book his character of "claws to the petals," for which there is no juſt foundation, that figure having been faultily drawn, from a dried ſpecimen.

12. M. *macrophylla*. Long-leaved Magnolia. Michaux Boreal-Amer. v. 1. 327. Ait. n. 9.—Leaves ſpatulate-obovate; heart-ſhaped at the baſe; glaucous and downy beneath.—Native of North America, to the weſt of the river Tennaſſée. *Michaux*. Brought by Mr. Fraſer and his ſon, in 1800, "from the wilderneſs in Kentucky, on

the banks of the fouth fork of the Cumberland river."—It flowers in June and July. We have feen but a *leaf*, which has a round, downy, ftriated *footftalk*, full of pith, as Michaux defcribes all the branches to be. The *leaf* itfelf is near 18 inches long, and nine broad, fomewhat panduriform, being contracted above the dilated heart-fhaped bafe, and then again extended: the upper furface is green and fmooth; the under fingularly glaucous, or nearly white, and finely downy; both are minutely reticulated with innumerable veins. Michaux fays the *petals* are fix, white, the lower ones purple at their bafe.

13. M. *cordata*. Heart-leaved Magnolia. Michaux Boreal-Amer. v. 1. 328. Ait. n. 11.—"Leaves heart-fhaped, fomewhat downy beneath."—Native of dry open hills in Georgia and North Carolina. *Michaux*. Meffrs. Frafer are recorded as having brought it to Kew in 1801, but it has not yet bloffomed. Michaux fays it is allied to M. *acuminata*, and that the *flowers* are yellow. We have never feen a fpecimen. S.

MAGNOLIA, in *Gardening*, contains plants of the ever-green and deciduous tree kinds, of which the fpecies ufually cultivated are, the laurel-leaved magnolia (M. grandiflora); the fwamp deciduous magnolia (M. glauca); the blue magnolia (M. acuminata); and the umbrella magnolia, or umbrella tree (M. tripetala.)

The firft fort has varieties with broad leaves, and with narrow leaves.

And in the fecond kind there is a variety with long leaves, which is evergreen.

Method of Culture.—All thefe plants may be increafed by feed, layers, and cuttings of the fhoots.

With regard to the firft mode, the feed, which is received annually early in the fpring from America, preferved in fand, fhould be fown, as foon after as poffible, in pots of light rich earth, half an inch deep, plunging them in a moderate hot-bed, to bring up the plants an inch or two in height, or in the common earth under a warm wall or hedge, or in a frame, in the full fun, till the middle or latter end of April, then replunging them in an eafterly border open to the morning fun; giving moderate fprinklings of water in dry weather. The plants will rife the fame year; thofe in the hot-bed, probably in April, and the others in May, inuring thofe in the firft fituation timely to the full air. The plants fhould, all fummer, be regularly fupplied with water, and at the approach of winter be removed into a greenhoufe, or, rather, under a garden-frame, to be fheltered from froft all winter, indulging them with the open air in mild weather. If the pots be plunged in a bark hot-bed, &c. about March, under a frame, two or three months, it will forward the plants greatly; being careful to give water, and harden them to the open air gradually, fo as to be removed into it in their pots fully in June, to remain till the autumn, when they fhould be allowed fhelter in winter, as before. The following fpring, they fhould be planted into feparate pots, and plunged into a hot-bed, as before, to fet them forward, giving water, occafional fhade, and the benefit of free air; and in June removing the pots to a fhady border for the remainder of the fummer. In winter they fhould have fhelter as before, from fevere froft, but have the full air in all open weather. They require the fame care for two or three winters, when fome of them may be turned out of the pots with balls of earth about their roots, into the full ground, in a warm fheltered fituation, particularly the deciduous kinds; but the firft, or evergreen fort, fhould not be too foon expofed to the winter's cold, but be continued in occafional fhelter in the above manner four or five years, till two, three, or more feet high; and when turned out, matted occafionally in fevere winters, retaining fome in pots to be managed as greenhoufe plants of the more hardy kind.

In the layering mode, the layers fhould be laid down in autumn or fpring, choofing the young pliable fhoots for the purpofe, giving them a gentle twift, or a flit in the part laid into the earth. Some will be well rooted in one year, others probably not in lefs than two; then take them off, and plant each in a pot in the early fpring, plunging them in a moderate hot-bed for a month or two, to promote their growth freely at firft, and they will generally form good ftrong plants by the following autumn, allowing them fhelter in winter for a year or two, when they may be planted out.

In the cutting plan, the cuttings fhould be made from the fhort young fhoots of the preceding year, and be planted in pots of good earth, plunging them to the rims in the common or ftove hot-bed, giving water and occafional fhade; fome of them will be rooted the fame year, when they muft be inured by degrees to the open air, after which they may be managed as the layers.

It may be noticed that the firft, or ever-green fort, is one of the moft beautiful trees in nature, both in its growth, and in the luxuriance of its noble leaves, which render it fingularly confpicuous at all feafons. And the deciduous forts are alfo highly ornamental trees, and may be introduced into clumps and fhrubberies, where, by their fine foliage, they exhibit an elegant variety.

In common, all the different fpecies are cultivated in the nurferies, for fale, from which they may be taken up and planted out in the early fpring or autumn months; but the former is the better in moft cafes.

With regard to their difpofition in the fhrubbery, as they are rather tender in their early growth, they fhould have a fheltered funny fituation, in a rather dry foil, being planted in the moft confpicuous places, and not too clofely crowded with other fhrubs. But they have a good effect even when difpofed fingly in different parts, as in open fpaces of fhort grafs-ground, in fheltered fituations; efpecially the firft fort, from its evergreen nature.

MAGNOLIÆ, in *Botany*, a natural order of plants, fo called from the genus *Magnolia*, which makes a principal figure among them, is the feventy-fifth in the fyftem of Juffieu, and the fifteenth of his thirteenth clafs. See GERANIA.

The *Magnoliæ* are thus characterized. *Calyx* of a definite number of leaves, fometimes bracteated. *Petals* generally of a definite number, truly inferted below the germen. *Stamens* numerous, diftinct, with the fame infertion; anthers coalefcing with the filaments. *Germens* feveral, either definite or indefinite in number, placed on a common receptacle; ftyles either one to each germen, or wanting; ftigmas one to each germen. *Capfules* or *berries* as many as there are germens, of one cell, containing one or many feeds; fometimes the pericarps coalefce into one fingle fruit. *Embryo* of the feed ftraight, deftitute of albumen. *Stem* fhrubby or arborefcent. *Leaves* alternate, moftly undivided, the younger ones fheathed by ftipulas which embrace the branch, being convoluted in the form of a horn, as in the Fig genus, and protecting the bud, which is terminal. Thefe ftipulas, however, foon fall off, leaving a circular fcar. The *flowers* are either terminal or axillary.

The genera referred by Juffieu to this order are *Euryandra* of Forfter, which Schreber makes a *Tetracera*, fee EURYANDRA; *Drymis* of Forfter, the *Wintera* of Schreber; *Illicium*, *Michelia*, and *Magnolia* of Linnæus; *Talauma* of Juffieu, which is the original *Magnolia* of Plumier; *Liriodendrum*

dendrum of Linnæus; and *Mayna* of Aublet, Lam. Illuſtr. t. 491.

To theſe are ſubjoined as akin to them, *Dillenia*, *Curatella*, *Ochna*, and *Quaſſia*.

MAGNON, John, in *Biography*, a French poet and advocate, who exerciſed his profeſſion ſome time at Lyons, and then quitted it for dramatic writing, was born at Tournay. He was aſſaſſinated in 1662, in the ſtreets of Paris. He is mentioned as the perſon who projected, but did not live to complete, an Encyclopédie in verſe. Moreri.

MAGNOTS, or Mainots, in *Geography*, an appellation diſtinguiſhing Greeks, who inhabit the ſouth part of the Môrea, the environs of Sparta, and more particularly the part which extends from Miſitra to Cape Matapan. As remains of the Lacedæmonians, they are as ardent as their anceſtors in defending their liberty and maintaining their independence. The Turks have ſometimes obtained a trifling tribute from them, without ever having been able entirely to ſubdue them. Cultivators or ſhepherds, mariners or pirates, according to the exigence of their circumſtances, they are always ready to quit the ſmall towns which they occupy on the gulfs of Coron and of Colokythia, for the purpoſe of penetrating into the interior of the country, and eſtabliſhing themſelves on the mountains. With this energy and love of liberty, it is to be regretted, that there are among them robbers, who, not content with making war on the Turks, who have unjuſtly diſpoſſeſſed them of a part of their territory, alſo go ſometimes to plunder the unfortunate Greeks of the ſmall iſlands of the Archipelago, who ought rather, on account of identity of religion and of intereſt, to unite againſt their common enemies.

MAGNUM Os, in *Anatomy*, a name of one of the bones of the carpus. See its deſcription in the article Extremities.

MAGNUS, John, in *Biography*, archbiſhop of Upſal, in Sweden, was born in 1488. He oppoſed moſt ſtrenuouſly the Reformation in Sweden, and finding his efforts ineffectual, he retired to Rome, where he died in 1544. He wrote a hiſtory of Sweden, and lives of the archbiſhops of Upſal: he had a brother Olaus, who was one of the perſons at the council of Trent, where he diſplayed conſiderable talents for buſineſs. He died at Rome in 1560. His greateſt work is a Hiſtory of the Northern Nations.

Magnus, organiſt of the church of St. Giles-in-the-Fields, who flouriſhed about the year 1730, was eſteemed, by his contemporaries, a great maſter of harmony, and an admirable extempore player on the organ; of whoſe great abilities many years after his deceaſe we have often heard Rouingrave and Dr. Arne ſpeak with rapture. Before Kelway and Stanley were arrived at great renown, which they afterwards acquired by their voluntary playing, Magnus drew crowds of young organiſts to St. Giles's every Sunday to hear him on the full organ, on which, deſpiſing ſingle ſolo ſtops, he had attained to ſuch command, as to be able to conduct four parts in fugue, with as much correctneſs and facility, as others could two parts, without fugue or imitation. Exceſſive ſtudy and application brought on a diſorder in his intellects, which put an end to his exiſtence, at an early period of his life.

MAGNY, in *Geography*, a town of France, in the department of the Seine and Oiſe, and chief place of a canton, in the diſtrict of Mantes; 12 miles N. of Mantes. The place contains 1402, and the canton 11,149 inhabitants, on a territory of 222½ kiliometres, in 29 communes.

MAGO, a town of the iſland of Ceylon, near the S.E. coaſt; 98 miles S.S.E. of Candy.

MAGOAR, a town of France, in the department of the North Coaſts; 10 miles S. of Guingamp.

MAGODUS, among the Romans, a name given to thoſe players who ſometimes acted the part of men, and ſometimes of women: the word is derived from μαγος, *magic*, and ᾠδὸς, *ſinger*, and properly denotes thoſe players who performed extraordinary feats and geſtures.

MAGOLSHEIM, in *Geography*, a town of Germany, in the kingdom of Wurtemberg; 30 miles S. of Stuttgart.

MAGON, a town of the iſland of Minorca, ſaid to have been founded by the Carthaginians.

MAGONA, in *Ornithology*, the name given by Buffon to the Macaragua of Maregrave, Ray, &c. and the great Tinamou of Latham. See Tetrao *Major*.

MAGOPHONIA, formed from μαγος, *magus*, and φονος, *ſlaughter*, the name of a feaſt among the ancient Perſians, held in memory of the expulſion of the Magians.

The Magus Smerdis having uſurped the throne of Perſia, upon the death of Cambyſes, 521 years before Jeſus Chriſt, ſeven of the principal lords of the court conſpired to drive him out of it. Their deſign was executed with good ſucceſs: Smerdis, and his brother, another Magus, called Patizithes, were killed. Upon which the people alſo roſe, and put all the Magi to the ſword; inſomuch that there would not have one eſcaped, had not night come upon them. Darius, ſon of Hyſtaſpes, was then elected king: and, in memory of this maſſacre of the Magi, a feaſt was inſtituted, ſays Herodotus, called *Magophonia*. See Magi.

MAGORA, in *Geography*, a town of Walachia; 14 miles S.E. of Ruſei.—Alſo, a ſea-port of Arabia, in the Red ſea; 150 miles N.N.W. of Loheia. N. lat. 17° 40′.

MAGOT, in *Zoology*, the name given by Buffon to the Barbary ape of Pennant, or the Simia *Inuus*; which ſee.

MAGOTTY Cove, in *Geography*, a bay on the N. coaſt of Jamaica; one mile W. of Muſketto cove.

MAGPIE River, a river of Canada, which runs into the gulf of St. Lawrence, about ſix miles W. from the mouth of the river St. John.

MAGPYE, in *Ornithology*, a well-known ſpecies of the *Corvus*, or the *corvus pica*, in the Linnæan ſyſtem: it is a crafty, reſtleſs, noiſy bird, called by Ovid *nemorum convicia pica*. See Corvus *Pica*.

MAGRA, in *Geography*, barren mountains of Africa, on the road from Tripoli to Egypt; 150 miles W. of Cairo.

Magra, or *Magora*, a river of Italy, which riſes in the Apennines, and paſſing through a valley, called the "valley of Magra," runs into the ſea, five miles S. of Sarzana.

MAGRACOTTA, a town of Hindooſtan, five miles W. of Palicandcherry.

MAGRE, a town of Hindooſtan, in the Myſore country, deemed by the Hindoos a place of peculiar ſanctity, and abounding in pagodas and choultries; ſix miles from Savindroog.

MAGREBIANS. See Mograbians.

MAGUA, a town of Hindooſtan, in Dowlatabad; five miles S. of Beder.

MAGUALBARI, or Rio das Galines, a river of Africa, in Guinea, which runs into the Atlantic, N. lat. 7°.

MAGUANA, St. John *of*, a canton and town on the S. ſide of the iſland of St. Domingo, on the left ſide of the river Neybe. The capital of the ancient kingdom of Maguana ſtood where the town St. John of Maguana is now ſituated. This canton was pillaged by the Engliſh privateers in 1543. In 1764, the diſtrict of the new pariſh contained 3600 perſons, of whom 300 were capable of bearing arms. Its population now amounts to more than 5000 perfons.

Maguana. See Mayaguana.

MAGUARI, in *Ornithology*. See Ciconia *Americana*.

MAGUDARIS, a name by which Diofcorides calls the filphium.

MAGUELONE, in *Geography*, a lake of France, in the department of the Gard, near the Mediterranean, communicating with it, and extending from Catte to Pecais. Its name is derived from that of an ancient town, which was a bifhop's fee, transferred in 1538 to Montpellier. Charles Martel deftroyed the town, becaufe it was an afylum for Saracen invaders. It was rebuilt in the year 1060, but is now a fmall place, fituated on a neck of land between the lake and the fea; five miles S. of Montpellier. N. lat. 43° 30'. E. long. 3° 58'.

MAGUIBA, a river of Africa, that runs into the fea, E. of cape Monte.

MAGULLACONDA, a town of Hindooftan, in Myfore; 30 miles from Chinna Balabaram.

MAGUMBA, a province of Africa, in the N.W. part of the kingdom of Loango.

MAGYDARIS, in *Botany*, a name ufed by Theophraftus, and other of the old authors, for the laferpitium or laferwort.

MA-HA, or Ma-coupa, in *Geography*, a city of China, of the fecond rank, in Koei-tcheou. N. lat. 26° 26'. E. long. 107°.

MAHABARAT, an epic poem in the Sanfkrita language, by an author very celebrated among all fects of Hindoos, named Vyafa, to whom alfo is afcribed the facred romances, the Puranas. (See Vyasa and Purana.) The fubject of the Mahabarat is the heroic adventures of the five fons of Pandu, called hence the Pandavas. (See Pandu.) It is a work of great extent, amounting it is faid to upwards of a hundred thoufand metrical ftanzas, of which more than a third have been tranflated by Dr. Wilkins, librarian to the Eaft India company. This learned gentleman publifhed in 1785, an epifode of the great poem, under the title of "Bhagavat Gita, or Dialogues of Krifhna and Arjun." An extract from that very curious work is given under the article Krishna. The Mahabarat contains the genealogy and general hiftory of the houfe of Bhaurat, fo named from Bharat its founder, the epithet Maha, or *great*, being prefixed in token of diftinction; but its more particular object is to relate the diffentions and wars of the two great collateral branches of it, called from their anceftors the Kurus and Pandus (fee Kuru), both lineally defcended in the fecond degree from Vichitravirya, their common anceftor, by their refpective fathers Dritrarafhtra and Pandu. In the dedication of the Bhagavat Gita, Mr. Warren Haftings, under whofe aufpices the tranflation was made, after noticing the banifhment of the Pandus, fays, "The exiles, after a feries of adventures, worked up with a wonderful fertility of genius and pomp of language into a thoufand fublime defcriptions, returned with a powerful army to avenge their wrongs, and to affert their pretenfions to the empire in right of their father. In this ftate the epifode opens." Without allowing the antiquity of four or five thoufand years as claimed by the Hindoo literati for their juftly admired Mahabarat, its great age is unqueftionable. In general eftimation it ranks next to the Ramayana, if it be not fuperior to it, in reputation for holinefs: the Vedas and Puranas only precede thefe works in the eftimation of a great portion of the Hindoos. See Ramayana.

Mr. Moor, in his Hindoo Pantheon, after noticing the allegorical character of Oriental mythology, fays, "This may ferve as a farther fpecimen of the endlefs allegories in which the poetical fabulifts have veiled the moral, fcientific, and theological knowledge of the Hindoos; all of which, as well as hiftory, and even arts, if not buried in, are obfcured by, and intimately connected with, their wild and bold mythology. Thus, again, the Mahabarat is a continued allegory of the conflicts between man's virtues and his vices: the former perfonified under the names of the five fons of Pandu; of whom Bhima, Yudifhtira, and Arjun, faid to reprefent Juftice, Fortitude, and Prudence, were by one mother, Koonti; and the other two, Nakal and Sahadeva, perfonifications of Temperance and Wifdom, were by Maderi. (See Koonti and Maderi.) Other legends attribute the virtues of Modefty and Tendernefs to Yudifhtira; Strength to Bhima; and Skill or Courage to Arjun; to Nakal, Beauty or Harmony; and to Sahadeva, Wifdom and Penetration. The two laft brothers are by fome faid to be the twin virtues of Temperance and Chaftity. Man's manifold vices are perfonated by the hundred fons of Kuru, the brother of Pandu: hence a near relationfhip exifts between Vice and Virtue." P. 92.

MAHABELI, a name in Hindoo mythological legends of a monarch who, although reafonably virtuous on other points, was ftill fo elated by his grandeur, that he omitted the effential ceremonies and offerings to the deities; and Vifhnu found it neceffary to check the influence of fuch an example, by refolving to become, for that purpofe, incarnated in the perfon of a wretched Brahman dwarf. This incarnation, or avatara, is one of the ten principal defcents of Vifhnu, and is called Vamana, or the dwarf. (See Vamana and Vishnu.) Sir William Jones furmifes the Belus of weftern hiftory, to be the fame with the Beli of this article, for the epithet of Maha prefixed, merely means *great* in the Sanfkrita language.

MAHABUTPOUR, in *Geography*, a town of Bengal; 33 miles S. of Dacca.

MAHACKAMACK, a river of America, which falls into the Delaware from the N.E. at the N.W. corner of New Jerfey.

MAHACONDAPALLY, a town of Hindooftan, in Myfore; 15 miles S. of Ouffoor.

MAHADEO, a temple of Thibet, fituated on the lake Manfaroar.

MAHA-DEVA, in *Hindoo Mythology*, is a name given to the god Siva, one of the perfons in their divine triad. (See Siva.) In Sanfkrit it means literally the great god; and although we might expect to find this name thus applied by the fect only, who exclufively worfhip Siva, indicating the pre-eminence of their deity, yet it is faid to be commonly given to him by other fects, as well as by his own.

MAHAKALA, a name of Siva, the deftructive attribute of the deity. The name feems to be the fame as Kal or Kala (which fee), with an epithet prefixed, meaning *great*. Mr. Paterfon, in the eighth volume of the Afiatic Refearches, thus defcribes this perfonification. "Mahal Kal, as reprefented in the caverns of Elephanta, had eight arms. In one he holds a human figure, in another a fword, or facrificial axe; in a third he holds a bafin of blood, and with a fourth he rings over it the facrificial bell. Two other arms are broken off; with the two remaining he is drawing behind him a veil, which extinguifhes the fun, and involves the whole univerfe in one undiftinguifhed ruin. One of the titles of this tremendous deity is Bhairava, the Terrific; but his principal

principal defignation is Kal-Agni-Rudra." Thefe three words, we are told in the Hindoo Pantheon, are efpecially defcriptive of Siva, and may be rendered Time, Fire, Fate. See KAL.

Niebuhr gives a print in his Indian Travels of the fculpture above defcribed, which Maurice has copied into his fixth volume of Indian Antiquities. In the Hindoo Pantheon, the following defcription is given of this fubject from the perfonal examination of the author. "Having lately been in the Elephanta cavern, and when there made fome memoranda, I will thence extract what relates to the fubject of Mahakala.—The compartment containing the group, of which Siva in this character makes the principal figure, is on the right of the entrance, facing a compartment of like fize, containing what, in another part of this work, I have fuppofed to be a marriage ceremony. The figure is of Siva *Vindex*, fourteen feet high, but the lower extremities broken off; his attention is from his attitude turned to his left, his afpect is terrific, indicating the immediate execution of fome avenging act,—he had eight arms; the fuperior right and left ftretched upwards, and either fupporting a cloth or curtain, or putting it over the terrible event he threatens—the fingers grafp the cloth. The left upftretched arm is finely executed; the right is broken at the elbow: the next right hand is broken off at the wrift; the correfponding left holds a bell, in good prefervation, over a cup in the palm of the next, having a ferpent twining near the elbow. A third right hand grafps a long ftraight fword, uplifted, perfect; the two inferior hands, right and left, are broken off above the elbow: they were in bolder relief, and the left appears to have fupported, or to have grafped, the leg of a kneeling figure, the trunk only of which remains; its legs, arms, and head being broken off. This kneeling figure may have been between five and fix feet in height; its back is toward the threatener, and leaning fo in his direction, as to drop its blood, if fpilled, into the cup before noticed. The head of the principal figure has a highly ornamented cap; a fcull and ferpent are among its frontal ornaments. It has alfo a pendent necklace, and a chaplet, if it may be fo called, of human heads, of which only two or three are plainly difcernible, flowing over the left fhoulder to the right thigh, where it is broken off: the Zennar, or holy thread (fee ZENNAR), and a broader belt, run in nearly a like direction. On all the wrifts are bracelets, and above the elbows of three of the arms is the ornament called bazuband. No figures remain in any prefervation to the right of the principal, or under him. On the left, near the fuppofed victim, are two bearded faces, expreffive of Pity; a compaffionate female is juft above them, leaning forward over the victim; fhe holds her fcarf in her hands, and is an elegant perfon: below the bearded men are two or three females with pitying afpects: the fame emotion, intermingled with terror, is evident in every face of this compartment, where features can be traced.

"Over the fubjects juft defcribed, is a row of males and females of rather diminutive fize; in the middle of the row, nearly over the head of Siva, is a thing like a mitre, with a crofier cut deep in it, and furmounted with a crofs; but the limbs of the crofs not exactly at right angles; two aged and emaciated figures are on the right (the fpectator's right) of the mitre, holding up their hands betokening pity and pain: on the other fide of the mitre are two fimilar figures; in front of each pair is a proftrate diftreffed male child, their heads near the mitre: beyond the laft mentioned pair, on the fpectator's left, are a male and female in great anxiety and diftrefs, holding fcarfs in their hands.

"The fubject, fuppofed to refemble a mitre, crofier, and crofs, appears alfo in another compartment of this cavern. Fancy may, perhaps, have had fome fhare in making this refemblance; but it is really curious, and I think ftriking, although, I believe, heretofore not remarked." Hin. Pan. p. 51.

The great antiquity of the cavern wherein is this curious piece of fculpture is unqueftionable, although no period approaching to exactnefs can be affigned for its origin. The Hindoos, and their Brahmans, with their accuftomed pronenefs to hyperbole, throw it back into very remote ages; and fome of our miffionaries and other European travellers, as if unwilling to be outdone in extravagance, have imagined the figure here defcribed of Mahakala deftroying a human being, typical perhaps of Time and the human race, to be a reprefentation of the judgment of Solomon! Without ftopping here to difcufs fuch ill-judged fpeculations, fimilar inftances of which will be found under our article KRISHNA; it may be fufficient to notice the progrefs that the art of fculpture had made in India in times certainly very remote in reference to art and fcience. The compartment defcribed in the preceding extracts is elaborate in figures powerfully expreffing one emotion of the mind; a precifion ftrongly indicating great refinement and fkill. It may be reafonably queftioned if any fpecimen equal in age and execution can be elfewhere pointed out. Of the cavern temples of India, fome account is given under the articles ELEPHANTA, ELORA, and KARLY.

MAHAKALI, a name of *Parvati*, the confort of *Siva*, in his character of *Mahakala*; under which articles, and *Kal* and *Kali*, farther information may be fought.

MAHA-LAKSHMI, a name given by certain fects of Hindoos to *Lakfhmi*, the confort of *Vifhnu*. See thofe articles. Under this name fhe is worfhipped at a pretty temple on the weftern fea-fhore of the ifland of Bombay, which is much reforted to at the annual jatra, or fair.

MAHALEB, in the *Materia Medica*, the name of the fruit of a fort of wild cherry, called *cerafus fylveftris amara*, or the wild bitter cherry, by Bauhin. The wood of the tree is of a greyifh caft, and fine grain, with a mixture of red in the veins, and is very firm, and of a fweet fmell, and ufed by the French in making cabinets; the leaves and flower carry a rude refemblance of thofe of the common cherry; the fruit is round, black, and refembles a cherry, having the fame fort of ftone in it, the kernel of which is like the bitter almond in tafte. It is commended in external applications, and the perfumers of France ufe it in their wafhballs. It is to be chofen frefh and fweet, for it very often has an intolerable ftinking fmell, like that of bugs. See PRUNUS.

MAHALOULE CASSIR, in *Geography*, a town of Africa, in the kingdom of Tunis; 9 miles E. of Zunghar.

MAHAMAIL, a town of Algiers; 27 miles W.S.W. of Tipfa.

MAHAMMA, a town of Arabia, in the province of Yemen; 24 miles S.E. of Chamir.

MAHAMUNDALA, a town of Hindooftan, in the Carnatic; 10 miles S. of Chittoor.

MAHAN, a town of Perfia, in the province of Kerman; 60 miles N.E. of Sirgian.

MAHANADA, or MAHA-NUDDY, a river of Hindooftan, which rifes in the mountains of Berar, in the country of Ruttunpour, traverfes the country of Oriffa, paffes by Cattack, where it is fometimes called the Cattack river, and difcharges itfelf by feveral mouths into the bay of Bengal; 40 miles E.S.E. of Cattack. The fartheft point to which it is navigable from the fea is Arung. Near this river is the fort called *Boad*, and a town called *Beiragur*, which fee

fee refpectively. The mouths of the river, which form an affemblage of low woody iflands, like the Ganges, and many other rivers, have never been traced, but are defcribed merely from report. At the mouth of the principal channel, near Falfe point, is a fortified ifland, named Cojung, or Codjung. Ptolemy's *Adamas* river anfwers perfectly to the Mahanuddy; and the diftrict "Sabaræ," on its banks, is faid to abound in diamonds.

MAHANÆDA, a river of Hindooftan, which rifes on the borders of Bootan, and runs into the Ganges; 20 miles N. of Moorfhedabad.

MAHANAGORE, a town of Bengal; 20 miles N. of Iflamabad.

MAHANAIM, or MANAIM, in *Ancient Geography*, a city of Paleftine, belonging to the Levites, of the family of Merari, in the tribe of Gad, on the brook Jabok. (Jofh. xxi. 38, xiii. 29, 30. 1 Chron. vi. 80.) Jacob gave it this name, becaufe he had here a vifion of angels. (Gen. xxxii. 2.) In the Vulgate it is fometimes called fimply "Caftra," or the camp. Gen. xxxii. 2. 2 Sam. ii. 8. 12. 29. xvii. 24. xix. 32.

MAHANASAN, in *Geography*, a city of Perfia, in the province of Mazanderan, compofed of three towns joined together. In 1392 it was taken, pillaged, and deftroyed by Timur Bec; 12 miles N.E. of Amol.

MAHANDPOUR, a town of Hindooftan, in the circar of Chanderee; 38 miles W. of Chanderee.

MAHANGANO, a province of Africa, in the kingdom of Angola, having a capital of the fame name.

MAHANY, a river of Hindooftan, in Bahar, which runs into the Ganges, about 25 miles below Bar.

MAHAPRALAYA, in *Metaphyfics*, is confidered among Hindoo philofophers as the grand confummation of all things: the great deftruction, as the word appears to mean. See hereon under KAL.

MAHARSHIS, an appellation applied in Hindoo books to departed fages or faints. The terms Devarfhi, Rajarfhi, and Maharfhi, feem nearly fynonimous with Rifhi, meaning faint, deified faint, great faint, or great fage. There are differences doubtlefs, for Nareda is reckoned the chief of the Devarfhis. Krifhna in the Bhagavat Gita (fee MAHABARAT) fpeaks of his "holy fervants the Brahmans and the Rajarfhis," and fays "I am Brighu among the Maharfhis, and of all the Devarfhis I am Nared," p. 86. (See NAREDA.) Nareda and Brighu are generally called fons of Brahma. The term Maharfhi occurring in the fixth fection of the firft book of the Ramayan, the learned tranflators fubjoin the following note—"There are four kinds of fages or Rifhis: the Rajarfhi, or royal fage; the Maharfhi, or great fage; the Brahmarfhi, or facred fage; and the Devarfhi, or divine fage: of thefe the firft is efteemed the loweft, and the laft the higheft." Hindoo Pantheon, p. 95. (See RISHI.) The names of thefe fages, and allufions to them, occur frequently in the writings of the Hindoos.

MAHA-RUDRA, in *Hindoo Mythology*, a name of Siva. It means the great Rudra. See SIVA and RUDRA.

MAHAUT BAY, in *Geography*, a bay on the W. coaft of the ifland of St. Vincent, S. of Cumberland bay.

MAHAWA GAUT, a mountain of Bahar; 24 miles W. of Saferam.

MAHBROOK, a town of Africa, in the Sahara; 160 miles W.N.W. of Tombuctoo. N. lat. 19° 10'. E. long. 0 15'.

MAHBUB, in *Commerce*, a Turkifh gold coin. See SEQUIN.

MAHDIA, in *Geography*. See MAADIÉ.

MAHE', a town and fortrefs of Hindooftan, on the coaft of Malabar. Mount Dilla, which is a remarkable promontory, fituated in N. lat. 12° 1'. E. long. 75° 2', or 1° W. of Cochin, appears to be W. 33° 15' N., or nearly N.W. by W. from Mahé, diftant from it 28.4 geographical miles. N. lat. 11° 45' 18". E. long. 75° 26' 30". —Alfo, a fmall ifland in the Indian fea. S. lat. 4° 45'. E. long. 55° 30'.

MAHENDRA, a name of the Hindoo deity *Indra*; which fee.

MAHERNIA, in *Botany*, is of uncertain derivation, unlefs, as profeffor Martyn fays, it be fancifully confidered as an anagrammatic inverfion of *Hermannia*: the two genera being very nearly allied, or rather, in reality, fcarcely to be feparated.—Linn. Mant. 8. Schreb. 208. Willd. Sp. Pl. v. 1. 1564. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 2. 198. Juff. 290. Lamarck Illuftr. t. 218.—Clafs and order, *Pentandria Pentagynia*. Nat. Ord. *Columniferæ*, Linn. *Tiliaceæ*, Juff.

Gen. Ch. *Cal.* Perianth of one leaf, bell-fhaped, permanent, cut into five, awl-fhaped, longifh teeth. *Cor.* Petals five, heart-fhaped, oblong, fpreading, twice as long as the calyx. Nectaries five, obcordate, on ftalks, furrounding the germen, fhorter than the calyx. *Stam.* Filaments five, capillary, placed upon the nectaries, fhorter than the calyx; anthers oblong; pointed, erect. *Pift.* Germen on a fhort ftalk, obovate, five-fided; ftyles five, briftle-fhaped, erect, the length of the petals; ftigmas fimple. *Peric.* Capfule ovate, of five cells, and five valves. *Seeds* few, kidney-fhaped.

Eff. Ch. Calyx five-toothed. Petals five. Nectaries five, joined at the bafe, obcordate, placed under the filaments. Capfule of five cells.

The following examples will be fufficient for the illuftration of this dubious genus.

M. *verticillata*. Linn. Mant. 59. Cavan. Diff. fafc. 6. 324. t. 176. f. 1. (Hermannia ciliaris; Linn. Suppl. 302.) —Leaves in whorls, linear and pinnatifid. Flowers in pairs, on long ftalks.—A native of the Cape of Good Hope.—Linnæus defcribes this plant in thefe words. "*Stem* fhrubby, diffufe. *Branches* thread-fhaped. *Leaves* frequently from eight to ten in a whorl, linear, flightly divided or pinnatifid. *Inflorefcence* the fame as in *Hermannia*, terminal, the ftalks generally two-flowered. *Corolla* yellow.—Take away the nectaries from the petals, and add them to the ftamens, and you will have a *Hermannia*, (paradoxical as it may feem) with whorled leaves. What a ftrange generic metamorphofis!"

M. *pinnata*. Linn. Syft. Veg. ed. 14. 308. Curt. Mag. t. 277.—Leaves three-parted, pinnatifid.—A native of the Cape, whence it was introduced by M. P. Miller, in 1752. It flowers from June to Auguft.—*Stem* fhrubby, nearly three feet in height. *Branches* flender and delicate, with a reddifh *bark*. *Flowers* in clufters, lateral, of a lively red colour when firft expanded, drooping like little bells, moftly two together. Linnæus originally efteemed this a fpecies of *Hermannia*.

M. *incifa*. Willd. n. 5. Curt. Mag. t. 353. Jacq. Hort. Schoenb. v. 1. 28. t. 54.—Stem erect, rough. Leaves pinnatifid, cut and hairy.—A native of the Cape, flowering through the fummer and autumn.—Nearly allied to the laft in fize and habit, but differs in the fingular hairinefs of its ftalks, form of its leaves, and colour of its flowers. *Stem*, when viewed with a magnifying glafs, befet with little protuberances from whence iffue tufts of pellucid hairs. *Leaves* deeply jagged at their edges. *Flowers*, when in bud, of a rich crimfon colour, but, when expanded, of a deep orange, becoming yellow as they fade.

M. *glabrata*. Willd. n. 6. Ait. Hort. Kew. ed. 2. n. 4. (M. odorata; Andr. Bot. Repof. t. 85.)—Leaves lanceolate, pinnatifid and toothed. Stalks very long, bearing two flowers.—Found alfo at the Cape. It blooms in the fummer.—This fpecies was firft fent to England about 1792.—*Stem* twiggy, and branched. *Leaves* dark green, the upper ones fimple and oppofite. *Flowers* yellow, fragrant like the Jonquil.

The remaining fpecies of *Mahernia*, enumerated by Willdenow, are, *pulchella*, *diffufa*, *heterophylla* and *biferrata*.

Mahernia, in *Gardening*, comprifes plants of the fhrubby exotic kind, for the green-houfe, of which the fpecies cultivated are, the wing-leaved mahernia (M. pinnata); and the cut-leaved mahernia (M. incifa.)

Method of Culture.—Thefe different plants may be increafed by planting cuttings of the young branches in the fummer feafon fingly, in pots of light mould, watering, and plunging them in a hot-bed till they have ftricken root. When they have been well rooted, they may be removed into the green-houfe for protection during the winter feafon; being managed as the lefs tender plants of this defcription.

All of them afford variety among other potted plants of a fimilar kind in green-houfe collections.

MAHESA and Maheswara, in *Mythology*, names of the Hindoo god Siva; the fame, indeed, as *Ifa* and *Ifwara* (which fee) with the epithet Maha, or *great*, prefixed. Thefe names and allufions to them occur perpetually in Hindoo books. The following example from the Gita Govinda of Jayadeva, (fee Jayadeva,) as tranflated by fir William Jones, fhews their prevalence, and is defcriptive alfo of the appearance and attributes of Mahefa, or Mahadeva, and of Krifhna. (See Krishna.) The laft-named deity, agonized by the jealous anger of Radha, exclaims "Grant me but a fight of thee, O lovely Radhika! for my paffion torments me. I am not the terrible Mahefa; a garland of water lilies, with fubtile threads, decks my fhoulders, not ferpents with twifted folds: the blue petals of the lotos glitter on my neck, not the azure gleam of poifon: powdered fandal wood is fprinkled on my limbs; not pale afhes. O god of love, miftake me not for Mahadeva; wound me not again (fee the fable here alluded to, under article Kama); approach me not in anger; hold not in thy hand the fhaft barbed with an amra flower. My heart is already pierced by arrows from Radha's eyes, black and keen as thofe of an antelope; yet mine eyes are not gratified by her prefence. Her's are full of fhafts; her eyebrows are bows, and the tips of her ears are filken ftrings: thus armed by Ananga (or Kama) the god of defire, fhe marches, herfelf a goddefs, to enfure his triumph over the vanquifhed univerfe. I meditate on her delightful embrace; on the ravifhing glances darted from the fragrant lotos of her mouth; on her nectar-dropping fpeech; on her lips, ruddy as the berries of the bimba." See Radha.

MAHESRA, in *Geography*, a town of Hindooftan, in Mewat; 15 miles S.W. of Cottila.

MAHESWARI, in *Hindoo Mythology*, a name of Parvati, as the Sakti, or confort of Siva, in his character of *Mahefa*, which fee. She is reprefented, like her lord, four-armed, holding a trident, with a vaft ferpent for a ring, a crefcent for a gem, and riding on a bull. She is reckoned one of the Matris, or divine mothers of the celeftials. See Matri.

MAHHRA, in *Geography*, a diftrict of Arabia, included by the Arabians within the province of Hadramaut. This diftrict feems, like Tehama, to be a fandy plain, extending in breadth from the fhores of the ocean, backward to the part in which the hilly country commences. Thefe plains have probably been once covered by the fea.

MAHIDESER, a town of Perfia, in the province of Irak; 78 miles S.W. of Hamadan.

MAHIE, the name given by the inhabitants of Otaheite, or George's ifland, to their bread-fruit when made into a kind of four pafte, which, in confequence of having undergone a fermentation, will keep a confiderable time, and fupply them with food when no ripe fruit is to be had. When, therefore, they fee a great fhow of new fruit on the trees, they ftrip them all at once of their former crop, of which they make mahie. This fuccedaneum for ripe bread fruit is thus made. They gather the fruit before it be perfectly ripe, and laying it in heaps cover it clofely with leaves. In this ftate it ferments, and becomes difagreeably fweet; the core is then taken out entire, and the reft of the fruit thrown into a hole in their houfes, dug on purpofe, and neatly lined in the bottom and fides with grafs. The whole is then covered with leaves, and heavy ftones are laid upon them. In this ftate it undergoes a fecond fermentation, and becomes four, after which it will fuffer no change for many months. It is taken out of this hole, as it is wanted for ufe, and being made into balls, it is wrapped up into leaves and baked, and thus dreffed it will keep for five or fix weeks. It is eaten, both cold and hot, and the natives of thofe countries feldom make a meal without it: but to captain Cook and his company the tafte was as difagreeable as that of a pickled olive generally is, the firft time it is eaten. Hawkefworth's Account, &c. vol. ii. p. 145, 193.

MAHIM, in *Geography*, a town of Hindooftan, in the northern part of the ifland of Bombay, with a cuftom houfe; 17 miles N. of Bombay.

Mahim, *Mahem*, *Maihem*, or *Mayhem*, in *Law*, a *maim*, or corporal hurt, whereby a man lofeth the ufe of any member, that is, or may be, of defence to him in battle; as, befides arms and legs, the eye, hand, foot, fcalp of the head, fore-tooth; or, as fome fay, a finger or toe: but the cutting off his ear or nofe, or lofs of his jaw-teeth, are not held to be mayhems at common law, becaufe they do not weaken but only disfigure him. (Finch L. 204. 1 Hawk. P.C. 111.) The word comes from the French *mehain*, of *mehaigner*, *to mutilate*: the canonifts call it *membri mutilatio*; and all agree it confifts in the lofs of a member, or of the ufe thereof.

By the ancient law of England, he that maimed any man was fentenced to lofe the like part, (membrum pro membro) which is ftill the law in Sweden; but this was difufed, and mayhem, by the common law, (1 Hawk. P. C. 112.) was only punifhable by fine and imprifonment; unlefs perhaps the offence of mayhem by caftration, which all our old writers held to be felony. But by fubfequent ftatutes the crime and punifhment of mayhem were put more out of doubt. By 5 Hen. IV. cap. 5. cutting out the tongue, or putting out the eyes of a man, to prevent him being an evidence againft thofe who beat, wounded, or robbed him, was an offence declared to be felony, if done of malice prepenfe, that is, as fir Edward Coke explains it, voluntarily, and of a fet purpofe, though done upon fudden occafion. The ftatute 37 Hen. VIII. c. 6. directs, that if a man fhall malicioufly and unlawfully cut off the ear of any of the king's fubjects, he fhall not only forfeit treble damages to the party grieved, to be recovered by action of trefpafs at common law, as a civil fatisfaction; but alfo 10*l.* by way of fine to the king, which was his criminal amercement; and by 22 and 23 Car. II. c. 1, called the Coventry Act, it is enacted, that if any one fhall of malice aforethought, or by lying in wait, cut out

out or disable the tongue, put out an eye, slit the nose, cut off the nose or lip, or cut off or disable any limb or member of another person, with intention in so doing to maim or disfigure him, it is felony without benefit of clergy in such offender, his counsellors, aiders and abettors; and, when the case is difficult to judge whether it be a mahim, or not, the judges commonly view the party wounded, and sometimes take the opinion of the surgeons. 2 Roll. Abr. 578. (See EXAMINATION.) By analogy to this, in an action of trespass for mayhem, the court (upon view of such maihem as the plaintiff has laid in his declaration, or which is certified by the judges who tried the cause to be the same as was given in evidence to the jury) may increase the damages at their own discretion. 1. Sid 108.

A person who maims himself, for the purpose of begging, and also a person who disables himself, that he may not be impressed for a soldier, may be indicted and fined. The offence of wilfully and maliciously shooting at any person, which may endanger either killing or maiming him, though no such evil consequence ensues, is made felony without benefit of clergy, by 9 Geo. I. c. 22.

A horrible practice having of late years prevailed among pickpockets and others, of lacerating those who were the objects of depredation or resentment, and the laws being found inadequate to reach and efficiently correct the evil, the legislature interfered, and by the 43 G. III. c. 58. (commonly called lord Ellenborough's act) which recites that divers cruel and barbarous outrages had been of late wickedly and wantonly committed upon the persons of his majesty's subjects, either with intent to murder, to rob, or to maim, disfigure or disable, or to do other grievous bodily harm to such subjects, and that the provisions by law made for the prevention of such offences had been found ineffectual for that purpose, it is enacted that if any person or persons shall willfully, maliciously, and unlawfully stab or cut any of his majesty's subjects, with intent in so doing, or by means thereof to murder or to rob, or to maim, disfigure, or disable such subject or subjects, or with intent to do some other grievous bodily harm, or to obstruct, resist, or prevent the lawful apprehension and detainer of the person or persons so stabbing or cutting, or of any of his, her, or their accomplices, for any offences for which he, she, or they may respectively be liable by law to be apprehended, imprisoned, or detained; such persons so offending, their counsellors, aiders, and abettors, knowing of or privy to such offence, shall be felons, and suffer death without benefit of clergy. Provided, that if it appear on the trial, that such acts of stabbing or cutting were committed under such circumstances as that, if death had ensued therefrom, the same would not have amounted to murder, in such cases, the person or persons so indicted shall be deemed not guilty of the felonies whereof they shall be so indicted, but be thereof acquitted. § 1.

If the maim come not within any of the descriptions in either of these acts, yet it is indictable at the common law, and may be punished by fine and imprisonment; or an appeal may be brought for it at the common law; in which the party injured shall recover his damages; or he may bring an action of trespass; which kind of action hath now generally succeeded to the place of appeals in smaller offences not capital. 2 Hawk. c. 23.

Malicious maiming of cattle in the night time incurs a forfeiture of treble damages, by action of trespass, or upon the case, 22 & 23 Car. II. c. 7.

MAHEM, *Appeal of*. See APPEAL.

MAHLBERG, in *Geography*, a town of Baden, with an annexed lordship; 16 miles S.S.E. of Strasburg. N. lat. 48° 19'. E. long. 7° 15'.

MAHLENDORF, a town of Silesia, in the province of Neisse; 9 miles N.W. of Neisse.

MAHMOODABAD, an ancient town of Hindoostan, formerly the capital of Guzerat, and founded by sultan Mahmood, in the 11th century. The Ayin Acbaree describes the walls of it, as including a vast extent of ground, and speaks of it, in the latter part of the 16th century, rather as an existing city, than as a place in ruins; 17 miles S.S.E. of Amedabad. N. lat. 22° 47'. E. long. 72° 52'.

MAHMORA, or MAMORA, a sea-port town of Fez, situated near the mouth of the river Seboo, which falls into the Atlantic. The fort of Mamora, which is to the south of the Seboo, is the first inhabited place in the province of Beni-hassen. It was begun by the Portuguese in 1515, and destroyed in the same year by the Moors. It was rebuilt in 1604 by the Spaniards, from whom it was taken by Muly Ishmael in 1681. This fortress, which was originally built at the mouth of the river Seboo, is now two miles distant from it, in consequence of the drifted sand-banks and bars, which have rendered the entrance of this river so difficult and dangerous, as to be no longer of any use to commerce or navigation. At this fort there are about 35 or 40 families, which gain a wretched subsistence by the profits of their ferry, and fishing for shads, of which they take such numbers as to be able to supply the whole neighbouring country between November and the end of March. Mamora is distant about five leagues N.N.E. from Sallee, and about twenty leagues by land S. of Laracha. Between these two last places the country is variegated by lakes, forests, and vallies, which were formerly tolerably populous. Some of the lakes are nearly eight leagues in extent, and supply great numbers of ducks and water-fowls, and also of eels. The boats used by the fishermen are a kind of skiffs, made of reeds and rushes, about six feet long, and two broad, and will scarcely hold a single person. The fisherman guides them with a pole, and pierces the eels when he has them on the water, with a sort of dart. On the banks of these lakes are several sanctuaries of the Maraboots, who are held in great veneration for their supposed holiness, and a number of camps of the Moors, who cultivate the adjacent lands, which are but moderately productive. This valley is very pleasant in winter and spring, but in summer it is parched and disagreeable. At the southern extremity is a sanctuary, on an eminence, appertaining to which are habitations and gardens. N. lat. 34° 25'. W. long. 6° 25'.

MAHMOUD, in *Biography*, first sultan of the Gaznevide dynasty, and a great conqueror, was son of the governor of Chorasan, and sovereign of Gazna. He was sixteen years of age when his father died in 997, and soon displayed a vigour of mind which announced his future greatness. Having secured himself upon the throne of Gazna, he marched to Chorasan, which had been seized by the king of Turkestan, drove him out, and took possession of the province. In 1001, this heroic prince carried his arms into Hindoostan, and captured Gebal, a powerful prince in that country, who, in consequence, resigned his crown to his son, and threw himself into the flames. In the following year, Mahmoud reduced Khalif, the revolted governor of Segestan, and assumed the title of sultan. He repeated his invasion of India, but was soon recalled by the irruption of Ilek Khan, king of Turkestan, into Chorasan. Ilek was soon expelled; but he called to his assistance Kader Khan, who joined him with 50,000 horse. This combined and very powerful army advanced to the city of Balk, where they were met by Mahmoud,

Mahmoud, when a battle enfued, which was fought with great obftinacy, but Mahmoud was victorious, and the greateft part of the Turkifh army perifhed on the field. Mahmoud now extended his conquefts far and wide, and acquired immenfe treafures. The emperor of Hindooftan, who had till now affumed the title of king of kings, dreading his arms, fent to demand peace from him, which was granted, on the condition of the payment of a large tribute. In 1029, he added to his other extenfive dominions the great province of Perfian Irak, and fettled his fon Maffoud, whom he deftined for his fucceffor. He died in 1030, after a profperous reign of thirty-one years. This great conqueror, who ftripped fo many neighbouring fovereigns of their territories, is extolled by Mahometan writers for his regard to juftice, and for his zeal in the propagation of his religion, which he fpread in India by the extermination of a vaft number of idolaters, and the demolition of their temples. Several anecdotes are given of him which do honour to his forbearance, and his regard to juftice. In one inftance a widow preferred a complaint againft fome perfons who had murdered her fon; the fultan replied, that the great diftance of Irak from Gazna rendered it very difficult for him to prevent fuch diforders: "Why then," faid the difconfolate woman, "do you conquer more territory than you can govern, and of which you can render no account at the day of judgment." The reproof awakened fuch impreffions in the mind of the monarch, that he caufed it to be proclaimed throughout Irak, that he would be refponfible for the lives and properties of all who fhould, in future, travel thence to India in caravans. MAHOMET, or Mohammed, in *Biography*, the founder of that fyftem of religious impofture which is called *Mahometanifm* (which fee), defcended from the tribe of Koreifh, and the family of Hafhem, the moft illuftrious of the Arabs, the princes of Mecca, and the hereditary guardians of the Caaba: he was the grandfon of *Abdalmotalleb* (which fee), and the only fon of *Abdallah* (which fee), and Amina; and he was born at Mecca, four months after the death of Juftinian, and two months after the defeat of the Abyffinians, whofe victory would have introduced into the Caaba the religion of the Chriftians, in the year 569 of the Chriftian era. As he was deprived of his grandfather, father, and mother in his infancy, and his inheritance confifted only of five camels and one Ethiopian female flave, the care and conduct of his youth devolved upon Abu Taleb, the moft refpectable of his uncles, by whom he was initiated in the occupation of a merchant, and with this view he was taken with him into Syria at the age of thirteen years. In his 25th year he was recommended to Khadijah, a noble and rich widow, as her factor, who foon rewarded his fidelity with the gift of her hand and fortune, and thus raifed him to an equality with the richeft perfons in Mecca. In his marriage contract he is defcribed as the moft accomplifhed of the tribe of Koreifh, and his dowry is ftipulated at twelve ounces of gold and twenty camels, which was fupplied by the liberality of his uncle. In confequence of this connection, he was reftored to the ftation of his anceftors; and he paffed many years in the habits of domeftic life, until at length, in the 40th year of his age, he affumed the title of a prophet, and proclaimed the religion of the Koran. According to the tradition of his companions, Mahomet was diftinguifhed by the graces of his perfon and manners, fo that before he fpoke he engaged in attachment and intereft the affections of a public or private audience. His attendants applauded his commanding prefence, his majeftic afpect, his piercing eye, his gracious fmile, his flowing beard, his countenance that painted every fenfation of the foul, and each gefture that enforced every expreffion of his tongue. In the intercourfe of private life he blended, with refpectful attention to the affluent and powerful, condefcenfion and affability to the pooreft citizens of Mecca; the franknefs of his manner concealed the artifice of his views; and the habits of courtefy were imputed to perfonal friendfhip or perfonal benevolence. His memory was capacious and retentive; his wit eafy and focial; his imagination fublime; his judgment clear, rapid, and decifive. He poffeffed, fays one of his biographers, the courage both of thought and action; and although his defigns might probably expand with his fuccefs, the firft idea which he entertained of his divine miffion bears the ftamp of an original and fuperior genius. Educated amidft the nobleft race, he acquired a fluency of fpeech in the pureft dialect of Arabia; and he had the art, on proper occafions, of obferving a difcreet filence. Notwithftanding all thefe accomplifhments, he was an illiterate barbarian; infomuch that his youth had never been inftructed in the arts of reading and writing. Some, indeed, have queftioned this fact, among whom we may reckon Mr. White (fee his Sermons, p. 203, 204.); but his incredulity, founded more on conjecture and reafoning, than authentic teftimony, is contradicted by numerous and unexceptionable authorities. Availing himfelf of the character of the age in which he lived, and of the circumftances of the people among whom his lot was caft, his fagacity led him to improve even his want of literature as a means of more fuccefsfully gaining profelytes and propagating his impofture. In his two journies to Syria, he reftricted his attention to commercial tranfactions at the fairs of Boftra and Damafcus; and at the early age in which he made thefe journies, he could derive no great advantage with regard to the purpofes of his pretended miffion from fuch hafty and fuperficial excurfions: nor could he have indulged his curiofity to any confiderable degree on account of his ignorance of the Syriac language. Whatever knowledge he acquired muft have been the refult of his intercourfe with thofe pilgrims who annually reforted to Mecca from various regions, with views of devotion, or of commerce; and from this fource he derived that acquaintance with the political ftate and character of the feveral Arabian tribes, as well as the theology and ceremonial inftitutions of Jews and Chriftians. Befides, from his earlieft youth, Mahomet was addicted to religious contemplation; and he was accuftomed, during the month of Ramadan, to retire from the world to the cave of Hera, about three miles from Mecca, where he probably formed his fyftem of impofture; or, as Mr. Gibbon expreffes it, where he confulted the fpirit of fraud or enthufiafm, whofe abode is not in the heavens, but in the mind of the prophet. The faith, as the hiftorian adds, which, under the name of

 "Iflam,"

"Islam," he preached to his family and nation, is compounded of an eternal truth, and a necessary fiction, "That there is only one God, and that Mahomet is the apostle of God." It is impossible, at this distance of time, and amongst the variety of opinions that have been held on the subject, to determine with certainty at what period of his life the idea of framing a new system of religion occurred to his mind; nor can it be ascertained by what kind of reflection he was led among idolaters to form his idea of the unity of God, nor to what degree he blended the ambition of personal grandeur with that of the prophetic character. History furnishes examples of persons whose conviction of truth and ardour in the prosecution and dissemination of it have terminated in the licentiousness of enthusiasm, the rage of conquest, and the violence of tyranny. Perhaps this might, in a degree, have been the case with Mahomet; and he might have proceeded from the honesty of enthusiasm to the extreme of imposture and despotism, and with a view of extending the influence of his system, he might find it necessary or expedient to accommodate it to the passions and prejudices of his countrymen, to enforce it by the terrors of the sword, and to unite the character of a conqueror with that of an impostor. It was, however, in the year 609, and about the 40th year of his age, called "the year of his mission," that he opened his pretended mission. His first convert was his wife Khadijah, to whom he communicated an interview, with which he had been favoured by the angel Gabriel, who had told him, that he was appointed the apostle of God; and to whom he also repeated a passage, which he pretended to have had revealed to him by the ministry of the angel, together with some other circumstances of this first appearance, which are related by Mahometan writers. Khadijah received the news with great joy, and hastened to impart it to her cousin Warahah, who, being a Christian, was well acquainted with the Scriptures, and who immediately became a proselyte. Cautious in announcing to the public the high and honourable office with which he was entrusted, he determined to strengthen his interest by the conversion of the other branches of his family. His next proselyte was Zeid, a confidential servant, to whom on this occasion he gave his freedom; and this circumstance established a precedent for his followers. The conversion of Zeid was succeeded by that of his cousin Ali, the son of Abu Taleb, who has been commonly styled, probably on account of his rank and zeal in the cause, "the first of believers." But the principal accession to his cause, with regard to respectability and influence, was that of Abubeker, a person of great authority in the tribe of Koreish, who prevailed on ten other principal inhabitants of Mecca to follow his example. During three years Mahomet proceeded without exciting public attention: but in the fourth year of his mission, he openly assumed the prophetic office, and announced his having received a divine appointment for the illumination and conversion of his near relations. With this view he directed Ali to prepare an entertainment, and to invite the sons and descendants of Abdalmotalleb to a participation of it. When about 40 of the race of Hashem were assembled, Mahomet addressed them with the offer of happiness both in this life and in that which is to come, for which he pleaded a divine authority and command: and he then asked them who would be his companion and vizir? Whilst a general silence prevailed, Ali exclaimed, "O Prophet, I am the man: I will be thy vizir; and I will inflict vengeance on those who oppose thee!" Upon this declaration of attachment and furious zeal in his service, Mahomet commanded all that were present to obey Ali as his deputy: the company, however, treated the order with contempt, and ironically exhorted Abu Taleb to respect the superior dignity of his son. In a more serious tone, the father of Ali advised him to abandon his impracticable, romantic, and dangerous design. Mahomet, however, was not intimidated, but resolutely told his uncle, "that if they set the sun against him on his right hand, and the moon on his left, he would not relinquish his enterprise." When Abu Taleb perceived that he was determined to proceed, he used no further arguments to dissuade him, but promised to stand by him against all his enemies. The Koreish, finding that reasoning and intreaty were ineffectual, had recourse to threats and violence; so that the followers of Mahomet could not continue any longer at Mecca with safety; upon which Mahomet, unable to protect them, gave them leave to depart and seek refuge wherever they could find it. Accordingly, in the fifth year of the prophet's mission, sixteen, of whom four were women, fled into Ethiopia; and these were afterwards followed by others, amounting to the number of 83 men and 18 women, besides children. The king of Ethiopia received them with kindness, and refused to deliver them up when the Koreish sent to demand them; and, as the Arab writers unanimously attest, became himself a proselyte to the Mahometan religion. Persecution, instead of retarding, accelerated the progress of this imposture. In the seventh year of the mission of the pretended prophet, his friends had become more numerous and powerful, by the conversion of his uncle Hamza, and of the inflexible Omar, who had been once his most violent opposer; and the Koreish having formed a league against the Hashemites occasioned a division of their tribe into two factions; one of which adhered to the prophet and the other combined against him. For three years this variance continued, but in the tenth year of his mission, Mahomet told his uncle Abu Taleb, that God had signally manifested his disapprobation of the league, which the Koreish had formed against them, by sending a worm to eat every word of the instrument, except the name of God. When a deputation had examined the league, that had been laid up in the Caaba, and found that Mahomet's declaration was true, it was declared void. In this year Mahomet lost two very important and useful friends, *viz.* his wife Khadijah, and his uncle Abu Taleb; and for this reason this year was called "the year of mourning." Upon the death of these two persons the Koreishites became more violent than ever, and determined on the death of the prophet; but being warned of their purpose by an angel or spy, he retired hastily, and in the dead of the night, with his friend Abubeker, to the distance of a league from Mecca, where he concealed himself for three days in the cave of Thor, and where he and his friend received a supply of food and of intelligence from the son and daughter of Abubeker. The Koreish made diligent search for the fugitives, but being at the entrance of the cavern in which they were hidden, their attention was diverted, as it is said, by a spider's web, and a pigeon's nest, which led them to imagine that the place was solitary and inviolate. "We are only two," said the trembling Abubeker: "there is a third," replied the prophet, "it is God himself." As soon as they had opportunity for escape, they mounted their camels; but on the road to Medina, they were overtaken by the emissaries of the Koreish, from whose hands they rescued themselves by the influence of prayers and promises. The flight of the prophet from Mecca to Medina has fixed the memorable era of the *Hegira*, which see. At Medina the two fugitives found an asylum. Some of the noblest citizens had previously, in a pilgrimage to the Caaba at Mecca, been converted by the preaching of Mahomet, and on their return they had diffused the belief of God and his prophet; and the new alliance was ratified by their depu-

ties

ties in two fecret and nocturnal interviews on a hill called Al Akaba, in the fuburbs of Mecca, when they protefted in the name of their wives, children, and abfent brethren, that they would for ever profefs the creed, and obferve the precepts of the Koran. The fecond was a political affociation, the firft vital fpark, fays Gibbon, of the empire of the Saracens. Seventy-three men and two women of Medina held a folemn conference with Mahomet, his kinfmen, and difciples, in the thirteenth year of his miffion, and pledged themfelves to each other by an oath of mutual fidelity. After reciprocal engagements to each other, they reiterated the oath of allegiance and fidelity, and their treaty was ratified by the people, who unanimoufly embraced the profeffion of Iflam. Such were their circumftances, when they impatiently expected the arrival of the prophet, at the fame time trembling for his fafety. After a perilous and rapid journey along the fea-coaft, he halted at Koba, two miles from the city, and made his public entry into Medina, 16 days after his flight from Mecca. He was met by 500 of the citizens, and received with acclamations of loyalty and devotion. His braveft difciples affembled round his perfon; and his followers were diftinguifhed into two claffes, the fugitives of Mecca and the auxiliaries of Medina, under the denominations of "Mohagerians" and "Anfars." When Mahomet was eftablifhed at Medina, he affumed the exercife of the regal and facerdotal office; and having acquired either by gift or purchafe a piece of ground, he built upon it a temple of worfhip, and a refidence for himfelf. After a reign of fix years, 1500 Moflems, in arms and in the field, renewed their oath of allegiance; and their chief repeated the affurance of protection till the death of the laft member; or the final diffolution of the party. Being now exalted by the choice of an independent people to the rank of a fovereign, he was invefted with the prerogative of forming alliances and of waging offenfive or defenfive war, and accordingly affumed a fiercer and more fanguinary tone, than he had been accuftomed to ufe, when his moderation was the effect of his weaknefs. In announcing his revelations, he pretended to have received commands for propagating his religion by the fword, for deftroying the monuments of idolatry, and with regard to the fanctity of days or months, for purfuing the unbelieving nations of the earth. In the firft months of his reign, he trained his followers for the warfare to which he intended to conduct them, and difplayed his white banner before the walls of Medina, but in the progrefs of his undertaking he fought in perfon at nine battles or fieges; and fifty military enterprifes were achieved in ten years by himfelf or his lieutenants. Uniting the profeffions of a merchant and robber, his petty excurfions for the attack of a caravan, gradually prepared his troops for the conqueft of Arabia. The diftribution of the fpoil was regulated, as he pretended, by a divine law; a fifth of the gold and filver, the prifoners, and the cattle, the moveables and immoveables, was referved by the prophet for pious and charitable ufes: the remainder was fhared in adequate portions by the foldiers who had obtained the victory or guarded the camp; the recompence of the flain devolved to their widows and orphans; and the increafe of cavalry was encouraged by the allotment of a double fhare to the horfe and the man. From all fides, fays the hiftorian, the roving Arabs were allured to the ftandard of religion and plunder; the prophet indulged the difpofition of his countrymen by fanctifying the licence of embracing the female captives as their wives or concubines; and the enjoyment of wealth and beauty was a feeble type of the joys of paradife prepared for the valiant martyrs of the faith. "The fword," fays Mahomet, "is the key of heaven and of hell; a drop of blood fhed in the caufe of God, a night fpent in arms, is of more avail than two months of fafting or prayer; whoever falls in battle, his fins are forgiven: at the day of judgment, his wounds fhall be refplendent as vermilion, and odoriferous as mufk; and the lofs of his limbs fhall be fupplied by the wings of angels and cherubim." By fuch declarations and profpects, the intrepid fouls of the Arabs were fired with enthufiafm; the picture of the invifible world was ftrongly painted on their imagination; and the death which they had always defpifed, became an object of hope and defire. The prophet, with a fagacity which diftinguifhed every part of his project, inculcated in the Koran the tenets of fate and predeftination, which have ferved in every age to exalt the courage of the Saracens and Turks. The firft companions of Mahomet advanced to battle with a fearlefs confidence; where there is no chance, there is no danger: they were ordained to perifh in their beds, or they were fafe and invulnerable amidft the darts of the enemy.

The firft military expedition of any importance, and which in the event ferved to eftablifh the reputation of the prophet, was directed againft the Koreifh. This was the battle of Beder, which was fought in the fecond year of the Hegira; for an account of which, fee BEDR. This was followed by a fecond battle, A. D. 623, on mount Ohud, fix miles to the north of Medina. On this occafion the Koreifh muftered a force of 3000 men, 700 of whom were armed with cuiraffes, and 200 mounted on horfeback. Three thoufand camels attended their march; and Henda, the wife of Abu Sophian, the chief of the branch of Ommiyah, who had fucceeded to the principality of the republic of Mecca, with 15 matrons of this city, inceffantly founded their timbrels to animate the troops, and to magnify the greatnefs of Hobal, the moft popular deity of Caaba. The ftandard of God and Mahomet was upheld by only 950 believers. The Koreifh advanced in the form of a crefcent, and the right wing of the cavalry was led by Caled, the fierceft and the moft fuccefsful of the Arabian warriors. The troops of Mahomet were fkilfully pofted on the declivity of a hill; and their rear was guarded by a detachment of 50 archers. The conteft was vigoroufly maintained on both fides: it was fevere and fanguinary; Mahomet was wounded, and 70 martyrs, as they were called, are faid to have died for the fins of the people. Their bodies were mangled by the inhuman females of Mecca; and the wife of Abu Sophian tafted the entrails of Hamza, the uncle of Mahomet. The Muffulmans rallied in the field; and the Koreifh wanted ftrength and courage to undertake the fiege of Medina. In the year 625 the city was attacked by an army of 10,000 enemies; and this third expedition is named from the "nations" which marched under the banner of Abu Sophian, and from the "ditch" which was drawn before the city and a camp of 3000 Muffulmans, the battle of the "Nations" or "Ditch." Mahomet prudently declined a general engagement; and though the conteft was protracted for 20 days, the confederates were at length obliged to feparate. A tempeft of wind, rain, and hail, overturned their tents; private quarrels were fomented by an infidious adverfary; and the Koreifh, deferted by their allies, no longer hoped to fubvert the throne, or to check the conquefts, of their invincible exile. As foon as the "nations" had retired from the "ditch," Mahomet, without laying afide his armour, marched againft the Jewifh tribe of Koraidha, who had incurred his refentment by exciting and joining the war of the Koreifh; and after a refiftance of 25 days, they furrendered at difcretion. It was in vain that they appealed to the judgment of a venerable elder; he pronounced the fentence of their death; 700 of them were dragged in chains to the market place of the city; and hav-

ing

ing been compelled to defcend alive into the grave prepared for their execution and burial, the prophet beheld the favage fcene without emotion. Plunder and cruelty marked his future footfteps; and the town of Chaibar, which was the feat of the Jewifh power in Arabia, and its numerous caftles, were fpeedily reduced. It is fomewhat fingular, that a hatred of the Jews, to whofe Scriptures he was indebted for the beft parts of his religion, formed fo diftinguifhing a feature in the character of the Arabian prophet. Under the fubfequent reign of Omar, the Jews of Chaibar were tranfplanted to Syria; and the caliph alleged the injunction of his dying mafter, that one and the true religion fhould be profeffed in his native land of Arabia. Such was the fpirit of perfecution and intolerance which actuated this impoftor. In the year 629 Mahomet directed his march, accompanied by 1400 men, towards Mecca: his views were peaceable; 70 camels, chofen and bedecked for facrifice, preceded the van; the facred territory was refpected, and the captives were difmiffed, without ranfom, to proclaim his clemency and devotion. But on his approach to the city, the Koreifh oppofed his progrefs, and he determined to attack it; but on their fuing for peace, he concluded with them and with their allies a truce of 10 years, engaging to reftore the fugitives of Mecca who fhould embrace his religion, and ftipulating merely, for the enfuing year, the privilege of entering the city as a friend, and of remaining three days to accomplifh the rites of the pilgrimage. After the cuftomary facrifice, Mahomet evacuated the city on the fourth day. The people were edified by the devotion of the prophet, who on this occafion acted the part of a crafty politician; the hoftile chiefs were awed, or divided, or fubdued; and both Caled and Amrou, the future conquerors of Syria and Egypt, moft feafonably deferted the finking caufe of idolatry. The Arabian tribes fubmitted and thus increafed the power of Mahomet; 10,000 foldiers affembled for the conqueft of Mecca, and the idolaters, being the weaker party, were eafily convicted of violating the truce. The fecret was preferved till 10,000 fires proclaimed to the aftonifhed Koreifh the defign, the approach, and the irrefiftible force of the enemy. The haughty Abu Sophian prefented the keys of the city, obferved that the fon of Abdallah had acquired a mighty kingdom, and confeffed, under the fcymetar of Omar, that he was the apoftle of the true God. Mahomet, inftead of indulging his own paffion of revenge or that of his followers, forgave the guilt, and united the factions of Mecca. His troops, in three divifions, marched into the city and took poffeffion of it; the chiefs of the Koreifh fell proftrate at his feet; the people of Mecca merited their pardon by the profeffion of Iflam, and after an exile of feven years, the fugitive miffionary was enthroned as the prince and prophet of his native country. But the 360 idols of the Caaba were ignominioufly demolifhed: the houfe of God was purified and adorned; and a perpetual law was enacted, that no unbeliever fhould dare to fet his foot on the territory of the holy city. The conqueft of Mecca determined the faith and obedience of the Arabian tribes; but an obftinate remnant ftill adhered to the religion and liberty of their anceftors; and the war of Honain derived its appellation from the "idols," whom Mahomet had vowed to deftroy, and whom the confederates of Tayef had fworn to defend. Four thoufand pagans advanced with fecrecy and fpeed to furprife the conqueror; the banners of Mecca and Medina were difplayed by the prophet; and 12,000 Muffulmen entertained a rafh and finful prefumption of their invincible ftrength. They defcended without precaution into the valley of Honain; but their number was oppreffed by the archers and flingers of the confederates who had occupied the heights, their difcipline was confounded, their courage was appalled, and the Koreifh anticipated with fatisfaction their impending deftruction. The prophet, on his white mule, was encompaffed by the enemies; of ten faithful companions, who attempted to ward off from him the fpears of the affailants, three fell dead at his feet; and in this moment of danger, he called on his brethren and on the Almighty for fuccour, whilft his uncle Abbas joined in the acclamations of his followers. At length the fugitive Muffulmen rallied; the battle was renewed by the exhortation and example of the prophet; and he animated his victorious troops to inflict a mercilefs revenge on the authors of their difgrace. From the field of Honain he haftened to the fiege of Tayef, 60 miles S E. of Mecca; but after an ineffectual attack of 20 days, he was obliged to retreat. The fpoil of this expedition amounted to 6000 captives, 24,000 camels, 40,000 fheep, and 4000 ounces of filver. Inftead of chaftifing the difaffection of the Koreifh, he endeavoured to fecure their attachment by extraordinary liberality; Abu Sophian was prefented with 300 camels and 20 ounces of filver; and Mecca was fincerely converted to the profitable religion of the Koran. The temples and idols of Arabia were every where demolifhed, and the ambaffadors who proftrated themfelves before the throne of Medina were as numerous, according to an Arabian proverb, as the dates that fall from the maturity of a palm-tree. Hence this year was called "the year of embaffies." The nation fubmitted to the God and the fceptre of Mahomet; and 114,000 Moflems accompanied the laft pilgrimage of the apoftle. On this occafion he took with him all his wives, with a great number of camels intended for victims; and the ceremonial which he obferved at the facred city has ferved as a model to the Moflems of fucceeding ages.

It was in the 7th year of the Hegira that Mahomet began to think of propagating his religion beyond the boundaries of Arabia, and deputed meffengers to invite the neighbouring princes to embrace Mahometanifm. The Perfians with their fovereign after fome hefitation avowed themfelves profelytes. The emperor Heraclius at firft treated his meffage with refpect; and fome have faid, that he would have profeffed the new faith, if he had not been afraid of lofing his crown. Mahomet prepared for effecting by conqueft what he had failed to accomplifh by a peaceful meffage; but he was obliged to defift from the undertaking, as too hazardous, and indeed impracticable. The firft conflict between the troops of Mahomet and the emperor Heraclius took place in the eighth year of the Hegira. A body under the command of Zeid advanced to the attack of Muta, a town of Paleftine, the governor of which had affaffinated one of the Moflem envoy. In the fharp conflict that enfued, Zeid with the two next in command was flain, and the death of Zeid was much lamented by Mahomet, his mafter and friend. However, the active and intrepid Caled, denominated "the Sword of God" fpread around the terror of his name: and the prophet received the fubmiffion of the tribes and cities from the Euphrates to Ailah, at the head of the Red fea. Mahomet, in the confidence of his power, had declared war againft Heraclius; and with an army of 20,000 foot and 10,000 horfe, he marched towards the Syrian frontier, and his unwilling followers fuffered extremely from the heat of the fummer and the drought of the defert. At Tabuc, a fertile fpot in the midway between Medina and Damafcus, they pitched their camp. The confequence of this toilfome expedition was the fubmiffion of fome Arabian princes, who became tributaries; but as the Imperialifts had retired to a diftance, without appearing to have any defign of making an attack upon Arabia, Mahomet fatisfied himfelf by writing a letter to Heraclius urging his converſion, and then returned back to Medina. After his return he promulgated a new chapter of the Koran, revoking all former edicts in favour of the idolaters, and annulling all treaties that had been made with them. To his Chriſtian ſubjects, Mahomet readily granted the ſecurity of their perſons, the freedom of their trade, the property of their goods, and the toleration of their worſhip. In this reſpect he purſued a conduct highly political, as it was the intereſt of a conqueror to propoſe a fair capitulation to the moſt powerful religion of the earth: and the ſame wiſe policy has ever ſince accompanied the Mahometan juriſdiction. Till the age of 63 years, Mahomet retained a vigour of conſtitution which enabled him to endure the corporeal and ſpiritual fatigues of his miſſion. The laſt conſpicuous act of his life was his pilgrimage to Mecca, already mentioned. His health had been declining for four years previous to his death; and he aſcribed this change not to the acceſs of epileptic fits which ſome writers have erroneouſly reported to have been the remote cauſe of his growing infirmities, but to poiſon adminiſtered to him at Chaibar by a Jewiſh female, from a motive of revenge, as ſome have ſaid, or according to others, from a deſire of putting his prophetic character to the teſt. However this be, his mortal diſeaſe was a fever of fourteen days, which at intervals deprived him of the uſe of his reaſon. During the intermiſſions of his diſorder he employed himſelf in haranguing his diſciples from the pulpit, and performing other religious duties of his function, and in giving inſtructions with regard to the meaſures that were fit to be purſued after his deceaſe. He beheld, it is ſaid, with firmneſs the approach of death, ſatisfied the demands of his creditors, enfranchiſed his ſlaves, directed the order of his funeral, moderated the grief of his weeping friends, on whom he beſtowed the benediction of peace, and regularly performed the exerciſe of public prayer till the third day before his diſſolution; from all which circumſtances it has been inferred, that he really believed the truth of his miſſion, and that he derived conſolation from the conſciouſneſs of having conferred great benefits on mankind. This may be eaſily accounted for by the conſideration that enthuſiaſm was blended in a very conſiderable degree with his impoſture. The choice of Abubeker to ſupply his place indicated his reſpect for this ancient and faithful friend, as he ſeems to have thought him a fit ſucceſſor in the ſacerdotal and regal office. When his faculties were perceptibly impaired he wiſhed to dictate a divine book, which ſhould contain the form and ſubſtance of all his revelations; but a diſpute ariſing in his chamber, whether he ſhould be allowed to ſuperſede the authority of the Koran, he was under a neceſſity of reproving the indecent vehemence of his diſciples. If any credit may be given to the traditions of his wives and companions, he maintained to the laſt moments of his life and in confidential intercourſe with his family, the dignity of an apoſtle and the faith of an enthuſiaſt; deſcribing the viſits of Gabriel, and expreſſing his lively confidence, not only in the mercy, but the favour, of the Supreme Being. In a familiar diſcourſe he had mentioned his ſpecial prerogative, That the angel of death was not allowed to take his ſoul till he had reſpectfully aſked the permiſſion of the prophet. The requeſt being granted, Mahomet fell into the agony of diſſolution, and expired in the arms or on a carpet near the feet of his favourite wife Ayeſha, the daughter of Abubeker, in the month of June, A.D. 632, Hegira 11, at the age of 63. Some of his followers would not for a time believe the reality or poſſibility of his death, till Abubeker calmly reaſoned them out of their deluſion. He was interred at Medina, in a grave dug beneath the bed on which he lay in the apartment of Ayeſha, over which a magnificent building was erected by one of the ſucceeding caliphs. It is hardly neceſſary to mention, unleſs with a view of expoſing it, the vulgar and ridiculous ſtory invented and propagated by the Greeks and Latins, that Mahomet's tomb is ſuſpended in the air at Mecca, by the action of equal and potent load-ſtones: for he was not buried at Mecca, and his tomb at Medina, which has been viſited by millions, is placed on the ground. The number of his wives, all of whom except Ayeſha were widows, was at leaſt fifteen: by Khadijah he had four children, one of whom, Fatima, the beſt beloved of his daughters, and married to Ali, ſurvived him; and he had alſo a ſon, by his Egyptian concubine, Mary, whoſe name was Ibrahim, and who died not long before him. However Mahomet might reſtrict the incontinence of his diſciples by the precepts of his religion, he claimed a ſpecial exemption for himſelf, and pretended a ſpecial revelation which diſpenſed with his obſervance of the laws which he impoſed upon his nation. During the life of Khadijah, who laid the foundation of his future fortune, and in the courſe of 24 years, he ſeems to have reſtrained his ruling paſſion within due bounds; but as he advanced in years and authority, this paſſion gained ſtrength, and he made his religion ſubſervient to the illicit indulgence of it. Beſides his numerous wives, he allowed himſelf in a variety of amours, which were prohibited by his own laws. His connection with Zeinab, the wife of his enfranchiſed ſervant and adopted ſon, Zeid, gave great offence to ſome of his friends. Zeid, in order to gratify his maſter, conſented to her being divorced; and the prophet, whoſe religion was eaſily accommodated to his paſſions and intereſt, feigned a revelation from heaven, recorded in a chapter of the Koran, which authoriſed him to marry her, notwithſtanding a degree of affinity that had been always regarded by the Arabs as an abſolute prohibition. Hafna, the daughter of Omar, who was one of his wives, diſcovered him in an improper ſituation with Mary, an Egyptian captive; but in order to ſilence her reproaches, he promiſed never to repeat the offence. Finding, however, that the circumſtance was divulged to his other wives, and that they concurred in reſenting it, he withdrew from them all for a month, and ſpent the time in company with Mary; and in order to juſtify his infidelity and violation of an oath, he recurred to his uſual practice of producing a new chapter of the Koran, containing a ſpecial diſpenſation. We may indeed be aſtoniſhed that ſucceſſive forgeries of this kind, intended to anſwer purpoſes of perſonal and licentious gratification, ſhould not have excited a prejudice in the minds of his followers and of his countrymen in general, which would have defeated all his efforts for propagating his impoſture. But we ſhould recollect the diſpoſition and character of the Arabs, whoſe libidinous complexion has been noticed by the writers of antiquity. (Ammian Marcell. l. xiv. c. 4.) Much has been ſaid by Mahometan writers in praiſe of the corporeal and mental endowments of the Arabian prophet; and though we cannot allow the very extraordinary qualities which have been aſcribed to him, it muſt be acknowledged that he poſſeſſed various accompliſhments, ſome of which have already been noticed, and a verſatility of talents and character, that ſerved to raiſe him above his contemporaries, and to qualify him for the undertaking in which he embarked. "Could I truly delineate," ſays Gibbon, "the portrait of an hero, the fleeting reſemblance would not equally apply to the ſolitary of mount Hera, to the preacher of Mecca, and to the conqueror of Arabia. The author of a mighty revolution appears to have been endowed with a pious and contemplative diſpoſition: ſo ſoon as marriage

had

had raifed him above the preffure of want, he avoided the paths of ambition and avarice; and till the age of 40, he lived with innocence, and would have died without a name. The unity of God is an idea moft congenial to nature and reafon; and a flight converfation with the Jews and Chriftians would teach him to defpife and deteft the idolatry of Mecca." Indeed, for every thing that is valuable in his religious fyftem he was indebted to Judaifm and Chriftianity: but his rude and barbarous civil policy, being rendered immutable by its alliance with religion, an alliance that is incongruous and unnatural, has prevented every kind of melioration and improvemement in thofe countries where his laws are received. "It was the duty of a man and a citizen to refcue his country from fin and error. The energy of a mind inceffantly bent on the fame object would convert a general obligation into a particular call; the warm fuggeftions of the underftanding or the fancy would be felt as the infpirations of heaven; the labour of thought would expire in rapture and vifion; and the inward fenfation, the invifible monitor, would be defcribed with the form and attributes of an angel of God. From enthufiafm to impofture the ftep is perilous and flippery: the dæmon of Socrates (fee DÆMON) affords a memorable inftance how a wife man may deceive himfelf, how a good man may deceive others, how the confcience may flumber in a mixed and middle ftate between felf-illufion and voluntary fraud. Charity may believe that the original motions of Mahomet were thofe of pure and genuine benevolence; but a human miffionary is incapable of cherifhing the obftinate unbelievers who reject his claims, defpife his arguments, and perfecute his life;"—hence "the paffions of pride and revenge were kindled in the bofom of Mahomet."—"The injuftice of Mecca, and the choice of Medina, transformed the citizen into a prince, the humble preacher into the leader of armies."—"In the exercife of political government, he was compelled to abate of the ftern rigour of fanaticifm, to comply in fome meafure with the prejudices and paffions of his followers, and to employ even the vices of mankind as the inftruments of their falvation: the ufe of fraud and perfidy, of cruelty and injuftice, was often fubfervient to the propagation of the faith; and Mahomet commanded and approved the affaffination of the Jews and idolaters, who had efcaped from the field of battle. By the repetition of fuch acts, the character of Mahomet muft have been gradually ftained; and the influence of fuch pernicious habits would be poorly compenfated by the practice of the perfonal and focial virtues which are neceffary to maintain the reputation of a prophet among his fectaries and friends. Of his laft years, ambition was the ruling paffion; and a politician will fufpect, that he fecretly fmiled (the victorious impoftor!) at the enthufiafm of his youth and the credulity of his profelytes." Mahomet, in his private and domeftic life, feems to have defpifed the pomp of royalty, and to have fubmitted to the menial offices of the family. The interdiction of wine was confirmed by his example, and his ordinary food confifted of barley-bread, milk and honey, dates and water. Although he indulged himfelf in fenfual gratifications, the incontinence of his countrymen was regulated by the civil and religious laws of the Koran: their inceftuous alliances were blamed; the boundlefs licence of polygamy was reduced to four legitimate wives or concubines; their rights both of bed and of dowry were equitably determined; the freedom of divorce was difcouraged; adultery was condemned as a capital offence; and fornication, in either fex, was punifhed with an hundred ftripes.

It is a natural inquiry how Mahomet, without literature, without pretending to the power of working miracles, and without a character that entitled him to veneration among perfons who made any pretence to religion and virtue, fecured the fuccefs of a fyftem of doctrine and practice, which muft have appeared to all but his prejudiced followers to have originated in enthufiafm and impofture?—a fyftem which reftricted the boundlefs licence of Arabian idolatry; which impofed obligations of prayer, purification, and almsgiving, that were burthenfome; and which undermined the intereft and influence of fome of the moft powerful and affluent of his countrymen? The bafis of his doctrine, we have already faid, was the truth of the unity and fpiritual nature of the deity: this truth muft have approved itfelf to the minds of the thoughtful; and the vulgar would be allured by the profpects which he held out to them of a future happinefs, adapted to their groffer apprehenfions and paffions. Whilft we admit that, in the early period of his pretended miffion, he might have been actuated by a fincere defire of ameliorating the faith and manners of his countrymen, and allow his character to have poffeffed fome traits of the patriot and reformer, pride and ambition were his ruling principles; and his difcriminating character muft be that of an ufurper and impoftor, who owed his fuccefs more to the accommodating nature of his doctrine, and to the power of the fword, than to any other caufe. "Are we furprifed," fays Mr. Gibbon, "that a multitude of profelytes fhould embrace the doctrine and the paffions of an eloquent fanatic? In the herefies of the church, the fame feduction has been tried and repeated from the time of the apoftles to that of the reformers. Does it feem incredible that a private citizen fhould grafp the fword and the fceptre, fubdue his native country, and erect a monarchy by his victorious arms? In the moving picture of the dynafties of the laft one hundred fortunate ufurpers, none have arifen from a bafer origin, furmounted more formidable obftacles, and filled a larger fcope of empire and conqueft. Mahomet was alike inftructed to preach and to fight; and the union of thefe oppofite qualities, while it enhanced his merit, contributed to his fuccefs: the operation of force and perfuafion, of enthufiafm and fear, continually acted on each other, till every barrier yielded to their irrefiftible power. His voice invited the Arabs to freedom and victory, to arms and rapine, to the indulgence of their darling paffions in this world and the other. The reftraints which he impofed were requifite to eftablifh the credit of the prophet, and to exercife the obedience of the people: and the only objection to his fuccefs was his rational creed of the unity and perfections of God. It is not the propagation, but the permanency of his religion that deferves our wonder: the fame pure and perfect impreffion, which he engraved at Mecca and Medina, is preferved, after the revolutions of 12 centuries, by the Indian, the African, and the Turkifh profelytes of the Koran."—The Turkifh dome of St. Sophia, with an increafe of fplendour and fize, reprefents the humble tabernacle erected at Medina by the hands of Mahomet. The Mahometans have uniformly withftood the temptation of reducing the object of their faith and devotion to a level with the fenfes and imagination of man. "I believe in one God, and Mahomet the apoftle of God," is the fimple and invariable profeffion of Iflam. The intellectual image of the Deity has never been degraded by any vifible idol, &c. "From the Atlantic to the Ganges, the Koran is acknowledged as the fundamental code, not only of theology but of civil and criminal jurifprudence; and the laws which regulate the actions and the property of mankind are guarded by the infallible and immutable fanction of the will of God."

In a review of the caufes which feem to have facilitated the original fuccefs of Mahometanifm, profeffor White (Sermons,

(Sermons, ii.) traces them in the ſcandalous diviſions and deplorable corruptions of the Chriſtian church; in the political and religious ſtate of Arabia; in the independence and want of union among its tribes; in the groſs ignorance (particularly with regard to religion) of its barbarous and uncivilized inhabitants; and, laſtly, in the nature and genius of Mahometaniſm itſelf; in the faſcinating allurements of its promiſed rewards, in their agreeableneſs to the propenſities of corrupt nature in general, and to thoſe of the inhabitants of warmer climates in particular; in the artful accommodation of its doctrines and its rites to the preconceived opinions, the favourite paſſions, and the deep-rooted prejudices of thoſe to whom it was addreſſed; in the poetic elegance with which its doctrines, its precepts, and its hiſtories were adorned, and in the captivating manner in which they were delivered. As the corrupt and diſtracted ſtate of the Chriſtian church had originally aſſiſted the riſe, ſo did it operate with ſtill greater force in favour of the ſubſequent progreſs of Mahometan impoſture. If, indeed, we allow to this cauſe its proper influence; if we conſider the weakneſs of the ſurrounding nations, and the natural ſtrength of Arabia, now collected and pointed to one object; if we reflect on that fervour of zeal, and that wildneſs of enthuſiaſm, which were now ſuperadded to the native valour of a hardy and warlike people; we ſhall ceaſe to wonder at the victories and triumphs they obtained over the lukewarm and degenerate defenders of the goſpel. Of theſe victories and theſe triumphs, the propagation of their new faith was the profeſſed object and deſign: thus, by violence and bloodſhed had the prophet himſelf finally eſtabliſhed his religion among his countrymen; and thus had he expreſsly commanded his followers to extend it over all the regions of the earth. Of the continuance of Mahometaniſm, when thus eſtabliſhed, and of its exiſtence to the preſent times, various cauſes might be aſſigned, whoſe joint operation would be ſufficient to account fully for the effect, without having recourſe to any miraculous or particular interpoſition of providence. Of theſe cauſes we ſhall ſatisfy ourſelves with mentioning only one, which appears to be of peculiar force and importance. In almoſt all thoſe countries, which acknowledge the authority of Mahomet, ſo intimate is the connection, ſo abſolute the dependence of the civil government on religion, that any change in the latter muſt neceſſarily and inevitably involve the ruin and overthrow of the former. The Koran is not, like the goſpel, to be conſidered merely as the ſtandard by which the religious opinions, the worſhip, and the practice of its followers are regulated; but it is a political ſyſtem; on this foundation the throne itſelf is erected; from hence every law of the ſtate is derived; and by this authority every queſtion of life and of property is finally decided. It is obvious, therefore, that in every country where Mahometaniſm had been once received and eſtabliſhed, the circumſtance now mentioned muſt have operated with uncommon weight to cruſh any important innovation in religion; ſince from this inſeparable connection between the ſanctions of religion and thoſe of the ſtate, every ſuch innovation would be conſidered in no other light, than as an attempt to overturn the civil government, to looſen the bands of ſociety, and to deſtroy every privilege of law, and every ſecurity of property.

Mahomet was ſucceeded by Abubeker, agreeably to the wiſhes of the deceaſed prophet; who, after a reign of two years, was followed by Omar; and in the 12th year of his government, he received a mortal wound from the hand of an aſſaſſin, and made way for the ſucceſſion of Othman, the ſecretary of Mahomet. After the third Caliph, 24 years after the death of the prophet, Ali was inveſted, by the popular choice, with the regal and ſacerdotal office. Among the numerous biographers of Mahomet, we may reckon Abulfeda, Maracci, Savary, Sale, Prideaux, Boulainvilliers, D'Herbelot, Gagnier, Gibbon, and the author of the article in the Modern Univerſal Hiſtory. See ALCORAN and MAHOMETANISM.

MAHOMET I., ſultan of the Turks, born about the year 1374, was one of the ſons of Bajazet, who was dethroned by Tamerlane. After his brother Solyman had loſt his life in the war with Muſa, he declared himſelf his avenger, and being aſſiſted by the Greek emperor Manuel, defeated Muſa, who was killed in the field, or made captive and put to death by Mahomet's orders. The victor was proclaimed ſultan at Adrianople in 1413, which city he made the ſeat of his empire. Soon after his acceſſion, he paſſed over with an army into Leſſer Aſia, and did much miſchief there. After having ſubdued Servia, part of Sclavonia, and Macedonia, and reduced to obedience the provinces of Leſſer Aſia, he died in the year 1421, having reigned eight years with diſcretion and ſucceſs, and leaving behind him a character reſpectable for juſtice and clemency. Univer. Hiſt. Gibbon.

MAHOMET II., emperor of the Turks, named "The Great," and "The Victorious," ſon of ſultan Amurath, or Morad II., was born at Adrianople in 1430, and received an education very ſuperior to that generally beſtowed on the princes of the Turkiſh empire. He was well ſkilled in five languages, and was converſant in hiſtory and geography. During the life of his father, he twice aſſumed the ſovereignty, and twice relinquiſhed it, at the command of his parent. He made no oppoſition to his father's will, but never forgave the miniſters who were the adviſers of the meaſure. One of his firſt acts, after the death of his father, was the ſiege of Conſtantinople, which commenced in the ſpring of 1453; he cauſed cannon of a prodigious ſize to be caſt, and aſſembled a vaſt army from all parts of his dominions, with a great fleet. He ſuperintended the operations himſelf, and by a ſeverity that puniſhed the ſmalleſt diſobedience with death, and the moſt magnificent promiſes of reward, he ſtimulated the exertions of his troops. The vaſt diſparity of force between the aſſailants and defenders, leaves little room for admiring the military ſkill and proweſs of the victorious party. The ſultan, reſolved to carry his point, let it coſt what it would, drove on his men to the attack, and it was by numbers that the final ſucceſs was obtained. (See CONSTANTINOPLE.) It was on the twenty-ninth of May 1453, that the general aſſault was made which determined the fate of that city. After a gallant reſiſtance with his few faithful followers, the laſt Greek emperor loſt his life in the preſs, and the Turks burſt into the city through the breaches of the walls. Mahomet ſullied his victory by the moſt brutal conduct, but as he determined to fix the ſeat of his empire in this admirable ſituation, he repaired and repeopled the city partly from his own ſubjects, and partly from the fugitive Greeks, to whom he allowed the free exerciſe of their religion. The great church of Santa Sophia was converted into a moſque, and the creſcent took place of the croſs, in this ſecond capital of Chriſtendom. After the event, the weſtern writers give Mahomet the title of emperor of the Turks. Almoſt the whole reign of this monarch was ſpent in martial projects, which rendered him equally the terror of the Chriſtian world, and the pride of the Mahometan. His conqueſts were very numerous: he invaded Servia, and made it tributary; he took Mitylene, the ancient Leſbos, with the other iſlands, and reduced Boſnia under his dominion, which, however, was afterwards recovered by Matthias, king of Hungary.

He fubdued Caramania, the fovereigns of which had long been the moft inveterate enemies of the Turkifh fultans. He conquered Negropont, the ancient Eubœa, and wrefted Kaffa in Crim Tartary from the Genoefe. One of his lateft attempts was the fiege of Rhodes, in which he was rendered unfuccefsful by the valour of the knights. He, however, as a compenfation for this difafter, captured Otranto in Italy, which gave him a footing in that country; but to him this was of little ufe; his end was haftily approaching; he died in the month of May 1481, at the age of fifty-one, after a reign of thirty years. The vigour of mind and body, and the loftinefs of enterprize by which this conqueror was characterifed, raife him vaftly above the mere poffeffors of an hereditary throne. His fucceffes, however, were chiefly obtained by the force of numbers, urged on by an unfeeling defpotifm, and it has been afferted that he generally failed in the conteft with combined fkill and valour. The evils which he brought upon Chriftendom have caufed his moral qualities to be painted in the darkeft colours by its writers. He has been accufed of irreligion, perhaps chiefly from the tolerant fpirit which directed his conduct towards the vanquifhed of different religions; yet he difplayed the ufual zeal of princes in founding fplendid edifices for the public worfhip of the eftablifhed faith. Univer. Hift. Gibbon.

Mahomet III., emperor of the Turks, fon of Amurath III., was born in 1564, and fucceeded to the throne on the death of his father in 1596. The firft act of his infamous reign was the murder of nineteen brothers, and of ten of his father's wives from whom offspring might be apprehended. Having thus fecured his throne, he gave himfelf up to indolence and fenfuality, little attentive to the affairs of the empire, which were feldom more unprofperous than in this reign. In his contefts with neighbouring powers he was commonly unfuccefsful. A feries of difafters excited againft him a confpiracy, to quell which, he was under the neceffity of facrificing fome of his officers, and banifhing the queen mother from his counfels. Mahomet died in 1603, at the age of thirty-nine, after an inglorious reign of about eight years.

Mahomet IV., emperor of the Turks, was born in 1642, and fucceeded his depofed father Ibrahim in 1649. During his minority the government was adminiftered by his mother, affifted by a council of bafhaws. He found his country at war with the Venetians, which was continued with various fuccefs. The empire at home was convulfed by the revolt of the bafhaw of Aleppo, who at firft gained great advantages over the grand vizier, but in the end loft his life. In the year 1660, war was rekindled with great vigour in Hungary, and the Turkifh arms were at firft fuccefsful. A great victory gained by Montecuculi, the imperial general at Raab, in 1664, inclined the Ottoman court to a peace, which was foon after concluded. The conqueft of the ifland of Candia from the Venetians in 1669, after a fiege of 25 years, was one of the moft memorable events of this reign. A war with Poland in 1672, was terminated with a peace very humiliating to the Poles, but the nation refufed to ratify it, and John Sobiefki in the following year gave the Turks a complete defeat at Choczim, which circumftance was the means of raifing him to the Polifh throne. After this, for feveral years, the tide fet in ftrongly againft the Turks. A career of ill fortune excited difcontents among them, and the army broke out into a fierce mutiny. Quitting their camp near Belgrade, they marched for Conftantinople, and fent before them a demand of the grand vizier's head; which was granted. They next upbraided the fultan with his neglect of public affairs, and entreated him to refign a government which he had proved himfelf unfit to conduct. Mahomet, as a meafure of felf-defence, determined to put his brothers to death, but being apprifed of his intention, they took methods of faving themfelves from the threatened danger. At length Mahomet fubmitted to pronounce the decree of his own refignation. He quitted the throne in 1687, and was confined to his apartment, where he furvived till the year 1691. He left two fons, who afterwards came to the throne of the empire. Mahomet IV. is defcribed as diftinguifhed for juftice, clemency, and valour, though the hiftory of his reign is that of his generals and minifters; his own activity was fhewn chiefly, if not wholly, in the purfuits of the chace. Univer. Hift.

Mahomet *Pigeon*, in *Ornithology*, the common Englifh name of a fpecies of pigeon, called by Moore the *columba Numidica alba*. It is of the fame fhape and fize with the Barbary pigeon, and has all the characters of that fpecies, but is always perfectly white, which gives the red circle about the eyes a more lively look. See Columba.

MAHOMETANISM, Mahometism, or Mohammedism; the fyftem of religion broached by Mahomet, and ftill adhered to by his followers. See Mahomet.

Mahometanifm is embraced by the Turks, Perfians, and feveral nations among the Africans, and many among the Eaft Indians.

Brerewood fays, that if we divide the known countries of the earth into thirty equal parts five of them are Chriftians, fix Mahometan, and nineteen Pagan.

The fyftem of Mahometanifm is contained in the Koran, commonly called the *Alcoran;* which fee.

The firft and chief article of the Mahometan creed is, that *there is no other God but one God;* which they have from the Koran, where thefe words are repeated inceffantly: *there is no other God but he. Your God is the only God. I am God, and there is no other God but I.* This grand axiom of their theology feems to have been taken from the Jews, who were continually rehearfing thofe words of Deuteronomy, *Hear, O Ifrael; the Lord our God is One.*

For this reafon, the Mahometans account all fuch as own any thing of number in the divinity, to be infidels or idolaters. And accordingly, one of the firft leffons they teach their children is, that God is neither male nor female, and, confequently, can have no children. (See the 2d, 57th, and 58th chapters of the Koran.) Hence, the profelytes of Mahomet, from India to Morocco, are diftinguifhed by the name of "Unitarians;" and the danger of idolatry has been prevented by the interdiction of images.

The fecond article of Mahometanifm confifts in this, *that Mahomet was fent from God.* By which they exclude all other religions; under pretence that their prophet was the laft and greateft of all the prophets that God would ever fend, and that as the Jewifh religion ceafed with the coming of the Meffiah, fo likewife the Chriftian religion was to be abrogated with the coming of Mahomet. Not but they own Mofes and Jefus Chrift to have been great prophets; but Mahomet they hold to be "The Prophet," by way of excellence, commiffioned to purge the holy fcriptures of the Old and New Teftament, which they allow, from the corruption introduced in them by Jews and Chriftians, and to reftore the law of God to its original purity; and the paraclete or comforter promifed in the fcriptures.

The Mahometans call their religion *Iflam*, denoting, as fome fay, *refignation* or *fubmiffion* to the fervice and commands of God; but, according to others, formed from the root *falama*, fignifying to *be faved*, and, therefore, the fame with the *religion* or *ftate of falvation;* and they divide it into two diftinct parts, *viz. iman*, i. e. *faith* or *theory;* and *din*,

i. e. *religion* or *practice:* and teach that it is built on five fundamental points, one belonging to faith and the other four to practice.

Under the confession of faith already recited, they comprehend six distinct branches, *viz.* belief in God; in his angels; in his scriptures; in his prophets; in the resurrection and day of judgment; and in God's absolute decree and predetermination both of good and evil. The four points relating to practice, are prayer, under which are comprehended those washings or purifications which are necessary preparations required before prayer; alms, fasting, and the pilgrimage to Mecca. Their faith in God has been already mentioned: with respect to their opinion of angels, they believe them to have pure and subtile bodies, created of fire, and that they are differently employed, in writing down the actions of men, or in carrying the throne of God, and other services. The four angels, whom they regard as most distinguished by God's favour, and on account of the offices assigned them, are Gabriel, called the holy spirit, and the angel of revelations, and supposed to be honoured with the peculiar confidence of God, and employed in writing down the divine decrees; Michael, the friend and protector of the Jews; Azrael, the angel of death, who separates men's souls from their bodies; and Israfil, whose office it will be to sound the trumpet at the resurrection. They also believe that two guardian angels, changed every day, attend on every man, to observe and write down his actions. Their whole doctrine concerning angels they have borrowed from the Jews, who learned the names and offices of those beings from the Persians. The devil, called by Mahomet "Eblis," from his despair, was one of those angels, who are nearest to God's presence, called Azazil, and fell, according to the doctrine of the Koran, for refusing to pay homage to Adam at the command of God. They also admit an intermediate order of beings, called genii, some of which are good, and others bad; and capable of future salvation or condemnation, as men are, whence Mahomet pretended, that he was sent for the conversion of genii as well as of men.

As to the scriptures, the Mahometans are taught by the Koran, that God, in divers ages of the world, gave revelations of his will in writing to several prophets, the whole, and every word of which, it is absolutely necessary for every good Moslem to believe. Mahomet acknowledges the divine authority of the Pentateuch, Psalms, and Gospel, and often appeals to the consonancy of the Koran with those writings, and to the prophecies, which he pretended, were contained concerning himself, which the Jews and Christians have suppressed.

Besides these books, the Mahometans take notice of the writings of Daniel and several other prophets, and even cite them, but they do not believe them to be divine scripture, or of any authority in matters of religion. Among the prophets, in number 224,000 according to some, and 124,000 according to others, they reckon 313 apostles, bearing special commission to reclaim mankind from infidelity and superstition; six of whom were entrusted with new laws or dispensations, successively abrogating the preceding: these were Adam, Noah, Abraham, Moses, Jesus, and Mahomet.

At death, they maintain, that the bodies of those, who believe the unity of God, and the mission of Mahomet, rest in peace, and are refreshed with the air of paradise; otherwise they are grievously tormented. The souls of the former are conveyed to heaven, where a place is assigned them according to their merit and degree; those of the wicked are tormented, till they are rejoined to their bodies at the resurrection; the approach of which will be known by certain signs that precede it: these are the lesser and the greater signs: the latter of which are the sun's rising in the west; the appearance of a monstrous beast, which shall rise out of the earth in the temple of Mecca; war with the Greeks and the taking of Constantinople; the coming of Anti-Christ; the descent of Jesus on earth; war with the Jews; the eruption of Gog and Magog; a smoke which shall fill the whole earth; an eclipse of the moon; the return of the Arabs to the worship of their ancient idols; the discovery of a vast heap of gold and silver by the retreat of the Euphrates; the demolition of the temple of Mecca by the Ethiopians; the speaking of beasts and inanimate things; the breaking out of fire in the province of Hejaz or Yemen; the appearance of a man, who shall drive men before him with his staff; the advent of the Mohdi, or director, a person of the family of Mahomet, to govern the Arabians, and fill the world with righteousness; and a wind that shall sweep away the souls of all who have but a grain of faith in their hearts. But the immediate sign of the resurrection will be the first blast of the trumpet, which will be sounded three times. The day of judgment will continue, as the Koran says in one place, 1000 years, but according to another passage, 50,000 years: the resurrection, say they, will be general, extended to all creatures, angels, genii, men, and animals; who will be assembled on the earth, give an account of their actions, and receive retribution. On this occasion each person will have the book, wherein all the actions of his life are written, delivered to him, and their works will be weighed in a balance, which they minutely describe. When the examination is finished mutual retaliation will follow; which will be executed by taking away a proportionable part of the good works of him who offered injury to another, and adding it to him who suffered it. Brutes will be changed into dust; and the believing genii be assigned a place near the confines of paradise, and the unbelieving punished eternally and cast into hell, with the infidels of mortal race. After this process, the good and wicked are conducted to a bridge, called Alsirat; over which the former shall safely pass, while Mahomet and his Moslems lead the way, but the latter will fall down headlong into hell; where there are seven different apartments, adapted to as many distinct classes of the damned, who will suffer both from intense heat and excessive cold. In this state infidels only will be liable to eternal punishment; but the Moslems or believers will be delivered thence, after they have expiated their crimes by their sufferings. This place of punishment is separated from paradise by a wall, called "Al draf," so small in breadth as to admit the blessed and damned to converse together. The righteous, after having passed the bridge above-mentioned, will be refreshed by drinking at the pond of their prophet, and then admitted into paradise, situated in the seventh heaven, and next to the throne of God; where they will feed on the most delicious fruits, be clothed in the most splendid silken garments, refreshed with rivers of water, wine, milk, and honey, and entertained with the most delightful music, and the ravishing girls of paradise with black eyes, the enjoyment of whose company will be a principal felicity of the faithful.

It appears from the Koran, that women as well as men will not only be punished for their evil actions, but also receive the reward of their good deeds, and that both will enjoy a perpetual youth.

Hence it appears, that the vulgar opinion, which charges the Mahometans with maintaining that women have no souls, or if they have any, that they will perish like the

 brutes,

brutes, without any future recompence, is erroneous. It is, however, a general notion, that they will not be admitted into the fame abode as the men, becaufe their places will be fupplied by the paradifiacal females already mentioned. One circumftance relating to thefe beatified females, conformable to what Mahomet had afferted of the men, he acquainted his followers with in the reply which he made to an old woman; who defiring him to intercede with God, that fhe might be admitted into paradife, was told by him, that no old women would enter that place; which caufing the aged female to figh and fhed tears, he explained himfelf by faying, that God would then make her young again.

Farther, the orthodox doctrine with refpect to predeftination is, that every thing which happens in this world proceedeth entirely from the divine will, and is irrevocably fixed from all eternity in the preferved table; God having fecretly predetermined not only the adverfe and profperous fortune of every perfon in this world, in the moft minute particulars, but alfo his faith or infidelity, his obedience or difobedience, and confequently his everlafting happinefs or mifery after death; which fate or predeftination it is not poffible for any forefight or wifdom to avoid.

Of this doctrine Mahomet makes great ufe in his Koran for the advancement of his defigns, encouraging his followers to fight without fear, and even defperately, for the propagation of their faith, reprefenting to them that no caution on their part could avert their inevitable deftiny, or prolong their lives for a moment.

In regard to the four fundamental points of religious practice; Mahomet is faid to have declared, that the practice of religion is founded on cleanlinefs, which is one-half of the faith, and the key of prayer, without which it will not be heard by God. Such is the opinion which the Mahometans entertain of cleanlinefs, that it is purely on this account they feem to have adopted circumcifion, though it be not mentioned in the Koran. Mahomet has obliged his followers to pray five times every twenty-four hours, at certain ftated feafons, turning their faces towards the temple of Mecca, which is pointed to by a niche in their mofques: the life and fpirit of prayer, they hold, are the inward difpofition of the heart; nor do they ever perform this duty in fumptuous apparel, nor fuffer their women to attend them on thefe occafions, left their prefence fhould infpire a different kind of devotion from that which is requifite in a place dedicated to the worfhip of God.

Alms, among the Mahometans, are legal and voluntary; the giving of which is frequently inculcated in the Koran. Hafan, or Hofein, the fon of Ali, and grandfon of Mahomet, is faid to have thrice in his life divided his fubftance equally between himfelf and the poor, and twice to have given away all he had; and the generality of Mahometans are fo addicted to acts of benevolence, that they extend their charity even to brutes. Fafting is called by Mahomet the gate of religion; and his followers are exprefsly required to faft during the month of Ramadan; which they obferve by abftaining from meat, drink, and women, from day-break till fun-fet. Befides this, they have feveral other voluntary fafts. The pilgrimage to Mecca is fo neceffary a point of practice, that, according to a tradition of Mahomet, he who dies without performing it may as well die a Jew or a Chriftian; and it is exprefsly commanded in the Koran. The various ceremonies prefcribed to thofe who perform this pilgrimage are extremely abfurd and ridiculous, and appear to be relics of idolatrous fuperftition.

Befides the fundamental points of faith and practice above recited, the Mahometans are required by the Koran, to abftain from wine, gaming, ufury, divining by arrows, the eating of blood and fwine's flefh, and whatever dies of itfelf, or is flain in honour of any idol, or ftrangled, or killed by accident, or by any other beaft. The Koran allows polygamy within certain limits; forbidding any man to have more than four, whether wives or concubines: but Mahomet had the privilege of marrying as many wives, and keeping as many concubines as he pleafed. It allows alfo of divorce; but feverely punifhes fornication and adultery.

Wilful murder, though forbidden by the Koran under the fevereft penalties to be inflicted in the next life, is neverthelefs by the fame book allowed to be compounded for, on payment of a fine to the family of the deceafed, and freeing a Moflem from captivity; but this commutation depends on the choice of the next of kin, who may either accept or refufe it. Manflaughter was redeemed by fine, and the freeing of a captive; and if a man were not able to do this, he was required to faft two months together, by way of penance. The fine for a man's blood was fet in the "Sonna" at 100 camels, and was diftributed among the relations of the deceafed. Theft was ordered to be punifhed by cutting off the hand. As to injuries done to men in their perfons, the law of retaliation, which was ordained by the law of Mofes, is alfo approved by the Koran; but it was feldom executed; the punifhment being generally turned into a mulct or fine, paid to the party injured. In the punifhment of leffer crimes, not provided for by the Koran, the Mahometans have commonly recourfe to ftripes or drubbing, according to the ufual practice of the Eaft. Under the head of the civil laws of the Mahometans, we may comprehend the injunction of warring againft infidels, which is repeated in feveral paffages of the Koran, and declared to be very meritorious in the fight of God; thofe who are flain fighting in defence of the faith, being reckoned martyrs, and promifed immediate admiffion into paradife.

The months which the ancient Arabs held facred were al Moharram, Rajeb, Dhu'lkaada, and Dhu'lkaja, the 1ft, the 7th, the 11th, and the 12th in the year. Mahomet by the Koran confirmed the obfervance of thefe months.

The day of the week which Mahomet has fet apart for public worfhip is Friday; befides which they have two annual feafts called *Beiram*.

After the death of Mahomet, a fchifm arofe among his followers, which divided them into two great factions, whofe feparation not only gave rife to a variety of opinions and rites, but alfo excited the moft implacable hatred, and the moft deadly animofities. Of thefe factions the one acknowledged Abubeker, the father-in-law of Mahomet, as his fucceffor, or the true caliph, and its members were diftinguifhed by the name of *Sonnites*; while the other adhered to Ali, his fon-in-law, and were known by the title of *Schiites*. Both, however, adhered to the Koran as a divine law, and the rule of faith and manners; to which indeed the former added, by way of interpretation, the Sonna, *i. e.* a certain law, which they looked upon as defcended from Mahomet by oral tradition, and which the Schiites refufed to admit. Among the Sonnites we are to reckon the Turks, Tartars, Arabians, Africans, and the greateft part of the Indian Mahometans; whereas the Perfians, and the fubjects of the grand mogul, are generally confidered as the followers of Ali, though the latter indeed feem rather to obferve a ftrict neutrality in this conteft. Befides thefe two grand factions, there are other fubordinate fects among the Mahometans, which difpute with warmth concerning feveral points of religion, though without violating the rules of mutual toleration. Of thefe fects there are four, which far furpafs the reft in point of reputation and importance, *viz.* the Hanefites, the fect of Malec, the fect of Al Shafei, and that of Ebn Hanbal, which are

are called the orthodox Mahometans. Sale's Preliminary Discourse. See ALCORAN.

The rapid success which attended the propagation of this new religion, was owing to causes that are plain and evident, and must remove, or rather prevent, our surprise, when they are attentively considered. We have enumerated the principal under the biographical article MAHOMET. But the subject is of importance, and we shall therefore here resume it. The terror of Mahomet's arms, and the repeated victories which were gained by him and his successors, were, no doubt, the irresistible arguments that persuaded such multitudes to embrace his religion, and submit to his dominion. Besides, his law was artfully and marvelously adapted to the corrupt nature of man; and, in a more particular manner, to the manners and opinions of the eastern nations, and the vices to which they were naturally addicted: for the articles of faith which it proposed were few in number, and extremely simple; and the duties it required were neither many nor difficult, nor such as were incompatible with the empire of appetites and passions. It is to be observed farther, that the gross ignorance under which the Arabians, Syrians, Persians, and the greatest part of the eastern nations, laboured at this time, rendered many an easy prey to the artifice and eloquence of this bold adventurer. To these causes of the progress of Mahometanism, we may add the bitter dissentions and cruel animosities that reigned among the Christian sects, particularly the Greeks, Nestorians, Eutychians, and Monophysites; dissentions that filled a great part of the East with carnage, assassinations, and such detestable enormities, as rendered the very name of Christianity odious to many. We might add here that the Monophysites and Nestorians, full of resentment against the Greeks, from whom they had suffered the bitterest and most injurious treatment, assisted the Arabians in the conquest of several provinces, into which, of consequence, the religion of Mahomet was afterwards introduced. Other causes of the sudden progress of that religion will naturally occur to such as consider attentively its spirit and genius and the state of the world at this time. Mosheim's Eccl. Hist.

MAHON, in *Geography*. See PORT *Mahon*.

MAHON, a river of Ireland, in the county of Waterford, which runs into the sea; 11 miles E. of Dungarvan.

MAHONE BAY, a bay on the coast of Nova Scotia, separated from Margaret's bay by the promontory, on which is the high land of Aspotagoen.

MAHONING, a township of America, in Pennsylvania, situated on Susquehanna river.

MAHONOY, a township of Susquehanna river, in Pennsylvania, having 1102 inhabitants.

MAHONY, a town of Hindoostan, in the circar of Sohagepour; 20 miles N. of Sohagepour.

MAHOU, a city of China, of the first rank, in the province of Se-tchuen, seated on the Kincha; comprehending, within its district, only one city of the third class, but a place of great trade. N. lat. 28° 32'. E. long. 103° 51'.

MAHOWLY, a town of Hindoostan, in Oude; 29 miles N.W. of Kairabad.

MAHR, HANNA, a town of Syria, where the Greek Catholics have a convent and a printing-office; 18 miles N.E. of Bairout.

MAHRABUT. See MARABBUT.

MAHRAJEGUNGE, a town of Hindoostan, in Bahar; 11 miles E. of Hajypour.—Also, a town of Bengal; 30 miles N.E. of Purneah.—Also, a town of Hindoostan, 20 miles W. of Benares.

MAHRAS, EL, a town of Tunis; 60 miles S. of Cairoan.

MAHRATTAS, a powerful people of Hindoostan, who derived their name, as some say, from "Marhat," a province of the Deccan, mentioned by Ferishta, and comprehending Baglana, or Bogilana, and other districts, which at present form the most central part of the Mahratta dominions. The original meaning of the term Marhat is unknown; but there is no doubt that the name of the nation is a derivative from it; for we may depend upon the testimony of Ferishta, who wrote at a period, when the inhabitants of the province of Marhat did not exist as an independent nation; but were blended with the other subjected Hindoos of the Deccan. We learn also from an earlier authority than that of Ferishta, *viz.* from Nizam-ul-Deen, an officer in the court of Acbar, who wrote a general history of Hindoostan, brought down to the 40th year of that emperor, that one of the kings of Delhi made an excursion from Deogur, or Dowlatabad, into the neighbouring province of "Marhat." This relation occurs also in Ferishta's history of Hindoostan. It was in the reign of Alla I. A.D. 1312. From a paper published in the "Asiatic Researches," (vol. ix.) we learn that it is asserted in India, that the "Mahrattas" are foreigners, and that they acknowledge this to be their origin. A tribe called Ranas, related to the Mahrattas, say, that they are descended from Nushirvan; and the Parsis, in India, fix the time of their emigration in the reign of Abu-Becr, which lasted only two years, in 632 and 633. Some of these emigrants left Persia at different periods, in consequence of the fanatic zeal of the Mussulmen, and their persecuting spirit; but the emigration of the children of Nushirvan is the most ancient. Of these emigrants, some retained their ancient religion, and are called Parsis; others termed Hindûs, and are called Ranas and Mahrattas. The Mahrattas are called "Maha-Rashtras" in Sanscrit: "Maha" is great and illustrious, and "Rasht-ra," synonymous with Raja-putra, implies their royal descent; and their name also indicates, that they were acknowledged to belong to the second class on their arrival in India, and of course that they were not Brahmans. When the new adventurers obtained power and influence, they assumed the title of Maha-Rashtras, and by striking out such letters as became useless, when brought to the standards of the dialects in use, they acquired the name of Maha rata, Mahrata, and Mahretor. The founder of the Mahratta empire may be considered as Sevajee, who was born in 1628, and disdaining the condition of a subject, embraced an early opportunity of becoming independent. The progress of his conquests was so rapid, that he became formidable to the armies of the Mogul empire, before Aurungzebe's accession to power; having seized on the principal part of the province of Baglana, and the country of Concan, situated between it and the western sea. He had also taken possession of other places of strength. In the Carnatic he had possession of Gingee, together with an extensive district round it; and this, perhaps, may be regarded rather as an usurpation of one of the Visiapour conquests, than as an acquisition made from the original sovereign of the Carnatic; for the king of Visiapour appears to have possessed the southern part of the Carnatic, including Tanjore. At the death of Sevajee, in 1680, his domains extended from the northern part of Baglana, near Surat, to the neighbourhood of the Portuguese districts of Goa, along the sea-coast. His conquests had been the fruits of hardy and persevering valour; partly acquired in despite of Aurungzebe, then in the zenith of his power. Sevajee had also plundered Surat and Golconda, and even attacked Goa, when the Portuguese power was at its height. His son Sambajee fell a sacrifice to his debauchery, having been seized on treacherously, in one of his licentious excursions, and cruelly put to death by Aurungzebe in 1689. The Mahrattas, however, remained unsubdued, and increasing in power. Sahoo, or Sahoojee, succeeded his father Sambajee, at a very early age; and as he inherited the ability and vigour of mind of his immediate ancestors, and reigned more than fifty years, during a period favourable to the aggrandizement of a rising state, the Mahratta power grew up to the wonderful height at which we have beheld it. The confusions occasioned by the disputed succession among Aurungzebe's sons, and their descendants, opened a wide field to all adventurers; and particularly to those hardy and enterprising people, who had contended even with Aurungzebe himself; and it would be matter of surprise that Sahoojee made so many conquests, if we did not consider that Hindoostan abounds with military adventurers, who readily enlist themselves under a chief, who holds out to his followers a prospect of plunder. At the time of Sahoojee's death, in 1740, the Mahratta state had swallowed up the whole tract from the Western sea to Orissa, and from Agra to the Carnatic; and almost the remaining portion of Hindoostan, Bengal excepted, had been over-run and plundered. It is difficult to trace the Mahratta conquests, according to the order of time in which they were made.

It is known that they took part in the disputes between the descendants of Aurungzebe at Delhi, as early as the year 1718; but it was not till the year 1735, that they were sufficiently powerful to demand a tribute from the emperor, Mahomed Shah. This terminated in their acquisition of the greatest part of the province of Malwa; and in a grant of the fourth part of the nett revenues of the other provinces in general. This proportion being denominated in the language of Hindoostan a "Chout," the subsequent demands of the Mahrattas were thus called, though they are not limited to that proportion. About the year 1736, they took part in the disputes between the nabobs of Arcot, in the Carnatic; and as the principal European settlements, on the coast of Coromandel, are situated within this district, these disputes eventually engaged the French and English East India Companies in scenes of hostility for several years. Sahoojee was succeeded, in 1740, by Ram Rajah, who was a weak prince; and it happened in the Mahratta state, as in other states of recent formation, and rapid growth, that what was gained by the ability of one despot was lost by the imbecility of another. The two principal officers of the state, the "Paishwah," or minister, and the "Bukshi," or commander in chief, agreed to divide the dominions of their master; the former assuming the government of the western provinces and continuing at Poonah, the ancient capital, and the latter occupying the eastern provinces and residing at Nagpour, in Berar. This violent usurpation of the empire by its ministers, encouraged the usurpations of others, according to their respective degree of power, and their opportunity; so that, in the course of a few years, the state, from being an absolute monarchy, became a mere confederacy of chiefs, exhibiting the most disjointed example of feudal government in the world. In 1742, and 1743, both the Mahratta states, for reasons which we shall not here recite, invaded Bengal, with armies said to contain 80,000 horsemen each. But as they acted without union, and Aliverdy had recourse to bribery, and to other means for creating a dissention between them, the inhabitants of Bengal, though great sufferers, were not injured to the degree which they were led to expect. The Mahrattas did not retire from the provinces till the year 1744, when they had collected a vast mass of plunder and established the claim of the "Chout," which, however, was never regularly paid. The Berar Mahrattas having afterwards obtained possession of the Orissa province, their proximity to Bengal afforded them frequent opportunities of plundering the frontier provinces; and it was not till the year 1761, when Cossim Ally, nabob of Bengal, ceded the provinces of Burdwan and Midnapour to the English, that the Mahrattas ceased to plunder them. Bajirow, who had taken possession of the Western provinces, wrested from the Portuguese the fortress of Basseen, and the island of Salsette, near Bombay, which were inferior in importance only to Goa. He died in 1759, and left the paishwahship, now considered as an hereditary establishment, to his son Ballajée. At this period the Mahrattas pushed their conquests into the Panjab, and even to the banks of the Indus. But their prosperity was of no long duration. The wars that ensued between them and Abdalla of Candahar, and which terminated with the famous battle of Pannipat, the most obstinate and bloody in the records of Hindoostan, decided the pretensions of the Mahrattas with regard to universal empire in Hindoostan, to which they were aspiring, for in this battle they lost the flower of their army, and their best generals; and from that period, *viz.* 1761, their power has been sensibly on the decline. Ballajée died soon after, and was succeeded by his son Maderow, who died in 1772. The son and successor of Maderow was murdered, in 1773, by his uncle Ragobah; by which act he excited general resentment and detestation; so that, needing allies to support his ill-gotten power, he made an advantageous treaty with the English, in order to secure the Bombay government in his cause; the consequence of this treaty was the commencement of hostilities both by sea and land, and the island of Salsette, a most desirable acquisition, was taken possession of by the English. A subsequent war between the English and the Mahrattas was attended with the conquest, on the part of the former, of the finest parts of Guzerat and the Concan, including the fortresses of Basseen and Amedabad; and, in short, of the whole country from Amenabad to the river Penn, and inland, to the foot of the Gauts; and on the side of Oude, the province of Gohud and other districts, together with the celebrated fortress of Gwalior, were reduced; and the war was carried into the heart of Malwa. This war was attended with an enormous expence, and a contest broke out with Hyder Ally in 1780, and therefore, in 1782 and 1783 a peace was negotiated and concluded between the English and the Mahrattas; and all the acquisitions made during the war were given up except Salsette, and the small islands situated within the gulf formed by Bombay, Salsette, and the continent. The eastern Mahratta state, or that of Berar, though preserved from foreign wars, has had its share of intestine broils. It is not likely, says major Rennell, that either of the Mahratta states will soon become formidable to the other powers of Hindoostan. The eastern state has not resources for it, and as for the western, it is so divided between different chiefs, that it will not be easy for one of them to gain such an ascendancy as to reunite its divided power. These Mahratta states, the western and eastern, collectively, occupy all the southern part of Hindoostan proper; together with a large proportion of the Deccan, Malwa, Orissa, Candeish, and Visiapour; the principal parts of Berar, Guzerat, and Agimere; and a small part of Dowlatabad, Agra, and Allahabad, are comprised

within

within their extenſive empire, which extends from ſea to ſea, acroſs the wideſt part of the peninſula; and from the confines of Agra northward, to the Kiſtnah ſouthward; forming a tract of about one thouſand Britiſh miles long, by ſeven hundred wide. To the weſtern ſtate, which is divided among a number of chiefs or princes, whoſe obedience to the paiſhwah, or head, reſembles that of the German princes to the emperor, being merely nominal, and whoſe confederacy never takes place except for mutual defence, belong ſeveral "jaghiredars," or holders of "jaghires," one on the north of Poonah, and two on the ſouth. The revenue of this ſtate is not eaſily aſcertained; but it has been ſtated by a native of India at 12 crores of rupees, or 12 millions ſterling; and the net receipts, jaghires deducted, at five crores. The ſame account makes the military eſtabliſhment in the field to be 200.000 troops, foot and horſe; beſides an equal number in garriſon. Another account of the revenue reckons ſeven crores for the net revenue. Major Rennell obſerves that if the provinces poſſeſſed by this ſtate were to be rated in the ſame proportion as in the time of Aurungzebe, the net revenue would be about eight crores of rupees, or eight millions ſterling. The moſt powerful jaghiredar within this ſtate is that of Sindia, who, ſince the Mahratta peace in 1783, has extended his frontier from Malwa towards the Jumnah, occupying moſt of the petty ſtates that heretofore exiſted there, and particularly that of Gohud. He alſo extended his arms ſouthward to Delhi, and into the provinces of Mewat and Jyenagur; reducing many fortreſſes and a conſiderable tract of country, which had been before poſſeſſed by the Jats and Nudjaff Cawn. The revenue of his paternal, or original dominions, in Malwa, &c. has been eſtimated at one crore of rupees *per annum*. Among his new acquiſitions, Gohud is eſtimated at 20 or 30 lacks *per annum*; Holkar has been ſuppoſed to poſſeſs 80 lacks *per annum* in his ſhare of Malwa. Sindia's capital city is Ougein, and Holkar's capital is Indore, about 20 coſſes S. or S.E. of Ougein. For an account of Berar, ſee Berar; and for further particulars relating to the Mahratta ſtates, ſee Hindoostan. Rennell's Introduction to his Memoir, paſſim, and his Map.

MAHRAUZEDURGAM, a town of Hindooſtan, in Myſore; ſix miles N.N.E. of Kiſtnagheri.

MAHRENBERG, or Marenberg, a town of the duchy of Stiria; nine miles N. of Windiſch Gratz.

MAHSENA, in *Ichthyology*. See Sciæna.

MAHU, in *Geography*, a town of Sweden, in Sudermanland; 28 miles N.W. of Nykioping.

MAHUDGEE, a town of Hindooſtan, in Oude; 12 miles N. of Fyzabad.

MAHUDWAH, a town of Hindooſtan, in Guzerat; 31 miles S.E. of Puttan Sumnaut.

MAHUR, a circar of Hindooſtan, in Berar, on the N. ſide of the Godavery river, E. of Ellichpour, and N. of Tellingana. The chief towns are Mahur and Neermul.—Alſo, a town, the capital of the above circar, 112 miles E. of Ellichpour. N. lat. 19° 24′. E. long. 78° 3′.—Alſo, a town of Hindooſtan, in the circar of Gurrah; 90 miles S.S.W. of Allahabad. N. lat. 24° 18′. E. long. 81° 2′.

MAHUREA, of Aublet and Juſſieu, in *Botany*. See Bonnetia.

MAHURRY, in *Geography*, a town of Hindooſtan, in the circar of Surgooja; 35 miles N.W. of Surgooja.

MAI, a town of Perſia, in the province of Lariſtan; 4– miles W. of Lar.

MAIA, a river of Ruſſia, which, riſing in N. lat. 59° 50′. E. long. 139° 10′, purſues a S.W. courſe to N. lat. 57° 40′, and then uniting with the Maimakan, changes its courſe to N.N.W. and runs into the Aldan, N. lat. 60° 20′. E. long. 133° 40′.

MAJA, in *Ornithology*, the name of a bird deſcribed by Nieremberg as very common in the iſland of Cuba, and frequenting the fields of rice in large flocks. It is deſcribed to be a ſmall bird of a yellowiſh colour, very delicate, and well taſted, and remarkable for having a ſtomach on the back or outſide of the neck. See Fringilla *Maja*.

Maja, or *Majan* of Buffon, a ſpecies of *Loxia*; which ſee.

MAIAGUE, the name of a Braſilian bird of the web-footed kind, but having its hinder toe looſe. It is of the ſize of the common gooſe; its head is large and round; its neck long, and it always carries it crooked like a ſwan; its beak is ſtrong and hooked at the end; it is all over of a browniſh-black colour, except that its throat is yellow. It is found about the mouths of rivers, and feeds on fiſh; it builds on the ground; it is very nimble in running, flying, and diving, and is not eaſily taken, but is a very well-taſted fowl. It is the Braſilian *petrel* of Latham. See Procellaria *Braſiliana*.

MAIAK, in *Geography*, an oſtrog of Ruſſia, on the coaſt of the Frozen ocean. N. lat. 71° 16′. E. long. 169° 14′.

MAIAKAR, a town of Ruſſia, in the government of Perm; 16 miles N. of Obrinſk.

MAIAN, a town of Perſia, in Farſiſtan; 18 miles S. of Iſpahan.

MAJANAH, a town of Algiers, in the province of Conſtantina, at the entrance of an extenſive plain, to which it gives name; 50 miles S.S.W. of Boojeiah.

MAIANTHEMUM, in *Botany*, from Μαιος, *the month of May*, and ανθεμον, *a flower*, a name given by ſome authors to the Lily of the Valley. See Convallaria.

MAIAR, in *Geography*, a town of Perſia, in Chuſiſtan; 12 miles N. of Kostha.

MAJARES, a town of Tranſylvania, in the Maros; 17 miles E. of Biſtricz.

MAIDA, a town of Naples, in Calabria Ultra; 9 miles W.N.W. of Squillace.

MAIDEN, an edged inſtrument uſed in ſome countries, and formerly in Scotland, for the beheading of criminals.

The maiden is a broad piece of iron, of a foot ſquare, ſharp on the lower part, and loaded above with lead, ſo as ſcarcely to be lifted: at the time of execution, it is pulled up to the top of a narrow wooden frame ten feet high, with a groove on each ſide for the maiden to ſlide in. The priſoner's neck being faſtened to a bar underneath, on a ſign given, the maiden is let looſe, and the head in an inſtant ſeparated from the body. It has been lately much uſed in France as an inſtrument of decollation, under the name of *Guillotine*.

Maiden is alſo the name of a machine firſt uſed in Yorkſhire, and ſince introduced into other places, for waſhing of linen; conſiſting of a tub nineteen inches high, and twenty-ſeven in diameter at the top, in which the linen is put, with hot water and ſoap, to which is adapted a cover, fitting it very cloſely, and faſtened to the tub by two wedges; through a hole in the middle of the cover paſſes an upright piece of wood, kept at a proper height by a peg above, and furniſhed with two handles, by which it is turned backward and forward: to the lower end of this upright piece is faſtened a round piece of wood, in which are fixed ſeveral pieces, like cogs of a wheel. The operation of this machine is to make the linen paſs and repaſs quick through the water. Gent. Mag. vol. xxii. p. 32.

Maiden-

Maiden-*Affizes*, are thofe where no perfon is condemned to die.

Maiden-*Hair*, *Adiantum*, in *Botany* and *Medicine*. See Adiantum, and Asplenium.

Maiden-*Hair*, *Black*, a name fometimes given to the dwarf-fern. See Asplenium.

Maiden-*Hair*, *Englifh*. See Trichomanes, and Asplenium.

Maiden-*Hair*, *White*, or *Wall-Rue*. See Asplenium.

Maiden *Islands*, in *Geography*, a clufter of fmall iflands in Five Ifland harbour, near the W. coaft of the ifland of Antigua.

Maiden *Paps*, a mountain of Scotland, in the county of Roxburgh: 8 miles from Havick.

Maiden *Plum*, in *Botany*. See Plum.

Maiden-*Rents*, in our *Old Writers*, a noble paid by the tenants of fome manors on their marriage. This was faid to be given to the lord, for his omitting the cuftom of marcheta, whereby he was to have the firft night's lodging with his tenant's wife; but it feems more probable to have been a fine for a licence to marry a daughter.

Maiden *Rocks*, in *Geography*, a chain of rocks in the Eaft Indian fea, near the N. coaft of the ifland of Java. S. lat. 7° 38'. E. long. 114° 36'.

MAIDENHEAD, anciently called *South Ealington*, a market-town in the hundred of Cookham, Berkfhire, England, is fituated 26 miles from London, on the borders of the Thames, in the parifhes of Bray and Cookham. It confifts principally of one long paved ftreet; and derives its chief importance from the bridge, by means of which the great weftern road was carried through the town. Previoufly the road paffed through Burnham, and travellers ufually croffed the river at a ferry called Babham's End, about two miles north of Maidenhead. The original bridge, which was of wood, Camden fays, was erected about the year 1400; but there is fufficient evidence of its being of greater antiquity, and that, in 1297, it had been built long enough to need repair; for which purpofe, a toll for three years was then granted. The prefent bridge, which is a work of confiderable merit, was conftructed from the defigns of fir Robert Taylor; and its foundation was laid in 1772. It confifts of feven large femi-circular arches of ftone, and three fmaller, at each end, of brick. The expence of building it was 19,000*l.*, independent of fome contiguous lands, which were purchafed to render the work complete. The approach to this ftructure is grand and fpacious, the ends being formed with curves outwards: along the fides is a broad pavement, fenced with a baluftrade. Maidenhead was originally incorporated in the 26th year of Edward III., under the name of the guild or fraternity of the brethren and fifters of Maydeneth, or Maidenhithe. After the Reformation, a frefh incorporation was granted, in the name of the warden and burgeffes of Maidenhead. King James II. granted another charter with the ftyle of mayor, bridge-mafters, and burgeffes, who are empowered to choofe a high-fteward. Two of the burgeffes, who are eleven in number, are annually elected bridge-mafters. The high-fteward, the recorder, the mayor, and his immediate predeceffor, are juftices of the peace. The mayor is clerk of the market, coroner, and judge of a court, which is held once in three weeks. The market, which was granted in 1452, is ftill kept on Wednefdays, and is a confiderable mart for corn. Here are three annual fairs. The revenues of the corporation confift chiefly of the tolls of the market and bridge. The principal trade of the town is in malt, meal, and timber; and the inhabitants derive additional affiftance from the continual paffage of travellers, for whofe accommodation feveral inns have been opened. In that part of the town which lies within the parifh of Cookham is a chapel, exempt from epifcopal jurifdiction; the minifter is appointed by the mayor and bridge-mafters. In this divifion of the town is alfo an alms-houfe for eight poor men and their wives, founded and endowed in 1659, by James Smith, efq. citizen of London. The number of inhabitants in Maidenhead, as returned to parliament in 1801, was 949, occupying 160 houfes: but either fome miftake was made in that enumeration, or the population has been rapidly on the increafe, for, in the year 1806, it amounted to 1100. At the eaftern extremity of the town is a large brick manfion, the feat of fir Ifaac Pocock, bart. Lyfons's Magna Britannia, vol. i. 4to. 1806.

Maidenhead, a fmall neat village of America, in Hunterton county, New Jerfey, fituated on the road between Princeton and Trenton; 6 miles from each, and having a Prefbyterian church: the townfhip contained, in 1790, 1032 inhabitants.

MAIDEN-LAND, a name given by fir Richard Hawkins, in 1594, to land which he difcovered in fteering towards the ftraits of Magellan, in honour of queen Elizabeth, and which, as he fays, lies "fome three-fcore leagues from the neareft part of South America." This land was afterwards found to be two large iflands by captain John Strong, of the Farewell, from London, who, in 1689, paffed through the ftrait which divides the eaftern from the weftern of thofe iflands. To this ftrait he gave the name of Falkland's Sound, in honour of his patron, lord Falkland; and the name has been fince extended, through inadvertency, to the two iflands that are feparated by it. See Falkland's *Iflands*.

MAIDHAT, a town of Perfia, in the province of Irak; 55 miles S.S.W. of Dainur.

MAIDSTONE, a borough and market-town in the hundred of that name, lathe of Aylesford, and county of Kent, England. It is beautifully fituated on the banks of the river Medway, whence it is fuppofed to have derived its name. The origin of this place is wholly uncertain. Camden, and fome others, have confidered it as the Vagniacæ of Antoninus, though upon very infufficient evidence. A few writers have alfo conjectured it to be the Caer Meguiad, or Megwad, mentioned in Nennius's Catalogue of Britifh Cities; but this opinion is equally doubtful with the former. The Saxons named it Medwegeftun, and it occurs in Domefday-book, by the appellation Meddeftane, of which terms its prefent name is an eafy and obvious corruption.

This town is a borough by prefcription, and the capital of the county of Kent. In ancient times it was governed by a portreve and twelve brethren. Edward VI., in the third year of his reign, formed it into a chartered corporation, by the ftyle of the "mayor, jurats, and commonalty;" and about the fame time members were firft returned from hence to ferve in parliament. The charter granted by this monarch was either renewed, or confirmed with additional privileges, by feveral fucceffive kings. By the laft charter, dated in 1748, the government was vefted in a mayor, twelve jurats, forty common council-men, a recorder, two ferjeants at mace, and other inferior officers. Freemen, not receiving alms, have the right of electing the burgeffes to parliament.

Maidftone extends about a mile in length, from north to fouth, and fomewhat more than three quarters in breadth, from eaft to weft. The principal portion of its buildings ftands on the eaftern bank of the river, by which it is watered, rifing gradually from its brink. It comprifes chiefly four principal ftreets, which interfect each other; with fome leffer ones branching off from them at right

nagles.

angles. The high ſtreet, in particular, is very ſpacious, and moſtly well-built. Every part of the town has been conſiderably improved within theſe few years. In 1791, an act of parliament was obtained for the purpoſe of having it new paved and lighted, and its different market-places repaired; which act has been carried into execution with great efficacy and judgment. The church, one of the largeſt parochial edifices in the kingdom, is a very handſome embattled building, conſiſting of a nave, aiſles, and chancel. It is adorned with a lofty embattled tower, which formerly ſupported a ſpire, but the latter was deſtroyed by lightning in November, 1730. The windows are large, and ornamented with rich tracery, particularly that facing the eaſt. By whom this church was firſt conſtructed, is uncertain; but it is well aſcertained to have been rebuilt by archbiſhop Courtney in the time of Richard II. from whom he obtained a licence to render it collegiate, for the uſe of the warden, chaplains, and other members of the new college, then building cloſe to the ſouthern ſide of the cemetery. This prelate was buried in the centre of the chancel, in a grave about five or ſix feet deep, whence his bones were diſcovered in 1794; but his monument has been long ſince deſtroyed. On the north ſide of the chancel ſtands a very ancient defaced tomb, raiſed in honour of one of the Woodvilles, anceſtors to king Edward IV.th's queen; and in the vaults within the communion-rails ſeveral of the ennobled families of Aſtley and Marſham lie buried. At the corner of Eaſt-lane is the priory, or friary, ſo called from having been anciently the houſe of a convent of Franciſcans, or Grey Friars, founded here by Edward III., but which was afterwards removed to Walſingham, in Norfolk. Faith's chapel, in the northern diſtrict of the town, appears to have been long uſed as a place of worſhip, but its hiſtory is very little known. The free grammar-ſchool is a foundation of conſiderable repute, ſome of the firſt literary characters in this country having been educated here. The ſchool-room, and part of the adjoining buildings, originally formed the chapel and lodgings of the "Fraternity of Corpus Chriſti," which was founded by a few of the inhabitants profeſſing the rule of St. Benedict. Beſides the free-ſchool, there are two charity ſchools, eſtabliſhed through the intereſt of the Rev. Dr. Joſiah Woodward; two ranges of alm-houſes, and a poor's-houſe, erected in 1720. The ſhire-hall, a good modern edifice, is appropriated to public buſineſs. The aſſizes for the county are held here, as are alſo the quarterly ſeſſions, and other county courts. Adjoining to this place is a priſon, called the *Brambles*, which anciently belonged to the archbiſhops of Canterbury, but now to the corporation. The gaol, in Eaſt-lane, erected in 1741, has ſince been much enlarged and improved. At the upper end of High-ſtreet is a conduit, which forms the chief reſervoir for ſupplying the inhabitants with water. Another building, of the ſame kind, alſo ſtood in the middle of this ſtreet previous to the year 1793, when it was pulled down. A new octagon ſtructure, in the lower part of the town, contains a third reſervoir. The water which ſupplies theſe reſervoirs is brought by pipes laid under the Medway, from an incloſed ſpring, called Rocky-hill, in the Weſt-borough. The theatre, ſituated on the weſt ſide of High-ſtreet, is a neat ſmall building. In Earl's-ſtreet is Earl's-place, a curious ancient ſtone manſion, having a large Oriel window, filled with painted glaſs, and at a ſhort diſtance beyond Week-ſtreet are very extenſive barracks, both for infantry and cavalry, the erection of which has greatly increaſed the population of the town.

Maidſtone has been long celebrated as the firſt hop-market in the kingdom. Some manufactures, however, are likewiſe carried on here. The linen trade, firſt eſtabliſhed by a few refugees from the Netherlands, in the reign of queen Elizabeth, ſtill continues to flouriſh. There are beſides many paper-mills in the immediate neighbourhood, an extenſive diſtillery of Engliſh ſpirits, or Maidſtone Geneva, and ſome very conſiderable beer and porter breweries. The circumſtance of the tide rendering the Medway navigable for veſſels of fifty or ſixty tons, contributes much to facilitate and encourage the trade of this town in all its departments.

The principal events of hiſtorical importance immediately connected with Maidſtone, are the rebellion of ſir Thomas Wyatt, and the battle fought here in 1648, between the Kentiſh loyaliſts and the parliamentary forces under general Fairfax, in which the former were defeated after a moſt ſanguinary conteſt. The plague has at different periods made great ravages here. A ſudden thaw, in January 1795, alſo occaſioned conſiderable damage, not only in the town but in the adjacent country. Here was a palace belonging to the archbiſhop of Canterbury, now demoliſhed.

The population of this town, according to the parliamentary returns of 1801, was eſtimated at 8027, *viz.* 3835 males, and 4192 females, of whom 5196 were returned as employed in various branches of trade, and 1306 in agriculture. The market days are Thurſday in every week, and the ſecond Tueſday of every month, when ſupplies of all kinds are abundant. The neighbourhood is adorned by a number of gentlemen's ſeats, ſpread throughout a fertile vale, where meadows, woodlands, rich orchards, and flouriſhing hop-grounds combine to exhibit a moſt extenſive variety of picturesque and romantic ſcenery. Gibraltar-houſe, on the oppoſite ſide of the river from the town, forms an agreeable place of reſort during the ſummer ſeaſon. The Mote, the ſeat of the earl of Romney, lying about a mile to the S.E. of the town, was anciently the reſidence of the Wyatt family, and forfeited upon the attainder of ſir Thomas by queen Mary. In the park, which is extenſive, is erected a pavilion, on the ſpot where his majeſty was entertained after the review of the Kent volunteers in 1799. Allington-caſtle, on the weſtern ſide of the river, is ſtill an intereſting ruin. It is ſaid to have been originally erected in the time of the Saxons by the noble family of the Columbavii, but being razed by the Danes, was rebuilt by the great earl Warrene. It was ſome time alſo the property of the Wyatts, and afterwards of the Aſtleys. The chapel, a ſmall gloomy edifice, contains ſeveral monuments in honour of the latter family. Newton's Hiſtory and Antiquities of Maidſtone, 8vo. Haſted's Hiſtory, &c. of Kent, 4 vols. folio, and 12 vols. 8vo. Alſo, Beauties of England and Wales, vol. vii.

Maidstone, a townſhip of America, in Eſſex county, Vermont, on Connecticut river, containing 152 inhabitants.—Alſo, a townſhip of Upper Canada, between Sandwich and Rocheſter, upon lake Erie.

MAJESTY, Majestas, a title or quality given to kings; and which frequently ſerves as an appellation to diſtinguiſh them by.

The word ſeems compoſed of the two Latin words, *major*, *greater*, and *ſtatus*, *ſtate*.

The emperor is called, his Cæſarian or Imperial majeſty; the king of Spain, his Catholic majeſty; the king of France, formerly, his moſt Chriſtian majeſty; the king of Great Britain, his Britannic majeſty, &c. Some have alſo extended this title to the popes.

Paſquier obſerves, that our forefathers uſed this quality very ſparingly; and that the frequent uſe of the word, which now obtains, had not its beginning before the reign of their Henry II. He inſtances ſeveral letters of St. Gregory.

gory, who, writing to king Theodoret and Theodoric, only compliments them with excellency.

Till the time of Charles V. the king of Spain had no title, but that of highneſs; Louis XI. was the firſt in France who aſſumed this title; and before our king Henry VIII. the kings of England were only addreſſed under the titles of grace, which began in the time of Henry IV., and excellent grace, under Henry VI., and highneſs. See King.

At the peace of Munſter, there was a great conteſt between the miniſters of the emperor and thoſe of France; the firſt would not allow the title of ſerenity to the king of France, and the latter would not give that of majeſty to the emperor. At laſt it was agreed, that whenever the French king ſhould write with his own hand to the emperor, he ſhould give him the title of imperial majeſty; and reciprocally, when the emperor ſhould write to the king, he ſhould give him that of royal majeſty.

Under the Roman republic, the title majeſty, *majeſtas*, belonged to the whole body of the people, and to the principal magiſtrates; ſo that to diminiſh or wound the majeſty of the commonwealth, was to be wanting in reſpect to the ſtate, or to its miniſters. But the power afterwards paſſing into the hands of a ſingle perſon, the appellation of majeſty was transferred to the emperor, and the imperial family. Pliny compliments Trajan on his being contented with the title of greatneſs; and ſpeaks very invidiouſly of thoſe who affected that of majeſty. And yet majeſty ſeems to be the moſt modeſt and juſt title that can be attributed to ſovereigns, ſince it ſignifies no more than the royalty, or ſovereign power.

MAIEUL, St., *Regular Clerks of.* See Fathers *of Somaſquo.*

MAIG, in *Geography*, a river of Ireland, in the county of Limerick, which riſes in the Galtees, croſſes the county, and falls into the Shannon, ſome miles below Limerick.

MAIGNAN, Emanuel, in *Biography*, an able philoſopher and mathematician, was born at Toulouſe in the year 1601. He gave early indications of an inquiſitive diſpoſition and an inclination for learning. He went through a courſe of grammar-learning at the college of the Jeſuits; here he ſpent his vacant hours in improving his mind, and at eighteen years of age he determined to renounce the world, and was admitted into the fraternity of the Minims. In ſtudying philoſophy, he became diſſatisfied with the principles of Ariſtotle, and took every opportunity of expoſing them to contempt. He took delight in inventing and ſolving geometrical problems, which he could do with eaſe and accuracy, though at this time he had never ſeen the Elements of Euclid, nor any other book written with the ſame view. When his mathematical acquirements were diſcovered, he was immediately appointed by his ſuperiors to the mathematical chair, which he filled with ſuch addreſs and judgment, that his reputation ſoon ſpread beyond the boundaries of his own country. He obtained higher preferment, and rendered himſelf diſtinguiſhed by his mathematical diſcoveries and phyſical experiments, which extorted the applauſe and admiration of thoſe who were moſt converſant in thoſe ſciences. A circumſtance that contributed to extend the fame of his learning, was a conteſt which aroſe between him and father Kircher concerning an invention in optics. In 1648, Maignan printed at Rome his treatiſe "De Perſpectiva Horaria," which met with a very favourable reception, and which contains a method of making teleſcopes, invented by himſelf, which he fully explains without any attempt at myſtery or diſguiſe. In the year 1650, Maignan returned from Rome to Toulouſe, and was created provincial, and in 1652 he publiſhed, in Latin, his "Courſe of Philoſophy," in four volumes, octavo, by which he might be conſidered as the reſtorer of it. When this work appeared, the adherents to the Ariſtotelian ſyſtem inſiſted that it was impoſſible to reconcile the author's opinions with the truths of religion. This objection Maignan undertook to refute, in a work entitled "Philoſophia Sacra." In 1657 he was choſen to ſupply the place of father Merſenne, in a ſociety of learned men, who held their meetings at the houſe of Henry Lewis de Montmort, maſter of the requeſts.' In 1660, when Lewis XIV. paſſed through Toulouſe on his return from his marriage, he viſited the cell of father Maignan as one of the moſt curious objects in the province. The monarch was ſo ſtruck with what he ſaw, that he was deſirous of tranſplanting the venerable father to his capital, but he had higher objects in view than to ſhine in courts; he was ſeeking after truth, and endeavouring to enlarge the boundaries of ſcience, and preferred the obſcurity of a cloiſter to the ſplendour attached to a palace. In 1662, father Maignan publiſhed the firſt volume of his "Philoſophia Sacra," which drew him into a long controverſy with ſeveral learned opponents, of which a full account is given by Bayle. In 1672 he publiſhed replies to all his antagoniſts, and in the ſame year he gave the world the ſecond volume of his "Philoſophia Sacra," which was followed by a diſſertation "De uſu licito Pecuniæ." Theſe literary labours did not prevent him from reading lectures to his pupils, and ſuperintending the inſtruction of the younger members of his order. Beſides this he was engaged in an extenſive correſpondence with the principal philoſophers of his own age. Scarcely was any man more induſtrious than Maignan: to uſe the expreſſion of one of our countrymen, it might be ſaid, that "Leiſure and he had taken leave of one another" from an early period of his life. He is ſaid to have ſtudied in his ſleep; for in his dreams he was often employed on ſome theorems, the deductions of which he purſued till he arrived at their demonſtration; and he was often ſuddenly awakened by the exceſſive pleaſure which he felt in ſuch diſcoveries. He died at Toulouſe in 1676, in the ſeventy-fifth year of his age. The innocence of his life, the ſimplicity of his manners, and his amiable virtues, rendered him no leſs the object of eſteem, than he was of reſpect, on account of his genius and learning. Bayle. Moreri.

MAIHERGA, in *Geography*, a town of Africa, in Sahara; 100 miles S.S.E. of Algiers.

MAII Inductio, in *Antiquity*, denotes an ancient cuſtom for the prieſt and people of country villages to go in proceſſion to ſome adjoining wood on a May-day morning; and return with a May-pole, boughs, flowers, garlands, and other tokens of the ſpring. This May-game, or rejoicing at the coming of the ſpring, was for a long time obſerved, and ſtill is in ſome parts of England; but it was condemned and prohibited in the dioceſe of Lincoln by biſhop Groſthead.

MAJIR, in *Geography*, a town of Africa, in Biledulgerid. N. lat. 33° 30′. E. long. 6° 29′.

MAIL, Maille, is primarily applied to the meſhes or holes in net-work.

This term in heraldry originally expreſſed the meſh of a net, and is derived from *macula*, Lat. or *maſcle*, Fr. ſignifying the ſame. Richlet ſays, *mailler* is uſed as a verb neuter, to expreſs the art of netting. Some derive it from the Iriſh word *mala*, ſaid to ſignify armour; or the word *mail*, which in Welſh properly means ſteel, and metaphorically hardneſs and armour. (See Rowland's Mona Antiqua.) Boyer in his French Dictionary tranſlates the word *maille*, a little iron ring.

Mail,

MAIL, *Black.* See BLACK *Mail.*

MAIL, *Coat of.* See COAT *of Mail.*

It is called alfo an *Habergeon;* which fee.

Anciently they alfo wore fhirts of mail under the waiftcoat, to ferve as a defence againft fwords and poniards. We alfo read of gloves of mail.

Of mail there are two forts, *viz.* chain and plate mail. Chain mail is formed by a number of iron rings, each ring having four others inferted into it; the whole exhibiting a kind of net-work, with circular mefhes, every ring feparately rivetted. This kind of mail anfwers to that worn on the ancient breaft-plates; whence they were denominated "loricæ hammatæ," from the rings being hooked together. Thus, "Loricam confertam hamis, auroque trilicem," Virg. Æn. l. iii. v. 67. Plate mail confifted of a number of fmall laminæ of metal, commonly iron, laid one over the other, like the fcales of fifh, and fewed down to a ftrong linen or leathern jacket, by thread paffing through a fmall hole in each plate. This was exactly the form of the ancient "lorica fquammofa." Similar to this is the Sarmatian cuiraffe (fee CUIRASSE), defcribed by Paufanias, as quoted by Lipfius and Montfaucon. They take the hoofs of their horfes, which they cleanfe and polifh, and then cut in little pieces like dragon's fcales; which done, they bore the fcales, and afterwards few them with the finews of an ox or horfe: the dragon's fcales refemble the divifions in a pine-apple when it is green. Thus they make their cuiraffes, which, for beauty and ftrength, are not inferior to thofe of the Gauls, for they very well fuftain both diftant and clofe blows; whereas the cuiraffes of linen are not fo fure, nor proof againft iron. The linen ones are commodious for hunters, as the lions and leopards cannot penetrate them with their teeth. The cuiraffe covered the body before and behind: it confifted of two parts, a breaft and back piece of iron, faftened together by means of ftraps and buckles, and other fimilar contrivances. They were originally, as the name imports, made of leather, but afterwards of metal, both brafs and iron. To the cuiraffe was buckled the armour for the fhoulders and arms; the firft called "pouldrons," the fecond "braffarts," garde bras, les avant bras, and corruptly in Englifh "vambraces." At the joint or bending of the arm, the vambraces were cut obliquely; the vacancies on the infide, when the arms were ftraightened, were covered by pieces of mail called "gouffets," and afterwards by a contrivance of plates refembling hearts. Cuiraffes with entire fleeves of mail are mentioned by different military writers. A defence for the arms, called "fplints," conftituted part of the fuit denominated an "almaine ryvett." The hands were defended by gauntlets, fometimes of chain mail, but more frequently of fmall plates of iron, rivetted together; in imitation of the lobfter's tail, fo as to yield to every motion of the hand. Some gauntlets inclofed the whole hand, as in a box or cafe; others were divided into fingers, each finger confifting of eight or ten feparate pieces, the infide being gloved with buff leather: fome of thefe reached no higher than the wrift, others to the elbow; the latter were ftyled long-armed gauntlets, many of which are to be feen in the Tower of London. The thighs of the cavalry were defended by fmall ftrips of iron plate, laid horizontally over each other, and rivetted together, forming what were called "cuiffarts," or thigh pieces: of thefe fome entirely enclofed the thighs, and others only covered the front of them, the infide next the horfe being unarmed. They were made flexible at the knees by joints, like thofe in the tail of a lobfter, and were called "genouillieres," or knee-pieces. Taffets, or fhirts, hooked on to the front of the cuiraffe, were ufed by the infantry. For the defence of the legs were worn a fort of iron-boots, called "greeves." Plates of iron covering the front of the leg were alfo frequently worn over the ftockings of mail. The greeves commonly covered the whole leg, as in the armour of John of Gaunt, and that of Henry VIII.; with thefe they had broad-toed iron fhoes, with joints at the ankle; fometimes they had fabatons of mail. Boots of jack-leather, called curbouly (cuir bouille), were alfo worn by horfemen: thefe are mentioned by Chaucer. The "hauberk" was a complete covering of mail from head to foot. It confifted of a hood, joined to a jacket with fleeves, breeches, ftockings, and fhoes, of double chain mail, to which were added gauntlets of the fame conftruction. Some of thefe hauberks opened before like a modern coat; others were clofed like a fhirt. In France only perfons poffeffed of a certain eftate, called "un fief de hauber," were permitted to wear a hauberk, which was the armour of a knight; efquires might only wear a fimple coat of mail, without the hood and hofe. The "haubergeon" was a coat compofed either of plate or chain mail, without fleeves; the fhirt of mail was much in the form of the fhirts now worn, except that it had no fleeves: it was always of chain mail. Grofe's Mil. Antiq. vol. ii. See ARMOUR.

MAIL, or *Mall,* alfo fignifies a round ring of iron; whence the play of pall-mall, from *palla,* a ball, and *maille,* the round ring on which it is to pafs.

MAIL is likewife ufed for the leathern bag in which letters are carried by the poft.

MAIL-*Coach,* a carriage particularly and exprefsly appropriated for the conveyance of letters to all parts of Great Britain. It is diftinguifhed for its expedition and fecurity; two moft important confiderations in a populous, commercial, and wealthy country. Previous to the year 1784, letters were conveyed from the metropolis to diftant parts of the kingdom, and *vice verfâ,* by carts with a fingle horfe to each, or by boys on horfeback; in confequence of which, many robberies were committed, delays occafioned, and loffes fuftained. John Palmer, efq. afterwards comptroller-general of the poft-office, devifed a new plan, which he recommended to government, as calculated to increafe the revenue, accommodate the public, and be highly advantageous to all parties. His propofal was acceded to, and the inventor has been rewarded with a large annual income. His plan was to provide a certain number of coaches, of light conftruction, and each to be adapted to carry the various bags or packets of letters, which were deftined for a particular part of the country, or line of road. All the coaches were to leave London precifely at 8 o'clock in the evening, and to arrive at and leave certain poft-towns at fpecific times. Each coach is drawn by four horfes, travels at the rate of eight miles an hour, including the time allowed for change of horfes, &c; and each coach is provided with a coachman, a guard with fire-arms, and allowed to carry four paffengers infide, and two outfide. The prefent fare (1812) is about *6d. per* mile for each of the former paffengers, and *4d.* for the latter. The fyftematic regularity, punctuality, fuperior fafety, and expedition of the mail-coaches of England render them peculiarly eligible and convenient for travellers. The property and profits of the poft, or conveyance of letters, are vefted in government, which contracts with the proprietors of coaches for the carriage of the mail; but thefe proprietors derive their chief profit from the fare of paffengers, and carriage of fmall packets. The mail-coach eftablifhment is under the fuperintendance of T. Hafker, efq. For further particulars, fee POST *Office.* The mail-coaches run above 13,000 miles daily. There is a fimilar eftablifhment in Ireland.

MAILAH, in *Geography*, a river of Africa, which rifes in the Sahara, and difcharges itfelf into the Shott.

MAILCOTTA, or MILGOTTAH, a town of Hindooftan, in the Myfore; where the Mahratta chiefs met lord Cornwallis in the year 1791; 15 miles N. of Seringapatam.

MAILED, implies a thing fpeckled, or full of fpecks; as the feathers of hawks, partridges, &c. or the furs of fome wild beafts.

MAILLA, JOSEPH-ANNE-MARY DE MOYRIAC DE, in *Biography*, a Jefuit miffionary, was born at Maillac, and, having been educated by the fociety, was fent on the miffion to China in 1703. He was employed by the emperor Kam-hi, with other miffionaries, to make the map of China and Chinefe Tartary, which was engraved at Paris. He afterwards made particular maps of feveral of the provinces. Being fixed at the imperial court, he had accefs to the "Great Annals of China," which he tranflated into French, and fent over his MS. to France, where it was partly printed, and intended to make 12 volumes 4to. This work forms the moft complete hiftory of the Chinefe empire. Mailla died at Pekin in 1748, in his 79th year, after a refidence of 45 years in China. His remains were interred at the expence of the emperor Kien-Long.

MAILLE, in the *French Coinage*, denotes a fmall weight ufed for gold and filver, 40 of which are equal to the ounce, or one-eighth of the mark = 3778 Englifh grains.

MAILLE, in our *Old Writers*, a fmall kind of money. Silver half-pence were likewife termed mailles, 9 Hen. V. By indenture in the mint, a pound weight of old fterling filver was to be coined into three hundred and fixty fterlings, or pennies, or feven hundred and twenty mailles, or halfpennies, or one thoufand four hundred and forty farthings. Hence the word maille was derived, which is now vulgarly ufed in Scotland to fignify an annual rent. Hence *white maille*, white rents, (vulgarly called quit-rents,) were rents made in filver; and *black maille* denoted properly rents paid in cattle, otherwife called *neat gelt;* but more largely it was ufed to fignify all rents not paid in filver. See BLACK *Maile*.

MAILLET, BENEDICT DE, in *Biography*, born of a good family of Lorraine in 1659, was nominated, at the age of thirty-three, conful-general of the French nation in Egypt: after which, he obtained the confulate of Leghorn. In 1715 he was appointed to vifit all the factories of Barbary and the Levant; and executed his commiffion fo much to the fatisfaction of the government, that he obtained leave to retire with a penfion He died at Marfeilles in the year 1738. He had, during his whole life, been a diligent ftudent of natural hiftory, which his lively fancy turned into fyftem, which for fome time interefted the public. He maintained that all the land of this earth, and its vegetable and animal inhabitants, rofe from the bofom of the fea, on the fucceffive contractions of the waters: that men had originally been tritons with tails; and that they, as well as other animals, had loft their marine, and acquired terreftrial forms, by their agitations when left on dry ground. The work was publifhed after the death of its author, by La Mafcrier; who alfo publifhed, in 1743, "A Defcription of Egypt," drawn up from the papers of De Maillet.

MAILLEZAIS, in *Geography*, a town of France, in the department of the Vendée, and chief place of a canton, in the diftrict of Fontenay-le-Comte; 6 miles S. of Fontenay. This was once the fee of a bifhop, fince removed to Rochelle. The place contains 135 , and the canton 12,622 inhabitants, on a territory of 200 kiliometres, in 13 communes.

MAILLS, on *Ship-board*, are fquare machines, compofed of a number of rings interwoven net-wife, and ufed for rubbing off the loofe hemp which remains on lines or white cordage, after it is made.

MAIMATSCHIN, in *Geography*, a Chinefe frontier town, or village, on the confines of Siberia, oppofite to *Kiakta*, which fee. Its name denotes the "fortrefs of commerce." It is fituated about 140 yards S. of the fortrefs of Kiakta, and nearly parallel to it. Midway between this place and the Ruffian fortrefs, two pofts about 10 feet high are painted, in order to mark the frontiers of the two empires; one is infcribed with Ruffian, the other with Manfhur characters. Maimatfchin is fortified with a wooden wall, and a fmall ditch about three feet broad; the latter having been dug in the year 1756, during the war between the Chinefe and Kalmucs. The town is of an oblong form; its length is 700 yards, and its breadth 400. On each of the four fides a large gate faces the principal ftreets; and over each of thefe gates is a wooden guard-houfe for the Chinefe garrifon, which confifts of Mongols in tattered clothes, and armed with clubs. Without the gate, which looks to the Ruffian fortrefs, at the diftance of about eight yards from the entrance, the Chinefe have raifed a wooden fconce, fo as to interrupt all view of the ftreets from without. This town contains 200 houfes, and about 1200 inhabitants. Its two principal ftreets, about eight yards broad, crofs each other in the middle at right angles, with two by-ftreets running from north to fouth. They are not paved, but laid with gravel, and kept very clean. The houfes are fpacious, uniformly built of wood, and of only one ftory, about 14 feet, in height: they are plaiftered and white-wafhed; they are conftructed round a court-yard of about 70 feet fquare, which is ftrewed with gravel, and appears neat. Each houfe confifts of a fitting-room, fome warehoufes, and a kitchen. The windows are large, and, on account of the dearnefs of glafs and Ruffian talc, are generally of paper, excepting a few panes of glafs in the fitting-room. The afpect of the fitting-room is feldom towards the ftreets: it is a kind of fhop, in which the feveral patterns of merchandize are placed in receffes, fitted up with fhelves, and fecured with paper doors for the purpofe of keeping out the duft. In this room there are feveral niches, covered with filken curtains, before which are placed lamps, that are lighted upon feftivals: thefe niches contain painted paper idols, a ftone or metal veffel, in which the afhes of incenfe are collected, feveral fmall ornaments, and artificial flowers. The fouth-weft quarter of the town is inhabited by the merchants of Bucharia, who bring to Ruffia cotton, ftuffs and half-filks, fpun and raw cotton, lamb-fkins, precious ftones, gold duft, unprepared nitre, fal ammoniac, &c. The governor of Maimatfchin has the care of the police, as well as the direction of all affairs relating to commerce: he is generally a perfon of rank, often a mandarin, who, having been guilty of mifconduct in fome other ftation, is fent here by way of punifhment. His power is confiderable; and though his falary is not large, the prefents he receives annually from the merchants amount to a confiderable fum. The moft remarkable public buildings in Maimatfchin are the governor's houfe, the theatre, and two pagodas. In the fmall pagoda is a picture reprefenting the god Tien, which, according to the explanation of the moft intelligent Chinefe, fignifies the moft high God, who rules over the 32 heavens. He is reprefented in a fitting pofture, with his head uncovered, and encircled with a ray of glory; holding in his right hand a drawn fword, and extending his left as in the act of giving benediction. On one fide of this figure are two youths; on the other a maiden and a grey-headed old man

man are delineated. In this temple there are no altars: it is opened only on feſtivals, and ſtrangers cannot ſee it without a ſpecial order. The great pagoda, which is larger and more magnificent than the former, is acceſſible to all ſtrangers, under the conduct of a prieſt. We cannot here deſcribe in detail the various parts of this ſtructure: the temple, which is an elegant Chineſe building, and richly decorated, contains five idols of a coloſſal ſtature, filling the whole northern ſide. The principal idol is denominated "Ghedſur," or "Gheſſur Chan;" his ſize is gigantic, and his face gliſtens like burniſhed gold; on his head he has a crown, and his garments are made of the richeſt ſilk; in his hand is a tablet, to which he directs a ſteady attention. Two ſmall female figures, reſembling girls about 14 years of age, ſtand on each ſide of the idol. The other idols are of an enormous ſize, though leſs in magnitude than Gheſſur Chan. Tapers and lamps are kept burning day and night before the idols. There are various utenſils in the temple, marked with Chineſe devices and inſcriptions; and, among others, a hollow wooden black lacquered helmet, which all devout perſons ſtrike with a wooden hammer, whenever they enter the temple. The firſt day of the new and full moon is appointed for the celebration of worſhip, upon each of which days no Chineſe ever fails to make his appearance once in the temple. Their principal feſtivals are held in the firſt month of the year, called the white month, and anſwering to our February. Mr. Pallas has given us the following deſcription of their ſuperſtitious behaviour during an eclipſe of the moon. At the cloſe of the evening in which it appeared, all the inhabitants were employed in raiſing an uproar, by hideous ſhrieks, knocking wood, and beating cauldrons; which noiſe was heightened by ſtriking the bell and beating the kettle drums of the great pagoda. The Chineſe ſuppoſe, that during an eclipſe the wicked ſpirit of the air is attacking the moon, and that he is frightened away by theſe hideous ſhrieks and noiſes. When a fire occurred at Maimatſchin, none of the inhabitants attempted to extinguiſh it, but ſtood round it in idle conſternation, occaſionally ſprinkling water on the flames, in order to ſoothe the fire god, who, as they imagined, had choſen theſe houſes for a ſacrifice.

The merchants of Maimatſchin come from the northern provinces of China, chiefly from Peking, Nanking, Sandchue, and other principal towns. They come hither without their wives and families; for there is not one woman at Maimatſchin. This circumſtance is owing to the policy of the Chineſe government, which totally prohibits women from having the ſlighteſt intercourſe with foreigners. For the mode of carrying on commerce between the Chineſe and Ruſſians, and the principal articles which they mutually exchange, we refer to the article KIAKTA.

MAIMBOURG, LEWIS, in *Biography*, an eccleſiaſtical hiſtorian, was born at Nancy, in France, in the year 1610. When ſixteen years of age he was entered in the ſociety of Jeſuits, and ſoon became a teacher of the claſſics in their ſchools. He was much celebrated afterwards as a preacher, though he has been generally charged with introducing into the pulpit low and vulgar deſcriptions, and ſallies of wit, or even buffoonery, highly unbecoming his ſacred office. As a writer, as well as a preacher, he was perpetually attacking the Janſeniſts, and in 1682 he wrote a treatiſe againſt the pretenſions of the church of Rome, and in ſupport of the liberties of the Gallican church: on account of this he was ordered by pope Innocent XI. to be expelled the ſociety. For this diſgrace, the king made him ample recompence by the grant of a penſion, on which he retired to the abbey of St. Victor at Paris, where he died in 1686, at the age of ſeventy-ſix. He was a very voluminous writer; his hiſtorical productions originally formed ſixteen volumes, in 4to.; they conſiſt of "The Hiſtory of the Cruſades;" "The Hiſtory of the League;" "The Hiſtory of the Decline of the Empire after Charlemagne;" "The Hiſtories of the Pontificates of St. Gregory the Great, and of Leo;" "The Hiſtory of the Schiſm of the Greeks; and of the Schiſm in the Eaſt;" "The Hiſtories of Arianiſm; of the hereſy of the Iconoclaſts; of Lutheraniſm; and of Calviniſm." Bayle. Moreri.

MAIMONIDES, MOSES, or Moſes the ſon of Maimon, a Jewiſh rabbi, was born at Cordova, in Spain, in 1131. He has, by way of eminence, been called "The Doctor," and "The Eagle of the Doctors." He was, in every ſenſe of the term, deſcended from illuſtrious anceſtors, ſix of his anceſtors having been diſtinguiſhed by the title of wiſe. The early part of his education was undertaken by his father; who in due time provided him tutors from the moſt learned men of his age. He poſſeſſed very ſuperior abilities, and made a rapid progreſs in all the branches of knowledge to which his attention was directed. He was perfectly ſkilled in the Hebrew, Arabic, Chaldee, Turkiſh, Median, and other languages. With all the branches of philoſophy and the mathematics he was intimately acquainted, and alſo with Jewiſh juriſprudence, as is evident, not only by the comments with which he illuſtrated the whole body of laws of the Hebrews, but by the ability and judgment with which, from a confuſed and moſt intricate maſs, clothed in corrupt and varying dialects, he reduced them to a regular ſyſtem, written in pure Hebrew, and in an eaſy and elegant ſtyle. He likewiſe acquired a profound knowledge of the medical art, in the practice of which he attained the higheſt reputation. His very extraordinary talents and accompliſhments in almoſt every ſpecies of learning excited the jealouſy of his contemporaries; to avoid the ill effects of this, he reſolved to quit Spain, and remove into Egypt, before he was thirty years of age. From this circumſtance, and from his reſiding in that country during the remainder of his life, he is, by ſome writers, called "Moſes Ægyptius;" by others he is named "Moſes Cordubenſis," from the place of his birth. In Egypt he opened a ſchool, to which a number of pupils reſorted from all parts, and particularly from Alexandria and Damaſcus, who made ſuch improvement under his inſtructions, that they proved the means of ſpreading his fame throughout the world. He was appointed phyſician to Saladin, ſultan of Egypt, who entertained for him the higheſt reſpect. His reputation was ſo great that he was applied to for advice and counſel by perſons of the very firſt rank. Among others, the rabbi Aben Tybbon, wiſhing for a ſolution of ſome ſerious difficulties, on important points, propoſed to pay him a viſit, that they might diſcuſs the matters at length in converſation. To which Maimonides replied, that nothing would afford him greater pleaſure than ſuch an interview: nevertheleſs he could not encourage him to undertake ſo long a voyage, becauſe his own time was ſo fully occupied, that he could ſcarcely promiſe him his company for a ſingle hour, either in the day or at night: "I live," ſaid the learned doctor, "in Egypt, at the diſtance of nearly two ſabbath-days' journey from Al-Cairo, where the king reſides. On him the duties of my appointment require a very regular attendance. I generally viſit him every morning; but when either himſelf, or any of his children, or of his concubines, are ſick, I am not allowed to ſtir from the palace, ſo that I very often ſpend the whole day at court: if I find nothing amiſs at court, I return home towards noon, but when arrived at my houſe, almoſt famiſhed for want of food, I find all the approaches to it crowded

with

with Gentiles and Jews, men of all ranks who have been impatiently waiting my return. No fooner have I alighted from my horfe, and wafhed my hands, than I humbly requeft the indulgence of the multitude till I have appeafed my craving appetite. As foon as I have dined, I examine the cafes of my patients, and prefcribe for them. This employment commonly lafts till night, when I am fo overcome with the fatigue of hearing, fpeaking, and prefcribing, that I can fcarcely fpeak any longer, or even keep myfelf awake." Maimonides, after having fpent a long and moft ufeful life, died at the age of feventy, in the 1204th year of the Chriftian era, and was interred, with the higheft funeral honours, in the land of Canaan. For three whole years did the people at large bewail his death, and they called the year in which it took place, "Lamentum Lamentabile;" and in fpeaking of him, they ufed to fay, that from the time of Mofes the prophet, no one approached fo nearly to him in wifdom and found learning, as Mofes the fon of Maimon. He is frequently defignated in the writings of the Jews by the name of Rambam, the confonants of which are the initials of the words Rabbi Mofes Ben Maimon. Notwithftanding his avocations as a phyfician, he devoted much of his time to the compofition of learned works, a few of which may be mentioned: the firft, in the order of time, was his "Pirufh Hemifhnah," or, a commentary on the Mifhna, which he began in Spain, when he was in the twenty-third year of his age, and finifhed in Egypt, when he was about thirty. It was written in the Arabic language, and tranflated into Hebrew by Rabbi Aben Tybbon. The beft edition of this work is publifhed with the Mifhna, at Amfterdam, in 1698, in 16 volumes, folio. The prefaces were publifhed in Arabic, but in the Hebrew characters by our countryman Dr. E. Pococke, under the title of "Porta Mofis," in the year 1655. The next work to be noticed is entitled "Jad Chazekeh," or *Strong Hand*, which is alfo named "Mifhna Hathora," or *The Reception of the Law;* it confifts of a compendium of the *Talmud*, which fee, and prefents a complete code of Jewifh, civil, and canon law, with a commentary. The beft edition is that of Amfterdam, in 1702, in four volumes, folio. The principal work of this great man is entitled "More Nevochim," or *Guide to the Perplexed*, which is partly critical, partly philofophical, and partly theological; its defign being to illuftrate and explain the meaning of the fcriptures. It was tranflated from the Arabic into Hebrew by R. Aben Tybbon, in the year 1551, and publifhed at Venice; Buxtorf the younger gave an excellent verfion of it in the Latin tongue, which was publifhed at Bafil in 1629. Another important work of Maimonides is his "Sepher Hamitzoth," or *Book of Commandments*, containing an expofition of the precepts of the Mofaic law. The titles of the other pieces of Maimonides may be feen in Wolfii Biblioth. Heb.

MAIN, East, or *Slude river*, in *Geography*, a river of Canada, which runs into James bay. N. lat. 52° 18'. W. long. 78 45'. On the eaft of this river is *Eaft Main Houfe*, a ftation for the Indian trade in Canada. N. lat. 52° 15'. W. long. 78° 42'.

Main, a town of Perfia, in the province of Farfiftan; 14 leagues N. of Schiras; the inhabitants of which being defcendants of the ancient Spartans, have never yet been conquered by the Turks.

Main, *Chief*, or *Principal*. Thus the main-maft is denominated, in contradiftinction to the fore or mizen-maft: the main-keel, main-wales, main-hatchway, main-breadth, &c. are thus diftinguifhed from the falfe-keel, channel-wales, and the fore and after hatchways. The main breadth is the broadeft part of the fhip, and is contained between the upper and lower heights of the breadth lines.

Main-*body of an army*, is the body of troops that marches between the advance and the rear guard. In a camp it is that part of an army which is encamped betwixt the right and left wings.

Main-*guard*. See *Great* and *Main* Guard.

Main *Harmonique*, Fr. See Harmonic-*Hand*, Hexachords, and Solmisation.

MAINA, in *Geography*, a fea-port town of the Morea, near the W. coaft; 30 miles S. of Mifitra.

MAINBAYA, a town of Ava; 15 miles N. of Prome.

MAINBURG, a town of Germany, in the circle of Bavaria, on the Ambs; 32 miles N.N E. of Munich.

MAINE, a divifion of France, before the Revolution, which was divided into Upper and Lower Maine; about 18 miles long and 20 broad. It now chiefly forms the departments of the Mayenne and Sarte.—Alfo, a river of Germany, which rifes in the marquifate of Culmbach, on the confines of Bohemia, and after paffing by a number of principal towns, joins the Rhine, a little above Mentz.

Maine, a diftrict or province of the United States of America, belonging to the Maffachufetts, bounded on the N. by Lower Canada, E. by the province of New Brunfwick, S. by the Atlantic ocean, W. by New Hampfhire, from which it is partly feparated by the Pifcataqua river, and fituated between N. lat. 43 and 48 15', and between W. long. 64° 53', and 70° 39'. Its average length and breadth are each 200 miles; and it contains 40,000 fquare miles, or 25,600,000 acres. The diftrict of Maine is divided into feven counties, as in the following table.

Counties.	No. of Inhabitants. 1700.	1800.	Chief Towns.
York	28,821	37,729	York.
Cumberland	25,459	37,921	Portland, the metropolis of the diftrict.
Kennebeck	——	24,394	Augufta.
Lincoln	29,962	30,100	Wifcaffet.
Hancock	9,549	16,316	Caftine.

The chief rivers of this diftrict are Penobfcot, Kennebeck, Saco, Androfcoggin, St. Croix, &c. The moft noted lakes are Moofehead, Scoodri, Sebacook, and Umbagog. The principal bays are thofe of Cafco, Penobfcot, Machias, Saco, and Paffamaquoddy. Its moft remarkable capes are thofe of Neddock, Porpoife, Elizabeth, Small Point, Pemaquid, and Petit Manan. Almoft the whole coaft N.E. of Portland is lined with iflands, among which veffels may generally anchor with fafety. This diftrict, though an elevated country, cannot properly be denominated mountainous. The foil is generally arable and very fertile, more efpecially between Penobfcot and Kennebeck rivers. On fome parts of the fea-coaft the lands are but indifferent; but they might be much improved by manuring them with the rock-weed, which grows on the rocks between high and low water mark, in very large abundance. The fwamps and funken lands might be eafily drained, and afford a rich fat foil. The foil of the interior country is reprefented as being excellent, and well adapted both for tillage and pafture. Where the foil is properly prepared for receiving the feed, it is faid to be favourable for the growth of wheat, rye, barley, oats, peas, hemp, and flax, and for the production of almoft all kinds of culinary roots and plants, Englifh lish grafs, and alfo for Indian corn of fhort ftalk. Kennebeck is much improving in apple-orchards. Hops are the fpontaneous growth of the country. Peaches are fcarcely known; but plums, fmall cherries, fmall pears, grapes, rafpberries, goofeberries, currants, blackberries, and cranberries, are among the wild fruits of Maine. This country is uncommonly good for grazing, and large ftocks of neat cattle may be fed in it both fummer and winter. It abounds in white pine and fpruce trees, fuitable for mafts, boards, or fhingles; and maple, beech, red, white, and grey oak, and yellow birch, may be confidered as the principal productions of the country. The moift land produces fir, which yields a balfam that is much prized. Here are alfo elms, poplars, and afh trees; alfo bafs, horn-beam, butter-nut, balm of Gilead, and hemlock trees. Upon the whole, the diftrict of Maine may be regarded in the three following divifions of it; the *firft*, comprehending the tract lying E. of Penobfcot river; the *fecond*, and beft tract, lying between Penobfcot and Kennebeck rivers; and the *third*, firft fettled, and at prefent moft popular, W. of Kennebeck river. The climate in this diftrict, as well as in every part of North America, is colder than is the fame degree of latitude on the eaftern fide of the Atlantic. The weather is more regular here in the winter than it is in the fouthern ftates. Frofts commence fometimes in September, and always before the middle of October; the fevere cold begins about the middle of December; and fpring opens in the clofe of March. Of late the winters in this country are more moderate, and lefs fnow has fallen than twenty years ago.

From the different rivers of this country water may be drawn for mills and all water works; and its rivers furnifh plenty and variety of fifh. The falmon fifhery, in the bays and around the iflands, has of late years become a confiderable object to the inhabitants. The animals of this diftrict were formerly deer, and moofe of a large fize; but there are now few to be feen. The fox, bear, wolf, beaver, &c. are found here. Cattle and horfes are eafily reared in this country; and the fheep, on the Kennebeck river, are larger than thofe in Maffachufetts proper, the mutton is of higher flavour, and the fleeces are much heavier. The rattlefnake is the only poifonous ferpent in this diftrict, and is rarely feen. Birds, though increafing, are not numerous.

The manufactures and commerce of this country are in an improving ftate. From the firft fettlement of Maine till the year 1774 or 1775, and even in fome places to a later period, the inhabitants neglected agriculture and generally followed the lumber trade; but when they found that Indian corn, rye, potatoes, and flax grew in their fields, and afforded an immediate profit, they applied to the cultivation of the foil; and they now raife a fufficient quantity of corn and other grain for their own confumption; and they export from the Kennebeck, either in cattle or other articles, more than they import. Their wool and flax are very good; hemp has been lately cultivated with fuccefs: and almoft every family manufacture wool and flax into cloth, and make utenfils of hufbandry fufficient for their own ufe. The principal exports of this country confift of various kinds of lumber, fuch as pine-boards, fhip-timber, and almoft every fpecies of fplit timber manufactured from pine and oak, which are exported from the various harbours in large quantities. Dried fifh alfo furnifhes an article of export, and alfo pickled fifh, fuch as falmon, fhad, &c. Mountain and bog-iron ore are found in fome parts, and works have been erected for its manufacture. A fpirit of literary improvement has been lately excited in this diftrict. Bowdon college in Brunfwick is in a profperous ftate. (See College.) Academies have been incorporated by the legiflature in Hallowell, Berwick, Fryeburg, Bath, Hamden, and Machias, and endowed with grants of the public lands; and another has been inftituted at Portland. Town fchools are alfo maintained in moft of the towns and in many of the plantations.

The people of this diftrict are diftinguifhed by no peculiar features from their neighbours in New Hampfhire and Vermont; but they are, like them, a brave, hardy, enterprifing, induftrious, hofpitable people. The prevailing religious denominations are Congregationalifts and Baptifts; and there are a few Quakers, Methodifts, Epifcopalians, and Roman Catholics. The remains of the Penobfcot tribe are the only Indians who refide in this diftrict: they confift of about 100 families, and live together in regular fociety, at Indian Old Town, which is fituated on an ifland of about 200 acres, on Penobfcot river, juft above the Great Falls. They are Roman Catholics, and conduct their worfhip in an orderly manner and without moleftation. The conftitution of Maine is the fame with that of the Maffachufetts, both being incorporated under one government. In the diftrict of Maine are large tracts of land belonging to the ftate, called the Eaftern lands. Of thefe lands the commonwealth have fold as much as has brought into the treafury a net balance of 269,005*l.* 8*s.* 2*d.* Exclufive of thefe lands, that have been fold, tracts for the encouragement of literature and other ufeful and humane purpofes have been granted to the amount of 431,000 acres.

The firft attempt to fettle this country was made in 1607, on the W. fide of Kennebeck river, near the fea: but this proving unfuccefsful, attempts for this purpofe were not renewed till between the years 1620 and 1630. In 1635 fir Ferdinando Gorges obtained a grant from the council of Plymouth of the tract of country between the rivers Pifcataqua and Sagadahfek or Kennebeck, and up Kennebeck fo as to form a fquare of 120 miles: and fir Ferdinando is fuppofed to have firft inftituted government in this province. In 1639 Gorges obtained from the crown a charter of the foil and jurifdiction, containing as ample powers as were ever granted by the king of England to any fubject. In this year he appointed a governor and council; and government was adminiftered in this form until the year 1652, when the inhabitants fubmitted to the Maffachufetts, and in 1691, by a charter from William and Mary, the province of Maine, and the large territory eaftward, extending to Nova Scotia, was incorporated with the Maffachufetts Bay; fince which time it has been governed and courts held as in other parts of Maffachufetts. Several propofals have been made for feparating this diftrict from the Maffachufetts; the laft was made in 1802; but the legiflature have not interfered in the bufinefs. Such, however, are the rapid fettlement and growth of this country, that the period when this contemplated feparation will take place, is probably not far diftant. Morfe's Geog.

Maine-*Port*, in *Ecclefiaftical Antiquity*, a fmall tribute, commonly of loaves of bread, which in fome places the parifhioners pay to the rector of their church, in recompence for certain tithes. Cowell.

MAINIS, in *Ichthyology*, a name ufed by Ariftotle, Athenæus, and others of the old Greek writers, for the fifh now called the *mana*, *menerela*, and *menola*. It is a fpecies of the fparus, and is diftinguifhed from all the other fpecies of that genus, by having four large teeth, and a variegated body, ornamented with a black fpot in the middle of the fides. This is the fifh the Narbons call *jafcle*. See Sparus *Mana*.

MAINLAND *of Shetland*, or *Zetland*, in *Geography*, the principal of the Shetland iflands, fituated in the Northern ocean.

ocean. It extends about fixty miles in length from north to fouth, and in fome places is upwards of twelve in breadth. The whole of this ifland may juftly be regarded as a feries of promontories, every part of it being interfected by fmall arms of the fea. Hence fcarcely a fpot is to be found more than three miles diftant from the fhore. The coaft is generally bold and rocky, but the numerous bays with which it abounds form fafe and commodious harbours for the fhipping which have occafion to frequent it. The interior prefents to the view many interefting fcenes, partaking both of the tranquil and of the wild. The latter, however, chiefly predominates; and while fpots of cultivated retirement are comparatively few, the romantic beauties of fimple nature are difplayed in abundance and variety. Numerous hills diverfify the face of the country, and traverfe it in different directions. Of thefe the moft lofty is called Rona's hill, or Mons Ronaldi, and is fituated in the parifh of North Maven. In the ftatiftical work of fir John Sinclair, it is ftated to rife 3944 feet perpendicularly above the level of the fea, but Dr. Edmonfton feems to think its height does not exceed 2000 feet, if indeed it is actually fo much. The view from the fummit of this hill in clear weather is fplendid and magnificent in the extreme. The clufter of iflands fcattered beneath, and curioufly divided by the ocean, afford a profpect infinitely diverfified and agreeable. On the higheft eminence there is a houfe conftructed of four large upright ftones, and two which ferve as a covering for the roof. It is called a watch-houfe, and was probably ufed in remote ages to give notice of any approaching danger. A pyramidal tower of fmall ftones is erected on the top of this hill, which is a land mark to the fifhers all round the country, and generally the firft land defcried by fhips if they fall to the weft of the ifland, as they approach it from the north.

The climate of the Mainland is extremely variable and damp, although by no means generally unwholefome to the inhabitants. Spring can fcarcely be faid to commence until April, and there is but little general warmth before the middle of June. The fummer ufually terminates with Auguft. Autumn is a very uncertain feafon, and winter commences as early as the beginning of October. The foil of Mainland is no lefs various than the climate. The arable land lies chiefly on the coaft, and bears but a fmall proportion to the wafte and uncultivated parts, though its productivenefs might be greatly increafed by labour and exertion. The only grains fown are a fpecies of barley, known by the name of beer or big, and a fmall kind of black or grey oats. Potatoes are raifed in confiderable quantity. The manure chiefly in ufe is fea weed, fometimes alone, but oftener mixed with earth or dung from the *byres*, or cow-houfes. Though lime-ftone is fufficiently abundant as well as the means of burning it, it is feldom employed. This is a matter of deep regret, as on thofe fpots where it has been tried, the increafe of fertility has much exceeded expectation. In confequence of this inattention of the natives to the management of their grounds, the vegetable products of the ifland are far from being adequate to its confumption. Hence the neceffity of importing confiderable quantities of grain from other more prolific diftricts. Carts are fcarcely known here, for the beft of all reafons, that there are no roads made by art in any part of the country. The conftruction of their ploughs is extremely rude, being in all probability of the fame defcription with thofe ufed in ancient times over the whole of Europe. They confift of a crooked piece of wood bent (naturally) almoft to a right angle, forming the beam, to which is fixed an oak ftaff about feven feet long, which is very pliable, and yields to the preffure of the driver's hand when he wifhes to deepen the furrow. The coulter ftands almoft even up and down, and is never of fufficient length. A fquare hole is cut through the lower end of the beam, wherein the mercal, a piece of oak about twenty-two inches long is introduced. The furrow is rendered deep or fhallow by driving a wedge below or above the mercal, on the outfide of the beam. The man who holds or governs the plough walks by its fide, and directs it by a ftilt or handle. The driver, or guide, precedes the oxen, ufually four in number, and draws them along by means of a rope faftened to their horns. The other agricultural implements correfpond to the mean conftruction of the plough. Owing to the limited extent of many farms the ground is very often dug with fpades. Seeding time commonly begins here about the middle of March, but it varies in different parts of the country. It is earlieft in the parifhes of Tingwall, Whitenefs, Weefdale, and Dunrofsnefs, where the foil is drier than in moft other places, and has a limeftone bottom. With refpect to the period of harveft, the feafons are fo various, as to render it impoffible to fay any thing precife concerning it, being fometimes over by the middle of September, and at other times fcarcely finifhed in November. When it happens to be thus late, the crop affords little fuftenance to man, and is only valuable as fodder for the cattle. The whole lands of the ifland nearly remain without inclofures. The cultivated lands are divided, but the extenfive hill paftures remain in common. For the divifion of thefe many propofals have been offered, but the attempt has hitherto proved abortive, and indeed it muft be confeffed, that upon the prefent Shetland fyftem of agriculture fuch an event would be attended with very little advantage, unlefs proper fences were conftructed, or fhepherds appointed to confine the fheep or cattle within any prefcribed boundaries. It is fomewhat remarkable that not a fingle tree is to be feen in the whole ifland, and ftill more extraordinary that no proper attempt has been made to afcertain whether the climate will permit their growth. Certain it is, however, that in early ages they muft have reached confiderable perfection here, as many decayed trunks of large trees are often found among the bogs and moffes.

With refpect to the domeftic animals of the Mainland of Shetland, it is well known they are the fmalleft of any in the Britifh dominions; a circumftance doubtlefs the confequence of their fcanty fupply of food, and the total difregard manifefted by the inhabitants for the improvement of their native breed. Some attempts have indeed been made by a few individuals to introduce breeds from more fouthern countries, but the climate of this northern region has been found unfavourable to the animals of warmer latitudes. The number of horfes reared here is very confiderable. They are generally about nine or ten hands high, full of fpirit, and better calculated to endure fatigue than much larger horfes. They are ufually denominated Shetland ponies, and are evidently fprung from the Norway horfe. Thefe animals are never put into a houfe, either in fummer or winter, nor do they receive any food but what they gather from the ground. The horned cattle are greatly inferior in every point of view to thofe of Orkney or the Weftern ifles of Scotland. The cows give very little milk; but as a great portion of the rents was of old paid in butter, now converted into money, it feems reafonable to conclude either that cows were formerly more numerous here, or produced greater quantities of milk than at prefent. Cheefe is feldom made, and indeed a great many of the farmers are yet ignorant how to manufacture it. Their method of making butter is peculiar to the Shetland iflands: Red-hot ftones are thrown into the churn juft at the time when the butter is about to feparate from the ferum, after which the churning is continued till the butter feparates, and rifes to the furface. The number of cattle in the whole ifland is eftimated at about 40,000 head. Swine are bred in great plenty, and are particularly remarkable for the extreme fhortnefs of their backs. The fheep are of different breeds, two of which produce a very fine wool, manufactured by the inhabitants into ftockings. Thefe animals feed at large on the hills, each proprietor having a peculiar mark upon them, to diftinguifh whofe property they are. The alertnefs of the inhabitants, and the fagacity of their dogs, in tracing and feparating their own flocks from the general ftock, are fubjects of wonder to every ftranger who vifits the Mainland.

In this ifland there are very few goats, and no hares or foxes: and in general few wild or ravenous quadrupeds of any kind. Tame and wild fowls, however, exift here in great abundance, particularly the latter; fome of which are extremely deftructive to the young lambs. By the police of the country, every perfon who kills an "erne" is entitled to a reward of *3s. 4d.*: for a corbie or raven he receives *3d.*; and for a crow *2d.* Thefe rewards are paid by the commiffioners of the land-tax, upon feeing the heads of the fowls that have been killed. The number of migratory birds which frequent the rocks on the coaft is immenfe, and though they build their nefts on the brink of precipices feemingly inacceffible, the inhabitants, difregarding the danger of the attempt, plunder them both of their eggs and young.

The mineralogy of this ifland, though of little importance for the purpofes of common life, prefents many interefting objects of contemplation to the geologift. Rocks of primary and fecondary formation can be diftinctly traced in moft places, and offer a variety of fatisfactory illuftrations of the Neptunian theory. Volcanic appearances are extremely uncommon, and purely adventitious. The hills chiefly run in ridges, or appear conical and detached. Except in the parifh of North Maven, there are few of them of the rugged or abrupt kind. Sumburgh-head, a bold and lofty rock at the fouthern extremity, is compofed entirely of indurated fandftone, and the fame material appears to form the coaft along the greater part of the peninfula of Dunrofsnefs. The cliffs of Coningfburgh are compofed chiefly of micaceous fchiftus, as are likewife the hills which bound the valley of Quarf. The coaft of North Maven prefents a grand difplay of natural beauties, the rocks affuming a variety of curious forms from the excavations of the fea. Rona's-hill, on the northern portion of this parifh, is an immenfe mountain of granite, and all the rocks on its weftern boundary are compofed of the fame foffil. About a hundred and fifty feet from the fhore, here ftands a very lofty rock or holm, the fides of which are perfectly mural. It is called Maiden Sherrie, and has never yet been trod by human foot, the black gulls maintaining it in exclufive and unmolefted poffeffion. Near Lerwick, the rocks are a mixture of fandftone and breccia. Limeftone is found in confiderable abundance near Coningfburgh. Beds of the fame mineral ftretch along Weefdale, as well as throughout the whole valley of Tingwall; in all which places it is wrought, and forms an article of exportation. Some ftrata of iron ore have likewife been difcovered in different parts of the country, and attempts have even been made to open mines, but none of them have yet proved fuccefsful.

The only remains of antiquity worthy of notice are what are called Picts'-houfes, and thefe abound in every diftrict of the ifland. They are ufually about fourteen feet high, but differ in the extent of their circumference at the bafe. The interior confifts of feveral cells or apartments, one of which, fituated in the centre, is of much larger dimenfions than any of the others. All of them are conftructed of large flat ftones, without any cement or mortar.

The only villages in the Mainland are Lerwick and Scallaway. The latter is the more ancient of the two, but the former the more confiderable. Lerwick is fituated on the Breffay found, long the general rendezvous of the Dutch fifhing-veffels; and, being the feat of the courts of juftice, is efteemed the capital of the Shetland iflands. See Lerwick and Scallaway.

As to the inhabitants of this ifland, the inferior claffes are ufually reprefented as depreffed and miferable. Both the men and women are, generally fpeaking, well proportioned, of fair complexion, and an agreeable expreffion of countenance. Great attention is paid by them to the growth of the hair, which is valued in proportion to its length. The peafantry are noted for their curiofity and acutenefs; but the acquifition of ufeful knowledge is feldom the object of their inquiries. Some of them, however, have excelled in the mechanical arts by the mere force of natural genius alone, unaided by education or example. Dr. Edmonfton mentions a blackfmith, who was completely mafter of clock and watch-making in all its branches, although he had probably never witneffed any part of that delicate manufacture. Small as their country is, a confiderable variety of manners and habits is difcernible in different diftricts; the inhabitants of fome parifhes being remarkable for their gaiety, and others no lefs fo for the gravity and fobriety of their deportment. Sufpicion, indolence, and fervility are qualities too generally diffufed among them, the confequence, no doubt, of the immemorial operation of feudalifm. Belief in witchcraft, fairies, and the efficacy of alms, is alfo ftill prevalent over the whole ifland, and freemafonry is univerfally confidered as conferring upon its votaries the rare faculty of detecting theft.

The manufactures carried on here are but few, and thefe in general imperfectly conducted. The knitting of worfted ftockings, caps, and gloves by the women, is among the moft ancient. Shetland hofiery has long been held in high repute, and formed a confiderable article of exportation. The demand for it has of late years, however, confiderably diminifhed even in the Britifh iflands, and fcarcely any of it now reaches the continent. A fort of coarfe cloth or claith is wove here by individual weavers, as well as blankets for home confumption. Kelp is now a ftaple manufacture, and at Lerwick there is both a ftraw and a rope manufactory. The chief employment of the inhabitants, however, and the principal fource of their wealth, are the fifheries eftablifhed on their coafts, which abound with herring, cod, tufk, and ling. The Dutch formerly owed to their Shetland fifheries in no fmall degree the elevated ftation their country held during the two laft centuries, among the nations of Europe. Almoft all the land proprietors here are engaged in this traffic, and as more profit arifes from it than from their eftates, their lands are made fubfervient to its profecution. Hence in fome meafure proceeds the low condition of hufbandry, and the dependent obfequioufnefs of the common people. Every laird endeavours to eftablifh on his eftate as large a number of perfons as he poffibly can, as he thereby obtains a greater number of fifhermen. Farms are therefore divided and fubdivided; and wafte lands allotted to all who are willing to fettle on them. The facility of obtaining poffeffions encourages marriage, and as a confequence, the population of the ifland is much greater than it can fupport. The young men being burdened with more numerous families than they can well fupport, find themfelves fpeedily involved in difficulties. Having no leafes of their poffeffions, and all the fifh they take belonging to the landlord at a fixed price, a ftate of ab-

 ject

ject dependence on their ſuperiors may be reaſonably concluded to exiſt; and it actually does exiſt over the whole of Shetland. The chief exports from the iſland are, fiſh, oil, butter, beef, hides, tallow, ſtockings, calf, and rabbit-ſkins. The imports conſiſt of the luxuries, and even neceſſaries of life, particularly cloth and corn; the whole iſland, as already hinted at, not producing grain ſufficient to ſupply the inhabitants more than eight months in the year. For a more particular account of the Mainland, and a view of its general hiſtory, ſee the article SHETLAND *Iſles*, alſo "A View of the ancient and preſent State of the Zetland Iſlands," by Arthur Edmonſton, M.D. 2 vols. 8vo. 1809.

MAIN-MORTE, a term in ſome ancient cuſtoms, ſtill obtaining in Burgundy, ſignifying a right which the lord has, on the death of a chief of a family that is *main-mortable*, of taking the beſt moveable in the houſe; or, in default of that, the right hand of the deceaſed was offered him, in token that he could ſerve him no longer. See MORTMAIN.

MAINO JASON, DEL, in *Biography*, an eminent Italian lawyer, born at Peſaro in 1405, was ſent to Pavia to ſtudy the law, having received the elements of a good education in his native place. Free from the conſtraint of parental obſervation, he applied himſelf more to the gaming table than to thoſe purſuits which were intended to fit him for future life. By this line of conduct he was ſoon reduced to a ſtate of almoſt abſolute indigence. The animadverſions of his father, together with his own ſufferings, effected ſuch a change in his mode of living, that he became the admiration of his ſuperiors on account of his learned acquiſitions. In 1467 he was elected a profeſſor at the univerſity of Pavia, and continued there with high reputation till the year 1485, when he accepted a profeſſorſhip at Padua. In 1488 he removed to the univerſity of Piſa, to which the republic of Florence invited him, on a very liberal ſalary. After this he reſumed the profeſſor's chair at Padua, where his reputation was ſo high, that he is ſaid to have had three thouſand auditors. Beſides the duties of his office as teacher, he tranſacted much public and important buſineſs with accuracy and fidelity. In 1492 he was ſent by the duke of Milan to do homage to pope Alexander VI., on which occaſion he pronounced an oration that was afterwards printed. He was, in 1494, ſent to compliment the emperor Maximilian on his marriage, and on this occaſion he was rewarded with the title of cavalier and count-palatine: and next from Ludovico, duke of Milan, he obtained the rank of patrician, and honorary poſt of ſenator. Lewis XII. of France, attended by five cardinals, paid a viſit to his ſchool; Jaſon, in introducing his majeſty, humbly requeſted him to enter firſt, to which Lewis replied, "I am no king here," and obliged the profeſſor to precede, he being entitled to the chief reſpect among his ſcholars. After the lecture the king embraced Jaſon with the utmoſt cordiality, and in the courſe of a familiar converſation, he hinted to his majeſty, that he might favour him, by mentioning his name to the pope as not diſqualified to wear a cardinal's hat. He was, however, unable to attain to the object of his ambition, and continued to hold his office as profeſſor till the year 1511; after this he fell into a ſtate of dotage, in which he continued till he died in 1519. This gentleman was eſteemed one of the greateſt maſters of juriſprudence in his time, and is mentioned by Alciatus among the five juriſts who alone deſerve to be read. Gen. Biog.

MAINOUR, MANOUR, or *Mainor*, Fr. *Mainveuvre*, *a manu*, in *Law*, ſignifies the thing that a thief takes away, or ſteals.

Thus, to be taken with mainour, is to be taken with the thing ſtolen about him. If the defendant were taken with the mainour, and ſo carried to court, in ancient times they would arraign him on the mainour, without any appeal or indictment. But this proceeding was taken away by ſeveral ſtatutes in the reign of Edward III., though in Scotland a ſimilar proceſs remains to this day. See ATTACHMENT *of the Foreſt*.

MAINPERNORS. See MAINPRISE.

MAINPRISE, compounded of the French *main*, *hand*, and *pris*, or *prins*, *taken*, the taking or receiving a man into friendly cuſtody, who otherwiſe might be committed to priſon; upon ſecurity given for his forthcoming at a day aſſigned.

They who thus undertake for any one, are called *mainpernors*, becauſe they receive the perſon into their hands; whence alſo comes the word *mainpernable*, denoting the perſon who may be thus bailed. F. N. B. 250. 1 Hal. P. C. 141. Coke on bail and mainpriſe, c. 10. See BAIL.

The writ of mainpriſe is a writ directed to the ſheriff, (either generally, when any man is impriſoned for a bailable offence, and bail hath been refuſed; or ſpecially, when the offence or cauſe of commitment is not properly bailable below), commanding him to take ſureties for the priſoner's appearance, and to ſet him at large. Mainpernors differ from bail, in that a man's bail may impriſon or ſurrender him up before the ſtipulated day of appearance. Mainpernors can do neither, but are barely ſureties for his appearance at the day: bail are only ſureties, that the party be anſwerable for the ſpecial matter which they ſtipulate: mainpernors are bound to produce him to anſwer all charges whatſoever. Coke, *ubi ſupra*, c. 3. 4 Inſt. 179.

MAINTAINERS, are thoſe that maintain or ſecond a cauſe depending between others, by diſburſing money, or making friends for either party, &c. not being intereſted in the ſuit, or attornies employed therein. Stat. 19 Hen. VII. cap. 14. See MAINTENANCE.

MAINTENANCE, MANUTENENTIA, an unlawful maintaining, or officious intermeddling in a ſuit between others, by aſſiſting either party with money or otherwiſe, to proſecute or defend it. Hawk. P. C. 249.

The word is metaphorically taken from the ſuccouring a young child, that learns to go by one's hand; but it is uſed in the bad ſenſe in ſome of our ſtatutes.

By the Roman law, it was a ſpecies of the *crimen falſi* to enter into any confederacy, or to do any act, to ſupport another's law-ſuit, by money, witneſſes, or patronage. A man may, however, maintain the ſuit of his near kinſman, ſervant, or poor neighbour, out of charity and compaſſion, with impunity; otherwiſe the puniſhment by common law is fine and impriſonment; and by ſtat. 32 Hen. VIII. cap. 9. a forfeiture of 10*l*. See BARATRY and CHAMPARTY.

There lies a writ againſt a *maintainer*, called a writ of *maintenance*.

MAINTENON, FRANCES D'AUBIGNE, in *Biography*, celebrated in the hiſtory of France as well for her great accompliſhments, as for the ſingularity of her fortunes, was born in a priſon at Niort in the year 1635. In this ſolitary abode her father, Conſtant d'Aubigné, was confined for ſome political offence. Here he and his infant daughter remained during the firſt three years of her life, at which time her father, having obtained his liberation, carried her with his wife and ſon to Martinique. She was indebted to her mother for an excellent education, that was unqueſtionably the baſe of her future elevation. On the death of her father, in 1647, the family returned to France, when the young lady was taken under the care and protection of madame de Villette, who infuſed into her mind thoſe principles of the Calviniſtic faith

faith to which her father had been zealoufly attached. Her mother, who was a ftrict Catholic, took great pains in converting her to her own opinions, which fhe effected. They removed to Paris, where the mother very foon died, leaving her children in the greateft indigence. Frances, from this circumftance, and from the feverity of fome other near relations, was induced to give her hand to the famous Scarron, who was not young, and who from difeafe was in a ftate of decrepitude. She accepted this union, it is faid, rather than the other alternative which he offered her, of paying her portion to be received into a nunnery. The houfe of her hufband was frequented by many men of rank and wit, and the young wife attracted general admiration by the graces of her perfon, and the elegant charms of her converfation. In this dangerous fituation fhe conducted herfelf in fuch a manner, that her virtue was unfullied and unfufpected. Her intimacy with the celebrated Ninon de l'Enclos did not in the leaft injure her reputation, and the teftimony of her friend, in favour of her morals, has been admitted as good evidence. Scarron died in 1660, and his widow was again left in a ftate of indigence: for a fhort time, and after much folicitation, fhe obtained from the queen-mother the penfion which her late hufband had enjoyed; but at the death of the queen, fhe was again deftitute. At this time a propofal was made to her to go to Lifbon to undertake the education of the children of a Portuguefe princefs. She gladly liftened to the propofal, and juft before her intended departure fhe waited upon the king's miftrefs, madame de Montefpan, who, ftruck with the elegance of her manners, and the graces of her converfation, told her fhe muft not think of quitting France. She immediately applied to Lewis XIV. for a penfion to be fettled on the forlorn widow, to which the monarch angrily replied, "fhall I never hear of any thing but the widow Scarron." Indeed, fire, replied the favourite, "you ought long fince to have ceafed to hear of her." The penfion was, however, granted, and fhe remained in France. Madame de Montefpan, who had now ftrong claims to her gratitude, conceived fuch an efteem for her, that fhe entrufted her with the fecret of the children which fhe had by the king, and placed them under her care. At firft fhe had the mortification to find that Lewis was not friendly to her. Her talents, however, were fuch as time would bring into notice, and fhe gradually rofe into favour, and was chofen by the monarch himfelf to attend his eldeft fon, by madame de Montefpan, the duke of Maine, to Bareges, for the recovery of his health. This fituation engaged her in a direct correfpondence with the king, a circumftance that operated very ftrongly in her favour: he augmented her penfion, and made her liberal prefents. Her ferene and equal temper, and rational converfation, gradually gained upon Lewis, till at length fhe became his confidential friend. Her age, which exceeded that of the king, the moderate fhare of perfonal attractions which fhe retained, and the ftrictnefs of her religious principles, feem to have been fufficient affurances of the innocence of their connexion. Madame de Maintenon has been charged with ingratitude towards her benefactrefs, who was now difcarded from the court, but fhe has found advocates who have fully vindicated her from the fufpicion. Her fituation with Lewis was, for fome years, equivocal: fhe was an acknowledged favourite, but to what extent was not known; there was a fingular mixture of devotion and gallantry in the correfpondence carried on between the king and his female friend, and in allufion to this, Voltaire obferves; "This ftrange commerce of tendernefs and fcruple on the part of the king, of ambition and devotion on that of the new miftrefs, feem to have lafted from 1681 to 1686, which was the epoch of their marriage. This union was never doubted, though never openly acknowledged at court, and madame de Maintenon preferved that name while fhe was regarded and honoured as a queen. She always conducted herfelf with extreme good fenfe and moderation; was very referved in afking favours for herfelf and family, and in thefe refpects fhe formed a ftriking contraft to preceding favourites. Exceffive caution, amounting to timidity, which appeared to extinguifh every warm and generous emotion, was a characteriftic feature of her conduct. She devoted herfelf entirely to the king, which fhe found to be a tafk that rendered her elevated fituation moft painful and joylefs." "What a punifhment," faid fhe, to a near relation, "to be obliged to amufe a man who is no longer amufable." That her feelings on this fubject were extremely acute, is evident from an extract of a letter to an intimate friend: "Why," fays fhe, "cannot I give you my experience? why cannot I make you fenfible of the wearifomenefs to which the great are a conftant prey, and the labour they undergo to fill up their days? Do not you fee that I am confumed with melancholy, in a condition which it was fcarcely conceivable that I fhould ever have attained." She attempted to fupply the void which fhe felt by the practices of a minute and fcrupulous devotion, and fhe infpired the king with a fimilar tafte; but, at the fame time, fhe was not infenfible to the ambition of ruling, and often exerted her influence when fhe was not fufpected of having an opinion. But fhe found it neceffary to ufe the utmoft circumfpection, for the king would not bear a rival; and if he fufpected any defign to controul his will, he was apt to determine on the contrary. As his infirmities increafed, fhe became more and more neceffary to his exiftence, and is faid to have fhared with his confeffors the poffeffion of his mind to the laft hour. She employed a confiderable portion of a fcanty income in deeds of charity and benevolence, but her moft fplendid work was the eftablifhment at St. Cyr, near Verfailles, including a religious community, and an inftitution for the gratuitous education of 300 young ladies of quality. For this fhe engaged Racine to compofe the facred dramas of Efther and Athaliah, in which the young ladies acted their parts fo well, in the firft reprefentation, that fhe determined they fhould not appear in the characters again. On the death of the monarch in 1715, madame de Maintenon retreated to this peaceful manfion, thenceforth refigning all concern with the great and political world, acting in the laudable duties of the directrefs of the inftitution, and inftructrefs of the young people educated in it. She was occafionally vifited by a few particular friends; among whom her former pupil, the duke of Maine, was always received with the expreffions of truly maternal affection. She lived to the great age of eighty-four, and died at St. Cyr in 1719. She is known in the literary world by a collection of letters in nine vols. 12mo. which were publifhed in 1756; thefe are well written, and contain many things worthy of attention. Gen. Biog.

MAINTENON, in *Geography*, a town of France, in the department of the Eure and Loire, and chief place of a canton, in the diftrict of Chartres; nine miles N. of Chartres. The place contains 1605, and the canton 13,369 inhabitants, on a territory of 205 kiliometres, in 21 communes.

MAJO, FRANCIS, or CICCIO DE MAJO, in *Biography*, a Neapolitan compofer of the firft clafs, who flourifhed from about the middle of the laft century to 1774: his works are few, as longevity was not allowed him. Metaftafio's Artaferfe in 1762, Antigono in 1769, a Didone Abbandonata, and Aleffandro nell' Indie, both thefe laft in 1774, are all his dramatic works with which we are acquainted. He was in very high favour at Naples and Rome in the year 1770,

 when

when natives as well as foreigners were eagerly collecting his opera airs composed for great singers; of which airs the style was noble, the accompaniments elegant and interesting, without disturbing or overpowering the voice, and each air is a more complete whole, perhaps when detached for occasional use at concerts, than those of any other great opera composer with whose productions we are acquainted.

M. Laborde's character of this charming composer is very just; but his dates are far from accurate. Artaxerxes was not the first opera which he composed, but Riccimero, for the theatre Delle Dame at Rome in 1759; and in 1763 his Demofoonte was performed at the Argentina theatre in the same city.

M Laborde tells us, that though he had often gone the rounds of the great theatres in Italy, he never would quit his country; but in 1764, we find by Metastasio's letters to Farinelli, that he was at Vienna in his way to Manheim, where he was engaged to compose an opera.

Farinelli seems to have given him a letter of recommendation to the imperial laureat, in the answers to which we may form some judgment of the private character of this gifted man..

Metastasio, in his first letter to Farinelli, in which Ciccio de Majo is mentioned, says, "Our dear Majo has been arrived some time, but I have seen him but once, and then only for a short time. I received him with all that affection which I cannot help bestowing on persons beloved by you, and whose merit is universally known. Nor shall I neglect any opportunity of serving him, as far as the august circumference of my limited faculties shall extend. The best of it is, that he not only never comes near me, but leaves me in perfect ignorance of the hiding place where he has hitherto amused himself here, during the leisure in which he has hitherto lived. Perhaps some ancient sparks have rekindled the extinguished conflagration, and the poor soul will be involved in the flames and smoke which formerly, as I am informed, scorched and confounded him."

In another letter of the same date, Metastasio says, "Your most amiable de Majo generously gives me credit for wishing to serve him, but hitherto has absolutely avoided putting my zeal to the test. A man of his merit, and your friend, would have a right to dispose of me at his pleasure. But he, who is no fool, knowing perhaps the little extent of my power, is unwilling to expose me to the shame of confessing it. I am unable to inform you whether he has been caught in the old net. I never frequent the woods which expose him to such danger, and have never been able to examine him; as during his long residence on the banks of the Ister, I have only had the pleasure of seeing him two or three times, at most. Indeed his continuing so constantly invisible, and remaining here so long, without any apparent motive, seems to favour your conjectures. If he is at sea, I wish him a prosperous gale; if such a wish is not inconsiderate: as the felicity of a navigation depends much on the cause for which we embark; and I never wish my friends to be possessed of such an inconsiderate courage."

And in a third letter, he says, "Our ardent and languid Majo, stimulated by his friends and by his duty, is at length set off for Manheim, where he is engaged to compose an opera for the elector palatine. With what heart he has left the banks of the Ister, enamoured turtles say!"

This exquisite composer and tender hearted swain, who had he been possessed of the world, would have *lost* it all *for love*, with as good a grace as Mark Antony, died in 1771. The last opera he composed, was Didone Abbandonata, for Venice, in 1770.

Majo *Bamba*, in *Geography*, a town of Peru, in the jurisdiction of Chacapoyas.

Major, John, in *Biography*, was born at North Berwick, in Scotland; he laid the foundation of a learned education in his own country, and afterwards studied some time at Cambridge and Oxford. In 1493 he went to Paris, where he prosecuted his studies at different colleges; in 1505 he was made doctor of the Sorbonne, and in 1519 he returned to his native country, and was elected professor of divinity at St. Andrews, where the celebrated Knox was one of his pupils. He afterwards attained to the office of provost of that university, where he died at the age of seventy-eight, in the year 1547. He was a voluminous writer in metaphysics and logic, but his works on these subjects have long been forgotten, and he is now remembered and quoted only as the historian of his own country. His main work is entitled "De Gestis Scotorum," in six books, first published at Paris in 1521, which bring down the history from the earliest periods to the year 1495. He rejects the fictions of antiquarians relative to the remote history of the nation, and reduces the list of its early kings. He is a strenuous advocate for the independence of his country, and speaks freely of the power of the people and the prerogatives of parliament; he is an enemy to public abuses, and speaks with decision of the acts of the kings whose conduct he never scruples to condemn. Bishop Leslie says of his history "Veritatis ubique quam eloquentiæ studiosior." Gen. Biog.

Major, John Daniel, a physician and naturalist, was born at Breslau, in August 1634. Having studied for some time at Wittemberg, he visited several universities of Germany and Italy, and graduated at Padua in 1660. He returned to Silesia through Austria; but, after a short visit to Breslau, he settled himself at Wittemberg, where he married the daughter of the celebrated Sennertus in 1661, who died in child-bed in the following year. This interruption of his domestic happiness impelled him to leave Wittemberg, and he settled at Hamburgh, where he undertook the office of superintendant of the treatment of the plague. The success of his practice obtained for him, in 1663, the honour of being enrolled among the members of the Academia Naturæ Curiosorum, under the name of Hesperus, and likewise an invitation, through the Russian consul at Hamburgh, to settle at that court, with the appointment of first physician: but he declined this offer, from a dislike to quit his own country, and to reside among a people, whose language and manners were so widely different from those with which he was familiar. In 1665, he was appointed professor of the theory of medicine in the recently established university of Kiel; and he was afterwards honoured with the appointments of professor of botany, and director of the botanic garden there. These offices called forth the exertion of his utmost zeal, in support of the reputation and utility of the rising university, which he essentially contributed to establish by his travels and researches, and by the valuable collections with which he enriched it. By these exertions his own reputation was likewise extended, so that in 1693, he was called to Stockholm by Charles XI. to superintend the treatment of the disorder of his queen. But he was himself attacked with disease, while in that capital, which terminated his life on the third of August, in that year.

Major was indefatigable in his researches, both in natural history and medicine, and was the author of a considerable number of publications: Eloy has enumerated the titles of upwards of twenty works, exclusive of a number of academical dissertations. The principal subjects of the former were,

were, petrifactions or fossils, renal calculi, transfusion, anatomy, botany, artificial medicated baths, &c. Eloy Dict. Hist. de le Méd.

MAJOR's *Bay*, in *Geography*, a bay of the island of St. Christopher. N. lat. 17° 20'. E. long. 62° 22'.

MAJOR, in *Law*, a person who is of age to manage his own affairs. See AGE.

By the civil law, a man is not a major till the age of twenty-five years; in England, he is a major at twenty-one, and in Normandy at twenty.

MAJOR, in *Logic*, is understood of the first proposition of a regular syllogism.

It is called *major*, because it has a more extensive sense than the *minor* proposition, as containing the principal term. See PROPOSITION.

MAJOR, in the *Art of War*, a name given to several officers of different qualities and functions.

MAJOR-*general*. See GENERAL, *Major*.

MAJOR *of a Brigade*, either of horse or foot, is he who receives orders, and the word, from the major-general; and gives them to the particular majors of each regiment. See BRIGADE-*major*.

MAJOR *of a Regiment* is an officer, whose business is to convey all orders to a regiment, to draw it up, and exercise it, to see it march in good order, to look to its quarters, and to rally it, if it happen to be broken in an engagement, &c.

The major is next in subordination to the lieutenant-colonel, and generally promoted from the eldest captain. He is the only officer of a regiment of foot, who is allowed to be on horseback in the time of service; but he always rides, that he may speedily get from place to place, as occasion requires.

The major of a regiment, either of foot or of horse, ought to be a man of honour, integrity, understanding, courage, activity, experience, and address; he should be skilled in arithmetic, that he may keep a detail of the regiment in every particular, and also in horsemanship; and he should be well acquainted with all military evolutions, that he may be competent to the exercise of his duty in the instruction of others.

MAJOR *of Artillery* is the next officer to the lieutenant-colonel. In the field he receives daily orders from the brigade-major, and communicates them, with the parole, to his superiors, and then dictates them to the adjutant.

The whole detail of the corps rests with this officer; to him all the non-commissioned officers are subordinate, as his title of serjeant-major imports, and to him they communicate an account of every circumstance that regards the duty or the wants of the artillery and soldiers. This officer should be well acquainted with all the powers and evolutions of the artillery, and with every thing that pertains to the train of artillery, &c.

MAJOR *of Engineers*. See ENGINEER.

MAJOR, *Serjeant*, is a non-commissioned officer, subordinate to the adjutant, as he is to the major.

MAJOR, *Town*, is the third officer in order in a garrison, being next to the deputy-governor.

He ought to understand fortification, and hath charge of the guards, rounds, patroles, and centinels.

There are also aids-major, drums-major, and other officers; so called, on account of some seniority or prerogative that they have over the rest. See AID-*major*, and DRUM-*major*.

MAJOR, *Fife*, has the same authority over the fifers as the drum-major has over the drummers. He teaches them their duty, appoints them for guards, &c.

MAJOR *Helicis*, in *Anatomy*, a name given by Albinus to one of the muscles of the eye, called by Santorini and others, helicis musculus. This author distinguishes it under the name *major*, from another muscle which he calls the *minor helicis*, and which Santorini calls only fibræ musculares in plana helicis facie, though it be a true and proper muscle.

MAJOR *and Minor*, in *Music*. See MAGGIORE.

MAJORAGIO, MARCANTONIO, in *Biography*, an Italian scholar of the sixteenth century, was born in a village of that name in the diocese of Milan. His father's original name was Conti, and he assumed the name of the place in which he settled, and to which he had been driven and reduced to poverty by the wars in Lombardy. The subject of this article was indebted to a relation for his education, whose cares he well repaid, by the diligence with which he pursued his studies. One of his preceptors was the famous Cardan, and such was his proficiency, that at the age of twenty-six he was appointed public professor of eloquence at Milan. He afterwards, on account of new wars, was obliged to go to Ferrara, where he improved himself in philosophy and jurisprudence. At the return of peace he resumed his station at Milan, and contributed greatly to revive the study of letters by restoring the practice of public declamations, by promoting the establishment of an academy, and by his attempts to found a public library. He died in 1555, at the age of forty-one. His works are numerous, consisting of orations, prefaces, poems, Latin and Italian, and tracts on various subjects. He employed his talents as a commentator on the works of Cicero and Aristotle. Bayle.

MAJORANA, in *Botany*, so called, says Ambrosinus, because it is cultivated with greater care (*majori curâ*) than other herbs; or because it has greater virtues and properties than are generally known; or because it is most powerful in the month of May; or because it agrees better with grown up persons (*majoribus*) than with infants. None of these derivations seems satisfactory. The plant however appears to be properly considered as the "*mollis Amaracus*" of Virgil, immortalized in those exquisite lines of the Æneid, book i. l. 695—8, inaccurately and incompletely translated by Dryden, who seems to take the *Amaracus* for Myrtle. These lines are indeed, as has been observed, the despair of all Virgil's translators. See ORIGANUM.

MAJORCA, in *Geography*, an island of the Mediterranean, belonging to Spain. It is the largest of the Balearic isles, and reckoned to be about 55 English miles in length, and 45 in breadth; and separated from Spain by about 40 leagues of sea. It is almost wholly surrounded by a chain of mountains, of which an interrupted branch extends into the interior; those of Puig Mayor and Galatz are the highest and most considerable. The climate is temperate; the fresh breezes tempering the heat of summer, and on the eastern coast little cold is felt in winter; but the temperature varies in different situations. But though it is well sheltered on the north, some winds occur, which sometimes entirely destroy the plantations. The vallies are fresh and fertile, though without water. However, some large brooks spring from the vicinity of the mountains, and run through some parts of the island; and two small rivers, particularly the Rierra, which rises under the ramparts of the capital. This island contains two cities, Palma and Alcudia, several small towns, and many hamlets. A Spanish author assigns to it two cities, 32 towns, a number of remarkable villages, 2001 farms, 1877 country houses, 10 castles or fortresses, 40 towers, where centinels are placed with fires during the night, to give alarm in case of danger, and 210 brooks or springs. The capital is Palma, or, as it is otherwise called, Majorca.

The kingdom of Majorca, comprehending the ancient Iberian iſlands, or the Balearic and Pituyſe, loſt much of its ancient population in the year 1229 by the defeat of the Moors, and the carnage made by the Chriſtians, in order to revenge the death of the celebrated viſcount de Bearn, William of Moncade, and his brother. In the year 1301 the Jews, who had been driven from Spain on account of their exactions and uſury and ſettled here, were baniſhed from the iſland. About the beginning of the 15th century, Majorca was afflicted with famine for 10 years, and its commerce declined with its population. In 1403 the river Rierra carried away 1600 houſes, and drowned 5500 perſons. A ſimilar cataſtrophe occurred in 1408 and 1444. Theſe diſaſters were ſucceeded by a civil war. In 1475 the iſland ſuffered great devaſtation from the plague. By theſe and other occurrences the population of Majorca was much diminiſhed; but in this ſtate it furniſhed troops for a militia, raiſed in order to defend the coaſt againſt the incurſions of the Barbarians. The nobility of Majorca was formerly conſiderable; and in the middle of the 16th century they engaged againſt the Africans, who endeavoured to invade the iſland. But after this epoch it enjoyed much internal tranquillity, though it never roſe to that eminence, which it is ſaid to have attained under the Moors. The number of inhabitants is now eſtimated at about 136,000 perſons, among whom are reckoned 1950 ſecular prieſts, 1000 monks and hermits, 600 cloiſtered nuns, and 600 women voluntarily engaged in charitable inſtitutions.

The agriculture of Majorca is in a flouriſhing condition. The mildneſs of the climate, and the fertility of the country, has given to the iſlands of this kingdom the name of the "Fortunate Iſlands." (Strabo, lib. iii.) The groves of orange trees produce excellent fruit, and the vines are loaded with grapes. The mountains in general are covered with trees of various kinds, as firs and holm-oaks, fit for carpenters and ſhip-builders; and the wild olives are abundant. The plains and vallies, which are well watered, exhibit the appearance of meadow ground. The flocks furniſh a great quantity of the fineſt wool; and by the culture of mulberry trees, they feed a number of ſilk worms, whoſe produce ſerves not only for domeſtic uſe, but promiſes to afford an article of exportation. In ſome territories they cultivate ſeveral kinds of corn, and delicious figs, which are dried; in others they graze cattle. The plain between Felonice, Montuyri, San Juan, and Petra is conſidered as the granary of the iſle. Corn, wine, oil, freſh and dried figs, and brandy, ſupply the wants of the interior. The eaſtern valley of Alcudia is very fruitful and rich. Grains of different ſpecies, honeycombs, olives, carobs, hemp, and every variety of fruits and herbs, are abundant. The valley of Soler is famous for its beauty and fertility, and is the pride of the iſlanders; and the canton of the mountains of Bagnabufar abounds in wine and flax, which are alſo produced in many other parts of the iſland. The Majorcans, however, are reproached with a laſſitude injurious to their proſperity. They import as much as 50,000 fanegas of wheat to ſupply the conſumption of 136,000 inhabitants, who poſſeſs a territory of 1234 ſquare miles, which are ſuppoſed to be the extent of the iſland. The Majorcans manufacture a ſort of coarſe ſtrong cloth for their own uſe, and a large quantity of corded woollen ſtuff, which is exported into Catalonia and the kingdom of Valencia. They have alſo looms for tapeſtry, blankets, and ſaſhes, all in wool, exported to Malta, Sardinia, Valencia, and even to America. They manufacture ſilk in the iſland, and make ſeveral ſtuffs uſed by the inhabitants, as well as linen cloths, ſome of which are very fine. The coarſe canvas, which they fabricate for the uſe of the marine, is exported. They make brooms, paniers, and baſkets, out of the leaves of the palm-tree, which are tranſported into Spain. Theſe iſlanders have been famous for their inlaid work, and this branch of commerce is profitable. The wines of Majorca are excellent. The lighteſt and fineſt, though friſky and delicate, are Muſcadel, Malvoiſia, Pampot Roda, and Montona. The oxen are ſmall and feeble; the ſheep large, with beautiful and heavy fleeces. The pigs are large and fat; game is very plentiful, and conſiſts of hares, rabbits, ſnipes, partridges, quails, &c. Poultry is very common. Their cheeſe is made of goats' and ſheep's milk, and ſome of it is very good. Their exports, conſiſting of oils, wines, brandy, oranges and lemons, almonds, cheeſes, capers and beans, amount in value to about 508,732*l.* 1[illegible]*s.* 4*d.* This ſum is augmented by the produce of ſome articles of manufacture. The inhabitants receive, in return, corn, ſalt proviſions, ſugar, coffee, rice, different ſorts of ſnuff, cloth, ſilk ſtuffs, linens of different qualities, hoſiery, hardware, medical drugs, planks and building wood, powder and ſhot for ſporting, &c. all which may amount to the value of 124,833*l.* 6*s.* 8*d.* ſterling. Hence it appears, that the balance in their favour amounts annually to about 383,899*l.* 11*s.* 8*d.* ſterling.

The iſland of Majorca is not only deſtitute of navigable rivers, but its highways are inconvenient for travelling, and very much out of repair; ſo that all the articles of land carriage, from the interior to the ſea, are conveyed on the backs of mules, or by carts of very clumſy conſtruction. It has been ſaid, that mines of gold and ſilver and precious ſtones were formerly found in this iſland; but of this there now remains no evidence. Its quarries of various ſorts of marble and of ſtone are, however, numerous. In the marſhes of Campos a quantity of natural ſalt is diſcovered, but for want of being worked it turns to little account: near the ſame town is a ſpring of ſulphureous water, called the holy, or St. John's fountain, which is reckoned ſalutary in various complaints. In this iſland are ſome birds of prey, particularly the hawk; but venomous animals are very little known. The coral fiſhery is carried on in the bay of Alcudia during the months of July and Auguſt.

The manners of the Majorcans are the ſame with thoſe of the Spaniards, and moſt ſtrikingly reſemble the Catalonians; they are both excellent ſoldiers and ſailors. The dreſs of the peaſants is a cap, which covers their ſhort hair, a jacket down to the waiſt, large breeches, and ſhoes tied with a ſtring; above the breeches they have a ſort of frock. The neat and ſimple head dreſs of the females is called "rebozillo;" it conſiſts of a double handkerchief, the upper part of which covers the head, and is hid under the chin, leaving only the face expoſed, then extending over the ſhoulders, and falling down half of the back, the two ends meet, croſs, and are tied before. Among the wealthy the rebozillo is an expenſive article of dreſs, on account of the embroidery and lace. The women are in general fond of ornaments; thoſe of fortune having a gold chain hanging along the petticoat, and ſometimes a chain of the ſame metal from the corſet, to which is fixed a valuable medallion: they have alſo all their fingers covered with rings, and make uſe of watches, bracelets, and other trinkets. When they go abroad, they wear a mantle like thoſe in Spain, and carry in their hands a fan and a long chaplet, ornamented with gold beads, and a croſs of the ſame metal.

The Majorcans value themſelves on their fidelity to their ſovereign; they are devout without bigotry, and their manners are ſoft and prepoſſeſſing. The women have a great degree of natural elegance.

Perſons

Perſons of diſtinction, men of buſineſs, and merchants ſpeak Caſtilian, but the language ſpoken among the reſt of the iſlanders is a kind of mixed jargon, the origin of which it would not be eaſy to trace. The authors, who have written on the Balearic iſlands, ſay, that the Limouſine tongue is uſed, but this language is merely a dialect differently pronounced, and ſpoken in the ſouthern provinces of France. The Balearic conſiſts of Greek, Latin, Arabic, Catalonian, Languedocian, and Caſtilian, intermixed with Syriac, Carthaginian, and Vandal or Gothic words, or rather it is a ſtrange medley of all. De Laborde's View of Spain, vol. iii. See BALEARES *Inſulæ*.

MAJORCA. See PALMA.

MAJOR-DOMO, an Italian term, frequently uſed to ſignify a ſteward or maſter of the houſehold.

The title of major-domo was formerly given in the courts of princes to three different kinds of officers. 1. To him who took care of what related to the prince's table, or eating; otherwiſe called *eleater*, *præfectus menſæ*, *architriclinus*, *dapifer*, and *princeps coquorum*. 2. Major-domo was alſo applied to the ſteward of the houſehold. 3. The title of major-domo was alſo given to the chief miniſter, or him to whom the prince deputed the adminiſtration of his affairs foreign and domeſtic, relating to war as well as peace. Inſtances of major-domos in the two firſt ſenſes are frequent in the Engliſh, French, and Norman affairs.

MAJORIANUS, JULIUS VALERIUS, in *Biography*, an emperor of the weſtern Roman empire, was raiſed to the throne in the year 457, having ſerved with much reputation in the army. His addreſs to the ſenate on this occaſion ſpoke the language of one fully ſenſible of the duties incumbent on him. He appears to have poſſeſſed many excellent qualities both of the heart and head. The laws which he cauſed to be enacted, and which are extant at the end of the Theodoſian code, are proofs of his attention to the happineſs of his ſubjects, and the welfare of the empire. He granted a diſcharge to the inhabitants of the provinces from all arrears of tribute, and removed many exactions in the collections of the taxes. He enjoined ſevere penalties againſt the dilapidation of the public edifices of Rome, and made many wholeſome regulations to encourage marriage, and reſtrain adultery. He rendered himſelf illuſtrious by his victories over the Vandals and Moors, who invaded his territories. He was at length the victim to the ambition of ſome of his chiefs, and compelled to abdicate his throne and authority in the year 461, after a reign of little more than three years; and in a few days after he was maſſacred by Ricimer, one of his generals. His character was that of an active, virtuous, and humane emperor. Univer. Hiſt. Gibbon.

MAIRAN, JOHN JAMES D'ORTOIS DE, an eminent French philoſopher, who flouriſhed in the eighteenth century, was born at Beziers in the year 1678. He devoted himſelf from a very early period to the ſtudy of literature and ſcience, and obtained ſeats in the Academy of Sciences, and the French Academy. To the former he was choſen perpetual ſecretary, after the death of Fontenelle in 1741. While he continued in that office, he was punctual and diligent in performing its duties, and poſſeſſed the happy art of placing the moſt abſtruſe ſubjects in a clear and intelligible light. In his eulogies he nearly equalled his predeceſſor in the faculty of characterizing the ſubjects of them, and of impartially appreciating their merits. He died in 1771: he was author of a great number of publications on intereſting topics, of which the following may be mentioned, "A Diſſertation on Ice;" "A Diſſertation on the Cauſe of Light of phoſphoric Bodies and Glow-worms;" "An hiſtorical and phyſical Treatiſe on the Aurora Borealis;" "A Letter to Father Parennin, containing ſeveral Queſtions relating to China," which is ſaid to be a very curious work, and full of that philoſophical ſpirit which characterizes the other works of the ſame author: ſome "Memoirs" publiſhed among thoſe of the Academy of Sciences: "Diſſertations," and "Eulogies" on deceaſed academicians, were printed in 1747.

For further information relative to Mairan, ſee Mem. de l'Acad. des Sciences, in which there are many curious articles concerning Harmonics and the philoſophy of Euclid. He accounts for the medicinal powers of muſic in the following manner. "It is from the mechanical and involuntary connection between the organ of hearing, and the conſonances excited in the outward air, joined to the rapid communication of the vibrations of this organ to the whole nervous ſyſtem, that we owe the cure of ſpaſmodic diſorders, and of fevers attended with a delirium and convulſions, of which our Memoirs furniſh many examples."

MAIRE, JOHN LE, a French poet, was born at Hainault in 1473, and died in 1524. He wrote among other pieces an allegorical poem, called the "Tales of Cupids, and of Atropos."

MAIRE, JAMES LE, a Dutch navigator, who ſailed from the Texel in 1615 with two ſhips, and in the following year he diſcovered the ſtraits, which bear his name in South America. After viſiting New Guinea, he ſailed to Batavia, where he was made priſoner, and his veſſel confiſcated, under the pretence of his having infringed on the rights of the Dutch Eaſt India company. He died on his paſſage to Europe in 1617.

MAIRE, LE, a French muſician of the 17th century, is generally allowed the honour of having invented, or at leaſt brought into uſe, in France, the ſyllable *ſi*, to expreſs the 7th of the key of C, inſtead of repeating the *mi* in ſolmiſation, by which ſtudents in ſinging eſcape the perplexing difficulty of the mutations. The title to the invention, ſmall as it ſeems, has been often diſputed; but having taken great pains to trace the firſt uſe of this ſyllable in ſinging, we have never been able to diſcover any muſician to whom it is ſo juſtly due as Le Maire. With reſpect to the utility of this invention, we think it would be much extended if the ſharp 7th of every major key, as well as that of *ut*, were called *ſi*.

MAIRE, LE, *Streight of*, in *Geography*, a narrow paſſage from the Atlantic to the Pacific ocean, between Terra del Fuego on the weſt, and the weſtward of Staten Land on the eaſt, about five leagues long and as many broad; ſo called from Le Maire, who, with his companion Schouten, ſailed from the Texel on the 14th of June 1615, diſcovered this paſſage: and they were the firſt who ever entered the Pacific ocean by the way of Cape Horn. In the account of lord Anſon's voyage it is ſaid, that it is difficult to determine exactly where this ſtreight lies, though the appearance of Terra del Fuego be well known, without knowing alſo the appearance of Staten Land; and that ſome navigators have been deceived by three hills on Staten Land, which have been miſtaken for the Three Brothers in Terra del Fuego, and ſo overſhot the ſtreight. But no ſhip, ſays lieutenant Cook, who paſſed this ſtreight in January 1769, can poſſibly miſs it that coaſts Terra del Fuego within ſight of land; for it will then, of itſelf, be ſufficiently conſpicuous: and Staten Land, which forms the eaſt ſide, will be ſtill more manifeſtly diſtinguiſhed, for there is no land in Terra del Fuego like it. The ſtreight of Le Maire can be miſſed only by ſtanding too far to the eaſtward, without keeping the land of Terra del Fuego

Fuego in ſight: if this is done, it may be miſſed, however accurately the appearance of the coaſt of Staten Land may have been exhibited; and if this is not done, it cannot be miſſed, though the appearance of that coaſt be not known. The entrance of the ſtreight ſhould not be attempted but with a fair wind and moderate weather, and upon the very beginning of the tide of flood, which happens here, at the full and change of the moon, about one or two o'clock: it is alſo beſt to keep as near to the Terra del Fuego ſhore as the winds will admit. By attending to theſe particulars, a ſhip may be got quite through the ſtreight in one tide; or, at leaſt, to the fouthward of Succeſs bay, into which it will be more prudent to put, if the wind ſhould be ſoutherly, than to attempt the weathering of Staten Land with a lee-wind and a current, which may endanger her being driven on that iſland. The bay of Good Succeſs lies about the middle of the ſtreight, on the Terra del Fuego ſide, and is diſcovered immediately upon entering the ſtreight from the northward; and the ſouth head of it may be diſtinguiſhed by a mark on the land, that has the appearance of a broad road leading up from the ſea into the country: at the entrance it is half a league wide, and runs in weſtward about two miles and a half. There is good anchorage in every part of it, in from ten to ſeven fathom, clear ground; and it affords plenty of exceeding good wood and water. The tides flow in the bay, at the full and change of the moon, about four or five o'clock, and riſe about five or ſix feet perpendicular. But the flood was two or three hours longer in the ſtreight than in the bay; and the ebb, or northerly current, was with nearly double the ſtrength of the flood. On the W. ſide of the Cape of Good Succeſs, which forms the S.W. entrance of the ſtreight, lies Valentine's bay, from which the land trends away to the W.S.W. for twenty or thirty leagues: it appears to be high and mountainous, and forms ſeveral bays and inlets. At the diſtance of fourteen leagues from the bay of Good Succeſs, in the direction of S.W. $\frac{1}{2}$ W. and between two and three leagues from the ſhore, lies New Iſland; about two leagues in length from N.E. to S.W., and terminates to the N.E. in a remarkable hillock. At the diſtance of ſeven leagues from New Iſland, in the direction of S.W. lies the iſle Evouts, and a little to the W. of the S. of this iſland lie Barnevelt's two ſmall flat iſlands cloſe to each other; they are partly ſurrounded with rocks, which riſe to different heights above the water, and lie twenty-four leagues from the ſtreight of Le Maire: at the diſtance of three leagues from Barnevelt's iſlands, in the direction of S.W. by S. lies the S.E. point of Hermit's iſlands, which from moſt points of view may be taken for one iſland, or a part of the main. From the S.E. point of Hermit's iſlands to Cape Horn, the courſe is S.W. by S. diſtance three leagues. Cook obſerves, that between ſtreight Le Maire and Cape Horn, they found a current ſetting, generally very ſtrong, to the N.E. when they were in with the ſhore; but they loſt it when they were at the diſtance of fifteen or twenty leagues.

Though the doubling of Cape Horn, ſays Cook, is ſo much dreaded, that in the general opinion it is more eligible to paſs through the ſtreight of Magellan, we were not once brought under our cloſe reefed top-ſails after we left the ſtreight of Le Maire. But ſuppoſing it more eligible to go round the Cape than through the ſtreight of Magellan, it may ſtill be queſtioned, whether it is better to go through the ſtreight of Le Maire, or ſtand to the eaſtward, and go round Staten Land. In the account of lord Anſon's voyage the advice is, that all ſhips bound to the South ſeas, inſtead of paſſing through the ſtreight of Le Maire, ſhould conſtantly paſs to the eaſtward of Staten Land, and ſhould be invariably bent on running to the ſouthward as far as the latitude of 61 or 62 degrees, before they endeavour to ſtand to the weſtward. "But, in my opinion," ſays captain Cook, "different circumſtances may at one time render it eligible to paſs through the ſtreight, and to keep to the eaſtward of Staten Land at another. If the land is fallen in with to the weſtward of the ſtreight, and the wind is favourable for going through, I think it would be very injudicious to loſe time by going round Staten Land, and I am confident, that by attending to the directions I have given, the ſtreight may be paſſed with the utmoſt ſafety and convenience; but if, on the contrary, the land is fallen in with to the eaſtward of the ſtreight, and the wind ſhould prove tempeſtuous or unfavourable, I think it would be beſt to go round Staten Land. But I cannot, in any caſe, concur in recommending the running into the latitude of 61° or 62°, before any endeavour is made to ſtand to the weſtward. We found neither the current nor the ſtreams which the running ſo far to the ſouthward is ſuppoſed neceſſary to avoid; and, indeed, as the winds almoſt conſtantly blow from that quarter, it is ſcarcely poſſible to purſue the advice. The navigator has no choice, but to ſtand to the ſouthward, cloſe upon a wind, and by keeping upon that tack, he will not only make ſouthing, but weſting; and, if the wind varies towards the north of the coaſt, his weſting will be conſiderable. It will, indeed, be highly proper to make ſure of a weſting ſufficient to double all the lands, before an attempt is made to ſtand to the northward, and to this every man's own prudence will, of neceſſity, direct him." Hawkeſworth's Voyages, vol. ii.

Maire, a ſmall iſland in the Mediterranean, near the coaſt of France. N. lat. 43° 14'. E. long. 6° 24'.

MAISBINNI, a town of Abyſſinia; ſix miles W. of Axum.

MAISERRY, a town of Bengal; 10 miles S. of Ghidore.

MAISEY, a town of Hindooſtan, in Bahar; 45 miles N. of Patna. N. lat. 26° 22'. E. long. 85° 18'.

MAISNAH, a town of Bengal; ſeven miles N.N.W. of Goragot.

MAISTRE, Antony de, in *Biography*, a French writer, was born at Paris in 1608; he was brought up to the bar, but quitted the profeſſion, and entered into the ſociety of Port Royal, where he died in 1658. The greater part of his life he ſpent in acts of the ſevereſt mortification, in writing various works, and in the ſtudy of theological ſubjects. His principal pieces are "Pleadings," which have been repeatedly reprinted; a French tranſlation of the treatiſe "On the Prieſthood by St. John Chryſoſtom;" a tranſlation of the works of St. Bernard: he had employed himſelf on a French verſion of the Old and New Teſtament. Moreri.

Maistre, Louis Isaac le, better known by the name of *Sacy*, brother of the preceding, was born at Paris in the year 1613. He was brought up for the church, and was ordained prieſt in 1648. The perſecution of the Janſeniſts, in which the members of Port Royal were involved, obliged him to conceal himſelf in the year 1661, but being diſcovered in the place of his retreat in 1666, he was ſent to the Baſtile. Here he was confined more than two years and a half, during which time he employed himſelf on the tranſlation of the Bible, and finiſhed the whole of the Old Teſtament. After his liberation he completed his verſion of the New Teſtament, which he went over thrice, before he could pronounce it finiſhed. His works are extremely numerous, and the topics very various. He was a perfect maſter of the French language, and wrote it elegantly. Moréri.

MAITEA, in *Geography*. See OSNABURG *Iſland*.

MAITED, a town of Perſia, in the province of Kerman; 16 miles N.E. of Sergian.

MAITLAND, JOHN, in *Biography*, lord Thyelſtane, and chancellor of Scotland, was born in 1545. He accompanied king James VI. to Norway, where his conſort, the princeſs of Denmark, was detained by contrary winds. He died in 1595. He was author of "Epigrammata Latina," publiſhed in the "Deliciæ Poetarum Scotorum." Gen. Biog. Dict.

MAITLAND, WILLIAM, a topographical and antiquarian writer, was born at Brechin, in Scotland, in 1693. His buſineſs as a hair merchant led him to travel, and he viſited Sweden, Denmark, and Germany, and finally ſettled in London. Here he began to apply himſelf to the ſtudy of antiquities; and in 1739 publiſhed the firſt fruit of his labours, which was his "Hiſtory of London." The work, which was an improvement upon that of Stowe, became popular, and has ſince been ſeveral times reprinted, with conſiderable additions: it has likewiſe furniſhed materials for many ſmaller and more modern publications. Soon after the publication of this work, the author is ſuppoſed to have retired to his native country, for the purpoſe of purſuing enquiries into its hiſtorical antiquities, and, in 1753, he publiſhed "A Hiſtory of Edinburgh." Succeſs in this inſtance led him to extend his reſearches to a much wider compaſs, and he employed himſelf in writing "The Hiſtory and Antiquities of Scotland, from the earlieſt Account of Time to the Death of James; continued by another Hand to the Acceſſion of James VI. to the Crown of England." This work was publiſhed in two volumes folio in 1757; the ſame year the author died at Montroſe. Mr. Maitland deſerves great applauſe for his induſtry, but he was not reckoned competent for ſuch a taſk, either with regard to learning or critical acumen.

MAITLAND, HENRY, a ſurgeon, is worthy of notice, principally as being the firſt perſon who performed the operation of *inoculating* the ſmall-pox in England. Mr. Maitland reſided at Conſtantinople, in the early part of the 18th century, with the Hon. Wortley Montague, then ambaſſador at the Ottoman court, where the only ſon of that gentleman was inoculated, at the age of ſix years, in 1717: and, on their return to England, Mr. Maitland inoculated the infant daughter of the ſame gentleman, in April, 1721. He publiſhed a detail of theſe caſes, and of thoſe of ſome condemned criminals in Newgate, in February, 1722, in a pamphlet, entitled "An Account of Inoculating the Small-Pox;" and ſubſequently, a ſecond pamphlet in "Vindication" of the former, in reply to the attack of Dr. Wagſtaffe. See INOCULATION.

MAITRE à CHANTER, *Fr.*, a ſinging-maſter. Rouſſeau has ſo well pointed out the functions of a ſinging-maſter in teaching the elements of the vocal art, that we ſhall tranſlate the chief part of his article on the ſubject. He includes the maſter's taſk in two principal objects. The firſt regards the cultivating and forming the voice, by making it capable of all that belongs to ſinging, with reſpect to compaſs, truth of intonation, clearneſs and ſweetneſs of tone, execution, ſwelling and diminiſhing the notes, hitting diſtances with preciſion, and acquiring a free and open ſhake.

The ſecond object regards the ſtudy of the muſical characters; that is, acquiring a facility in reading muſic at ſight, as accurately and readily as a printed book, in the ſtudent's own language.

A third part of a maſter's buſineſs is to enforce the duty of pronouncing and articulating the words with accuracy and energy; becauſe defects in pronunciation are much more ſenſible in ſinging than ſpeaking; as the ſinger is expected to tune and ſoften the harſh ſyllables, and render the ſoft ſtill more ſweet.

Millieo uſed to ſay, that a voice ſhould be ſo cultivated and exerciſed in *ſolfeggi*, as to reſemble a ball of wax, ſo long tempered in the hand that it can receive any impreſſion.

Rouſſeau ſays nothing of *expreſſion*, but that muſt come from the heart as well as the voice. It is perhaps only to be learned by imitation, and taught by example. There are many clear and powerful voices which give the hearer no pleaſure, however accurately they may execute the notes; while a feeble voice has often the undefinable power of affecting us by a natural pathos and intereſting expreſſion that touches and delights us the inſtant it is heard. See CANTARE, SOLFEGGIA, and EXPRESSION.

MAITRE-JEAN, ANTHONY, in *Biography*, an oculiſt and ſurgeon, was educated at Paris, and practiſed at Mery on the Seine, with great reputation, at the beginning of the eighteenth century. He was particularly diſtinguiſhed for his ſucceſs in the treatment of diſeaſes of the eyes, both the healthy and morbid ſtructure of which he had inveſtigated with great induſtry and accuracy, as his work, entitled "Traité des Maladies de l'Œil, et des Remèdes propres pour leur Gueriſon," 1707, ſufficiently proves. This treatiſe, which was ſeveral times reprinted and tranſlated, was long a ſtandard, and is ſtill entitled to eſteem. It contained the firſt ſatisfactory proofs that the ſeat of cataract was excluſively in the cryſtalline lens, and treated copiouſly on all the varieties of the operation of couching. He likewiſe publiſhed, "Obſervations ſur la Formation du Poulet," Paris 1722, with figures, drawn by himſelf; a work which contains many original experiments and remarks, and which, according to Haller, is not ſufficiently eſteemed. Maitre-Jean was a correſponding member of the Academy of Sciences at Paris, and ſome of his papers were printed in the Memoirs of that learned body. Eloy Dict. Hiſt. de la Méd. Gen. Biog.

MAITS, in *Geography*, a lake of Pruſſia, in Natangen; 20 miles S. of Raſtenburg.

MAITTAIRE, MICHAEL, in *Biography*, an eminent bibliographer and philologiſt, was born about the year 1668. The place of his birth has not been aſcertained, but it has been inferred from the name that he was deſcended from parents, refugees from France. He was educated at Chriſt-church, Oxford, and took his degree of M.A. in 1696: previouſly to this, he had been nominated ſecond maſter of Weſtminſter-ſchool, a poſt which he occupied till 1699. He was intended for the church, and wrote ſome controverſial pieces, but it does not appear that he took orders. He was patronized by the firſt earl of Oxford, and enjoyed the favour of the ſecond earl, and was afterwards appointed tutor to lord Cheſterfield's natural ſon, Mr. Stanhope. He was deeply ſkilled in claſſical learning, and was author of many works, which ſtill bear a good reputation. His firſt piece was entitled "Græcæ Linguæ Dialecti;" which was ſucceeded by an "Engliſh Grammar." Typographical antiquities were his ſtudy and delight, and he gave the public, in connection with theſe ſubjects, the following works: "Stephanorum Hiſtoria, vitas ipſorum ac libros complectens;" "Hiſtoria Typographorum aliquot Pariſienſium;" "Annales Typographici ab artis Inventione." In the firſt volume, the hiſtory of printing was brought down to the year 1500: the ſecond continued it till 1536;

1536; and the third to the year 1664. This was publifhed in 1725. A volume, publifhed at Amfterdam in 1773, ufually reckoned the fourth, is, in fact, a revifion of the other three. This is a work of great labour, and highly regarded by bibliographers. A fupplement to it was publifhed in 1789, at Vienna, fince which an enlarged edition of the whole has been printed at Nuremberg. Mr. Maittaire edited a number of claffical authors, both feparately and in a collected form: of thefe may be mentioned "Opera et Fragmenta veterum Poetarum," in two volumes, folio: "A Greek Teftament;" "Mifcellanea Græcorum aliquot Scriptorum-Carmina;" "Anacreontis Carmina;" and an edition of Livy in feven volumes 12mo. He addreffed to the emprefs of Ruffia, a "Carmen Epinicium," of his own compofition; and publifhed a volume of Latin poems under the title of "Senilia."

MAJUMA, or New Gaza, in *Geography*, a fea-port town of Paleftine, near *Gaza;* which fee.

MAIXENT, St., a town of France, in the department of the Two Sevres, and chief place of a canton, in the diftrict of Niort; 6 miles N.E. of Niort. The place contains 5000, and the two cantons 19,767 inhabitants, on a territory of 230 kiliometres, in 14 communes.—Alfo, a town of France, in the department of the Sarthe, feated on the Seure; badly built, furrounded with walls, and containing an ancient caftle with two fauxbourgs, and about 5000 inhabitants; 6 miles S. of La Ferte Bernard.

MAIZ, in *Agriculture*, a provincial term applied to a large light fort of hay bafket, in fome diftricts.

MAIZE, or Indian Corn, in *Botany*. See Zea.

Maize, in *Agriculture*, a fpecies of grain much ufed for food in America, under the name of Indian corn. It is very productive; the fize of its ears, where it is cultivated on good warm foils, being, on a medium, nearly a fpan long, having commonly eight or more rows of grain, each of which ufually contains about thirty feeds of various colours, as red, white, yellow, blue, olive, greenifh, blackifh, fpeckled, ftriped, &c. fometimes in the fame field and fame ear; but the white and yellow are the moft common: nor does this diverfity of colours ever reach beyond the outfide of the grain, the flower of which is always white, with a little tinge of yellow. The feeds, which are as big as large peas, are round at the outer furface, very fmooth, and fet extremely clofe in ftraight lines. The ear is clothed and armed with feveral ftrong thick hufks, which defend it not only from unfeafonable rains, and the cold of the night (for it does not ripen fully in fome places till towards the latter end of September), but alfo from birds. In the northern diftricts, the ftalk of this plant, which contains a remarkable fweet pith, and is jointed like the fugar-cane, does not grow near fo high as in the fouthern parts. It has long leaves, almoft like the flag at every joint, and at the top a bunch of flowers of various colours. Its culture upon any extenfive fcale has not hitherto been attempted in this climate.

Soil, Preparation, and Method of fowing or planting.—This kind of crop may be grown on moft forts of foils. On a light, poor, fandy foil, in Miller's trials, the method of preparation for it was to have the land ploughed up deep before winter, and laid up in high ridges till the fpring, when it was broken fine with the harrow. It was ploughed again in April, laid level, harrowed fmooth, and then fowed in drills, four feet afunder, into which the feeds were dropped at the diftance of about eight or nine inches from each other. When the plants were about three inches high, they were thinned with a hand-hoe, by cutting up fome of them where they grew too clofe, and the intervals between the rows ploughed fhallow, to deftroy the young weeds: but when the ftems were advanced, the ground in the intervals was ploughed deep, and the earth laid up to the plants on both fides; and when the weeds began to grow again, a third ploughing was given, to deftroy them. This kept the ground pretty clean from weeds till the corn was ripe, as the feafon did not prove wet; otherwife a fourth ploughing would have been neceffary.

In Ireland, in the experiments of fir Richard Bulkeley, the grains were fet a foot afunder, in rows about a yard diftant from each other. In the former of thefe cafes, there were from each ftalk from three to fix fpikes of grain, and in the latter from three to fix ftems, and upon each ftem three fpikes, or ears of corn, with two hundred and forty grains on each fpike, which was an amazing increafe.

In M. Duhamel's attempts to raife this fort of grain, he found it to thrive better in a light and fandy foil, than in ftiff and clayey land. It did not anfwer without dung; and the ground intended for it received two good ploughings in March. A third ploughing, given towards the end of April, made the furrows for the feed; and what clods remained after this were either broken by hand or the roller.

And a fine clear day was chofen in May for fowing the feed, which was done by making at the bottom of the furrows, with a ftick or other inftrument, fmall holes, into each of which two grains of maize were dropped. The furrows were a foot and a half afunder, and the holes at the fame diftance, difpofed in fuch a manner, as to form a kind of quincunx. When the corn-plants appeared, the weakeft of the two were plucked up, where both feeds had fprung; and where neither of them had grown, two new grains were planted. Towards the middle of June the ground was hand-hoed round each plant; and as they *ftud* at the bottom of the furrow, the mould which crumbles down from time to time, laid frefh earth to their roots, and helped to fupport them. About the end of July, a flight hoeing was again given them, which was the laft; and the earth laid towards the roots of the plants.

It is fuggefted, that the panicles of the male flowers, which grow at the top of each plant, and are well known not to contain any grain, fhould be cut off about the middle of Auguft, but care muft be taken that the grain be impregnated before this is done, which may be known by the turgid appearance of the outward covering of the ears: and they fhould not be cut off from all the plants at the fame time, as fome of the ears are not impregnated till a fortnight after others. Thefe panicles are excellent food for cattle. When they are cut, or fhortly after, all the leaves fhould be ftripped off the ftalks, together with all the blighted and fmutty ears: for it is faid, that the good ears would not grow fo large, nor the grains be fo well nourifhed, if they fhould be left upon the ftalks. All thefe leaves and ears are given as fodder to oxen.

The proper time for reaping maize is towards the end of September. The ears are then gathered by hand, and put into bafkets, in which they are carried, and laid in heaps, from fpace to fpace, in the field, after which they are loaded in carts, carried home, and fpread upon an even floor prepared for that purpofe. They are then taken out of their fheath, or hood, and dried in the fun, before they are laid up in the granary, or elfe the grain is taken out at that time. Maize, which has been well dried in the fun, will keep feveral years, and not be the lefs fit for fowing. The granary fhould be very dry, and the corn laid up in it fhould be turned at leaft every three months, to prevent its growing mufty, or being attacked by infects. There are two ways of taking out the grain; the firft, which is the moft expeditious, is by threfhing it with a flail; but in this method a deal of the corn is broken or bruiſed. The 2d, and more common, is by rubbing the ears hard againſt the edge of a flat piece of iron; this eaſily ſeparates the grains from the ſpike, or cob, without hurting them, and this remainder of the ear is very good food for oxen. As ſoon as the ears are gathered, the ſtalks remaining in the ground are plucked up, and laid by for winter fodder for oxen or other cattle. The field is afterwards ploughed up as ſoon as poſſible, it being the general opinion of farmers, that the roots of the maize would otherwiſe continue to ſuck up the rich particles of the earth: whether this be true or not, their notion is, that if this ploughing ſhould be deferred, the next year's crop would certainly ſuffer by it.

When maize is planted only for fodder, particularly for cows and oxen, it is ſowed very thick, and harrowed in, or covered with a rake, in a good ſoil which has been ploughed twice, and well dunged; but it is obſerved, that in theſe thick ſowings, all the female flowers are barren, and produce no grain: and it likewiſe is ſo great an impoveriſher of land, that though the ground be dunged every time it is planted, wheat never does ſo well where this corn has grown, as in the neighbouring fields where it never was grown.

In M. Amien's trials it was found of importance to ſow maize rather in the beginning than at the latter end of May, becauſe, if it be ſown early, the plants will have acquired ſufficient ſtrength, before the great heats, to ſhoot out then with vigour, and the ears be not liable to that barrenneſs to which they are ſubject when ſown late; beſides, the ſtalks will be ſtronger, and their ears larger and fuller of grain; the ears of maize alſo are greatly hurt by cutting the panicles too late, which ought to be done before the hoods are open. By leaving a plant with its male flowers at every twenty feet diſtance, all the female ears may be impregnated.

In order to aſcertain whether it is beſt to ſow maize thick or thin, he planted three different ſpots of ground with this corn in April; the ſeed uſed for the firſt, where the grains were placed about a foot and a half aſunder, according to the common practice of the country, weighed one ounce and one penny-weight; the ſecond, in which the grains were only a foot aſunder, was ſowed with two ounces and two penny-weights of ſeed; and the third, in which they were but ſix inches apart, was ſowed with four ounces and a half. The firſt of theſe ſpots produced eighteen pounds and four ounces of grain; the ſecond fifteen pounds ſeven ounces; and the third eleven pounds two ounces. A manifeſt proof, M. Amien thinks, that ſome ſorts of grain do not thrive unleſs they are ſown very thin, and that for want of this precaution, a great deal of corn is often loſt, and the crops conſiderably diminiſhed.

It is found that this plant, when cut green, affords a good cattle food: the grain is likewiſe highly uſeful for feeding poultry and hogs, and, when ground into flour, for various purpoſes.

But in America, according to a late writer, the common method to prepare land for Indian corn, is in the fall (Autumn) to plough it, or what is termed *fluſhing* it. The foil is raiſed in a rough manner by ploughing broad furrows; it being ſo thin, that it is not turned over, but ſtands very much on the edge: the ploughs are of a bad conſtruction. In the latter end of April, or beginning of May, the plan is to *liſt* it out, that is, croſſing the field five or ſix feet aſunder, ſetting two furrows back to back, then the like the other way, which forms a ſort of hill where theſe furrows croſs each other. The practice is then to go with a large hoe, ſuch as that its weight will break the clods in the ſame manner as malls (beetles) for that uſe, and make the mould very fine, ſomething in the manner that gardeners do for cucumbers in the field-gardens in this country. In theſe hills are put four or five corns, and this is generally done in the firſt of May.

Reckoning four corns to one hill, four thouſand only will be required to plant an acre containing a thouſand hills. When the corn is come up, the cuſtom is to go with their hoes, and draw a little mould to the plants, deſtroy any weeds that may appear, and plant freſh corn, if any be wanting, which often happens; that done, to plough from thoſe hills both ways, then to go with the hoes, and work the hills again, and to draw the plants of an inferior kind out, leaving two of the beſt on each hill, or if the land be good, three and ſometimes four, and to tranſplant thoſe drawn out where any are wanting. However, when more than two plants are left on one hill, there will be little corn, but much tops and blades. Then to plough all the land towards the plants one way; after this it is neceſſary to what they term *ſucker* them, that is, to take off any young ſprouts that have tillered, otherwiſe the corn will not grow in the ear to its proper length or ſize, but grow ſhort, what they call *cobbings;* this done, juſt before it goes into ſilk, they plough the land to the corn the contrary way, which is five times in all. The expence would be about ſeven pounds *per* acre, if the work were done by hired labourers, and horſes for ploughing.

Expences per Acre.

After the laſt time of ploughing, which is during the latter end of Auguſt, ſome of them ſow wheat under furrow, for which the Indian corn crop is a preparation, but which is harrowed in by others in September; the ploughing is done in a ſkimmering manner, very thin.

It is found that "the raiſing of Indian corn is an abſolute preparation for wheat, rye, or winter barley, and perhaps better for the land in that hot country, than if nothing was grown, coſting little more than the ſeed wheat. It is a general practice to cut the tops, and pull the blades, before they ſow the wheat; the topping and blading is done by cutting the tops off with a knife, juſt above the uppermoſt ear, as there are or ought to be two ears on each ſtalk, which are thrown out about four feet above the ground; the writer has had from five to ſeven ears put out ſilk, but they never came to perfection."

The writer, however, in his own practice, put the corn into the ground in drills, at different diſtances from three to

ſix

fix feet, harrowing the feed in, and found on actual trials, that a better crop of Indian corn may be raifed by planting at fix feet apart, and eighteen inches in the drills, than by any other mode which he has attempted, where the land is rich. Upon very poor land he does not, however, doubt but that the hill method may be fuperior, as by hoeing and ploughing there may be rather more of the beft earth added to the roots of the corn. This fort of drilling was found the beft and cleaneft method, as well as probably the cheapeft.

It is further ftated, that "good Indian corn will be from twelve to fourteen feet high, and that the white corn is much higher than the yellow; but the yellow is by far the fweeteft, although the tops and blades are not fo abundant. There are feveral kinds or varieties, both of yellow and white corn; the yellow is earlier than the white by one month." And, that, "the tops are fet up in bunches or fhocks; the blades are pulled off, tied up in fmall bundles, about one pound each, and hung on one of the corn ftalks by the tie or band, and in two or three days it is ready to carry." It is added, that "the ufual method of preferving them for the winter is to make what is termed a fodder-houfe, by fetting up long grained pofts, and laying a rail upon the top, then placing other rails upon the ground, leaning againft what may be termed the ridge-tree, they then lay the tops on like thatch, the blades are ftored within the houfe; the hufks are put into the houfe after the corn is gathered and hufked, and given in the winter to the cattle. The white corn generally hangs on till frofty weather, as it takes a great deal of curing or hardening, having a very thick hufk and a large cob. One leaf hangs over another, and the ear hangs downwards, and would not take harm all the winter, were not the ear to drop off the ftalk. It is generally gathered in frofty weather, and fometimes when fnow is on the ground. One reafon for this may be, that it does lefs injury to the wheat, as they are obliged to cart upon the land where the wheat grows. The corn is taken from the cob by hand, as it cannot be threfhed as grain is. The farmers have generally a hufking feaft, when all the neighbours come and help to hufk."

It may be noticed that this fort of crop was formerly introduced in rotation with other forts of grains, fo as to greatly injure the ground, as well as be lefs productive; and the practice ftill prevails in many places; but in the more improved methods of cultivation, and where the better forts of hufbandry prevail, it is now the cuftom to grow this kind of grain in courfes with crops of the green ameliorating fort, fuch as thefe below, and in that manner.

Courfes of Crops.

I. Old American Maize Courfe.	II. Better Maize Courfe.	III. Improved Maize Courfe.
1. Maize,	1. Maize,	1. Maize,
2. Wheat or rye,	2. Wheat, or fpring barley,	2. Beans,
3. Lay, or mean pafture;	3. Clover,	3. Barley,
or,	4. Rye or winter barley,	4. Clover,
1. Maize,	5. Clover,	5. Wheat,
2. Naked fallow,	6. Clover.	6. Clover.
3. Wheat,		
4. Lay, or mean pafture.		

This is not a beneficial crop, and from calculation it cannot; yet it muft be a ufeful one, as it is the whole fupport of the American population. They begin to eat it as foon as it is formed in what is termed roafting ears; they boil them, and eat the corn in the fame manner as we do green peas, with drawn butter, and no bacon, ham, beef, mutton, or any other kind of meat. The blades and tops feed the horfes, cattle, and fheep; the corn feeds both man and beaft, and is very excellent food for fowls, hogs, &c. The people eat it in *hominy*, mufh and bread, or cakes; the *hominy* is made in like manner to our creed wheat buttered, by knocking the hufk off in a wooden mortar; the mufh is made of the flour as our hafty pudding, and eaten with milk or treacle. The better fort of people make a very nice cake, with eggs and milk, about the thicknefs of pyflects, or what are called crumpets in London; the lower clafs of people mix the flour with water, make a fort of pafte, and lay it before the fire on a board or fhingle to bake, and generally eat it hot, as it is but very indifferent food when cold; it is called *Johnny* cake.

MAIZIERES, in *Geography*, a town of France, in the department of the Upper Marne, and chief place of a canton, in the diftrict of Joinville; four miles N.W. of Joinville.

MAKADAMA, in *Mythology*, a name of the Hindoo god of love, *Kama;* which fee.

MAKALLA, in *Geography*, a fea-port town of Arabia, in the province of Hadramaut; 60 miles S.S.W. of Hadramaut.

MAKANNA, a kingdom of Africa, fituated between the rivers Senegal and Gambia; 300 miles from the Atlantic ocean.

MAKARA, a fabulous marine monfter, frequently mentioned and alluded to by Indian authors. It is borne in the banner of *Kama*, the Hindoo god of love, as noticed under that article; one of whofe names is hence Makara-ketu. It is alfo the fign Capricorn in the Indian zodiacs, and fome writers deem it the horned fhark. A combination of the goat and fifh in that fign is not unfrequently feen on the zodiac of feveral nations, both eaftern and weftern, of which notice is taken under the article CAPRICORN.

MAKAREV, in *Geography*, a town of Ruffia, in the government of Niznei-Novgorod, on the Volga; 24 miles E.N.E. of Niznei-Novgorod. N. lat. 56° 25'. E. long. 44° 44'. Alfo, a town of Ruffia, in the government of Koftrom, on the Unza; 80 miles E. of Koftroma. N. lat. 58° 50'. E. long. 44° 14'.

MAKAYA, a town of Africa, in the kingdom of Kayor, about 21 miles from the Atlantic ocean. N. lat. 15° 20'. W. long. 16° 24'.

MAKE, in *Law*, fignifies to perform and execute.

Thus, to make his law, is to perform that law to which a man had formerly bound himfelf; *v. gr.* to clear himfelf of action commenced againft him by his own oath, and the oath of his neighbours, otherwife called to wage law. See WAGER *of Law*.

So, to make fervices or cuftoms, is nothing elfe but to perform what belongs to them.

MAKE-

MAKE-*hawk*, in *Falconry.* See HAWK.

MAKE, *To*, in *Sea Language*, is varioufly applied : *e. g. to make a board*. See BOARD.

To make the land, is to difcover it from a diftant fituation, in confequence of approaching it after a fea voyage: to make fail is to increafe the quantity of fail already extended, either by letting out the reefs, and by hoifting an additional number of fmall fails, or by either of thefe operations feparately: to make ftern way, is to retreat or move with the ftern foremoft : to make water cafually fignifies to leak ; but a fhip is faid to make foul water, when running in fhallow water, her keel difturbs the mud or ooze, lying at its bottom.

MAKEN KUR-ASSAY, in *Geography*, one of the Kurile iflands, about 20 verfts in length, and ten in breadth. It is fcattered with rocks, efpecially about the fhores, and many meadow grounds and moift places. It has no ftanding wood, but a few fhrubs ; its red foxes are few; fea-beavers and feals lie about its fhores. It has neither lake nor ftream, though it abounds with fprings ; it is altogether uninhabited.

MAKEFIELD, UPPER *and Lower*, townfhips of America, in Berks' county, Pennfylvania, the former containing 1101, and the latter 963 inhabitants.

MAKENABAD, a town of Perfia, in Segeftan ; 90 miles S.E. of Zareng.

MAKER, a village of England, in the county of Devon, on the Cornifh fide of the Tamar, near Plymouth found : the church tower of which is a fea mark. N. lat. 50 20′. W. long. 4° 11′.

MAKER-DUR, a town of Hindooftan, in the circar of Kitchwara ; 22 miles N. of Budawar.

MAKERRA, a river of Algiers, that rifes about 26 miles E. from Tremecen, and after a courfe of about 30 miles changes its name to Sig.

MAKESIN, a town of Afiatic Turkey, in the province of Diarbekir, on the Khabur ; 105 miles S.W. of Moful.

MAKIAN. See MACKIAN.

MAKINBOY, a name given by the people of Ireland to a kind of fpurge, or tithymale, common there : this is a very violent purge, as all the other fpurges are ; but the Irifh have an opinion that it will produce this effect only by being carried in the pocket. This opinion, which had been univerfally believed for many ages, was proved to be falfe by Dr. Mullen, who carried a large quantity of it about him many days together, on purpofe to give a fair trial ; but it had not any the leaft effect on him.

MAKING-UP, a term ufed by diftillers to exprefs the bringing fpirits to a certain ftandard of ftrength by the addition of water. See LOWERING.

It is ufed principally in the diftilling fpirits, after their firft drawing, either by way of rectifying them, or of giving them the virtues of aromatic ingredients, in order to make the compound waters ; fuch as cinnamon, anifeed, and the like. See DISTILLATION.

In the making of thefe compounds, fome ufe an alcohol, or totally inflammable fpirit, which is much the beft method ; others ufe ordinary proof fpirit of malt, or molaffes. If the latter be ufed, it is beft not to put any water with it into the ftill ; but if the former, fo much water is to be added as will reduce it to the proof ftrength, which is juft an equal quantity. When this is done, there fhould be drawn off three-fifths of the whole by diftillation ; and the far better way would be to keep this liquor in this very ftate, which is juft the ftrength of the trois-cinques brandy of the French : but as people require thefe waters to be kept for drinking, in fuch a ftate as not to exceed at the utmoft the ftrength of proof fpirit, generally to fall much fhort of it, it is neceffary to reduce this three-fifths to the whole, or more than the whole quantity of the proof fpirit put into the ftill. The apothecaries, to this end, ufually let the ftill continue to work without changing the receiver, till an equal quantity is produced to the fpirit put in, or one-fourth more ; it being the ufual ftandard in thefe waters to have five quarts made from a gallon of the fpirit. By the method of doing this, by letting the ftill run, the faints are taken into the water, and give it a vapid and difagreeable tafte. Inftead of this, the diftiller, when he has drawn off his three-fifths of the quantity of proof, makes up the whole of the deftined quantity, by adding the two other fifths, or more than that, if required, of common water, in which it is alfo cuftomary to diffolve fome fine fugar, and this gives a fulnefs in the mouth to the water, and makes it mellow, or lofe the fiery tafte of the ftill much fooner. If it be only made up to the ftrength of proof, it will mellow much fooner than if reduced one-fifth below that ftandard, as the oil is much more perfectly diffolved in fpirit of a ftandard proof ftrength, than in fuch as is weaker. The water employed in the making up, fhould be either foft and clear river-water, or elfe fpring-water rendered foft by diftillation, otherwife it is apt to turn the water thick, and precipitate a fediment, efpecially if the water be drawn lower than proof, or if the fpirit, originally employed, partake of an alkaline nature from the falts ufed in its rectification, as is ufually the cafe in the malt fpirits, the grofs oil of which requires to be feparated by mixing falt of tartar or pot-afh with it in the ftill in the rectification

When it is neceffary to make up waters lower than proof, they are generally cloudy ; but this may be remedied, and they may be fined down in a day or two with a fmall quantity of alum, or with whites of eggs, or the jelly of ifinglafs beat up to a froth, and mixed in the fame manner as is ufually done in the refining of wines.

The fugar, added to thefe cordial waters, has not only the advantages of mellowing and filling the mouth, but it unites the oil to the fpirit in a manner that it could never be united in without it. Shaw's Effay on Diftillery.

MAKKEDAH, in *Ancient Geography*, a royal city of the tribe of Judah, in Paleftine, near which the five kings of the Amorites were put to death by Jofhua. It was once a very ftrong city, and placed by Eufebius about eight miles from Eleutheropolis.

MAKO, PAUL, in *Biography*, canon of the cathedral of Waizen, a learned Hungarian, defcended from a noble family, was born at Jafz-apatin in the year 1724 ; he entered the order of the Jefuits, and made fuch progrefs in his ftudies, that he was foon appointed teacher of logic and metaphyfics at Tymau, and afterwards profeffor in the univerfity of Vienna. He filled the fame department afterwards in the Therefianum, where he procured, by his amiable difpofition, the love and efteem of all the young nobility who frequented that feminary from almoft every part of Europe ; and when the Hungarian high fchool of Tymau was afterwards transferred to Ofen, the emprefs, Mary Therefa, appointed him a member of the academic fenate. He exerted himfelf with great zeal and ability to introduce a tafte for fcientific purfuits into Hungary ; and during his moments of leifure, he purfued, with unabating ardour, the belles lettres. He died in 1793. The principal works which he left behind him are, "Defcriptio Provinciæ Moxitarum in regno Peruano, quam e Scriptis pofthumis Franc-Xav. Eder e Soc. Jef. Annis XV. facri apud eofdem curionis digeffit, expolivit et adnotatiunculis illuftravit, P. Mako ;" "Differtatio Phyf. de natura et remediis Fulminum ;" "Elementa Mathefeos puræ;" "Elementa Geometriæ Puræ." Gen. Biog.

MAKONDA, in *Geography*, a town of Africa, in Loango, on the fea-coaft; 40 miles N.W. of Loango.

MAKOONDA, a town of Hindooftan, in the country of Allahabad; 60 miles S. of Allahabad. N. lat. 24° 33'. E. long. 84 37'.

MAKOVITZE, a town of Hungary; 16 miles S.E. of Palotza.

MAKOUSKI, John, in *Biography*, generally known by the name of *Maccovius*, a celebrated Polifh Proteftant divine, and profeffor of divinity at Franeker, was born at Lobzenic in the year 1588. He went through his courfe of philofophy at Dantzic, under the celebrated Keckerman, and rofe to eminence among his fellow ftudents. He was admitted doctor of divinity at Franeker in the year 1614, and was in the following year elected to the profefforfhip of divinity in the univerfity. In the exercife of the duties attached to his office, he was accufed of herefy, and the charge being made, it was examined by the fynod of Dort, who gave it as their opinion, that he was unjuftly accufed. He died in 1644, leaving behind him feveral works relating to the controverfy againft the Arminians and Socinians. Moreri.

MAKOVSKOI, in *Geography*, a town of Ruffia, in the government of Tobolfk, on the Ket; 48 miles W. of Emfeifk.

MAKOW, a town of Perfian Armenia; 81 miles S. of Erivan.—Alfo, a town of the duchy of Warfaw; 40 miles N.N.E. of Warfaw.

MAKRAN. See Mecran.

Makran, a town of Arabia, in the province of Hedsjas, the refidence of a fcheich.

MAKSCHOUS, a town of Arabia, in the highlands of Hedsjas, the refidence of an independent fovereign fcheich, whofe domain contains feveral towns and villages. This fcheich is of the tribe of Harb, and he is fo powerful that on occafion he can bring 2000 men into the field. During the months favourable for pafturage, the moft diftinguifhed perfons of this tribe live in tents; during the refidue of the year, they inhabit the towns and villages. The lower clafs live commonly through the whole year in huts thatched with grafs. Their principality is fituated upon the mountains between Mecca and Medina. The chief of the tribe of Harb is the perfon who principally harafles the caravans, and lays them under contribution. Unlefs the Syrians and Egyptians pay the tribute he demands, for permiffion to pafs through his territories, he mufters up an army of his own fubjects and his neighbours, all of whom are very willing to pillage a caravan.

MAKSENOVKA, an oftrog of Ruffia, in the government of Irkutfk, on the coaft of the Frozen fea. N. lat. 72. E. long. 134° 24'.

MAKSIMA, St., a fmall ifland of Ruffia, in the Frozen fea. N. lat. 71° 20'. E. long. 133° 34'.

MAKSUDEGHI, a town of Perfia, in Farfiftan; eight miles S. of Komfha.

MAKSZYN, a town of Bulgaria; 50 miles W.S.W. of Ifmael.

MAKTIN, a town of Beffarabia; 34 miles S.S.W. of Akerman.

MAKU, or St. Thaddeus, a town of Perfian Armenia, on the Akfiai, a river which runs into the Aras; 60 miles S. of Erivan.

MAL des Ardens, or *Morbus ardentium*, in *Medicine*, terms which have been applied by fome medical writers to two or three different epidemic difeafes, in an acceptation nearly fynonimous with the *ignis Sti. Antonii*, and *ignis facer* of others. See Ignis *facer*, and Ergot.

MALA, or Demala, in *Geography*, a town of European Turkey, in the Morea; 45 miles S.E. of Argos.

Mala, a river of Peru, which runs into the Pacific ocean, S. lat. 12° 40'.

Mala *Aurea*, in *Botany*, a name by which fome authors have called the *poma amoris*, or fruit of the lycoperficon.

MALAAC, in *Geography*, a town of Meckley, 12 miles S.S.E. of Munnypour.

MALABAR, a name given to the weftern coaft of Hindooftan, from cape Comorin to about 100 miles S. of Goa.

The name of Malabar is faid to be derived from the Malabar word "Malayalam," denoting "mountainous;" the terminations *ar*, *tar*, and *bar*, fignifying, in that language, a *people* or *nation*; confequently "Maleiwar" or "Maleibar" would denote as much as "mountaineers," or "inhabitants of the mountains." The fyllable *lai*, when uttered with rapidity, takes the found of *la*, and the name of Malabar was applied to the people, from the hilly country, who defcended from the mountains, and fettled upon the coaft.

That tract of country which is properly called the Malabar, lies nearly in the direction of N.W. and S.E. from cape Comorin to Canara, between the 18th and 14th degrees of north latitude; to the eaft, it is divided from the coaft of Coromandel, by a high range of mountains, called the "Ghauts," and to the fouth-weft it is wafhed by the Arabian fea. The principal kingdoms which it comprehends are thofe of Travancore, Cochim, Cranganore, and Calicut; of which the firft has become the principal and the moft powerful. The Malabar, or rather the forts of Coylang, Cali Coylang, Cranganore, and Cananore, eftablifhed by the Portuguefe on that coaft, were conquered by the Dutch in the years 1662 and 1663, and they long retained the poffeffion of all, except Cananore. The extent of the Dutch company's poffeffions from Coylang to Chittua, Cananore not being under their dominion, comprifed, from S.E. to N.W. a diftance of 32 leagues; but if we except *Paponetty*, (which fee,) and fome fmall diftricts interfperfed along the coaft, the company poffeffed no other actual property in the foil, than in that upon which their fortifications were conftructed. The land is every where low, interfected by many rivers, which defcend from the interior mountains; it abounds in plantations of trees, and more efpecially of the cocoa-nut tree, and affords a very pleafant profpect. The rivers render it extremely fertile, particularly in rice; the fea furnifhes a copious fupply of fifh, and provifions are cheap. The feafons are diftinguifhed into the dry and rainy, called the bad and good monfoon; the former being reckoned from October to April, and the latter comprehending the other months. This divifion is occafioned by the mountains of the Ghauts; for upon the coaft of Coromandel, the reverfe takes place with refpect to the monfoons.

The firft and principal article of trade produced upon the coaft of Malabar is pepper, which is very abundant, and reckoned the beft in Afia. The Areca nut is the fecond production of the country; and this is conveyed by land to all parts of the peninfula, and likewife by fea, to the coaft of Coromandel, and to Bengal. A third production is the wild cinnamon (Caffia lignea), of which it is faid that a quantity of one million of pounds is yearly exported to the gulf of Perfia, and to the Red fea; and a fmall proportion is fent to Europe, where it is principally ufed to adulterate the genuine, or Ceylon, cinnamon. Coarfe cotton cloths are alfo made in the fouthern parts, in the Travancore country, which, without forming a confiderable object of trade, were moftly

moftly difpofed of to the Englifh at Anfjengo. Capok forms alfo an article of trade, and is exported to Bengal, to the coaft of Coromandel, and to China.

The native inhabitants of the country are inclined to be lean; they are ufually of the fame fize and ftature as the Gentoos at Surat and in Bengal; but they are much blacker, nearly as black as the African negroes, though with better formed countenances. Their religion is that of the Hindoos, but many of them have been converted by miffionaries to the Roman Catholic perfuafion, and they have many Roman Catholic churches. Here are alfo many Chriftians, of thofe denominated Chriftians of St. Thomas. Among the Malabars, the "Nairs" are the nobles and warriors of the land, who are diftinguifhed by the fcymetar which they always wear, and who poffefs many privileges above the common people. Their princes poffefs almoft an abfolute authority over their fubjects. Befides the original Malabars, many other people have been allured to fettle here, by the profits of trade; fuch as Moors, Arabians, Perfians, and a colony of Jews, who, as they pretend, are the pofterity of the ten tribes carried away into captivity by Shalmanefer. Thefe dwell in a feparate town, in which are three fynagogues. The towns, or villages, which they inhabit, and where they are employed in trade, has received the appellation of "Makwan-Sieri."

Cranganore was fold by the Dutch to the king of Travancore, taken from him by Hyder Ali, and re-taken by the Englifh in 1790. Cochim, Quilon, Quila-Quilon, and the other fettlements of the Dutch, on the coaft of Malabar, have fhared the fate of the greater part of their Indian poffeffions, and are actually in the hands of the Englifh.

MALABAR, *Cape*, or *Sandy Point*, a narrow ftrip of land, projecting from the S.E. part of cape Cod, in the Maffachufetts, eight miles S. by W. N. lat. 41° 33'. W. long. 70° 3'.

MALABAR *Nut*, in *Botany*, a fpecies of the *jufticia*; which fee.

MALABATHRUM, among the *Ancients*, an excellent fweet-fcented ointment.

MALABATHRUM, *Indian leaf*, in *Botany*. See TAMALAPATRA.

MALABRIGO, in *Geography*, a harbour on the coaft of Peru, in the South fea.

MALACATLAN, a town of Mexico, in the province of Mechoacan; 16 miles S.E. of Colima.

MALACCA, or MALAYA, a peninfula of Afia, at the extremity of the kingdom of Siam, furrounded by the fea, except at its junction with this kingdom. The northern limits are not ftrictly defined; but the peninfula is reckoned to be about 80°, or 560 Britifh miles in length, and in medial breadth about 150 miles. It derives its name from the Malays, who are moftly Mahometans, and in a confiderable degree civilized; but the inland parts feem to be poffeffed by a more rude native race, of which our knowledge is very imperfect. In the laft century Mandelflo, or rather Olearius, who publifhed his voyage, defcribes Malacca as divided into two kingdoms, that of "Patani" in the north, and that of "Johor" in the fouth. The former was inhabited by Malays and Siamefe; who were by profeffion Mahometans, and tributary to Siam. The town is built of reeds and wood, but the mofque of brick; and the commerce was conducted by the Chinefe and Portuguefe fettlers, while the native Malays were chiefly employed in fifhing and agriculture. From this traveller we learn, that in Malacca there are continued rains with a N.E. wind during the months of November, December, and January. Agriculture was conducted with oxen and buffaloes, the chief product being rice. Game and fruits were abundant, and the forefts fwarmed with monkies, tigers, wild boars, and wild elephants. Befides the tiger and elegant, Malacca produces the civet-cat, and Sonnerat fays that wild men are found here, meaning perhaps orang-outangs. Some fingular birds are alfo found; and it likewife produces a delicious fruit called the Mangoften. The Portuguefe were accuftomed to purchafe annually from Patani about 1500 cattle for their fettlement at Malacca. The kingdom of Johor comprehended the fouthern extremity of the Cherfonefe, and its chief towns were Linga, Bintam, Carimon, and Betufabea, the laft of which was the capital, fituated in a marfhy fituation, on the river Johor, about fix leagues from the fea, and confifting of houfes elevated about eight feet from the ground. The whole of this country belonged to the king, who affigned lands to thofe who demanded them; but the indolence of the Malays left it to the wild luxuriance of nature. According to the account of Valentyn, the peninfula of Malacca is bounded on the north by the river Riadang, which runs by Linga to the eaft, and by a fmall range of hills that feparate it from the kingdom of Siam; and it contained five provinces, which derive their names from their capitals. On the eaftern coaft are thofe of Patani and Pahang, followed by the moft fouthern kingdom of Djohor or Johor; and on the weftern coaft are thofe of Keidah, or Quedah, and Perah, followed by another province called the Malay coaft, and of which the capital is Malacca. The inland part of the peninfula feems to remain full of extenfive and original forefts, without towns or villages; but the country, though not fufficiently explored, is now known to produce pepper and other fpices, with fome precious gums and woods. The chief mineral is tin, in which Quedah and Perah, as Hamilton denominates them, are rich; and a high mountain N.E. of Malacca fupplies rivers that afford fmall quantities of gold duft. In the river Pahaung, flowing near the town of Malacca, lumps of gold about five or fix ounces in weight have been found at the depth of from three to ten fathoms. Of the government of Malacca we may form an idea from the account which Mr. Marfden has given of that of the Malays in Sumatra. See MENANGEABOW.

From an account of the ancient hiftory of this country, cited by Valentyn in his "Defcription of the Dutch Settlements in the Eaft Indies," 1726, from a Malay MS. written in the Arabian character, we are led to believe, that the Malays were firft fettled on the eaftern coaft of Sumatra, in the kingdom of Palambang, oppofite to the ifle of Banca, at the river Malajee, which encircles the mountain Mahameirac, and afterwards joins the river Tatang. Some have fuppofed that the river derives its name from the Malays; but Valentyn is of opinion that they derived their name from the river, and communicated it to their prefent peninfula, which formerly belonged to the king of Siam, and was inhabited by fifhermen. This MS. being recent, we can only infer from it that the Malays came from the weft. The traditions founded on this and other fimilar MSS. report, that the Malays, during their refidence in Sumatra, chofe a king, who reigned 48 years, and pretended to be a defcendant of Alexander the Great. This happened about the year 1160 of the Chriftian era. During this reign, it is faid, the Malays proceeded to the oppofite coaft and fettled on the N.E. corner, whence they gradually fpread, and the country affumed the name "Tanah Malajee," or Malay land, extending from 2 to 11 N. lat. After a refidence of fome years, the Malays built their firft town "Singapoera," which gave its name to the fouthern ftrait.

ſtrait. The laſt king of Singapoera was compelled by a hoſtile ſovereign of a diſtrict in the iſle of Java to retire northward, where, in the year 1253, he built a new capital, called Malacca, as it is ſaid, from the name of a tree, the Mirabolan, under which he had taken ſhelter, while he was hunting. Having eſtabliſhed ſalutary laws, he died in the year 1274. As this king had adopted the appellations "Shah" and "Sultan," it furniſhes a preſumption, that Mahometaniſm was now introduced. The ſecond in ſucceſſion after this prince, who is eſteemed the firſt Mahometan ſovereign, reigned 57 years. He extended more widely the name of Malays, and having acquired by marriage the kingdom of Aracan, he died in 1333. In proceſs of time, the commercial town of Malacca was regarded, with Madjapit and Poſi, as the third celebrated city in theſe regions. Sultan Mantſoer Shah, who aſcended the throne in 1374, and in the courſe of his long reign of 73 years, annexed by marriage the kingdom of Andrigiri on the E. ſide of Sumatra, to Malacca, became ſo powerful that he was ſtyled emperor. In conſequence of an alliance with the emperor of China, whoſe daughter he married, he ſubdued the kingdom of Pahang. Malacca was now eſteemed the chief city in theſe parts of the eaſtern world. Mantſoer died in 1447. During an inglorious reign of his ſon and ſucceſſor, the 11th king of the Malays, the 6th of Malacca, and the 5th who profeſſed the Mahometan religion, Malacca became ſubject to Siam; but at his death, in 1477, he was ſucceeded by a prince, under whoſe government, in the year 1509, the Malays threw off the yoke of Siam. It was in this year that the Portugueſe diſcovered Malacca, to which they were led by the vain idea of finding the golden Cherſoneſe of the ancients.

With this view Emanuel, king of Portugal, ſent out a fleet of 16 ſhips under the command of Sequeira. Among the officers of this fleet was Magalhaens or Magellan, who afterwards became famous as the firſt circumnavigator of the globe. Many attempts were made to aſſaſſinate Sequeira, and finding it impoſſible to make a commercial arrangement advantageous to his country, he returned to Portugal. At this time Albuquerque (ſee his article) was the Portugueſe viceroy in the Eaſt Indies. On the 1ſt of Auguſt, 1511, he arrived before Malacca with a powerful fleet, while the king of Pahang was in the town on occaſion of celebrating his nuptials with the daughter of ſultan Mahmud Shah, the ſovereign of the peninſula. Malacca was taken by ſtorm; and the king fled to Johor, where he founded a new town and kingdom. The Portugueſe, having gained complete poſſeſſion of Malacca, formed an alliance with Siam. The king of Johor died in 1513, and was ſucceeded by his ſon ſultan Ahmud Shah, who afterwards made a treaty with the Portugueſe. Among the Portugueſe governors of Malacca was Peter Maſcarenhas in 1526, from whom was, probably, derived the name anciently given to the iſle of Bourbon. During the reign of a ſovereign, called Alawoddin, who took poſſeſſion of the throne in 1591, the Dutch arrived, and formed an alliance with this prince againſt the Portugueſe. In 1606 the Dutch, in conjunction with the king of Johor, attacked Malacca; and they made various attempts in ſucceeding years to gain poſſeſſion of the country. But they were obliged to content themſelves with a factory in Johor. At length Anthony Van Diemen, the famous governor-general of the Dutch ſettlements in the Eaſt Indies, finding a favourable opportunity for the execution of his purpoſe, diſpatched in June 1640, a fleet of 12 ſhips and ſix ſloops to blockade Malacca; and theſe were joined by about 20 ſmall veſſels of Johor. The Dutch ſoon erected a battery, and the ſiege was accompanied with famine and peſtilence. In January, 1541, the famine was ſo ſevere, that the inhabitants were obliged to expel their women and children. The Dutch alſo ſuffered much from heat and fatigue; and at length impatience and deſperation produced a general aſſault, which was executed on the 14th of January; and the governor capitulated. Valentyn reports, that during the ſiege more than 7000 died in the town and a greater number found means to eſcape. The Dutch loſt about 1500, chiefly by the plague. Thus the Portugueſe, after a poſſeſſion of nearly 130 years, loſt this valuable ſettlement, then eſteemed, after Goa, the richeſt in the Eaſt Indies. Malacca, which is repreſented as a ſtrong place, was taken poſſeſſion of by the Engliſh in Auguſt 1795. The Malay empire is now added to the dominions of Great Britain in the Eaſt by the capture of Java, in conſequence of which Britain is become the miſtreſs of the whole of the Malayan Archipelago.

The Malays, whoſe origin is not ſatisfactorily aſcertained, are in general a well made people, ſomewhat below the middle ſtature. Their limbs are ſmall, but well ſhaped, and they are particularly ſlender at the wriſts and ankles. Their complexion is tawny, their eyes large, their noſes ſeem to be flattened more by art than nature; and their hair is very long, black, and ſhining. They are reckoned the moſt ingenious, ſagacious, and poliſhed people in the Eaſt Indies. As the Malays reſemble the Chineſe and Tartars in their features, it has been ſuggeſted as probable that they are deſcended from thoſe nations. Their progreſs from Malacca, acroſs the narrow ſtrait of that name, to Sumatra, from thence to Java, and from Java to all Polyneſia, was ſo eaſy, even in the moſt frail veſſels, that there is no difficulty in accounting for their being found, as they really are, in poſſeſſion of the ſea-coaſts of almoſt every iſland. Mr. Marſden, in the laſt edition of his valuable work, ſeems to have retracted the opinion which he once held of Malacca being the original country of the Malays, and to think that they paſſed thither from Sumatra. Not only their phyſical appearance, but their manners and cuſtoms, as well as language, have undergone a conſiderable change by the overwhelming influence of the Arabs, who from the 9th to the 14th century, appear to have enjoyed the excluſive commerce and dominion of the oriental iſlands, the greater part of which has received the religion of Mahomet. Theſe people in former times poſſeſſed great powers, and made a very conſiderable figure on the theatre of Aſia; and their country was well cultivated and populous. The ſea was covered with their ſhips, and their commerce was very extenſive. At different times they ſent out various colonies, which in ſucceſſion peopled a great part of Sumatra, Java, Borneo, Celebes, and Macaſſar, the Moluccas, the Philippines, and thoſe innumerable iſlands of the Archipelago, which bound Aſia on the E. and which occupy an extent of 700 leagues in longitude from E. to W. and about 600 in latitude from N. to S. Every where the people ſeem to be the ſame. They ſpeak almoſt the ſame language, and they have the ſame laws and the ſame manners. To this purpoſe Kæmpfer ſays in his "Hiſtory of Japan," that the Malayans had in former times the greateſt trade in the Eaſt Indies, and frequented with their merchant ſhips not only all the coaſts of Aſia, but ventured even over to the coaſts of Africa, particularly to the great iſland of Madagaſcar. That the Malayans have not only frequented Madagaſcar, but that they have been the progenitors of ſome of the preſent race of inhabitants, is confirmed by the teſtimony of M. de Pages, who viſited that iſland ſo late as 1774. The title which the king of the Malayans aſſumed to himſelf, ſays Kæmpfer, of "Lord of the Winds and Seas to to the Eaft and Weft," is an evident proof of their extenfive migration; but much more the Malay language, which fpread almoft all over the Eaft, much after the fame manner as formerly the Latin, and of late the French, did all over Europe.

M. le Poivre, cited by Mr. Pennant in his "Outlines of the Globe," fays, that travellers, who make obfervations on the Malays, are aftonifhed to find in the centre of Afia, under the fcorching climate of the line, the laws, the manners, the cuftoms, and the prejudices of the ancient inhabitants of the north of Europe. The Malays are governed by feudal laws, "that capricious fyftem, conceived for the defence of the liberty of a few againft the tyranny of one, whilft the multitude is fubject to flavery and oppreffion." Thus we have here a chief, who has the title of king or fultan, iffuing his commands to his great vaffals, who obey when they think proper; thefe have inferior vaffals whofe conduct is fimilar to that of their fuperiors. The "Oramcai," or noble, forming a fmall part of the nation, live independent, and fell their fervices to thofe who are difpofed or able to give them the beft price; whilft the body of the nation is compofed of flaves, and lives in perpetual fervitude. With thefe laws, fays M. le Poivre, the Malays are reftlefs, fond of navigation, war, plunder, emigrations, colonies, defperate enterprifes, adventures, and gallantry. They talk inceffantly of their honour and bravery, whilft they are univerfally confidered by thofe with whom they have intercourfe as the moft treacherous and ferocious people on the face of the globe; and yet, which appears extremely fingular, they fpeak the fofteft language of Afia. The ferocity of the Macaffars is the reigning characteriftic of all the Malay nations, and as an evidence of their faithleffnefs and treachery, it is alleged, that their treaties of peace and friendfhip never fubfift beyond that felf-intereft by which they were induced to make them; and they are almoft always armed, and either at war among themfelves, or employed in pillaging their neighbours. Their ferocity, mifnamed courage by the Malays, is fo well known to the Europeans who have fettlements in the Indies, that they have univerfally agreed in prohibiting the captains of their fhips, who may put into the Malay iflands, from taking on board any feamen of that nation, except in the greateft diftrefs, and then on no account to exceed two or three. It is not uncommon for a few of thefe horrid favages fuddenly to embark, attack a veffel by furprife, poignard in hand, maffacre the people, and make themfelves mafters of her. Malay barks, with 25 or 30 men, have been known to board European fhips of 30 or 40 guns, in order to take poffeffion of them, and murder with their poignards great part of the crew. Thofe Malays who are not flaves always go armed; and they would think themfelves difgraced if they went abroad without their poignards, or criffes.

The attire of the males confift of pantaloons with a wide robe of blue, red, or green; the neck is bare, but the head is covered with a turban. The female drefs, like that generally ufed in the Eaft Indies, is a long narrow petticoat, reaching from the breaft to the feet, whilft the other parts are naked, and the hair is commoly tied. The women are reckoned more intelligent than moft others in the eaft, and their converfation is of courfe fenfible and agreeable.

The other inhabitants of Malacca are Portuguefe, Moors, and Chinefe, and fome fettlers from Bengal and Guzerat. The chief articles of commerce are azel wood and camphor from the kingdom of Pahang; tin, gold, pepper, pedra de porco, and ivory. The manufactures are various articles of drefs, worn here and in Hindooftan, cottons, chintz, &c. and fome articles of copper. When Malacca came into the poffeffion of the Dutch, the Dutch Eaft India company appointed the governor, under whofe controul were feveral factories, fome in the peninfula, and others on the coaft of Sumatra. The factories are thofe of Peirah, or Perah, on the Malay coaft, for the tin trade; of Keidah, or Quedah, on the fame coaft, for carrying on commerce with the petty king of Xeedah, for tin, gold, and ivory; of Oedjan-Salang, for tin and ivory; of Andrigiri, on the coaft of Sumatra, for pepper and gold. The Dutch alfo traded with Ligor and Tanaferim, in the dominions of Siam, for tin; and with Bangkoelo, for gold and pedra de porco before the Englifh eftablifhed themfelves there. The ifland Dending was alfo confidered as a dependence of Malacca.

The language of the Malays, which is original in the peninfula, has been called the Italian of the eaft, on account of the melody of its frequent vowels and liquids, and the infrequency of any harfh combination of mute confonants. Their character is the Arabic. Mr. Marfden could never difcover that the Malays have any original written characters peculiar to themfelves, before they acquired thofe now in ufe; though it is poffible that fuch may have been loft. The adoption of the Mahometan religion has occafioned an influx of Arabic words into their language: the Portuguefe have alfo furnifhed them with many new terms. They write on paper with ink of their own compofition, and pens made of the twigs of a tree. The pureft Malay is fuppofed to be fpoken in the peninfula, and it has no inflexions of nouns or verbs; and, confequently, no cafes, declenfions, moods, or conjugations; all which inflexions are performed by the ufe of certain words expreffive of a determinate meaning. The Malay language, or that which may be confidered as its radix or foundation, has branched out into various dialects, that have been extended to all the iflands of the eaftern fea; from Madagafcar to the remoteft of Capt. Cook's difcoveries, comprehending a wider extent than the Roman or any other tongue has yet boafted.

Of the connection and fimilarity of thefe various languages, Mr. Marfden has exhibited indifputable examples in a paper addreffed to the Society of Antiquaries, and publifhed in the "Archæologia," (vol. vi.) In different places it has been more or lefs mixed and corrupted, but between the moft diffimilar branches, an evident famenefs of many radical words is apparent, and in fome, very diftant from each other in point of fituation, *e.g.* the Philippines and Madagafcar, the deviation of the words is fcarcely greater than is obfervable in the dialects of neighbouring provinces of the fame kingdom. See Marfden's Hiftory of Sumatra, and Dictionary.

In the third volume of the "Afiatic Refearches" (p. 11 and 12.) fir William Jones has pointed out, in a clear and decided manner, the connection between the Malayan and Sanfcrit languages; and Mr. Marfden (Id. vol. iv. p. 217.) obferves, that the Malayan is indebted to the Sanfcrit for a confiderable number of its terms. This ingenious writer conceives, that the intercourfe by which this communication was effected muft have taken place in times anterior, probably by many centuries, to the converfion of thefe people to the Mahometan religion; and before a great number of Arabic words, borrowed from the Koran and its commentaries, were introduced into the language. Our author, however, does not imagine, that the affinity between thefe languages is radical, or that the names for the common objects of fenfe are borrowed from the Sanfcrit. The Malayan, as we have already ftated, is a branch or dialect of the widely extended language prevailing throughout the iflands of the Archipelago, called the "Malay-archipelago" and comprehending the Sunda, Philippine, and Molucca iflands, in the maritime parts of which the Malayan is ufed as as a "lingua franca," and alſo thoſe of the South ſea, including, between the fartheſt limits of Madagaſcar on one ſide and Eaſter iſland on the other, the ſpace of full 200 degrees of longitude. This conſideration alone is ſufficient to give it claim to the higheſt degree of antiquity, even to originality, as far as that term can be applied. The various dialects of this ſpeech, though they have a wonderful agreement in many eſſential properties, have experienced thoſe changes, which ſeparation, time, and accident produce; and in reſpect to the purpoſes of intercourſe, may be claſſed into ſeveral languages, differing conſiderably from each other. The marks of cultivation which diſtinguiſh the Malayan from his ruder neighbours, are to be attributed, in the opinion of Mr. Marſden, to the effects of an early connection that muſt have ſubſiſted between the inhabitants of this eaſtern peninſula, and thoſe of the continent of India. The Malayan, as he conceives, has not received any portion of its improvement, except from the genuine Hinduvee of the northern provinces, prior to its debaſement by the mixture of Arabic nouns, and the abuſe of verbal auxiliaries. If the communication ſhould be ſuppoſed to have its origin in commerce, our author inclines to conſider the people of Guzerat, notwithſtanding their diſtance, as the inſtructors of the Malays; as it is well known that the Hindu language has been preſerved with greater purity in that, than in any other maritime province of India. The probability is ſtrong, that the inhabitants of the Malay peninſula were in poſſeſſion of an alphabet, of the ſame model with that of the Hindus, and were even ſkilled in compoſition, before the Mahometans introduced their learning and character among them. Frequent alluſions to the moſt celebrated works of the Hindu mythological poets, eſpecially the Mahabharat and the Ramayan, occur in the Malay writings; and theſe alluſions imply that tranſlations of the works were formerly in the hands of the Malays.

The Malayan language poſſeſſes, as we have already obſerved, a ſmoothneſs and ſweetneſs of ſound, rendering it well adapted to poetry, to which the Malayans are paſſionately addicted. They amuſe all their leiſure hours, including the greater portion of their lives, with the repetition of ſongs, which are, for the moſt part, proverbs illuſtrating, or figures of ſpeech applied to, the occurrences of life. Some, which they rehearſe in a kind of recitative at their bimbangs, or feaſts, are hiſtorical love tales, like our old Engliſh ballads, but often extempore. There are numerous works written in the Malay language, beſides hiſtorical ballads, or ſongs on national traditions. See the writers already cited, and Pinkerton's Geog. vol. ii. For an account of the Malays of Ceylon, ſee Percival's Ceylon.

Malacca, the chief town of the country above deſcribed, ſituated on the Malay coaſt, about eight leagues from the iſland of Sumatra. N. lat. 2° 12′ 6″. E. long. 102° 8′ 45″. It is ſituated partly upon a hill, and partly on level ground, which is low, wet, and unhealthy. Its circumference is about 1800 paces, and towards the ſea there is a ſtrong wall, about 600 paces long, and alſo another by the ſide of the river. Its fortifications have long ſince been conſiderably decayed. The adjacent country is ſo flat, that the ſea ſhore is dry to a conſiderable diſtance at low water, and the ſhore is difficult of acceſs, on account of the ſoftneſs and muddineſs of the bottom. The juriſdiction of the town is about 30 miles in length, and from eight to ten in breadth. Two ſmall iſles, called "Ilha des Naos" and "Ilha des Padras," at a ſmall diſtance ſupply clay for bricks; and formerly the Portugueſe veſſels uſed to anchor between them. Two rivers are contiguous to the town; one on the N. called Cryſorant, and another on the S. which is more conſiderable, called Pahaung. The ſhape of the town, which preſents many broad ſtraight ſtreets, is that of a creſcent.

Before the conqueſt of the Portugueſe, Malacca was a fiſhing town; it afterwards contained 11,000 inhabitants; but in the time of Valentyn, the number had decreaſed to between two and three hundred Dutch, Portugueſe, and ſome Malays in huts at the extremities of the town, who poſſeſſed ſome plantations in the vicinity. Around the town are woods infeſted with wild beaſts, eſpecially tigers; and elephants are very numerous. This city was founded by the Mahometans in the 13th century, and held by the Portugueſe till 1641, when it was ſeized by the Dutch. It gained great importance from its advantageous poſition for Indian and Chineſe commerce. See the preceding article.

Malacca, *Strait of*, the narrow ſea between the iſland of Sumatra, and the peninſula of Malacca, extending from the equinoctial line to about 5° N lat. This ſtrait preſents favourable opportunities for commerce, which has been maintained for a long time, and in a conſiderable degree, with Bengal, Coromandel, Surat, Perſia, Ceylon, Java, Sumatra, Siam, Tonquin, China, and other places. This was a convenient ſtation for the veſſels paſſing through the ſtrait from Japan to Hindooſtan, and ſome choſe this route to Batavia. In this ſtrait proviſions are ſcarce, except fiſh and a few fruits.

Malacca *Stones*, a name given by many authors to the *pedr del porco*, or hog-bezoar.

MALACHE, formed of μαλασσω, *I ſoften*, a term uſed by authors in a different ſenſe; ſometimes expreſſing ſuch medicines as gently looſen the belly, and ſometimes ſuch ointments as relax and mollify.

MALACHI, *the Prophecy of*, is one of the canonical books of the Old Teſtament, written by Malachi, who, according to a tradition among the ancients, was of the tribe of Zebulon, and born at Sapha, after the return of the captivity from Babylon, and who died young. He was probably contemporary with Nehemiah, and muſt have lived after the time of Haggai and Zechariah, becauſe his prophecy ſuppoſes the temple to be rebuilt, and the worſhip of God eſtabliſhed in it. Uſher places him in the year 416, and Blair in 436 B.C. Some have doubted whether Malachi was a proper name, or a general appellation, ſignifying the angel or meſſenger of the Lord. Malachi, מלאכי, denotes "my angel;" but the LXX have rendered the word, his angel, and not my angel, as the original expreſſes it; and ſeveral of the fathers have quoted Malachi under the name of "the Angel of the Lord" It is the opinion of the ancient Hebrews, of the Chaldee Paraphraſt, and of St. Jerom, that Malachi was Ezra. The chief corruptions which he charges upon the Jews are the ſame with thoſe for which they were reproved by Nehemiah; he forbids them to expect any farther ſucceſſion of prophets, exhorts them to obſerve the law of Moſes, and predicts the coming of Elias, or John the Baptiſt, as the forerunner of the Meſſiah.

Biſhop Lowth, in his "Prelectiones," ſays, that this book is written in a kind of middle ſtyle, which ſeems to indicate that the Hebrew poetry, from the time of the Babyloniſh captivity, was in a declining ſtate, and being paſt its prime and vigour, was then faſt verging towards the debility of age.

MALACHITES. See Copper, *Ores of.*

MALACHODENDRUM, in *Botany*, ſo called by Mitchell and Cavanilles, from μαλακος, *ſoft*, and δενδρον, *a tree*, on account of its ſoft or downy leaves. Hence alſo the origin of μαλαχη, *a mallow*. This ſuppoſed genus differs in nothing from Stuartia, to which we refer the reader, except in the ſeparation of its five ſtyles, which in the other

ſpecies.

ſpecies are combined into one.—M. *corchoroides*, Mart. Mill. Dict. v 3, is erroneouſly referred hither after Forſkall, and is *Sida ſpinoſa*, Vahl. Symb. v. 2. 78.

MALACHRA, like *Malachodendrum* and other genera, owes its derivation to μαλακος, *ſoft*, or *delicate*, doubtleſs from the ſoftneſs of its pubeſcence. Schreb. 464. Willd. Sp. Pl. v. 3. 768. Mart. Mill. Dict. v. 3. Juſſ. 272. Cavan. Diſſ. faſc. 2. 97. Lamarck Illuſtr. t. 580.—Claſs and order, *Monadelphia Polyandria*. Nat. Ord. *Columniferæ*, Linn. *Malvaceæ*, Juſſ.

Gen. Ch. *Cal. Common Perianth* large, bearing about five flowers, divided into three or five, heart-ſhaped, acute, permanent leaves: *proper* of one leaf, bell-ſhaped, ſmall, five-cleft, permanent, ſet round with briſtle-ſhaped ſcales. *Cor* Petals five, obovate, entire, adhering below to the tube of the ſtamens. *Stam.* Filaments numerous, united below into a tube, gaping and looſe above, over the whole ſurface of the cylinder; anthers kidney-ſhaped. *Piſt.* Germen orbicular; ſtyle cylindrical, ten-cleft; ſtigmas globoſe. *Peric.* Capſules five, aggregate, roundiſh, compreſſed on one ſide, gibbous on the other. *Seeds* ſolitary, roundiſh, angular.

Eſſ. Ch. Common calyx of three leaves and many flowers, large. Capſules five, ſingle-ſeeded.

Obſ. Cavanilles has remarked, that, in *Malachra*, the diviſions of the ſtyle and the ſtigmas are twice as many as the capſules.

1. M. *capitata*. Linn. Syſt. Veg. ed. 14 624. Willd. n. 1. Swartz. Obſ. 262.—Stem rough. Flowers ſeven in a head. Leaves ſomewhat heart-ſhaped, ſlightly lobed.—A native of marſhy places in the Caribbee iſlands.—*Stem* thick, erect, two feet high. *Leaves* ſtalked, furniſhed with awl-ſhaped ſtipulas. *Flowers* aggregate, ſeſſile, yellow.

2. M. *faſciata*. Willd. n 2. Jacq. Ic. Rar. v. 3. t. 548.—Stem villoſe Flowers about five in a head. Leaves roundiſh, ſomewhat lobed.—A native of the Caraccas.—*Stem* ſix feet in height, remarkably rough, with rigid hairs. *Leaves* on long, hairy footſtalks, the lower ones five-lobed at the margin, the upper ones three-lobed. *Flowers* axillary, ſmall, bluſh-coloured on the outſide; whitiſh, with purple ſtreaks, within.

3. M. *alceæfolia*. Willd. n. 3. Jacq. Ic. Rar. v. 3. t 549.—Flowers about ten in a head. Leaves cordate, deeply five-lobed.—A native of Martinique.—*Stem* ſix feet high, upright, branched, hairy. *Leaves* alternate, heart-ſhaped at the baſe, veiny, widely ſpreading, obtuſely ſerrated or notched. *Flowers* axillary, rather ſmall, of a deep yellow colour.

4. M. *radiata*. Linn. Syſt. Veg. ed. 14. 624. Cavan. Diſſ. t. 33. f. 3. (Sida radiata; Linn. Sp. Pl. 965.)—Flowers many in a head. Leaves palmate.—Found at St. Domingo.—*Stem* ſix feet in height, tender, round, whitiſh-green, hairy. *Leaves* crenate, hairy, bright green. *Flowers* ſmall, purpliſh.

5. M. *bracteata*. Willd. n. 5. Cavan. Diſſ. t. 34. f. 2.—Flowers many in a head, bracteated. Leaves palmate.—Native of America.—*Stem*, like the whole plant, very hairy. *Leaves* crenate, with ſeven deep, acuminated lobes. *Flowers* about fourteen in each head, whitiſh, ſtreaked with red at the bottom.

6 M. *plumoſa*. Willd. n. 6. (Sida plumoſa; Cavan. Diſſ. t. 12 f. 4.)- Flowers many in a head. Leaves undivided, elliptical, toothed.—A native of the Brazils. *Leaves* truncated. *Involucrum* of many leaves, the outer ones elliptical and toothed, the inner linear and fringed.

MALACIA, μαλακια, nearly ſynonimous with *pica*, and *citta*, ſignifies a depraved appetite, which induces the patient to deſire to eat things which are indigeſtible, and not capable of affording nutriment; or that ſort of depravation of appetite, which was formerly deemed a ſort of privilege attached to the ſtate of pregnancy in women, which induced them to *long for* ſome particular food, with extraordinary earneſtneſs, and eat of it to exceſs. While the *danger* of refuſing indulgence to theſe longings was held as an axiom, they appear to have occurred perpetually; but they are now generally treated with ridicule, and therefore are ſeldom heard of. See Pica.

MALACODERMATA, formed of μαλακος, *ſoft*, and δερμα, *ſkin*, in *Natural Hiſtory*, a term uſed to expreſs ſuch animals as have only ſoft ſkins for their covering; in oppoſition to the oſtracodermata, which have hard ſhelly matters for their covering, ſuch as crabs, lobſters, &c.

MALACOIDES, in *Botany*. See Malope.

MALACOLITE, in *Mineralogy*. See Sahlite.

MALACOPTERIGII, in *Ichthyography*, the name of a large order of fiſhes, which have not prickly fins.

The term is derived from the Greek μαλακος, *ſoft*, and πτερυγιον, *a fin*. The fiſh of this order, are thoſe which have bony fins, with all their extremities not pointed or ſharp, but ſoft and harmleſs. Of this order are the carp, &c.

MALACOSTEON, (from μαλακος, *ſoft*, and οστεον, a *bone*,) in *Surgery*, a morbid ſoftneſs of the bones. See Mollities *Oſſium*.

MALACOSTOMOUS, in *Ichthyography*, the name of a large genus of fiſhes, called in Engliſh the leather-mouthed kind. Theſe fiſhes are wholly deſtitute of teeth in their jaws, but have them placed in their throats, near the orifice of the ſtomach.

The word is derived from the Greek μαλακος, *ſoft*, and στομα, *a mouth*. All the fiſh of this genus have their ſwimming, or air-bladder, divided into two parts; and of this genus are the carp, tench, bream, chub, and the like.

MALACOSTRACA, in *Natural Hiſtory*, a term uſed by ſome, as Ariſtotle, to diſtinguiſh what we call cruſtaceous animals of the ſea, &c. from thoſe which he calls oſtracodermata, or teſtaceous, as we expreſs it. See table of teſtaceous and cruſtaceous animals. See Crustaceous.

MALACOTTA, in *Geography*, a town of Africa, in the country of Warada; the inhabitants manufacture ſoap from the oil of ground nuts: 42 miles E. of Satadoo. N. lat. 12° 30'. W. long. 9° 15'.

MALADUGNO, a town of Naples, in the province of Otranto; 9 miles N.W. of Otranto.

MALAGA, a ſmall, but very ancient city of Spain, in the province of Granada. It was built by the Phœnicians ſeveral centuries B.C.; and it was called "Malacha," or "Malaca," on account of the great quantities of ſalt fiſh ſold here. In proceſs of time it paſſed ſucceſſively under the dominion of the Carthaginians, Romans, Goths, and Moors. Strabo ſays, that a great quantity of ſalt was manufactured in its environs, which was diſpoſed of on the oppoſite coaſt of Africa. That it was a place of importance under the Romans, we may infer from the wrecks of monuments that have been diſcovered in its vicinity. Some of theſe remains, which have been found on the eminences where the light-houſe is placed, and where the caſtle called by the Moors Gibral faro ſtands, have been thought to have belonged to a magnificent Pharos, or perhaps to a temple built on this ſpot by the Romans. It was not till the year 1487, that Ferdinand and Iſabella recovered Malaga, after an obſtinate reſiſtance, from the dominion of the Moors. Malaga is ſituated on the coaſt of the Mediterranean, at the bottom of a deep bay, on on a foil of flate and limeftone. To the fouth it has the fea: to the weft it opens into a fertile plain, watered by two rivers; and to the eaft and north, it is protected by lofty mountains, the tops of which are fometimes covered with fnow, and the fides with olive, almond, orange and lemon trees, and vineyard grounds. The town cannot be called handfome, though the houfes are high: the ftreets are narrow, ill paved, and dirty; and it has not one good fquare. It has, however. a marble fountain, very finely executed, which was a prefent from the republic of Genoa to Charles I. The town has three fauxbourgs. It is the fee of a bifhop, fuffragan to the archbifhop of Seville, and the bifhopric is worth 150,000 ducats, or 16,439*l.* 9*s.* 10*d.* but one-third of this revenue is difpofed of by the king. The whole chapter confifts of the bifhop, with eight dignitaries, twelve canons, twelve minor canons, and the fame number of prebendaries. The dean receives 600*l.* a-year; but the other dignitaries only 450*l.* The town has four parifh churches, two chapels of eafe, twelve monafteries, ten nunneries, four beaterios, fix hofpitals, and feveral chapels and oratories. Of the friars, the Francifcans take the lead, and are held in greateft veneration by the common people; and among thefe, the Capuchins are the moft ufeful members of fociety, devoting themfelves to the fervice of the poor. Malaga has a civil and military governor, a king's lieutenant, a major, aid-major, and a fixed regiment of infantry of three battalions, bearing its name and attached to the place; an alcade major for the adminiftration of juftice, a municipality compofed of a certain number of regidors, a poft-captain, a minifter and an auditor of the Marine, and a board of public economy. This town has alfo a college for the inftruction of youth, and another college, under the title of St. Elmo, for the inftruction of mariners. The population of Malaga under the Moors, was reckoned at 80,000 inhabitants; and in 1747 it was reduced to 32,000; it is now eftimated at 50,000, according to the ftatement of La Borde; but Mr. Townfend, in his "Travels," mentions the number at 41,592, of whom the greateft proportion confifts of females.

Of the buildings, public or private, the only one, particularly worthy of notice, is the cathedral, begun in the year 1528, and, fays Mr. Townfend, not yet completed. It is 360 feet by 180, and 135 in height. The choir in this edifice is admirable on account of its carved work, which reprefents, in very bold relief, the twelve apoftles, and the moft diftinguifhed faints. The cuftom-houfe was erected on a magnificent plan in 1792. The confulate at Malaga have founded a very beneficial eftablifhment, which is a "Mont de pieté," defigned for lending money without intereft to farmers, in order to prevent their felling their commodities, particularly wines, at a great lofs. The funds of this inftitution arife from vacant benefices.

The port of this town is large and fecure: it has water for firft-rate fhips of the line, and holds 400 merchant men, and 19 men of war. Ships may fail in and out with every wind, and are well fheltered in the harbour, particularly from the N. and E. winds, which are here the moft violent. For greater fafety two piers have been lately conftructed. Malaga has a confiderable trade, particularly with England, Its imports confift of broad cloths and iron ware, which it takes from the Englifh; of mercery, from Germany, and more efpecially from Hamburgh; and fpices, cutlery, tapes, and laces, from Holland. It furnifhes thofe countries, as well as Italy and the northern nations, with wine, fruits, fumac, anchovies, and oil. Its exportation of wine alone amounts to about 400,000 quintals yearly, and that of raifins to 250,000 quintals. The amount of the imports is valued at 1,800,000 piaftres, or 281,250*l.* fterling: that of the exports at 3,300,000 piaftres, or 515,625*l.* fterling; fo that the balance of trade is in its favour.

The foil in the vicinity of Malaga is fertile and well cultivated, producing great quantities of wheat and all forts of grain; and olive trees are abundant, fupplying 500 oil preffes in this diftrict alone. Fruit trees, fuch as the almond, fig, and lemon, are alfo very plentiful. The number of vineyards is immenfe, and they yield grapes of different fpecies and of delicate quality. About 300,000 quintals are dried annually: 750,000 quintals of wine are made yearly; of which about 400,000 are exported. The vineyards are cultivated with great labour and expence; the expence, as ftated by Mr. Townfend, being equal to $\frac{4}{5}$ths of the produce. In the diftrict of Malaga there are 14,000 wine-preffes, chiefly employed in making the rich wines, which, from the nature of the country, is called *mountain;* if red, from the colour, *vino tento,* known to us by the name of "tent." The manufactures of Malaga, which are inconfiderable, confift of one for fkins, leathers, and foles, and another of about 40 looms for filk ftuffs, velvets, taffetas, ferges, and filk cloth.

The inhabitants, blended with many foreigners, and occupying a beautiful country, in a mild climate and under a fine fky, are lively, induftrious, and active. The men are polite and prepoffeffing: the women, lively, gay, and alluring, accounted the moft agreeable in Spain.

Malaga *Bay*, a bay on the eaft coaft of the ifland of Leyta. N. lat. 10° 30′. E. long. 125 12′.

MALAGMA, formed of μαλασσω, *I foften*, a word ufed by fome authors to exprefs a cataplafm in general, of whatever nature, or made of whatever ingredients; but fome have ufed it only for emollient cataplafms.

MALAGRIDA, Gabriel, in *Biography*, a native of Milan, and a member of the fociety of Jefuits, who was burnt at an "auto da fè," at Lifbon, in the year 1761, as an heretic and falfe prophet. He had been fent out as miffionary to Portugal, where he became exceedingly popular, by his infinuating addrefs, and the fluency of his oratory: he was venerated as a faint, and confulted as an oracle. When the duke d'Aveiro was convicted of a confpiracy againft the life of the king of Portugal, Malagrida was accufed of being an accomplice in the plot: he was pronounced guilty of the charges exhibited againft him, but whether with or without juftice is a matter of difpute; at any rate, advantage was taken of it to banifh all the Jefuits from Portugal, excepting Malagrida and two others, who were referved for punifhment. To this probably the confent of the king could not be obtained, and, therefore, another method was adopted for getting rid of him. He was accufed of herefy; in proof of which, two of his treatifes were appealed to, *viz*, one entitled "Tractatus de Vita et Imperio Antichrifti;" and the other, written in the Portuguefe language, entitled "The Life of St. Anne, compofed with the Affiftance of the bleffed Virgin Mary and her moft holy Son." From thefe, feveral extracts were collected that were pronounced extremely heretical; and others were adduced to prove that he laid claim to the power of working miracles: and he alfo affumed that God himfelf had declared him his ambaffador, his apoftle, and prophet. He was burnt on the 21ft of September 1761.

MALAGUETTA, in *Geography*. See Grain *Coaft.*

MALAHA, a town of Perfia, in the province of Farfiftan; 90 miles E. of Schiras.

MALAHIDE, a fmall town of the county of Dublin, Ireland,

Ireland, situate on the Irish sea. There is a well here, dedicated to the Virgin Mary; and also a castle, now the residence of the Talbot family. It is two miles E. from Swords.

MALAI, a town of Arabia; 15 miles S. of Medina.

MALAKERY, a town of Hindoostan, in Mysore; 21 miles N.E. of Seringapatam.

MALALAIS, a small island in the sea of Mindoro. N. lat. 11° 18'. E. long. 120° 51'.

MALALEO, a port on the north-west coast of the island of Tappa, in the East Indian sea. N. lat. 0° 6'. E. long. 123° 35'.

MALAMBETO, a town of South America, in the province of Carthagena; 40 miles E. of Carthagena.

MALAMBO, or BARRANCA DE MALAMBO, a town of South America, in the province of Carthagena; 55 miles N.E. of Carthagena.

MALAMOCO, an island in the Adriatic, about four miles long and half a mile broad, near the city of Venice; upon which island is a town of the same name, containing about 1100 inhabitants. Besides the cathedral, which is the parochial church, it contains a nunnery, a church, and some neat buildings. This was anciently the chief town of the Venetians, the residence of government, and the see of a bishop. The port of Malamoco is situated at the farthest point of the shore, towards Chioggia, and is defended by two forts, *viz.* St. Pietro and Della Punta. It is the safest and most convenient port, and therefore most frequented; but on account of its sand-bars and shallows, ships cannot enter into it without pilots. At this port was constantly garrisoned some thousands of regular troops.

MALANDERS, MALANDRIA, a disease in horses, so called from the Italian *malandare, to go ill.*

It consists in certain ulcerous chaps, or chinks, appearing on the inside of the fore-legs, just against the bending of the knee, which void a red, sharp, and pungent humour.

This distemper may be cured by washing the parts with a warm lather of soap, or old chamber-ley; and then applying over the cracks a strong mercurial ointment, spread on tow, with which they should be dressed night and morning, till all the scabs fall off; but if this treatment fail, make an ointment of half an ounce of æthiops mineral, one dram of white vitriol, six ounces of soft green soap; and having clipped off the hair, and cleared away the scabs, anoint often with this, and apply the above unguent over the sores. When they dry up, give a gentle purge or two; or let the nitre balls be taken for two or three weeks. Bartlet.

After washing the parts with soap and water, Mr. Denny advises to rub on a powder, made by mixing together vitriolated zinc and alum, of each pulverized half an ounce twice a day. Mr. White recommends the following ointment, prepared by mixing two ounces of ointment of wax, one ounce of olive oil, oil of turpentine and camphor, of each a dram, and two drams of acetated water of litharge. For the same purpose, Mr. Ryding recommends to mix one ounce of strong quicksilver ointment and ten grains of muriated quicksilver in fine powder.

MALANEA, in *Botany*, received its name from Aublet, but has been referred by Schreber and Willdenow to another genus CUNNINGHAMIA (see that article). Jussieu and Lamark, however, retain the original name; but we are utterly incompetent to trace its derivation, of which Aublet himself gives no indication.

MALANEE, in *Geography*, a small island in the Florida stream. N. lat. 24° 56'.

MALANEO ISLANDS, two small islands in the North Pacific ocean, near the east coast of the island of Luçon, N. lat. 18° 2'. E. long. 122° 28'.

MALANGER, a town of Norway, at the northern extremity of the diocese of Drontheim.

MALANOVA, a town of Russia, in the government of Tobolsk, on the Irtisch; 28 miles N. of Tara.

MALAO, a town on the north-west coast of the island of Mindanao.

MALAPERT, CHARLES, in *Biography*, a learned Jesuit and excellent mathematician, was born at Mons in the year 1581. He entered into the order in 1600, and was afterwards elected professor of mathematics in Poland; and he next filled the same office in the Jesuits' college at Doway. In 1630 he was appointed, by order of Philip IV., mathematical professor in the new university at Madrid; but he died on his journey to that capital, being in the 50th year of his age. While he was in Poland he published a volume of poems, which have gone through many editions; but his most important works were mathematical. In one, entitled "Oratio de Laudibus Mathematicis," he treats of the phenomena of the newly-discovered Dutch telescope. He published the "Institutions of practical Arithmetic," and the "Elements of Geometry;" "A Paraphrase on the Dialectics of Aristotle;" and "Commentaries on the first six Books of Euclid."

MALAR. See MÆLER.

MALARIA, or MALARUM OSSA, in *Anatomy*, a pair of bones belonging to the face, and corresponding in situation to the cheeks. See CRANIUM.

MALARMAT, in *Ichthyology*, a name given by authors to the fish called by some *lyra altera*, and *cornuta*. It is a species of the trigla, and is distinguished by Artedi by the name of the trigla with many cirrhi, and with an octagonal body. See TRIGLA *Cataphracta*.

MALARUM OSSA, in *Anatomy*. See MALARIA.

MALASHLAH, in *Geography*, a town of Africa, situated on the Atlas, in the southern part of Algiers; 170 miles S. of Algiers.

MALATIA, a town of Asiatic Turkey, in Aladulia, situated on the west side of the Euphrates; the residence of a Jacobite and Nestorian bishop. This town was taken in 1400 by Timur Bec. The Mussulmen redeemed themselves by money, and the Christians were made slaves; 90 miles W.N.W. of Diarbekir. N. lat. 37° 56'. E. long. 38°.

MALATIVOE, a fortified port of Ceylon, in a romantic and delightful situation, between Trincomalee and Jafnapatam. Here the Dutch had a small factory, and a house for the commanding officer. It depended upon the garrison of Trincomalee, and was employed chiefly as a port of communication, and to collect provisions for that garrison. For these purposes, and to keep the natives in awe, a few Malay or Sepoy soldiers were stationed here; but it never was considered as capable of any defence. Close to the fort is a small village; and a river, which here falls into the sea, forms a harbour sufficient to admit small craft. The principal employment of the inhabitants is fishing; and with this article they supply the fort of Trincomalee. Cattle and poultry are abundant and cheap. Game is plentiful, and the woods abound with wild hogs and deer. Percival's Ceylon.

MALATS, in *Chemistry*, are salts formed by the union of malic acid with alkaline, earthy, or metallic bases. See MALIC *Acid*.

MALATZKA, in *Geography*, a town of Hungary; 14 miles N. of Presburg.

MALAVERD, a town of Persia, in the province of Irak; 45 miles N.E. of Ispahan.

MALA-

MALAUCENE, a town of France, in the department of the Vauclufe, and chief place of a canton, in the diftrict of Orange; 14 miles E. of Orange. The place contains 2506, and the canton 5458 inhabitants, on a territory of 185 kiliometres, in 7 communes.

MALAVISTA, a town of the ifland of Cuba; 36 miles W. of Villa del Principe.

MALAXIS, in *Botany*, a name applied by Profeffor Swartz to this new and very diftinct genus of the Orchis tribe, eftablifhed by Dr. Solander and himfelf. The word, μαλαξις, expreffes *foftnefs*, and feems to allude to the delicacy of habit and ftructure which marks thefe plants.—Swartz Act. Holm. ann. 1789. 127. t. 6. f. 2. ann. 1800. 233. t. 3. f. P. Prodr. 119. Orchid. 68. t. 1. f. P. Tracts on Botany, 162. t. 5. Schreb. 603. Willd. Sp. Pl. v. 4. 89. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 940. Michaux Boreal-Amer. v. 2. 157.—Clafs and order, *Gynandria Monandria*. Nat. Ord. *Orchideæ*, Linn. Juff.

Gen. Ch. *Cal.* Perianth reverfed, three-leaved, more or lefs acute, fpreading, permanent, two upper leaves equal; lower folitary, in front, deflexed. *Cor.* permanent. Petals two, linear, deflexed, fpreading, fmaller than the calyx. Nectary an afcending or erect lip, between the two upper calyx-leaves, embracing the organs of fructification with its concave bafe, its termination obtufe or acute, undivided or flightly lobed. *Stam.* Anther an hemifpherical, deciduous, obliquely terminal lid, of two cells; maffes of pollen folitary, feffile, oblong or globular, lying on the anterior margin of the top of the ftyle. *Pift.* Germen inferior, either oblong, fomewhat cylindrical, or obovate, erect, flightly gibbous, excavated in front and at the fummit; ftyle erect or afcending, fhort and thick; ftigma on the fide towards the lip, beneath the anther, concave. *Peric.* Capfule oblong or obovate, with three or fix ribs, of one cell and three valves, opening by clefts between the ribs. *Seeds* numerous, minute, each clothed with a chaffy tunic.

Eff. Ch. Calyx reverfed, fpreading. Petals deflexed. Lip afcending, concave at the bafe, without a fpur. Anther a terminal lid, deciduous.

Obf. This genus is moft allied to *Cymbidium* (fee that article) in character, but differs in its reverfed flower, as well as in its peculiar habit, indicated by the fmall, ufually yellow or greenifh bloffoms, and a general delicacy of ftructure and texture. In what regards the habit of the flowers, however, independent of their pofture, it muft be confeffed that *Cymbidium corallorrhizon* approaches *Malaxis* very nearly, though not at all in herbage.

1. M. *fpicata*. Sw. n. 1.—Leaves two, ovate, fhorter than their footftalks. Flower-ftalk fquare, racemofe. Lip obfcurely three-lobed, pointed.—Native of Jamaica. The *root* is perennial, confifting of an oblong upright *caudex*, with numerous downy fibres, appearing to grow amongft rotten wood or leaves. *Leaves* two, radical, fpreading, thin, delicate and pale, ovate, rather acute, entire, fomewhat wavy, ribbed, fmooth, about two inches long, each fupported by a membranous, ribbed, tubular, fheathing *footftalk*, about three inches long. *Flower-ftalk* about a foot high, folitary, radical, quadrangular, fmooth, fheathed by the footftalks at the bottom, and terminating in a corymbofe clufter of numerous, fmall, pale yellowifh *flowers*, each of whofe partial ftalks is half an inch, or more, in length, and has at its bafe a linear, acute, membranous, permanent *bractea*. The *lip* is acute, with a fmall lobe at each fide near the bafe, and has a dark central ftripe. This feems to be the fpecies which firft caufed the eftablifhment of the genus; yet it does not well anfwer to the generic character in Swartz's *Prodromus*, unlefs we conceive the central point of the lip to be bent backwards, while the two lateral lobes, projecting forward, have a heart-fhaped figure. The fpecific name is liable to objection, for the flowers are racemofe, or corymbofe, thofe of fome other fpecies being much more truly fpiked.

2. M. *umbellulata*. Sw. n. 2.—Leaves two, ovate, fhorter than their footftalks. Flower-ftalks five-angled. Umbel denfe. Lip obfcurely three-lobed, pointed.—Native of Jamaica, apparently in fimilar fituations with the foregoing, from which it differs chiefly in being of rather more humble ftature, with fmaller and greener *flowers*, growing in a little denfe umbel, at the top of the pentagonal ftalk.

3. M. *latifolia*. Leaves feveral, ovate, longer than their footftalks. Spike cylindrical. Bracteas deflexed. Lip three-lobed, the middle lobe largeft.—Native of the woods of Upper Nepal; gathered by Dr. F. Buchanan, Auguft 12th, 1802, at Narainhetty, where it is called by the inhabitants *Namly*. The *root* is like that of the former, with many ftrong, downy, twifted fibres. *Leaves* about four, on fhortifh, broad, ribbed, fheathing footftalks, broad-ovate, pointed, plaited, ribbed and ftriated, three or four inches long, being more than twice the length of their ftalks. *Flower-ftalk* central, folitary, above a foot high, erect, with feveral acute angles. *Spike* terminal, erect, cylindrical, denfe, many-flowered, three inches long. *Bracteas* folitary, deflexed, awl-fhaped, concave, membranous, permanent. *Flowers* feffile, fmall, yellow. *Germen* incurved, ftrongly furrowed, with crifped angles, its bafe tapering and elongated. Lower leaf of the *calyx* linear, reflexed at the fides, afcending at the point; two upper ones fhorter, half-ovate and obtufe. *Petals* linear, widely fpreading. *Lip* fhort, broad, erect, with three acute lobes, of which the middlemoft is the largeft, and entire, the fide ones ftained.

4. M. *odorata*. Willd. n. 6. (Katou-ponnam-maravara; Rheede Hort. Mal. v. 12. 55. t. 28.)—Leaves feveral, elliptic-lanceolate. Spike cylindrical. Bracteas deflexed. Lip heart-fhaped, cloven at the point.—Gathered by Dr. Buchanan on the moffy rocks of Upper Nepal, where it is called *Bun Pinali*. Rheede fays it loves funny retired places, flowering in January and February, and having a very delightful fmell. It has altogether the habit of the laft, but the *leaves* are narrower, and more elliptical than ovate. The *fpike* is longer, and *flowers* larger. The *lip* differs effentially, being of a broad heart-fhaped figure, cloven half way down at the upper part, or point, which is obtufe, and embracing the organs of fructification between the bafes of its rounded fide-lobes. The *flowers* are altogether of a pale dull yellow, or buff-colour.

5. M. *Rheedii*. Swartz. n. 4. Willd. n. 5.—(Epidendrum refupinatum; Forft. Prodr 61. Bafaala-poulou-maravara; Rheede Hort. Mal. v. 12. 53. t. 27.)—Leaves feveral, elliptic-lanceolate. Spike cylindrical. Bracteas deflexed. Lip inverfely heart-fhaped, rounded, fringed.—Native of the Eaft Indies and the Society Iflands, upon trees or rocks. We know it only by Rheede's and Forfter's works. It is nearly allied to the laft, and the *flowers* are faid to be delightfully fragrant, but are effentially different from thofe of M. *odorata*, not only in being much fmaller, and of a vermilion hue, but in the ftructure of their *lip*, which is inverfely heart-fhaped, its two rounded lobes being directed upwards; and their edge, moreover, is finely fringed.

6. M. *nervofa*. Swartz. n. 8. Willd. n. 10.—(Ophrys nervofa; Thunb. Jap. 27. Epidendrum nervofum; Thunb. Ic. Jap. t. 10.)—Leaves feveral, ovate, ribbed, acute. Stalk angular, racemofe. Bracteas minute, fpreading. Lip obovate, emarginate, reflexed, with a pair of tubercles at the

the base.—Gathered by Thunberg, flowering in May and June, near Osacca and Jedo in Japan, where it is called *Gin Ran*. It appears to differ from the last in having the *flowers* fewer, and much more distant, each supported by a slender partial stalk, forming a cluster, not a spike. By Thunberg's long and exact description it is evidently well referred by Swartz to this genus, with which its habit accords. The *calyx* consists of three equal linear leaves, two of which are lateral, the third lowermost. *Petals* lateral. *Lip* uppermost, twice as broad as the petals, obovate, emarginate, forming a sort of *galea*, bent backwards in the middle, marked with two callosities, and a furrow, at the base, without any spur. *Style* semi-cylindrical, curved upwards towards the lip. *Capsule* slender, twisted. The *flowers* are said to be purple, and the minute ovate *bracteas* are of the same colour.

7. M. *lancifolia*. Leaves several, ovato-lanceolate, ribbed, acute. Flowers spiked. Bracteas lanceolate, spreading. Lip obovate, abrupt, reflexed, convex.—Found by Dr. Buchanan in the woods at Suembu in Upper Nepal, July 17, 1802. Its affinity to the last did not escape its learned discoverer, but the present is rather a taller plant, being twelve or eighteen inches high. The *leaves* are much narrower and longer, about three or four in number, with long sheathing bases. *Stalk* angular, bearing a long slender spike of numerous green unspotted *flowers*, rather smaller than Thunberg delineates those of his *Ophrys nervosa*. The *bracteas* are lanceolate, and nearly as long as the germens. The *lip* has no tubercles at its base, but is bent back towards the middle, as is *M. nervosa*.

8. M. *ophioglossoides*. Willd. n. 3. (M. unifolia; Michaux Boreal-Amer. v. 2. 157. Swartz Orchid. 71.)—Leaf solitary, ovate, clasping the stem. Stalk with many angles. Lip cloven at the extremity.—Native of shady woods in North America. Sent from near Lancaster in Pennsylvania by the Rev. Dr. Muhlenberg. A delicate species, with much of the aspect of the two first, but distinguished from all hitherto discovered by its solitary *leaf*, which is ovate inclining to heart-shaped, acute, finely ribbed and reticulated, near an inch and a half long, clasping the stalk with its base, and sheathing two inches or more of the lower part with its close, tubular, radical *footstalk*. The *flower-stalk* is solitary, rising four or five inches above the leaf, pale, slender, with several unequal angles not exactly five, and terminating in a very delicate corymbose cluster, of numerous small greenish *flowers*, on capillary stalks, with a small, ovate, acute, membranous *bractea* at the base of each stalk. Willdenow observed the *lip* to be cloven; and its lobes appear to us to be distant and divaricated, with a semicircular sinus between them.

9. M. *monophyllos*. Swartz. n. 3. Willd. n. 4. (Ophrys monophyllos; Linn. Sp. Pl. 1342. Fl. Suec. ed. 2. 316. Wulf. in Jacq. Coll. v. 4. 340. t. 13. f. 2. O. monophyllos bulbosa; Loef. Pruss. 180. t. 57. O. lilifolia Suecica; Linn. Sp. Pl. 1341. n. 7. O. latifolia; Fl. Suec. ed. 2. 316. n. 811, on the authority of Dr Swartz. Epipactis n. 1293; Hall. Helvet. v. 2. 151. t. 36.)—Leaf nearly solitary, elliptic-ovate. Stalk triangular. Lip undivided.—Native of boggy shady alpine places, in Prussia, Sweden, Russia, Carniola, and, though very rarely, in Switzerland, flowering in the spring. This is closely allied in habit to the last. *Root* an aggregate bulb, with numerous fibres, and invested with several ribbed sheaths, altogether more like an *Allium*, as Wulfen observes, than any of the *Orchis* tribe. Such, however, is the nature of all the foregoing species, as far as has been ascertained. One elliptical, delicately ribbed, *leaf*, acute at each extremity, and running down into a long sheathing base, or radical *footstalk*, embraces the stalk, attended by one or two shorter external sheaths, and often accompanied by a much smaller internal leaf. The *stalk* is triangular, terminating in a long slender cluster, of very numerous small green *flowers*, with every character of the genus. Their *bracteas* are like those of the last, but their *lip* is undivided, with a taper point. Dr. Swartz assures us the *Ophrys latifolia* of Linnæus's *Flora Suecica*, (erroneously so printed for *lilifolia*,) was no other than a specimen of the species we are describing, in which the second leaf was more remarkable than usual.

10. M. *paludosa*. Swartz. n. 5. Willd. n. 7. Sm. Fl. Brit. 940. Engl. Bot. t. 72. (Ophrys paludosa; Linn. Sp. Pl. 1341. Fl. Suec. 316. Rose Elem. of Bot. append. 450. t. 2. f. 3. Dicks. H. Sicc. fasc. 7. 16. Ehrh. Phytoph. 16.)—Leaves several, spatulate, rough at the tip. Stalk with five angles. Lip undivided, concave, half the length of the calyx.—Native of turfy bogs in the north of Europe, flowering in July. It is found in Cambridgeshire, Bedfordshire, and on Felthorpe bogs a few miles north of Norwich, though now far more rare than formerly, from the general improvement of such grounds by draining. This is perhaps the smallest species of its genus, or even of the whole natural order. The *roots* consist of little bulbs, connected by a thread-shaped fibre, and exactly accord with those of the foregoing. The *leaves* are about four, sheathing, an inch long, spatulate, firm and rather fleshy, jagged or rough at the point, slightly glaucous. *Flowers* in a long dense cluster, of a yellowish-green. *Calyx-leaves* nearly equal, ovate. *Petals* rather smaller, reflexed. *Lip* erect, ovate, concave, undivided, but half the length of the calyx. *Germen* obovate.

11. M. *lilifolia*. Swartz. n. 6. Willd. n. 8. (Ophrys lilifolia; Linn. Sp. Pl. 1341. Andr. Repos. t. 65.)—Leaves two, ovate. Stalk triangular. Petals linear-thread-shaped. Lip prominent, obovate, acute. Style deflexed, recurved.—Native of wet places in Pennsylvania. The late Peter Collinson cultivated it about 50 years ago, and plants are from time to time brought to England, though seldom long preserved. This and the two following belong to a tribe which have not so clearly the character of *Malaxis* as could be wished. The *flower* is seldom truly reversed, though more or less turned, and the lip, of the present species at least, is rather directed forward than upward, while the column, or *style*, though curved upward, stands opposite, not parallel, to the lip. The whole habit, however, agrees so entirely in every point with *Malaxis*, and with nothing else, that Dr. Swartz has finally determined to place them here, rather than in the less natural genus of *Cymbidium*; especially as the position of their flowers will very often excuse, if not justify, the measure. The *root* of *M. lilifolia* is an ovate bulb, with a spongy reticulated coat, and many woolly fibres. *Leaves* two, radical, three or four inches long, equal, opposite, ovate, keeled, ribbed, bluntish, embracing each other at the base, and accompanied by one or two broad, short, external, sheathing scales. *Stalk* erect, straight, about twice as tall as the leaves, triangular, furrowed, terminating in a loose upright *cluster* of numerous *flowers*, as large as those of most of our common *Orchideæ*. The *calyx-leaves* are linear, half an inch long, spreading, of a pale yellowish-green. *Petals* whitish, as long but much narrower, almost capillary, dependent. *Lip* rather longer than the calyx, olive-green, projecting, somewhat recurved, obovate with a small point, channelled at the base. *Style* incurved, with a hooked tip to the cover of the anthers. *Germen* slender, furrowed, gradually swelling upwards, twisted.

12. M.

12. M. *cordifolia.* Leaf nearly folitary, heart-fhaped. Stalk furrowed. Petals linear-thread-fhaped. Lip prominent, inverfely heart-fhaped, with a fmall point. Germen acutely triangular.—Gathered by Dr. Buchanan, Oct. 2d, 1802, at Narainhetty in Upper Nepal. It grows in watery places, amongft dead leaves, in a micaceous foil. This is clofely allied to the laft, though abundantly diftinct as a fpecies. In fize they exactly agree. The *roots* of the prefent have a thick, fpongy, whitifh coat, and very long woolly fibres. There is one principal *leaf*, which is radical, heart-fhaped, pointed, ribbed, near three inches long and above two broad, with a fhortifh fheathing bafe or *footftalk*, enveloped in one or two fcales. Sometimes, if not always, there occurs, as in *M. monophyllos*, *n.* 9, a very fmall folded ovate leaf, in the bofom of the other. The *flower-ftalk* is twice as tall as the leaf, loofely racemofe. *Flowers* apparently very much like thofe of *M. lilifolia*, but the *lip* is obcordate with a fmall point, and the *germen* is very acutely triangular, becoming club-fhaped as it advances, ftraight, not twifted, with three very evident membranous or winged angles. We have only feen one dried fpecimen.

13. M. *Loefelii.* Swartz. n. 7. Willd. n. 9. (Ophrys Loefelii; Linn. Sp. Pl 1341. Sm. Fl. Brit. 935. Engl. Bot. t. 47. Dickf. H. Sicc. fafc. 9. 11. Ehrh. Herb. 110. O. lilifolia; Hudf. 389. O. paludofa; Fl. Dan. t. 877. O. diphyllos bulbofa; Loef. Pruff. 180. t. 58. O. bifolia bulbofa; Ger. em. 403. Cymbidium Loefelii; Swartz Nov. Act. Upfal. v. 6. 76.)—Leaves two, elliptic-lanceolate. Stalk triangular. Petals linear. Lip prominent, obovate, channelled, undivided, recurved.—Native of marfhes on a fandy foil, among rufhes, flowering in July, chiefly in the north of Europe. We have it in Cambridgefhire and Norfolk, but it is efteemed a rare plant, and confidering its hiftory and affinities, is certainly one of the moft interefting in our Britifh Flora. The habit of the *roots*, with their white fpongy covering and woolly fibres, exactly accords with the two laft defcribed, and indeed with *M. paludofa*, *n.* 10. The *leaves*, however, are much narrower than in *lilifolia* or *cordifolia*, and more refemble thofe of Lily of the Valley. The *flowers* alfo are fewer and fmaller, more frequently reverfed, with broader *petals*, and a yellow, obovate, flightly wavy, but not divided, *lip*, oppofite to which ftands the incurved *ftyle*. The *germen* is obovate, with fix angles. The late Mr. Pitchford, who firft met with this fpecies in Norfolk, exchanged his only fpecimen with Mr. Lightfoot, for above 60 of the rareft Britifh plants.

14. M. *enfiformis.* Leaves feveral, fword-fhaped, equitant, riblefs. Spike very long, dependent. Lip heart-fhaped, four-lobed.—This grows parafitically upon trees at Narainhetty in Upper Nepal, where it was gathered by Dr. Buchanan, November 13, 1802. It is a genuine *Malaxis*, though different in habit from the ufual afpect of the genus. The *root* confifts of long, ftrong, woolly fibres, with fcarcely any bulb. *Leaves* numerous, radical, two-ranked, equitant, feffile, a foot long, fword-fhaped, very acute, coriaceous, quite fmooth, without ribs, of a fine fhining grafs-green, feparating, by age or drying, at a kind of joint near the bafe. *Flower-ftalk* folitary, central, radical, roundifh, longer than the leaves, terminating in an extremely long, recurved or pendulous, denfe, cylindrical *fpike*, of innumerable fmall *flowers*, of a dull orange hue. They are truly reverfed, the *calyx-leaves* and *petals* ovate; the *lip* erect, longer than the petals; heart-fhaped at the bafe, where it embraces the fhort erect *ftyle;* four-lobed in the margin, the two middle lobes rather elongated. *Germen* fhort, elliptical, with fix ribs.

Such are all the fpecies that we can fatisfactorily refer to this genus, not without fcruples refpecting the 11th, 12th, and 13th. Three others, indicated as doubtful by Swartz, and adopted by Willdenow, we prefume, without the leaft hefitation, to exclude. Thefe are

M. *cernua,* Willd. n. 11. (Béla póla; Rheede Hort. Mal. v. 11. 69. t. 35.)

M. *nutans,* ib. n. 12. (Limodorum nutans; Roxb. Corom. v. 1. 33. t. 40.)

M. *caudata,* ib. n. 13. (Epidendrum caudatum; Linn. Sp. Pl. 1349. Helleborine florum foliis maculofis et longiffimis; Plum. Cat. 9. Ic. t. 177.)

Of thefe the two firft, natives of the Eaft Indies, appear to us to have the character of *Cymbidium,* (fee that article,) and not in any manner to accord with *Malaxis.* With them certainly agrees in genus the *Limodorum recurvum,* Roxb. Corom. v. 1. 33. t. 39, L. n. 9. Willd. as well as *Epidendrum terreftre* of the Linnæan herbarium, and a nondefcript fpecies from Dr. Buchanan.

The laft, *E. caudatum* of Linnæus, a plant we believe known to Plumier only, does indeed, by his plate, feem to have the reverfed flower of a *Malaxis;* but the habit is fo different, and the figure is fo incorrectly drawn, the calyx being reprefented interior with refpect to the petals, and the column extremely various and confufed, that we conceive nothing can fafely be deduced from it. We will neverthelefs venture to obferve, that if this fpecies be referrible, by its effential character, to *Malaxis,* fome new one muft be fought to define the genus, in order to exclude a plant fo foreign to it, and which evidently belongs either to *Cymbidium* or *Dendrobium.* In fuch cafes, however, no prudent botanift will truft to any figure, much lefs to fo inaccurate an one as that before us, but will fufpend his judgment till he can examine Nature herfelf. S.

MALAZKERD, in *Geography*, a town of Turkifh Armenia, on the Aras; 140 miles N.E. of Diarbekir. N. lat. 39°. E. long. 41° 59'.

MALBARY, a town of Hindooftan, in Vifiapour; 6 miles N.E. of Merritch.

MALBAY, a bay of the county of Clare, Ireland, on its weft coaft, which is deemed unfafe, and not frequented.—Alfo, a river of Canada, which runs into the St. Lawrence, 63 miles below Quebec.

MALBUNGAT, a town of Lower Carinthia; 15 miles S.W. of Villars.

MALBURY, a town of Bengal; 14 miles S.S.E. of Kifhenagur.

MALBY, a town of Sweden, in Weft Gothland; 35 miles E.N.E. of Uddevalla.—Alfo, a town of the fame province; 26 miles S.E. of Uddevalla.—Alfo, a town of Sweden, in the province of Skonen; 21 miles S. of Chriftianftadt.

MALCAPOUR, a town of Hindooftan, in Candeifh; 25 miles E.S.E. of Burhampour.

MALCHOW, a town of Mecklenburg; 40 miles S. of Roftock. N. lat. 53° 30'. E. long. 12° 33'.

MALCOLM, ALEXANDER, in *Biography*, author of "A Treatife of Mufic, fpeculative, practical, and hiftorical," thick 8vo., Edinburgh, 1721. This work, which has confiderable merit, is dedicated to the moft illuftrious directors of the Royal Academy of Mufic. (See OPERA.) We are old enough to remember feveral of the illuftrious perfonages who were fubfcribers to this eftablifhment, yet never

never heard of any one of them that was likely to read this book, colonel Blathwaite and general O'Hara excepted: the firſt a dilettante of eminence; the ſecond poſſeſſed of good taſte, and, from hearing and comparing great performers and good compoſitions, an excellent judge of muſical talents. The reſt were pleaſed they knew not why, and were drawn into the vortex of faſhion by example.

Upon a late peruſal of this work, which we had not ſeen for near half a century, we find in it indiſputable proofs of the author's learning, diligence, and knowledge. He has drawn from the pureſt ſources of information concerning ancient muſic, and does not ſeem ignorant of the modern. His chapters on compoſition, however, go but a little way into the myſteries of the art. He has indeed given common examples of the three ſpecies of movement in melody: *retto, obliquo,* and *moto contrario;* riſing and falling together; one part ſtationary, and the other moving up or down; and contrary motion. He has alſo given the treble and baſe of a few uſual cadences, in two parts only. But though his explanations, deſcriptions, and diſcuſſions are numerous, they are rendered ſo tedious and full of repetitions and amplifications, that many years ſtudy, experience, and reading, would be ſtill neceſſary for a ſtudent, after the moſt careful and attentive peruſal of this book, to render him a complete contrapuntiſt. His inſtructions are rendered obſcure, perhaps, by too great a deſire to render them clear: they are involved in too many words. "In vitium ducit culpæ fuga, ſi caret arte." The ſtyle is not alluring: it abounds in Scotticiſms, is rough, and often dark and uncouth. The work is too ſcientific for an elementary tract, and too ſuperficial in the rules for practical harmony. We well remember, at an early ſtage of ſtudy, to have taken up this book with a ſure and certain hope of finding in it a ſolution of all our doubts and difficulties; but ſoon laid it down in deſpair. The author ſeems to have begun at the wrong end of his labour, plunging into theory and ſpeculation before he ſpeaks of practice. The plates at the beginning have a hieroglyphic appearance, and muſt be totally unintelligible to inexperience; and the author ſeems deficient in that agreeable and faſcinating manner of writing, in the lively ſtrokes, and variety of occaſional inſtruction, which Bayle allows even to his enemy, Maimbourg. "There are few hiſtorians," ſays he, "even among thoſe who write better, and are more learned and exact, that have the art of engaging the reader's attention ſo much as he does." Though our author has read and meditated much, yet, by being ſelf-taught, there is an awkwardneſs of expreſſion in communicating his knowledge to his readers, which wanted practice and good taſte to render it clear, uſeful, and pleaſant.

As this work is become ſomewhat ſcarce, and was publiſhed before the Monthly and Critical Reviews were eſtabliſhed, we ſhall ſpecify ſome of the principal ſubjects which the author has treated, and the authorities upon which he builds. His doctrine of vibration is taken from s'Graveſande and Keil. He mentions Vincenzo Galileo, but not his more learned ſon. Kircher, Dr. Holder, and Dr. Wallis, are cited; the latter on his doubts concerning the vibrations which conſtitute intervals, from their celerity, as we are unable to count them. He conſiders ratios and coincidences under the guidance of Merſennus. He does not mention Galileo, in ſpeaking of the doctrine of pendulums; nor does he give any authorities in explaining arithmetical, harmonical, and geometrical proportions. Kepler is quoted, and Des Cartes, on the geometrical part of harmonics by dividing right lines. He denominates the loweſt ſound of a common chord the *fundamental,* five years before it was uſed by Rameau as the generator of a chord. The word *concinnous,* ſo frequently uſed by Graſſineau, ſeems adopted from Malcolm. Salmon's Temperament conſidered; and his propoſal for reducing all claſſes to one, diſcuſſed and approved. Solmiſation, according to the hexachords, he ſeverely cenſures. M. Laborde, in his "Eſſais ſur la Muſ.," has given a ſhort article to this work, without ſaying who or what the author was; but in the index, he calls him "Ecrivain Francois ſur la Muſique." None of our biographical dictionaries have honoured him with the leaſt notice; though he certainly ranks high among muſical writers in our own language. Walther, however, tells us from Mattheſon, that he was "ein geleheter Schottlandiſcher edilmann," a learned Scots nobleman. From the materials which he had collected, an ingenious and lively writer might have made a captivating and inſtructive work. The diſciples of Dr. Pepuſch, the only ſtudious muſicians of that time, condemned him for having diſputed the utility of ſolmiſation and the mutations, according to the hexachords. But Chambers, in the firſt edition of his Cyclopædia, was indebted to Malcolm for moſt of his muſical articles. And the French ſeem better acquainted with this book than the Engliſh, though we have never ſeen a tranſlation of it in that language; yet, in Rouſſeau and others, we perceive a frequent anonymous uſe of this book. The author has indeed often availed himſelf of Perrault's philoſophy of ſound, but not without naming him. He denies muſic in parts to the ancients, and ſeems to have been one of the firſt writers on the ſubject, who dared to doubt that a muſic, capable of ſuch miraculous effects as were aſcribed to it, ſhould be deficient in that part of modern muſic which affords us the greateſt pleaſure.

MALDA, in *Geography,* a town of Hindooſtan, in Mewar; 30 miles S.S.W. of Aſawully.

MALDE'E, a town of Perſia, in the province of Segeſtan; 141 miles E.N.E. of Zareng.

MALDEN, or MALDON, an ancient and populous borough and market town in the hundred of Dengey, and county of Eſſex, England, is ſituated ten miles diſtant from Chelmsford, and 37 from London, on the acclivity of an eminence S.W. of the eſtuary of the Blackwater, or river Idumanum. Many of our ancient topographers aſſign this place as the Camalodunum of the Romans: but this ſubject has been fully inveſtigated in the Beauties of England and Wales, vol. v. under COLCHESTER; which town ſee alſo in this work. The earlieſt mention of Malden, by hiſtorians, refers to the year 913, when Edward the Elder encamped here to impede the progreſs of the Danes: the entrenchment he formed lies on the W. ſide of the town, and appears to have been of an oblong form, and to have incloſed about twenty-four acres: three ſides of the ramparts may yet be traced; the other is defaced by buildings. Its ſtrength was probably conſiderable, as in 921 a great army of Danes beſieged it without effect. In 993 it was again attacked by the Daniſh forces commanded by Unlaf. In the Domeſday Survey, Malden is ſtyled a half hundred, and had then 180 houſes, and a hall held by the burgeſſes of the king, who had alſo a houſe here in his own poſſeſſion. When Malden was conſtituted a borough is uncertain: a charter appears to have been granted to the burgeſſes by Henry II. By another charter from queen Mary in 1553, the borough was incorporated, and its government veſted in two bailiffs, ſix aldermen, and eighteen capital burgeſſes. Two members are returned to parliament; the right of election is confined to thoſe who obtain their freedom by birth, marriage, or ſervitude; the number of voters is about 200. The firſt return was made in the year 1329. The cuſtom of Borough-Engliſh, by which the youngeſt ſon ſucceeds to the burgagetenement on the death of his father, ftill prevails here. The town confifts of one principal ftreet, extending nearly a mile eaft and weft, a crofs ftreet of confiderable length, and feveral fmaller avenues and back lanes. The defcent from the upper part to the river is very fteep: many of the houfes are refpectable, having been rebuilt within the laft fifty years. The import trade is confiderable; confifting of coal, iron, deal, corn, &c. At fpring-tides the river will bring up veffels that draw eight feet water; but the coals are brought to the town in lighters. Two fairs are held annually, and a weekly market on Saturdays. In the population furvey of the year 1801, the number of houfes was ftated to be 454, inhabited by 2358 perfons. Malden had formerly three parifhes, but two of them have long been confolidated. The principal church, that of All Saints, is an ancient and fpacious edifice, with a fquare tower terminated by a triangular fpire: in the fouth, or d'Arcy's aifle, three chantries were founded in the reign of Henry VI. by Robert d'Arcy, efq. of Danbury, feveral of whofe family were buried here. Near this church is the town-hall, which is a large and ancient brick building. St. Mary's church is a fpacious pile, fituated in the lower part of the town, and recorded to have been founded by Ingelric, a Saxon nobleman, previous to the Norman conqueft: the tower, with part of the church, was rebuilt in the reign of Charles I. St. Peter's, the parifh united to All Saints, had formerly a church, of which the tower only is now ftanding: attached to it is a building, erected by Dr. Thomas Plume, archdeacon of Rochefter, for a grammar fchool and library. This gentleman was born at Malden in 1630, and in the latter part of his life became a great benefactor to his native town, as well as to feveral other places. The books contained in the library were his own collection, and are ordered to be lent out for general ufe. He appropriated the rents of a farm at Iltney, to keep the fchool and library in repair. He alfo gave 200*l.* to build a workhoufe for the poor; and 1000*l.* more to eftablifh the trade of weaving fackcloth to employ them. The Plumian Profefforfhip of Aftronomy and Natural Philofophy at Cambridge was founded by a bequeft of 1902*l.* which he left for that purpofe. He died in 1704.

Richard de Gravefend, bifhop of London, about the year 1291, founded a fmall priory for Carmelites or White monks, in Malden, which continued till the diffolution. Several eminent fcholars are mentioned by Ball and others, as having been inmates of this monaftery.

In the forty-feventh volume of the Philofophical Tranfactions, is an account of Edward Bright, a fhop-keeper of this town, who was fo enormoufly fat, that his fize and weight are almoft unparalleled in the hiftory of the human race. At the age of twelve years and a half, his weight was 144lbs.; increafing in bulk as he grew up, in feven years more he weighed 336lbs. He increafed in bulk in nearly the fame proportion, and at the age of twenty-eight his weight was 584lbs.: this was the laft time he was weighed; but as he was manifeftly bigger at the time of his death, his weight muft then be upwards of 600lbs. His height was five feet nine inches and a half; and his circumference, round the belly, fix feet eleven inches. He died in 1750, aged 29; after his death feven men were buttoned in his waiftcoat. Till within a year or two of his death he was comparatively an active man; but afterwards his extreme corpulency rendered his life burthenfome. He left a widow pregnant of her fixth child.

Nearly one mile weft from Malden ftood Bileigh abbey, founded, in the year 1180, by Robert de Mantell, for monks of the Premonftratenfian order. Some parts of the monaftic buildings ftill remain, and are now connected with a fmall farm. The chapel is the moft perfect part; its roof is formed with very fine-grained lime-ftone, and has groined arches, fupported by three flender Purbeck columns. Henry Bourcher, earl of Effex, who died April 4, 1483, and Ifabel his wife, were buried here. Beauties of England and Wales, vol. v. Morant's Hiftory, &c. of Effex, 2 vols. folio.

Malden, a town of the county of Zutphen; feven miles E. of Borckeloe.—Alfo, a town of America, in Middlefex county, Maffachufetts, four miles N. of Bofton, containing 1059 inhabitants.—Alfo, a diftrict or townfhip of Effex county, in Upper Canada, occupying a confiderable extent, and fituated on the eaftern fide of Detroit river, about eighteen miles below the town of Detroit. At the lower end of the diftrict there are but few fcattered houfes; but at the upper end, bordering upon the river, and adjoining to the new Britifh poft that has been eftablifhed fince the evacuation of Detroit, a little town has been laid out, which is rapidly increafing. Hither feveral of the traders have removed, who formerly refided at Detroit. This little town and the new poft are denominated "The new Britifh town and poft near the ifland of Bois-Blanc," an ifland in the river near two miles in length, and half a mile in breadth, that lies oppofite to Malden.

MALDENANTRE, a fmall ifland near the coaft of Sardinia. N. lat. 40° 1'. E. long. 8° 13'.

MALDIVES, a clufter of fmall iflands in the Eaft Indian fea, about 270 miles S.W. of cape Comorin, amounting in number, as it is faid, to more than 1000, and moftly uninhabited. They form a kind of oblong inclofure, around a clear fpace of fea, with very fhallow water between one another. According to Mr. Dalrymple's chart, they feem to be divided into thirteen groups, nearly equi-diftant, and each bearing its proper name. The inhabitants of thofe that are occupied appear to be a mixture of Arabs and Indians of Malabar, from which coaft thefe iflands probably were originally colonized. They were difcovered in 1508 by the younger Almeyda, and conquered by the Portuguefe from the Moors, who had ufurped the fovereignty from the natives. The Portuguefe, however, were foon cut off by the original Maldives. Among the inhabitants, who are governed by a chief called *Atoll*, who are miferably poor, and who are governed in an oppreffive manner, there are fome Mahometans. Their language is the Singalefe: their articles of commerce are fails and cordage, cocoa-nuts, oil, honey, dry fifh, tortoife-fhell, and cowries, and thefe articles are collected in four ports. Thefe iflands lie in N. lat. 5° 30' to 7° 5'; and E. long. 72° 30' to 73° 45'.

MALDONADO, a town of South America, in the government of Buenos Ayres, on the river Plata; 100 miles W. of Buenos Ayres. S. lat. 34° 50'. W. long. 55° 36'.

MALDONAT, John, in *Biography*, a learned Spanifh Jefuit, was born near Lerena, in Eftramadura, in the year 1534. He purfued his ftudies at the univerfity of Salamanca, where he afterwards taught the Greek language and divinity with much fuccefs and applaufe. He affumed the habit of the order when he was at Rome, in the year 1562. In the following year he was appointed profeffor of philofophy in the college at Paris, which the Jefuits had juft founded in that city; after this he commenced a courfe of divinity in the fame feminary which occupied him four years. Thefe lectures were attended by a prodigious concourfe of fcholars, who would affemble two or three hours before the time in which the lectures began to infure themfelves places. In 1570 he was fent with nine other Jefuits to Poictiers, with the view of forming an eftablifhment of the order in that city, but in this they were unfuccefsful. He next re-

turned

turned to Paris, and refumed his lectures with great fuccefs. but in the midft of his labours he was interrupted by the exhibition of certain accufations againft him, one of which was, that by his influence over the mind of the prefident St. Andre, he had obtained a fraudulent will, by which his eftates were bequeathed to the Jefuits, and the other was an accufation of herefy, for maintaining that the doctrine of the immaculate conception of the Holy Virgin was not a point of faith. After a regular hearing he was acquitted of both thefe charges, but his mind was unhinged, and he determined to relinquifh his lectures, and to retire in a good meafure from the world. In his retreat at the college of Jefuits at Bourges, he employed himfelf in commentaries on the fcriptures, till he was called out of his obfcurity by pope Gregory XIII., to fuperintend the publication of "The Septuagint," at Rome. Here alfo he finifhed his Commentaries on the Gofpels, which was in 1582; and in the following year he fell fick, and died in the fifty-ninth year of his age. Maldonat was reckoned one of the ableft fcholars of the fociety to which he belonged: he was a capital linguift, an eloquent preacher, and a judicious commentator on the fcriptures. He is highly fpoken of by Dupin, father Simon, and other learned men. Simon, in reference to his qualities as a commentator and critic, fays, "he does not allow one difficulty to pafs without examining it to the bottom. When a great number of literal interpretations of the fame paffage prefent themfelves, he ufually fixes on the beft, without paying too much deference to the ancient expofitors, or even to the majority, regarding nothing but Truth alone, ftript of all authorities but her own." The principal works of Maldonat are "Commentarii in quatuor Evangeliftas;" "Commentarii in quatuor Prophetas, Hieremiam, Baruch, Ezekielem, et Danielem;" he was author of many other works, but they were all given to the world after the death of the author; and fome pieces have been attributed to his pen, which were not only unworthy of his high reputation, but which have generally been regarded as fpurious. Bayle. Moreri, &c.

MALDUAR, in *Geography*, a fmall circar of Bengal, between Dinagepour and Purneah, about nine miles long, and fix broad; which may be confidered as part of Rajemul. The chief town is Rahny.

MALE, the chief and moft fertile of thofe iflands called the "Maldives;" fituated nearly in the centre of the group, about four miles in circumference, and containing a town, in which the princes refide. N. lat. 6° 20'. E. long. 73° 10'.

MALE, the fex which has the parts of generation withoutfide, and which has ordinarily the pre-eminence over the other.

In this fenfe male ftands oppofed to female.

For the proportion of males to females, fee MARRIAGE.

MALE *Balfam Apple*, in *Gardening*. See MOMORDICA.

MALEBAYE, LA, in *Geography*, a town of Canada, on the river St. Laurence; 70 miles N.E. of Quebec.

MALEA, in *Ancient Geography*, *Capo Malio*, a town of Laconia, fituated at the extremity of a chain of mountains, advancing into the fea between the Argolic and Laconic gulfs.

MALEBRANCHE, NICHOLAS, in *Biography*, a celebrated philofopher, was born at Paris in the year 1638, and inftructed in the Latin and Greek languages by a domeftic tutor. He afterwards profecuted the ftudy of philofophy at the college of de la Marche, and of divinity in the Sorbonne. At the age of 22 years, he determined to embrace a monaftic life, and was admitted into the congregation of the Oratory. Weary of the refearches of ecclefiaftical hiftory, to which he firft directed his attention, he was advifed by father Simon to apply to oriental literature and biblical criticifm; but when he had acquired fufficient knowledge of the Hebrew language to read the Old Teftament in the original, he defifted from the purfuit of ftudies of this kind; and under the influence of a temporary enthufiafm, he feemed inclined to give himfelf up wholly to devotion, and filently to wait for divine illumination. But he was roufed from this ftate by the accidental perufal of Des Cartes's treatife "On Man," with the perfpicuous reafoning of which he was fo much pleafed, that he determined to make himfelf thoroughly acquainted with this author's fyftem of philofophy. With this view, he devoted ten years to profound meditation, and to metaphyfical refearches, which led him, under the influence of a warm and exuberant imagination, into the very vifionary regions of enthufiafm. Conceiving the foul of man to be myfterioufly united to his body, and apprehending alfo that a no lefs myfterious union fubfifted between the human foul and God, he publifhed, in 1673, the refult of his meditations and conclufions, in his famous treatife, entitled "Recherche de la Verité," or "Search after Truth," in three volumes, 12mo. In 1676, he attempted to evince the agreement between true philofophy and religion, in a work, entitled "Chriftian Converfations, in which the Truth of the Religion and Morality of Jefus Chrift is vindicated," 12mo. In 1680 appeared "A Treatife on Nature and on Grace," 12mo., which was the refult of a controverfy between him and M. Arnauld on the fubject of grace; and this treatife was fucceeded by feveral controverfial tracts, written by both thefe authors. He publifhed alfo feveral other pieces in vindication of his fyftem announced in the "Search after Truth." Our author alfo publifhed "A Treatife on Phyfical Premotion," againft Bourfier's book, "On the Action of God," and "Reflections on Light and Colours, and on the Generation of Fire," and alfo other papers, inferted in the "Memoirs of the Academy of Sciences," of which body he was admitted an honorary member in the year 1699. By temperance he maintained a good ftate of health, notwithftanding the delicacy of his conftitution, till near the clofe of life, which terminated at the age of 77 years, in 1715. His manners in private life were fimple, cheerful, and complaifant. He paid little regard to thofe fubjects of erudition which employed the thoughts and time of other literary perfons; and which merely ferved to make them acquainted with the opinions of different philofophers, without leaving them fufficiently at leifure to think for themfelves. For poetry he had no tafte; and it is faid, indeed, that he never read ten verfes without difguft. It was his cuftom to ftudy with his windows fhut, that he might not be difturbed by the light. The fpeculations of his retirement were the fubjects of his converfation, with regard to which he was communicative, and yet modeft and unaffuming. His company was much valued and defired; and no foreigner of learning vifited Paris without wifhing to be introduced to him; and we are informed by one of his biographers, that an Englifh officer, being taken prifoner in the war between the king of France and William III., expreffed his fatisfaction at being fent to Paris, becaufe he had long wifhed to fee Lewis XIV. and father Malebranche. See the next article.

MALEBRANCHISM, the doctrine or fentiments of father Malebranche (fee the laft article); which is in a great meafure the fame with Cartefianifm. It muft be owned, however, that though F. Malebranche thought the fame with Des Cartes, yet he does not fo properly feem to have followed him, as to have met with him.

Malebranchiſm is chiefly contained in the "Recherche de la Verité," of which M. Fontenelle ſays, "The Inquiry after Truth" is full of God: God is the only agent, and that too in the ſtricteſt ſenſe. All power of acting, all actions, belong immediately to him. Second cauſes are no cauſes. They are only occaſions that determine the actions of God; or occaſional cauſes. This work, which was firſt publiſhed in 1673, paſſed through ſeveral editions; the beſt of which was that publiſhed by himſelf in 1712, in two volumes 4to, and four volumes 12mo., with conſiderable variations and enlargements.

F. Malebranche, however, does not here lay down his ſyſtem entire, with regard to religion, or rather the manner in which he would reconcile religion to his ſyſtem of philoſophy; that he reſerved for his "Entretiens Chrétiens," already mentioned, where he proves the exiſtence of a God, the corruption of human nature by original ſin, and the neceſſity of a Mediator, and of grace.

Dr. Enfield, in his Abridgment of "Brucker's Philoſophy," (vol. ii.) has given the following account of the ſyſtem of Malebranche. "The doctrine of this book," referring to his 'Search after Truth,' "though in many reſpects original, is raiſed upon Carteſian principles, and is, in ſome particulars, Platonic. The author repreſents, in ſtrong colours, the cauſes of error, ariſing from the diſorders of the imagination and paſſions, the abuſe of liberty, and an implicit confidence in the ſenſes. He explains the action of the animal ſpirits, the nature of memory; the connection of the brain with other parts of the body, and their influence upon the underſtanding and will. On the ſubject of intellect, he maintains, that thought alone is eſſential to mind, and deduces the imperfect ſtate of ſcience from the imperfection of the human underſtanding, as well as from the inconſtancy of the will in inquiring after truth. Rejecting the ancient doctrine of *ſpecies* ſent forth from material objects, and denying the power of the mind to produce ideas, he aſcribes their production immediately to God; and aſſerts, that the human mind immediately perceives God, and ſees all things in him. As he derives the imperfection of the human mind from its dependence upon the body, ſo he places its perfection in union with God, by means of the knowledge of truth and the love of virtue."

"Singular and paradoxical as the notion of 'ſeeing all things in God,' and ſome other dogmas of this writer, muſt have appeared, the work was written with ſuch elegance and ſplendour of diction, and its tenets were ſupported by ſuch ingenious reaſonings, that it obtained general applauſe, and procured the author a diſtinguiſhed name among philoſophers, and a numerous train of followers. Its popularity might, perhaps, be in part owing to the appeal which the author makes to the authority of St. Auguſtine, from whom he profeſſes to have borrowed his hypotheſis concerning the origin of ideas. The immediate intercourſe which this doctrine ſuppoſes, between the human and the divine mind, has led ſome to remark a ſtrong reſemblance between the notions of Malebranche, and thoſe of the ſect called Quakers."

Dr. Reid (Eſſay ii.) does not allow, that either Plato or the latter Platoniſts, or St. Auguſtine, or the Myſtics, thought, that we perceive the objects of ſenſe in the divine ideas. This theory of our perceiving the objects of ſenſe in the ideas of the Deity, he conſiders as the invention of Father Malebranche himſelf. Although St. Auguſtine ſpeaks in a very high ſtrain of God's being the light of our minds, of our being illuminated immediately by the eternal light, and uſes other ſimilar expreſſions; yet he ſeems to apply thoſe expreſſions only to our illumination in moral and divine things, and not to the perception of objects by the ſenſes. Mr. Bayle imagines that ſome traces of this opinion of Malebranche are to be found in Amelius the Platoniſt, and even in Democritus; but his authorities ſeem, as Dr. Reid conceives, to be ſtrained. Malebranche, with a very penetrating genius, entered into a more minute examination of the powers of the human mind than any one before him; and he availed himſelf of the previous diſcoveries made by Des Cartes, without ſervile attachment. He lays it down as a principle admitted by all philoſophers, and in itſelf unqueſtionable, that we do not perceive external objects immediately, but by means of images or ideas of them preſent to the mind. "The things which the ſoul perceives," ſays Malebranche, "are of two kinds. They are either in the ſoul, or without the ſoul: thoſe that are in the ſoul are its own thoughts, that is to ſay, all its different modifications. The ſoul has no need of ideas for perceiving theſe things. But with regard to things without the ſoul, we cannot perceive them but by means of ideas." He then proceeds to enumerate all the poſſible ways by which the ideas of ſenſible objects may be preſented to the mind: either, 1ſt, they come from the bodies, which we perceive; or, 2dly, the ſoul has the power of producing them in itſelf; or, 3dly, they are produced by the Deity in our creation, or occaſionally as there is uſe for them; or, 4thly, the ſoul has in itſelf virtually and eminently, as the ſchools ſpeak, all the perfections which it perceives in bodies: or, 5thly, the ſoul is united with a Being poſſeſſed of all perfection, who has in himſelf the ideas of all created things. The laſt mode is that which he adopts, and which he endeavours to confirm by various arguments. The Deity, being always preſent to our minds in a more intimate manner than any other being, may, upon occaſion of the impreſſions made on our bodies, diſcover to us, as far as he thinks proper, and according to fixed laws, his own ideas of the object; and thus we ſee all things in God, or in the divine ideas.

However viſionary this ſyſtem may appear on a ſuperficial view, yet when we conſider, ſays Dr. Reid, that he agreed with the whole tribe of philoſophers in conceiving ideas to be the immediate objects of perception, and, that he found inſuperable difficulties, and even abſurdities, in every other hypotheſis concerning them, it will not ſeem ſo wonderful that a man of very great genius ſhould fall into this; and probably it pleaſed ſo devout a man the more, that it ſets in the moſt ſtriking light our dependence upon God, and his continual preſence with us. He diſtinguiſhed more accurately than any philoſopher had done before, the objects which we perceive from the ſenſations in our own minds, which, by the laws of nature, always accompany the perception of the object: and in this reſpect, as well as in many others, he had great merit. For this, as Dr. Reid apprehends, is a key that opens the way to a right underſtanding, both of our external ſenſes, and of other powers of the mind.

It is obvious, however, that the ſyſtem of Malebranche leaves no evidence of the exiſtence of a material world, from what we perceive by our ſenſes; for the divine ideas, which are the objects immediately perceived, were the ſame before the world was created. Malebranche ſaw and owned this conſequence, and therefore he reſts the complete evidence which we have of the exiſtence of matter upon the authority of revelation; by which we are aſſured, that God created the heavens and the earth, and that the word was made fleſh. No author, not even biſhop Berkeley, hath ſhewn more clearly, that either upon his own ſyſtem, or upon the common principles of philoſophers, with regard to ideas, we have

have no evidence left, either from reafon or from our fenfes, of the exiftence of a material world. It is no more than juftice to Father Malebranche to acknowledge, that bifhop Berkeley's arguments are to be found in him in their whole force.

Malebranchifm, notwithftanding, appears to many perfons not only illufive and vifionary, but even dangerous, and deftructive to religion; and it has accordingly been vigoroufly oppofed by many zealous French authors. The firft was M. Foucher. After him came M. Arnauld; and in 1715, F. du Tertre, a Jefuit, publifhed an ample confutation (as he imagines) of his whole fyftem. It was alfo charged with atheifm by F. Hardouin, in the "Atheifts Unmafked;" though his fyftem, formed by a warm and exuberant imagination, tends more to fanaticifm and enthufiafm than to atheifm. That part which relates to our feeing all things in God, was anfwered by Mr. Locke, in a fmall tract printed among his pofthumous works.

Thofe who choofe to fee this fyftem, attacked on the one hand and defended on the other, with fubtilty of argument and elegance of expreffion, and on the part of Arnauld with much wit and humour, may find fatisfaction by reading Malebranche's Enquiry after Truth; Arnauld's book of True and Falfe Ideas; Malebranche's Defence; and fome fubfequent replies and defences. It fhould be remembered, however, that Malebranche was a Jefuit, and Arnauld a Janfenift; and the antipathy between the Jefuits and Janfenifts left Malebranche no room to expect quarter from his learned antagonift. Bayle juftly remarks on this controverfy, that the arguments of M. Arnauld againft the fyftem of Malebranche were often unanfwerable, but they were capable of being retorted againft his own fyftem; and his ingenious antagonift well knew how to ufe this defence.

Mr. Norris, an Englifh divine, efpoufed the fyftem of Malebranche in his "Effay towards the theory of the ideal or intellectual World," publifhed in two volumes 8vo. A.D. 1701.

MALECKH, in *Geography*, a town of the duchy of Stiria; eight miles N. of Fridaw.

MALECOTTA, a town of Hindooftan; 42 miles E. of Cochin.

MALEDICTION, MALEDICTIO, in *Law*, a curfe ufually annexed to donations of lands, &c. to churches and religious houfes; imprecating the moft direful punifhments on thofe who fhould infringe them.

MALEEPOETHAS, one of the Soloo iflands, in the Eaft Indian fea. N. lat. 6° 3'. E. long. 120° 18'.

MALEGHERY, a town of Hindooftan, in Myfore; 20 miles S. ofOuffoor.

MALEK SHAH, in *Biography*, third fultan of the Seljukian dynafty, and the moft powerful prince of his time, born in 1054, was fon, heir, and fucceffor of Alp Arflan. On the death of his father he found himfelf placed on a throne which had the rule of Afia from the banks of the Oxus to the borders of Syria. The caliph of Bagdad conferred upon him the facred title of commander of the faithful, which had never before been conferred on a fubordinate prince. Malek had many enemies to contend with, fome of whom were among his neareft relations. In 1075 one of his generals took Damafcus, and reduced a great part of Syria. He invaded Egypt the following year, but was compelled to retreat by the inhabitants of Cairo. In 1078 Malek Shah undertook to complete the conqueft of Turkeftan, which had been commenced by his father. He reduced many cities to obedience, and extended a nominal fovereignty over the Tartar kingdom of Cafhgar. And by allowing his generals to conquer diftricts for themfelves, acknowledging his paramount authority, he ftretched his authority from the Chinefe frontier to the mountains of Georgia, the vicinity of Conftantinople, the Egyptian border, and the coafts of Arabia. His activity was fo great that he is faid to have vifited all parts of his dominions twelve times during his reign. In thefe wide and extenfive progreffes his favourite amufement was hunting, which he purfued with vaft pomp, and fometimes with a train of many thoufand horfemen. In 1088 he made a pilgrimage to Mecca, in which he difplayed more magnificence than any prince had done before on the fame occafion. He abolifhed the tribute ufually paid by pilgrims: he furnifhed them all with provifions, caufed a great number of wells and refervoirs to be made in the defert, and erected places for reft and refrefhment at the different ftages, and he took every means of promoting the profperity of his dominions, by the erection of public buildings, by diminifhing the taxes, and by attending to the exact and rigid adminiftration of juftice. The reformation of the kalendar was one of the acts which diftinguifhed his reign; for which purpofe he affembled all the aftronomers of the Eaft to rectify the errors that had crept into the computations, and they inftituted the Jalalean era, fo named from Jalal, the firft word of one of the fultan's titles, which era is reckoned to commence from March 15th, 1079. Much of the fplendour and excellence of this reign was attributed to the illuftrious vizir Nizam al Molk, who towards the clofe of it fell into difgrace, though very undefervedly, and who was not only deprived of his employments, but in the 93d year of his age fell by the hand of an affaffin. The wound, though fatal, did not prevent him previoufly to his death, from writing a dignified epiftle to his fovereign, afferting his fidelity, and recommending his fon to the fultan. Malek, proceeding to Bagdad, with the intention, it is faid, of fixing there the feat of his empire, and removing the caliph to fome other place, was taken ill of a fever, which put an end to his life in 1092, in the 38th year of his age and the 21ft of his reign. This prince is highly extolled for his mental and bodily qualities, and for many virtues that adorn a throne. The houfe of Seljuk attained its higheft greatnefs in his perfon, from which it declined at his death, or rather at the death of his minifter Nizam. Gibbon. Univer. Hift.

MALEL, or MELLI, in *Geography*, a town of Nigritia, on a river which runs into the Niger. N. lat. 13° 40'. E. long. 9° 36'.

MALELA, or MALELES, JOHN, in *Biography*, a monk of Antioch, known chiefly by a chronicle, written in the Greek language, from the creation to the reign of Juftinian. It was publifhed from a manufcript in the Bodleian library, by Edward Chilmead, of Oxford. It has been republifhed as a kind of appendix to the Byzantine hiftorians at Venice, in 1733.

MALEMBO, in *Geography*, a fea-port of Africa, in the kingdom of Cacongo. It contains about 700 huts or houfes, and is furrounded by a wall conftructed of rough ftones, without mortar. The king has a palace here in which he occafionally refides. The Dutch and Portuguefe have warehoufes for ivory and raw minerals, which they obtain in exchange for European goods; 15 miles S.W. of Cacongo.

MALERMI, fometimes called MALERBI, NICHOLAS, in *Biography*, a native of Venice, and by profeffion a monk, is entitled to a fhort notice, as having been the author of the

firft

first printed version of the fcriptures into the Italian language, which was publifhed in two volumes folio, in the year 1471, under the title of "Biblia volgare Iftoriata." It was reprinted in 1477, and again in 1481. He was author alfo of "The Lives of all the Saints," publifhed at Venice in 1475.

MALESHERBES, Christian-William de Lamoignon de, born at Paris in 1721, was fon of the chancellor of France, William de Lamoignon, a defcendant of an illuftrious family. He received his early education at the Jefuits' college, and afterwards applied himfelf with ardour to the ftudy of the law, and to other fubjects connected with political economy. At the age of twenty-four he was appointed a counfellor in the parliament of Paris, and in December 1750 he fucceeded his father as prefident of the "court of aids," an important jurifdiction, the duties of which were to regulate the public taxes. The fuperintendance of the prefs had been conferred upon Malefherbes by his father, at the fame time that he received the prefidentfhip of the court of aids, and this function, which had ufually been exercifed to the fuppreffion of all free enquiry, became in his hands the means of promoting it to a degree beyond all former example in that country. It was through his favour that the French Encyclopédie, the works of Rouffeau, and the writings of other eminent men, iffued from the prefs, notwithftanding the oppofition and anathemas of the hierarchy. In this view of the fubject, Malefherbes, as well as the philofophical party with whom he was affociated, may be charged with having been materially inftrumental in preparing the way for that revolution which has been the pregnant fource of fo many calamities. In 1771, when the tyranny of the government had proceeded to the diffolution of the whole legal conftitution, and the banifhment of parliaments, the court of aids participated in the general deftruction, which it provoked by its remonftrances. Malefherbes was banifhed to his country-feat by a "lettre de cachet," and the duke de Richelieu, at the head of an armed force, abolifhed the tribunal. He was diftinguifhed by his private virtues, and his time was occupied with his family and his books, and the cultivation of his grounds. His expenditure in public objects was large: he drained marfhes, cut canals, conftructed roads, built bridges, planted walks, and carried his attention to the comfort of the lower claffes fo far, as to raife fheds on the fides of the river for the fhelter of the women at their domeftic labours. Thus he fulfilled the part of the beneficent parent of a village, till the acceffion of Lewis XVI. recalled him to a public ftation, and in 1774 Malefherbes received an order to appear at the place where the court of aids had fat, and refume the prefidentfhip of the reftored tribunal. On this occafion he pronounced a very affecting and patriotic harangue, and afterwards addreffed the king in an eloquent fpeech of thanks. He particularly inveighed againft that fpirit of defpotifm which had abrogated law and juftice, and abolifhed every veftige of conftitutional liberty. Such fentiments were in perfect unifon with thofe of the young and uncorrupted king, and they procured for Malefherbes the appointment of minifter of ftate in June 1775. This elevation was regarded by him only as affording an opportunity of extending his fphere of ufefulnefs. One of his firft concerns was to vifit the prifons, and reftore to liberty the innocent victims of former tyranny, and his praifes were carried throughout France by perfons of all defcriptions returning to the bofoms of their families from the gloom of dungeons. He was defirous of abolifhing the arbitrary power of iffuing lettres de cachet, but not being able to effect this great reform, he procured the appointment of a commiffion, compofed of upright and enlightened magiftrates, to which every application for fuch letters fhould be fubmitted, and whofe unanimous decifion fhould be requifite for their validity. Malefherbes was alfo a great encourager of commerce and agriculture, in which he had the cordial cooperation of the illuftrious Turgot, at that period the comptroller of the revenue. The latter was foon difmiffed from his high office by the intrigues of courtiers, and the former, owing to the rejection of fome important meafures, which his zeal for the public good led him to propofe, refigned his poft in the month of May 1776. To obtain an accurate view of the manners and policy of other countries and foreign ftates, he fet out on his travels, and vifited Switzerland and Holland, and in the courfe of his journey he noted down every occurrence worthy of obfervation, and that might, hereafter, poffibly be ufeful to himfelf, and promote the melioration of his country. On his return, at the end of a few years, he found his native country fo much advanced in philofophical principles, that he was encouraged to draw up and prefent to the king two elaborate memoirs, one on the condition of the Proteftants, the other on the principles of civil liberty, and toleration in general, replete with the enlarged views of an enlightened ftatefman, who was at the fame time a friend to the interefts and happinefs of mankind. Difficulties were now accumulating in the management of the government, and the king, in 1786, called Malefherbes to his councils, but without appointing him to any particular poft in the adminiftration. He foon found it impoffible to act with the men already poffeffed of the powers of government, but he was determined, in this critical ftate of things, to make one effort for opening the monarch's eyes, and drew up two energetic memoirs "On the Calamities of France, and the Means of repairing them;" but fuch was the afcendancy which the queen's party had over the mind of the king, that he was prevented from even reading them, nor could he be prevailed upon to grant the writer one private interview; he therefore took his final leave of a court, apparently bent on its own and the nation's ruin. He retreated to his country refidence, determined to confult the beft means of ferving his country by philofophical and agricultural purfuits, and in 1790 publifhed "An Effay on the Means of accelerating the Progrefs of Rural Economy in France," in which he propofed an eftablifhment to facilitate the national improvement in this important point. He was particularly led to make his propofal at this period, with the hope that the revolutionary changes, though fo awful and fanguinary, would finally iffue in a free and well balanced conftitution. The dreadful fcenes which very foon followed in horrible fucceffion extinguifhed his hopes, and left him to mourn in folitude over the miferies of France. Every energy of his foul was, at length, roufed, by the decree of the national convention for the trial of the dethroned and imprifoned king. He now feemed wholly to forget the neglect which had been offered him by the court, at a time when his advice might have effentially ferved it, and he felt nothing but the defire of ferving the king and his family with the utmoft extent of his talents. He accordingly wrote to the prefident of the convention, requefting the liberty of being permitted to act as one of the counfel of the fallen monarch. Three had already been appointed, but one having, from prudential motives, declined the office, Lewis, who wept at this proof of attachment from his old fervant, immediately nominated Malefherbes in his ftead. Their interview was extremely affecting, and Lewis, during the fhort interval before his death, fhewed every mark of affection for, and confidence in, his generous advocate. Malefherbes was the perfon who announced to him his cruel doom, and was one of the laft who took leave of him previoufly to his execution. After that

cataftrophe

cataftrophe he again withdrew to his retreat, and with a deeply wounded heart, refufed to hear any thing of what was acting among the blood-thirfty Parifians. As he was one morning working in his garden, he obferved four favage looking wretches directing their courfe to his houfe, and haftening home, he found them to be officers from the revolutionary tribunal come to arreft his daughter and her hufband, who had formerly been prefident of the parliament of Paris. The feparation of thefe perfons from his family was deeply afflicting to his heart, and it is probable that his own arreft fhortly after was a relief to his feelings. He had long been efteemed as father of the village in which he lived, and the ruftic inhabitants crowded round to take leave of their ancient benefactor with tears and benedictions. Four of the municipality accompanied him to Paris, that he might not be efcorted by foldiers like a criminal. He was fhut up in prifon with his unfortunate family: and in a few days the guillotine feparated his fon-in-law Lepelletier from his wife; and the accufation of Malefherbes with his daughter and grand-daughter, "for a confpiracy againft the liberties of the people," was followed, as a matter of courfe, by a fentence of death. The real crime, as it was bafely denominated, of this excellent man and worthy patriot, and which the convention never pardoned, was his defence of the king, an act in which he gloried to the lateft hour of his exiftence. He probably thought it an honour to die by the fame ruffian hands that had fpilt the blood of his mafter. The condemnation of the females almoft overcame the manly fortitude which he difplayed in every perfonal fuffering; his courage, however, returned at the prifon, and they prepared for the death which was the laft and only important event that they had to encounter. His daughter had exhibited the noble fpirit with which fhe was infpired, for upon taking leave of Mademoifelle Sombreuil, who had faved her father's life on the fecond of September, fhe faid to her, "You have had the happinefs to preferve *your* father, I fhall have the confolation of dying with *mine*." On the fatal day, Malefherbes left the prifon with a ferene countenance, and happening to ftumble againft a ftone, he faid with much pleafantry, "a Roman would have thought this an unlucky omen, and walked back again." Thus perifhed the venerable Malefherbes in April 1794, when he had attained to his feventy-third year. He was unqueftionably one of the moft fpotlefs and exemplary characters of his time. The fubfequent government has fince made fome reparation for the injuftice done him, by ordering his buft to be placed among thofe of the great men who have reflected honour upon their country. Gen. Biog.

MALESHERBES, in *Geography*, a town of France, in the department of the Loiret, and chief place of a canton, in the diftrict of Pithiviers; 10 miles N.E. of Pithiviers. The place contains 945, and the canton 6587 inhabitants, on a territory of $242\frac{1}{2}$ kiliometres, in 22 communes.

MALESTROIT, a town of France, in the departmen of Morbihan, and chief place of a canton, in the diftrict of Ploermel; 7 miles S. of Ploermel. The place contains 1800, and the canton 11,734 inhabitants, on a territory of 255 kiliometres, in two communes. N. lat. 47° 49'. W. long. 2° 18'.

MALHAR, a town of Hindooftan, in Vifiapour; 20 miles E of Poonah.

MALHATTY, a town of Bootan; 60 miles N. of Dinagepour.

MALHERBE, FRANCIS DE, in *Biography*, a celebrated French poet, was born about the year 1556 at Caen, in Normandy. His father, who was an inferior law-officer, embraced the Calviniftical doctrines a fhort time before his death, which fo much difpleafed the fon, whofe governing maxim on this point was, "That a gentleman's religion fhould be that of his prince," that he left his native province, and entered into the houfehold of Henry d'Angoulême, natural fon of king Henry II., and governor of Provence. Little is known of the fubject of this article, till he was mentioned by Perron to Henry IV., as one who had furpaffed all other compofers of French poetry: two or three years after this time, *viz.* in 1605, Malherbe firft came to court, being then about 50 years of age. The king received him into his fervice, and gave him a liberal falary, and after the death of the monarch he had a penfion from the queen dowager. He died at Paris in 1628. He is reprefented as of a very unamiable temper; fplenetic and farcaftic, and as having little feeling for the common charities of his kindred. He was perpetually engaged in lawfuits, and his bon mots were frequently rude and fevere: to a young lawyer who fhewed him a poem of his own compofition, he faid, "Had the alternative been given you of being hanged or writing thefe verfes, you might have been excufed producing fuch a ridiculous piece." Dining once with the archbifhop of Rouen, he fell afleep after dinner: the prelate waked him to go and hear a fermon he was to preach: "I can," faid Malherbe, "fleep well enough without that." His ruling paffion was that of guarding the purity of the French language, of which he exhibited a proof almoft in his dying moments, when he reproved his nurfe for ufing a word that was not of good authority: and it is farther faid, that when his confeffor was defcribing to him the happinefs of a future world in mean and vulgar terms, he exclaimed, pray fay no more, your ftyle is too difgufting to be borne. With all his defects Malherbe is revered as the father of cultivated French poetry. His works confift of odes, ftanzas, fonnets, epigrams, fongs, and other fhort pieces, fome of which are merely complimentary addreffes to the great, and fome are of a devotional caft. The beft editions of his works are in 3 vols. 12mo. 1722; and in octavo 1756, edited by St. Marc. Moreri.

MALHEUREUX, in *Geography*, a fmall ifland in the gulf of Mexico, near the coaft of Weft Florida. N. lat. 30° 6'. W. long. 89° 28'.

MALIANA, or MANIANA, a town of Algiers, much frequented by pilgrims, on account of the tomb of a faint, called "Sede Youfeph;" 12 miles S.S.E. of Tefeffad.

MALIC ACID, in *Chemiftry*, is a vegetable compound, which exifts ready formed in many unripe fruits; and contributes, almoft exclufively, to give fournefs to the apple, the barberry, the plum, and the floe. It was difcovered by Scheele in the year 1785. He has given us the following procefs for extracting it, in Crell's Chemical Journal for that date. Saturate the juice of unripe apples with carbonat of potafh, and to the folution add acetat of lead till a turbidnefs ceafes to be produced. The precipitate, which is a compound of the malic acid with oxyd of lead, muft be wafhed in a large quantity of water, and afterwards treated with dilute fulphuric acid; frefh portions being poured on, until the mixture has loft its faturnine flavour, and become perfectly four. The malat of lead, by this treatment, will be decompofed, a fulphat being formed in its place, and the malic acid remaining free in the fupernatant liquor. To feparate them the fluid muft be paffed through a filter. Vauquelin has fince afcertained, that the acid in queftion may be obtained from the *fempervivum tectorum*, or common houfe leek, more advantageoufly even than from the apple. It exifts in this vegetable combined with lime; and the mode of operating, which he has recommended, differs but little from the preceding, except in adding acetat of lead to the expreffed juice, without the previous intervention of carbonat of potafh. Annales de Chimie, t. 34. p. 127.

Befides the above proceffes for extracting malic acid, it may alfo be formed artificially by the action of nitric acid upon fugar. If equal quantities of nitric acid and fugar be beat together, till the mixture affumes a brown colour, two new acids will be found to have been created, having very different properties from the one originally employed. The moft abundant of thefe is the oxalic, or that which gives fournefs to the *oxalis acetofella*, or common wood forrel, whence its name, and which will be more particularly treated of under that article. (See Oxalic *acid*.) The other is the malic; and the mode of feparation employed by Scheele, who was the difcoverer of this fact, is as follows: Add lime-water till a precipitate ceafes to be produced; and after having filtered the liquor, prefent a farther quantity, fufficient to neutralize the malic acid. Alcohol muft next be poured in, which will caufe a coagulation to take place. The product is a malat of lime, which, when feparated by the filter, and wafhed with frefh alcohol, muft be rediffolved in water. This, as before, muft be decompofed by acetat of lead; and the fame means reforted to, to collect the free acid.

Malic acid, obtained by any of thefe methods, is a brownifh-red liquid of a pungent and very four tafte. It is incapable of cryftallization, and prefents thus a particular diftinction from the other vegetable acids. When evaporated, it becomes thick and vifcid; and if expofed in thin layers to an atmofphere tolerably free from moifture, it dries, forming a brilliant varnifh. By heat it is eafily decompofed, becoming firft of a deep colour, and exhaling a thick and pungent vapour. The coaly matter which it leaves behind is very light and fpungy, fimilar to that yielded by mucilage of fugar. The volatile products, when collected in clofe veffels, are, according to Fourcroy, (Syftem vii. 270.) an acid water, much carbonic acid, and fome carburetted hydrogen. The malic acid is liable to fpontaneous decompofition, when long kept in a fluid ftate. All the powerful acids act upon it, and change its nature. By the fulphuric it is reduced to coal, and nitric acid changes it into the oxalic; a proof of the latter containing the greateft proportion of oxygen. Malic acid unites with different bafes, and forms a clafs of falts denominated *malats*. Thefe have been but little examined, except by their difcoverer Scheele. The malats of potafh, foda, and of ammonia are very foluble and deliquefcent. The neutral malat of lime exifts in the form of irregular cryftals, which are difficult of folution, even at a high temperature. The prefence of a flight excefs of acid, however, forms a fuper-malat, which is very readily diffolved. It is this compound which is contained in the common houfe leek. Malic acid, on being added to barytic water, caufes an immediate precipitation; but no fuch effect occurs with ftrontian. The latter falt, therefore, we may infer, is confiderably more foluble than the former. Of its combination with the other earths, but little more is known, than that with magnefia it forms a compound which is deliquefcent; while its product with alumine is very difficult of folution. It unites with fome metallic oxyds; and precipitates mercury, lead, and filver from the nitrats of thofe metals. In this latter refpect, it exhibits a ftriking difference from the citric acid, with which it is almoft always more or lefs mixed in vegetables; that fubftance caufing no change in the folutions juft mentioned. (See Citric *acid*.) Malic acid diffolves iron and zinc; the former of which yields a brown mixture incapable of cryftallization; but the latter falt may be obtained in fine regular cryftals. It decompofes muriat of gold, the oxyd being reduced to the metallic ftate. This acid is not applied to any ufeful purpofe.

MALICANDURGAM, in *Geography*, a town of Hindooftan, in Myfore; 19 miles N. of Allumbaddy.

MALICE, in *Ethics* and *Law*, is a formed defign of doing mifchief to another; it differs from hatred. In murder it is malice makes the crime; and if a man, having a malicious intent to kill another, in the execution of his malice kills a perfon not intended, the malice fhould be connected to his perfon, and he fhall be adjudged a murderer. The words *ex malitia præcogitata* are neceffary to an indictment of murder, &c. And this *malitia præcogitata*, or *malice prepenfe*, may be either *exprefs* or *implied* in law. *Exprefs* malice is, when one with a fedate, deliberate mind, and formed defign, kills another; which formed defign is evidenced by external circumftances, difcovering that intention; as lying in wait, antecedent menaces, former grudges, and concerted fchemes to do him fome bodily harm. (1 Hal. P. C. 451.) Befides, where no malice is expreffed, the law will imply it; as where a man wilfully poifons another; in fuch a deliberate act the law prefumes malice, though no particular enmity can be proved And if a man kills another fuddenly, without any, or without a confiderable provocation, the law implies malice; for no perfon, unlefs of an abandoned heart, would be guilty of fuch an act, upon a flight or no apparent caufe. See Murder.

MALI-CHAN, in *Geography*, a fmall ifland near the coaft of China, in Quang-tong; 10 miles S.W. of Macao.

MALICHO, a town on the S. coaft of the ifland of Mindanao. N. lat. 7° 48′. E. long. 124° 21′.

MALICIOUS Mischief, in *Law*. See Mischief.

Malicious *Profecution*. See Injury.

MALICORNE, in *Geography*, a town of France, in the department of the Sarthe, and chief place of a canton, in the diftrict of La Flêche; fix miles N. of La Flêche. The place contains 1023, and the canton 10,226 inhabitants, on a territory of 225 kiliometres, in 11 communes.

MALICOY, a low fmall ifland in the Indian ocean, between the Laccadive and Maldive iflands, furrounded with breakers, and dependent on a rajah of the Malabar coaft. N. lat. 8° 16′ 30″. E. long. 73° 9′ 30″.

MALICURGINAGUR, a town of Hindooftan, in Myfore; 50 miles S. of Seringapatam.

MALIDIA, a town of Africa, on the E. coaft of Tunis; 110 miles S.S.E. of Tunis.

MALIGHERY, a town of Hindooftan, in Baramaul; 30 miles S.E. of Darempoory.

MALIGNANT, in *Medicine*, that quality in a difeafe which renders it more than ordinarily dangerous, and difficult of cure.

Malignant

Malignant is generally applied to ſuch fevers as are epidemical or infectious, and are attended with ſpots and eruptions of various kinds. See *Malignant* Fever.

MALIKERY, in *Geography*, a town of Hindooſtan, in Myſore; 18 miles N. of Seringapatam.

MALIKUL, a lake of Ruſſia. N. lat. 48° 20′. E. long. 60° 14′.

MALILLA, a town of Sweden, in the province of Smaland; 45 miles N.N.W. of Calmar.

MALINES, or Mechlin, a city of France, and principal place of a diſtrict, in the department of the Two Nethes; lately the capital of a province of the Netherlands, comprehending a ſmall territory with about nine towns and villages. It was the ſee of an archbiſhop, and contains ſix pariſh churches. The number of inhabitants in the town is eſtimated at 16,612, and in the two cantons at 24,640, in a territory of 87½ kiliometres, in nine communes. The manufactures of the place, which are conſiderable, are thoſe of bed-quilts, thread, and particularly lace, which is in high eſtimation all over Europe. In the arſenal is a foundery for cannon, and other inſtruments of war. The town is diſtant 12 miles N. from Bruſſels. N. lat. 51° 1′ 50″. E. long. 4° 28′ 45″.

MALINHEAD, the moſt northern cape of Ireland, in the diſtrict of Iniſhowen and county of Donegal. N. lat. 55° 23′. W. long. 7° 16′.

MALINOV, an iſland in the mouth of the Volga, at its entrance into the Caſpian ſea. N. lat. 45° 8′.

MALISTA, one of the ſmall Weſtern iſlands, near the W. coaſt of Lewis. N. lat. 58°. W. long. 7° 4′.

MALIT, a town on the N. coaſt of the iſland of Timor. S. lat. 8° 24′. E. long. 125° 55′.

MALIVAGONGA, a large river of Ceylon, in the country of Candy, which riſes at the foot of Adam's peak, a high mountain S.W. of Candy, and taking a N.E. direction, nearly ſurrounds the capital, and at length falls into the ſea at Trincomalee.

MALIUTO, a town of Naples, in Calabria Citra; 12 miles N.W. of Biſignano.

MALKAR, a town of Hindooſtan, in the country of Golconda; 54 miles W. of Hydrabad. N. lat. 17° 17′. E. long. 77° 53′.

MALKARABÆLA, in *Zoology*, the name of an Eaſt Indian ſpecies of ſerpent found in the iſland of Ceylon. It is remarkably variegated with white and duſky brown, in various figures.

MALKUITZ, in *Geography*, a town of Sileſia, in the principality of Breſlau; nine miles S.W. of Breſlau.

MALL, or Mallet, a ſmaller kind of mace, a weapon uſed by our ancient Engliſh archers for diſpatching the enemies whom they had wounded with their arrows.

Mall, or *Sea-mall*, in *Ornithology*, the Engliſh name of the Larus *Canus;* which ſee.

MALLA, in *Geography*, a town of Africa, in the country of Woolly; 15 miles E. of Medina.

MALLABAUQUEN, a lake of Chili; 60 miles N.E. of Valdivia.

MALLAMA, a town of South America, in Popayan; 30 miles S.W. of Paſto.

MALLANCY Choky, a town of Aſſam; 50 miles E. of Rangamatty.

MALLAPILLY, a town of Hindooſtan, in Myſore; 12 miles N. of Venchatighery.

MALLARD, the *Anas Boſches*, in *Ornithology*. See Duck.

MALLAWALLE, in *Geography*, a ſmall iſland in the Eaſt Indian ſea, N. of Borneo. N. lat. 7° 2′. E. long. 117° 29′.

MALLEABILITY, in *Phyſics*, a property principally confined to ſome of the metals, by which their form can be changed by the action of the hammer. When the change of figure is effected by rollers, the ſubſtance is ſaid to be *laminable:* when by wire drawing, it is called *ductility*. The property, however, is the ſame in all theſe proceſſes. Some bodies are malleable only at a certain temperature, ſuch as glaſs, and ſome of the metals: others at all temperatures, to a certain degree. This is the caſe with moſt of the malleable metals.

Some bodies are not malleable till they have received a certain mechanical treatment. In ſuch caſes, it is obſerved, that when the body is brittle, it is under its cryſtalline form, or that ſtate in which its fracture exhibits ſome regular figures. This is the caſe with iron and zinc. See Metal and Zinc.

MALLEABLE, ſomething hard and ductile, and that may be beaten, forged, and extended under the hammer, without breaking.

All metals are malleable, not excepting even quickſilver; but gold is ſo in the greateſt degree of all. The chemiſts have long ſought the fixation of mercury, or to render it malleable. See Mercury, and Freezing.

MALLEAM, in *Geography*, a town of Hindooſtan, in the Carnatic; 24 miles S.S.W. of Tritchinopoly.

MALLEAMOTHE, in *Botany*, a low tree, or rather ſhrub, growing in Malabar. Of the roots are made hafts for knives, the leaves ſerve to dreſs the ground, and being fried in oil of palm, furniſh a liniment for removing the impetigo, and drying the puſtules of the ſmall-pox. A decoction of the ſame, in common water, is uſed as a fomentation to mitigate the pains of the hæmorrhoids.

The root pulverized with ginger and ſaffron, and exhibited in an infuſion of rice, cures the dropſy by powerfully promoting a diſcharge of ſuperfluous ſeroſities by the urinary paſſage. Acoſta commends the ſhrub principally for two effects; firſt, againſt fluxes of the belly, for which purpoſe, however, it is of leſs efficacy than other medicines; ſecondly, for curing all kinds of eryſipelas, eſpecially ſuch as proceed from mere bile. They macerate the whole root or trunk, bruiſed in a decoction of rice, and ſuffer them to remain there for ſome hours, that the water may contract an acidity; after which they anoint the eryſipelas with it, and order the patient to drink a ſufficient quantity of the ſame twice a-day, the ſtomach being firſt purged. They give the ſame water to thoſe who labour under an inflammation of the liver, and the burning heat of a fever; and uſe it mixed with a ſmall quantity of the juice of the leaves of tamarind, to anoint the lips of the wounds, in order to prevent an inflammation.

MALLEI Externus, in *Anatomy*, the name given by Albinus and others to a muſcle of the malleus, ſometimes called laxator tympani. See Ear.

Mallei *Internus*, the name under which Winſlow and others have deſcribed the tenſor tympani muſcle. See Ear.

Mallei *Superior*, is the muſcle deſcribed by Albinus as the laxator tympani, and by ſome others as the laxator tympani minor. See Ear.

MALLEMANS, Claude, in *Biography*, deſcended from a noble family, was born at Beaune, in Burgundy, about

about the year 1646. He came to Paris while he was very young, where he purfued his early ftudies, and, in 1664, he entered among the priefts of the congregation of the Oratory, and afterwards attached himfelf to the univerfity of Paris. Here he fulfilled the duties of profeffor of philofophy for more than thirty years with great reputation, and had the honour of giving inftructions in this fcience to the duchefs of Burgundy. He died in 1723, at the advanced age of feventy-feven, and in circumftances of diftrefs and great poverty. He poffeffed a very inventive genius, and was a zealous advocate for the philofophy of Des Cartes. He invented a machine for making all forts of dials, and was author of "A Phyfical Treatife on the World;" "A new Syftem of the Load-ftone;" an attempt to folve "The famous Problem of the Quadrature of the Circle;" he publifhed many papers in the "Journaux des Sçavans," between the years 1674 and 1716. Moreri.

MALLE-MUCKE, in *Ornithology*. See FULMAR and PROCELLARIA *Glacialis*.

MALLENOWITZ, in *Geography*, a town of Moravia, in the circle of Hradifch; 10 miles N.E. of Hradifch.

MALLEOLARIS, in *Anatomy*, *malleolar*, an epithet applied to two fmall branches of the anterior tibial artery, diftributed on the ankle joint. They are diftinguifhed as external and internal. (See ARTERY.) The term is fometimes ufed in fpeaking of a procefs of the tibia, and one of the fibula. See MALLEOLUS.

MALLEOLI, among the *Romans*, bundles of any combuftible matter befmeared with pitch, and ufed by the Roman foldiers either for giving light in the night-time, or for fetting fire to fome of the enemies' works.

The malleoli were fometimes fixed to a dart or javelin, that they might be fure to catch firm hold, and communicate the fire wherever they happened to light.

MALLEOLUS, in *Anatomy*, a technical term equivalent to ankle. It denotes the bony prominences, which protect the joint of the ankle. The inner and fmaller of thefe (*malleolus internus*) is a procefs of the tibia; the outer and larger (*malleolus externus*) is a part of the fibula. See EXTREMITIES.

MALLEOLUS, in *Ichthyology*, a name given by Gaza and fome others, to the fifh called by Ariftotle and the other old writers, fphyræna, and by the Italians luzzo marino.

It is a beautiful fifh, and feems to belong to the fcombri, or mackarel kind. Salvian has figured it under the name of fudis, a name by which it is alfo called by Varro and fome other old authors; but Salvian's figure is very imperfect; he has omitted the back-fin.

MALLEPALEAM, in *Geography*, a town of Hindooftan, in Myfore; nine miles S. of Sankeridergam.

MALLESUNDRUM, a town of Hindooftan, in Myfore; 10 miles E. of Sankeridergam.

MALLET, DAVID, in *Biography*, a poet and mifcellaneous writer, a native of Scotland, was probably born in Perthfhire. The name of his family was Malloch: little is known of him in early life, but in 1720 he was tutor to the children of a Mr. Home, near Edinburgh, and at the fame time attended lectures in the univerfity of that city. He had already diftinguifhed himfelf by fome poetical compofitions, particularly by a paftoral, which brought him into notice among the Scottifh literati. The treatment which he met with at Mr. Home's did not accord with his expectations, and in 1723, he gladly accepted the offer of accompanying the two younger fons of the duke of Montrofe to Winchefter. About this time he printed in the "Plain-Dealer" his admired ballad of "William and Margaret;" its fuccefs induced him to refume his poetical ftudies, and in 1728 he publifhed "The Excurfion." About this time he changed his name from Malloch to Mallet, and in 1731 his tragedy of "Eurydice," which had been planned fome years before, was brought on the ftage, and was favourably received. He had now attained to a fufficient degree of confequence to be admitted to the company of men of rank and literary eminence; among thefe was Pope, whofe ridicule of critics and commentators he echoed, in a poem publifhed in 1733, "On Verbal Criticifm." Immediately after this, the prince of Wales appointed him his fecretary, with a falary of two hundred pounds a-year. In 1734, he attended the prince of Orange on a vifit to Oxford, and prefented to him a copy of verfes written in the name of the univerfity, on which occafion he was admitted to the degree of M.A. His tragedy of "Muftapha" was brought on the ftage in the year 1739, and met with fome degree of temporary fuccefs. The longeft poem of this author is entitled "Amyntor and Theodora;" it is a pathetic tale in blank verfe, interfperfed with much poetical defcription, but it is generally deemed tedious. Among the profe pieces of Mallet, the moft important was "The Life of Lord Bacon," prefixed to an edition of his works, which appeared in 1740; this, though an elegant and judicious article of biography, is defective in the difplay of what conftitutes the main point of that wonderful man's merit, his character as a luminary of fcience. After the death of Pope, lord Bolingbroke employed Mallet to blacken his memory, in revenge for clandeftinely printing his "Patriot King." In reward for this fervice, his lordfhip left him his works, which in 1754 he publifhed in five volumes quarto, but which not only involved him in difficulties, on account of certain fentiments contained in them fubverfive of the principles of revealed religion, but which did not produce to the editor any profit. After this he was engaged to write the life of the great duke of Marlborough, for which he was liberally paid, with an annual penfion, though it is pretty well afcertained that he never made any progrefs in the bufinefs. He was next employed by the miniftry to attack admiral Byng, with the view, no doubt, of diverting the public odium from the real delinquents, and to throw it on the unfortunate commander. Byng was executed, and Mallet rewarded with a confiderable penfion. He died in 1765; he is defcribed as a man of agreeable manners and converfation, fufficiently attentive to his own intereft, but ready to ferve his friends. "Nothing," fays his biographer, "elevated or dignified can be difcerned in his character or principles. As a poet he may lay claim to elegant diction, fplendid imagery, and pathetic fentiment, but he is deficient in energy and judgment." Johnfon's Lives of the Poets.

MALLET, EDME, was born at Melun in the year 1713; and in 1751 we find him engaged in ferving a *cure* near his native place, when he came to Paris, and was chofen profeffor of theology in the college of Navarre. He made himfelf known by various publications, of which the following were the principal; "Principes pour la Lecture des Poetès;" "Effai fur l'Etude des Belles Lettres;" "Effai fur les Bienfeances Oratoires;" "Principe pour la Lecture des Orateurs;" "A Tranflation of Davila's Hiftory of the Civil Wars of France." He engaged to furnifh the articles of theology, and the belles lettres for the Encyclopédie. His ftyle in all his works is neat, clear, and unaffected. In his feveral treatifes on poetry and polite literature, he limited himfelf to an accurate expofition of the precepts laid down by the beft mafters, illuftrated by felect examples. As a man and a friend, a friend, he was an object of esteem to all who knew him, on account of his mildness, moderation, and candour.

Mallet, James Andrew, a professor at Geneva, descended from a good family in that city, was born in 1740; he was destined for a military life, but was prevented from pursuing it by an accident in his youth, by which the muscles of his legs became contracted, and he continued lame through the whole of his life. He was educated in the public school of Geneva, and displayed an early attachment to the mathematics. From Geneva he went to Basil, and studied with great success under the celebrated David Bernouilli. In 1764 he obtained a prize from the academy of Lyons for the best answer to a mathematical prize question, and in the following year he made a tour to France and England, in the course of which he formed an acquaintance with Lalande at Paris, and the late Dr. Maskelyne, at London, and the taste which M. Mallet acquired for astronomy, was no doubt a consequence of his intimacy with these eminent men. In this science he was greatly assisted by his profound knowledge of the mathematics, in which he was continually exercising his genius and talents. He wrote two papers on the calculation of chances, which were inserted in the "Acta Helvetica;" and at the request of Lalande, he calculated a table of the aberration and nutation of the stars of the first and second magnitude, which was published in the "Connoissance des Temps," and afterwards in Lalande's great work on astronomy. On his return, he lived some time in the bosom of his family, till he was appointed by the academy of Petersburgh, by the recommendation of Lalande and Bernouilli, to observe the transit of Venus in 1769, at one of the northern stations made choice of for that purpose. He was accompanied by M. J. L. Pictet, but the object of their mission was in a great measure lost by the unfavourableness of the weather. On his return, he formed an intimate acquaintance with J. A. Pictet of Geneva, who assisted him in his astronomical observations, with instruments which Mallet had procured at his own expence from England. In 1777 he was elected a member of the commission appointed to draw up a plan for settling the disputes by which the harmony of the little republic had for fifteen years been disturbed, and which were at length silenced for some time, by the intervention of foreign powers. Though Mallet was not at all ambitious of literary fame, he was honoured with unsolicited marks of distinction by several foreign societies. He was one of the members of the Academy of Sciences at Paris, and some of his best astronomical observations may be found in the memoirs of that learned society. He maintained an epistolary correspondence with the most learned astronomers in Europe; and at his country house, where he spent the greater part of his time, he employed himself in making astronomical observations, and in conversing with the neighbouring farmers on subjects of rural economy. While at Geneva, he led a retired life, but had a weekly meeting of literary friends at his house, and attended the sittings of the Society for the Encouragement of Arts. He was visited by many foreigners of distinction, and was universally esteemed for his talents, integrity, and benevolence. He died in the year 1790, of an apoplexy. Gen. Biog.

Mallet, a large kind of hammer, made of wood; much used by artificers who work with a chissel, as sculptors, masons, and stone-cutters, whose mallet is ordinarily round; and by carpenters, joiners, &c. who use it square. See Hammer.

There are several sorts of mallets used for different purposes on ship-board. The *caulking-mallet* is chiefly employed to drive the oakum into the seams of a ship, where the edges of the planks are joined to each other in the sides, deck, or bottom. The head of this mallet is long and cylindrical, being hooped with iron to prevent it from splitting in the exercise of caulking. There is also the *serving-mallet*, used in serving the rigging, by binding the spun-yarn more firmly about it than it possibly could be done by hand; which is performed in the following manner; the spun-yarn being previously rolled up in a large ball, or clue, two or three turns of it are passed about the rope, and about the body of the mallet, which, for this purpose, is furnished with a round channel in its surface, that conforms to the convexity of the rope intended to be served. The turns of the spun-yarn being strained round the mallet, so as to confine it firmly to the rope, which is extended above the deck, one man passes the ball continually about the rope, whilst the other, at the same time, winds on the spun-yarn by means of the mallet, whose handle, acting as a lever, strains every turn about the rope as firm as possible. Falconer.

Mallet, *Maule*, or *Mall*, in *Military Language*, a weapon formerly used both by the English and Scots. In the memorable combat fought in Bretagne, in the year 1315, between thirty champions on the part of the English, and the like number on that of the French, one of the English champions, named Billefort, was armed with a leaden mallet weighing twenty-five pounds. We learn also from father Daniel, that the English archers still used mallets in the time of Louis XII., who began his reign in 1515, and died in 1524. In the ancient poem of the battle of Flodden, the mention of leaden mallets often occurs; and from the following description there given of it, it seems as if the head of the mall was entirely of lead, hooped round at the ends with iron:

"Some made a mall of massy lead,
Which iron all about did bind."

Ralph Smith equips an archer with a maule of lead, five feet long, and a pike with the same, hanging by a girdle with a hook; meaning, probably, by this description, that the handle of the mall should be of this length, the end armed with a pike or spike; and this implement, we may imagine, was worn at the back, hung by a hook fixed in the centre of its handle, with a loop, or some other contrivance, to keep it nearly perpendicular. Father Daniel has engraved one of these mallets, which, in form, exactly resembles the present wooden instrument of that name, except that its handle is somewhat longer. This weapon seems to have been of French extraction; for we find, that in the reign of Charles VI., on occasion of a riot, the populace forced open the arsenal, and armed themselves chiefly with mallets, whence they were styled "Mailliotins." Mallets were tremendous weapons in the hands of strong active men, such as are described to have wielded them in the following verses:

"Two Scotch earls of an ancient race,
One Crawford called, the other Montrose,
Who led twelve thousand Scotchmen strong,
Who manfully met with their foes
With leaden malls and lances long."

"Then on the English part with speed
The bills stept forth, and bows went back;
The Moorish pikes and malls of lead
Did deal there many a dreadful thwack."

Grose's Mil. Ant. vol. i.

MALLETAR, in *Geography*, a town of Hindoostan; 60 miles E.S.E. of Cochin.

MALLEUS, in *Anatomy*, one of the ſmall bones contained in the cavity of the tympanum. See Ear.

MALLI, in *Ancient Geography*, the inhabitants of the country now called *Moultan*, which ſee. Their capital was ſituated not far from the river Rauvee (anciently Hydraotes), ſomewhat below the preſent town of Toulumba, which is a famous paſs on the Rauvee, between Lahore and Moultan.

MALLICOLLO, or Manicola, in *Geography*, one of the New Hebrides, which, to the S.E., extends N.W. and S.E., and in that direction is eighteen leagues long. Its greateſt breadth, which is at the S.E. end, is eight leagues, the N.W. end is two-thirds this breadth, and nearer the middle one-third; a contraction which is occaſioned by a wide and pretty deep bay on the S.W. ſide. Captain Cook repreſents it as fertile and well inhabited: the land on the ſea-coaſt is rather low, and lies with a gentle ſlope from the hills which are in the middle of the iſland. The inhabitants, forming what Cook denominates an ape-like nation, are deſcribed as the moſt ugly ill-proportioned people he ever ſaw, and different from any met with in this ſea. They are a very dark-coloured and diminutive race; with long heads, flat faces, and monkey countenances. Their hair, moſtly black or brown, is ſhort and curly; but not quite ſo ſoft and woolly as that of a negro. Their beards are very ſtrong, criſp, and buſhy, and generally black and ſhort. But what moſt adds to their deformity is a belt, or cord, which they wear round their waiſt, and tie ſo tight over the belly, that the ſhape of their bodies is not unlike that of an overgrown piſmire. The men go quite naked, except a piece of cloth, or leaf, uſed as a wrapper. Few women were ſeen, but they were not leſs ugly than the men; their heads, faces, and ſhoulders are painted red; they wear a kind of petticoat; and ſome of them had ſomething over their ſhoulders like a bag, in which they carry their children. Their ornaments are ear-rings made of tortoiſe-ſhell, and bracelets, wrought with thread or cord, and ſtudded with ſhells, worn juſt above the elbow. Round the right wriſt they wear hogs' tuſks, bent circular, and rings made of ſhells, and round their left a round piece of wood, deſigned probably to ward off the bow-ſtring. The bridge of the noſe is pierced, in which they wear a piece of white ſtone, about 1½ inch long, and of a curved form. As ſigns of friendſhip, they preſent a green branch, and ſprinkle water with the hand over the head. Their weapons are clubs and ſpears made of hard and iron-wood, and bows and arrows. The bows are four feet long, made of a ſtick ſplit down the middle, and partly circular; the arrows are a ſort of reeds, ſometimes armed with a long ſharp point of bone, and the points were covered with a ſubſtance found to be poiſon. Their arrows they carefully preſerve in a quiver; and ſome of them are armed with two or three points, each with ſmall prickles on the edges, to prevent the arrow from being drawn out of the wound. Their language is different from that of any other nation: the letter R often occurs in their words; and they expreſs their admiration by hiſſing like a gooſe. Their houſes are like thoſe of the other iſles, low, and covered with palm thatch. Their fruits, ſuch as the bread-fruit, plaintains, and cocoa-nut trees, are not ſo good as thoſe of the Society or Friendly Iſles; but their yams appeared to be very good. Their animals are pigs and fowl; they have not ſo much as a name for a dog, and conſequently they have none. Pieces of cloth, and marbled paper, were articles which they moſt eſteemed; but edge tools, nails, and beads, they ſeemed to diſregard.

The harbour, viſited by captain Cook, is ſituated on the N.E. ſide of Mallicollo, not far from the S.E., and in S. lat. 16 25′ 20″. E. long. 167 57′ 23″, and was called by him Port Sandwich. It lies in S.W. by S. about one league, and is one-third of a league broad. A reef of rocks extends out a little way from each point; but the channel is of a good breadth, and has in it from forty to twenty-four fathoms of water. In the port the depth of water is from twenty to four fathoms; and it is ſo ſheltered, that no winds can diſturb a ſhip at anchor there. Another great advantage is, that you can lie ſo near the ſhore, as to cover your people, who may be at work upon it. Two reddiſh fiſh, reſembling a large bream, and of the ſame ſize, were caught in the harbour, which appeared, by their effects on thoſe who partook of them, to be poiſonous. This ſort of fiſh is mentioned by Quiros under the name of pargos. Cook's Second Voyage, vol. ii. See *New* Hebrides.

MALLING, West, or *Town Malling*, a market-town and pariſh in the hundred of Larkfield, lathe of Aylesford, and county of Kent, England, is ſituated ſix miles diſtant from Maidſtone, and thirty from London. The manor was given, ſays Lambard, "to Burbicus, biſhop of Rocheſter, by king Edmund, the brother of Athelſtane, under the name of Three Plough-lands in Mealinges." After a temporary alienation, it was reſtored to the biſhops of this ſee, previouſly to the Domeſday Survey, at which time "here were a church and a mill." In the year 1090, biſhop Gundulph founded a Benedictine nunnery here, and endowed it with the manor, church, and other eſtates: he governed it in perſon during his life, but directed that in future it ſhould be under the juriſdiction of an abbeſs, ſubordinate to the biſhops of Rocheſter. In 1190, the abbey, as it was then called, and the village, ſuffered by fire, but were ſoon reſtored: in the time of king John, the abbeſs had a grant of free-warren for all her demeſne; and Henry III. added the privilege of a weekly market, and three annual fairs. After the diſſolution, the manor and abbey-buildings were exchanged with archbiſhop Cranmer, and have ſince paſſed through various families to the Honeywoods. The late Filmer Honeywood, eſq. pulled down the abbey-houſe, and with the materials erected the preſent manſion, preſerving, as much as poſſible, the ancient ſtyle and form. It is now the reſidence of George Talbot Hatley Foote, eſq. Many parts of the conventual pile are, however, yet ſtanding, being uſed as offices, together with a portion of the weſt end of the abbey-church, which is an intereſting remain of Norman architecture, and is ornamented with ſculptures of heads, animals, and interſecting arches. The abbey grounds are watered by a clear ſtream, which flows from Nether-Well, in the hamlet of St. Leonard's; where is yet ſtanding the ruined tower of St. Leonard's chapel, a very ſtrong remain, much reſembling the keep of a Norman caſtle: its preſent height is ſeventy-one feet; the walls are ſeven feet in thickneſs.

The town of Weſt Malling conſiſts principally of one ſpacious ſtreet, well built, and about half a mile in length, together with ſeveral detached manſions belonging to reſpectable families. The pariſh-church is a large fabric, conſiſting of a nave and chancel, with a Norman tower: the nave has been moſtly rebuilt ſince the year 1778, when the whole roof fell in, through the decay of the main columns. Here are ſome ancient and curious braſſes. A ſmall free-ſchool was built in 1632, by a bequeſt of Mr. Francis Treſſe. The population return in the year 1801, ſtated the inhabitants of Weſt Malling to be 1093, occupying 192 houſes.

In Eaſt Malling, a village about a mile diſtant, is Bradbourne, the ſeat of ſir John Papillon Twyſden, bart., which, though not particularly extenſive, forms one of the moſt delightful reſidences in Kent. Some good portraits of the learned

learned judge Twyfden, who died here in 1666, are preferved in Bradbourne-houfe. Hafted's Hiftory and Topographical Survey of Kent, twelve vols. 8vo. Beauties of England and Wales, vol. vii.

MALLOCOCCA, in *Botany*, fo called by Forfter and in the Upfal Tranfactions, is a fpecies of GREWIA. See that article.

MALLOTUS, according to Loureiro, was fo named from μαλλωτος, *hairy*, the capfule of this plant being profufely and remarkab y befet with hairs. Loureir. Cochinch. v. 2. 635.—Clafs and order, *Diœcia Polyandria*. Nat. Ord. *Tricoccæ*, Linn. *Euphorbiæ*, Juff.

Gen. Ch. Male, *Cal.* Perianth inferior, of three roundifh, concave, woolly leaves. *Cor.* none. *Stam.* Filaments numerous, fhort, inferted into the receptacle; anthers two-lobed, roundifh.—Female, *Cal.* Perianth of three triangular, equilateral, hairy, expanded leaves. *Cor.* none. *Pift.* Germen fuperior, roundifh, three-lobed; ftyle none; ftigmas three, oblong, hairy, coloured, reflexed. *Peric.* Capfule roundifh, of three lobes, fix valves, and three cells, fingle-feeded, covered with a multiplicity of long and foft hairs. *Seeds* roundifh on one fide, angular on the other, remaining on their proper ftalks upon the receptacle, after the capfule has fallen away.

Eff. Ch. Male, Calyx of three leaves. Corolla none. Stamens numerous.—Female, Calyx of three leaves, inferior. Corolla none. Stigmas three. Capfule three-celled. Seeds folitary, ftalked.

Obf. Loureiro remarks, that this genus is nearly related to *Cliffortia*, but that it differs in having the capfule fuperior and three-celled, as well as in having three feffile ftigmas.

1. M. *Cochinchinenfis*. Cây. Bèt. of the natives. Loureir. —Found about hedges and neglected gardens, in Cochinchina and China.—The only fpecies known.—This *tree* is of middling height, with fpreading *branches*. *Leaves* alternate, roundifh, generally three-lobed, a few however are undivided, ovate, pointed, all of them ftand on footftalks, are toothed and downy. *Flowers* reflexed, in loofe clufters, ending in a fpike.

Loureiro found the Male Flowers of *Mallotus* occafionally to vary, in having their calyx-leaves lanceolate, hairy, and fpreading. Filaments upwards of forty, fhorter than the calyx; anthers ovate, erect.—He met with this variety growing near Canton, but could find no female flowers in that neighbourhood.

MALLOW, in *Botany*, &c. See MALVA.

MALLOW, *Baftard*. See MALOPE.

MALLOW, *Jews'*. See CORCHORUS.

MALLOW, *Indian*, See URENA.

MALLOW, *Indian*, or *Yellow*. See SIDA.

MALLOW, *Rofe*. See ALCEA.

MALLOW, *Sea*, *Malva marina*, in *Natural Hiftory*, a name not very judicioufly given by fome writers to a fpecies of fubmarine fubftance, fuppofed in fome degree to refemble the leaves of the common mallow. It is very common in the places where they fifh for coral, and grows to the rocks without any regular root; it is found at different depths, but moft ufually far from the furface, and its height is ufually about two inches; it is of a dufky greenifh colour, with an admixture of faint yellow; it is compofed of feveral leaves about half an inch broad, and a little more than that in length: each of thefe is faftened to a pedicle of about an inch and a half long; the leaves are of a fine thin membranaceous fubftance, but their ftalks or pedicles are thick and rough like horn. When examined by the microfcope many glandules difcover themfelves upon the furfaces of the leaves, but the ftalks or pedicles are entirely covered with glandules in form of fmall protuberances, which make it as rough in thofe parts as the common fhagreen. The ftalks when cut tranfverfely fhew an infinite number of pipes or veffels running up to every part of the leaves. Count Marfigli has given an elegant figure of this, both as it appears to the naked eye, and by the microfcope.

MALLOW, *Syrian*, in *Botany*. See HIBISCUS.

MALLOW, *Tree*, *varied-leaved*, or *Venetian*. See LAVATERA.

MALLOW, *Vervain*, a fpecies of the *malva*, or common mallow. Some have called the *alcea* by this name.

MALLOW, *Yellow*. See SIDA.

MALLOW, in *Geography*, a poft-town of the county of Cork, Ireland, fituated on the river Blackwater, over which it has a ftone bridge. It is much frequented on account of a foft and tepid fpring (difcovered in 1724), of the fame nature and efficacy as the Hot-wells of Briftol. Mallow was incorporated in 1688, and is governed by a provoft and burgeffes; and it fends a member to parliament. It is 117 miles S.W. from Dublin, and 15 N. by W. from Cork. A tract of country on each fide of the river conftitutes the liberties of Mallow, and is inhabited by feveral refpectable families.

MALM, in *Agriculture*, a term fometimes applied to a fort of white marley clay. It is a fubftance that has been found beneficial on foils of the ftiff clayey kind when laid on in pretty large proportions, as about fixty tons *per* acre. In one inftance of this kind of foil, mentioned in the fourth volume of Communications to the Board of Agriculture, when applied in this proportion on a very large fcale, the produce was full three times as great *per* acre, as in the original ftate. It is afferted that the quality of this fubftance may be beft proved by common vinegar; in which cafe a portion fhould be dried, and put into a wine glafs full of vinegar; when, if it inftantly begins to effervefce and attract the acid, it may be depended on to be highly ufeful as a manure. It may be ufed in other cafes alfo with great benefit.

MALMEDY, in *Geography*, a town of France, and principal place of a diftrict, in the department of the Ourte; 23 miles E.S.E. of Liege. The place contains 4344, and the canton 12,007 inhabitants, on a territory of 232½ kiliometres, in fix communes. This town has fome mineral fprings, which are reckoned equal, if not fuperior, to thofe of Spa. Its principal manufacturers are employed in making cloth and dreffing of cotton. The town was taken by the French in October, 1794. N. lat. 51° 24'. E. long. 6° 7'.

MALMESBURY, a borough, market-town, and parifh in the northern part of Wiltfhire, England, is a place of note in the monaftic annals of the country, and ftill retains fome interefting remains of its ancient fplendour. Its early hiftory is involved in doubt, and is fo blended with the romances of monachifm and fuperftition, that it is difficult to feparate the facts from the fables of old chronicles. Leland ftates that a caftle was built here four or five centuries before the Chriftian era. Other writers fay that Dunwallo-Malmutius, king of the Britons, gave it the appellation of Caer Bladon, and that it was afterwards fucceffively denominated Ingleburne, Maildulfburgh, Aldelmfbirig, and Meildunum.

The hiftory of this town is intimately connected with the hiftory of its religious eftablifhents. A convent of Britifh nuns, under the direction of Dinoth, is faid to have been fettled here towards the clofe of the fixth century, but its inhabitants being accufed of living in a ftate of incontinency with

with the soldiers in the castle, it was suppressed by Augustin, the first archbishop of Canterbury. About this time Medolph, a Scot, remarkable for his piety and strict holiness of life, who had left his own country on account of persecution, fixed his residence here, and established a school for his support. Having collected a number of persons disposed to embrace a monastic life, he built a small monastery, which was shortly afterwards received under episcopal jurisdiction. The town, at this period, seems to have been a place of considerable importance, but no records in its secular history are extant prior to the year 878, when it appears to have been attacked and burned by the Danes. It afterwards suffered again by fire in the reign of Edward the Elder, who constituted it a borough by charter, so that it is amongst the most ancient corporations in the kingdom. In the time of his successor Athelstan, two battles appear to have been fought in this neighbourhood, with the piratical invaders, already mentioned, in which the men of Malmesbury displayed great valour, and in consequence received a confirmation of their charter, with additional privileges. The place was subsequently the theatre of the contest, which king Stephen had to maintain against his turbulent barons, as well as against his competitor Henry of Anjou. The latter prince having laid siege to, and took it in a very short time, together with the castle, except one tower, which finding too strong to be taken by assault, he blocked it up with the view of reducing it by famine, and notwithstanding the vigorous attempts of Stephen to produce its relief, ultimately effected his object. After this period nothing worthy of notice occurs in the history of Malmesbury, till the era of the civil wars in the reign of Charles I. when it was several times besieged and taken both by the republicans and royalists.

This town is built on a commanding eminence, peninsulated by two streams which unite to form the lower Avon. According to the parliamentary returns of 1801, it then contained 207 houses, and 1027 inhabitants, of whom 83 were returned as employed in different branches of trade, but this must be erroneous. In former times it was much more extensive than at present, many of the streets described in old records being totally demolished. The principal manufacture carried on here is that of woollen cloth, for which it was famous at an early period, but a number of hands are employed in the leather trade, and in the manufacture of gloves, parchments, glue, &c. There is a weekly market on Saturdays, and one also on the last Tuesday of each month, called the great market. Besides the churches belonging to the establishment, there are four places of public worship appropriated to the meetings of dissenters. The only charitable institutions are two alms-houses, and two free schools.

It has been already mentioned that the original charter to this town was granted by Edward the Elder, and confirmed by his successor Athelstan. Charters of confirmation, with additional privileges, were likewise bestowed by several succeeding monarchs. The present one is dated in the reign of William III. and by virtue of it the government is vested in an alderman, a high steward, twelve capital burgesses, and twenty-four assistants. The alderman and high steward, or their deputies, are justices of the peace.

The other persons connected with the borough are styled landholders and commoners. In the latter charters the commoners are denominated free-burgesses, and constitute the lowest members of the corporation. The landholders occupy a situation between them and the assistant burgesses, and are entitled by their office to the possession of an acre of land for life. Two members have been sent by this borough to parliament, from the third year of the reign of Edward I. During the last century it was celebrated for its electioneering contests, the higher branches of the corporation claiming the exclusive privilege of voting at elections, while the lower members maintained their title to participate in the nomination of their representatives. The point, however, was finally decided by a committee of the house of commons in the year 1796, in favour of the alderman and twelve capital burgesses, who will, therefore, probably enjoy their privileges henceforth without opposition.

Malmesbury abounds with remains of antiquity, which sufficiently declare its former greatness. The most extensive and important of these is the abbey. By the donations and grants, both of princes and private individuals, this institution soon rose into great celebrity. The church was built in the form of a cross, and the whole buildings are said to have covered no less than forty-five acres of ground, including the garden and offices belonging to the monks. The church was a noble structure of great extent, and surmounted by two magnificent towers, one of which stood in the middle of the transept, and the other at the west end. This, as well as every other portion of the monastery, was built at different times, at least underwent such alterations and repairs as, no doubt, changed materially the original edifice. The western front is said by Brown Willis to have been an uncommonly fine piece of architecture, and richly adorned with sculpture. Over the entrance, on this side, was a very magnificent window filled with painted glass. About a fourth of the building only now remains. Both the towers are long ago levelled with the ground, that at the west end having been battered down during the civil wars, when, it is probable, the cloisters also were demolished, as no trace of them can be discovered above ground. Part of a mosaic pavement, however, was found a few years ago, in a garden to the north-west of the church which is supposed to have formed the floor of that portion of the monastery. The southern porch of this church is a truly curious and interesting specimen of ancient architecture. It consists of two distinct divisions; an exterior arch, or coved recess, with a series of archivolt mouldings, charged with a great variety of sculptured figures in basso-relievo: within this is a square apartment, or vestibule, on each side of which are large statues in basso-relievo, and over the door is another compartment, said to be meant to represent the Deity on a throne, supported by angels, and just within it is a head, supposed to represent our Saviour crowned with thorns. In the interior, the nave is divided from the side aisles by round columns, with plain capitals, above which are three rows of arches. The groins in the vaulting are adorned with foliage and heads. On this altar-piece are carved griffins, dragons, and other grotesque figures. At the north-east of the church stands a building, denominated the abbot's house, the lower part of which is a remnant of that edifice.

A particular history and description of the abbey church, with several plates, illustrative of its architecture, have been published in the first volume of Britton's "Architectural Antiquities of Great Britain."

The remains of the old parish church of St. Paul stands on the southern side of the cemetery, and opposite, on the same side, is the old vicarage house. The building called Chapel-house, on the western side of the town, is supposed to have constituted the chapel of the ancient nunnery, already mentioned. The White-lion inn, and the alms-house, together with the workhouse, and some other buildings, present remnants of more ancient structure, in general dedicated to religious purposes, or connected with monastic establishments.

As

As to the caftle, erected by Roger, bifhop of Sarum, as fome fuppofe on the fcite of an older one, no traces of it can now be difcovered with any certainty; but there is a well, ftill called the Caftle-well, which probably belonged to it. In the market place ftands a very beautiful market crofs of ftone, of an octangular fhape, and much enriched with a variety of fculpture. About a mile fouth from the town lies a field, called "Cam's Hills," in which are two enclofures, one of them perfectly fquare, and the other of an oblong fhape, both of which are ufually efteemed veftiges of a Roman encampment.

Malmefbury no lefs claims the attention of the biographer than of the antiquary, fome of the greateft luminaries of remote and modern times having been born here. Among the more ancient worthies may be reckoned Meydulph, Aldhelm, Johannes Scotus, and Roger le Poer, all of them men diftinguifhed for their piety and learning. William of Malmefbury is one of the moft celebrated hiftorians this country can boaft of; and Thomas Hobbs, whatever prejudice may reply to the affertion, was undoubtedly a philofopher of great acutenefs. He it was who laid the foundation of that moral and metaphyfical fyftem, the illuftration and developement of which have beftowed immortality on the names of Hartley, Hume, and Prieftley. Moffatt's Hiftory, &c. of Malmefbury, 8vo. 1805.

MALMIGNATTO, in *Natural Hiftory*, a name given by the inhabitants of the ifland of Corfica to a fpecies of animal, or large infect, called by fome *tarantula*, and ignorantly fuppofed to be the fame with the tarantula of Apulia. (See TARANTULA.) This ifland produces neither wolves, ferpents, nor many other of the mifchievous and deftructive animals which infeft the neighbouring countries: but it produces two fpecies of this venomous infect, called the *malmignatto;* the one of thefe has a round body, and the other an oblong one, refembling that of our large kind of ant; it has alfo fix legs, not eight, and never makes any web: from all which it appears not to be a fpider, but truly of the ant kind, though a monftrous fized one, and very venomous. The round-bodied kind, by its bite, occafions violent pains, a fenfation of coldnefs and cramps all over the body; and the long-bodied one is yet more venomous. Its fting occafions an immediate lividnefs of the flefh, with intolerable cramps and convulfions over the whole body; fometimes the natural evacuations by ftool and urine are alfo wholly ftopt by it. The cure, in both cafes, is to be attempted by cutting and cauterizing the wound, and dreffing it with Venice treacle, as alfo by giving the fame in large dofes diffolved in wine.

MALMISCH, in *Geography*, a town of Ruffia, in the government of Viatka, on the Viatka; 100 miles S. of Viatka. N. lat. 56° 44'. E. long. 50° 14'.

MALMO, a fmall ifland on the W. fide of the gulf of Bothnia. N lat. 63 13'. E. long. 18 40'.

MALMOE, a fea-port town of Sweden, reckoned by fome writers the capital of Scania or Schonen, fituated on the Sound. This town is furrounded with walls, moats, and baftions, and is defended by feveral fortifications and a caftle towards the fea. Here are two burgo-mafters, a good fchool, one Swedifh and one German church, an orphan-houfe, a large market-place, fine regular ftreets, and feveral woollen manufactures; nine miles S.W. of Lund. N. lat. 55° 36' 37". E. long. 13° 1' 4".

MALMSAS, a town of Sweden, in Sudermanland; 23 miles W.N.W. of Nykoping.

MALMSEY, or MALVASY, a rich lufcious kind of wine brought from Greece or Candia; fo called from Malvafia, a city in Peloponnefus, the ancient Epidaurus, whence this celebrated liquor was firft brought.

That brought from Candia is now efteemed the beft.

MALMSEY, or *Malvify*, is alfo the name of a kind of mufcadine wine brought from Provence.

MALNAIR, in *Geography*, a town of Hindooftan, in the province of Sirhind; 40 miles S.W. of Sirhind. N. lat. 30° 26'. E. long. 75° 25'.

MALNOS, a town of Hindooftan, in the circar of Sirhind; 20 miles W.S.W. of Sirhind.

MALO, a town of Italy, in the Vincentin; 11 miles W. of Vicenza.—Alfo, a town of Africa, in the kingdom of Fonia.

MALO, or *Maloes, St.* a fea-port town of France, and principal place of a diftrict, in the department of the Ille and Vilaine, fituated on a fmall ifland joined to the continent by a mole, at the head of which is a ftrong fort. Before the revolution, it was the fee of a bifhop fuffragan of Tours, who was lord of the town. The harbour is large, and much frequented, though difficult of accefs on account of the rocks which furround it. It is ftrong by its fituation on a peninfula, connected with the land by a narrow mole about fix or feven hundred yards in length, and by the defence of 250 pieces of cannon mounted on its ramparts. But as it has no outworks, its fortifications could not long refift a regular fiege: its ftrength both by nature and art lies towards the fea. Several attempts have been made againft it, at different times, but without fuccefs. It has always been a port for privateers, and on this account has been injurious to the trade of England. N. lat. 48° 39' 3". W. long. 2° 1' 26".

MALO-*de-la-Lande, St.*, a town of France, in the department of the Channel, and chief place of a canton, in the diftrict of Coutances. The place contains 449, and the canton 10,252 inhabitants, on a territory of 140 kiliometres, in 13 communes.

MALOBATHRUM, among the Romans, a precious kind of ointment, brought from the Indies through Syria to Rome.

MALOGOCZ, in *Geography*, a town of Auftrian Poland, in the palatinate of Sandomirz; 60 miles W. of Sandomirz. N. lat. 50° 4'. E. long. 20° 18'.

MALOGRANATUM. See POMEGRANATE.

MALOIAROSLAVETZ, in *Geography*, a town of Ruffia, in the government of Kaluga; 32 miles N. of Kaluga. N. lat. 55°. E. long. 36° 14'.

MALOKETSKOI, a town of Ruffia, in the government of Tobolfk; 30 miles S.W. of Kamfkoi.

MALONG, a town of Hindooftan, in the Carnatic; 18 miles S. of Madura.

MALOOD, a town of Hindooftan, in the circar of Cicacole; 16 miles N.E. of Ganjam.

MALOPE, in *Botany*, is thought by profeffor Martyn to be a corruption of *μαλαχη, a mallow.*—Linn. Gen. 355. Schreb. 467. Willd. Sp. Pl. v. 3. 799. Mart. Mill. Dict. v. 3. Juff. 272. Cavan. Diff 2. 84. Desfont. Atlant. v. 2. 120. Lamarck Illuftr. t. 583. (Malacoides, Tournef. t. 25.)—Clafs and order, *Monadelphia Polyandria.* Nat. Ord. *Columniferæ*, Linn. *Malvaceæ*, Juff.

Gen. Ch. *Cal.* Perianth inferior, double; outer of three, heart-fhaped, acute, permanent leaves; inner of one leaf, more erect, permanent. *Cor.* Petals five; inverfely heart-fhaped, abrupt, affixed at the bafe to the tube of the ftamens. *Stam.* Filaments numerous, united below into a tube, feparate and loofe above; anthers nearly kidney-fhaped. *Pift.* Germens fuperior, roundifh; ftyle fimple, the length of of the ftamens; ftigmas many, fimple, briftle-fhaped. *Peric.* Capfules roundifh, of many cells, equal in number to the ftigmas, forming a little head. *Seeds* folitary, kidney-fhaped.

Eff. Ch. Calyx double, the outer one of three leaves. Capfules irregularly heaped together, fingle-feeded.

1. M. *malacoides.* Linn. Sp. Pl. 974. Cavan. Diff. t. 27. f. 1.—Leaves oblong, obtufe, undivided, notched, fmooth above. Stalks folitary, axillary.—A native of meadows in Tufcany and Algiers.—*Root* annual. *Stem* erect, hairy, rough. *Leaves* fomewhat heart-fhaped; the lower ones obtufe; the upper generally three-lobed. *Flowers* rofe-coloured; the petals wedge-fhaped, truncated. *Fruit* collected into a head, like the blackberry.—The whole plant has greatly the appearance of a mallow, efpecially in the fhape and colour of its flowers. Desfontaines notices a variety of this, whofe leaves and corolla are twice the ufual fize.

2. M. *parviflora.* Mart. Mill. Dict. L'Herit. Stirp. Nov. fafc. 5. 105. t. 50.—Calyx fimple. Leaves almoft heart-fhaped, even. Peduncles fcarcely longer than the petiole. A native of Peru, where it was difcovered by Dombey.—*Root* annual. *Stem* about a foot high, much branched, red, villofe. *Leaves* alternate, on footftalks, nerved, bright green. *Flowers* axillary, on ftalks, folitary, occafionally two together, purple.—Profeffor Martyn obferves that "there are other Peruvian fpecies with a fimple calyx, which might therefore conftitute a diftinct genus."

3. M. *multiflora.* Willd. n. 2. Cavan. Diff. 2. 85.—Leaves roundifh, undivided, notched, villofe. Stalks three or four together, axillary.—A native of Spain.—Cavanilles defcribes it thus. "*Stem* about fix inches high, not much branched. *Flowers* fmall and white. *Fruit* proportionably larger than in the other fpecies."

4. M. *trifida.* Willd. n. 3. Cavan. Diff. t. 27. f. 2.—Leaves oblong, three-lobed, pointed, toothed, fmooth. Stalks folitary, axillary.—Found in meadows both in Spain and Barbary.—Willdenow fays it differs from the laft in having its *leaves* three-lobed, more acute, and thicker.

Malope, in *Gardening,* contains a plant of the herbaceous kind, of which the fpecies cultivated is, the betony-leaved malope (M. malacoides.)

Method of Culture.—This plant may be increafed by fowing the feeds, in the places where the plants are defigned to remain, as it does not bear tranfplanting well; when they are fown upon a warm border in Auguft, the plants alfo frequently ftand through the winter, and flower early the following feafon, fo as to produce good feeds; but when fown in the fpring, this is rarely the cafe.

It is moftly neceffary that the plants fown in the fpring in pots fhould be protected in winter under a frame. They feldom continue longer than two or three years at moft, as good plants.

All of them afford variety among other plants in the borders, clumps, &c. of ornamented grounds.

MALOPINGOVSKOI, in *Geography,* a town of Ruffia, in the province of Ufting; 108 miles N. of Ufting.

MALORN, a fmall ifland in the N. part of the gulf of Finland. N. lat. 65° 32′. E. long. 23° 27′.

MALO-RUSSIANS, the denomination of thofe people who inhabit the country between the Dnieper and the Donetfk, called in the maps Little Ruffia. They are defcribed by Dr. Clarke (Travels in Ruffia) as a race much fuperior to the Ruffians; being not only of a better afpect, but more induftrious, more courageous, more cleanly, and more polite. With regard to their cleanlinefs, a traveller might fancy himfelf tranfported from Ruffia to Holland. In their features, the Malo-Ruffians refemble the Coffacks; and the fimilitude which both bear to the Poles, feems to imply a defcent from a common origin. In one point, however, *viz.* the love of liquor, the Malo-Ruffians are unfortunately as grofs delinquents as their neighbours to the eaftward.

MALORY, a town of Hindooftan, in Myfore; 13 miles N.E. of Ouffoor.

MALOSCHANY, a town of Ruffia, in the government of Pfkov; 24 miles N.E. of Pfkov.

MALOUCA, a town of Syria, which has two churches; 20 miles N.N.E. of Damafcus.

MALOUR, a town of Hindooftan, in Baramaul; 13 miles N. of Namacul.

MALOWITZ, a town of Bohemia, in the circle of Konigingratz; feven miles E. of Gitfchin.

MALOWPOUR, a town of Hindooftan, in Oude; 48 miles W. of Lucknow.

MAL-PADDY, a town of Hindooftan, in Myfore; 11 miles W. of Tripatore.

MALPARTIDA, a fmall town of Spain, in the province of Eftramadura, containing a population of about 1300 inhabitants. It is tolerably well built; and has a handfome parifh church, built with granite, fupplied from an adjacent quarry; about three miles from Placentia.

MALPAS, a mountain of France, through which the Languedoc canal paffes.

Malpas, a market town and parifh in the hundred of Broxton, and county palatine of Chefter, England. It is fituated on a lofty eminence at a fhort diftance from the river Dee. The name of this place is fuppofed to have been derived from the term *Mala-platea,* illuftrative of the fteep, narrow, and intricate road by which it was anciently approached. The manor was one of the baronies granted, at the time of the conqueft, to Hugh Lupus, earl of Chefter, from whom the prefent noble family of Cholmondeley is defcended. The magnificent caftle by which it was adorned for feveral centuries, is now fo entirely demolifhed, that fcarcely a veftige of it can be difcovered. Three ftreets, tolerably well built and paved, form the chief part of the town, which, according to the parliamentary returns of 1801, contained 191 houfes, and 906 inhabitants. In the church is a vault, appropriated as the burying place of the earls of Cholmondeley, who derive their title of vifcount from this town. The living is a rectory, and being very valuable, is divided into two portions, fupporting two rectors, and the like number of curates. Malpas has a free-grammar-fchool and alms-houfe, both of which were founded by fir Randle Brereton. Adjoining the town is Cholmondeley Hall, the magnificent manfion of earl Cholmondeley, a modern building, feated on a pleafant, and fomewhat elevated feite. The ancient ftructure, though venerable in appearance, and moated round, was a very difagreeable refidence, from being placed in a low and marfhy fituation. Lyfons's Magna Britannia, vol. ii. 4to.

MALPICA, a town of Portugal, in the province of Beira; 16 miles S S.E. of Caftel Branco.

MALPICO, a town of Spain, in Galicia, on the fea-coaft; 20 miles W. of Corunna

MALPIEV, a town of Spain, in New Caftile; 25 miles W. of Toledo.

MALPIGHI, Marcello, in *Biography,* a celebrated Italian naturalift, was born at Crevalcuore, near Bologna, in 1628. Having devoted himfelf to the ftudy of medicine, which he felected for his profeffion by the advice of Natalis, his tutor in philofophy, he began to apply himfelf to anatomy

tomy with great zeal under Maſſari, who had a ſchool for diſſection in his own houſe. He ſoon became diſtinguiſhed by the philoſophical ſpirit of obſervation with which he purſued his enquiries, and his ardent zeal for natural knowledge was accompanied with ſingular modeſty. His merit procured him, in 1653, the degree of doctor in medicine, and the appointment of profeſſor of phyſic, in the univerſity of Bologna, in 1656: ſoon after which he was invited to Piſa by the grand duke of Tuſcany, Ferdinand II. This prince, partly from his own hereditary taſte, and partly at the inſtigation of his accompliſhed brother, the cardinal Leopold de Medici, was very deſirous of encouraging the arts and ſciences in his dominions. Here he formed a friendſhip with the celebrated Borelli, to whoſe communications he acknowledges himſelf indebted for the diſcovery of the futility of the philoſophy of the ſchools, and of the neceſſity of experiment as the ſole foundation of a true philoſophy. The air of Piſa, however, did not agree with Malpighi, whoſe health was always delicate, and he was obliged to return to Bologna in 1659, where he was immediately re-appointed to the profeſſorſhip of medicine. Here he reſumed his inquiries with great diligence, and was the firſt who employed the microſcope in examining the circulation of the blood. In 1662, on the death of Caſtelli at Meſſina, Malpighi was invited by the magiſtracy to ſucceed him as profeſſor of medicine in that ſchool, with a large ſalary. He occupied this poſt almoſt four years with conſiderable reputation; but as he paid little reſpect to the doctrines of the Galeniſts and Arabians, and excited much jealouſy in his colleagues, he became involved in controverſies, which rendered his life very uneaſy. He therefore reſolved to return to Bologna in 1666, and accepted the offers of his countrymen to continue among them, notwithſtanding the preſſing invitations which he received from Meſſina to reſume his chair in that city. His anatomical purſuits now occupied a great portion of his time, at a villa, in the vicinity of Bologna; and his reputation extended throughout Europe, as a philoſophical inquirer; ſo that, in 1669, he was elected a member of the Royal Society of London; which body afterwards teſtified their regard for him by printing his works at its own expence. At Bologna, he continued to teach others, and to inſtruct himſelf, with great reputation, till the year 1691. Cardinal Pignatelli, who had known him, during his own reſidence as legate at Bologna, being that year raiſed to the papacy, by the name of Innocent XII. choſe Malpighi for his chief phyſician and chamberlain. The latter of courſe gave up his academical appointments, and removed to Rome, where, having previouſly ſuffered from gout and nephritic complaints, he died of an apoplexy at the palace of Monte Cavallo, November 29th, 1694, in the 67th year of his age. His remains were embalmed, and conveyed to Bologna, where they were interred with great funeral honours in the church of St. Gregory, and a ſtatue was erected to his memory. He was married to the ſiſter of his preceptor Maſſari; but left no iſſue. Malpighi is deſcribed as a man of a ſerious and melancholy temperament, which is confirmed by his portrait in the meeting-room of the Royal Society at Somerſet houſe. He was indefatigable in the purſuit of knowledge, on the ſure ground of experience and obſervation, ever candid in his acknowledgments to thoſe who had given him any information, and devoid of all oſtentation or pretenſion on the ſcore of his own merits. He ranks very high among the philoſophers of the phyſiological age in which he lived, the age of Harvey, of Redi, of Rudbeck, and of Bartholin, when nature began to be ſtudied inſtead of books, and the dreams of the ſchools gave place to practical enquiries and obſervations. Hence aroſe the diſcoveries of the circulation of the blood, the abſorbent ſyſtem of the animal body, and the true theory of generation. To ſuch improvements the inveſtigations of Malpighi, relative to the anatomy and transformation of inſects, particularly the ſilk-worm, and the developement of the chick in the egg, lent no ſmall aid. From theſe enquiries he was led to the anatomy and phyſiology of plants, in which he is altogether an original, as well as a very profound, obſerver. His line of ſtudy was the ſame as that of Grew, but theſe philoſophers laboured independent of each other, and their frequent coincidence evinces the accuracy of both. See Grew.

The firſt work which he publiſhed in 1661, and which was afterwards frequently reprinted, compriſed his microſcopical obſervations relative to the intimate ſtructure of the lungs, and was entitled "Obſervationes Anatomicæ de Pulmonibus," fol. He publiſhed ſeparate tracts concerning the brain, the tongue, the external organ of touch, the omentum, throat, and the adipoſe ducts, between the years 1661 and 1665; and ſubſequently, other tracts reſpecting the ſtructure of the viſcera, the kidnies, ſpleen, liver, membranes of the brain, &c.

Malpighi became a fellow of our Royal Society, as we have already mentioned, in 1669, in which year his eſſay "*de formatione pulli in ovo*" was firſt printed, at London, in quarto, as well as his remarks on the "*Bombyx*" or ſilk-worm, and "De Glandulis conglobatis," forming his three "Diſſertationes Epiſtolicæ." His "*Anatome Plantarum*," addreſſed to the Royal Society, accompanied by obſervations on the incubation of the egg, was publiſhed by that learned body in folio, with many plates, in 1675 and 1679. His works were republiſhed at London in 1686, making two folio volumes; and more correctly at Amſterdam, in 1687, 4to. and a poſthumous volume appeared here, accompanied with an account of his life, in 1697, of which a re-impreſſion was given at Venice, and another at Leyden, the enſuing year. Some other diſſertations are to be found in the "Bibliotheca Anatomica," publiſhed by Le Clerc and Marget at Geneva in 1685; eſpecially "De Cornuum Vegetatione," "De Utero et Viviparorum Avis;" and "Epiſtolæ quædam circa illam de ovo diſſertationem." His only medical work, "Conſultationum Medicinalium Centuria prima," was edited by Gaſpari, in 1713, 4to. Patau. He is not, indeed, diſtinguiſhed as a practitioner, but he deſerves praiſe for pointing out the miſchiefs of blood-letting, in the malignant epidemics prevalent in Italy in his time. An edition of the whole of his works was printed at Venice, in 1733, in folio, by Gavinelli.

The merits of Malpighi as a vegetable anatomiſt are of the higheſt and moſt original kind. The ſtructure and component parts of plants had been little attended to before he entered upon his enquiries. His illuſtrations of their anatomy, as well as of their external configuration, even of ſuch of their diſeaſes as ariſe from the attacks of inſects, whence the various kinds of galls are formed, (ſee Galls,) are all no leſs faithful than original. As a vegetable phyſiologiſt, too, he doubtleſs advanced very far; and that ſubject being ſo entirely new when he and Grew entered upon it, nothing could be more unjuſt than to complain of the errors into which they have fallen. The principal of theſe, however, requires to be mentioned. They both conceived the woody fibres of plants to tranſmit the ſap, though no perforation could be diſcovered in them. If this hypotheſis now excite our wonder, we muſt recollect that no leſs a philoſopher than Du Hamel adopted, and laboured with all his might to ſupport, the ſame opinion. Grew went a ſtep nearer the truth than Malpighi, when he obſerved what they both took for *tracheæ*, or air-veſſels, to be ſometimes filled with ſap; but he did not hence correct his original idea, of those spiral-coated vessels being the lungs of plants, nor were they, till very lately, known to be the real sap-vessels, or arteries of the vegetable frame. (See CIRCULATION *of Sap*, GREW, and DU HAMEL.) Malpighi Opera. Hall. Bibl. Bot. Dryandr. Bibl. Banks. Dict. Eloy Dict. Hist. de la Méd.

MALPIGHIA, in *Botany*, was named by Plumier in commemoration of the scientific attainments of Marcello Malpighi, professor of medicine at Bologna, the celebrated vegetable anatomist; see the last article. Plum. Nov. Gen. 46. t. 36. Linn. Gen. 227. Schreb. 306 and 803. Willd. Sp. Pl. v. 2. 731. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 3. 102. Juss. 253. Cavan. Diss. 8. 405. Lamarck Illustr. t. 381.—Class and order, *Decandria Trigynia*. Nat. Ord. *Trihilatæ*, Linn. *Malpighiæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, deeply five-cleft, erect, very small, permanent, converging; with two honey-bearing, oval, gibbous glands, adhering to three, four, or to all the segments, on the outside at the bottom. *Cor.* Petals five, orbicular, large, plaited, fringed, spreading, concave; with long, linear claws. *Stam.* Filaments ten, awl-shaped, short, erect, forming a cylinder, combined at the base; anthers ovate, or rather heart-shaped *Pist.* Germen superior, ovate; styles three, two, or only one, short; stigmas globose. *Peric.* Drupa globose, torulose, large, one-celled. *Seeds* three or two, bony, oblong, obtuse, angular, single-celled; occasionally solitary, globose, and three-celled. *Kernels* oblong, obtuse.

Eff. Ch. Calyx of one leaf, very deeply five-cleft, with two honey-bearing pores at the base of the segments externally. Petals five, roundish, with claws. Filaments cohering at the base. Drupa of one cell, with three seeds.

Obs. Most authors have described the calyx of *Malpighia* as composed of five leaves, but it is rather to be considered as of one leaf only, very deeply cloven.—We find nine species in Linnæus, thirteen in the new edition of *Hortus Kewensis*, and twenty in Willdenow, from which we select the following as sufficiently illustrative of the genus. Many of them are beautifully figured in Jacquin's works.

M. *glabra*. Smooth-leaved Barbadoes Cherry. Linn. Sp. Pl. 609. Curt. Mag. t. 813.—Leaves ovate, entire, smooth. Peduncles umbellated.—A native of the West India islands, where it is cultivated for the sake of its acid pulpy fruit, in size and shape somewhat resembling our cherries. Jacquin says that the fruit is usually made into a preserve with sugar, but that he has eaten it in a crude state without suffering any inconvenience. This tree flowers in the winter and spring, and grows to the height of sixteen or eighteen feet, seldom however exceeding ten feet in this country. *Trunk* erect, delicately branched. *Leaves* opposite, nearly sessile. *Flowers* in terminal, axillary clusters, of a beautiful pink colour, and sweetly-scented, somewhat like a jasmine.

M. *polystachia*. Many-spiked Barbadoes Cherry. Ait. Hort. Kew. ed. 2. v. 3. 103. Andr. Repos. t. 604.—Leaves entire, oblong, smooth, shining, with two glands at the base underneath. Clusters axillary. Flower-stalks with one gland.—A native of Trinidad, and one of those splendid plants sent over by lord Seaforth when he was governor of Barbadoes. It flowered in the stove of A. B. Lambert, esq. at Boyton, in Wiltshire, in the month of April, whence Andrews's figure was taken.—A *shrub* of free growth. *Branches* twiggy, covered with a brownish *bark*. *Leaves* opposite, large and handsome, on silky bristly stalks. *Flowers* in a spiked cluster, yellow, appearing in November, but not expanding till the spring.

M. *glandulifera*. Quadriglandular Malpighia. Ait. Hort. Kew. ed. 2. v. 3. 103. Jacq. Ic. Rar. v. 3. t. 469.—Leaves elliptic-ovate, acute, undulated, downy, with four glands at the base underneath. Clusters axillary on uniglandular stalks.—A native of woods in the Caraccas, flowering in our stoves about July or August, but never bearing fruit.—This *shrub* is about twelve feet high, branched. *Leaves* opposite, on short footstalks, from three to five inches long. *Clusters* axillary, solitary. *Petals* yellow, crisped at their edges, with furrowed claws and roundish borders.

M. *urens*. Stinging Barbadoes Cherry, or Cowhage Cherry. Linn. Sp. Pl. 609. Cavan. Diss. 8. t. 236. f. 1. (Mespilus americana; Tournef. Inst. 642.)—Leaves oblong-ovate, with rigid, decumbent bristles underneath. Stalks single-flowered, aggregate.—Native of South America, flowering from July to October.—*Stem* about three feet high, covered with a brownish *bark*, much branched. *Leaves* acutely pointed, sessile, very finely clothed beneath with depressed needle-like bristles. *Flowers* of a light purple colour, on long, slender stalks, four, five, or six together in a sort of whorl. *Seed* not perfected in England.

M. *crassifolia*. Thick-leaved Barbadoes Cherry. Linn. Sp. Pl. 610. Brown. Jam. 231. Aubl. Guian. t. 182.—Leaves obovate, acute, entire, downy beneath. Clusters terminal.—Found in the West India islands, and at Guiana.—The *trunk* of this *tree* is sixteen feet or more in height, branched at the summit. *Leaves* opposite, thick, somewhat rigid, smooth and green above, downy and rusty-coloured beneath. *Flowers* in a long, terminal, clustered spike, yellow. Among the Caribbees this plant is called *Moureila*.

M. *volubilis*. Twining Barbadoes Cherry. Ait. Hort. Kew. ed. 2. v. 3. 105. Sims in Curt. Mag. t. 809.—Branches twining. Leaves oval, acute, shining. Clusters corymbose, terminal.—A native of the West Indies, flowering in our stoves during the Autumn.—*Stem* shrubby. *Bark* beset with warty excrescences, of an extremely small size. *Leaves* opposite, drooping, on weak, flattish footstalks. *Flowers* chiefly terminal, yellow, of very short duration.—"This shrub (says Dr. Sims) is known in our nurseries by the name of *Hiræa reclinata*, but does not at all correspond with the character of that plant in Jacquin's *Historia Stirpium Americanarum*."

M. *coccigera*. Linn. Sp. Pl. 611. Jacq. Ic. Rar. t. 470.—Leaves subovate, toothed, or spinous.—Found also in the West Indies.—*Stem* two or three feet high, branched. *Leaves* lucid, cut off apparently at the ends, thorny. *Flowers* lateral, on single-flowered *stalks*, pale blush-coloured.

Professor Martyn has added five species from Jacquin, which are unnoticed by other authors, though perhaps comprehended by them. These are called *martinicensis*, *diphylla*, *odorata*, *grandifolia*, and *altissima*.—Jacquin says also that the fruits of several species of *Malpighia* are gathered promiscuously and eaten in the West Indies. They have a pleasant acid flavour, which is always grateful to the inhabitants of hot climates. M. *glabra* however is most esteemed on this account.—This genus is well deserving of attention from cultivators possessed of stoves or hot-houses, because many of its species retain their leaves all the year, and continue flowering from December to March, when there is the greatest scarcity of other flowers.

MALPIGHIA, in *Gardening*, comprehends plants of the exotic, evergreen, shrubby kind for the stove, of which the species cultivated are, the smooth-leaved Barbadoes cherry (M. glabra); the pomegranate-leaved Barbadoes cherry (M. punicifolia); the stinging Barbadoes cherry (M. urens); the narrow-leaved Barbadoes cherry (M. angustifolia); the shining-leaved Barbadoes cherry (M. nitida);

da); the thick-leaved Barbadoes cherry (M. craffifolia); the mullein-leaved Barbadoes cherry (M. verbafcifolia); and the fcarlet grain-bearing Barbadoes cherry (M. coccigera).

Method of Culture.—All thefe forts of plants may be increafed by fowing the feeds in the fpring in pots of light rich earth, and plunging them in a hot-bed. When the plants have attained a few inches in growth they fhould be planted out into feparate fmall pots, re-plunging them in a bark hot-bed in the ftove; where they fhould remain the two firft winters, being afterwards placed in a dry ftove, and kept in a moderate warmth, water being occafionally given in fmall quantities at a time.

They all afford ornament among collections of plants of fimilar kinds in hot-houfes.

MALPIGHIÆ, in *Botany*, fo called from the principal genus among them, a natural order of plants, the 67th in Juffieu's fyftem, or feventh of his thirteenth clafs. For the characters of this clafs, fee GERANIA and GUTTIFERÆ. The *Malpighiæ* are thus defined.

Calyx in five deep divifions, permanent. *Petals* five, alternate with the calyx, furnifhed with claws, and inferted into a glandular difk placed under the germen. *Stamens* ten, inferted into the fame difk, five of them oppofite to the petals, the five alternate ones oppofite to the fegments of the calyx; the filaments are fometimes united at their bafe, anthers roundifh. *Germen* either fimple or three-lobed; ftyles three; ftigmas three or fix. *Fruit* either confifting of three capfules, or of three cells, the capfules or cells fingle-feeded. *Corculum* deftitute of albumen, with a ftraight radicle, the lobes reflexed at their bafe. The *plants* are either fmall trees or fhrubs. *Leaves* oppofite, fimple, with more or lefs appearance of ftipulas. *Flower-ftalks* fometimes terminal, more frequently axillary, either fingle-flowered and feveral together, or folitary and many-flowered, the flowers either fomewhat umbellate, or fpiked, or panicled, their partial ftalks being, for the moft part, jointed in the middle, and furnifhed there with a pair of fmall fcales.

The firft fection, with a three-lobed germen, and a fruit of three capfules, contains *Banifteria* and *Triopteris*.

The fecond fection, with a fimple germen and fruit, confifts of *Malpighia* alone; fee the preceding article.

A third fection, of genera allied to the above, comprifes *Trigonia* of Aublet, and *Erythronium* of Browne and Linnæus.

Cavanilles refers the genera of this order to the clafs *Monadelphia* of Linnæus, on account of a flight, and by no means univerfal, combination of the bafes of their filaments; or rather perhaps from the infertion of thofe parts into one common annular difk or receptacle. This appears to us to be not only forcing nature, but to lead to much inconvenience in practice. It is the error of thofe who, undertaking the ftudy or explanation of any particular tribe, or family, of natural productions, are ever defirous of augmenting it by all poffible means, and perhaps, with prejudiced eyes, fee almoft every thing as appertaining to their favourite fubject.

MALPLAQUET, in *Geography*, a village of Hainaut, famous for a battle fought there Sept. 11, 1709, between the allies under the command of the duke of Marlborough and prince Eugene, and the French under marfhals Villers and Boufflers. Victory was valiantly and obftinately contefted; till at length the field of battle was abandoned to the confederates, who loft on this occafion 20,000 of their beft troops, whereas the vanquifhed enemy did not lofe half the number; 8 miles S. E. of Mons.

MALPOLON, in *Zoology*, the name of a fpecies of ferpent found in the ifland of Ceylon, and beautifully variegated with red marks in the form of ftars.

MALSARA, in *Hindoo Mythology*, a manifeftation of the goddefs Parvati to accompany her lord Siva, in his avatara, or incarnation, under the name and form of *Kandeh Rao*, which fee. She and her lord are very popular deities in the country of the Mahrattas, where, at the elegant temple of Jejury, they are propitiated by numerous pilgrims. (See JEJURY.) It does not, however, appear that the tales related of this avatara are extenfively known, or that they are to be found in any very ancient books.

MALSCH, in *Geography*, a town of the duchy of Baden; ten miles E. of Spire.

MALSESENA, a town of Italy, in the Veronefe; 18 miles N.N.W. of Verona.

MALSKAR, two fmall iflands in the gulf of Bothnia. N. lat. 61° 55'. E. long. 21° 7'.—Alfo, a fmall ifland on the E. fide of the gulf of Bothnia. N. lat. 61° 55'. E. long. 21° 7'.

MALT, in *Agriculture*, a name applied to barley, after it has undergone the procefs of malting; as by this means it becomes fit for making ale, beer, or other fimilar liquors.

It is faid, that the foil on which barley grows makes a confiderable difference in the grain, and that the barley fitteft for malt is that which grows on a rich, light, or gravelly foil, and which has been raifed from feed brought from a farm of a different foil and fituation. The fulleft and largeft grained parts of fuch crops fhould be chofen for making malt. It fhould be heavy, and perfectly found, and fuch as has not fuffered any accident in the field. Its being a very little heated in the mow is by fome confidered rather an advantage, as the grain will be more equally dried, and will confequently the more equally imbibe water; but when it has been fo much hurt in the mow as to look blackifh when broken at the thick end, it is unfit to make good malt. It is alfo found by experience, that barley taken immediately from the field does not malt fo kindly as that which has been fome time in the houfe or mow. And particular care fhould be taken that it is free from the feeds of weeds; for thefe in the malting are apt to give the grain a bad tafte, which cannot afterwards be got rid of.

It is noticed that in the procefs of germination, all the principles of the grain are put in action. The heat which it undergoes feparates and divides its parts; and the vifcidity which it before poffeffed, is removed or converted into a fweet principle, or fugar.

But in order to its being malted, the barley is put into a ciftern lined with lead or ftone, and covered with water about fix inches deep above the barley, to give room for its fwelling. All the good grains fink in the water, but after ftirring it, the imperfect or diftempered ones rife to the furface. Thefe fhould be fkimmed off, and given to poultry or hogs, for they will never make good malt. By the water's gaining admittance into the barley, a great quantity of the air is expelled, as appears from the number of bubbles which rife on the furface.

It is ufual for the barley to be left in the water two or three days, more or lefs, in proportion to the heat of the weather and the drynefs of the grain. A judgment is formed that grain is fully faturated with water, from its appearing turgid, and eafily giving way to an iron rod, dropped perpendicularly into it. Or, by taking a corn from the middle of the ciftern, and holding it fteadily, by the two ends, between the fore-finger and thumb; preffing it gently, and if it continues firm when fo preffed, and the fkin does not break, it muft foak longer; but if it crufhes together and feels mellow, and the fkin crack, it is watered enough. Nicety in this is a material point, and can be learnt only by experience. If the grain fhould be fuffered to remain too ſong in the water, it would begin to loſe part of its ſweetneſs. When it has been ſteeped ſufficiently, the water is drawn off.

And the water uſed for this purpoſe ſhould be that of a clear running ſtream, or rain-water; or if ſuch cannot be had, pond-water, provided it be ſweet and clean, will do very well; or pump-water, which ſhould be rendered ſoft, if it be naturally hard. If the water made uſe of is any way tainted, it communicates to the malt a taſte which it never loſes.

When taken from the ciſtern, the barley is laid in a regular heap, where it muſt remain thirty hours, or till it contracts a heat. It muſt then be worked in one or more heaps, and turned every four, ſix, or eight hours, according to the temperature of the air; and as it *comes*, as its ſpiring is commonly termed, the heap muſt be ſpread thinner to cool it, leſt it be heated too much, and the germination be carried on too faſt. The turning of it muſt be continued in proportion as it is more or leſs ſlow in growth, ſo that it may be brought tolerably dry to the ſkin. When the ſpires begin to deaden, the couch muſt be thickened again, and often turned, that the growth of the ſprout may not revive. At this time the ſpire ſhould be near piercing through the outer ſkin of the barley; as if it grows quite out, the ſtrength of the malt will be too much conſumed. After the malt is made thus far, the common practice is to lay it at once on the kiln: but the beſt way is to gather it all up in one heap, to let it lie in that ſtate for twelve hours, and then to turn it every fourth hour during the ſpace of twenty-four hours. No perſon ſhould be ſuffered to tread on the malt with their ſhoes while it is on the floor, becauſe many grains are inevitably bruiſed thereby, and theſe, vegetating no longer, afford the roots of the other grains a ſubſtance into which they extend their fibres, and are by that means entangled in bunches: and beſides this, the bruiſed corn acquires a degree of putrefaction which taints the liquor made from the malt. Equal care ſhould alſo be taken, that the grain be not bruiſed by any other means.

According to ſome, the time moſt proper for malting is, when the temperature of the air is ſuch, that the grain naturally begins to germinate. How far the limits may be extended, experience alone can determine. The warmer the weather is, the greater muſt be the diſadvantage under which the maltſter labours; becauſe the motion of the fluids is then ſo ſtrong, that the proceſs goes on too quick, and the finer parts are apt to fly off, the conſequence of which is, that inſtead of a ſweet, the malt inclines to a bitter taſte. This is ſo univerſally experienced, that brewers carefully avoid purchaſing what is termed latter made malt.

The grain thus prepared for drying is ſpread on the kiln, where, meeting with a heat greater than is ſuited to vegetation, its farther growth is ſtopped. It is ſpread on the kiln three or four inches thick, and turned every three or four hours. The laying of it thicker is attended with inconveniences, among which is particularly its being unequally dried; and therefore that ſhould be avoided. The ſtrength and duration of the fire are different, according as the malt is intended to be dried pale, amber, or brown. The pale malt requires more leiſure, and leſs fire, than the amber or brown. Pale and amber malt are dried with coke or culm, which not emitting any ſmoke, give it a brighter colour, and do not communicate that bad flavour which it has when dried with wood, ſtraw, &c. Coke is beſt, as it affords a ſteady and conſtant heat, whereby the malt is dried more uniformly. Where wood, or any vegetable fuel is uſed, it ſhould be extremely well dried, in order that, being as free as poſſible from moiſture, it may yield leſs ſmoke.

An ingenious and attentive maltſter found the degree of heat in the malt whilſt on the floor to be, during the firſt ten days, between fifty and ſixty degrees. During the next three or four days, from ſixty to ſixty-five, and ſeventy-ſeven degrees; and during the laſt days of its being there eighty, eighty-four, and eighty-ſeven; which laſt was the degree of heat when the malt was put on the kiln. There cannot be any abſolute rule as to the difference of heat during the different times in the proceſs of malting, becauſe it muſt be ſuited to the heat of the air; at leaſt we have not yet ſufficient data whereon to found ſuch a calculation. The heat of the malt on the kiln, when fit for pale malt, was 120 degrees, and when it was fit for brown malt, 147.

The obſervation, that malt is fit for what is called pale, when its heat is 120 degrees, ſuggeſts a caution which ſhould be carefully attended to, namely, that whatever colour it be intended to give the malt, the heat at firſt ſhould be the ſame: thus, for example, malt which is dried to the degree of high brown, ſhould firſt be rendered pale malt, then amber, and ſo on progreſſively; not by a ſudden increaſe of the fire, but by a longer continuance of it. In this manner the whole body of the grain is equally and gradually dried; whereas a ſtrong and quicker fire would parch, or as it were, ſinge the outſide, while the internal parts remained moiſt; and as that moiſture is afterwards evaporated, it muſt crack the ſurrounding hardened cruſt, and damage the grain in another reſpect.

As ſoon as the malt is dry, it muſt be removed from the kiln, and ſpread thin, that it may cool to the temperature of the air. It cannot be ſuppoſed that any of its parts are capable of retaining the heat in ſuch a manner as not to ſuffer it to eſcape, though ſome have conceived that to be the caſe. In proportion as malts are dried, their particles are more or leſs ſeparated, and coming in contact with water, they ſtrongly attract from it particles which fill up their interſtices. In maſhing, this action between the malt and the water generates a ſmall degree of heat, but not durable; though from hence aroſe the opinion, that brown malt is full of fire or heat.

It ſhould be ſtated that the ſize of the malt-kiln ſhould be proportioned to the quantity of malt for which it is intended. Some build their kilns ſquare, and others make them round; but this laſt is undoubtedly the beſt form, as the heat of the fire is more equally diffuſed therein, and the grain is of courſe more equally dried. Various ſubſtances have been made uſe of for covering the kiln, ſuch as tiles, plates of tin, and wire: of theſe the wire is to be preferred, becauſe it does not contract ſo great a degree of heat as to parch the grain in contact with it; but for this very reaſon, hair-cloth is probably preferable to any other covering; as when any part of the malt is in immediate contact with a ſubſtance much more ſolid than itſelf, and therefore capable of receiving a proportionally greater degree of heat, the malt in contact with that heated body is parched or burnt, by the heat which is not equally diffuſed through the whole maſs; which maſs cannot, therefore, be all equally heated. The hair-cloth is ſpread upon ſmall wooden rafters, and theſe are ſupported by bars of iron laid acroſs the kiln. See Kiln.

There can be little doubt that the grain may, at a medium, be ſaid to loſe by malting one-fourth of its weight, including what is ſeparated from it by the ſpires ſcreened off; but this proportion varies according as it is more or leſs dried. The condition of the barley, as to its greenneſs or ripeneſs, at the time of its being gathered in, is clearly diſcernible when it is malted. If it was gathered green, it rather loſes than gains in quantity; the malt becomes

comes of a ſmaller body, appears ſhrivelled, and often is unkindly hard; whilſt, on the contrary, that which was cut at full maturity increaſes in malting, appears plump, bright, and clear, if properly carried through the proceſs, and on being cracked, readily yields that fine mealy ſubſtance ſo much deſired by the brewers.

Malt which has not had a ſufficient time to ſhoot, ſo that its plume, or *acroſpire*, as the adepts in malting call it, may have reached the inward ſkin of the barley, remains charged with too large a quantity of its unattenuated matter. All thoſe parts which have not been put in motion by the act of germination being, when laid on the kiln to dry, ſo hardened as not to be readily ſoluble in water, and conſequently will be loſt to the ſtrength of the liquor. When it is ſuffered to grow too much, or until the ſpire has ſhot through the ſkin of the barley; though all that is left be malt, yet, as too large a portion of its eſſential part will have been expended in vegetation, the malt muſt be greatly diminiſhed in proportion to what it ought to have been, and what remains cannot be ſo fit for brewing drink for long keeping. And ſuch as has been duly worked on the floor will, if it has not been ſufficiently dried on the kiln, be apt to germinate or ſprout afreſh, perhaps take on a very great heat; and ſhould it continue long with a moderate degree of heat, the leaſt evil that can be expected is, that it will grow mouldy and have an ill flavour. When it has been well worked, but over dried, it will be ſo hardened, that it will not imbibe from the air that moiſture which is neceſſary to mellow it, and render it fit for brewing; for when it has been previouſly ſoftened by the moiſture of the air, it mixes more eaſily and more intimately with the water, and by that means yields a more copious extract than it would otherwiſe do. Such malt as has juſt, or but lately been taken from the kiln, remains warm a conſiderable time. Until it becomes as cool as the ſurrounding air, it does not mellow by the addition of a due quantity of moiſture from the air; and the wort made of ſuch malt requires a much longer boiling before it breaks, than that which is made of malt ſome months old.

The practice of ſprinkling water upon malt newly taken from the kiln, to give it the appearance of having been made a proper time, or to plump it, is highly prejudicial, as tending not only to defraud, as leſs grain fills the buſhel, but if not uſed ſpeedily, heats, ſoon grows mouldy, and ſuffers great damage.

It is obvious, that malt dried on a kiln not ſufficiently heated muſt require a proportionably longer time for it to receive the due effect of the fire; for want of which it will be in the ſame ſtate as that not thoroughly dried. Or if the fire be too quick, or too fierce, inſtead of gently evaporating the water from the corn, it ſcorches the outward ſkin, and ſeparates it from the body of the grain. The malt to which this happens is called brown malt, and is very bulky; and if ſuch a fire be continued, it changes ſome parts of the grain into ſo brittle a ſubſtance, that the malt is ſaid to be glaſſy. The particles which are thus hardened will not diſſolve, or but in ſmall proportion; ſo that they frequently occaſion an almoſt total want of extract, which, in the phraſe of the art, is termed the ſetting the *griſt*.

It is ſuggeſted that the goodneſs of malt may be known by the following marks: when a grain of it is broken, and it taſtes mellow and ſweet, breaks ſoft, and is full of flour from one end to the other, it is good. If it has a round full body, and upon putting ſome grains into water, they ſwim on the ſurface, it is good. Barley ſinks in water, and malt that is not well made will do the ſame: but it is to be obſerved that this is not an invariable proof, becauſe, if the malt be broken, or in the leaſt cracked, it will take in water, and ſink. Malt that is rightly made will not be hard, but of ſo mellow a nature, that if drawn over an oak board, acroſs the grain, it will leave a white line upon the board, like a mark of chalk. Its ſmell alſo may be conſulted; for malt, though otherwiſe good, may have contracted an ill ſcent from the fuel, or from the water uſed in the ſteeping.

In reſpect to the changing the water in ſteeping, ſome maltſters think it no wiſe neceſſary; others, on the contrary, approve of it, but do it indiſcriminately in the ſame proportion during the whole ſeaſon. They are probably in both reſpects wrong; for the times when the water requires to be changed ofteneſt, are the beginning and latter end of the ſeaſon, in autumn and ſpring, when the weather is warm; for in the middle of the winter the weather is too cold to admit of the water being at all changed to any advantage. Suppoſe the barley to be left in ſteep forty-eight hours in the ſpring; if the weather is inclinable to be warm, the water may in that ſpace of time be changed three times; in other caſes twice may be enough: but the beſt rule is, as it is well known, that in the autumn and ſpring, if barley is left too long on the ſteep in the ſame water, the water will grow ſlimy, and ſometimes ſour: the maltſter ſhould watch the changes of the water, and when he finds that it is ſmooth and oily to the touch, and that it is inclinable either to ſmell or taſte ſour, let him by all means have it inſtantly changed; but he muſt obſerve, if he regards his intereſt, a particular method even in doing this. The uſual way of changing the water is, firſt to draw off that in which the barley was ſteeping, and afterwards, by pails full, or by pumping, fill the ciſtern again. But it is adviſed, as a better method, to have ſome water in readineſs to pour on immediately after the firſt is withdrawn, as by that means the danger of heating is prevented. Much miſchief often ariſes from the not changing the water at theſe ſeaſons.

In converting this ſubſtance to the purpoſe of brewing, it ſhould be freed from the tails and duſt before it is ground, which would otherwiſe heighten the colour of the wort, render the liquor muddy, and give it a bad taſte, which cannot afterwards be got rid of. A cylindrical ſieve will be uſeful for this purpoſe.

In grinding, when too ſmall, its flour will mix too freely with the water, and cauſe the wort to run thick. Many are of opinion that the beſt way is only to crack it, ſo that none of the grains may come out whole; for the intent is, that the water ſhould draw out an extract, but not be mixed with the mealy part, in the manner of a paſte or gruel. Some think that malt is better ground by a ſtone-mill than by a ſteel one, becauſe the former bruiſes it, and the latter only cuts the grains.

After it is ground it ſhould lie ſome time to mellow in a cool room, where no ſun comes. The time for this is different, according to its kind. Brown malt may be ground as from three to four or five days before it is uſed, in order that the corn, which is rendered uncommonly hard by the degree of drying, may be gradually ſoftened by the moiſture of the air; by which means it will become the more ſoluble in water. The pale malts require only one or two days. After lying thus in the air, leſs maſhing ſuffices; the ſtrength of the malt is more perfectly extracted, and the beer will be conſiderably ſtronger than it would be with the ſame quantity of malt taken directly from the kiln; but care muſt be taken that it get no damage

damage in lying. Further experiments on these points, however, are wanting to render them satisfactory. See Brewing.

In addition to what has been stated above, on the drying of malt, an experienced maltster remarks, that his constant practice has been to give his malt as much drying as he could on the floor; this is not only a great saving of fuel, but also attended with several other advantages. The malt, by being thus gradually divested of its outward moisture, does not shrink so much when it comes to be laid on the kiln; and of course it measures to more advantage, and is besides of a better quality, having acquired no foreign taste. It is supposed that where malt is laid very damp on the kiln, a thick smoky vapour immediately arises from the surface of it, which, being repelled and condensed by the cold circumambient air, falls again on the malt, where, by the heat from the furnace, it is a second time rarefied, and ascends in clouds of steam; and that this alternate rarefaction and condensation of the moisture is of great disservice to the malt, by often giving it a disagreeable musty flavour, and making it more unfit for keeping. But by the method of suffering the malt to receive a part of its drying on the floor, this inconvenience is, it is believed, in a great measure avoided; as the gross moisture is evaporated before it is laid on the kiln, and that which remains creates no great degree of steam, provided the fire in the furnace is not at first made to burn too fierce. The above maltster states that with this precaution he has often made pale malt as fine as he has seen any where, such as was constantly praised. In drying it, he took care that there was, during the whole time it was on the kiln, but a very moderate, yet equal, fire in the furnace.

It is suggested in the fifth volume of the Farmer's Magazine, that the best *pale malt*, for making beer, is only capable of being produced by drying it with steam; and that such grain as is intended to be malted, should have its dampness corrected, and be rendered fit for keeping only by the heat of steam, as it is known that exposure to a naked fire, however cautiously managed, destroys a great part, if not the whole, of the embryo germs of seeds.

In order to have malt highly dried, as some like brown malt better than pale, when the moisture was nearly evaporated, the above-mentioned maltster caused the fire to be gradually increased till it roared in the furnace, taking care that the malt should be properly stirred, lest it proved kiln-burnt; and by this method he had a fine, sweet, brown malt, fit for making harvest beer, such as some farmers are very fond of brewing.

It is the opinion of some, that brown malt, used in the same proportion with pale, will make the strongest beer; but this is certainly a mistake, as the above maltster has often made the experiment with great precision, but could never find any material difference, and what difference there was at any time, seemed to him to be rather in favour of the pale than the brown malt: this may easily be accounted for, as the flour in the pale malt always remained sound and uninjured in the drying; while the brown malt sometimes, notwithstanding all the care of the maltster, is liable to be injured or parched by the fire, and that part must, of course, lose much of its virtue. It is, however, noticed, that such pale malts as are slack dried make a raw, unwholesome liquor, which will not keep well, but if pale malt be gradually and slowly dried by an uniform gentle heat, it will certainly answer the character he has given of it, and besides, keep as well as any brown malt whatever, as he has fully experienced.

It is stated, that in the spring and autumn, the making of malt in all its branches is a very critical business; as it is then particularly necessary that the beds, or couches, should be frequently turned, or the malt will not come kindly: as the first root will be apt to shoot forth vigorously, starving the other roots, and preventing them from accompanying it in its growth: this must be checked, and the remedy is, to turn the couch often, spread it thin, and give it a sufficient quantity of air, at the same time keeping it cool and temperate. This will stop the progress of the first root, give the others time to sprout, and the barley will then malt kindly and more regularly.

A thin-skinned fine-coated barley is said to be best for making malt, and it is not worse for not being very full-bodied; but a lean, half-starved, unripe grain should not by any means be recommended. And such as has grown on lands highly manured is not so good for making malt as that which has been produced on land of a moderate richness without it. In fact, a luxuriant soil, whether naturally so or enriched by art, is not, in general, best for yielding barley for the maltster's use. Some prefer, for malting, a grain which is the produce of a soil that is rather poor than rich, rather light than strong, and more inclined to a gravel than a clay; as this grain is clean-coated, taper, and elegant in its form, is full of flour, mostly transparent when watered, and will be sufficiently wetted in forty-eight hours. It also increases in the malting, fills the bushel well, and makes a fine, sweet, wholesome, clean, full-bodied malt, from which the best beer may be brewed, either brown or pale, according as the malt has been dried higher or lower.

Mixed grain, or such as is grown on various soils, and in different situations, should never be purchased when it can be avoided, as it will be apt to disappoint the buyer, from the kernels spiring at different times, and some of them not at all; so that after the couch is dried, some part of it will only be half malted, and a great deal not malted at all.

The following method is recommended to discover malt that has been made of mixed, or in part unripe barley. Take a bowl of water, throw into it a couple of handfuls of the malt, giving it a gentle stirring, and the barley which has not been malted will sink to the bottom; the half-malted grains will have one end sunk, being in a vertical position; and the true good malt swim. It is, however, remarked, that the same barley, though ever so good, will not malt alike well at all times: for instance, take it as soon as it is housed, it comes well, but while it is in its sweat, by no means so; yet after it has done sweating, it comes well again, and barley which has been got in early in a very dry season, makes but indifferent malt; while the same barley, if it is left abroad till rain falls on it to loosen the husk from the kernel, malts very well, and yields a large increase. Also old barley, mixed with that of the last harvest, does not malt well, as it does not all spire or put forth its beard, at the same time. These niceties, though little attended to, are of importance in the making of good malt in all cases.

Several regulations relating to the manufacture and sale of malt are enacted by various and successive acts of the British legislature: of which the principal are as follow.

By 12 Ann. stat. 1. cap. 2, continued yearly, and by 33 Geo. II. cap. 7, there shall be paid by the maker for all malt made in England, except it be made for exportation only (12 Geo. c. 4.) a duty of nine-pence a bushel: and by 19 Geo. III. c. 25, an additional duty of 15*l. per cent.* which duty is under the management of the commissioners and officers of excise. (See Tax, *Malt.*) By 43 Geo. III. c. 69,

c. 69, additional duties are likewife impofed. The laft annual malt act is the 50 Geo. III. c. 1. Every maltfter fhall take out a licence from the office of excife annually, paying for the fame 5*s*., if the quantity of malt made by him fhall not exceed within the year, ending the 23d of June in each year previous to his taking out fuch licence, the quantity of 50 quarters.

				£.	s.	d.

	500		550	2	15	0
	550			3	0	0

and a furcharge.

And every perfon who fhall firft become a maltfter, for every fuch licence 5*s*. and within 10 days after the 5th of July next after taking out fuch licence, fuch further additional fum as with the faid 5*s*. fhall amount to the duty hereinbefore charged, according to the quantity of malt made by him within the preceding year. (43 Geo. III. c. 69.) If he fhall neglect to take out fuch licence and renew the fame annually, 10 days at leaft before the end of the year, he fhall forfeit 10*l*. (24 Geo. III. c. 41.) No malt fhall be imported, on pain of forfeiting the fame and its value. (12 Ann. ftat. 1. c. 2.) By the fame act places for making malt are to be entered, on pain of 50*l*.

The maltfter is required to give 24 hours notice within a city or market town, and elfewhere 48 hours notice in writing to the officer, of the time of the day when he intends to wet the corn to be made into malt; and he fhall not begin but between eight in the morning and two in the afternoon: nor empty any grain out of the ciftern, &c. ufed for wetting or fteeping, except between feven in the morning and four in the afternoon: the omiffion of fuch notice, &c. incurs a forfeiture of 100*l*. by 3 Geo. III. c. 13. 42 Geo. III. c. 38. 48 Geo. III. c. 74.

Out of every 20 bufhels of malt, gauged and charged upon the floor, after the fame fhall have been taken out of the ciftern or other utenfil, by the fpace of 26 hours or more, and before it fhall be dried upon the kiln, fhall be allowed 10 bufhels, and fo in proportion for any greater or lefs quantity. But if corn be continued under water for 40 hours, before the water be taken from it, the maltfter fhall not be entitled to the faid allowance. (42 Geo. III. c. 38. 33 Geo. II. c. 7.) Every round bufhel, with a plain bottom, 18½ inches wide throughout, and eight inches deep, fhall be deemed a legal Winchefter bufhel. (12 Ann. ftat. 1. c. 2.) No maltfter fhall wet, fprinkle, &c. any corn or grain in the procefs of being made into malt, after the fame has been emptied out of the fteeping veffel, until the expiration of 12 days, or 288 hours, on pain of 200*l*. (48 Geo III. c. 74.) And if malt be wetted after it hath been taken from the kiln, and before it be delivered to the brewer who may have agreed for the fame, except in the ordinary procefs of brewing beer from fuch malt; every fuch offence fhall incur a forfeiture of 100*l*. (42 Geo. III. c. 38.) And by 48 Geo. III. c. 74, the penalty incurred by every workman, who fhall wet corn contrary to the provifions above-mentioned, is 50*l*., and in default of payment, commitment to the houfe of correction for a term, not exceeding 12 months. But a maltfter may drain water from grain whilft fteeping before the expiration of 40 hours after being firft wetted; provided that no fuch water fhall be drained unlefs the maltfter fhall have given notice of the fame and the precife time between eight in the morning and four in the afternoon; nor fhall the water be drained more than once during the faid fpace of 40 hours, and fuch corn or grain fhall be again completely covered with water within one hour from the beginning fo to drain. (42 Geo. III. c. 38.) Servants of maltfters beginning to wet or remove any corn or grain, in a manner contrary to this act, may be fined 50*l*. by any juftice, who may commit him for non-payment. (48 Geo. III. c. 74.) By 42 Geo. III. c. 38, excife officers may at all times enter every malt-houfe or place ufed for the making of malt, and furvey; and the penalty of obftruction is 200*l*. (See 44 Geo. III. c. 34.) And if the officer fhall refufe or neglect (after demand in writing, 12 Geo. II. c. 28.) to leave a copy of the gauge for the maker at the time of taking it, he fhall forfeit 40*s*. The officer fhall meafure corn making into malt by the gauge only, and not by the bufhel. (12 Ann. ft 1. c. 2.) By 2 & 3 Edw. VI. c. 10, no perfon fhall make any barley malt, except in June, July, and Auguft, which fhall not be three weeks at leaft in making; nor in thefe months, under 17 days, (unlefs it be for his own houfe,) on pain of forfeiting for every quarter 2*s*.; and felling of malt, which has not been well dreffed, fo that there may not be fanned out of one quarter half a peck of duft or more, incurs a forfeiture of 20*d*. for every quarter: and mixing bad malt with good for fale is liable to a forfeiture of 2*s*. for every quarter. In the procefs of malting, preffing of malt in the ciftern to prevent its fwelling, mixing corn of one wetting with corn of a former wetting, and mixing malt with unmalted corn, incur each of them a penalty of 5*s*. a bufhel. (1 Geo. III. c. 3. 2 Geo. II. c. 1. 1 Geo. I. c. 2. 48 Geo. III. c. 74.) Again, mixing of malt that has been gauged with the ungauged, fubjects to a forfeiture of 200*l*. (1 Geo. III. c. 3.) By 48 Geo. III. c. 74, if any maltfter fhall tread, ram, or otherwife force together in the ciftern, &c. any grain fteeping or fteeped in order to its being made into malt, he fhall forfeit 100*l*. inftead of the fum of 5*s*. for every bufhel of corn or grain fteeping or fteeped, that fhall be fo trodden, &c. mentioned in 48 Geo. III. c. 2.; and if any corn or grain, in the procefs of making malt, be found fo hard and compact, as to manifeft its having been forced together for preventing its rifing and fwelling, the maltfter, &c. in fuch cafe fhall forfeit 100*l*.

If any maltfter, &c. fhall fraudulently conceal any grain making into malt from the view of the gauger, or officer appointed to take an account of the fame, he fhall forfeit 200*l*. (48 Geo. III. c. 74.) And any maltfter fraudulently conveying away from the ciftern, &c. any fteeping or part of any fteeping of corn making into malt, fo that no gauge can be taken in the back by the officer, fhall forfeit 100*l*. (1 Geo. III. c. 3. 48 Geo. III. c. 74.) By the latter act, the penalty for erecting or extending cifterns, &c. for the manufacture of malt, without previous notice, is 200*l*. The maltfter is required to make monthly entry at the office of excife of all the malt made by him in fuch month (for fale or not for fale), on pain of 100*l*. (12 Ann. ftat. 1. c. 2. 44 Geo. III. c. 34.) By 48 Geo. III. c. 74, every maltfter fhall within the fpace of 14 days, next after the time of entry (as before) clear away all the duties, unlefs fecurity fhall have been given, to the fatisfaction of the commiffioners of excife, by bond in double the value of fuch duties as are likely to become due within any five months, for the due payment

payment at the end of every four months at the day of entry, and if such security be not given, and any maltster, &c. neglect to clear off at the end of 14 days such sums as shall have become due, he shall for every such offence forfeit double the duties.

A drawback of the duty is allowed for malt damaged in exportation, and also for malt destroyed by fire or water. (12 Ann. stat. 1. c. 2.) By the 12 Geo. c. 4. and 33 Geo. II. c. 7, no malt entered and made for exportation shall be liable to the duties, and no drawback shall be allowed for any malt exported. By 1 Geo. III. c. 3. and 44 Geo. III. c. 16, there shall be allowed for every 20 quarters of grain made into malt for exportation 30 quarters of malt and no more, on exportation: and notice shall be given of steeping and the quantity, on pain of 50*l.* and this shall be kept separate from that designed for home consumption, on pain of 5*s.* a bushel, (12 Geo. c. 4.) and the corn of one steeping shall be kept separate from any other, until it hath been measured, on pain of 50*l.* (3 Geo. II. c. 7.) Persons opposing officers shall forfeit 50*l.* (12 Geo. c. 4.) Notice of measuring shall be given; and the malt carried on ship-board, or kept separate and locked up, on pain of 50*l.* (12 Geo. c. 4. 3 Geo. II. c. 7. 50 Geo. III. c. 1.) Opening such locks, and carrying away the malt, without consent of the officer, or notice given to him, incur a forfeiture of 100*l.* (3 Geo. II. c. 7. 50 Geo. III. c. 1.) The officer having received 40 hours notice shall attend, keep an account of the malt delivered out, and of the person to whom it belongs, and give a certificate to the officer of the division to which it is to be removed, who shall file the same and make entry thereof: and if the proprietor neglect to deliver such certificate, he shall forfeit 50*l.* (12 Geo. c. 4.) Those intending to ship malt for exportation shall give 48 hours notice to the officer of the port in writing, with the name of the ship, on pain of 5*s.* a bushel. The ship shall be locked, and persons breaking open the hatches, forfeit 50*l.* The landing of malt after shipping for exportation, subjects, besides the penalty of the bond for its exportation, to a forfeiture of the same, and treble the value. (1 Geo. III. c. 3. 50 Geo. III. c. 1.) Storehouses shall be cleared out in 15 months, on pain of 50*l.* Unmalted oats or barley mixed among malt for exportation incurs a forfeiture of 5*s.* a bushel. (6 Geo. c. 21.) If ground malt shall be exported, it shall be computed at so many bushels as it contained before it was ground. (12 Ann. st. 1. c. 3.) The penalties relating to this article (unless otherwise directed) shall be sued for, levied and mitigated as by the laws of excise, or in the courts at Westminster; half to the use of the king, and half to him that shall sue. (6 Geo. c. 21. 24 Geo. II. c. 40. 44 Geo. III. c. 38.) Persons aggrieved may appeal to the next quarter sessions, giving six days notice in writing. (12 Ann. st. 1. c. 2. 1 Geo. II. st. 2. c. 16.) The act 48 Geo. III. c. 74. has made several alterations of the penalties and regulations pertaining to the making of malt, and enacted several provisions by which maltsters and makers of malt are to ascertain, and make entry of the quantity of barley in their possession, and also other provisions for rendering appeals more certain; for which we refer to the act itself. (See BARLEY and CORN.)

The infusion of malt has been much recommended as an antiscorbutic. See SCURVY and WORT.

Good malt may be made of the grain of the maize or Indian corn, but then a particular method must be taken for the doing it. Our barley malt makers have tried all their skill to make good malt of it in the ordinary way, but to no purpose; that is, the whole grain will not be this way malted or rendered tender and floury, as in other malt; for it is found, by experience, that this corn, before it be fully malted, must sprout out both ways, that is, both root and blade, to a considerable length, that of a finger at least and if more the better. For this purpose it must be laid in a heap a convenient time; and in this process, if it be of a sufficient thickness for coming, it will quickly heat and grow mouldy, and the tender sprouts will be so entangled, that the least moving of the heap will break them off; and the farther maturation of the grain into malt, will be hindered by this means; and on the other hand, if it be laid thin, and often stirred and opened to prevent too much heating, those sprouts which have begun to shoot cease growing, and consequently the corn again ceases to be promoted to the mellowness of malt. Phil. Trans. N 142.

To avoid all these difficulties, the following method is to be used: take away the top of the earth in a garden or field, two or three inches, throwing it up half one way, and half the other; then lay the corn for malt all over the ground so as to cover it; the earth that was pared off is now to be laid on again, and nothing more is to be done till the field is all over covered with the green shoots of the plant. The earth is then to be taken off, and the roots of the grain will be found so entangled together, that they will come up in large cakes or parcels; it must be gently washed in order to take off all the dirt, and then dried on a kiln, or on a clean floor exposed to the sun. Every grain of the maize will be thus transmuted into good malt, and the beer brewed with it will be very pleasant and very wholesome, and of an agreeable brown colour, but very clear.

It may be worth trying whether the same process is not with due care applicable to the malting of turnips, potatoes, carrots, parsnips, and the like. It might possibly be of service also to attempt this less laborious way of making malt of barley and other small grains: the disadvantages would be the not so easily separating the dirt from the grain as in the larger kind; and as barley requires the root only, not the ear, to shoot in order to the making of malt, it would be some difficulty to know the exact time of taking it up; but with all these disadvantages the method is worth a trial.

MALT-*Dust*, in *Agriculture*, the dust or substance that separates from the malt in the act of drying, or during its preparation. It is sometimes called malt-combs, and has been found useful as a manure, in lessening the cohesion of stiff heavy soils. But it may probably be made use of to the greatest advantage, as a top dressing when sown over crops in the early spring season. The following experiments are recorded, with respect to the disputed point of its being more adapted to barley than wheat crops. It has often been asserted, by some, that malt-dust is much better suited as a manure to barley than wheat; as from the latter lying a whole year in the ground, and the malt-dust being sown with it, the virtues of the manure are exhausted long before the summer, when the corn principally wants nourishment; being too early advanced in its growth, and rendered winter-proud by it; while others, contradicting this assertion, say it is best for wheat, making it appear, that it often causes very good crops of corn, particularly after a hard winter. In order to make some experiments to ascertain this matter, a field of ten acres was fixed upon, which had borne a good crop of horse-beans; after which it was sown with turnips which, being fed off, it was summer-fallowed, being intended for wheat. The soil was a stiffish loam, in good heart, and tolerably clean. It was divided by by deep furrows into ten equal parts, each containing one acre, and numbered 1, 2, 3, 4, 5, 6, 7, 8, 9, and 10. The whole field during the courfe of the fallowing had four ploughings given it, which reduced it to a fine tilth or mould. As wheat-feed time came, No. 1 was fown broad-caft, with three bufhels of wheat, and ploughed in, laying on no manure whatever. No. 2 was fown with the fame quantity of wheat, after which ten quarters, or eighty bufhels, of malt-duft were ftrewed over it, and that and the feed ploughed in together. No. 3 was alfo fown with wheat in the fame manner, except that the ftrewing on the malt-duft was deferred till the latter end of January. No. 4 had a dreffing of dung in the ordinary way, and was fown with three bufhels of wheat like the other parts. No. 5 was dreffed by fheep-folding, and was alfo in like manner fown with wheat. No. 6 was fown with wheat in the fame quantity: and in February, after fowing, received a half dreffing of very rotten dung which had been feveral times turned and mixed. No. 7, after receiving a ploughing in the fpring, was fown with ten pecks of barley, which was harrowed in, and no manure at all applied. No. 8 was fown with barley, as above, but had ten quarters of malt-duft laid on it. No. 9 had in the winter a good dreffing of dung, and was in the fpring fown with the fame quantity of barley. No. 10 was fown with barley, like No. 8, only it had five inftead of ten quarters of malt-duft laid on it.

It is obferved, that all the pieces of wheat were fown the firft week in October, and all the barley the fecond week in March. In January, on examining the wheat, it was found that the acre marked No. 2 looked moft forward and flourifhing; though there was in appearance but little difference between that and No. 4. The Nos. 1, 3, and 6, neither of them looked fo vigorous as thofe already-noticed; and No. 5 feemed rather thin on the land; but the wheat-plants were in good condition and healthy. And on another examination in May, of the wheat-crops, it was found that No. 1 was tolerably clean and promifed well; and No. 2 gave hopes of a large crop, and was furprifingly clear of weeds. No. 3 was greatly improved fince the laying-on of the dreffing of malt-duft. No. 4 looked very vigorous and ftrong, but was very foul, having feveral forts of weeds not to be met with in other parts of the land. No. 5 was thin of plants, and they did not branch much: however, they ftill feemed healthy and ftrong. No. 6 was like No. 3, greatly improved; but it was foul, and what appeared ftrange, had many weeds of a nature quite different from thofe with which No. 4 was infefted, though the dung laid on both thefe parts was taken from the fame heap.

And at this time, on looking at the pieces fown with barley, No. 7 was found promifing and clean. No. 8 was forwarder, and afforded the profpect of a large crop. No. 9 was forward and fine, but foul with weeds. No. 10 bore much the fame appearance as No. 1, and promifed well.

At harveft, No. 2 of the wheat was firft fit to reap, after which fucceeded No. 4; the reft were ready nearly at the fame time.

Of the barleys, Nos. 8 and 10 were firft ready to mow.

It is almoft unneceffary to obferve, that thofe crops which were cleareft of weeds were the fooneft fit for carrying.

Thefe crops were all laid feparately, as well as all feparately threfhed, and dreffed as early as poffible in the winter.

The produce of the feveral crops, on being diftinctly noted, were the following:

Crops.	Produce. Bufhels.	Pecks.
No. 1, manured, wheat - -	20	1
— 2, manured with malt-duft when fown	28	3
— 3, manured with malt-duft after Chriftmas, by way of top-dreffing -	40	1
— 4, manured with dung in the ordinary way - - - -	32	2
— 5, folded with fheep - - -	29	3
— 6, dreffed with rotten dung in February	30	0
— 7, unmanured barley - - -	32	3
— 8, manured with ten quarters of malt-duft when fown - - -	48	0
— 9, manured with dung in the winter -	40	2
— 10, manured when fown, with five quarters of malt-duft - - -	44	0

From thefe trials it is concluded, firft, that when malt-duft is ufed as a manure for wheat, it is the beft to lay it on by way of top-dreffing after the corn is come up, as the crop of No. 3 yielded above twelve bufhels more than that of No. 2; and it is fuppofed that the virtue of the malt-duft laid on No. 2 was exhaufted before it could be of any effential fervice to the crop, whereas, in No. 3 the manure began to yield forth its virtues juft as the wheat-plants began to be in want of a frefh fupply of nourifhment. It was alfo evident, that the grains of wheat which grew on No. 2 were thinner and had lefs fubftance than thofe of No. 3, the grain of which was fine, plump, and heavy.

It was alfo clear, from the produce of No. 4, that malt-duft is, in many cafes, a better manure for wheat than dung, not only as it gives a larger increafe, but alfo becaufe it does not ftock the land with deftructive and devouring weeds.

The wheat grown on No. 5, was as fine as that of No. 3, but confiderably lefs in quantity, as appears by the account.

The method purfued in No. 6 is not defirable: it is a good alternative, if the farmer happens to have too little dung to drefs all his fallow-lands with.

It is alfo fuppofed that malt-duft is a very good and profitable manure for a barley crop; but the yielding of No. 10 being forty-four bufhels, and of No. 8 only forty-eight bufhels, which laft is not an increafe in proportion to the additional quantity of manure laid on, it may be concluded, that eight quarters, or fixty-four bufhels, of malt-duft is the proper quantity to lay on an acre for a barley crop, and that at the time of fowing. In fpeaking of malt-duft, it is meant the kiln-duft, or that which falls from the malt in drying: as to the tail-duft, that falls through the fcreen whilft the malt is cleaning before it is put in facks, that may be applied to a better ufe, being generally given to pigs, and often to cows, in which laft cafe it makes them give a great deal of milk.

It has been fuggefted that the virtue of malt-duft, as a manure, lafts only for one crop; but this is a miftake, for when the manure is laid on in January or February, a good crop of the green kind may be had after the wheat.

This manure is fuppofed to be of a very warm nature; this has induced many farmers to think that it may burn crops; and it may, perhaps, do fo on a hot gravelly foil; but on clay land or a ftiff loam, it feldom or ever does any damage: and indeed the only danger is a dry time enfuing after it is fpread on the land, for the firft fhower of rain wafhes it in, and fecures the crop from all hazard of being burnt or injured in that way.

It is fuppofed by fome, that malt-duft is for a ftiff foil

a better

a better manure than dung; but the difficulty is, whether it is moſt profitable to lay it on when the wheat is ſown, or by way of top-dreſſing in January or February. The above experiments ſeem to ſhew, that the beſt time to dreſs heavy land with it, is in January or the following month.

It is alſo ſtated, that nothing ſurpaſſes this manure when laid on cold graſs grounds, to the amount of about eight quarters or ſixty buſhels an acre. Its effects in this way are ſaid to be very great.

In an experiment of Mr. Bedford's, in which a piece of land was manured with this ſubſtance at the rate of four quarters to the acre, and ſown with barley and clover, the barley was very luxuriant, producing near ſeven quarters *per* acre, and the clover extremely fine; from which it is concluded, that it is a valuable ſort of manure, being cheaper than rape-duſt or any other ſort of top-dreſſing, as it only coſts about twelve ſhillings the acre.

About Dunſtable this ſort of manure coſts one ſhilling a buſhel, is ſown by hand at the rate of from twenty-four to thirty-two buſhels the acre over the barley land, and harrowed-in with the ſeed. It is ſeldom uſed to wheat in that diſtrict, but would probably anſwer well to it as a top-dreſſing, in the proportion of about thirty buſhels to the acre, ſown over the crops in March.

The black malt-duſt, or that which falls through the kiln-plate, is preferable to the white, from the ſeeds of weeds being deſtroyed by the heat in drying.

MALT, *for the manner of preparing liquors of*, see BREWING.

MALT *Liquors* have different names as well as different virtues, properties, and uſes, both from the different manners of preparing the malt, whence they are diſtinguiſhed into *pale* and *brown*; and from the different manners of preparing or brewing the liquors themſelves, whence they are divided into *beer* and *ale*, *ſtrong* and *ſmall*, *new* and *old*.

Malt drinks are either pale or brown, as the malt is more or leſs dried on the kiln; that which is the ſlendereſt dried, tinging the liquor leaſt in brewing, and therefore being called *pale*: whereas that higher dried, and as it were roaſted, makes it of a higher colour. A mixture of both theſe makes an amber colour; whence ſeveral of theſe liquors take their name.

Now, it is certain, the pale malt has moſt of the natural grain in it, and is therefore the moſt nouriſhing; but for the ſame reaſon, it requires a ſtronger conſtitution to digeſt it. Thoſe who drink much of it, are uſually fat and ſleek in their bloom, but are often cut off by ſudden fevers; or, if they avoid this, they fall early into a diſtempered old age.

The brown malt makes a drink much leſs viſcid, and fitter to paſs the ſeveral ſtrainers of the body; but, if very ſtrong, it may lead on to the ſame inconveniences with the pale; though a ſingle debauch wears off much more eaſily in the brown.

Dr. Quincy obſerves, that the beſt pale malt liquors are thoſe brewed with hard waters, as thoſe of ſprings and wells, becauſe the mineral particles, with which theſe waters are impregnated, help to prevent the coheſions of thoſe drawn from the grain, and enable them to paſs the proper ſecretions the better; as the viſcid particles of the grain do likewiſe defend theſe from doing the miſchief they might otherwiſe occaſion. But ſofter waters ſeem beſt ſuited to draw out the ſubſtances of high-dried malts, which retain many fiery particles in their contexture, and are therefore beſt loſt in a ſmooth vehicle.

For the differences in the preparation of malt liquors, they chiefly conſiſt in the uſe of hops, as in beer; or in the more ſparing uſe of them, as in ale.

The difference made by hops is beſt diſcovered from the nature and quality of the hops themſelves: theſe are known to be a ſubtle grateful bitter: in their compoſition, therefore, with this liquor, they add ſomewhat of an alkaline nature, *i. e.* particles that are ſublime, active, and rigid. By which means, the ropy viſcid parts of the malt are more divided and ſubtilized; and are, therefore, not only rendered more eaſy of digeſtion and ſecretion in the body, but alſo, while in the liquor, they prevent it from running into ſuch coheſions as would make it ropy, vapid, and ſour.

For want of this, in unhopped drinks, that clammy ſweetneſs, which they retain after working, ſoon turns them acid, and unfit for uſe; which happens ſooner or later, in proportion to the ſtrength they receive from the malt, and the comminution they have undergone from fermentation.

It is a common opinion, that ale is more diuretic than beer, that is, liquor leſs hopped more than that with a greater quantity of hops in it: which may hold in ſome conſtitutions, becauſe ale being more ſmooth, ſoftening, and relaxing, where urine is to be promoted by enlarging the paſſage, as in thin, dry conſtitutions, this is the moſt likely to effect it. But where the promoting of urine is to be done by attenuating and breaking the juices, and rendering them more fluid, it is certainly beſt anſwered by thoſe drinks which are well hopped.

As to the diſpute, whether or no hops tend to breed the ſtone, it is too long to enter upon here. Quincy is of opinion, there is but little reaſon for the affirmative ſide of the queſtion; and, in general, makes no ſcruple to ſay, that, for one conſtitution damaged by beer, there are numbers ſpoiled by ale. This laſt manifeſtly fouls the glands, ſtuffs the veſſels with ſlime and viſcidity, makes the body unwieldy and corpulent, and paves the way for cachexies, jaundice, aſthmas, and at laſt incurable dropſies. The urinary paſſages, alſo, which it is ſuppoſed to clear, will, in time, be filled by it with ſlough, and matter of as ill conſequence as gravel.

The different ſtrengths of malt liquors alſo make their effects different. The ſtronger they are, the more viſcid parts they carry into the blood; and though the ſpirituous parts make theſe imperceptible at firſt; yet when thoſe are evaporated, which will be in a few hours, the other will be ſenſibly felt by pains in the head, nauſeouſneſs at the ſtomach, and laſſitude or liſtleſſneſs to motion. This, thoſe are the moſt ſenſible of, who have experienced the extremes of drinking theſe liquors and wines; for a debauch of wine they find much ſooner worn off, and they are much more lively and briſk afterwards, than after intemperately uſing malt liquors, whoſe viſcid remains will be long before they be ſhaken off.

Malt liquors, therefore, are, in general, the more wholeſome for being ſmall, *i. e.* of ſuch a ſtrength as is liable to carry a ſmall degree of warmth into the ſtomach, but not ſo great as to prevent their being proper diluters of the neceſſary food. Indeed, in robuſt people, or thoſe who labour hard, the viſcidities of the drink may be broken into a convenient nouriſhment; but in perſons of another habit and way of living, they ſerve rather to promote obſtructions and ill humours.

The age of malt liquors is the laſt thing by which they are rendered more or leſs wholeſome. Age ſeems to do nearly the ſame thing as hops; for thoſe liquors which are longeſt kept are certainly leſs viſcid; age breaking the viſcid

cid parts, and, by degrees, rendering them ſmaller, and fitter for ſecretion.

But this is always determined according to their ſtrength; in proportion to which, they will ſooner or later come to their full perfection, as well as decay; for, when ale or beer is kept till its particles are broken and comminuted as far as they are capable, then it is that they are beſt; and, beyond this, they will be continually on the decay, till the finer ſpirits are entirely eſcaped, and the remainder becomes vapid and ſour.

MALT *Diſtillery*. This is an extenſive article of trade, and by which very large fortunes are made. The art is to convert fermented malt liquors into a clear inflammable ſpirit, which may be either ſold for uſe in the common ſtate of a proof ſtrength, that is, the ſame ſtrength with French brandy; or is rectified into that purer ſpirit uſually ſold under the name of ſpirit of wine; or made into compound cordial waters, by being diſtilled again from herbs and other ingredients. See BREWING, SPIRITS, and WASH.

To brew with malt in the moſt advantageous manner, it is neceſſary, 1. That the ſubject be well prepared; 2. That the water be ſuitable and duly applied; and, 3. That ſome certain additions be uſed, or alterations made, according to the ſeaſon of the year, and the intention of the operator; and by a proper regulation in theſe reſpects, all the fermentable parts of the ſubject will thus be brought into the tincture, and become fit for fermentation.

The due preparation of the ſubject conſiſts in its being juſtly malted and well ground. When the grain is not ſufficiently malted it is apt to prove hard, ſo that the water can have but very little power to diſſolve its ſubſtance; and if it be much malted, a part of the fermentable matter is loſt in that operation. The harder and more flinty the malt is, the finer it ought to be ground; and in all caſes, when intended for diſtillation, it is adviſable to reduce it to a kind of finer or coarſer meal. When the malt is thus ground, it is found, by experience, that great part of the time, trouble, and expence of the brewing is ſaved by it, and yet as large a quantity of ſpirits will be produced; for thus the whole ſubſtance of the malt may remain mixed among the tincture and be fermented and diſtilled among it. This is a particular that very well deſerves the attention of the malt diſtiller, as the trade is at preſent carried on; for the diſpatch of the buſineſs, and the quantity of ſpirit procured, are more attended to than the purity or perfection of it.

The ſecret of this matter depends upon the thoroughly mixing, or briſkly agitating and throwing the meal about, firſt in cold, and then in hot water; and repeating this agitation after the fermentation is over, when the thick turbid waſh being immediately committed to the ſtill, already hot and dewy with working, there is no danger of burning, unleſs by accident, even without the farther trouble of ſtirring, which in this caſe is found needleſs, though the quantity be ever ſo large, provided that requiſite care and cleanlineſs be uſed; and thus the buſineſs of brewing and fermenting may very commodiouſly be performed together, and reduced to one ſingle operation. Whatever water is made choice of, it muſt ſtand in a hot ſtate upon the prepared malt, eſpecially if a clear tincture be deſired, but a known and very conſiderable inconvenience attends its being applied too hot, or too near to a ſtate of boiling, or even ſcalding with regard to the hand. To ſave time in this caſe, and to prevent the malt running into lumps and clods, the beſt way is to put a certain meaſured quantity of cold water to the malt firſt; the malt is then to be ſtirred very well with this, ſo as to form a ſort of thin uniform paſte or pudding; after which the remaining quantity of water required may be added in a ſtate of boiling, without the leaſt danger of making what, in the diſtillers language, is called a pudding.

In this manner the due and neceſſary degree of heat in the water, for the extracting all the virtues of the malt, may be hit upon very expeditiouſly, and with a great deal of exactneſs, as the heat of boiling water is a fixed ſtandard which may be let down to any degree by a proportionate mixture of cold water, due allowances being made for the ſeaſon of the year, and for the temperature of the air.

This little obvious improvement, added to the method juſt above hinted for the reducing brewing and fermentation to one operation, will render it practicable to very conſiderable advantage, and the ſpirit improved in quality as well as quantity.

A much more profitable method than that uſually practiſed for the fermenting malt for diſtillation, in order to get its ſpirit, is the following: Take ten pounds of malt reduced to a fine meal, and three pounds of common wheatmeal: add to theſe two gallons of cold water, and ſtir them well together, then add five gallons of water boiling hot, and ſtir all together again. Let the whole ſtand two hours, and then ſtir it again, and when grown cold, add to it two ounces of ſolid yeaſt, and ſet it by looſely covered in a warmiſh place, to ferment.

This is the Dutch method of preparing what they call the waſh for malt ſpirit, whereby they ſave much trouble, and procure a large quantity of ſpirit: thus commodiouſly reducing the two buſineſſes of brewing and fermenting to one ſingle operation. In England the method is to draw and maſh for ſpirit as they ordinarily do for beer, only inſtead of boiling the wort, they pump it into large coolers, and afterwards run it into their fermenting backs, to be there fermented with yeaſt. Thus they beſtow twice as much labour as neceſſary, and loſe a large quantity of their ſpirit by leaving the groſs bottoms out of the ſtill for fear of burning.

All ſimple ſpirits may be conſidered in their different ſtates of low wines, proof ſpirit, and alcohol, the intermediate degrees of ſtrength being of leſs general uſe; and they are to be judged of only according as they approach to, or recede from, theſe. Low wines, at a medium, contain a ſixth part of pure inflammable ſpirit, five times as much water as ſpirit neceſſarily ariſing in the operation with a boiling heat. Proof goods contain about one-half of the ſame totally inflammable ſpirit; and alcohol entirely conſiſts of it. See SPIRITS.

Malt low wines, prepared in the common way, are exceedingly nauſeous; they have, however, a natural vinoſity, or pungent agreeable acidity, which would render the ſpirit agreeable to the palate, were it not for the large quantity of the groſs oil of the malt that abounds in it. When this oil is detained in ſome meaſure from mixing itſelf among the low wines, by the ſtretching a coarſe flannel over the neck of the ſtill, or at the orifice of the worm, the ſpirit becomes much purer in all reſpects; it is leſs fulſome to the taſte, leſs offenſive to the ſmell, and leſs milky to the eye. (Shaw's Eſſay on Diſtillery.) When theſe low wines, in the rectification into proof ſpirits, are diſtilled gently, they leave a conſiderable quantity of this groſs fetid oil behind them in the ſtill along with the phlegm; but if the fire be made fierce, this oil is again raiſed and brought over with the ſpirit; and being now broken ſomewhat more fine, it impregnates it in a more nauſeous manner than at firſt. This is the common fault both of the malt diſtiller and

 of

of the rectifier; the latter, instead of separating the spirit from this nasty oil, which is the principal intent of his process, attends only to the leaving the phlegm in such quantity behind, that the spirit may be of the due strength as proof or marketable goods, and brings over the oil in a worse state than before. To this inattention to the proper business of the process, it is owing that the spirit, after its several rectifications, as they are miscalled, is often found more stinking than when delivered out of the hands of the malt distiller. All this may be prevented by the taking more time in the subsequent distillations, and keeping the fire low and regular, the sudden stirring of the fire, and the hasty way of throwing on the fresh fuel, being the general occasions of throwing up the oil by spurts, where the fire in general, during the process, has not been so large as to do that mischief.

The use of a balneum Mariæ, instead of the common still, would effectually prevent all this mischief, and give a purer spirit in one rectification, than can otherwise be procured in ten, or indeed according to the common methods at all.

Malt low wine, when brought to the standard, or proof spirit, loses its milky colour, and is perfectly clear and bright, no more oil being contained in it than is perfectly dissolved by the alcohol, and rendered miscible with that proportion of phlegm, which is about one-half the liquor; its taste also is cleaner though not more pleasant; there being less of the thick oil to hang on the tongue in its own form, which is not the case in the low wines, where the oil, being undissolved, adheres to the mouth in its own form, and does not pass lightly over it.

When proof spirit of malt is distilled over again, in order to be rectified into alcohol, or, as we usually call it, spirits of wine, if the fire be raised at the time when the faints begin to come off, a very considerable quantity of oil will be raised by it, and will run in the visible form of oil from the nose of the worm. This is not peculiar to malt spirit, but the French brandy shews the same phenomenon, and that in so great a degree, that half an ounce of this oil may be obtained from a single piece of brandy.

Malt spirit, more than any other kind, requires to be brought into the form of alcohol, before it can be used internally, especially as it is now commonly made up in the proof state, with as much of this nauseous and viscous oil as will give it a good crown of bubbles. For this reason it ought to be reduced to an alcohol, or totally inflammable spirit, before it is admitted into any of the medicinal compositions. If it be used without this previous caution, the odious taste of the malt oil will be distinguished among all the other flavours of the ingredients.

Malt spirit, when it has once been reduced to the true form of an alcohol, is afterwards more fit for all the curious internal uses than even French brandy, it being after this purification a more uniform, hungry, tasteless and impregnable spirit, than any other spirits which we esteem so much finer.

A pure spirit being thus procured, should be kept carefully in vessels of glass or stone, well stopped to prevent the evaporation of any of its volatile part. If preserved in casks, it is apt to impregnate itself very strongly with the wood. The quantity of pure alcohol obtainable from a certain quantity of malt, differs according to the goodness of the subject, the manner of the operation, the season of the year, and the skilfulness of the workman; according to which variations, a quarter of malt will afford from eight or nine, to thirteen or fourteen gallons of alcohol. This should encourage the malt distiller to be careful and diligent in his business, as so very large a part of his profit depends wholly on the well conducting his processes.

After every operation in this business, there remains a quantity of faints, which in their own coarse state ought never to be admitted into the true spirit; these are to be saved together, and large quantities of them at once wrought into alcohol. It is easy to reduce these to such a state, that they will serve for lamp spirits. Their disagreeable flavour being corrected by the adding of aromatics during the distillations, the reducing them to a perfect and pure alcohol is practicable, but not without such difficulties, as render it scarcely worth the trader's while. One way of doing it is by distilling them from water into water, and that with a very slow fire. By this means a pure alcohol may be made out of the foulest faints.

The malt distiller always gives his spirit a single rectification *per se*, in order to purify it a little, and make it up proof, but in this state it is not reckoned fit for internal uses, but serves to be distilled into geneva and other ordinary compound strong waters for the vulgar.

The Dutch, who carry on a great trade with malt spirit, never give it any farther rectification than this, and it is on this account that the malt spirit of England is in general so much more in esteem. The Dutch method is only to distil the wash into low wines, and then to full proof spirit; they then directly make it into geneva, or else send it as it is to Germany, Guinea, and the East Indies, for the Dutch have little notion of our rectification. Their spirit is by this means rendered very foul and coarse, and is rendered yet more nauseous by the immoderate use they make of rye meal. Malt spirit, in its unrectified state, is usually found to have the common bubble proof, as the malt distiller knows that it will not be marketable without it.

The whole matter requisite to this is, that it have a considerable portion of the gross oil of the malt well broke and mixed along with it; this gives the rectifier a great deal of trouble if he will have the spirit fine; but in the general run of the business, the rectifier does not take out this oil, but breaks it finer, and mixes it faster in by alkaline salts, and disguises its taste by the addition of certain flavouring ingredients. The spirit loses in these processes the vinosity it had when it came out of the hands of the malt distiller, and is, in all respects, worse, except in the disguise of a mixed flavour. Shaw's Essay on Distillery.

The alkaline salts used by the rectifier, destroying the natural vinosity of the spirit, it is necessary to add an extraneous acid in order to give it a new one. The acid they generally use is the *spiritus nitri dulcis*; and the common way of using it is the mixing it to the taste with the rectified spirit: this gives our malt spirit, when well rectified, a flavour somewhat like that of French brandy, but this soon flies off; and the better method is to add a proper quantity of Glauber's strong spirit of nitre to the spirit in the still. The liquor in this case comes over impregnated with it, and the acid being more intimately mixed, the flavour is retained. See SPIRITUS *nitri dulcis*.

MALTA, in *Geography*, anciently *Ogygia* and *Melite*, from which latter the Saracens have formed *Malta*, an island in the Mediterranean, about fifty miles from the coast of Sicily, twenty miles long, and twelve miles in its greatest breadth, and about sixty miles in circumference. It consists of an immense white soft rock of free-stone, covered with a thin stratum of earth, most of which has been brought from Sicily, seldom more than a foot above the surface of the rock; and this earth is removed once in ten years,

years, in order to clear the rock of a thick cruft which forms, and prevents the moifture from fufficiently penetrating, It was anciently reckoned a part of Africa, but now belongs to Europe. The foil, watered by the night-dew and well cultivated, produces cumin-feed, anife-feed, cotton, excellent fruits, fuch as melons, oranges, lemons, and particularly figs, vegetables, and paftures; but it yields neither grain nor wine fufficient for its inhabitants, who are eftimated at about 63 or 64,000, including thofe in the neighbouring iflands. It furnifhes plenty of excellent and finely-flavoured honey, fea-falt, confiderable fifheries, and a profitable coral-fifhery. The ifland is divided into fmall inclofures of free-ftone, is well planted, and contains feveral towns and villages; the principal of the former are La Valetta, Citta Vittoriofa, Senglea, Barmola, Citta Nuovo Cottonera, and Malta. The coaft is for the moft part fecured by fhelves and perpendicular rocks, without one port or fafe road for fhips; but on the eaft and weft fhores there are feveral commodious harbours. The two moft confiderable are thofe on the S. E. fide, one called Marza Murzet, and the other Marza, which fignifies *port*, and is the largeft of the two. They are divided by an oblong peninfula, on which is built a ftrong fort or caftle, called St. Elmo, which defends the entrance into both. Within that of Murzet lies a fmall ifland, near which the fhips fufpected of infection are obliged to perform quarantine. Thofe places which are acceffible are defended by fortifications of great ftrength, fo that it would be very difficult to reduce it by force. Mortars, the mouths of fome of which are fix feet wide, are cut out of the rocks near the different creeks, where a debarkation might be attempted. Confiderable quantities of fea-fhells and fifhbones petrified are found all over the ifland, even in parts moft elevated and remote from the fea.

During fummer Reaumur's thermometer is generally below 25°, and feldom above 28°, or from about 88° to 95° of Fahrenheit. In the winter it is feldom lower than 8° below zero of Reaumur's, or 14° of Fahrenheit. The alternate changes from heat to cold are often very fudden. Cold is occafioned by the north and north-weft winds; and a fouth wind brings heat. This wind, paffing over the barren fultry continent of Africa, is dangerous, but is of no long duration, and frequently fucceeded by a calm, during which the heat is fuffocating. Whilft the firocco continues, iced beverages are copioufly ufed; and, therefore, fnow is confidered at Malta as one of the neceffaries of life. It is brought from Sicily, and adminiftered to the fick; and whenever there is a fcarcity, all that remains in the ice-houfe in entirely referved for the ufe of the hofpitals. Cold bathing is alfo fuccefsfully ufed as a prefervative againft the ill effects of the firocco.

This ifland has often changed its mafters. Its original inhabitants were the Phæacians, who were expelled by the Phœnicians, and thefe again by the Greeks. It next became fubject to the Carthaginians, and they were fucceeded by the Romans, who eftablifhed in it a prefect, as he is called in the Acts of the Apoftles, ch. xxviii. 7, and this prefect was dependent on the prætor of Sicily. Upon the declenfion of the Roman empire, it fell under the dominion of the Goths, and afterwards of the Saracens. Roger, the Norman, earl of Sicily, took poffeffion of it about the year 1190; and from that time it continued under the dominion of the kings of Sicily, till it fell under that of Charles V., by his conqueft of Naples and Sicily, who gave it in 1525, by a grant which was ratified by the pope in 1530, to the knights of Rhodes, afterwards of Malta. (See the next article.) Charles V. was induced to make this grant by an ambition of becoming the reftorer and fecond founder of an order, which for many ages had been devoted to the defence of Chriftians, and alfo by the hope of thus protecting the ifles of Sicily and Sardinia, the kingdom of Naples, and the coafts of Italy from the incurfions of the infidels; ftipulating with the knights that they fhould maintain a perpetual war againft the Turks and Corfairs. Thefe knights, after their eftablifhment in Malta, fortified the ifland. Solyman, incenfed by obferving that his fhips were conftantly expofed to the attacks of enemies, which he had, in his own imagination, deftroyed when he drove them from Rhodes, determined, in 1565, to make an attempt againft Malta. For this purpofe he fent 30,000 men againft the town of Malta, which was defended by 700 knights and 8000 foldiers, under the command of the grand mafter John de Valette, at the age of feventy-one years. When fome of his friends faw that their brave commander was wounded, they intreated him to retire; but he replied, "At feventy-one, can I finifh my life more glorioufly than by dying with my brethren?" After having fuftained a fiege of four months, they were relieved by a force of 6000 men, fent from Sicily to their fuccour, and the Turks were compelled to raife the fiege.

Hence this town obtained the name of "Citta Vittoriofa," which it retains to this day: La Valetta was built by La Valette, and called after his name. One of his fucceffors made a magnificent aqueduct in 1616, to bring water to this new city; and others conftructed various works of importance to the fafety of the place. When the town was finifhed, the convent and habitation of the knights were removed hither. That the work might not be interrupted, when money failed, they paid in copper, which was afterwards called in at its full value. The infcription on it was, "Non æs fed fides," not money but loan. In procefs of time this ifland maintained itfelf againft the whole Ottoman power; but the order was never rich enough to attempt foreign conquefts, nor to equip numerous fleets. They were, however, as liberal as they were brave in affifting their neighbours, and alfo in defending themfelves againft the Turks and the Corfairs of Algiers and Tripoli. In the year 1724, a truce was concluded with the Turks for twenty-one years, fubject to renewal if both parties fhould think proper. While it continued, the Maltefe were to enjoy in the ftates of the grand feignior the fame privileges as the French. They alfo ftipulated for the exchange and ranfom of flaves. The fultan agreed not to give any affiftance to the ftates of Barbary; and the treaty was to be void when any of the Chriftian princes were at war with the Porte. In 1798 the ifland furrendered to the French, and the knights were difperfed; and in September 1800, it was taken by the Britifh, who retained the poffeffion of it. The principal difadvantages, fays Barrow (Travels in Southern Africa, vol. ii.), that would refult to England by leaving Malta in the poffeffion of the French, appear to be, in the firft place, the power it would give them of excluding our fhips from that port, undoubtedly the beft in the Mediterranean, and of increafing their forces here to the complete deftruction of our Mediterranean trade; and, fecondly, the means it affords of facilitating their views upon Egypt, by enabling them to throw into that country a force fufficient to renew their project upon India. See the next article.

Before the knights took poffeffion of that ifland, it was fo barren and uninviting, that when Charles V. offered it to them, they fent commiffaries to examine, and after their report, they could hardly be induced to accept the grant. But by fubfequent exercifes of fkill and induftry, they have

 effected

effected a furprifing alteration, not only in its means of defence, but in its internal cultivation. The capital of the ifland is "La Valetta," or Citta Nuova, which is fituated on the eaft coaft, and was founded, as we have already obferved, in 1566, on an elevated peninfula, having at its extremity the caftle of St. Elmo. This town contains the palace of the grand mafter, the arfenal, the infirmary, the church of the prior of St. John, and hotels for the knights of different languages. On either fide of the peninfula is a good harbour. "Citta Vittoriofa" is a fortified town on a narrow point of land that projects into the Marza, or great harbour, oppofite to Valetta, and is defended by the ftrong caftle of St. Angelo, ftanding on a high rock, and communicating with the town by a bridge. In this town was the palace of the inquifition, an arfenal, and a lodgment of flaves; the Greeks have alfo a church here. "Senglea," or the ifle of St. Michael, is a confiderable town on a peninfula, feparated from Citta Vittoriofa by the canal Porto della Galere, and joined to the harbour by the canal Porto della Rennella. But we muft not confound this Malta with old Malta, called "Citta Vecchia." Melita, or Medina, the capital, was a confiderable town previous to the arrival of the knights of Rhodes; it is now a fmall fortified place and bifhop's fee, containing a cathedral and feveral religious houfes, on an eminence near the centre of the ifland. In its vicinity are extenfive catacombs, which form a labyrinth. "Barmola" is a little town of 700 houfes behind Senglea. "Citta Nuovo Cottonera" is a regularly fortified town, including the old fort of St. Margherita. The five towns above enumerated, may be confidered as portions of one large city, feparated from each other by havens, and containing 20,000 inhabitants. The houfes are built of ftone, flat-roofed, and covered with plaifter. The harbours are capable of receiving whole fleets; and, as the fituation is naturally ftrong, no art is wanting to render the fortifications impregnable.

"Forte di S. Thomaffo" ftands on a point of land projecting into the fea, about two miles S.E. of the capital, "Malta." "Forte Roffo" ftands on a peninfula oppofite to the ifland of Comino.

The climate of Malta is not infalubrious: the exceffive heat being mitigated by the wefterly and north-wefterly winds. Although there are no rivers in the ifland, there are interfperfed fome excellent fprings of frefh water; but where thefe fail, the people are forced to dig wells in the rock. Their towns are commonly fupplied by rain-water, which they preferve in cifterns. Fuel is very fcarce, as there is little wood upon the ifland; fo that the common people are under a neceffity of ufing dried cow-dung or wild thiftles to drefs their meat, heat their ovens, and warm their apartments in cold weather. Although pafturage is fcarce, they breed here a great number of fheep and goats, whofe flefh is exquifite, as they chiefly feed on aromatic plants that grow on the rocks. Here are hogs in abundance, and good affes, mules, and fome horfes that are fed with barley and chaff. The poultry are large; thofe of the wild kind, particularly partridges, come from other countries in large flights, efpecially in the months of March and October.

The Maltefe refemble the inhabitants of Barbary; and their language is nearly the fame, being the old Punic or Arabic, which is very differently fpoken in different places. But in the city of Valetta and among perfons of rank the language moft in ufe is the Italian. The natives are induftrious, active, economical, and brave; but they are mercenary, paffionate, jealous, fuperftitious, and vindictive. Their drefs in general confifts of a cotton fhirt, a veft, a cloak, with a girdle round the waift. They alfo wear trowfers, and a fort of fhoes called "korch," which is merely a leathern fole, with ftrings to faften it round the leg. Their cap is white or coloured. They are remarkably temperate; a clove of garlic, or an onion, anchovies dipped in oil, and falted fifh, being their ufual diet. On great feftivals they eat pork.

Their principal trade is in cotton; of which a great quantity is annually exported. The imports are corn, cloth, wood, oil, wine, brandy, &c. As they are feldom without cruifers at fea, their captures of the Turkifh and Barbary corfairs conftitute the principal branches of their commerce; for they are thus able to furnifh Sicily and other parts of the Levant, with fpices, fugar, and other commodities, in return for which they bring back grain, pulfe, flefh, both frefh and falted, wood, oil, falt, and other neceffaries. But the chief profit of thefe goes to the order, the native inhabitants having no other fhare than by the exchange they make of them with the produce of their own lands and induftry. The forces of the ifland, exclufive of the knights and thofe who belong to the order, confift of thofe who are able to bear arms, and who are in general robuft and well difciplined. They are obliged, at the firing of the fignal cannon three times, to appear under their proper ftandards, in all their martial accoutrements. Under the difcipline of the Maltefe knights, they are become expert in the ufe of fire-arms. They are alfo reckoned good horfemen. Every knight that has four fcudi *per* day is obliged to maintain a horfe for his own ufe and at his own charge. The number of gallies which the order furnifhes is greater or lefs, according to the exigence of the occafion. Thefe gallies are ftrongly built, well manned and commanded; having ufually each 100 warriors and 25 knights on board; and that, which is called the "Capitania," and carries the ftandard of the order, has moft commonly 30 knights. Befides thefe, they have a number of galleons, and other inferior veffels, the crews of which confift chiefly of flaves, of whom they have feldom lefs than two or three thoufand. All along the coaft the ifland is well garrifoned and fortified; and on the leaft appearance of danger, beacons are fet on fire on the high grounds, and thefe fignals are anfwered by the firing of the city guns; fo that the alarm is foon fpread through the whole ifland. The grand mafter has the whole revenue of Malta, as well as of Gozo, over which he is invefted with the fovereign power during his life. His revenues arife from a certain tax upon the ifland, and include the duties on falt goods imported and exported, and fuch like imports. Thefe, with fome additional perquifites, formerly amounted, *communibus annis*, to about 60,000 crowns. Boifgelin's Ancient and Modern Malta, &c. 3 vols. 4to.

Malta keeps accounts in fcudi of 12 tari, each taro being fubdivided into two carlini, 20 grani, or 120 piccioli. Thefe monies of account are valued both in filver money and copper money; meaning by copper money (not metal) but the current value of the coins of the ifland, and by filver money their value in foreign exchange. Silver money is to copper money as three to two. The gold coins are double, fingle, and half Louis-d'ors, coined by the grand mafter Rohan, at 20, 10, and 5 fcudi, copper or current money. The filver coins are ounces and half ounces, coined by the fame grand mafter, at 30 and 15 tari; fcudi and halves, at 12 and 6 tari; pieces of one, two, and four tari, all in current money. The real copper coins are tari, and pieces of 10, 5, 2½, and 1 grani. Spanifh quadruples pafs for 38¾ fcudi; Venetian fequins for 6 fcudi; Dutch ducats for 5⅓ fcudi; Sicilian ounces for 6¼ fcudi; Spanifh dollars

dollars for $30\frac{1}{3}$ tari; current or copper money. The fineneſs both of gold and ſilver is expreſſed in carats; but the gold is divided into 24 carats, and the ſilver into 12. Gold and ſilver are weighed by the pound of 12 ounces; the ounce is divided into 16 parts, or 32 trapeſi; and the trapeſo into 18 grani. This pound weighs 4888 Engliſh grains; ſo that 720 lb. or oz. of Malta is = 611 lb. or oz. troy. According to the rate of coinage, the double Louis-d'or is to weigh $\frac{23}{36}$ of an oz. of Malta, or $260\frac{1}{2}$ Engliſh grains; and the gold is to be $20\frac{1}{2}$ carats fine. The ounce or piece of 30 tari is to weigh $1\frac{1}{3}$ oz. of Malta, or $458\frac{1}{4}$ Engliſh grains, and the ſilver is to be 10 carats (or $\frac{10}{12}$ths) fine. The ſcudi and inferior ſilver coins are almoſt 9 carats, fine. The ſingle Louis-d'or is worth 19*s.* 8*d.* ſterling; the piece of 30 tari, or $2\frac{1}{2}$ ſcudi, is worth $53\frac{1}{3}$*d.* Thus the ſcudo current money is worth $21\frac{1}{3}$*d.* ſterling.

The commercial weights are the heavy and the light cantaro; the former conſiſting of 111 heavy rottoli, each of $2\frac{3}{4}$lb.; the latter of 100 light rottoli, each of $2\frac{1}{2}$ lb. The heavy cantaro is = 213lb. avoirdupois, and the heavy rottolo = $30\frac{1}{2}$ oz. do. The light cantaro = 175lb. avoirdupois; and the light rottolo = 28 oz. do.; 10lb. of Malta = 7lb. avoirdupois.

The meaſures are a ſalma of corn, nearly equal to an Engliſh quarter, or 64 ſalma = 63 Engliſh quarters: the caffiſo, a meaſure for oil, contains $5\frac{1}{2}$ Engliſh gallons. The canna, a long meaſure, is divided into 8 palmi, and is $922\frac{1}{2}$ French lines, or $81\frac{9}{10}$ Engliſh inches; hence 40 canna = 91 Engliſh yards. The foot of Malta is $11\frac{1}{6}$ Engliſh inches, and 72 feet of Malta = 67 Engliſh feet. The Sicilian weights and meaſures are likewiſe uſed here, for which ſee SICILY.

In 1808 the Sicilian dollar of $2\frac{1}{2}$ ſcudi or 30 tari was exchanged for $56\frac{1}{4}$ pence ſterling, in government bills in England at 30 days ſight. Kelly's Univerſal Cambiſt, vol. i. N. lat. 35° 42'. E. long. 14° 10'.

MALTA, a town of America, in Saratoga county, New York, taken from the weſtern part of Stillwater; four miles E. of Ballſtown ſprings.

MALTA, *Knights of*, an order of military religious, who have borne various other names; as Hoſpitalers of St. John of Jeruſalem, knights of St. John, knights of Rhodes, order of Malta, religion of Malta, &c.

About the year 1048, ſome Neapolitan merchants founded a church after the Latin rite at Jeruſalem, giving it the name of Santa Maria della Latina, or St. Mary of the Latins. They alſo founded a monaſtery of religious after the order of St. Bennet, for the reception of pilgrims; and afterwards an hoſpital near the monaſtery, to take care of the diſeaſed, under the direction of a maſter or rector, to be nominated by the abbot of Santa Maria della Latina. Beſides which, they alſo built a chapel in honour of St. John Baptiſt.

In 1099, Godfrey of Bulloign, having taken Jeruſalem, endowed this hoſpital with ſome demeſnes, which he had in France; and others imitating his liberality, the revenues of the hoſpital became conſiderably augmented. Upon this, Gerhard de Didier, a native of Provence, their rector, in concert with the Hoſpitalers, reſolved to ſeparate from the abbot and religious of Santa Maria, and to form a diſtinct congregation, under the name and protection of St. John Baptiſt: and hence it was that they had the name of "Hoſpitalers, or Brothers of St. John of Jeruſalem." Their habit was black; and they wore on their breaſts a white croſs of eight points, in token of the eight beatitudes.

Pope Paſcal II. by a bull in the year 1113, confirmed the donations made to this hoſpital, which he ſettled under the protection of the holy ſee; ordering, that the rectors, after Gerhard's death, ſhould be choſen by the Hoſpitalers. Raymond du Puy, Gerhard's ſucceſſor, took the title of "maſter;" and he gave a rule to the Hoſpitalers, which was approved by pope Calixtus II. in 1120. Such was the firſt riſe of the order of Malta.

Their firſt grand-maſter, finding the revenues of the hoſpital vaſtly to exceed what was neceſſary for the entertainment of poor pilgrims, and diſeaſed perſons, reſolved to employ the ſurplus againſt the infidels; and with this view he offered himſelf to the king of Jeruſalem.

He divided his Hoſpitalers into three claſſes; the firſt conſiſted of nobles, whom he deſtined to the profeſſion of arms, for the defence of the faith, and the protection of pilgrims; the ſecond conſiſted of prieſts or chaplains, who were to ſay maſs; and the third of ſervitors, who were not noble, but were alſo appointed for the war. He alſo regulated the manner of admitting knights brothers; and had the whole confirmed in 1130, by pope Innocent II. who commanded that the ſtandard of the knights ſhould be "gules, a full croſs argent."

After the loſs of Jeruſalem, they retired firſt to Margath, then to Acre, which they defended very vigorouſly in 1290. After the entire loſs of the Holy Land they withdrew to Cyprus, where king Henry of Luſignan, whom they had followed thither, gave them the city of Limiſſon. Here they continued eighteen years, when, taking the iſland of Rhodes from the Saracens in 1308, they ſettled there. And now it was that they firſt took the name of "knights," and ſoon after "knights of Rhodes."

Andronicus, emperor of Conſtantinople, granted to their grand maſter, Fulk de Villaret, the inveſtiture of this order, and the donation was confirmed by pope Clement. The year following, with the aſſiſtance of Amadeus IV. duke of Savoy, they defended themſelves, and their iſland againſt an army of Saracens. In 1480, their grand maſter d'Aubuſſon made a vigorous defence againſt Mahomet II. and preſerved the iſland in ſpite of a formidable army, which beſieged it for the ſpace of three months. But in 1522, it was attacked by Solyman II. with an army of 300,000 men, and taken by him, after having been in the poſſeſſion of the knights 213 years.

After this loſs, the grand maſter and knights retired firſt into the iſle of Candia. Some time after pope Clement VII. gave them Viterbo. Laſtly, Charles V. in 1525, gave them the iſland of Malta, which grant was confirmed by the pope in 1530: and hence they obtained the appellation of "knights of Malta;" though their proper name is that of "knights of the order of St. John of Jeruſalem;" and their grand maſter among his other titles, ſtill retains that of "maſter of the hoſpital of St. John," and "guardian of the poor of our Saviour Jeſus Chriſt." The badge of the order is a "gold croſs of eight points enamelled white, and worn by all the knights at their breaſt, pendant to a black ribbon." The knights of this order, whether novices or profeſſed, when they go to war with the Turks, wear over their coats "a red jacket or tabard, charged both before and behind with a great full white croſs, without points." See the preceding article.

The order of Malta have no other dominions beſides their iſland, and ſome other little places in the neighbourhood, the chief whereof are Gozo and Comino.

The government is both monarchical and ariſtocratical, the grand maſter being the ſovereign, and the chapter the ſenate. It is monarchical with regard to the inhabitants of Malta, and the iſles adjacent, and even with regard to the knights in every thing relating to the ſtatutes and rules of their

their order; and it is ariſtocratical with regard to the deciſion of any important affairs, which are not to be diſpatched but by the grand maſter and the chapter. There are two councils; the one ordinary, compoſed of the grand maſter, as chief, and the grand croſſes; the other complete, conſiſting of the grand maſter, the grand croſſes, and the two ſenior knights of each language.

By the languages of Malta are meant the ſeveral nations of which the order is compoſed. Of theſe, authors have reckoned eight, *viz*. Provence, Auvergne, France, Italy, Arragon, Germany, Caſtile, and England.

The pillar (as he has been called) of the language of Provence is the grand commander of the order; he of Auvergne the grand marſhal; he of France the grand hoſpitaler; he of Italy the grand admiral; he of Arragon grand conſervator, or draper, as he was anciently called; the pillar of the language of Germany is grand bailiff; and he of Caſtile grand chancellor; the language of England, which has been extinct ſince the time of the Reformation under king Henry VIII. had for its pillar or chief, the grand turcopolier, or colonel of the cavalry. The language of Provence is the firſt, on account of Gerhard, a native of Provence, or of Raimond du Puy, their firſt grand maſter, who was a Provençal.

In each language there are ſeveral grand priories, and capital bailiages. To each language belongs a hall, where the knights eat, and hold their ordinary aſſemblies. Each grand prior has a number of commanderies.

The commanderies are either magiſterial, or elſe by right, or, finally, by favour. The magiſterial are thoſe annexed to the grand maſterſhip, of which there is one in each grand priory: commanderies by right are thoſe which come by right of ſeniority; their ſeniority is computed from the time of their admiſſion; but they muſt firſt have lived five years at Malta, and have made four caravannes, or cruiſing voyages, on the Turks and Corſairs: commanderies by favour are thoſe which the grand maſter, or the grand prior, have a right of conferring; one of theſe they confer every five years on whom they pleaſe. The noble knights are called knights by right; and none but theſe can be bailiffs, grand priors, or grand maſters. Knights by favour are thoſe who, not being noble of themſelves, are raiſed on account of ſome great exploit, or ſome notable ſervice, into the rank of nobles.

The ſervitors, or ſerving-brothers, are of two kinds: 1. The ſervitors of war, whoſe functions are the ſame with thoſe of the knights. 2. The ſervitors of religion, whoſe whole buſineſs is to ſing the praiſes of God in the conventual church, and to officiate each in his turn as chaplain on board the veſſels and gallies of the order.

The brothers of obedience are prieſts, who, without being obliged to go to Malta, take the habit of the order, make the vows, and attach themſelves to the ſervice of ſome of the churches of the order, under the command of a grand prior, or commander, to whom they pay obedience.

The knights of majority are thoſe who, according to the ſtatutes, are admitted at ſixteen years of age. The knights of minority are thoſe who are admitted from the time of their birth; which, however, cannot be done, without a diſpenſation from the pope.

The chaplains can only be admitted regularly from ten to fifteen years of age: after fifteen they muſt have a brief from the pope; till fifteen, the grand maſter's letter is ſufficient. Theſe are called *diacos*, and muſt give proof of their being born of creditable families.

For the proofs of nobility to be made before the admiſſion of knights, in the language of Germany, they go back ſix generations; in the reſt, it is ſufficient to go back to the great grandfather on the father's or mother's ſide.

There are alſo female hoſpitalers of the order of St. John of Jeruſalem, ſometimes alſo called *chevalier eſſes*, or *ſhe-knights*, whoſe buſineſs was to take care of the women-pilgrims, in an hoſpital apart from that of the men. This order was inſtituted in the year 1107, by Agnes, abbeſs of the hoſpital of St. Mary Magdalene, who, with her companions, made profeſſion of the ſame rule, took the ſame habit, and bound themſelves to obſerve the ſame vows, as Gerhard de Didier had done in the year 1099. The badge of this order was the ſame with that of the knights of Malta.

Since treaties of alliance between Chriſtian and Infidel powers are now as common as between Chriſtian powers alone; and ſince the Barbary Corſairs are leſs formidable and injurious to commerce than they were formerly, the order of Malta, notwithſtanding its claim to the gratitude of European powers for a long, long ſeries of paſt ſervices, ſeems to have declined in importance and eſtimation.

Under the grand maſterſhip of Rohan, indeed, the poſſeſſions belonging to the order of St. Anthony were added to thoſe of Malta; ſeveral commanderies, ſituated in Poland, were reſtored; and a new language was inſtalled, the Anglo-Bavarian; to which was afterwards united the grand priory of Ruſſia, created by the emperor Paul, who, enamoured of chivalrous exploits, and well aware of the commercial and political advantages which Ruſſia would derive from the poſſeſſion of Malta, aſſumed the title of protector of the order, and was inveſted, together with the whole imperial family, with the grand croſs of Malta.

Nevertheleſs, the European powers were very indifferent as to the independence of the order.

That the legiſlative aſſembly of France ſhould paſs a decree, annulling the order of Malta, was not matter of ſurpriſe: it was the natural conſequence of a previous law, that every Frenchman, who was a member of any order of knighthood which required proofs of nobility, ſhould no longer be regarded as a French citizen. Nor can it be matter of ſurpriſe that, by the ſame decree (Sept. 19, 1792), all its property ſhould be annexed to the demeſnes of France. The original hoſpitalers, and the firſt knights were Frenchmen; out of the eight languages France had three, beſides commanderies ſituated in Alſace, Rouſillon, and French Navarre, which were all dependencies of the two languages of Germany and Arragon. The confiſcation of all this property was quite conſonant with the prevaling atrocious ſyſtem of revolutionary policy and morals. The enormous deficit which this plunder occaſioned, ought to have excited the compaſſion, if it had not called forth the generoſity, of other ſtates; inſtead of which we find the order aſſeſſed to ſupport the coalition againſt France. Thus, between two armies, the knights of Malta bear the blows of both! The Spaniſh and Portugueſe commanderies, which had never before paid any taxes to their reſpective governments, were now called upon for a tenth of their revenue; thoſe in the kingdom of Naples and in Sicily were ſubjected to heavier ones; and the order was treated ſtill worſe in Piedmont, where part of the property of the knights of Malta was ordered to be ſold.

The revenue of the order in the year 1788 amounted to 3,156,719 French livres, and the expenditure to 2,967,503, leaving a ſurplus of 189,216. To the confiſcation of its property in France, yielding an annual revenue of 1,392,974 livres, and its taxation by different ſovereigns in ſupport of the war againſt France, muſt be added the enormous loſs which the treaſury ſuſtained by the depreciation of paper money, when it became neceſſary to realize the revenues due

due from Spain and part of Italy. The left bank of the Rhine being ceded to the French by the treaty of Campo Formio, the order was deprived of all its property in these four new departments; and the different new republics, formed on every side, successively robbed it of what it possessed in Helvetia, and the Ligurian and Cisalpine republics. Malta, by these accumulated losses, was deprived of two-thirds of its revenue. It was compelled to borrow to the amount of six millions of livres; and at last its credit was fallen so low, that no one could be found to advance more. In the year 1796, the plate belonging to the men of war and to the gallies was melted down, and coined into money, as was also part of the grand master's, together with some of that employed for the use of the sick in the hospital. It was very evident, therefore, that this noble order, which for seven hundred years had been the terror of infidels and the bulwark of Christendom, was no longer held in that estimation and respect by the European potentates, which the remembrance of its valorous achievements might have been expected to inspire. Russia, under Paul I., certainly manifested a desire to afford Malta relief: the order also expected the payment of about a hundred thousand crowns from Spain, which most unfortunately did not arrive till a few days after the French had landed in the island, and which, of course, became a prey to them.

Notwithstanding the low state of the finances, Malta, at the time the French fleet made its appearance, was perfectly able to have made a formidable resistance against any attempt at landing; and if a landing had been effected, a still more powerful defence of the city Valetta. "Never to reckon the number of the enemy" made a part of the oath of every knight, on his admission into the order; and "to die at his post was a first principle of honour." The bulwarks of the island were master-pieces of fortification, and if the knights and the Maltese had been as faithful to themselves and to each other as at the siege by Solyman, Bonaparte would have retired from this rock of resistance abashed, confounded, and defeated. The treacherous surrender of the island gives an ample verification to the statement of the Maltese deputies: "The defection," say they, "and treason of which the order was guilty, will form an epoch in the annals of the world as striking as that by which we are again thrown under its despotic dominion, after it had abandoned us to an army unfaithful to all its promises and engagements."—"No one is ignorant that the plan of the invasion of Malta was projected in Paris, and confided to the principal knights of the order, resident at Malta. Letters in cyphers were incessantly passing and re-passing, without, however, alarming the suspicions of the deceased grand master de Rohan, or of the grand-master Hompesch." On the evening of the 9th of June, 1798, the French landed their troops at Magdalen creek, and on their approach "one single cannon shot" was fired from fort St. George! At day-break their shallops were seen advancing towards seven different points, Gozo, Cumino, La Mallcha, Salmon, St. George, St Julian, and La Trombrella, none of which made any resistance, except Goza, which was attacked by general Regnier, and defended by the commander de Megrjny. A dreadful scene of slaughter ensued: the Maltese people fought with a two-edged sword; they attacked the invaders with valour, and slew, without discrimination, the knights of the order, by whose treachery they had been suffered to effect a landing. That some among the Maltese were deluded by the promises universally lavished by the French, of liberty, equality, &c. cannot be doubted; but by their subsequent conduct it is fully proved, that the bulk of the people were most determinedly hostile to the admission of the French, and that their detestation of the order was inexpressibly increased by a detection of its treachery on this occasion. When Bonaparte set sail, some of the knights actually enlisted under his banners!

It is unnecessary to give an account of the conduct of the French on their possession of Malta: every thing in the public buildings, "which bore the stamp of nobility, or recalled to mind the celebrated exploits performed by illustrious chiefs, was broken and destroyed." The arms of the order, together with those of the principal chiefs, were effaced not only in the principal inns, but in the palace of the grand master, himself being present on the occasion! The knights who were not in the French interest, were ordered to quit the island in three days, and a disgraceful salary was voted to Hompesch, as an equivalent for the property annexed to the grand mastership. The knights who were attached to the French interest had but little reason to applaud the wisdom of their political speculations: exposed to the rage of the Maltese, and unprotected by their new friends, they were shut up in different fortresses, some fled, some absolutely perished from want, and all were despised and hated.

They who remained faithful to their duty were scattered in different places. Hompesch retired to Trieste, separated himself from the companions of his flight, and resigned the office of grand master, which he had so ingloriously filled. Many retired to the dominions of the emperor of Russia, who took upon himself the title of grand master, and created a new Russian priory for the benefit of the nobles in his dominions, who followed the rites of the Greek church.

Notwithstanding the flight of Hompesch, and the knights who accompanied him, and notwithstanding the treachery of those apostate members of the order who remained behind, attached to the provisional government established in the island by the French, the brave inhabitants rose in arms against their invaders, who were shut up within the gates of Valetta, without daring to issue forth and face the terrible vengeance of the people. The blockade of Malta by the English lasted two years; namely, from September 2, 1798, to September 4, 1800, when the city surrendered. The situation of the city was so deplorable from the alarming mortality among the troops and inhabitants, arising doubtless from the scarcity of provisions, that a surrender appeared absolutely certain. In September, 1799, a fowl, which before the blockade, used to sell for *6d* sold for from *2l. 3s.* to *2l. 10s.* English; a pigeon was worth *10s.*; a rabbit about the same; a *rat* from *1s.* to *1s. 6d.*; fresh pork sold for *7s.* a pound, and cheese for the same. The flesh of mules and asses was in such request, that the people complained bitterly whenever they were deprived of it. The French, however, raised vegetables, bred poultry, rabbits, &c.; and, under the vigilance and unceasing encouragement of their general Vaubois, contrived, as much as possible, to relieve their wants and support their spirits. The garrison was put upon half-pay in the month of August; in the following December it was entirely stopped, as was their allowance of wine and brandy. To the honour of the French troops, for it is impossible to contemplate such conduct without admiration, not a murmur was heard, and during a whole twelve-month there were scarcely twenty deserters, and the greatest of these were either volunteers or sailors! The situation of the inhabitants now became every day more and more disastrous; and such were the effects of poverty, disease, and frequent emigration, that of 40,000 souls in September 1798, there only remained 13,000 in 1799: these were reduced to 10,000 in the following October, and to 7500 in March 1800. In the last period

period of the blockade provisions rose to an incredible price: a bottle of oil sold for a guinea, a pound of coffee for 2*l.* 8*s.* and a pound of sugar for a few shillings less; asses, mules, horses, dogs, and cats, were almost all consumed; and general Vaubois was at last compelled, by famine, to propose terms of capitulation. He received from the English such as were due to so persevering and courageous a resistance, and such at the same time as proved that Britons pay just homage to the bravery of an enemy. The native Maltese were the only party who had reason to complain of the capitulation, and still greater of the treaty of Amiens, which again consigned them to the order which had given such irrefragable proofs of cowardice and treachery.

By the treaty of peace between Great Britain and the French republic, concluded at Amiens 27th March 1802, it was stipulated, that the islands of Malta, Gozo, and Cumino, should be restored to the order of St. John of Jerusalem, to be held on the same conditions on which it possessed them before the war, and under the following stipulations. 1. The knights of the order, whose languages shall continue to subsist after the exchange of the ratification of the present treaty, are invited to return to Malta as soon as the exchange shall have taken place. They will there form a general chapter, and proceed to the election of a grand master, chosen from among the natives of the nation which preserve their language, *i. e.* a right of election, as belonging to a particular Catholic nation, unless that election has been already made since the exchange of the preliminaries. It is understood that an election made subsequent to that epoch, shall alone be considered valid, to the exclusion of any other that may have taken place at any period prior to that epoch. 2. The governments of the French republic, and of Great Britain, desirous to place the island and order of Malta in a state of entire independence with respect to them, agree that there shall not in future be either a French or English language, and that no individual belonging to either the one or the other of these powers shall be admitted into the order. 3. There shall be established a Maltese language which shall be supported by the territorial revenues and commercial duties of the island. This language shall have its peculiar dignities, an establishment, and an hotel. Proofs of nobility shall not be necessary for the admission of knights of this language; and they shall be moreover admissible into all offices, and shall enjoy all privileges, in the same manner as the knights of other languages. At least half of the municipal administration, civil, judicial, and other employments depending on the government, shall be filled by inhabitants of the islands of Malta, Gozo, and Cumino. 4. The forces of his Britannic majesty shall evacuate the island and its dependencies, within three months from the exchange of the ratifications, or sooner if possible. At that epoch it shall be given up to the order in its present state, provided the grand master or commissaries, fully authorized according to the statutes of the order, shall be in the island to take possession; and that the force which is to be provided by his Sicilian majesty, as is hereafter stipulated, shall have arrived there. 5. One-half of the garrison at least shall be always composed of native Maltese; for the remainder the order may levy recruits in those countries only which continue to possess the languages. The Maltese troops shall have Maltese officers. The command in chief of the garrison, as well as the nomination of the officers, shall pertain to the grand master; and this right he cannot resign, even temporally, except in favour of a knight, and in concurrence with the advice of the council of the order. 6. The independence of the isles of Malta, Gozo, and Cumino, as well as the present arrangement, shall be placed under the protection and guarantee of France, Great Britain, Austria, Spain, Russia, and Prussia. 7. The neutrality of the order, and of the island of Malta, with its dependencies, is proclaimed. 8. The ports of Malta shall be opened to the commerce and navigation of all nations, who shall there pay equal and moderate duties; those duties shall be applied to the cultivation of the Maltese language, as specified in paragraph 3; to that of the civil and military establishments of the island; as well as to that of a general lazaretto, open to all ensigns. 9. The states of Barbary are excepted from the conditions of the preceding paragraphs, until, by means of an arrangement to be procured by the contracting parties, the system of hostilities which subsists between the states of Barbary and the order of St. John, or the powers possessing the languages, or concurring in the composition of the order, shall have ceased. 10. The order shall be governed, both with respect to spirituals and temporals, by the same statutes which were in force when the knights left the isle, as far as the present treaty shall not derogate from them. 11. The regulations contained in the paragraphs 3, 5, 7, 8 and 10, shall be converted into laws and perpetual statutes of the order, in the customary manner: and the grand master (or if he shall not be in the island at the time of its restoration to the order, his representative), as well as his successors, shall be bound to take an oath for their punctual observance. 12. His Sicilian majesty shall be invited to furnish 2000 men, natives of his states, to serve in garrison of the different fortresses of the said islands. That force shall remain one year, to bear date from the restitution of the knights; and if, at the expiration of this term, the order should not have raised a force sufficient, in the judgment of the guaranteeing powers, to garrison the island and its dependencies, such as is specified in the paragraph, the Neapolitan troops shall continue there until they shall be replaced by a force deemed sufficient by the said powers. 13 The different powers designated in the sixth paragraph, *viz.* France, Great Britain, Austria, Spain, Russia, and Prussia, shall be invited to accede to the present stipulations.

The Maltese remonstrated in spirited and indignant terms against that portion of the treaty of Amiens which consigned their island to the order: and demanded that it might be restored to them; or that the expences they had incurred might be paid to them, or that they might be indemnified for the losses occasioned by the war, and by the plunder of the French. They then contest the title of the knights to the possession of the island, and placing, as they state their case, a full reliance in the sincerity of the British government, and in the faith of the British nation, the Maltese were more desirous of becoming subjects of the king of England, and of enjoying all the advantages of free subjects of a monarch, who is the father of all his people, than to assert and maintain their own independence; but never did they suspect, nor can they now for a moment believe, that, violating all the laws of justice, divine and human, they are to be forcibly delivered up by their auxiliary allies, as a conquered people, or as vile slaves sold for a political consideration to other masters, to masters, "whose tyranny, extortion, and sacrilege, have rendered them the execration of every virtuous mind, and to whom, whatever horrible calamity may ensue, the Maltese nation will never submit." The representation proceeds to assert, that if the island were again delivered up to the order, it would virtually be in the hands of the French, since they are not (even including those of the new Anglo-Bavarian language), more than a *thirtieth* part of the knights who are not at the blind disposal of France. Indignantly is it observed, "if the knights of the order, in possession of an independent sovereignty and revenue, enjoying every ease and pleasure that imagination can form, engaged in objects of luxury, careſſed and reverenced as ſo many ſovereigns; if in this condition the French could command them to quit their terreſtrial paradiſe, to wander in the wide world, and could induce them to become partiſans of their cauſe, what muſt not the power of the ſame French over them be, dependent, degraded, diſhonoured, reduced to beggary, in whom is extinct every ſpark of honour, and who have been guilty of the blackeſt, the moſt horrible infidelity, apoſtacy towards their God, and violation of the ſacramental ordinances?"—"With reſpect to the guarantee of this or that power, but too well is our iſland acquainted with the French and the order, not to be convinced of the fallibility of ſuch a propoſition. The firſt war, whether of length or ſhort duration, puts an end to it entirely. If ever a third power were to occupy ſome parts of the fortreſſes, the troops would be corrupted by French money and French principles; and immenſe are the ſums that would be expended for that purpoſe. The military poſts are dependent one upon the other. We are able to point out," ſay the repreſentatives, "the utter impoſſibility of occupying a part, without the whole. We can clearly demonſtrate how they can, and will obtain their ſeveral ends. We can make it evident, that there is no ſecurity for the inhabitants, unleſs Britiſh troops are placed in poſſeſſion of all the fortreſſes, and unleſs the adminiſtration of juſtice is placed in the hands of a Britiſh civil government." Boiſgelin's Anc. and Mod. Malta.

MALTA, or *Medina*. See CIVITA *Vecchia*, and MALTA, *ſupra*.

MALTA *Earth*, in the *Materia Medica*. See MELITENSIS *terra*.

MALTEPEC, in *Geography*, a town of Mexico, in the province of Mechoacan; 60 miles E.S.E. of Mechoacan.

MALTESE, in *Biography*. The proper name, the birthplace, and the education of the ingenious painter who bears this appellation, are alike unknown; but his works, which conſiſt chiefly of objects in ſtill life, are valued for their exhibition of freedom, boldneſs, and truth. They are generally compoſed of fruit, carpets, jewellery, ſhells, tapeſtries, &c. to which, by a judicious management in their compoſition, a brilliant colour, and a ready and powerful touch, he produced a ſtrong and brilliant relief; and often a moſt enchanting effect of chiaro-oſcuro.

MALTHA, Μαλθα, in *Antiquity*, denotes any cement, or glutinous body, which has the faculty of binding things together. See *Calcareous* CEMENT.

Ancient writers make mention of divers ſorts of maltha, native and factitious; one of the latter much in uſe was compoſed of pitch, wax, plaſter, and greaſe.

Another kind, with which the Romans plaſtered and whitened the inſides of their aqueducts, was made of lime ſlaked in wine, incorporated with melted pitch, and freſh figs.

Natural maltha is a kind of bitumen, called "mineral pitch," with which the Aſiatics plaſter their walls. When this is once ſet on fire, water will not quench it; but ſerves rather to make it burn more fiercely. See BITUMEN.

MALTHA, in *Ichthyology*, the name of a voracious fiſh of the ſhark kind, called the *ſorrat*, and the *lamiola* by ſome authors, a diminutive of *lamia*, ſignifying a ſmall ſhark. Its teeth are broad and pointed, like thoſe of the ſhark; the fiſh has alſo many rows of theſe; the noſe is ſhort, and its fleſh lax and ſoft. See SQUALUS.

MALTHOCODE, a term by which the Greek writers expreſs the emollient topical remedies prepared with oil. Hippocrates expreſsly forbids the uſe of theſe in old ulcers.

MALTON, or NEW MALTON, in *Geography*, a borough and market-town in the wapentake of Ryedale, North Riding of the county of York, England, is ſituated 18 miles diſtant from York, and 217 from London, on an eminence overlooking the river Derwent, which runs through a beautiful vale on the ſouth-eaſt ſide of the town. Malton was of ſome note in the Saxon times. Immediately before the Norman conqueſt, it was poſſeſſed by a nobleman named Colebrand, from whom it was taken by the Conqueror, who gave it to Gilbert Tyſon, one of his followers. In the reign of Henry I., Euſtace St. John poſſeſſed this lordſhip by inheritance from his mother, who was grand-daughter and heireſs of Gilbert Tyſon. In the conteſt between the empreſs Maud and king Stephen, the town was reduced to aſhes. It was rebuilt by Euſtace, and then acquired the name of New Malton. In the reign of James I., Ralph, lord Eure, who was then in poſſeſſion of the manor, built a magnificent houſe here: but leaving no iſſue, his eſtates came to his uncle William, lord Eure, who left two daughters, coheireſſes. Theſe diſagreeing about this noble manſion, it was, after a tedious and expenſive litigation, determined that it ſhould be pulled down, and its materials divided: and ſo ſcrupulouſly was the diviſion made, that the "ſtones were even ſhared one by one." But it ſeems that ſome compromiſe took place before the dilapidation was completed, as the lodge in the front, with three arched gateways, are yet ſtanding. The manor was afterwards conveyed to ſir Thomas Wentworth, and from him deſcended to Thomas, marquis of Rockingham, who was ſucceeded in titles and eſtates by his ſon Charles, the late marquis; after whoſe death, the eſtates devolved on his nephew, earl Fitzwilliam.

Malton is about half a mile in length from eaſt to weſt. The entrance at the eaſt end is by a ſpacious ſtone-bridge over the Derwent, whence the principal ſtreet riſes with a continued, but gentle aſcent through the town. The houſes are moſtly built of ſtone; and in the year 1801 were in number, according to the population ſurvey, 604, and were occupied by 3047 perſons. The town comprizes two pariſhes, St. Michael's and St. Leonard's; each having its reſpective church: the ſpire of the latter has a ſingular appearance. Malton is a borough by preſcription, and has ſent two members to parliament ever ſince the 23d year of Edward I.; the right of election being veſted in the holders of about 100 burgage tenures. The town is governed by a bailiff. Markets are held on Tueſdays and Saturdays; and a briſk trade is carried on in corn, of which a great quantity is ſent into the weſtern parts of Yorkſhire, and to ſeveral other places. The Derwent is navigable to Malton, where the quantity of corn ſhipped in the year 1796 amounted to 56,065 quarters. Here are three annual fairs, which exhibit a great ſhow of horſes and cattle, and are much frequented by farmers, graziers, and horſe-dealers. Hinderwell's Hiſtory of Scarborough. Beauties of England and Wales, vol. xvi. by John Bigland.

MALTOY, a town of Hindooſtan, in Goondwana; 60 miles N.W. of Nagpour. N. lat. 21° 45'. E. long. 78° 58'.

MALTRA, a town of Sweden, in Angermanland; 42 miles N.N.W. of Hernoſand.

MALVA, in *Botany*, is thought by Ambroſinus to have obtained its name from *mollis*, alluding to the ſoothing or emollient qualities with which it is endued. The ancients reckoned it an excellent ſtomachic, frequently mixing it with *Lactuca* in their ſallads. Its Greek name μαλαχη is of ſimilar origin, being derived from μαλασσειν, *to ſoften*. Horace, as every body knows, ſpeaks of "*leves malvæ*," apparently meaning light of digeſtion; and Martial ſays, "Utere lactucis, et mollibus utere malvis." Linn. Gen. 354. Schreb. 466. Willd. Sp. Pl. v. 3. 774. Mart. Mill.

Mill. Dict. v. 3. Sm. Fl. Brit. 740. Ait. Hort. Kew. ed. 1. v. 2. 446. Juff. 272 Lamarck Illuftr. t. 582. Gærtn. t. 136.—Clafs and order, *Monadelphia Polyandria*. Nat. Ord. *Columniferæ*, Linn. *Malvaceæ*, Juff.

Gen. Ch. *Cal.* Perianth double, inferior; the outer generally narrower, of three ovate or heart-fhaped, acute, permanent leaves; the inner of one leaf, five-cleft half way down, larger, broader, permanent. *Cor.* Petals five, obcordate, abrupt, flat, fixed by their bafe to the tube of the ftamens. *Stam.* Filaments numerous, united below into a tube, feparate and loofe at the top, and along the furface; anthers kidney-fhaped. *Pift.* Germen fuperior, orbiculate, depreffed; ftyle cylindrical, fhort; ftigmas many, briftly, as long as the ftyle. *Peric.* Capfule roundifh, compofed of the fame number of two-valved cells as there are ftigmas, placed in a whorl about a columnar receptacle; finally deciduous. *Seeds* folitary, occafionally two or three, kidney-fhaped.

Eff. Ch. Calyx double; the outermoft of three leaves. Capfules numerous, circularly arranged. Seeds moftly folitary.

Obf. Schreber remarks that fome fpecies have only two leaves to the outer calyx, and that in *M. caroliniana* each capfule is divided into two cells by a tranfverfe membrane.

This extenfive genus furnifhes many ornamental plants, though chiefly of exotic growth. We felect the following fpecies to illuftrate its hiftory. Linnæus has defined only twenty-fix in the 14th edition of his *Syftema Vegetabilium*. Profeffor Martyn however has thirty-four, and Willdenow defcribes fifty-five. They are arranged under two fections, namely, fuch as have undivided leaves, and fuch as have angular leaves, all our three native Mallows belonging to the latter fection.

Sect. 1. *Leaves undivided.*

M. *fpicata*. Spiked Mallow. Linn. Sp. Pl. 967. (Althæa fpicata, betonicæ folio villofiffimo; Sloan. Jam. v. 1. 219. t. 138. f. 1.)—Leaves ovate or heart-fhaped, notched, downy. Spikes oblong, hairy.—A native of barren, rocky lands in Jamaica, flowering in September and October. *Stem* two or three feet high, pale green, branched. *Leaves* roundifh, on footftalks, pale green and fmooth. *Flowers* in fpikes at the fummits of the twigs and branches, orange-coloured.

M. *fcoparia*. Small yellow-flowered upright Mallow. Willd. n. 4. L'Herit. Stirp. t. 27. Jacq. Ic. Rar. t. 139.—Leaves ovate, notched or ferrated. Flowers axillary, crowded together. Stem fhrubby.—A native of Peru, difcovered near Lima by Dombey, flowering late in the fummer. The inhabitants of Spanifh America make brooms of its branches, whence the fpecific name. *Stem* about fix feet high, upright, round, fmoothifh, much branched. *Leaves* rather drooping, fomewhat heart-fhaped, acute, entire at the bafe, downy, rugged, pale green. *Flowers* on fhort ftalks, of a yellow colour fpotted with red.

Sect. 2. *Leaves angular.*

M *fylveftris*. Common Mallow. Linn. Sp. Pl. 969. Engl. Bot. t. 671. Curt. Lond. fafc. 2. t. 51. Woodv. Med. Bot. t. 54.—Stem upright, herbaceous. Leaves with feven fharpifh lobes. Leaf-ftalks and flower-ftalks hairy.—By hedges and paths both in cultivated and wafte ground all over England, flowering from May to September.—*Root* perennial, fpindle-fhaped, branched, whitifh. *Stem* generally erect, branched, round, hairy, many-flowered. *Leaves* alternate, on footftalks, heart-fhaped, folded, feven-lobed, roughifh, notched; the upper ones nearly palmate. *Stalks* crowded together, hairy, fingle-flowered. *Flowers* reddifh-purple or lilac-coloured, veined with a deeper tinge; petals obcordate, thrice as long as the *calyx*, which is hifpid. "The whole herb," fays Dr. Smith, "efpecially the root, abounds with a pure mucilage, and poffeffes the emollient qualities of the Marfh Mallow, *Althæa*, though perhaps in an inferior degree. It has, however, the advantage of being much more common, and within every body's reach."

M. *rotundifolia*. Dwarf Mallow. Linn. Sp. Pl. 969. Engl. Bot. t. 1092. Curt. Lond. fafc. 3. t. 43.—Stems proftrate. Leaves roundifh heart-fhaped, five-lobed. Fruit-ftalks bent downwards.—Common in wafte ground, flowering copioufly from June to September. *Root* annual, branched, whitifh, mucilaginous. *Stems* numerous, proftrate, almoft fimple. *Leaves* fmaller than in *fylveftris*, five or feven-lobed. *Flowers* flefh-coloured. A variety of this is fometimes found with fmaller petals, indeed not longer than the calyx. This was confidered as a diftinct fpecies by Mr. Hudfon, who called it *parviflora*, and Dr. Smith figured it in Engl. Bot. t. 241, under the name of *pufilla*, but he afterwards was fatisfied of its being a mere variety of *M. rotundifolia*.

M. *mofchata*. Mufk Mallow. Linn. Sp. Pl. 971. Engl. Bot. t. 754. Curt. Lond. fafc. 4. t. 50.—Radical leaves kidney-fhaped, cut; thofe on the ftem in five deep pinnatifid and finely divided fegments. Calyx hairy.—Not uncommon by the fides of fields and roads in a gravelly foil, flowering in July and Auguft. *Root* perennial, fomewhat woody, tenacious. *Stems* erect, rather branched. *Lower leaves* heart or kidney-fhaped, lobed; *upper* divided to the bafe into five fegments, which are deeply pinnatifid, cut and channelled. *Flowers* large, handfome, rofe-coloured. The whole herb gives out a ftrong, mufky odour, which is fcarcely perceptible, however, in cold or damp weather.

M. *Alcea*, was once reckoned a Britifh fpecies, and Willdenow ftill mentions it as fuch, but without reafon. Some variety of *mofchata*, with broader leaves than ufual, is fuppofed to have been taken for it.

Malva, in *Gardening*, comprehends plants of the herbaceous, annual, biennial, perennial, and fhrubby kinds, of which the fpecies cultivated are, the fpiked mallow (M. fpicata); the American mallow (M. americana); the Peruvian mallow (M. peruviana); the creeping mallow (M. caroliniana); the oriental mallow (M. orientalis); the whorl-flowered mallow (M. verticillata); the curled mallow (M. crifpa); the palmated mallow (M. egyptia); the vervain mallow (M. alcea); the mufk mallow (M. mofchata); and the goofeberry-leaved or cape mallow (M. capenfis).

In the laft or Cape fpecies, there are varieties in which the ftems are thicker and higher, of a brownifh-red colour; the leaves hirfute, broader, with wider fegments, lefs deeply cut, but with the toothlets fharper and ferrate; the whorls of fruit a little larger, and not muricated, and in which the hairs of the leaves and ftem are fimple, not compound; the flowers almoft upright, not drooping or bending downwards.

Method of Culture.—It may be obferved that the ten firft forts are all capable of being raifed from feeds, which, in the hardy kinds, fhould be fown in the fituations where the plants are to grow, in patches of four or five in each, in the fpring or beginning of autumn, covering them to the depth of half an inch. They may likewife be fown upon a bed of fine earth, and be afterwards removed to the places where they are to flower. Thofe which are natives of hot climates fhould be fown in pots, and plunged in a hot-bed.

In the two latter modes, when the plants have attained fome growth, they fhould be removed into their proper fituations, or into other pots, to be afterwards managed according to the difference of the kinds.

And

And the laſt ſort and varieties may be raiſed alſo by ſeed, which ſhould be ſown upon a hot-bed, or in pots, and plunged in it. When the plants have attained ſome growth, they ſhould be removed into ſeparate pots, replunging them in the hot-bed till freſh rooted, when they ſhould be gradually inured to the full air, managing them afterwards in the ſame manner as other exotics of the green-houſe kind.

The hardy ſorts afford a pleaſing variety in the ſhrubbery and other parts, while thoſe of the more tender and ſhrubby kind produce a good effect in the green-houſe, and among potted collections in other places.

Malva *Arborea*, in *Botany*. See Hibiscus and Lavatera.

Malva *Roſea*. See Alcea and Hibiscus.

Malva *Sylveſtris*. *Common Mallow*, in the *Materia Medica*, has a ſtrong affinity to the althæa or marſh mallow, both in a botanical and in a medicinal reſpect; but the roots of the malva are uſeleſs, while thoſe of althæa are of greater efficacy than any other part of the plant. Accordingly we find, that only the leaves and the flowers of the former are directed by the college for pharmaceutical purpoſes. Formerly the malva was admitted among the more common articles of diet. To this purpoſe it is referred to by Horace, l. i. od. 31.

" ——— Me paſcunt olivæ
Me cichorea leveſque malvæ."

The Chineſe are ſaid to eat the leaves of mallow, either raw as ſallad, or boiled as ſpinach. As to the medicinal qualities of this plant, we ſhall refer to the article Althæa; obſerving, that the leaves afford a ſimilar glutinous juice, which is fitted to anſwer the ſame purpoſes as thoſe of marſhmallow, and are therefore principally uſed in fomentations, cataplaſms, and emollient enemas; but the internal uſe of theſe leaves ſeems to be wholly ſuperſeded by the radix althææ. Cicero (Epiſt. lib. vii. ep. 26.) mentions the laxative quality of this plant. Woodv. Med. Bot.

Malva, in *Ancient Geography*, a large and deep river of Africa, in Mauritania Cæſarienſis, which runs into the Mediterranean.

MALVACEÆ, in *Botany*, a natural order of plants, the 74th in Juſſieu's ſyſtem, or the 14th of his 13th claſs, equivalent to the *Columniferæ* of Linnæus, which article the reader will find in its proper place.

MALVANA, in *Geography*, a town of the iſland of Ceylon; 12 miles E. of Columbo.

MALVASIA, a town of European Turkey, ſituated on a promontory, almoſt ſurrounded by the ſea, on the eaſtern coaſt of the Morea: its harbour is good, but not large. It is the ſee of a Greek archbiſhop, and one of the ſtrongeſt towns in the Morea: the territory belonging to it is about three miles in circuit, and furniſhes, in part, thoſe celebrated vines, from which was obtained the wine, formerly much valued, under the name of Malmſey. This was formerly a place of great reſort for the worſhip of Eſculapius, which was brought hither by the inhabitants of *Epidaurus* (which ſee). This place is called by the Turks "Menewtſche;" and it is diſtant about a league from the ruins of Epidaurus *Limera* (which ſee), and 40 miles E.S.E. of Miſitra. N. lat. 36° 52′. E. long. 23° 4′.

MALVAVISCUS, in *Botany*, ſo called by Dillenius in his *Hortus Elthamenſis*, v. 2. 210. t. 170. f. 208. Linnæus however conſidered it as a ſpecies of *Hibiſcus*, and gave it the name of *H. Malvaviſcus*, Linn. Sp. Pl. 978. It is now the *Achania* of Banks and Solander, and is characteriſed by a convoluted corolla, ten ſtigmas, and a pulpy fruit. (See Hibiscus and Achania.) *Malvaviſcus* of Gærtner, t. 135, is *Hibiſcus populneus* of Linnæus, certainly a diſtinct genus from *Hibiſcus*, but the name is untenable.

MALUCA, in *Geography*, a town of Peru, in the dioceſe of Truxillo, on the coaſt; 45 miles N. of Payta. S. lat. 4° 25′.

MALVENTRA, a ſmall iſland near the weſt coaſt of Sardinia.

MALVERN, Great, a village and pariſh in the lower diviſion of the hundred of Perſhore, and county of Worceſter, England, is ſituated on the eaſtern declivity of the Malvern hills, at the diſtance of eight miles from Worceſter, 24 from Cheltenham, and 120 from London. A hermitage, or religious ſociety for ſeculars, was founded here in the time of Edward the Confeſſor, and obtained ſome endowment from that monarch. About the year 1083, Aldewine, the chief of this place, was perſuaded by St. Wolſtan, biſhop of Worceſter, to become a Benedictine monk: upon which he immediately ſet about procuring benefactions for building and maintaining a priory of that order. Giſlebert, then abbot of Weſtminſter, aſſigned ſeveral manors and eſtates to its ſupport, whereby, with the munificence of devotees, the monaſtery was raiſed to great wealth and conſequence. Few veſtiges now remain, except the church, which, at the diſſolution, was purchaſed by the inhabitants, and rendered parochial. This is ſtill a magnificent ſtructure, being 171 feet in length, and 63 in breadth, with an embattled and pinnacled tower, riſing from the centre to the height of 124 feet. The painted glaſs in the windows, repreſenting many ſcenes from Scripture hiſtory, was once the object of univerſal admiration; but, through time and neglect, is now in a mutilated ſtate, though enough is left to afford an idea of its former beauty. Several parts of the choir are ornamented with teſſellated pavement, exhibiting the arms of many ancient and noble families. The tombs and monumental inſcriptions are very numerous, and ſome of them of remote antiquity: the inſcription on Walcher, the ſecond prior of Malvern, which was diſcovered in 1711, is dated 1135. Among the tombs is one of a Saxon knight, with his battle axe and other accoutrements, ſuppoſed to be the only one of this kind in England. Malvern has long been noted for two medicinal ſprings: that called St. Anne's well, about a quarter of a mile from the church, is bituminous, and eſteemed very ſalutary; the other is chalybeate, but is in a great meaſure neglected. Great Malvern, according to the population return in the year 1810, contained 819 inhabitants.

About three miles diſtant is the hamlet of *Little Malvern*, which was once a conſiderable village, but now contains only ſix houſes, inhabited by 34 perſons. A Benedictine priory was founded here, in the year 1171, by two brothers, Joceline and Edred, who were ſucceſſively priors. The church was rebuilt in 1482 by John Alcock, biſhop of Worceſter, but is now in a ruinous ſtate.

Malvern *Hills*, are ſituated in the counties of Worceſter, Glouceſter, and Hereford, but principally on the ſouth-weſt part of the former, making a diſtinct boundary to the rich vale of the Severn, lying to the eaſt, and ſtanding as a frontier between Worceſterſhire and Herefordſhire. This lofty range of hills occupies a ſpace about nine miles in length from north to ſouth, and from one to three miles in breadth. The higheſt parts are thoſe called the Herefordſhire and Worceſterſhire Beacons, about four miles diſtant from each other; the former riſing to the height of 1280 feet, and the latter to 1313 feet above the ſurface of the Severn. On the Herefordſhire Beacon are the remains of an ancient encampment, conſiſting of a double entrenchment; the outermoſt about half a mile in circumference. The

The avenues and paſſes are ſtill to be ſeen, and the greateſt part is in ſine preſervation. The veſtiges of another entrenchment, conſiſting only of a ſingle ditch, appear about a mile and half further to the ſouth; and on the declivity of the Beacon is a cave cut in the rock, about ten feet long, ſix broad, and ſeven high, of rude workmanſhip and unknown origin.

From the Malvern hills iſſue various ſprings, of different qualities, according to the ſubſtances they are impregnated with; but that which has for ſeveral ages been reputed of peculiar medicinal efficacy, and has obtained the name of the Holy-well, riſes about half-way up the eaſt ſide of a hill, nearly mid-way between Great and Little Malvern. The ſource of the ſpring is ſecured by a convenient erection, containing a bath and other accommodations. The diſtrict called Malvern-Chaſe contains about 8000 acres, chiefly in Worceſterſhire; only about 700 being in the two adjoining counties. Ruff's Hiſtory of Cheltenham, 8vo. 1803. Shaw's Tour into the Weſt of England, 8vo.

Malvern *Waters.* See *Malvern* Waters.

MALVINDA, in *Botany*, Indian Mallow, a name of Dillenius for ſome ſpecies of the *Sida* of Linnæus. It is ſtill more exceptionable than *Malvaviſcus*.

MALVISANO, in *Geography*, a town of Italy, in the Breſſan; 13 miles S.S.E. of Breſcia.

MALUNG, a town of Sweden, in Dalecarlia; 55 miles W. of Fahlun.

MALURA, in *Botany*, the Sanſkrit name of the Cratæva marmelos of Linnæus. (See Crateva.) It is alſo called bilwa or bilva by the Hindoos, who reckoned it a ſacred ſhrub and fruit eſpecially dedicated to Siva, probably becauſe the latter is of a conical form, cones being typical of Siva, as the perſonification of fire. Many ſuperſtitious practices, and apparently idle tales, are connected with this fruit, in the mythological uſages and legends of the Eaſt Indies. Chaplets of bilwa flowers decorate the ſtatues of Siva, but of no other deity, nor are they offered in ſacrifices to any other. A pious Hindoo ſeeing any of theſe flowers fallen on the ground, would, it is ſaid, reverently remove them to a temple of Siva. The Hindoo poets call it Sriphul, the flower of Sri, or Lakſhmi, the goddeſs of abundance; who is fabled to have beſtowed it on mankind, at the requeſt of Iſwara, or Siva. (See Lakshmi.) The fruit is warm, cathartic, of delicious taſte, and exquiſite fragrance, and of valuable aperient and deterſive qualities. The mucus of its ſeed is uſed as a cement. See Aſiatic Reſearches, vol. ii.

MALUS, the ancient Latin name of an apple-tree, derived from the Greek μηλεα, is retained generically by Juſſieu, Gen. 334, after Tournefort, t. 406, to diſtinguiſh the apple from the pear, merely becauſe the fruit of the former is umbilicated at its baſe, and the ſtyles united at their lower part. The latter character is the moſt material, and appears to be founded in truth; but ſurely theſe plants form one natural genus. See Pyrus.

Malus *Aſſyria*, one of the many names given by the ancients to the citron: they alſo call it *malus Medica*, and by ſeveral other names, as theſe were expreſſive of the country whence they had the fruit. See Citrus and Citreæ *Menſæ*.

Malus *Americana*. See Cactus, Crateva, and Hippomane.

Malus *Armeniaca*. See Prunus.

Malus *Aurantia*. See Citrus.

Malus *Indica*. See Rhamnus *Jujuba*.

Malus *Limonia*. See Citrus.

Malus *Perſica*. See Achras, Amygdalus, and Mammea.

Malus *Punica*. See Punica *Granatum*.

MALUTAYA, in *Geography*, a ſmall iſland in the ſea of Mindoro. N. lat. 11° 12′. E. long. 120° 52′.

MALWA, a province or ſoubah of Hindooſtan, one of the moſt extenſive, the moſt elevated, and highly diverſified in Hindooſtan; and belonging to the extenſive empire of the Mahrattas. It is bounded on the N. by Agimere and Agra, on the E. by Allahabad, on the S. by Candeiſh, and on the W. by Guzerat. Ougein is the capital of one Mahratta prince, and Indore of another. It is now ruled in ſovereignty by Dowlut Rao, nephew and ſucceſſor of the late Madaji Sindiah. The noble river Narmada, or Nerbudah, waſhes it on the ſouth, dividing it from the province of Candeiſh. The Chumbul on the N.W. divides it from Ajmeer and Guzerat. On the S.E. it joins the dominions of the raja of Berar, and on the N.E. the Britiſh territories under the government of Bengal. Malwa may be roundly eſtimated at about 350 miles in length, and nearly as much in breadth. This ſoubah is very temperate in reſpect of climate, its capital city, Ougein, nearly centrally ſituated, being juſt within the northern tropic. (See Ougein.) It is well watered, having, beſides numberleſs lakes and ſmaller ſtreams, the rivers Sipera, Kaliſind, Neem, and Narmada flowing through it. It is an elevated region; and is very productive in grain and fruit, including wheat and grapes. Here are ſeveral noble cities and flouriſhing towns, of which Ougein, Gurrah Mandla, Chandery, Bopal, Manduah, Dhar, and Naderbar, may be reckoned the chief. In the Ayeen Akbery, Ougein is ſtated, on the perſonal knowledge of the author of that work, to have contained, when he viſited it in 1596, 360 Hindoo temples. Chandery is deſcribed as having 14,000 ſtone houſes, 384 markets, 360 caravanſerais, and 12,000 moſques. Its military ſtrength is alſo very highly rated. We take this occaſion to correct a typographical error in the article Indra, whence reference is made to this. About the middle of the ſecond column of that article is a ſtop and break at the word Malwa, and a new article commenced with Indra *Malwa*. Theſe two words are to be ſtruck out, and the lines will then run thus— "particularly Ujaini, or Oojein, the capital of Malwa; the hereditary poſſeſſion of the family of Sindia." For further particulars, ſee Mahrattas.

MALWALLY, an iſland in the Eaſt Indian ſea, about 15 miles in circumference, containing two good harbours. N. lat. 7° 0′. E. long. 115° 20′.

MALZIEU, a town of France, in the department of the Lozere, and chief place of a canton, in the diſtrict of Marvejols; five miles N.N.E. of St. Chély. The place contains 1060, and the canton 5742 inhabitants, on a territory of 160 kiliometres, in 10 communes.

MAMADEBAD, or Mamed-abad, a town of Hindooſtan, inhabited by Banians, who carry on a conſiderable traffic in thread and cotton.

MAMADISCH, a town of Ruſſia, in the government of Kazan, on the Viatka; 16 miles N.E. of Kazan. N. lat. 56° 26′. E. long. 50° 30′.

MAMAK, a ſea-port town of Abaſcia, on the Black ſea; 110 miles W. of Iſgaur. N. lat. 43° 26′. E. long. 38° 25′.

MAMA-KATING, a townſhip of America, in Ulſter county, New York, on Delaware river; containing 1631 inhabitants.

MAMAKATUN, a town of Turkiſh Armenia, on the Euphrates; 12 miles N. of Arzingan.

MAMA-

MAMALEGERY, a town of Hindooftan, on the confines of Dindigul ; 60 miles E. of Cochin.

MAMALAKJE, one of the Calaur iflands. S. lat. 6° 40′. E. long. 123° 33′.—Alfo, a clufter of fmall iflands extending about 60 miles in length from N.W. to S.E. and 30 in breadth, in S. lat. 6° 50′. E. long. 121°.

MAMALUKES, Mammelukes, *Mammalucks*, or *Mamlouks*, the name of a dynafty, which reigned a confiderable time in Egypt.

The word comes from מלך, *regere*, *imperare*, the Arabic participle of which is ממלוך, *Mamluc*, which fignifies *fubject*, or one under the dominion of another. Scaliger holds, that the word is Arabic, and that it properly fignifies fomething bought with money ; but others will have it fignify any thing acquired or poffeffed either as prize or purchafe ; and this gives the fenfe of *flave*.

The Mamalukes, or Mamlouks, were originally Turkifh and Circaffian flaves, who were introduced into Egypt, in confequence of an expedition which took place in the year 1227. The Moguls, fword in hand, pillaging, burning, and murdering, without diftinction either of age or fex, reduced the whole country of Sihoun, quite to the Tigris, to a heap of afhes ; and paffing to the north of the Cafpian fea, extended their ravages even into Ruffia and the Cuban. The Tartars, weary of maffacring, had brought back with them a prodigious number of young flaves of both fexes, filling with them their camps and the markets of Afia. The fucceffors of Salah-el-din, or Saladin, fon of Aiûb, who ufurped the title of fultan of Egypt in 1174, and who died in 1193, perceived that, having an opportunity, as Turkmans, of correfponding with the coafts of the Cafpian fea, they might form, at a cheap rate, a body of foldiers of tried courage and remarkable beauty. Accordingly one of them, *viz.* Malek Salah, about the year 1230, purchafed to the number, as Volney fays, of 12,000 of thefe young men, who were Tfcherkaffes (Circaffians), Mingrelians, and Abazans. Thefe he defigned to be his guard and marine ; and by training them up to military exercifes, he foon obtained a body of the handfomeft and beft foldiers in Afia, though at the fame time, as experience foon taught him, the moft mutinous. This foldiery, like the Prætorian bands of Rome, ere long gave laws to their mafter. Malek Salah died in 1149, and was fucceeded by his fon Tûran Shah, who in the following year captured St. Louis, and his army of 20,000 men. On the 1ft of May 1250, the Mamluks depofed and maffacred Tûran Shah, and affigned the fceptre to his ftep-mother, and afterwards to a Bey of the Aiûbite race ; and this event clofed the dynafty of the Aiûbites in Egypt. At this period commenced the dynafty of the Mamluks. The firft fovereigns of this denomination were the "Baharite Mamlouks," who were fo ftyled, from having been originally employed as "mariners" on board the fhips of the fultan of Egypt. Thefe were Turks or Tartars from Kipzak. The firft fovereign of this dynafty was Ezz-ed-din Moaz Ibegh, who began his reign A. D. 1254 ; and terminated it in the fame year by affaffination. Moft of his fucceffors clofed their lives in the fame manner. The laft of the Baharite Mamlouks was Sheban Aferaf, who was the firft fultan who ordered the fherifs, or defcendants of the prophet, to wear a green turban. The next race of Mamlouks was denominated "Borgite Mamlouks :" it was of Circaffian extract, and continued to rule Egypt till the French invafion. This dynafty commenced in 1382 : but under fucceeding fultans of this dynafty the Mamlouk ariftocracy became gradually more and more precarious. From their firft eftablifhment, the effects correfponded with the means. Without any other bond of union than the intereft of the moment, or any public right to authority, but that of conqueft, thefe Mamlouks, or military flaves, had no other rule of conduct and government than the violence of a licentious and infolent foldiery. The firft leader whom they elected, having found employment for their turbulent fpirit in the conqueft of Syria, reigned 17 years ; but the government of his fucceffors was of fhorter duration. The fword, the bow-ftring, or poifon, public murder, or private affaffination, have been the fate of a feries of tyrants, 47 of whom are enumerated in the fpace of 257 years. At length, in 1517, Selim, fultan of the Ottomans, having taken and hanged Tomân Bey, their laft chief, put a period to that dynafty. Selim was contented with abolifhing the "monarchy" of the Mamlouks, but fuffered their "ariftocracy" to retain its former power, on certain conditions ; the chief of which were, an annual tribute, obedience in matters of faith to the mufti of Conftantinople, and the infertion of the name of the Ottoman emperors in the prayer, and on the coin. At the fame time he projected fuch a form of government that the power, being diftributed among the different members of the ftate, fhould preferve fuch an equilibrium as fhould keep them all dependent on himfelf. See Bey.

The Mamlouks, on obtaining the government of Egypt, adopted meafures which feem to fecure to them the poffeffion of the country. The moft efficacious is the precaution they have taken to degrade the military corps of the Arabs and Janizaries. Thefe, and the other Turkifh troops, are only a rabble of artizans and vagabonds, who guard the gates of thofe who pay them, and tremble in the prefence of the Mamlouks, as much as the populace of Cairo. In reality, the whole military force of Egypt confifts in the Mamlouks.

Some hundreds of thefe are difperfed throughout the country, and in the villages, to maintain the authority of their corps, collect the tributes, and improve every opportunity of extortion ; but the main body continually remains at Cairo. From the computation of well-informed perfons, it appears, their number cannot exceed 8500 men, reckoning Beys and Cachefs, common freed-men, and Mamlouks who are ftill flaves. In this number there is a multitude of youth under 20 and 22 years of age.

The moft powerful houfe is that of Ibrahim Bey, who has about 600 Mamlouks. Next to him is Mourad, who has not above 400, but who, by his audacity and prodigality, forms a counterpoife to the infatiable avarice of his rival : the reft of the Beys, to the number of 18 or 20, have each of them from 50 to 200. Befides thefe, there is a great number of Mamlouks who may be called *individual*, who, being fprung from houfes which are extinct, attach themfelves fometimes to one, and fometimes to another, as they find it their intereft, and are always ready to enter into the fervice of the beft bidder. The Mamlouks, therefore, permit the inhabitants of Egypt to be carried only by mules or affes, referving to themfelves the exclufive privilege of riding on horfeback ; and of this they make fufficient ufe ; for whether they are in town or the country, or if they only make a vifit to the next door, they are never feen but on horfeback. Their drefs, as well as the fupport of their dignity, obliges them to this.

Their drefs confifts in a wide fhirt of thin cotton, of a yellowifh colour, over which they wear a fort of gown of Indian linen, or the light ftuffs of Damafcus and Aleppo. This robe, called *antari*, defcends from the neck to the ankles, and folds over the fore-part of the body, towards the hips, where it is faftened by two ftrings. Over this firft covering is a fecond, of the fame form and width, the ample fleeves of which defcend likewife to the finger-

[illegible]

ends. This is called a *coftan*, and is ufually made of filk ftuff, richer than the former. Both thefe are faftened at the waift by a long belt, which divides the whole drefs into two bundles. Above them is a third, which is called *djouba*, which is of cloth without lining, and is made nearly in the fame manner, only the fleeves are cut at the elbow. In winter, nay frequently even in fummer, this djouba is lined with fur, and is converted into a peliffe. Laftly, over thefe three wrappers, they put on an outer garment, called the *benifhe*. This is the cloak or robe of ceremony, and completely covers the whole body, even the ends of the fingers, which it would be deemed highly indecent to fuffer to appear before the great. The whole habit, when the benifhe is on, has the appearance of a long fack, from out of which is thruft a bare neck, and a bald head, covered with a turban. The turban of the Mamlouks, called a *kaouk*, is of a cylindrical fhape, yellow, and turned up on the outfide with a roll of muflin artificially folded. On their feet, they wear a fock of yellow leather, which reaches up to the heels, and flippers without quarters, always liable to be left on the road. But the moft fingular part of this drefs is a fort of pantaloon, or trowfers, fo long as to reach up to the chin, and fo wide, that each of the legs is large enough to contain the whole body, and made of that kind of Venetian cloth which the French call *faille*, which, although as pliant as the *d'Elbœuf* cloth, is thicker than the *burre* of Rouen; and that they may walk more at their eafe, they faften, with a running fafh, all the loofe parts of the drefs we have been defcribing.

As to their horfe accoutrements, they are far from having adopted any modern improvements. Continually the flaves of cuftom, the horfes faddle among them is a clumfy frame, loaded with wood, leather, and iron, on which a truffequin rifes behind, eight inches in height above the hips of the horfeman. A pummel before projects four or five inches, fo as to endanger his breaft, fhould he ftoop. Under the faddle, inftead of a ftuffed frame, they fpread three thick woollen coverings, and the whole is faftened by a furcingle, which, inftead of a buckle, is tied with leather thongs, in very complicated knots, and liable to flip. They ufe no crupper, but have a large martingale, which throws them on the fhoulders of the horfe. Each ftirrup is a plate of copper longer and wider than the foot, with circular edges, an inch high in the middle and gradually declining toward each end; the edges are fharp, and are ufed inftead of fpurs, to make long wounds in the horfe's fides. The common weight of a pair of thefe ftirrups is between nine and ten pounds, and frequently exceeds twelve or thirteen. The faddle and faddle-cloths do not weigh lefs than five-and-twenty; thus the horfe's furniture weighs above fix-and-thirty pounds, which is fo much the more ridiculous, as the Egyptian horfes are very fmall.

The bridle is equally ill contrived; it is a kind of fnaffle, but without a joint, and with a curb, which, being only an iron ring, binds the jaw fo as to lacerate the fkin, fo that the bars are injured, and the horfe abfolutely has no mouth. This neceffarily refults from the practice of the Mamlouks, who, inftead of managing the mouth, like us, deftroy it by violent and fudden checks, which they employ particularly in a manœuvre peculiar to them. This confifts in putting the horfe on a full gallop, and fuddenly ftopping him, when at his higheft fpeed. Checked thus by the bit, the horfe bends in his hind legs, ftiffens the fore, and flides along like a horfe of wood. How much this manœuvre muft injure the legs and mouth may eafily be conceived; but the Mamlouks think it graceful, and it is adapted to their mode of fighting. Notwithftanding however their fhort ftirrups, and the perpetual motion of their bodies, it cannot be denied that they are firm and vigorous horfemen, and that they have a warlike appearance, which pleafes the eye even of a ftranger; it muft alfo be allowed, they have fhewn more judgment in the choice of their arms.

The principal weapon, among the Mamlouks, is an Englifh carbine, about thirty inches long, and of fo large a bore as to difcharge ten or twelve balls at a time, which, even without fkill, cannot fail of great execution. They befides carry at their belt two large piftols, which are faftened to fome part of their garments by a filk ftring. At the bow of the faddle fometimes hangs a heavy mace, to knock down their enemy, and on the left thigh is fufpended, by a fhoulder-belt, a crooked fabre, of a kind little known in Europe; the length of the blade, in a right line, from the hilt to the point, is not more than twenty-four inches, but meafured in the curve is at leaft thirty. This form, which appears whimfical to us, has not been adopted without motives; experience teaches us, that the effect of a ftraight blade is limited to the place and moment of its fall, as it acts merely from preffure: a crooked blade, on the contrary, prefenting its edge in retiring, flides by the effort of the arm, and continues its action longer. The Barbarians, who generally apply themfelves moft to the deftructive arts, have not fuffered this obfervation to efcape them; and hence the ufe of fcymetars, fo general and fo ancient in the Eaftern world. The Mamlouks commonly procure theirs from Conftantinople, and from Europe; but the Beys rival each other in Perfian blades, and in fabres of the ancient fteel of Damafcus, for which they frequently pay as high as forty or fifty pounds fterling. The qualities they efteem in them are lightnefs, the equality and ring of the temper, the waving of the iron, and, above all, the keennefs of the edge, which it muft be allowed is exquifite; but thefe blades have the defect of being as brittle as glafs.

The art of ufing the arms above defcribed, conftitutes the education of the Mamlouks, and the whole occupation of their lives. Every day, early in the morning, the greater part of them refort to a plain, without Cairo, and there, riding full fpeed, exercife themfelves in drawing out their carbine expeditioufly from the bandaleer, difcharging it with good aim, and then throwing it under their thigh, to feize a piftol, which they fire and throw over their fhoulder; immediately firing a fecond, and throwing it in the fame manner, trufting to the ftring by which they are faftened, without lofing time to return them to their place. The Beys who are prefent encourage them; and whoever breaks the earthen veffel which ferves by way of butt, receives great commendations and money, as a recompence. They practife alfo the management of the fabre, and efpecially the *coup de revers* which cuts upwards, and is the moft difficult to parry. Their blades are fo keen, and they handle them fo well, that many of them can cut a clew of wet cotton, like a piece of butter. They likewife fhoot with bows and arrows, though they no longer ufe them in battle. But their favourite exercife is throwing the *djerid*: this word, which properly means a reed, is generally ufed to fignify any ftaff thrown by the hand after the manner of the Roman pilum. Inftead of a ftaff, the Mamlouks make ufe of branches of the palm-tree, frefh ftripped. Thefe branches, which have the form of the ftalk of an artichoke, are four feet long, and weigh five or fix pounds. Armed with thefe, the cavaliers enter the lifts, and riding full fpeed, throw them at each other from a confiderable diftance. The affailant, as foon

as

as he has thrown, turns his horfe, and his antagonift purfues, and throws his in his turn. The horfes, accuftomed to this exercife, fecond their mafters fo well, that they feem alfo to fhare in the pleafure. But this pleafure is attended with danger; for fome can dart this weapon with fo much force, as frequently to wound, and fometimes mortally.

As to military fkill the Mamlouks know nothing of our military arts; they have neither uniforms, nor order, nor difcipline, nor even fubordination. Their troops are a mob, their march a riot, their battles duels, and their war a fcene of robbery and plunder, which ordinarily begins even in the very city of Cairo; and, at the moment when there is the leaft reafon to expect it. A cabal gathers together, the Beys mount on horfeback, the alarm fpreads, and their adverfaries appear: they charge each other in the ftreet, fabre in hand: a few murthers decide the quarrel, and the weakeft or moft timid is exiled. The people are mere cyphers in thefe affrays. Of what importance is it to them that their tyrants cut each other's throats? But it muft not be imagined that they ftand by indifferent fpectators, that would be too dangerous in the midft of bullets and fcymetars; every one makes his efcape from the fcene of action till tranquillity is reftored. Sometimes the populace pillage the houfes of the exiled, which the conquerors never attempt to prevent.

In the field, they advance towards their enemies, mutual defiances pafs, the attack begins, and every one choofes his man: they fire, if they can, and prefently fall on with the fabre: it is then the manageablenefs of the horfe and dexterity of the cavalier are difplayed. If the former falls, the deftruction of the latter is inevitable. In defeats, the valets, who are always prefent, remount their mafters; and if there are no witneffes near, frequently knock them on the head to get the fequins they happen to have about them. The battle is often decided by the death of two or three of the combatants.

The interefted and inconftant character of this militia, is a neceffary confequence of its origin and conftitution. The young peafant, fold in Mingrelia or Georgia, no fooner arrives in Egypt, than his ideas undergo a total alteration. A new and extraordinary fcene opens before him, where every thing conduces to awaken his audacity and ambition; though now a flave, he feemed deftined to become a mafter, and already affumes the fpirit of his future condition. He calculates how far he is neceffary to his patron, and obliges him to purchafe his fervices and his zeal; thefe he meafures by the falary he receives, or that which he expects; and as in fuch ftates money is the only motive, the chief attention of the mafter is to fatisfy the avidity of his fervants, in order to fecure their attachment. Hence, that prodigality of the Beys, fo ruinous to Egypt, which they pillage; that want of fubordination in the Mamlouks, fo fatal to the chiefs whom they defpoil; and thofe intrigues, which never ceafe to agitate the whole nation. No fooner is a flave enfranchifed than he afpires to the principal employments; and, who is to oppofe his pretenfions? In thofe who command, he difcovers no fuperiority of talents which can imprefs him with refpect; in them he only fees foldiers like himfelf, arrived at power by *the decrees of fate*; and if it pleafe fate to favour him, he will attain it alfo, nor will he be lefs able in the art of governing, which confifts only in taking money, and giving blows with the fabre.

From this fyftem alfo has arifen an unbridled luxury, which, indulging the gratification of every imaginary want, has opened an unlimited field to the rapacity of the great. This luxury is fo exceffive, that there is not a Mamlouk, whofe maintenance cofts lefs than 2500 livres (or 104*l.*) annually, and many of them coft double that fum. At every return of the Ramadan, they muft have a new fuit, French and Venetian cloths, and Damafcus and India ftuffs. They muft often likewife be provided with new horfes and harnefs. They muft have piftols and fabres from Damafcus, gilt ftirrups, and faddles and bridles plated with filver. The chiefs, to diftinguifh them from the vulgar, muft have trinkets, precious ftones, Arabian horfes of two or three hundred pounds value, fhawls of Cafhmire worth from five-and-twenty to fifty pounds each, and a variety of peliffes, the cheapeft of which cofts above twenty pounds. The women have rejected the ancient cuftom of wearing fequins on the head and breaft, as not fufficiently fplendid and coftly, and in their ftead have fubftituted diamonds, emeralds, rubies, and the fineft pearls; and to their fondnefs for fhawls and furs, have added a paffion for Lyons ftuffs and laces. When fuch luxuries are become the neceffaries of thofe whofe authority is without controul, and who neither refpect the rights of property, nor the life of their inferiors, it is eafy to conceive what muft be the condition of their fubjects who are obliged to furnifh them with whatever their caprice may require.

As to the manners of the Mamlouks, though born for the moft part in the rites of the Greek church, and circumcifed the moment they are bought, they are confidered by the Turks themfelves as renagadoes, void of faith and of religion. Strangers to each other, they are not bound by thofe natural ties which unite the reft of mankind. Without parents, without children, the paft has done nothing for them, and they do nothing for the future. Ignorant and fuperftitious from education, they become ferocious from the murders they commit, perfidious from frequent cabals, feditious from tumults, and bafe, deceitful, and corrupted by every fpecies of debauchery. They are, above all, addicted to that abominable wickednefs which was at all times the vice of the Greeks and of the Tartars, and is the firft leffon they receive from their mafters. It is difficult to account for this tafte, when we confider that they all have women, unlefs we fuppofe they feek in one fex, that poignancy of refufal which they do not permit the other. It is however very certain, that there is not a fingle Mamlouk but is polluted by this depravity; and the contagion has fpread among the inhabitants of Cairo, and even the Chriftians of Syria who refide in that city. Brown's Travels; Sonnini's Travels; and Volney's Travels, vol. i.

MAMANDY, a town of Hindooftan, in the Carnatic; 35 miles E. of Coilpetta.

MAMANOOK, one of the Sooloo iflands. N. lat. 6° 3'. E. long. 121° 45'.

MAMARACPOUR, a town of Hindooftan, in Benares; 20 miles S.E. of Chunar.—Alfo, a town of Bengal; nine miles S. of Moorley.

MAMARONECK, a townfhip of America, in Weft Chefter county, New York, containing 512 inhabitants.

MAMAT, St., a town of France, in the department of the Cantal, and chief place of a canton, in the diftrict of Aurillac. The place contains 1408, and the canton 8181 inhabitants, on a territory of 325 kiliometres, in 13 communes.—Alfo, a town of France, in the department of the Gard, and chief place of a canton, in the diftrict of Nimes; nine miles N.W. of Nîmes. The place contains 561, and the canton 6066 inhabitants, on a territory of 162½ kiliometres, in 15 communes.

MAMBARY, a town of Hindooftan, in the province of Dindigul; 20 miles N. of Dindigul.

MAMBATENAWAN, a fmall ifland in the Eaft Indian

Indian sea; 50 miles N.E. of Borneo. N. lat. 6° 26′. E. long. 118 45′.

MAMBIPILLY, a town of Hindoostan, in Mysore; 23 miles E.S.E. of Chinna Balabarum.

MAMBURAO, a town on the W. coast of the island of Mindoro. N. lat. 13′ 12′. E. long. 120 45′.

MAMDEBAD, a town of Hindoostan, in Oude; 12 miles S.W. of Furruckabad.

MAMELLS, a small island on the N. side of lake Superior. N lat. 48 26. W. long. 88 4′.

MAMENDA, a town of Hindoostan, in the circar of Guntoor; 10 miles N.W. of Innaconda.

MAMERS, a town of France, and principal place of a district, in the department of the Sarthe; 23 miles N.N.E. of Le Mans. The place contains 5382, and the canton 15,913 inhabitants, on a territory of 212½ kiliometres, in 22 communes.

MAMERTINI, in *Ancient Geography*, a people of Italy, in Campania; they passed over into Sicily, and established themselves at Messina, where they became so powerful, that they were masters of the place.

MAMERTIUM, a town of Italy, in Brutium, near the source of the Metaurus, and the Brutian forest. The name was formed of Mamers, which was the appellation of the god Mars, in the language of the country. It is probable, that the soldiers of whom Polybius speaks, who made themselves masters of Messina, and who were denominated Mamertins, derived their name from this town.

MAMERVAN, a town of Persian Armenia; 45 miles S.S.W. of Kars.

MAMHOFKA, a town of Poland, in the palatinate of Braclaw; 56 miles S.E. of Braclaw.

MAMIRA, in the *Materia Medica of the Arabians*, a root frequently mentioned by Avicenna, Serapion, and other of the Arabian writers. It seems mentioned as a poisonous drug, and is so described, that it seems to be the same with one species of the durunegi, or doronicum of the same authors, and the common doronicum of the shops, distinguished from the antithora, or other sort of durunegi, by the yellowness of the inside of the root. Avicenna says that it is hard and woody, and formed of knots or joints. This is the very description the same author gives of the durunegi of the first or poisonous kind. Paulus Ægineta says its root is composed of several joints also; and Alphagus calls it a nodose or jointed root. Some have supposed that the mamira was the same plant which we call small celandine, but this has no title to be placed among the plants suspected as poisonous, nor any other plea to be guessed at as the mamira, but only because its roots consist of many tubercles. Many things beside have been conjectured to be the mamira of the Greeks and Arabians, but the doronicum seems to be the plant See DORONICUM.

MAMISTA, in *Geography*, a town of Asia, in Cilicia, which was taken by the emperor Phocas, and which probably was the same with "Mamistra," often mentioned by William of Tyre. See MOPSUESTIA.

MAMMA, in *Anatomy*. See BREAST.

MAMMA, *Cancer of*. See CANCER *and* SCIRRHUS.

MAMMA, *Removal of*. The operation of amputating a diseased breast is described in the article EXTIRPATION.

MAMMALIA, in *Natural History*, the first class of animals in the Linnæan system, divided into seven orders, *viz. primates*, *bruta*, *feræ*, *glires*, *pecora*, *belluæ*, and *cete*.

The characters of this class, according to the description of Linnæus, are as follow; the heart has two auricles and two ventricles; the blood is warm and red; the lungs respire regularly, alternate; the jaws are horizontally incumbent on each other, and covered with lips, within which the teeth are, for the most part, included; they procreate by an intrant penis; and are viviparous and lactiferous: their organs of sense are the tongue, nostrils, eyes, ears, and cutaneous papillæ: they are covered with hair, which is thin on the animals of the warmer regions, and very scanty on aquatic animals: their motive organs are four legs and feet; except those which are entirely confined to the water, whose hinder legs are wanting: most have tails.

MAMMALIA, *Anatomy of*, has had much attention bestowed upon it, under the supposition of its being immediately applicable to the explanation of the functions of the human body. Particular parts of the subject have been successfully prosecuted with this view, both on the continent and in this country, but it is only lately that the anatomical history of the class has been formed into a system, chiefly by the labours of Cuvier and his assistants, who have not only filled up many details that were required, but have also added very interesting dissections of several quadrupeds, hitherto but little known.

Naturalists have almost universally included human beings in the class of mammalia, in consequence of their possessing the peculiar characters which distinguish this class from those of other animals. In this dictionary, however, the arrangement of animals for the purpose of describing their anatomy has been made under a contemplation of the mental endowments, and the social and moral propensities of man, which we conceive entitle him to a distinct rank in the scale of living beings; but if it were even otherwise, it became necessary, according to the plan of the dictionary, to separate man from mammalia, in order that human and comparative anatomy might be treated as distinct subjects.

Organs concerned in the Exercise of the vital Functions.

The Mouth and its contained Parts, or the Organs of Mastication.—The *aperture* and *internal cavity* of the mouth have a different form in mammalia from that in the human subject, with the exception of those species of *monkey* which approach mankind in general conformation.

The mouth of mammalia, in general, is capable of being opened widely, in consequence of the division of the lips being extended on each side backwards. This structure is most remarkable in the *beasts of prey*, and least so in the gnawing quadrupeds. The aperture of the mouth is peculiarly small in the *ant-eaters* and other *insectivorous* quadrupeds.

The *cavity* of the mouth, except in some of the *monkey* tribe, is considerably longer from before backwards, than in the transverse direction. This is particularly the case in the *ruminant* and *gnawing* quadrupeds, and is a shape of the mouth peculiarly well adapted for the minute division of the aliments, as they are more completely subjected to the action of the grinding teeth, and to the motions of the tongue, and the muscular parietes of the mouth.

The figure and magnitude of the cavity of the mouth depend upon the form and mechanism of the two jaws, but especially the lower one, which we shall describe when treating of the organs of motion.

The membrane which lines the mouth of mammalia is commonly more largely supplied with mucous glands than it is in the human subject; it is also more plainly covered by cuticle. Many of the *graminivorous* quadrupeds have a very thick cuticle spread over the inside of the mouth.

Several quadrupeds, and especially those which ruminate, have the roof and sides of the mouth covered with flat and pointed processes: these are mostly directed backwards, from which it would seem, that they are designed to facilitate

tate the paffage of the food through the mouth. When thefe proceffes form foft pointed projections, fomewhat like fringe on the infide of the lips, they may conftitute a furface for receiving the impreffion of fapid bodies.

There are three forts of *teeth* found in mammiferous animals. The firft are employed in the fimple divifion, and the grinding or chewing of the food: the fecond can only be ufed for feizing and detaining the prey until it is fwallowed; and teeth of the third kind are intended for weapons or inftruments of defence.

The firft defcription of teeth admits of being fubdivided into three forts; firft, the *incifive* or *cutting* teeth; fecondly, the *canine* or *lacerating*; and thirdly, the *molar* or *grinding* teeth. We fhall firft defcribe the form and compofition of the teeth, and afterwards fpeak of their mode of growth.

The *incifive* teeth are always fituated, as a matter of neceffity, in the front of the mouth.

They are commonly fuppofed to be formed of two fubftances; the proper offeous part which conftitutes the bafis of teeth in general, and the enamel. In fome quadrupeds, however, we have found the third fubftance that enters into the compofition of teeth, or the *crufta petrofa*, upon the fangs and fides of the incifors of fome quadrupeds. The front teeth appear to be originally covered with crufta petrofa in the *horfe*: certainly fome of this fubftance remains in the cavity of the cutting edge, and upon the fides and fangs of the incifors of the *horfe* during life.

The figure of the incifor teeth is more or lefs that of a wedge. In the *monkey* tribe, they almoft refemble thofe of the human fubject, having rather thin and flat bodies, fuftained upon round ftalks. In the *lemur*, the lower incifors have a fingular pofition; they lie down before. In the *flying lemur* (*galeopithecus*) the front teeth are divided for fome way from the edge into narrow proceffes, which ftand parallel to each other, like the teeth of a comb. Some *cats* likewife have them denticulated upon the edge. Several *carnivorous* quadrupeds have the incifors terminating in one or more points.

The *faltigrade* mammalia are diftinguifhed by the peculiar ftructure of their incifive teeth. There are ufually two of them in each jaw, placed in the centre of the front of the mouth. They have moft commonly a thin fharp edge. In fome fpecies of the *rat* kind and the *fquirrels*, the inferior incifors are pointed and compreffed upon the fides. The enamel often does not furround the teeth, but is depofited only upon the anterior furface; the confequence of which is, that as the fubftance wears fafter than the enamel, the latter always prefents a fharp edge. The enamel is fometimes ftriated tranfverfely, or is longitudinally grooved, as in the *hare*. There are feveral incifor teeth in the upper jaw of the *kanguroo*, but only two in the lower jaw: thefe are directed fo much forwards, that they would feem to have but little concern in the divifion of the food. All the front teeth of the *kanguroo* are covered with an enamel of fo clofe a texture that it refembles porcelain, or a femi-vitrified fubftance. No animals employ their incifor teeth fo conftantly or with fo much effect as the *faltigrade* quadrupeds. Every perfon is well acquainted with the deftructive powers of the *rat* kind. The *beaver* is able to gnaw trees acrofs. It is upon the mode of ufing the front teeth that Cuvier has eftablifhed his order in mammalia of *Rodentia*, which includes the fame animals that we have denominated *faltigrade*, from their leaping manner of progreffion. The incifive teeth of the *rodentia* are continually wearing away at the end, more efpecially thofe in the lower jaw; and to make up for the wafte, they poffefs a long root, which contains a large vafcular pulp that is always adding new offeous matter to the tooth. In the *beaver*, and many of the *rat* genus, the length of the roots of the gnawing teeth is very remarkable. They extend backwards as far as the coronoid procefs of the lower jaw, and are contained in a canal which runs beneath the molar teeth in the fubftance of the maxillary bone. In the upper jaw this canal does not pafs farther back than above the firft molar tooth. In order to prove the continual wear and growth of the front teeth in the gnawing quadrupeds, it is only neceffary to take one of this tribe that makes much ufe of its incifors, and fuftain it for fome time upon foft food, when it will be found that the lower teeth will grow fo long as to turn up and penetrate the fkull.

Amongft the large quadrupeds with feveral hoofs, or the *pachidermata* of Cuvier, there is confiderable variety in the incifive teeth. They are wanting in the *elephant* and in the *African rhinoceros*. The *Afiatic rhinoceros* has in the upper jaw two large wedge-fhaped teeth and two fmall lateral ones, which are caft early, and in the lower jaw there are two large cylindric teeth, and two very fmall conic teeth between.

Cuvier remarks that, generally, the *many-hoofed* quadrupeds lofe the whole or part of their incifors at a certain period of life, without their being replaced by others.

The *bifulca* want incifors in the upper jaw.

The incifive teeth of the *horfe* have a depreffion or flight cavity in their cutting furface. The enamel is continued into this cavity, and we have likewife difcovered that the crufta petrofa paffes into it, and gives a covering to the enamel, notwithftanding which the front teeth of the *horfe* gradually wear down until thefe cavities are obliterated. The degree of wafte which the incifors experience ferves to determine the age of horfes. The incifors of the *beaver*, *marmot*, *fquirrel*, &c. are of a brown colour on their anterior furface. This would feem to be a ftain of the enamel, and not an incruftation, fuch as takes place upon the teeth of feveral of the *cloven-footed* quadrupeds. The latter is a dark coloured earthy fubftance, which receives a polifh and a green metallic appearance upon the furface. This incruftation has always appeared to us to be of the nature of the bezoar ftones, found in the alimentary canal of the fame quadrupeds.

All the front teeth of the *feal* are conical and fharp-pointed, and are therefore more calculated for holding the animal's prey than dividing it.

The *morfe* (*trichecus rofmarus*) has two little truncated teeth, fimilar to molares, in the intermaxillary bone between the tufks, but no front teeth in the lower jaw.

The *canine* or *lacerating* teeth in the *ourang-outang*, and fome other *monkies*, have the fame form of the incifors, in which circumftances thefe animals refemble the human fubject. In moft of the *monkey* kind, however, the teeth in the corners of the front of the mouth poffefs their proper characters, being pointed, conic, and fo long as to pafs each other in a greater or lefs degree when the jaws are fhut. In fome *baboons* the canine teeth are remarkably long.

The *lemurs* have them hooked and compreffed upon the fides. They are long and conic in the *loris*. The *flying lemur* (*galeopithecus*) has them fhort, broad, and notched like a faw.

In fome of the *plantigrade* mammalia, as the *hedge-hogs* and *frews*, they do not rife much above the neighbouring teeth, and are bicufpid.

Blumenbach defcribes fmall canine teeth in the *bear* genus, which are fituated immediately behind the principal canini. He found this remarkable ftructure to exift in the *brown bear* of the Alps, the *black bear*, the *polar bear*, and in the

fkeleton

ſkeleton of one whoſe country is unknown, preſerved in the National muſeum at Paris.

It is in the *digitigrade* quadrupeds that the form of the canine teeth is moſt perfect: in theſe they always are long, pointed, ſharp, curved backwards, and generally thoſe of one jaw paſs the correſponding ones of the other jaw conſiderably, when the mouth is cloſed The moſt ſtriking inſtances of this are ſeen in the *tyger*, *pole-cat*, and *badger*.

Naturaliſts have conſidered the tuſks of the *multungulata*, and of the *morſe*, *dugong*, and *narwhal* as canine teeth, which from their ſituation they are entitled to be conſidered, but as they can only be employed as weapons, we ſhall refer their deſcription to a ſubſequent part of this article.

The canine teeth exiſt only amongſt ſuch of the *cloven-footed* quadrupeds as want the true horns. In the *ſtag*, *camel*, *dromedary*, and *lama*, they do not grow to any length, and appear to be in a great meaſure uſeleſs to theſe animals. The ſame ſtructure obtains in the *horſe*. The *tuſhes*, as they are popularly called, in this animal are ſhort, and ſoon become blunt. They are peculiar to the male, who it is ſaid in a wild ſtate employs them as weapons, but this does not ſeem to be practicable.

The interior compoſition of the canine teeth agrees with that of the inciſors. They are made in all the carnivorous quadrupeds of the common ſubſtance of the teeth, and covered with enamel; but we have diſcovered cruſta petroſa upon the tuſks of the *horſe*, and we conceive it probable that it exiſts upon the canini of the other graminivorous beaſts.

The *grinding* or *molar teeth* are always ſituated in the back part of the mouth, in order to gain the advantage of the lateral motion of the jaws, the ſupply of ſaliva, and the aſſiſtance of the tongue and cheeks in moving the food while it is undergoing trituration.

The figure and compoſition of the molares vary according to the nature of the food, and the habits of the animal to which they belong.

In the genus *Simia* the grinding teeth are very ſimilar to thoſe of the human ſubject: in ſome ſpecies of *monkey*, however, the laſt molar is larger than the reſt, and furniſhed with a fifth tubercle; others have the laſt molar the ſmalleſt.

In the genus *Lemur* the molares begin to be pointed.

In the truly carnivorous quadrupeds they are (with the exception of the moſt poſterior teeth) thin or conical, and end in either one or more ſharp points. They are ſo placed in the two jaws likewiſe, that they are not exactly oppoſed to each other when the jaws are brought together, but paſs each other in a degree, ſo as to divide rather than bruiſe and comminute the food.

The *cat* genus has only one molar tooth with a flat crown and blunt proceſſes, which is ſituated in the upper jaw, and does not correſpond with any teeth of the inferior jaw. It is often loſt without any inconvenience.

The *weaſels* and *martins* have a ſingle tuberculated molar tooth at the back of both jaws. Thoſe of the upper jaw are broad.

The *hyæna* has one large molar, with blunt tubercles on each ſide the upper jaw, and a correſponding one with a pointed proceſs in the lower jaw.

In the genus *Canis* there are two tuberculated molares on each ſide, above and below.

In the other *digitigrade* quadrupeds there is ſome little variety in the number and ſhape of the poſterior tuberculated molares, which ſcarcely deſerves notice.

In all theſe animals the molar teeth have the ſame compoſition as the canine and inciſors, *i. e.* the form of the tooth depends upon the common oſſeous ſubſtance, which is covered on that part ſeen above the gums by enamel: The molars of the carnivorous quadrupeds, from the manner in which they are uſed, do not wear.

The ſmall *plantigrada*, ſuch as the *hedge-hog*, the *mole*, and the *ſhrew*, and amongſt the *pedimana*, the *opoſſum* tribe and the *perameles*, reſemble each other with reſpect to the ſharp tubercles upon ſeveral of their molar teeth. Cuvier has obſerved, that this form of the poſterior molars belongs to the *inſectivorous* quadrupeds, and that another general character of theſe animals is to have their ſuperior teeth broader tranſverſely than thoſe below.

Amongſt the *ſaltigrade* quadrupeds thoſe that live upon a mixed food, as the *marmots* and the *rat* genus, have the molar teeth with tubercles, covered with enamel which does not wear. The other animals of this order have the crowns of the molares flat upon the top. The oſſeous ſubſtance of the teeth is not clothed but intermixed with layers of enamel, which produce a ſtriated or grooved appearance on the ſurface as it wears. Some of the *ſaltigrada* have their molares entirely compoſed of tranſverſe and vertical layers; others have the enamel only forming upon the crown ſome angles, circles, or other figures, without dividing the teeth into ſeparate parts.

The *cavy* has in the upper jaw the firſt molar compoſed of one plate, the ſecond of two, the third of three, the fourth of four, and the fifth of ſix. In the lower jaw each of the three firſt is made of two laminæ and the laſt tooth of eleven laminæ. Many of theſe laminæ, eſpecially anteriorly, are bifurcated. The grinding ſurface of theſe teeth is quite plain, and aſcends obliquely from within outwards.

In the *guinea-pig* the molars are compoſed each of two bifurcated laminæ. The molares of the *hare* and *rabbit* are likewiſe made of two laminæ, but they are not bifurcated. The *phaſcolomys* has molares reſembling thoſe of the *cavy*.

In the *beaver* there is to each molar an angle returning to the external ſide from below, and to the internal from above, and three others more deep on the oppoſite ſide. When the teeth are worn by uſe, the laſt form only elongated and tranſverſe ellipſes upon the crown.

The *jerboa* of the Cape has but one angle returning to the internal ſide below, to the external above.

The molares in the *kanguroo* are furniſhed with tubercles, and thoſe ſituated poſteriorly have their tubercles united by tranſverſe eminences.

The molar teeth of the *dormouſe* have their crowns flat upon the grinding ſurface, which is regularly ſtriated or grooved. The teeth appear, however, to receive only a ſuperficial covering of fine pearl-coloured enamel.

In the *ſeal* the molars are, like all the other teeth, conical. The poſterior ones, however, preſent ſome points. They cannot be uſed in any other manner than as inciſive or lacerating teeth.

The *morſe* and *dugong* have the molares cylindric in their ſhape, and with a flat grinding ſurface. The latter animal has them alſo grooved upon the ſide.

The *lamantin* has two rectilinear tranſverſe eminences, except on the laſt molar teeth, which has three. They are notched before they are worn.

The teeth of the *cetacea*, as before obſerved, are not calculated to perform any of the maſticating proceſs; they can only be uſed to ſeize and detain the prey of theſe animals.

The moſt perfect examples of the true grinding teeth are found amongſt the *large herbivorous* quadrupeds, particularly the *multungulata*. The teeth, neceſſarily, are continually wearing in thoſe quadrupeds that are ſuſtained, excluſively, upon vegetable matters. They are, therefore, moſt commonly

monly found to be intermixed with the enamel, and to be either covered externally or filled up with the crufta petrofa.

If a fection be made of the grinding tooth of the *fheep*, the appearance of two crefcents will be feen with an oblong dark coloured hole in the centre. The crefcents are formed by the defcending productions of enamel, covered on the infide by a layer of the crufta petrofa.

In the *cow*, and in the *cloven-footed* beafts generally, the enamel and crufta petrofa are depofited in the interior of the teeth, fo as to produce upon the grinding furface, or on a tranfverfe fection, the appearance of crefcents, leaving a fpace in the centre, which is ufually kept full of the mafticated food of the animal. Mr. Home has fuppofed that the portions of food impacted in the cavities of the grinding teeth of graminivorous quadrupeds, fupplies the place of crufta petrofa, and contributes to form the mafticating furface. We have never obferved it to be fo hard as to anfwer this purpofe, and the cavity which contains it is always, we believe, covered by a layer of the crufta petrofa.

In the graminivorous quadrupeds there is generally (and perhaps always, though not obferved) more or lefs of the crufta petrofa depofited around the bodies of the molares as well as in the interior. When the teeth are a very little worn, the prominent parts appear uncovered, and fhew the enamel, and the crufta feems only to have filled up the inequalities upon the furface. In the *fheep* there is no crufta apparent upon the outfide of the tooth after it has been ufed; but it is not improbable, from analogy of ftructure, that when the grinders of the *fheep* firft come out of the gums, that they have a thin covering of crufta petrofa.

The grinding furface of the molares of the *horfe* prefents an undulating or zig-zag line, formed by the offeous fubftance of the tooth and enamel encompaffed in the crufta petrofa. The holes in the *horfe's* teeth are much fmaller than thofe of ruminating quadrupeds. Mr Home has fuppofed that they originally gave paffage to a blood-veffel, but in the *horfe*, as well as the *bifulca*, the cavities of the teeth were occupied by the proceffes of the capfule which fecreted the crufta petrofa.

In the *rhinoceros* and *daman* (*hyrax*), the inferior molars are formed of two crefcents placed in a row, and a little obliquely. The tooth fartheft back in the mouth has three crefcents, the anterior molar only one. The molares of the upper jaw are fquare, have a prominent line parallel to the external fide, and two others which pafs tranfverfely and a little obliquely. The fecond of thefe tranfverfe lines in the *rhinoceros* fends forwards a large hooked procefs. In the *daman* they have each a fmall one. The pofterior molar of the upper jaw has fomewhat of a triangular fhape. The anterior tooth has but one tranfverfe line.

In the *hippopotamus*, the molars in the middle part of both jaws have two pair of cones, fet, as it were, back to back. Thefe have two grooves on the oppofite fides to thofe that are applied to each other: each cone, when worn down, prefents on the top the figure of a trefoil. Both Dr. Blake and Mr. Home reprefent that the crufta petrofa does not enter into the compofition of the teeth in the *hippopotamus* and the *rhinoceros*. It has, however, been fince difcovered, by Mr. Macartney, upon the whole of the external furface of the grinding teeth of the *hippopotamus*. It is a thin layer, which is feen worn away from the prominent parts, thus expofing the enamel, and occafioning the miftake refpecting its exiftence. It is highly probable that a fimilar layer of the crufta petrofa is fpread over the molar teeth of the *rhinoceros* when they are firft formed.

The molares of the *elephant* are the plaineft examples of the conftruction of graminivorous teeth. In the Afiatic fpecies, each grinder confifts of a number of thin proceffes of the offeous fubftance, covered with enamel, united and enclofed by a mafs of the crufta petrofa. Thefe proceffes or plates are fituated tranfverfely with refpect to the tooth; and when a vertical fection is made of the latter, they have exactly the form of the teeth of a comb, imbedded in a third fubftance, which is the crufta petrofa. The grinding furface, after it has been ufed, prefents a number of tranfverfe narrow rough ridges, which are continuous at the edges of the tooth, fo as to exhibit the appearance that would arife from the two fides of an oval being compreffed together. They correfpond to the offeous plates that are covered with the enamel. The interfpaces between them are filled up with the crufta petrofa, which wears fafter than either of the other two fubftances compofing the teeth.

In the *African elephant* the proceffes of the offeous fubftance and the enamel are difpofed in the crufta petrofa in fuch a manner, as to give the appearance of rough lines or ridges which form lozenges upon the grinding furface that touch each other in the middle of the tooth.

In the *fus æthiopicus* the molares are formed of feveral cylindric proceffes of offeous fubftance and enamel confolidated together by the crufta petrofa: their grinding furface exhibits oval or angular figures in rows of three each.

The *mammoth*, or the animal whofe foffil remains have been found on the banks of the Ohio, has long been known to poffefs molar teeth that have the fame ftructure as thofe of carnivorous animals, notwithftanding that in the general its fkeleton refembles the *elephant's* fo much, that moft people now believe it to have been the elephant of the American continent. The teeth of this animal are very large: the crown is entirely covered with a thick coat of enamel, and there is no crufta petrofa intermixed with it. The grinding furface is not flat, nor worn down, but prefents two rows of fhort cones. The only appearance there is of friction prefents itfelf upon the fides of thefe cones, or pyramidal eminences, and feems to be occafioned by the teeth of the two jaws fitting into each other, notwithftanding the molar teeth of the *mammoth* appear to be fo well adapted for mafticating animal food. If we may judge from the fkeleton exhibited in this country, it is utterly impoffible the *mammoth* could have been a beaft of prey. It muft have been difqualified from hunting by the ftructure of its limbs, the form of the head and neck, and the unwieldy figure of its whole body. It has been conjectured by fome, and not improbably, that the *mammoth* fubfifted upon the fifh of the large rivers, on the banks of which its bones have been occafionally found.

The *duck-billed* animal of New Holland (*ornithorhynchus paradoxus*) has parts in the back of its mouth which correfpond to the molars of other mammalia, but which have a different compofition. They are not bone, but a horny fubftance: they are oblong, flat, and are merely fixed in the gums. There is one on each fide in both jaws. Mr. Home has defcribed, likewife, two horny proceffes in this animal on the back of the tongue, which he fuppofes to be defigned to prevent the food being fwallowed before it is fufficiently mafticated.

The molar teeth of the *Cape ant-eater* (*Orycteropus*, Geoff.) are extremely fingular. They have the form of two cylinders joined to each other in the fides. They are entirely compofed of a great number of minute, ftraight, and parallel tubes. If a tranfverfe fection be made of thefe teeth, it prefents exactly the fame appearance that is feen on cutting acrofs a ratan, or other monocotyledon; that is, a number of very fmall pores. This tubular ftructure pervades the whole tooth, except at the grinding furface, which is folid.

Cuvier ſtates, that there is no large cavity in the teeth of the *ornithorhynchus*.

The *Ornithorhynchus hyſtrix* has ſix tranſverſe rows of pointed proceſſes at the back of the palate, and about twenty ſimilar ones on the baſe of the tongue: theſe have all a horny ſtructure as the teeth of the *O. paradoxus*.

The *grampus* (*delphinus orca*) has been reported to have teeth in the palate. Cuvier ſuppoſes they may be horny proceſſes, ſimilar to thoſe of the *O. hyſtrix* above-mentioned. But we have lately diſſected this ſpecies of *delphinus*, and have found that nothing of the kind exiſted in the animal.

The organization and mode of growth of teeth, in general, have been much illuſtrated by obſerving their formation in the larger quadrupeds. The vaſcular tender ſubſtance which ſecretes the rudiment or nucleus of the tooth, and on which the tooth continues to grow, is popularly called the *nerve* in the human teeth, from the ſuppoſition of its being a prolongation of the dental branches of the maxillary nerves. In large teeth the pulp is eaſily ſeen to be formed of a peculiar ſpongy ſubſtance, which in the young animal is nearly as ſoft as jelly; its blood-veſſels are extremely numerous and minute; its nerves are probably the ſame, for there is no large branch of the dental nerve contained in the pulp. The ſtructure of the pulps of the teeth ſeems to reſemble in a great degree that of the pulps of feathers and hairs, and of other excrementitious productions. See the articles FEATHERS, HAIRS, HORNS, &c.

In thoſe animals which have the enamel paſſing down into the ſubſtance of the teeth, there are ſeveral proceſſes of the pulp which produce a correſponding number of oſſeous ſhells or moulds, which have been called *denticuli* in ſpeaking of the compound teeth of quadrupeds.

The oſſeous part of the teeth is more compact and hard, particularly in the molares of the large herbivorous quadrupeds, than it is in the teeth of the human ſubject. There is alſo a ſenſible difference between the compoſition of the external and internal parts of the oſſeous moulds of the teeth in quadrupeds. The firſt depoſits of the pulp are very hard, ſtreaked longitudinally of a yellow-greeniſh hue, and ſemi-tranſparent, like topaz. The parts depoſited by the pulp afterwards are more opaque, of the common colour of bone, and ſhewing but little appearance of laminæ. They approach very nearly in ſtructure the fangs, which being laſt formed, moſtly reſemble common bone. The gradual variation in the hardneſs of the oſſeous part of the teeth may be diſcerned, though leſs plainly, in the human ſubject. The ſtreaked appearance above-mentioned, ſhews evidently that the oſſeous moulds of the teeth are ſecreted by the pulp in layers. The growth of this part of the tooth by layers has been likewiſe proved by Mr. Hunter's experiment of feeding a young pig with madder, when the teeth were forming. The oſſeous layers that were depoſited during the uſe of the madder, were ſtained of the pink colour which this dye-ſtuff produces with phoſphat of lime, and the portions of the tooth formed either before or after the madder had been employed, retained their natural colour. Cuvier deſcribes the formation of the oſſeous moulds of the teeth as being effected by ſucceſſive layers, as in the ſhells of the bivalve molluſca, which fact, he ſays, he had an opportunity of obſerving very ſatisfactorily in the gums of the teeth in the young elephant.

In *carnivorous* quadrupeds, as in *man*, the *roots* or *fangs* of the teeth are formed about the time that the crowns make their way through the gums, but in thoſe *graminivorous* quadrupeds whoſe teeth are ſubjected to much wear, the roots are added ſome time after the eruption of the teeth from the gums, by which means their proper length is preſerved a longer time for maſtication.

The ſtructure of the enamel is very plainly ſeen in the teeth of the large quadrupeds. The eccentric arrangement of its fibres is particularly ſtriking, when a ſection is made of any of the large grinding teeth, in which the enamel paſſes beyond the ſurface. The ſtriæ are in theſe inſtances intermixed at their extremities with the cruſta petroſa, and produce an appearance not unlike the barbs of a feather. Cuvier, in ſpeaking of the enamel, compares it in the tooth of the young *elephant* to the fibres of aſbeſtos, or to the pile of velvet. He obſerves, alſo, that theſe fibres are not always rectilinear, more frequently deſcribing curves, of which the convexity is turned towards the crown of the tooth. The ſame arrangement of the fibres of the enamel, he ſays, exiſts in the *ruminant* quadrupeds. It has, however, eſcaped our attention.

It is well known that the enamel is a production of the capſules of the teeth, but it ſeems yet undecided whether it be a ſecretion immediately performed by the capſule, or a cryſtallization of the fluid contained in it. Mr. Home adopts the latter opinion, and ſuppoſes that the fluid in the capſules of the teeth is ſimilar to ſynovia, which yields, upon chemical examination, a certain portion of phoſphat of lime. It appears to us that the quantity of earthy matter found in ſynovia, ſuppoſing it to be the ſame in the fluid of the capſules of the teeth, is quite inſufficient to account for the production of the enamel. There are only 21 parts of reſidue out of 970 parts of ſynovia, and but a ſmall part of this reſidue is found to be phoſphat of lime: beſides, it ſhould be obſerved, that the fibrous arrangement of the enamel is unlike what would probably be produced by a proceſs of cryſtallization; the diſtribution of the enamel as to quantity alſo would be different from what it is upon the ſurface of the tooth: thus in ſome teeth there is little or no enamel upon the poſterior ſurface, as in the inciſors of the *gnawing* quadrupeds and the tuſks of the *hippopotamus*.

Writers have diſagreed with reſpect to the chemical compoſition of the enamel. Some have denied that it contains any animal matter; moſt, however, allow that it poſſeſſes a very little, upon which, moſt probably, its fibrous ſtructure depends. Morrichini, a chemiſt at Rome, found fluoric acid in the enamel of the foſſil teeth of the *elephant*, and afterwards in leſs quantity in the enamel of the human tooth, the different proportions he aſcribed to the foſſil teeth containing leſs animal matter. His experiments upon the human teeth go to ſhew that the enamel conſiſts of 30 parts of animal ſubſtance, 22 parts of fluat and phoſphat of lime, with ſome magneſia, alumine, and carbonic acid. Mr. Hatchett and Mr. Brande both failed to detect any fluat of lime in the enamel of teeth.

In the compound teeth of the graminivorous quadrupeds, where the enamel is extended from the ſurface between the denticuli, there are correſponding proceſſes of the capſule which paſs from the ſide of the gums. Theſe have, in our opinion, been very improperly called ligaments by Mr. Home. They neither reſemble ligaments in their functions or ſtructure; they are much more like the pulps.

The third ſubſtance entering into the compoſition of the teeth is peculiar to certain mammiferous animals, and is not found in the human ſubject: the hiſtory of it, therefore, is only to be obtained from the late writers upon the teeth. It was firſt called *cruſta petroſa* by Mr. Blake, a very appropriate name, as it appears like a ſtony or inorganic incruſtation on the other ſubſtances of the teeth. Mr. Home, from conſidering that it more nearly approaches the nature of common bone than the other parts of the teeth, has termed

termed it the *offeous* or *bony portion*. The French writers have called it the *cement*, on account of its confolidating into one the different denticuli of the grinding teeth in *graminivorous* quadrupeds.

This fubftance has a pale yellow colour, is uniform in its texture, exhibiting neither fibres nor layers; it is more folid, denfe, and heavy, but lefs hard, friable, or elaftic, than the other parts of the tooth: it refembles more the callous or the offeous matter, poured out in confequence of inflammation, than any other fubftance in the animal body. It always is found depofited in the interftices or depreffions of the teeth; and it is only after thefe are filled, that it appears to give a covering to the more prominent parts. The fuperficies of the crufta petrofa is never regular or fmooth, until it is worn by maftication; and on many parts of the teeth, particularly about the roots, it prefents the appearance of congealed drops of a matter which had been in a fufed ftate. In the *cavy*, however, it contains a multitude of regularly arranged pores.

Tenon fuppofes that the crufta petrofa is produced by the offification of the membrane which had enveloped the teeth. Mr. Blake afcribes its formation to the furface of the membrane oppofite to that which fecretes the enamel. Cuvier, however, gives a more rational account of the matter: he fays, that the internal membrane of the capfule, after it has depofited the enamel, undergoes a change of ftructure, becoming thick, fpongy, opaque, and more vafcular, in order to furnifh the crufta petrofa; that this laft is fhed, as it were, in drops, which form irregularly upon the furfaces of the teeth. When the internal membrane of the capfule is prolonged into proceffes that pafs into the interfpaces of the compound teeth of the large quadrupeds, they become changed in like manner, after depofiting the enamel in thefe fituations, and then fecrete the crufta, which ferves to unite the denticuli into one tooth. This circumftance he had an advantageous opportunity of obferving, during the developement of the teeth in the *elephant*.

The crufta petrofa wears fafter than either the offeous mould or enamel of the teeth, and thence its ufe in the herbivorous animals; the two firft always prefenting upon the grinding furface of the teeth certain eminences, which vary in their figure in different fpecies, as already defcribed, and which operate in the divifion of the food in the fame manner as the irregular eminences on mill-ftones.

The *fucceffion* of the teeth is regulated in mammalia in general as in the human fubject. The front teeth are replaced by larger ones, at an early age; and after thefe and the grinders all come forth, they remain during the life of the animal. In thofe quadrupeds which employ their teeth in a way that fubjects them to much wear, particular provifions become neceffary. We have already mentioned, that the gnawing teeth of the *faltigrade* mammalia continue to grow in the fame proportion as they wear; and the confumption of the grinding teeth, in fome of the large herbivorous quadrupeds, is fupplied by a fucceffion not only of frefh teeth, but by the manner in which thefe come forth from the jaw.

The *elephant* affords the moft ftriking example of this mode of fucceffion. Although this animal has the rudiments of feveral teeth formed in its jaws, we never find more than two on each fide of both jaws at once, *i. e.* eight grinders in the whole: often there is only one apparent in each fide of both jaws. The molares of the *elephant*, as before obferved, are compound, or confift of feveral laminæ or denticuli, united together by crufta petrofa. The firft, or milk grinder, as it is called, pufhes through the gum eight or ten days after birth, and is not completely expofed until the third month: it confifts of four laminæ or denticuli. The fecond grinders, which confift each of eight or nine denticuli, are uncovered in two years. In proportion as the new teeth appear, the preceding ones gradually wear down, and finally have their fangs, and the fockets which contain them, removed by abforption. The whole of a tooth is never feen in the mouth at any one time: indeed it does not exift; for the pofterior portion of the tooth is not completely formed, and does not penetrate the gum, until the anterior portion is entirely worn down. Thus a grinder, confifting of twelve or fourteen denticuli, will have the anterior part worn, and even abforbed, a few denticuli of the middle partially worn and in ufe, and the pofterior denticuli imbedded in the jaw, and their fangs in a ftate of growth, all at the fame moment. This mode of growth and prefentation of the teeth in the *elephant* is admirably calculated for maintaining the grinding furface.

In proportion to the *elephant's* age, the new grinders are formed, larger and of a greater number of denticuli, by which they remain longer in ufe. Thus the third fet have each twelve or thirteen denticuli. They begin to appear when the fecond fet have been all expofed, and difplace thefe at fix years of the animal's age. The fourth fet of grinders are made of fifteen denticuli, and prefent the different parts of their grinding furface from the fixth to the ninth year of age. From the fourth fet to the eighth the number of denticuli varies from fifteen to twenty-three, which is the greateft number that has yet been difcovered in the grinding teeth of the *elephant*. The periods at which the laft fets of teeth penetrate the gums have not been clearly afcertained; but it is fuppofed by Mr. Corfe, who has paid much attention to this fubject, that each fet requires one year longer for its developement than the fet preceding it.

Mr. Home has difcovered that the teeth of the *fus æthiopicus*, which are compofed of feveral denticuli, have a mode of fucceffion fimilar to what has been defcribed in the *elephant*. He concludes from hence, that this animal has greater longevity than the others of the fame genus.

Something of the fame kind exifts in the *wild boar*, and in the *animal incognitum*, according to Mr. Home's obfervations.

The periods at which the molares of the *horfe* come forth, and are fhed, have been lately afcertained by Mr. Tenon; by which it appears that the anterior molares are fhed, and the pofterior are late in appearing: the laft molar cuts the gum only at the fifth or fixth year. The milk grinders of the *horfe* are oblong at firft from before backwards; but, by the preffure of thofe behind, become fquare: the teeth which replace them are alfo fquare.

The mode of fucceffion is nearly the fame in the teeth of the ruminating quadrupeds.

It is only upon animals which live in a domeftic ftate, that accurate obfervations can be made with refpect to the fucceffion of the teeth. This partly accounts for the very few number of facts known upon the fubject. Blake ftates, that the grinders of the *beaver* prefent themfelves in a manner fomewhat fimilar to what has been defcribed in the *elephant*.

The fecond kind of teeth, or thofe for feizing and detaining the prey of the animal, are found in the *cetaceous* tribe of *mammalia*.

In the genus *delphinus*, the teeth are numerous in both jaws. They are nearly conical in their form; thofe of the *porpoife*, however, have the bodies of the teeth flattened, and the roots cylindrical. In the *grampus*, the natural fhape is very much altered by wearing. In this genus, the teeth are lodged in regular bony alveoli; and we have afcertained that a fuca fucceffion is kept up, by new teeth forming in the bottom of the fockets, which pufh out the old ones as they are worn down.

The teeth of the genus *delphinus* are compofed only of two fubftances: the ufual offeous part, which conftitutes the mould or bafis of all teeth; and a cortical fubftance of an intermediate texture between enamel and crufta petrofa. In the *porpoife* this external part is hard and polifhed, and does not readily wear; but in the *grampus* we have found it to be fcarcely, if at all, different from the common crufta petrofa, and to wear like it fafter than the offeous fubftance of the teeth. In fact, there is a gradation to be obferved in the cortical part of the teeth of different animals, from the pure cryftalline enamel to the opaque and comparatively foft incruftation found in the true graminivorous teeth. This variation might be expected, when we confider that both thefe fubftances are fecretions of the internal membrane of the capfules of the teeth.

In the *fpermaceti whales* (*phyfeter*), the teeth are fituated in the lower jaw, and received into correfponding fockets of the upper jaw. They are conical, according to Hunter, at both extremities, and are not placed in alveoli, but grow in the gums. In a fpecimen we poffefs, the root of the tooth is nearly as large as any other part; the crown is worn into the fhape of a compreffed pyramid; and the cortical part refembles almoft exactly crufta petrofa in its texture, and not enamel: it is extended entirely over the root of the tooth.

Hunter ftates that the fmall *bottle-nofe whale* has a number of conical teeth in both jaws, *viz.* forty-fix in the upper jaw, and fifty in the lower. He fuppofed that the teeth of the whale tribe were renewed by the jaws growing forwards, and being abforbed at the fymphyfis, while new teeth made their appearance in the pofterior part of the jaws.

The *narwhal* (*monodon*) has only the two remarkable tufks, which we fhall fpeak of under the head of the weapons of mammalia.

The *hyperodon*, formerly placed in the genus *delphinus*, but lately feparated by Lacepede, is faid to have teeth in the palate, fimilar to thofe of the *ornithorhynchus*, and alfo in the jaws.

But the moft fingular apparatus for retaining the prey in the mouth is the *whale-bone* of the *true whales* This fubftance refembles, in its organization and mode of growth, *hair*, *horn*, and *feathers*, &c. (See thefe words in this dictionary.) The whale-bone is fituated only in the palate and upper jaw: it forms a great number of lamellæ, even fo many, according to Hunter, as 300 on each fide of the mouth. Thefe are of various fizes and lengths. Towards the interior of the mouth they are very fhort, about fix inches; and become gradually wider and longer, as they approach the pofterior and outer part of the palate and jaws: the moft external laminæ in the large *whale-bone whale* are ftated by Hunter as meafuring 12 or 15 feet long, and 15 inches broad. According to Cuvier, they meafure 10 feet long. All the plates are placed tranfverfely, with refpect to the line of the body, and growing downwards, their unequal lengths give the palate and upper jaw the figure of a vault, or the interior of the roof of a houfe.

The plates of *whale-bone* are always found to terminate in a number of long fibres or hairs. This has hitherto been confidered the effect of a mechanical divifion of the end of the plate from ufe; but thefe fibres are, at leaft when firft formed, round and fmooth, and of a thicknefs in fome degree proportioned to the fize of the lamina to which they belong, which makes it probable that the interior part of the plates confifts of round fibres agglutinated into one mafs, fomewhat in the manner of the horn of the *rhinoceros*. The fuperficies of the plates of whale-bone is fmooth, and appears to have a lamellated form.

The laminæ of whale-bone are hollow at their root, and are penetrated for fome way by pulps, in the fame manner as hairs. The interior parts of the whale-bone are fecreted by the pulps, and the external layer by the fame vafcular fubftance extended upon the jaws. This likewife fecretes a whitifh horny fubftance, which furrounds and fills the interfpaces of the bafis of the plates.

Both the plates and the intermediate fubftance are worn by ufe, and renewed by a continual growth. The external part of the plates very foon, (or rather, we believe, immediately upon their protrufion.) breaks off in fcales, and expofes the fibrous or hairy appearance at the extremity of the plates As the hair wears, more of the external part of the plate gives way, fo that the end of the plate that is turned towards the mouth always terminates in loofe fibres.

The white intermediate fubftance, when it grows as high as the edge of the fkin of the jaw, becomes foft, and decays away like old cuticle.

The *third defcription of teeth*, or thofe exclufively intended for *weapons*, ufually occupy the fituation of the canine or lacerating teeth. They are peculiar to fome of the large quadrupeds with feveral hoofs, or the *multungulata*, to two of the genus *trichecus*, and to the *narwhal*. Naturalifts have fo often defcribed the form of thefe defences, that it is unneceffary to repeat the account of it here.

The interior fubftance of the *tufks* has been diftinguifhed by the name of *ivory*: its compofition is fomewhat different from the bony part of teeth in general. In the *elephant* the ivory is lefs hard than in other animals; it likewife becomes fooner yellow on expofure to the air: it is marked by many curved lines, which run from the centre to the circumference of the tufk. The cortical part in the *elephant* is fmooth and harder than the reft of the tufk. Cuvier believes it poffeffes a thin layer of enamel; but in our opinion, the fuperficies of the tufk is crufta petrofa.

In the *hippopotamus* the fubftance of the tufks is hard, and regularly ftriated. There is a moderately thick layer of fine cryftalline enamel on the fore part of the tufks.

The ivory in the tufks of the *fus æthiopicus*, Cuvier ftates to be nearly fimilar to the preceding. In the common *boar* there are no ftriæ to be obferved, but fometimes layers of a brown fubftance.

The maffy tufks of the *morfe* are very denfe in their ftructure, and want the ftriated appearance. The middle part of the tufk is formed of little round grains, not arranged in any order, but like the ftone called *pudding-ftone*. The ivory of the *dugong* has a uniform compofition.

The fingular teeth, or horns, as they are fometimes called, of the *narwhal*, have appeared to us to confift of an offeous fubftance throughout, which is fimilar to the crufta petrofa of the teeth in quadrupeds. The fuperficies is polifhed, as it would feem, by friction. The fpirally grooved appearance of thefe teeth it is very difficult to explain, either with refpect to its production or its ufe.

All the tufks of mammalia appear to continue to grow during the animal's life. The cavity in the root remains of a confiderable fize, and is always filled by a vafcular pulp. The protracted growth of this fort of teeth has produced fome effects that have been made ufe of as arguments for the exiftence of vafcularity and organic actions in the earthy fubftances of the teeth. Thus, feveral inftances have been difcovered of balls, fpear-heads, &c. being lodged in the tufks of *elephants*, and being furrounded by offeous matter, evidently depofited in confequence of inflammation. In all the

the cafes of this kind which have come under our obfervation, the offific depofit appeared to have been made from the interior of the tufk, and no doubt was the confequence of an injury to the pulp; indeed we cannot conceive that it could poffibly be effected in any other manner. To fuppofe that the offeous fubftance of teeth is capable of being inflamed by a mechanical injury, is abfolutely inconfiftent with the very purpofes for which teeth are defigned, not to fay that it is contrary to fome particular facts and experiments. Teeth actually exhibit no morbid actions, either in confequence of injury, conftitutional difeafes of the bones, or the gradual decline of the vital powers. They wear, like any inorganic fubftance, by friction, and what is called their *caries* is a change in the interior arrangement of their particles, commencing on the furface, and proceeding in a manner perfectly fimilar to the decay of artificial teeth, when placed under fimilar circumftances. The pain of tooth-ache depends upon an affection of the pulp, a part extremely fufceptible of difeafe, either in confequence of external influence, or of conftitutional derangement. The irregular and exuberant depofits of offeous matter are made by the fame parts which produce the natural tooth. Thus, the internal membrane of the oyfter, when wounded, is excited to a more copious and irregular fecretion, and thofe excrefcences called pearls are formed. For a more detailed difcuffion of the queftion of the vafcularity of the teeth, we fhall refer the reader to the article TEETH. *Plate* I. of the *Anatomy of Mammalia*, is explanatory of the ftructure and growth of the teeth. *Fig.* 1. fhews a grinder of the *fheep*; *a* is the crown of the tooth polifhed, in order to expofe more diftinctly the crefcentic form of the enamel which penetrates the body of the grinder, and the dark coloured cavity left in the centre. *Fig.* 2. exhibits the grinding furface of the molar tooth of the *horfe*, polifhed: *a* indicates the zig-zag line, formed by the enamel in the interior of the tooth; *b* is the crufta petrofa; *c*, the hole. *Fig.* 3. fhews the grinding furface of the molar teeth of the *African elephant*, in a certain degree worn down; *a*, *a*, *a*, point out the lozenge figures of the denticuli, the fides of which are clothed with enamel; *b b b* refer to the crufta petrofa, a cement which is interpofed amongft thefe denticuli. *Fig.* 4. is the molar tooth of the *cape ant-eater* (*orycteropus*) divided longitudinally, and worn upon the crown: *a*, the lateral view of the tubular ftructure of the tooth; *b*, the appearance of pores upon the end of the tooth. *Figs.* 5 and 6 reprefent the horny fhells, which exift in place of offeous teeth in the *ornithorhynchus paradoxus*. *Fig.* 5. fhews the external furface, and *fig.* 6. the furface by which the tooth is connected with the gums. *Fig.* 7. is the capfule of a grinding tooth in the *calf*, laid open on one fide; *a*, *a*, the parietes of the capfule; *b*, *b*, the proceffes of the pulp, feen paffing upwards, the fhell of the tooth having been removed; *c*, *c*, the proceffes from the capfule which fecrete the enamel and crufta petrofa, paffing downwards. *Fig.* 8. exhibits the lower jaw of the *rat*, divided in a vertical direction, in order to bring into view the courfe and manner of growth of the gnawing tooth; *a* is the jaw-bone; *b*, the gnawing tooth, alfo divided, to expofe the cavity into which the pulp paffes, and remains always of a confiderable fize, for the purpofe of affording a continual fupply of offeous matter. The root of this tooth is feen to be lodged in a canal, extending below the molares to the back of the jaw. *Fig.* 9. is a large grinder of the *Afiatic elephant* divided vertically: *a a a* indicate the offeous part of fome of the denticuli; *b b b* the enamel with which they are covered; *c c c* the crufta petrofa, filling the interfpaces between the denticuli; *d* points to the fore-part of the tooth, which is worn down; *e*, the fangs of the anterior denticuli, nearly abforbed; *f*, *f*, the middle and back parts of the crown of the tooth, with the crufta petrofa entirely enveloping the ends of the denticuli; *g*, the fangs of the pofterior denticuli, not fully formed, that portion of the teeth not yet having been brought into ufe. *Fig.* 10. exhibits a lateral view of one of the plates of *whale-bone* in the *Balæna roftrata*: *a* is the part of the plate which projects beyond the gum; *b*, the portion funk in the gum; *c*, the white fubftance that furrounds the whale-bone and forms a projecting bead, and alfo paffes between the plates to produce their internal lamellæ; *d* is the part analogous to the gum; *e*, a flefhy fubftance, covering the jaw-bone, on which the inner lamellæ of the plate are formed; *f*, the fibres in which the lamellæ terminate.

The *tongue* of mammalia, as far as it is concerned in the acts of maftication and deglutition, does not differ materially from the fame organ in the human fubject, except in the *ant-eaters* and the *cetacea*. The former have the tongue very long, projectile, and furnifhed with fome fingular mufcles for its protrufion and retraction: the latter have the tongue fhort, flat, and very limited in its motions even in the mouth, in which circumftance the *cetacea* refemble fifhes, as might be expected from their having fimilar modes of feeding.

Cuvier has thus defcribed the mechanifm of the tongue in the *porcupine ant-eater* (*echidna*). The organ in this animal becomes fuddenly flender at the place where it arifes from the palate, and appears to be compofed afterwards of two very fmall and long mufcular cones, lying in contact with each other; their point is that of the tongue itfelf. Each of thefe cones confifts of two mufcles; the one external, compofed of a great number of little diftinct fafciculi, which encompafs in fo many circles or rings the internal mufcle. This laft is cylindric and very long. It arifes from the middle and fuperior part of the fternum, proceeds forwards the length of the neck, penetrates between two layers of the mylo-gloffus mufcle, next between two bands of the little portion of the genio-gloffus, and foon after enters the *annular mufcle* above defcribed. The internal longitudinal mufcle is compofed of diftinct fafciculi rolled fpirally upon themfelves. The moft fuperficial of thefe fafciculi terminate at the firft rings of the mufculus annularis. Thofe deeper feated end upon the next rings, and fo on with refpect to the other fafciculi, until they are all expended. The moft internal finifh at the tip of the tongue. The annular mufcles ferve to protrude the tongue by diminifhing its thicknefs; the longitudinal mufcles withdraw it into the mouth, and are likewife capable of turning it in every direction.

In the *echidna*, the *genio-gloffi* mufcles form the greateft part of the bafe of the tongue, but do not enter into the compofition of the elongated part, that proceeds from the palate. There is a kind of *mylo-gloffus* which has the fame attachments as the *mylo-hyoideus*. There is no *ftylo-gloffus* in the *echidna*.

The *common ant-eaters* have a tongue conftructed nearly like the preceding animal. There are a longitudinal and annular mufcle, which conftitute, as in the *echidna*, the elongated part of the tongue. The longitudinal mufcles arife from the enfiform cartilage of the fternum, which is broad and flat, to give them attachment. They pafs on the inner fide of the fternum, through the breaft, and upon the fides of the larynx and os hyoides, to reach the back of the tongue. They are enclofed in this paffage by a tendinous fheath, furnifhed by the genio-gloffus. Blumenbach found, in the *two-toed ant-eater*, the tongue $3\frac{1}{2}$ inches long, and not larger than a crow's quill at the root. It was cylindrical, and faintly

marked

marked with a groove along the ſuperior ſurface. He ſtates that the uſual muſcles of the tongue, particularly the *genio-gloſſus*, were very ſtrong.

According to Cuvier in the *dolphin* (*delphinus delphis*) the *ſtylo-gloſſi* muſcles ariſe from the ſuperior and anterior edge of the ſtyloid bone. The *hyo-gloſſus* comes from the middle of the convexity of the body of the os hyoides. There is but one *mylo-gloſſus*, the fibres of which proceed obliquely backward and inward, from the anterior circumference of the lower jaw towards the tongue.

There is a curious tendinous faſciculus under the tongue of the *dog*, which is popularly known by the name of the *worm*. It lies in a kind of membranous ſheath, and has no connection, like other tendons, to any muſcle.

Caſſerius thought it was uſeful to the dog in the peculiar method of taking liquids by *lapping*, and Blumenbach is inclined to agree with him in this opinion, from finding the ſame ſort of tendon under the tongue of an *opoſſum* he had obſerved to drink, by lapping as dogs do.

A very dangerous notion has been entertained ſince the days of Pliny, that removing the worm from the tongue of a dog will prevent the animal becoming afterwards mad. Another opinion, which is probably as ill founded, is that dogs which have been wormed, if they ſhould be affected with hydrophobia, will not ſhew any diſpoſition to bite. The credulity which has always prevailed reſpecting the mode of preventing and of curing this diſeaſe, has been attended with the moſt miſchievous effects in ſuperſeding the only rational means of ſecurity.

The tongue, as an inſtrument of manducation, is very actively employed. Its muſcles give it the power of moving in every poſſible direction, and therefore of conveying the food from any one part of the mouth to another; it places the unbroken aliments between the grinding teeth; retains them there until they are ſufficiently divided; and then carries them into the pharynx to be ſwallowed. The performance of theſe actions requires a nice feeling in the tongue, which it is known to poſſeſs in an eminent degree. Beſides being an organ of taſte, the tongue has a more diſcriminating touch than any other part of the body, and hence it is employed by jewellers and other artiſts in aſcertaining properties that would eſcape the examination of the other ſenſes

The ſpiculæ upon the ſurface of the tongue in many quadrupeds are calculated to improve the prehenſile powers of this member in a great degree. In the *cat* genus theſe are horny proceſſes, which are ſo ſharp and ſtrong, that they will tear off the ſkin in licking it. Many of the *herbivorous* quadrupeds, likewiſe, have the tongue armed with proceſſes, which are ſerviceable in tearing up their food. The horny proceſſes on the back of the tongue of the *ornithorhynchus* ſhould perhaps be claſſed with the papillæ of that organ, inſtead of being placed amongſt the teeth.

Fig. 11. in *Plate* I. of the *Anatomy of Mammalia*, repreſents the peculiar muſcles of the tongue in the *echidna*: *a* is the *mylo-hyoideus* muſcle; *b* its aſſiſtant portion; *c*, a part of the *genio-hyoideus*; *d*, the *genio-gloſſus*, with its additional portion, *e*, are turned aſide; *f* is the inferior layer of the *mylo-gloſſus*, ſeparated from the palatine membrane, by which the ſuperior layer of this muſcle is ſeen at *g*; *h h h* indicate the *ſterno-gloſſus*, terminating in ſucceſſive faſciculi in the muſculus annularis; *i i i* ſhew the annular muſcle partially expoſed, and at one place cut and turned back to expoſe the ſterno-gloſſus paſſing through it; *k* is the membrane covering the tongue.

The *ſalivary* glands are the ſame in number, with a very few exceptions, in mammalia as in the human ſubject. The *buccales* and *labiales*, however, are often hardly perceptible. The ſtructure of the ſalivary glands is eſſentially the ſame in all caſes; we have only to point out ſome varieties in the relative ſize of the glands, to notice thoſe inſtances where one or all of them may be abſent, and to deſcribe ſome auxiliary glands which exiſt in a few ſpecies.

The ſalivary ſyſtem is leſs ſtriking in the *carnivorous* quadrupeds, than in thoſe that conſume vegetable food. The *parotids* are diminiſhed in particular, being generally as ſmall as the ſub-maxillary glands, and ſometimes even ſmaller; as may be obſerved in the *bat*, the *dog*, and the *American opoſſum* (*didelphis virginiana*). The texture of the ſalivary glands alſo is firmer, and their colour more red in the *carnivorous* than other quadrupeds.

The *ſublingual* glands are not found in the *cat*, and in the *dog* they are but the prolongation of the *ſub-maxillary*.

The *molar* glands, which are ſo ſmall and obſcure in man, are often very plain, and indeed conſiderable in quadrupeds. In the *cat* they form a cloſe oval maſs. In the *dog* they make an uninterrupted ſeries, extended oppoſite the inferior molar teeth. In this animal there is a ſalivary gland, alſo ſituated in the zygomatic foſſa; it is half the ſize of the ſub-maxillary gland: it aſcends as far as under the globe of the eye: its duct, which is very large, deſcends behind the ſuperior jaw, and opens into the mouth, at the extremity of the alveolar border of the ſuperior maxillary bone.

The *ſaltigrade* mammalia have the ſalivary glands larger than the *carnivorous* or *digitigrade*, but, like them, the glands which pour out their fluid into the front of the mouth exceed the *parotids* in ſize.

The *tardigrade* mammalia have the parotids ſmaller than the ſub-maxillary glands.

There are greater varieties to be obſerved in the ſalivary ſyſtem of the *edentata* than in that of any other tribe of mammalia

In the *two-toed ant-eater*, the *ſub-maxillary* glands are of great ſize, they form a cone-ſhaped maſs, which covers the fore-part of the neck, and the top of the breaſt. They are ſunk in between the mammæ, oppoſite the ſternum, and extend forwards as far as the larynx. They then proceed upon the ſides of the neck, and aſcending round the ears furniſh a narrow proceſs, which paſſes forwards between the maſſeter and mylo-hyoideus muſcles. Although this gland ſeems to be only one maſs, it appeared to Cuvier, from whom this account is borrowed, to have two principal excretory ducts, which inſinuate themſelves along the edge of the mylo-hyoideus, and accompanying this muſcle on each ſide as far as behind the arch of the chin, where they open into the mouth. Cuvier, however, ſpeaks doubtingly of this deſcription, as the ſubject from which it was taken had not been well preſerved.

The *molar* glands in the ſame animal are united into one long maſs, covered by the buccinator muſcle.

The *ſublingual* are formed of glandular grains diſpoſed in a ſeries under the membrane of the mouth, the length of the genio-gloſſi muſcles.

The *parotids* appear to be replaced by the ſuperior part of the glandular maſs already deſcribed as the ſub-maxillary glands.

Another ſalivary gland, which from its ſituation in ſome quadrupeds might be called the *zygomatic*, or *temporal*, alſo exiſts of a large ſize in the *two-toed ant-eater*. It is contiguous inferiorly to the upper edge of the maſſeter muſcle: poſteriorly and above, it correſponds to the temporal muſcle, and it embraces anteriorly the globe of the eye. The ſubſtance

ſtance of this gland is more compact than that of the parotid: its duct opens behind the ſuperior maxillary bone.

There is, laſtly, a gland in the *ant-eaters*, the uſe of which is probably to furniſh a mucus to the tongue, that is neceſſary for detaining the inſects on which theſe quadrupeds ſubſiſt.

This gland is of an oval flattened figure, and deſcends before the tendon of the maſſeter, behind the angle of the lips, and then along the border of the lower lip, as far as the middle of it. The excretory duct of this gland opens externally in a groove at the commiſſure of the lips. When the gland is preſſed, there iſſues from this orifice a white thick adheſive matter, which, no doubt, is deſtined for the uſe already mentioned.

In the *porcupine ant-eater*, (*echidna*,) the *ſub-maxillary* glands are extremely large. They extend far backwards. The lobes of which they are formed are very diſtinct, and the ſmall excretory ducts of the glands are ſeen to terminate by plain orifices in a principal duct, the diameter of which is very conſiderable. The chief duct proceeds in the direction of the axis of the gland, upon the muſcles which go to the tongue, and penetrates the membrane of the mouth very near the ſymphyſis of the jaw.

There are alſo in the *echidna* two *ſublingual* glands, of an oval form, ſmaller than the ſub-maxillary, and with more compact lobes. They are ſituated behind the membrane of the mouth, on each ſide of the baſe of the tongue, and pour out their ſecretion through a number of ſmall foramina at that place.

In the *multungulata* the ſalivary ſyſtem is extenſive. The *pig* has two *ſublingual* glands. The firſt is very narrow and long, compoſed of little lobes of a pale red colour, and accompanies the duct of the ſub-maxillary gland from the angle of the jaw as far as the ſecond ſublingual gland, and opens by one ſmall orifice. The other ſublingual gland is placed anterior to this; it is ſquare, flat, and compoſed of lobes of a larger ſize, and a redder colour, than thoſe of the firſt ſublingual gland. It has eight or ten excretory ducts, which perforate the membrane of the mouth in a row.

The *molar* glands of the *pig* are two long maſſes, which are of a reddiſh colour, and conſiſt of large lobules, like the ſecond ſublingual of this animal.

In the *biſulca*, or *cloven-footed* quadrupeds, the ſalivary glands are of a great ſize, particularly thoſe which are ſituated poſteriorly with reſpect to the mouth.

In the *ox* and *ſheep* there is a cluſter of glands in the zygomatic foſſa, which extends as high as the globe of the eye, and deſcends below the zygoma, under the maſſeter. Its excretory ducts open behind the laſt molar tooth.

The *zygomatic glands* in the *horſe* are the continuation of the molars, which aſcend behind the upper jaw to near the abductor of the eye. The *parotids* in the *horſe* are very large, paſſing upwards behind the external ear, and downwards as far as the angle of the jaw.

In all thoſe animals that inhabit the water, the ſalivary glands are either very ſmall, or abſent altogether. In the *common ſeal*, the *parotids*, the *ſublingual*, and the *zygomatic* glands are wanting. There are two *ſub-maxillary*, the one is larger than the other, and they have a common excretory duct, which opens as uſual under the frænum of the tongue.

In the *cetacea* there is no veſtige of ſalivary glands.

From the preceding deſcription it will be ſeen the relative and abſolute ſize of the ſalivary glands depend upon the uſe that is made of the teeth. When a ſpecies of food is taken that requires much maſtication, the glands that pour their ſaliva into the ſides of the mouth are particularly large. When the food is of a kind that needs but little diviſion, the ſalivary glands are ſmaller, eſpecially thoſe which furniſh their fluid to the grinding teeth. In the *whale tribe*, which do not maſticate at all, the ſalivary ſyſtem is unneceſſary, and accordingly does not exiſt. The great ſize of the ſalivary glands of the *inſectivorous* quadrupeds would ſeem to be an exception to general rules, but it is to be remarked that in theſe animals the ſalivary glands immediately ſubſervient to maſtication are wanting. The great bulk of the others may, therefore, be neceſſary for entangling and detaining the ants upon the tongue, and facilitating their paſſage into the œſophagus.

No accurate or comparative examination has yet been made of the chemical properties of the ſaliva of quadrupeds, but the ſtructure of the glands being ſimilar, it is probable that the fluid they ſecrete does not differ materially from the ſaliva of the human ſubject.

In ſome mammalia, there are dilatations of the internal membrane and integuments of the mouth in which the food is depoſited for a time previous to its being ſwallowed, and in which it is ſoftened by maceration in the ſaliva. Theſe cavities have received the names of *cheek pouches*, and *jaw ſacs*.

A great number of ſpecies of *monkey* poſſeſſes cheek pouches. They are not large, and the openings into the mouth are nearly as wide as the ſacs themſelves Being ſituated oppoſite to the inferior molar teeth, they are well ſupplied with ſaliva from the parotids. When they are empty, the face of the monkey looks thin and ſunken.

The *macerating pouches* connected with the mouth are much larger in the *hamſter* (*mus cricetus*), and ſeveral other ſpecies of *mus* allied to the *hamſter*. The moſt remarkable pouches, however, are found in the *Canada rat*, (*mus burſarius*,) a ſpecies deſcribed by doctor Shaw in the 5th vol. of the Linnæan Tranſactions. He has diſtinguiſhed it by a ſpecific name expreſſive of its enormous pouches. In the figure he has given of it, the pouches are ſeen to hang down like two oval bags from the jaws, each of them equalling the ſize of the whole head.

Where the macerating pouches are large, they are ſaid to be uſed for carrying the animal's food to their habitations, in which they depoſit a winter ſtore.

Pouches which appear ſtrictly for macerating, have been deſcribed by Mr. Home in the *ornithorhynchus paradoxus*.

In *Plate* II. of the *Anatomy of Mammalia*, *fig.* 1. repreſents a front view of the head and ſhoulders of the *mus burſarius*, with its enormous pouches diſtended. The appearance of blood-veſſels ramifying upon them is to be ſeen.

The *pharynx* of mammalia reſembles in moſt particulars that of the human ſubject. Cuvier mentions ſome ſlight alterations in the direction and actions of the *ſtylo-pharyngeus* muſcle. He ſtates that in the *paca* this muſcle ſeems to be the continuation of the *ſtylo-maſtoideus*, and in the *elephant* it is united to the *ſtylo-hyoideus* as far as the top of the pharynx.

In addition to the uſual muſcles of the pharynx, many quadrupeds, particularly the *elephant*, *bear*, &c. have been obſerved to have the proper muſcles of the tube of the œſophagus continued upon the bag of the pharynx. Theſe layers Cuvier calls the *pharyngeus proprius*.

It is ſomewhat ſingular that the *uvula* is a part peculiar to *man* and the *monkey*.

The pharynx of the *whale* tribe is formed into two paſſages, by means of the curious larynx of theſe animals, which is elevated ſo high as to be inſerted into the aperture, correſponding in ſome degree to the poſterior nares. The ſtructure of theſe parts will be better underſtood after the deſcription of the larynx in the *whale*.

Œſophagus.—This tube in moſt mammalia has the muſcular coat formed of two layers, the fibres of which have a ſpiral direction; the external layer takes one courſe, the internal an oppoſite one; ſo that they always decuſſate each other. Some anatomiſts have ſuppoſed that theſe ſpiral muſcles were peculiar to the œſophagus of *ruminant* quadrupeds, although they were figured in the *dog* above a century ago by Blaſius. They have likewiſe been found by Cuvier in ſeveral quadrupeds, and by us in others, from which it would ſeem to be a tolerably general ſtructure in mammalia. The muſcular coat has been found to reſemble that of the human ſubject in the *kanguroo*, in which animal it is alſo thicker than the muſcular tunic of the reſt of the alimentary canal.

The œſophagus of mammalia, generally ſpeaking, is richly ſupplied with mucous glands.

The cuticular membrane is very plain in many quadrupeds, eſpecially thoſe that have the ſtomach partially lined with cuticle. There is a very ſtrong white cuticle in the œſophagus of the *whale* tribe.

The internal membrane of the œſophagus exhibits longitudinal folds in many quadrupeds. Cuvier has remarked, beſides theſe, ſome tranſverſe folds about the middle of the œſophagus in ſeveral *carnivorous* mammalia, as the *tiger*, *lion*, *lynx*, and the *Virginian opoſſum*, in all of which theſe folds are very ſtriking, forming a ſpecies of valves. They exiſt likewiſe, but in a ſlighter degree, in the *civet*, and in the *couguar* (*felis concolor*).

Theſe valves, or tranſverſe folds, are placed cloſe to each other. They do not include the whole of the circumference of the œſophagus; but there are uſually two or three which unite at an acute angle, in order to complete the circle.

The œſophagus of quadrupeds, in conveying ſubſtances into the ſtomach in a direction contrary to their gravity, exemplifies very clearly its functions in all animals. Its actions are always periſtaltic, like thoſe of the inteſtines. The ſucceſſive contraction and dilatation of the different parts of the canal are obviouſly ſeen when a horſe, or other long-necked quadruped, is drinking; the water does not paſs in a ſtream along the gullet, but in the form of globes, the muſcular fibres contracting behind them, as they paſs onwards. The œſophagus is, therefore, always in a comparatively collapſed ſtate, except at the very parts of the canal which contain the portions of food or drink.

The termination of the œſophagus is open and direct in the *carnivorous* quadrupeds, but in many of the *herbivorous*, particularly thoſe with complicated ſtomachs, it is contracted, or enters obliquely. The œſophageal orifice of the ſtomach in the *horſe* is diminiſhed by a projection of the tunics, which has ſomewhat the appearance, and, as it is ſuppoſed, the effect of a valve. This ſtructure is commonly believed to render the *horſe* incapable of vomiting. We are, however, well informed that *horſes* have been known to vomit when very active medicines have been employed. We believe, alſo, that it is equally difficult to excite vomiting in the *ruminant* animals, although they have the power of ſpontaneouſly bringing back the contents of the ſtomach into the mouth at all times. We muſt, therefore, ſeek for ſome other explanation for the indiſpoſition to vomit in theſe animals, than the mode in which the œſophagus terminates in the ſtomach. Shall we attribute it to the parts of the ſtomach adjoining the œſophagus being leſs ſuſceptible of ſtimuli, from being covered with cuticle? or is it that the medicines that have an emetic effect upon the human ſubject have a different operation upon them? It is a fact well known, that medicines have different, or even oppoſite effects upon different animals. The ſtomach of the *dog* is provoked to vomit by eating graſs.

A peculiar glandular and moveable bag has been deſcribed behind the palate in the *camels*, which is ſuppoſed to carry water for moiſtening their fauces. Cuvier ſtates it to exiſt only in the *dromedary*, in which it is thruſt forth on the neck in the rutting ſeaſon.

Stomach.—The hiſtory of this organ in mammalia forms one of the moſt intereſting branches of comparative anatomy. The varieties in its form and ſtructure, ſuited to the various kinds of food uſed by this claſs of animals, are highly inſtructive, and have been particularly inveſtigated as being applicable to the explanation of the functions of the ſtomach in man.

The moſt ſimple *form* of the ſtomach belongs to thoſe mammalia which ſubſiſt upon fleſh. In many of the beaſts of prey the ſtomach is nothing more than a ſlight dilatation of the alimentary canal. The cardiac or œſophageal end is larger than the pyloric, but there is no cul-de-ſac, or dilated part placed out of the courſe of the ſubſtances through the viſcus in which they can be detained. The beſt examples of the carnivorous ſtomach are found in the *pole cat*, and moſt of the genus *muſtela*, the *dog*, *hyæna*, *badger*, ſome of the genus *felis*, &c. In all theſe caſes the ſmaller curvature, as it is called, is ſlightly hollowed, the dilatation being entirely in the great or lower curvature, and chiefly, as before obſerved, at the left or cardiac end. In the *ſeal* the ſtomach has great reſemblance to that above deſcribed; the œſophagus forms even leſs of an angle with the ſtomach, but enters it at the end of the left extremity. The leſſer curvature is not concave, but nearly preſents a ſtraight line, and there is near the pylorus a degree of circular contraction.

The enlargement of the great end of the ſtomach, and the inſertion of the œſophagus ſomewhat nearer to the middle of the organ, is the firſt deviation of form to be obſerved. This figure is calculated to receive a larger quantity of food, and to retard in ſome degree its progreſs through the viſcus; we accordingly meet with it in thoſe animals that live upon a mixed food, or upon vegetable matters, either prepared by cooking, or ſome other means, to render them more digeſtible. This form of ſtomach exiſts in the *human ſubject*, in moſt of the *monkey* tribe, and of the *bats*, in ſome of the *plantigrade*, and many of the *ſaltigrade* mammalia.

The *orangs* reſemble man with reſpect to the form of the ſtomach more than any other of the *monkey* genus. Several of the other ſpecies differ in the degree of cul-de-ſac produced at the great end, by the ſituation of the œſophageal orifice, and ſome other immaterial circumſtances which are pointed out in Cuvier's Anatomie comparée, tom. iii.

In the *galeopithecus* the pyloric half of the ſtomach is prolonged ſomewhat in the form of an inteſtine.

In the *brown bear* the portions on each ſide of the entrance of the œſophagus are directed towards the diaphragm. In the *hedge-hog*, alſo, the pyloric and cardiac ends of the ſtomach turn a little towards the diaphragm.

In the *brown coati* the ſtomach reſembles in figure a pear, the pyloric end correſponding to the ſtalk, and the œſophagus being inſerted into the ſide of the fruit.

The Pariſian academicians deſcribed the ſtomach of the *lion* as being in the ſame direction as the œſophagus, until near the pylorus, when it turns upwards, or forms the ſmall curvature, in the ſame manner as frequently is ſeen in the ſtomach of fiſhes. The academicians alſo found ſome dilated parts or pouches in the *lion's* ſtomach, but theſe differed in form and ſituation in different individuals. In the figure given by Cuvier of the *lion's* ſtomach, it has the ſame direction, but wants the dilated parts obſerved by the academicians. The preparations we have ſeen of the ſtomach of the *lion* reſemble thoſe of the *common cat*, in which

which the cavity is larger than in the perfect carnivorous ſtomach.

The figure of the ſtomach is ſingular in the *garden ſquirrel* of Pennant (*myoxus nitela.*) It is that of a globe, at the top of which both the œſophageal and pyloric orifices are ſituated cloſe to each other. The tubes of the œſophagus and inteſtine are both ſmall compared with the ſize of the ſtomach.

The form of the ſtomach is alſo globular in the *cape ant-eater* (*oryčteropus*), but the part which leads to the inteſtine is a proceſs from the right of the upper part of the globular ſac: this prolongation has a very ſtrong muſcular coat.

In the *echidna* the ſtomach is large and has thin coats; the figure is oval; the cardiac and pyloric orifices are nearly at the two ends of the ellipſis: there is a ſlight oval enlargement at the origin of the inteſtines. The ſtomach is glandular near the pylorus, and the muſcles are diſtinct at the ſame place. The internal membrane is thrown into ſome fine rugæ at the cardia, and forms larger and more numerous folds near the pylorus, which make a kind of radiated fringe. The pyloric orifice is not diminiſhed by a circular fold, but the parietes of the ſtomach, which are thicker than thoſe of the duodenum, form a projection into the latter.

The moſt extraordinary form found amongſt the ſingle ſtomachs of mammalia belongs to the *ornithorhynchus paradoxus.* It reſembles a wine bottle, flat at the bottom, nearly ſtraight on the ſides, and tapering at the top. The œſophagus correſponds to the neck of the bottle. The duodenum ariſes from the part ſimilar to the top of the body of the bottle, and ſoon becomes about half as wide as the ſtomach, which is extremely ſmall in proportion to the reſt of the alimentary canal, and to the ſize of the animal.

The *rhinoceros* has an unuſual form of ſimple ſtomach. The cardiac portion is diſtinguiſhed from the pyloric by a permanent contraction of the ſtomach. The former is an elongated oval. The œſophagus enters at nearly midway between the great end and the contracted part. The pyloric portion has a globular figure. The inteſtine ariſes out of the centre of it, and in a direction towards the great or left end of the ſtomach. The *rhinoceros* affords a real inſtance of a diſtinction of two portions of the ſtomach, without any proceſs of the internal membrane forming a line of ſeparation.

Mr. Home has fancied that a diſtinction of the ſtomach into two cavities exiſts in all ſingle ſtomachs during life, by means of a permanent contraction of the muſcular fibres of the middle of the ſtomach.

The effect of ſuch an hour-glaſs contraction of the ſtomach would neceſſarily be to detain the food in the great end, either as a temporary or a preparatory reſervoir, neither of which are required from the nature and preparation of the food of thoſe animals which poſſeſs a ſimple ſtomach. Mr. Home's hypotheſis tends to reduce the complicated and ſingle ſtomachs to one kind, or claſs, and to break down all the diſtinctions eſtabliſhed by nature, to correſpond with the different kinds of food, and the various modes of its preparation.

It has frequently occurred to many experimental phyſiologiſts, and to ourſelves, to ſee the figure of the ſtomach in the living body, but a regular and conſtant diviſion into two portions by means of the muſcular coat has not been remarked. We have obſerved different parts of the ſtomach in a contracted ſtate: the muſcles near the pyloric act moſt ſtrongly, as might be expected, in order to propel the alimentary matters into the inteſtine, and the great end of the ſtomach is in general found moſt diſtended, as being the part in which the food firſt arrives, and, conſequently, is in ſome degree accumulated.

In many of the ſimple ſtomachs, the great end, or cardiac portion, is diſtinguiſhed from the pyloric by having a thinner muſcular coat: this difference of ſtructure is uſually accompanied by a larger capacity of that part. In ſome of theſe caſes, likewiſe, the cuticle of the œſophagus is continued over the cardiac portion of the ſtomach. Theſe facts prove the gradual approaches that are made in the ſtructure of the ſtomach from a ſimple digeſtive organ, to the additional functions of a preparatory reſervoir. The diſtinction of the ſtomach into two cavities, by means of ſtructure and the prolongation of the great end into a more perfect cul-de-ſac, are particularly well ſeen in ſeveral of the *rat* genus, and ſome other ſpecies of *ſaltigrade* mammalia.

In ſome of the laſt mentioned tribe, the ſtomach is even more decidedly divided into two cavities than in the ſpecies to which we have alluded.

The *hamſter* (*mus cricetus*), has the ſtomach formed of two cavities, the ſides of which are conjoined, and communicate together by an orifice, apparently about the width of the duodenum, in the ſame animal. The œſophagus belongs to the left cavity, but enters at the junction of the two. The cardiac cavity or portion firſt extends outwards, and then turns up at the part correſponding to the great end of the ſtomach. The pyloric half is of a more irregular ſhape, and has thicker coats than the firſt. When diſtended, it has, in a degree, a ſacculated appearance from ſome dilated parts of its parietes. The communication between the two ſides of the ſtomach is guarded by a fold, which is fringed upon the edge.

In the *water rat* the ſtomach is converted into two cavities, by means of a contraction ſituated a little to the right of the cardiac orifice, which is nearly about the middle of the ſtomach. The left or cardiac cavity is almoſt tranſparent from the thinneſs of its coats, ſhewing the diviſion of the ſtomach to be deſigned to produce the effect of a reſervoir.

The *ſhort-tailed rat* of Pennant (*mus arvalis*) has the ſtomach divided in the ſame manner as the *water rat.*

The *lemming*, or *Lapland marmot* of Pennant, and the *mus lagurus* of Pallas, have alſo two cavities: they are ſeparated in the latter animal by a very thick fold, that projects interiorly, and is fringed upon the edge.

The ſtomach of the *mole rat* of the Cape (*mus capenſis*), is curved upon itſelf, and the œſophagus opens near to the pylorus; it is alſo divided into two cavities by a ſemi-lunar fold, which is furniſhed poſteriorly by the internal coat.

In the *muſk rat* (*mus zibethicus*), there is a contraction of the middle of the ſtomach, by which two cavities are formed.

The *mus aſpalax*, and *mus œconomus*, have the ſtomach divided into three pouches. In the former there are two reflections of the internal membrane, which proceed from each ſide of the cardia. The one on the right is carried on throughout the whole circumference of the ſtomach. It has a denticulated edge, and there is a round gland in the moſt projecting part of its large curvature.

The ſtomach has a very ſingular conformation in the *kanguroo.* It is greatly elongated, and doubled twice upon itſelf. It reſembles very much the great inteſtine of the *horſe,* not only in figure and great extent, for it nearly fills up the abdomen, but in being divided into a great number of ſacculi by means of longitudinal muſcular bands, ſuch as exiſt upon the ſides of the colon. The œſophagus

gus enters the ſtomach at about $\frac{1}{6}$th of its length from the end of the cul-de-ſac. The cardiac end furniſhes two proceſſes; the external one has thick and glandular coats, while the other is ſmooth, whitiſh, and irregularly corrugated, like the reſt of the internal ſurface in the cardiac portion of the ſtomach. This appearance of the internal membrane is preſerved around the cardia, and in a part of the right portion where there are two long triangular bands. In the remainder of this portion, the inner ſurface is more grey, mucous, ſemi-tranſparent, uniform, and without rugæ. There are two appendices which ariſe beyond the middle of the pyloric portion, and are curved backwards, like two ſhort cæca. The muſcular coat forms a projection around the pylorus, by which it is much contracted, and the internal ſurface preſents an annular burr at the ſame place, which conſiſts of follicular glands. The muſcular coat of the ſtomach in the *kanguroo* has tranſverſe fibres going from the one longitudinal band to the other on the right portion, but on the left part of the organ there are only the longitudinal muſcles to be ſeen.

The ſtomach of the *kanguroo rat* is divided into two portions, not only by its figure, but a difference of ſtructure. The œſophagus opens at the place where the cardiac and pyloric cavities join, and there is a projecting fold which is continued from the œſophagus into the pyloric cavity, the deſign of which is evidently to conduct the food, under certain conditions, more immediately into the ſecond cavity. The whole ſtomach poſſeſſes longitudinal bands, which produce contractions in its parietes, but this ſtructure is particularly ſtriking in the cardiac half, which is thrown into numerous deep ſacs or pouches. The internal membrane of the left portion forms ſtrong longitudinal rugæ on the poſterior half of this cavity, and ſlight folds paſſing between ſome many-ſided areas on the reſt of the cardiac, and the beginning of the pyloric diviſion of the ſtomach. The remainder of the latter is ſmooth, and without rugæ internally. There is a narrow gland, which extends the length of the firſt diviſion of the ſtomach, and diſcharges its fluid through numerous ſmall orifices upon the internal membrane.

In the *daman* (*hyrax*), the ſtomach has two cavities. The firſt is nearly globular, and receives the œſophagus in its right ſide: the ſecond is pyriform, and has the pylorus at the top, where there is a ſtrong marked annular contraction. The part by which the two cavities are conjoined is very ſmall.

The *porcupine* has the ſtomach conſiſting of three globular pouches. One correſponds to the cardiac portion; another to the pyloric: and the third, a ſmaller pouch than either, is placed between the two firſt, juſt at the termination of the œſophagus. Interiorly there is a fold which proceeds from the right of the cardia, and ſeparates the left pouch from the two others. There is at the pylorus, on the ſide of the little pouch, a ſemi-lunar burr, compoſed of glands. The inteſtine and œſophagus are ſeen to ariſe cloſe to each other, ſo that the whole figure gives the idea of a heart with the large veſſels. The internal membrane is uniform throughout.

In the *vampyre bat*, the œſophagus, before it enters the ſtomach, is dilated into a large oval ſac, which communicates very freely with the cavity of the latter, and may therefore perhaps be conſidered as belonging to it. The ſtomach is long, reſembling, in ſome degree, the colon of an animal. The left end is turned upwards, and at the extremity is curved backwards. Mr. Home deſcribes this portion of the ſtomach as being divided into two dilatations, with a neck between them, the one having a rugous, and the other a ſmooth ſurface. The diſtance from the œſophageal orifice to the pyloric is more than two-thirds of the whole length of the ſtomach: it firſt proceeds to the right ſide, and then turns back upon itſelf; the reflected part is puckered, or thrown into ſacculi. The pylorus has a valve, which, when cloſed, will not permit air to paſs through it.

The *ſpectre bat* has alſo the dilatation at the termination of the œſophagus; but all the other ſpecies of *veſpertilio* appear to have a ſimple globular ſtomach.

We ſhall now proceed to the deſcription of ſome ſtomachs which are more complicated in their forms than any hitherto mentioned.

In the *Pecari*, or *Mexican hog*, there are two remarkable proceſſes from the cardiac portion of the ſtomach, which are turned downwards, and appear to render the cavity of three parts. There are ſeveral contractions dividing the pyloric portion of the ſtomach from the other. The cardiac portion is by much the larger. Daubenton has repreſented the ſtomach as being divided into a greater number of pouches or proceſſes than are deſcribed by Cuvier or Home.

In the *hippopotamus* the cardiac portion contains three pouches, two of which only appear on the outſide: the ſtomach then becomes long and cylindric, like an inteſtine, and terminates in a narrow appendix, which opens into the duodenum. There are many tranſverſe folds or valves in the firſt part of the cylindric portion. The internal membrane is hard and granular in this part, from the laſt valve and in the two larger pouches: beyond the valves it is ſmooth and folded; there are no folds in the appendix, but the muſcular coat of it is very thick, particularly around the pylorus.

The ſtomach is extremely complicated in the *tardigrade* quadrupeds, and approaches, in a conſiderable degree, the conformation of this organ in thoſe that chew the cud. In the *two-toed ſloth*, it appears, when viewed externally, to conſiſt of two cavities. The left is very large in proportion to the œſophagus and the inteſtines; is nearly ſquare in its figure, and exhibits, at leaſt upon the anterior part, three elevations, or dilated parts. When the ſtomach is laid open, theſe are found to correſpond to three cavities, or apartments, which are ſeparated from each other, interiorly, by projections of the coats. The left, or cardiac diviſion, of the organ in theſe animals ſhould, therefore, be properly conſidered as three cavities. The pyloric, or right diviſion of the ſtomach, is formed like an inteſtine, or rather, from its dilatation towards the middle, it reſembles the ſimple carnivorous ſtomach in its figure. It is much ſmaller than the left portion, under which it is curved in the direction from right to left. The firſt half of it has very thin coats. The remainder has them thicker, particularly about the pylorus, the orifice of which is much contracted. Theſe two parts of the right diviſion of the ſtomach are ſtated to be ſeparated by a ſemilunar fold. The firſt of theſe ſeems to be again divided by a little fold, finely denticulated upon the edge. The internal coat is different in the two portions. The firſt portion terminates in a little cul-de-ſac, which is ſeen anteriorly upon the right ſide of the firſt, or cardiac diviſion of the ſtomach, between two others. Theſe little appendices appear to be glandular.

The inner coat is ſmooth in both the cardiac and pyloric diviſions of the ſtomach of the *two-toed ſloth*: it appears even to be tendinous in the two firſt cavities, or pouches, of the cardiac diviſion.

In the *three-toed ſloth*, the appendix of the ſecond ſtomach is is much longer than in the preceding ſpecies, and is divided into three apartments by two longitudinal ſepta.

In both theſe ſpecies, the œſophagus, on entering the cardiac diviſion of the ſtomach, becomes connected with a canal, which arrives, by a circuitous courſe, in the pyloric, or right diviſion, into which it opens by a contracted orifice. The exiſtence of ſuch a communication as this would lead us to expect, that the *ſloths* had the power of ruminating; but Cuvier ſtates, that he found both diviſions of their ſtomach equally filled with ſome ligneous ſubſtances, reduced to a ſort of mould, or earth. We ſhall refer the reader for a more particular account of the ſtomachs of the *tardigrade* mammalia to Cuvier's Anatomie comparée, tom. iii. Daubenton Hiſtoire Naturelle, tom. xiii. and Wiedeman's Archives, vol. i.

We have next to deſcribe the ſtomachs of the *ruminating* quadrupeds. There are ſome differences to be obſerved between the ruminants with horns, and thoſe without. We ſhall firſt give an account of the ſtomachs of the horned ruminants, and as the moſt familiar example, take for this purpoſe the *ox*.

In this tribe of animals there are four ſtomachs, which fill up a great part of the abdominal cavity. The firſt ſtomach is called the *paunch*, (*rumen*, *penula*, *magnus venter*, *&c.*) It occupies the left ſide of the belly, and is larger in the adult than the three other ſtomachs taken together. It has an irregular globular figure. When laid open, it is found to be, in a certain degree, divided into three cavities, by means of two ridges, or projections of its coats, which croſs it obliquely. The upper hollow contains the mouth of the ſecond ſtomach, which is ſo large, that the two firſt ſtomachs ſhould, perhaps, be conſidered as parts of the ſame cavity. The reflections of the coats, which form the ridges above mentioned, contain, beſides the muſcular coat, ſome tendons. The edges of the ridges are, therefore, thick and rounded. All the muſcles of the paunch are particularly firm in their texture. The internal membrane is of a brown colour, and covered with ſtrong papillæ in moſt places. The edges of the ridges are ſmooth. There is a thick cuticle lining the paunch, which may be detached by maceration, when it is ſeen to have given a covering to each of the papillæ. The contents of the paunch are the vegetable matters imperfectly maſticated, and unmixed with any of the animal juices, or even the drink. It is in this ſtomach, therefore, that fermentation of green food is liable to occur. Many of the horned cattle have their body greatly diſtended by the extrication of air during this proceſs in the paunch. The only remedy is to plunge a knife into the left loin of the beaſt; when the paunch will be penetrated, and an immenſe quantity of air will ruſh out. This expedient, although apparently ſo deſperate, we believe, is never followed by any bad conſequence. It is generally in the firſt ſtomach, rarely in the ſecond, that the concretions of hair, or of vegetable fibres, or calcareous ſubſtances, are found. The *hair-balls*, occaſionally met with in the paunch of the cow, are licked off from the body. They are curiouſly interwoven, and ſometimes are covered with an earthy matter, which receives a fine poliſh. The balls found in the ſtomach of the *chamois* are compoſed chiefly of the fibres of the *ethuſa meum*, and are covered with a fine black incruſtation. The bezoar ſtones are earthy concretions, formed in a ſimilar manner. See Bezoar, in this Dictionary.

The ſecond *ſtomach* of the *ox*, which is called the *honey-comb bag*, the *bonnet*, and *king's-hood*, (*reticulum*. *cellula*, *&c.*) might be conſidered, if it were not for its internal ſtructure, as a globular appendage of the paunch: it is placed upon the right ſide of the former, with which it communicates very freely, as before-mentioned. The internal ſurface is elevated into thin folds, which unite to each other, ſo as to produce many-ſided meſhes, or ſuperficial cells. The ſides of the folds are grooved, and their edges denticulated. The area of the cells is papillated as the paunch, but with finer eminences. The ſecond ſtomach is lined by a continuation of the cuticle which covers the firſt. The muſcular coat is generally thicker and ſofter in the ſecond than in the firſt ſtomach.

The œſophagus opens at the junction of the firſt and ſecond ſtomachs, ſo as to be capable of communicating freely with the cavity of both, but the operations of ſwallowing and regurgitation are materially influenced by the actions of a muſcular groove, or channel, which is continuous with the tube of the œſophagus, and ultimately leads into the third ſtomach. This groove is formed by two muſcular columns, which proceed from the ſides of the œſophageal orifice. The right band, or column, extends the length of the ſuperior ſurface of the honey-comb ſtomach. The left runs within the edge of the opening from the firſt into the ſecond ſtomach, and is prolonged upon the left ſurface of the latter. Each of theſe columns paſſes round the orifice leading from the ſecond into the third ſtomach, decuſſating upon the inſide of it. The internal membrane, where it covers theſe muſcular columns, is thick and regularly plaited tranſverſely. The membrane, on the contrary, is very thin between the columns, and forms, in the concave part of the groove, ſome longitudinal folds. There alſo is in this ſituation a layer of muſcular fibres, which paſs behind the groove, and connect one border of it with the other. This channel is the chief characteriſtic of the ruminating ſtomachs. When a portion of food is to be re-conveyed to the mouth, it is received into the groove, which, by the contraction of its muſcles, approximates the two borders, and forms a perfect tube, and thus tranſmits the morſel into the œſophagus. Again, when rumination is finiſhed, and the morſel ſwallowed, the groove forms a tube, and conveys it into the third ſtomach directly. When the food and water are firſt received into the ſtomach, the ſides of the groove are neceſſarily open, but it is probable, at the ſame time, that the orifice of the third ſtomach is cloſed. The different actions of the groove are evidently ſubjected to the will of the animal, which is extremely curious, as it cannot be accounted for by any peculiarity in the anatomy of the part. The ſame ſyſtem of nerves and veſſels belong to the groove as to the ſtomach of other quadrupeds.

Mr. Home ſtates, that the food contained in the paunch is always dry, and that the water the animal drinks paſſes into the ſecond ſtomach, without mixing with the food in the firſt. The office of the honey-comb bag, therefore, ſeems to mix in a gradual and convenient manner the liquid and dry aliments. In this point of view, the firſt ſtomach is the receptacle of the meat; the ſecond, of the drink, which will appear ſtill more probable, after we have deſcribed the ruminating apparatus of the *camel*, &c.

The third ſtomach has received the names of *many plies*. (*echinus centipellio*, *omaſum*, *&c.*) This cavity in the *ox* is larger than the honey-comb bag, and reſembles in figure a hedge-hog rolled up, and thence one of its appellations. Its connection with the ſecond ſtomach is very contracted. The cavity is filled with thin folds, or reflections of its coats, which ariſe from the ſmaller curvature, and have few edges at the large curvature correſponding to the back of the hedge-hog. Theſe folds, or ſepta, are of unequal dimenſions. According to Mr. Home's obſervations there are twenty-four ſepta, ſeven inches broad; about twenty-three that are four inches broad; and about forty-eight of one inch

inch and a quarter in breadth. Thefe are arranged in the following order. A broad one, with one of the narroweft next it: then a narrow one, with one of the narroweft next it: then a broad one; and fo,on. Whatever paffes into the cavity of the third ftomach muft fall between thefe fepta, and defcribe three-fourths of a circle, before it can arrive at the orifice of the fourth ftomach, which is fo near the other, that the direct line between them does not exceed three inches. The many plies are covered with cuticle as well as the firft and fecond ftomachs: they are covered alfo with little granular papillæ. The many plies form a projecting valve at the orifice of the fourth ftomach, at which place the cuticle terminates.

The food that is found in the third, or plicated ftomach, is diftributed amongft the different fepta in a compreffed form. It has the confiftence of thick pafte, and a peculiarly unpleafant fmell.

The fourth ftomach is called the *red bag*, (*abomafum*, *falifcus*, *ventriculus inteftinalis*, *&c.*) It has an elongated pyriform fhape, fomewhat like the fimple digeftive ftomach of mammalia. According to Mr. Home, it meafures in the *ox* about two feet nine inches in length: its internal membrane has eighteen longitudinal plicæ (nine on each fide), beginning at its orifice, and extending about twenty-two inches in the cavity. They are four inches broad, and increafe very much the internal furface. Beyond thefe, the inner coat forms fome ferpentine, or zig-zag rugæ. The cavity is a little enlarged near the pylorus, where there is a glandular body, which blocks up the pylorus when the parts are in a contracted ftate.

The ftomachs of the other *ruminants with horns* differ very little from thofe of the *ox*. In the *deer*, the paunch has three projections, feen externally, which correfpond to as many dilatations of its cavity. In the *deer*, *fheep*, and *antelope*, the papillæ, and other eminences of the inner coat of each of the ftomachs, are lefs eminent than they are in the *ox*.

The ftomachs of the *camel*, although agreeing in many refpects with thofe above defcribed, differ in fome points materially. The beft defcription of thefe ftomachs has been given by Mr. Home, from which we fhall chiefly borrow the prefent one.

The paunch of the *camel* is divided into two compartments, on its pofterior fide, by a prominent ridge, or column compofed of mufcle, which paffes down from the right fide of the orifice of the œfophagus. This column forms one fide of the groove that proceeds from the cardia to the orifice of the fecond ftomach, and it is continued beyond that to the lower part of the paunch. Beneath the orifice of the fecond ftomach the column fends off, at right angles, from its left fide, eight ftrong mufcular bands, which afterwards form curved lines, till they are infenfibly loft in the coats of the ftomach. Thefe are at equal diftances from each other, and being interfected, in a regular way, by tranfverfe mufcular fepta, form the mufcular parietes of a number of large cells, fituated on the left fide of the back of the paunch. There is a feries of twenty-one fmaller cells of the fame kind, which extend towards the right fide of the paunch. They commence on the right of the chief mufcular column, but have no connection with it. On the left fide of the termination of the œfophagus, a broad mufcular band has its origin from the coats of the firft ftomach, and paffes down in the form of a fold parallel to the great ridge already defcribed, and with it forms the groove as far as the entrance of the fecond ftomach. After entering this cavity, it takes a new direction, paffing along the upper edge of it, and terminates within the orifice of the third ftomach.

The orifice of the fecond ftomach is at right angles with the fide of the paunch: it is nearly clofed when the mufcular band, which paffes through it, is not in action. It is a pendulous bag, in which there are twelve rows of cells, formed by as many ftrong mufcular bands, paffing in a tranfverfe direction, and interfected by weaker mufcular bands, fo as to form the orifices of the cells. Above thefe cells, and between them and the mufcle which paffes along the upper part of the ftomach, is a fmooth furface extending from the orifice of this ftomach to the termination in the third.

The fecond ftomach of the *camel* neither receives the folid food in the firft inftance, as in the *ox*, nor does it afterwards pafs into its cavity or cellular ftructure. The food goes firft into the general cavity of the firft ftomach, and that portion of it which lies in the recefs immediately below the entrance of the œfophagus, under which the cells are fituated, is kept moift, and is readily returned into the mouth, along the groove formed for that purpofe, by the action of the ftrong mufcle, which furrounds this part of the ftomach, fo that the cellular portion of the firft ftomach in the *camel* performs the fame office as the fecond in the *ruminants with horns*. While the *camel* is drinking, the action of the mufcular band opens the orifice of the fecond ftomach, at the fame time that it directs the water into it; and when the cells of that cavity are full, the reft runs off into the cellular ftructure of the firft ftomach immediately below, and afterwards into the general cavity. It would appear that *camels*, when accuftomed to go journies in which they are kept for an unufual number of days without water, acquire the power of dilating the cells, fo as to make them contain a more than ordinary quantity as a fupply for their journey; at leaft fuch is the account given by thofe who have been in Egypt.

When the cud has been chewed, it has to pafs along the upper part of the fecond ftomach before it can reach the third. How this is effected, without its falling into the cellular portion, could not from any infpection of dried fpecimens be afcertained; but when the recent ftomach is examined, the mode in which this is managed becomes obvious. At the time that the cud is to pafs from the mouth, the mufcular band contracts with fo much force, that it not only opens the orifice of the fecond ftomach, but, acting on the mouth of the third, brings it forwards into the fecond, by which means the mufcular ridges that feparate the rows of cells are brought clofe together, fo as to exclude thefe cavities from the canal through which the cud paffes.

It is this very curious mechanifm which forms the peculiar character of the ftomach of the *camel*, *dromedary*, and *lama*, fitting them to live in the fandy deferts, where the fupplies of water are fo precarious.

The third *ftomach* of the *camel* is very fmall, and quite unlike that of the *ox*. It is nearly fpherical; four inches in diameter; is not lined with cuticle; nor has it any fepta projecting into it. It has a honey-comb appearance upon its internal furface, but this is fo flight as to require a clofe infpection to perceive it. This ftomach anfwers the purpofe of retarding the progrefs of the food, and making it pafs by fmall portions into the fourth cavity; effects which are produced by the leaves of the many plies of the *ox*, in a more perfect manner.

The fourth *ftomach* of the *camel* has, for a great part of its length, the appearance of an inteftine; it then contracts partially, and the lower portion has a near refemblance in its fhape to the human ftomach.

The whole length is four feet four inches: when laid open, the

the internal membrane of the upper portion is seen to be thrown into longitudinal narrow folds, which are continued for about three feet of its length: these terminate in a welted appearance: the rugæ are large, as in the *ox*, but not so prominent, nor so serpentine in their course; and for the last nine inches the membrane has a villous appearance, as in the human stomach. Close to the pylorus there is a glandular mass of a conical shape, the larger end of which rests upon the orifice of the pylorus. The same gland exists in the *ox*, but it is not so conspicuous as in the *camel*. The aperture of the pylorus is also diminished, by the usual annular projection of the coats. Immediately succeeding the pylorus, there is a very considerable globular dilatation, appearing like a fifth cavity of the stomach. The duodenum arises abruptly from one side of it.

The description given of the stomachs of the *dromedary* by the Parisian dissectors, is so very brief and imperfect, that scarcely any knowledge can be obtained from it. They describe the four stomachs as succeeding each other in nearly the same line. The third as being very long, and the second as containing about 20 cells for holding water.

Cuvier has given a very excellent description of the ruminating stomachs of the *lama*, as he found them in an individual that had been born dead. The age is very necessary to bear in mind, as the size and even internal structure of the different cavities of the ruminating organs are much influenced by it. Thus, before the *calf* or *lamb* begins to feed upon grass, rumination cannot be performed; the milk passes immediately into the digestive stomach, the groove always forming itself into a tube during the act of deglutition; the paunch is small, and the fourth stomach large in relation to what it afterwards becomes, and the cells and other eminences of the two first stomachs are comparatively slight.

In the *young lama* dissected by Cuvier, the *paunch* had an irregular globular figure, being elevated upon some parts, to correspond with pouches or dilatations interiorly. It was larger than all the other three stomachs together; two of the pouches contained square water-cells, similar to those of the *camel*; one pouch had six rows of cells, each containing about 12, which could be discovered externally, by some swellings of the coats. The other pouch had only five similar cells. Between this pouch and the cardia, there was a third dilatation, which was the smallest of all, and exhibited some folds upon its inner surface, but no cells. The remainder of the inner coat of the paunch had some irregular folds, which, however, generally lay in the direction from before backwards.

The second stomach, placed anteriorly, and on the right of the paunch, was an oval bag, divided transversely by eight principal rows of cells, which were divided into smaller cells, and each of these terminated in a gutter grooved in a transverse direction, which was prolonged and lost in the paunch.

The channel leading from the œsophagus to the third stomach, was distinguished by a large fold, such as exists in the *camel*.

The third stomach was elongated and cylindrical; its internal surface exhibited some longitudinal folds, united to each other by transverse ones. These disappear towards the end.

The fourth stomach was not separated by any contraction. It was wider and shorter than the third, and turned backwards upon it. Its inner surface appeared villous, and presented on the posterior part some convolutions and irregular folds near the pylorus. A rounded glandular body projected into the cavity at the orifice of the pylorus, which it completely closed as a valve. Immediately beyond the pylorus the canal was dilated into a round sac, as in the *camel*.

From the preceding descriptions of the stomachs in the *camel* and *lama*, it will be seen that the chief distinctions in the ruminants without horns, are the second stomach being exclusively designed for a reservoir of water; the third being a sort of assistant digestive one: and from Cuvier's dissection of the *lama*, we may suppose the paunch of that animal is nearly as large before, as after rumination commences. These animals have long been known to carry a quantity of water in their stomach, which was only mixed with the food as occasion might require. This water is retained in the cells already described, by means of the muscular fibres surrounding their orifices, contracting so as to close the cells. The *camel*, it is said, will not drink every day, but when it does, it takes in between seven and eight gallons of water. All that found in the cells of the second stomach is perfectly pure and limpid, and hence it is, that the animal is sometimes killed when travelling in the deserts, for the sake of the water in its stomach.

The stomachs of the *southern lamantin*, and of the *cetacea*, are as complicated as those of the ruminant animals, although they do not perform the same office.

In the *southern lamantin* (*trichecus australis*), there are properly two stomachs with appendages from them. The first is globular in its figure, but longer in the transverse direction than any other. It receives the œsophagus into the middle of its anterior part. The internal membrane of this stomach is villous, and it has its cavity divided into two at the anterior part, by a fold which is on the right of the cardia. There is a little process or appendix from the side of the first stomach, the orifice leading into which is so small, that no food can pass into it. This process discharges a liquor into the stomach, and should therefore be considered as a gland. The second stomach is smaller than the first, and of a long shape; it gives origin at its commencement to two little processes; the one superior, the other inferior. The internal membrane is villous, and slightly corrugated transversely.

Anatomists are not agreed as to the number of stomachs in *cetacea*. Cuvier and Blumenbach reckon four. Hunter, on the contrary, described five in the *porpoise*, *grampus*, *dolphin*, and *piked whale*, and seven in the *bottle-nosed whale*. This difference arises from the manner in which the parts are considered, and not upon any errors of observation; perhaps it would be still more proper to view the two first cavities as the first and second stomachs, and the subsequent ones as belonging to the intestinal canal.

The first cavity in the *porpoise* is a large oval bag, into the top of which the œsophagus opens. It is lined with a thick cuticle. The other opening of this bag is near the œsophageal orifice, or, as one might state it, in the shoulder of the bag, the œsophagus constituting the neck. It seems not improbable, from the vicinity of these two apertures, that food may, under some circumstances, pass from the œsophagus directly into the second stomach. The communication of the first and second stomachs is extended into a short canal, into which the cuticle of the first passes and abruptly terminates. This canal is corrugated in the longitudinal direction.

The second stomach in the *porpoise* is considerably less than the first, and situated on the right side of it. It is likewise an oval cavity, but dilated or rounded at the ends. It is divided upon the anterior part by a deep contraction, which leaves on the right the appearance of a distinct cavity. This portion is that which some anatomists have considered confidered as the third ftomach. The internal furface is in both thefe cavities fmooth and fpongy, without cuticle, and forms rugæ, which crofs each other at right angles.

The opening into the fourth cavity, or ftomach, as it has been confidered, is at the right fide of the bottom of the cavity laft defcribed, and is marked by a decided annular contraction, fimilar to a pylorus. The fourth cavity alfo refembles exactly an inteftine. It makes three ferpentine turns, and terminates in the lower fide of an oval fac, of an inconfiderable fize, which is the *fourth ftomach* of fome authors, or the *fifth* of others. The coats of this cavity are thin, fmooth internally, and tinged with bile, as it is into it, that the biliary and pancreatic ducts open, which is a ftrong reafon, in addition to the form of thefe parts, for confidering all, except the two firft ftomachs, as belonging to the inteftine. At the place where the contraction and projection of the coats inwards form the fecond ftomach into two cavities in the *grampus*, we have found two glandular maffes. They are like roundifh cakes in the coats; the one meafures about feven inches and a half in diameter, the other about four inches. There are fome ragged irregular depreffions upon the inner furface, correfponding to thefe glands, which appear to be the outlets of mucous follicles upon a very large fcale. The glandular cakes, therefore, probably take the place of the pyloric glands in other animals.

The projections of the inner coat in the ftomachs of the *whales*, are much more remarkable than in the *porpoife* or *grampus*; the rugæ are very eminent, and in fome there is a ftrong reticulation on the inner membrane that projects into folds, which are indented into each other.

In defcribing the ftomachs of fome mammalia, we have mentioned the exiftence of *cuticle* and *glands*, when thefe happened to have occurred along with other peculiarities. Thefe points of ftructure are, however, fo remarkable in other inftances, that they deferve a diftinct confideration.

The *cuticle* of the œfophagus is extended for fome way into the ftomachs of feveral of the *faltigrade* animals, generally covering a little more than the great end, and terminating by a prominent denticulated edge, as inftances of which we may mention fome of the *rat* kind. There is fome cuticle alfo in the ftomach of the *kanguroo*, the *common hog*, and the *pecari*. The cuticular covering of the great end exifts in all the *folipeda*, whofe ftomachs are otherwife very fimple in form and ftructure. It is obvious, that the portion of the cavity which is covered by cuticle, is incapable of performing any other function than that of a refervoir.

The *glands* that we have had occafion to notice in the preceding account of the digeftive organs, were generally fituated at the pylorus, and were not very remarkable as to fize; but fome mammalia have a glandular apparatus at the cardiac orifice of the ftomach, which is very curious.

In the *beaver* there is a large oval mafs of glands on the right fide of the œfophageal orifice of the ftomach. It confifts interiorly of a number of cells, decreafing in fize, and uniting with each other from the furface next the infide of the ftomach. It pours out its liquor into the ftomach through a number of irregularly-fhaped holes. Mr. Home reckons 32 of thefe holes, which he ftates to be arranged upon three ridges, on the furface of the gland next the infide of the ftomach; nine on each fide of a middle ridge, and feven on each of the lateral ridges.

The glandular ftructure of the *beaver's* ftomach has been long known, and was confidered the only inftance of the kind; but a fimilar apparatus was difcovered feveral years ago in the ftomach of the *common dormoufe* by Mr. Macartney. The œfophagus, juft before its entrance into the ftomach, makes a ferpentine turn, and at that place becomes greatly enlarged, and furrounded by a cellular glandular ftructure. The cells produce on the fuperficies of the gland a number of flight elevations, which give it the appearance of a mulberry. The entire fize of the gland is, however, about that of a pea. The œfophagus, before it enters the gland, would fcarcely receive a pin; and after the dilatation in the gland, it again contracts in a degree, where it opens into the ftomach. The openings of the gland into the œfophagus are much fewer and larger in proportion than they are in the *beaver*, fo that nearly the whole of the cellular ftructure can be feen by looking at the interior furface, if the part be diftended or fpread out. This gland approaches more nearly to the bulbus glandulofus of birds, than any fimilar ftructure does in the clafs mammalia. In Mr. Home's account of this gland, he appears to claim the difcovery of the internal ftructure, although preparations and drawings of both the external and internal appearances were annually fhewn by Mr. Macartney at his lectures, for feven years before Mr. Home wrote upon the fubject.

In the *wombat*, there is a glandular mafs that occupies a great part of the fmall curvature of the ftomach, which almoft exactly refembles the glands in the *beaver*. There are many irregular-fhaped openings on the inner furface, within which are fmaller openings or cells. A very fine plate of this ftructure has been publifhed by Mr. Home in the Phil. Tranf. for 1808.

A perfectly fimilar apparatus was found by Cuvier in the pofterior part of the ftomach of the *pangolin* (*manis pentadactyla*). The ftomach of this animal is alfo remarkable on account of the great thicknefs of the coats towards the pylorus, which appears to operate in the fame manner as the gizzards of birds, for the *pangolin* fwallows fmall ftones and gravel.

The *ornithorhynchus hyftrix* is likewife reported to take fand into its ftomach. Thefe extraneous fubftances, in both cafes, are, no doubt, defigned to triturate the food, and fupply the want of teeth in thefe animals.

Cuvier defcribes in the *northern lamantin* (*trichecus borealis*), an oval gland, as large as the human head. It is placed near the cardia, and appears to poffefs exactly the fame ftructure with thofe above-mentioned. The fluid fecreted is a whitifh colour. Cuvier fuppofes, and with every appearance of probability, that the fmall appendix of the firft ftomach in the *fouthern lamantin* correfponds to this gland. The appendix is evidently defigned for fecreting a fluid, and not retaining the food: from the alliance between the two animals, therefore, it can fcarcely be doubted, that the appendix and gland perform fimilar offices.

The ufe of the cardiac glands is commonly fuppofed to be for furnifhing an extraordinary quantity of the gaftric fluid, and Mr. Home endeavours to prove that fimilar glands, upon a fmaller fcale, exift in all ftomachs. There are, however, fome reafons for queftioning this opinion. The ftructure of thefe cardiac glands, and of thofe fmall glandular pores that are generally found in the ftomachs of mammalia, more nearly refembles that of mucous follicles than any other fecretory apparatus. The fluid furnifhed by the glands of the ftomach is in every refpect fimilar to the mucus of the inteftines. The fituation of the cardiac glands, alfo, is not the moft favourable for the application of a digeftive fluid, it being immediately adjoining that portion of the ftomach which receives the food in the firft inftance, and in which it is depofited for fome time, as a refervoir in certain fpecies. The cardiac glands might be fuppofed, perhaps with greater

propriety,

propriety, to be deſigned for the ſecretion of a fluid capable of macerating and preparing the food for digeſtion, inſtead of a really ſolvent or aſſimilating liquor.

Plates II., III., and IV. of the *Anatomy of Mammalia*, are intended to exhibit the ſtructure of the *ſtomach*. *Fig.* 2. *Plate* II. repreſents the ſtomach in the *ferret*, as an example of the form of this organ in the *carnivorous* mammalia. *Fig.* 3, of the ſame plate, is the ſtomach of the *garden ſquirrel* of Pennant (*myoxus nitela*): *a* is the œſophagus; *b*, the inteſtine ariſing cloſe to it; *c*, the globular ſtomach. *Fig.* 4. exhibits the ſtomach of the *ornithorhynchus paradoxus*, which is ſelected on account of the ſingularity of its form: *a*, the œſophagus; *b*, the inteſtine; *c*, the bottle-ſhaped ſtomach; *d*, the biliary duct. *Fig.* 5. repreſents the double ſtomach of the *hamſter*: *a*, the œſophagus; *b*, the cardiac half or portion of the ſtomach, much turned up at the left end; *c*, the pyloric half of the ſtomach, exhibiting three dilated parts; *d*, the duodenum. *Fig.* 6. ſhews the ſtomach of the great *kanguroo*: *a* indicates the œſophagus; *b*, the cardiac portion of the ſtomach, at the left extremity of which are ſeen two proceſſes, *c* and *d*. At the doubling of the pyloric portion *e*, are alſo ſeen two proceſſes like cæca, which are pointed out by the letters *f* and *g*. The pylorus is ſhewn by the letter *h*. *Fig.* 7. repreſents the ſhape of the digeſtive organ in the *vampyre bat*: *a* is the œſophagus; *b*, the dilated part, by which that tube communicates with the ſtomach; *c*, the cardiac end of the ſtomach; *d*, *d*, the two convolutions of the pyloric portion of the ſtomach; *e*, the duodenum. *Fig.* 8. exhibits the external form of the ſtomach in the *two-toed ſloth*: *a* is the œſophagus; *b*, *b*, *b*, indicate the elevations upon the ſurface of the cardiac or firſt diviſion of the ſtomach, that are produced by the three cavities into which it is ſeparated internally; *c*, the pyloric portion of the ſtomach. *Fig.* 1. *Plate* III. of the *Anatomy of Mammalia*, repreſents a view of the firſt ſtomach or paunch of the *camel*, laid open on the anterior part to expoſe its internal ſtructure and communication with the ſecond ſtomach: *a* is the œſophagus; *b b*, the longitudinal ridge, dividing the cavity into two compartments; *c c*, the muſcle which paſſes to the third ſtomach; *d*, the opening into the ſecond ſtomach; *e e*, the muſcular cells on the right ſide of the cavity; *f f*, the larger cells on the left ſide, the water of which ſerves to moiſten the food lying over them, and to make it of a fit conſiſtence to be regurgitated into the mouth, along the canal formed by the longitudinal ridge, and the muſcle going to the third ſtomach; *g g*, a broad muſcular band ſeparating the cellular ſtructure into two portions. *Fig.* 2, of the ſame plate, exhibits a poſterior view of the four ſtomachs of the *camel*, in which the firſt is unopened, but the ſucceeding three are cut open, and preſerved in three relative ſituations to the firſt ſtomach: *a* is the œſophagus; *b b*, point out the poſterior ſurfaces of the firſt ſtomach in a diſtended ſtate; *c* ſhews the communication between the firſt and ſecond ſtomachs; *d d*, the muſcle running along its upper part to terminate in the orifice of the third ſtomach. This muſcle, when it acts with its greateſt force, brings forward the orifice of the third ſtomach nearly cloſe to that of the ſecond, and by ſo doing, ſhuts up the rows of cells in the lower part of the cavity, ſo that no part of the ſolid food can paſs into them; *e*, *e*, the rows of cells which form a reſervoir for the water; *f*, the opening leading into the third ſtomach; *g*, the cavity of that ſtomach; *h*, the orifice of the fourth ſtomach; *i i*, the longitudinal plicæ of the fourth ſtomach; *k k*, the rugous ſtructure at the lower part of the ſame cavity; *l*, the glandular projections oppoſed to the orifice of the pylorus; *m*, the pylorus; *n*, the dilatation or membranous cavity between the pylorus and duodenum; *o*, the duodenum.

Fig. 3. *Plate* III. of the *Anatomy of Mammalia*, is deſigned to ſhew the directions of the muſcular fibres, which run upon the orifices and ſides of the cells in the firſt and ſecond ſtomachs of the *camel*. The cells of the left ſide of the firſt ſtomach are employed as examples, on account of their being the largeſt, and their muſcles the moſt diſtinct, but the ſame ſtructure exiſts in the cells of the ſecond ſtomach alſo: *a a*, the longitudinal ridge, to ſhew its muſcular ſtructure, and the mode in which the fibres go off, to furniſh the orifices of the cells; *b b b b* point out the courſe of the fibres going from cell to cell to cloſe their orifices; *c*, *c*, the muſcular fibres, by means of which the cells throw out their contents. In *Plate* IV. of the *Anatomy of Mammalia*, *fig.* 1. is a view of the internal ſurface of the ſtomach in the *rat*: *a* is the portion of the ſtomach over which the cuticle of the œſophagus is continued. This cuticular coat terminates in an eminent puckered border; *b*, the pyloric portion of the ſtomach. This figure is of the natural ſize.

Fig. 2. of the ſame plate, exhibits the external appearance of the ſtomach of the *dormouſe* of the natural ſize, ſeen poſteriorly: *a*, the œſophagus; *b*, the gland, ſeen full, on account of the curvature which the œſophagus makes before it enters the ſtomach. *Fig.* 3. is a view of the cellular ſtructure of the gland, which is expoſed by ſlitting the part open: a portion of the ſtomach is left with the gland. *Fig.* 4. ſhews the ſtomach of the *wombat*, leſs than the natural ſize, and inverted, to expoſe the internal appearance and foramina of the cardiac gland. The inner ſurface of the ſtomach diſplays ſome reticulated lines at the great end, from which longitudinal lines are extended towards the pyloric portion of the ſtomach: *a*, the œſophagus, covered with cuticle; *b*, the gland. *Fig.* 5, of the ſame plate, ſhews the ſtomach of the *porpoiſe*, of courſe much leſs than natural: *a* is the œſophagus; *b*, the firſt ſtomach or reſervoir of the food; *c* is the ſecond ſtomach; *d* is a portion of it, diſtinguiſhed on this ſide by a fiſſure, which ſome have conſidered as ſeparating it into a third ſtomach; *e* is the inteſtine-ſhaped ſtomach, which we are diſpoſed to admit as the beginning of the duodenum; *f* is the laſt ſtomach, or, as we ſuppoſe, the dilated part of the duodenum for receiving the pancreatic and biliary fluids; *g* is the inteſtinal canal.

Inteſtines.—It may be ſtated as a general obſervation, from which there are ſcarcely any exceptions, that the capacity of the alimentary canal is in proportion to the difficulty of aſſimilating the kind of food uſed by the animal. It is, therefore, greateſt of all in thoſe animals that live upon raw, fibrous, or woody vegetables; leſs in thoſe that conſume ſucculent or cooked vegetables; leſs ſtill in thoſe that eat animal food occaſionally; and leaſt of all in thoſe that ſubſiſt excluſively upon fleſh, fowl, and eggs.

It ſhould, however, be remembered, that the length of the inteſtinal canal by no means determines the extent of the digeſtive apparatus. The length ſhould always be calculated in reference to the width in general of the inteſtines; the dilatation of particular parts, and the extenſion of their internal ſurfaces by folds or valves. The complication of the ſtomach, and the perfection of the organs of maſtication, ſhould alſo be conſidered as influencing any concluſion to be drawn from the length of the inteſtinal canal.

In the truly *carnivorous mammalia*, the whole tract of the inteſtines uſually exceeds the length of the body, only in the ratio of three, four, or five to one. In the *great bat* (*veſpertilio noctula*,) the inteſtines are but twice the length of the animal. The proportion of the circumference to the length of the inteſtine, in this ſpecies of *bat*, is as one to twenty-eight. In the *hyæna*, the inteſtinal canal is eight times longer than the body, but then the proportion of the cir-

 circumference

cumference to the length of the ſmall inteſtine, is as one to one hundred and ten; that of the cæcum as four to nine; and that of the colon and rectum, taken together, as one to ſix.

In the *human ſubject*, the length of the inteſtines is ſix or ſeven times that of the body.

In the *monkey tribe*, this proportion varies from five to eight.

In the *lemur genus*, with the exception of the *loris*, the inteſtines vary from four to ſix times the length of the body. The *lemurs*, it ſhould be obſerved, have a larger cæcum than the *monkey* kind. The *loris* have ſtill ſhorter inteſtines in proportion to their body; but the latter is very long.

Amongſt the *cheiropterous mammalia*, the *vampyre bat* has the inteſtine about ſeven lengths of its body. It has a complicated ſtomach and no cæcum.

In the greateſt number of the *plantigrade* quadrupeds, the inteſtines have a conſiderable length. This is counteracted by the ſmallneſs of the canal, and the want of a cæcum. The *ſhrews* have the inteſtines ſhort, and in other reſpects like the *carnivorous digitigrade* mammalia.

In the *herbivorous ſaltigrade*, the length of the alimentary canal is conſiderable, beſides the addition of cæca, but in the *rat* genus, which live on a mixed food, the length of the inteſtines does not exceed that of the *monkies*.

The inteſtines are ſhort in the *edentata*, and very much ſo in the *tardigrada*, which ſeems hard to explain, as they want the cæcum, and live, nevertheleſs, upon vegetable matters. Cuvier ſuppoſes that the gaſtric juice may be particularly active in the *tardigrade* animals.

The *echidna* has the inteſtines ſeven times its own length. In the *armadillos* they are only five lengths of the body.

In the *elephant*, the inteſtinal canal is only ſeven times as long as the body, but it is very wide. In the *hippopotamus* it is nine times as long as the body. In the *daman* it is about the ſame.

The *ruminating* quadrupeds have the longeſt inteſtinal canal of all. In the *ram* it is twenty-ſeven lengths of the body.

The *ſolipeda* have the inteſtines about eight to ten times as long as the body, but the want of extent is amply made up by the prodigious volume of the cæcum and colon.

The *ſeal*, although ſupported by animal food, has the inteſtinal canal eighteen times as long as its body, the diameter, however, is ſmall, and its ſtomach is very ſimple, and its teeth incapable of minutely dividing its food,

The *ſouthern lamantin* (*trichecus auſtralis*) has the inteſtines only about ſix lengths of its body, although it lives upon vegetables; but it has a complicated ſtomach furniſhed with a large gland.

The *cetacea* have a long alimentary canal, but it is very narrow, and wants the cæcum. In the *grampus* we found the large blood-veſſels, as the vena cava and portæ, and the aorta, to be nearly the ſame width of the inteſtine.

It is curious to obſerve the occaſional difference between the length of the inteſtines in the wild and tame ſpecies of the ſame genus. Thus, in the *wild boar*, the body bears the proportion to the inteſtines of 1 to 9; in the *hog*, of 1 to 13.5; in the *wild cat*, it is as 1 to 3; and in the *domeſtic cat*, as 1 to 5. This proportion is different in the *wild* and *tame rabbits*; the former has it as 1 to 11.4, the latter as 1 to 9.3.

Cuvier has given a very full table of the proportionate lengths of the different parts of the alimentary canal, and alſo of their circumference, in the third volume of the "Anatomie comparée," to which we ſhall refer the reader.

The length of the whole inteſtinal canal, in relation to that of the animal, is greater in mammalia than in the other claſſes of animals. This unqueſtionably becomes neceſſary from the food undergoing a more tedious proceſs of aſſimilation, but it likewiſe depends in a degree on the more elongated form of the body. This obſervation particularly applies to *fiſhes*, in whom the tail becomes incorporated with the general figure of the animal. To calculate the relation of the inteſtinal canal to the body, the capacity of the one, in all directions, ſhould be compared with the entire bulk of the other. The length and the width alſo of the great inteſtines are greater in proportion to the ſmall inteſtines of mammalia than in any other claſs. It is in theſe animals that the terms of great and ſmall inteſtines are only indeed appropriate.

The great and ſmall inteſtines are nearly of the ſame length in the *ſaltigrade* quadrupeds; ſometimes the former are even longer: for inſtance, in the *paca*, the length of the ſmall inteſtines is to that of the great, as 1 to 1.3, and in the *water-rat*, as 1 to 1.2. In the *hamſter* and *field rat*, it is, however, in the proportion of 2 to 1, and in the *Norway rat* and *common mouſe* the ſmall inteſtines are four times the length of the great.

In the *hoofed* quadrupeds there is not a great difference between the length of the two diviſions of the inteſtine in general. What there is, however, is in favour of the ſmall inteſtines, but it ſhould be recollected that the great inteſtines are commonly wide in theſe tribes of quadrupeds.

In the *omnivorous* quadrupeds, the ſmall inteſtines exceed the great in length ſomewhat more, although the great are not ſo much dilated as in the *large herbivorous* ſpecies.

But it is in the *carnivorous* tribes that the ſmall inteſtines are very materially longer than the great. Thus, in the *lion* and *jaguara*, they bear the proportion of 6 to 1; in the *dog* and *wolf*, 5 to 1; in the *hyæna*, 6.2 to 1, &c. In ſome *monkies*, and in the *human ſubject*, they are alſo about 5 to 1, but this is in a degree counteracted by the width of the great inteſtines.

We ſhall now proceed to the deſcription of the forms and ſtructure of the inteſtines in mammalia, which it will be neceſſary to treat a little in detail.

The inteſtinal canal of the *monkey* kind approaches in general ſtructure that of the human ſubject. In the *ourang-outang*, there are both a cæcum and an appendix vermiformis, as in *man*; but in the other ſpecies of *monkey* the latter is wanting. The cæcum of the *ourang-outang*, according to the repreſentation given of it in Tyſon's Anatomy of the *pigmy*, does not project much out of the line of the inteſtine; but in the other ſpecies of *ſimia*, the cæcum forms more of a cul-de-ſac than in man, except the *gibbon* or *long-armed ape*. The Pariſian diſſectors deſcribe the cæcum of the *ſapajous*, or the ſubgenus *callitrix*, as being two inches and a half long and one inch wide at the origin, after which it becomes ſmaller, and ends in a pointed manner. They likewiſe deſcribe ſome valves on the inſide of the colon of the *ſapajous*, ſimilar to thoſe found in the colon of the *oſtrich*.

The *lemurs* have the cæcum more elongated than the *monkies*. In the *lemur macaco*, the colon is much wider in the beginning than the ſmall inteſtines, but afterwards becomes rather leſs. The cæcum is wider than the latter at its origin, but becomes gradually ſmaller at the end. It is a conſiderable length, and forms many ſpiral convolutions, and has a good deal the appearance of a coiled worm. In the *tardigrade* and *ſlender lemurs*, the parietes of the inteſtinal canal are thin, and dilated at intervals into ſacs; the cæcum is long and but little dilated. The *lemur tarſius* of Pallas has the great and ſmall inteſtines about an equal width,

width, except the cæcum, which is long and prodigiouſly dilated.

In the *galeopithecus*, the firſt portion of the colon and the cæcum have three longitudinal bands, which throw them into numerous and regular facs. This facculated part of the gut is very wide compared with the reſt. The ſmall inteſtine opens into it at a right angle, about half way between the extremity of the cæcum and the termination of the dilated and facculated part of the colon, which is continuous with the cæcum.

The *bats* have the great and ſmall inteſtines nearly of the ſame width, and the internal coat has no tranſverſe folds or valvulæ conniventes. It has merely villi on the ſurface, which decline as uſual in the great inteſtines. They have no cæcum, but ſometimes a ſlight projection at the origin of the colon. The *vampyre bat* has the firſt part of the canal wider than the reſt, and with very thin coats. It is more contracted and has thicker coats in the rectum, in which there are alſo ſome longitudinal folds internally.

The *carnivorous plantigrade* quadrupeds, except the *ichneumons*, have the inteſtinal canal nearly of the ſame width throughout. In general the coats of the rectum are thicker than in the other parts, and there are ſome longitudinal folds in it. There is no cæcum, but at the part correſponding to it there is a row of mucous glands upon one ſide of the inteſtine. The internal coat of the canal is more or leſs villous in the different genera. In the *mole*, for inſtance, the villi are ſhort; in the *hedge-hog* they are long in the ſmall inteſtines. The *ichneumons* have a ſmall proceſs at the origin of the colon, which Cuvier terms a cæcum, but which ought rather, perhaps, to be called an appendix vermiformis. In the figure he has given of this part in the Egyptian *ichneumons*, it appears a good deal leſs than the ſmall inteſtine, which is itſelf not half the diameter of the colon. Hedwig deſcribes the inteſtines of the *bear* as having long and handſome villi.

Amongſt the *digitigrade carnivorous* quadrupeds, the genus *muſtela* is diſtinguiſhed by the want of a cæcum. The *otter* has a ſlight dilatation at the place where the cæcum might be. The inner membrane is finely villous in the ſmall inteſtine. This appearance diminiſhes towards the part of the canal correſponding to the great inteſtine, and is again to be found near the anus. The row or ſtripe of mucous glands, which is uſually obſerved to cover a conſiderable extent of the ſide of the canal at the origin of the colon, is very ſtriking in this genus.

The other *digitigrade carnivora* have always more or leſs of cul-de-fac at the origin of the colon. Their great inteſtines are however ſhort, and without any facs or dilatations by which the progreſs of the food is retarded through them. There are, likewiſe, no valvulæ conniventes in the ſmall inteſtines, but the inner coat has fine villi. The genus *viverra* has a ſhort ſlender cæcum, ſimilar to that of the *ichneumon*. The ſmall inteſtine has an oblique or a valvular opening, and the inner coat exhibits at that place ſome marked longitudinal folds.

In the genus *felis*, the ſmall inteſtines have a much leſs diameter than the others. The villi are very evident, in ſome ſpecies particularly. In the *lion* the villi are long and floating. The cæcum in this genus is ſhort, and terminates in an obtuſe cone, of which the coats are thick, and contain many mucous glands. There are ſome longitudinal rugæ towards the end of the colon, and in the rectum.

In the *dog* kind, the villi of the ſmall inteſtines are long. The cæcum forms ſome curves, which adhere to each other, and to the ſide of the ſmall inteſtine, by means of the cellular ſubſtance, which renders the paſſage of any ſubſtances through it more difficult. There are ſome longitudinal folds in the great inteſtines, as in the *cats*. The whole canal is nearly of the ſame width.

The coats of the inteſtinal canal are thin in the *hyæna*. Their diameter continues to increaſe from the pylorus to the cæcum. The latter is long and narrow, and has a rounded termination.

In the *pedimanous* or *marſupial* animals, there is ſome variety in the inteſtinal canal. The *Virginian opoſſum* has the ſmall inteſtine a third leſs than the great: they have fine villi interiorly: there are no rugæ or valvulæ. The cæcum is not long, and appears to be a prolongation of the colon. In the *marmoſe* or *murine opoſſum*, the ſmall and great inteſtines are about the ſame diameter: they have ſome contractions. In the *cayopollin*, or *Mexican opoſſum*, the duodenum is wider than the reſt of the ſmall inteſtines. The cæcum is long, ſtraight, and twiſted in a ſpiral manner. The colon is larger at the origin than elſewhere. The *brown phalanger* (*didelphis orientalis*) has the ſmall inteſtines one-third leſs in diameter than the great. The cæcum is very long, wide, and formed into numerous ſacculi along the ſides, and terminates in a ſmall canal, which Cuvier conſiders a ſpecies of appendix vermiformis.

In the *kanguroo rat*, the coats of the inteſtines are thin. The ſmall guts have the internal membrane without villi, but it is thrown into very fine folds, which form zig-zags tranſverſely: the cæcum is ſhort, wide, and round. The colon is very large at its origin.

In the large *kanguroo* the inteſtinal canal differs very much from that of the preceding ſpecies. The diameters of the ſmall inteſtines diminiſh gradually from the duodenum to the ileum. Their inner ſurface is without rugæ, but is villous. The cæcum is capacious, very long, and is facculated by two longitudinal bands, which alſo extend for ſome way upon the colon, producing the ſame effect upon it. The great inteſtine afterwards becomes narrow. The facculated portion of the colon has irregular folds internally, and there are ſome ſlight longitudinal rugæ in the remainder of the great gut. The inteſtines of the *kanguroo* reſemble thoſe of the *ſaltigrade* quadrupeds, in which tribe we have placed it in our claſſification.

In the *phaſcolomys*, or *marſupial rat* of New Holland, which alſo ſhould be claſſed with the *ſaltigrade* quadrupeds, the whole tract of the inteſtines, even the cæcum, is nearly of the ſame width. The cæcum is ſhort, round, and ſmooth: there is an appendix vermiformis which goes off at the angle formed by the ſmall inteſtine with the cæcum. It has a ſmall orifice guarded by a valve. The *phaſcolomys* and the *ourang-outangs* are the only inſtances in mammalia which have both a cæcum and vermiform appendix: in this circumſtance they reſemble the human ſubject.

The *porcupine* has the duodenum very wide, ſomewhat reſembling an additional ſtomach. The remainder of the ſmall inteſtines is narrow. The villi of the mucous membrane have the figure of thin conical ſcales, as in the human inteſtine, but more narrow and prominent. The cæcum is large, divided into facs by three muſcular bands. At the origin of this inteſtine, there is one of thoſe facs much larger than the reſt, projecting out of the line formed by the colon with the cæcum. This gut altogether has a good deal the figure of a ſcythe. The colon has ſome cells of a ſmaller ſize than thoſe of the cæcum.

In the *guinea-pig* the cæcum is very capacious, and is in a degree coiled when it gives origin to the colon, which is almoſt as wide as the cæcum for a little way, but afterwards gradually contracts to the dimenſions of the ſmall inteſtine.

The

The *paca* and *agouti* refemble the *guinea-pig*. The opening from the cæcum in thefe animals is contracted by a valve. The colon of the *agouti* forms behind the liver many little concentric convolutions before it terminates in the rectum. The glands at the origin of the colon are very remarkable in the *paca*, forming a thick mafs.

In the *rabbit* and *hare* the fmall inteftines are uniform in their fize. They are villous, and have fome longitudinal folds internally in the ileum. The cæcum is very extenfive. It has a conical figure, and exhibits regular contractions upon the furface, which correfpond to a fpiral fold that interrupts the cavity internally, like the fpiral valve in the cæca of the *oftrich*. The colon is as wide as the cæcum at its origin, but it very foon contracts: it is facculated at firft by three longitudinal bands, and afterwards by only one. The internal coat is fmooth in the cæcum, papillated in the firft portion of the colon, and longitudinally rugous in the rectum.

The *fquirrel* has a long cylindric cæcum with fmooth parietes. The *flying fquirrel* has a fimilar inteftinal canal, but the cæcum ends in a pointed manner.

The *beaver* has a fhort dilatation at the origin of the duodenum. The cæcum is of great fize, elongated, and conic. The colon alfo is very wide at its origin. There are numerous contractions and dilatations throughout the great guts.

The *Polifh marmot* has the fmall inteftines ftraight. The cæcum is very voluminous, and divided externally by contractions, and internally by a correfponding number of annular folds. The colon is large at the beginning. The inteftines of the *marmot* of the Alps are fimilar to the preceding.

In the *ondatra*, or *mufk rat*, the cæcum is of a prodigious extent: it paffes from the umbilical region to the left iliac; then into the right iliac, extending as far as the hypochondriac region of that fide. The colon at its commencement is convoluted in a fpiral manner.

The greateft part of the inteftinal canal of the *water-rat* has a fmall diameter. The cæcum is long and wide, with contractions. The colon is very wide at its origin; it diminifhes afterwards, and is twifted in a clofe fpiral manner for a great part of its length. The twifted part of the colon is diftinguifhed by regular folds, which are vifible from the outfide of the gut. The coats of the whole inteftinal canal are thin and tranfparent in this animal.

The inteftinal canal in the *campagnol* (*mus arvalis*) refembles that of the *water-rat*.

The cæcum is wide, fhort, a little curved, and without contractions, in the *black* and *Norway rats*; longer and narrower in the *common moufe*; elongated alfo, tapering at its extremity, and divided by contractions in the *field rat*. In the *Norway* and *black rat* the colon is at firft ftraight, has thick coats, and fome longitudinal folds interiorly; after which it is dilated, and exhibits, for fome way, fimilar fpiral traces to thofe of the *water-rat*: it then contracts again, and has but a fmall diameter in the greateft part of its extent towards the anus.

In the *moufe* and *field rat* the colon is wide at the commencement, but afterwards it becomes much contracted. There are oblique or fpiral ftriæ, formed by the folds of the internal membrane.

The *hamfter* has the fmall and great inteftines of the fame diameter, except where the cæcum is formed. Both the ileum and colon open into a dilated part, which produces at one fide feveral fpiral turns, and at the other the cæcum. This laft is of confiderable fize, and divided into a number of facs by means of one band or cord, which runs along the concave fide of this gut.

In the *mole rats* the cæcum is long and wide, and the colon fpirally twifted. The *jerboa* has the cæcum formed into three fpiral turns.

Amongft the *edentata* there is a good deal of variety to be obferved.

In the *three-toed ant-eater* the fmall inteftines are very much puckered by the mefentery, by which the canal is irregularly contracted and dilated, like the great inteftines of many animals. The large inteftines of this animal form a fhort, wide, fmooth canal; and on each fide of the termination of the ileum in this great gut, there is a little procefs or appendix, with a contracted neck and bulbous head. Thefe appendices correfpond in fituation to the cæca of birds, with which clafs of animals the toothlefs quadrupeds are allied in many parts of their ftructure and economy. The cæca of the *ant-eaters* are too fmall to ferve as refervoirs for their food: they communicate with the great inteftine by a fmall orifice, as does alfo the ileum.

In the *echidna* the fmall inteftines are about half the width of the great: they have villi, but no valves upon the interior furface. The mucous glands are numerous, and particularly plain from being of a black colour. The cæcum is fingle: it is a fhort, ftraight, blunt procefs.

In the *ornithorhynchus* the duodenum is wider than the reft of the inteftinal canal, which gradually diminifhes to the cæcum. This part is a long narrow procefs or appendix. The great inteftines grow wider the nearer they approach the anus. The internal membrane in the fmall inteftines is formed into numerous prominent laminæ, fomewhat like thofe of fifhes; and in the beginning of the great inteftines it produces fome longitudinal folds.

The *long-tailed manis* has no cæcum: the commencement of the colon is diftinguifhed by an increafe in the width of the inteftine, and the thicknefs of its coats. There is no cæcum likewife in the *pangolin*, or *fhort-tailed manis*.

There is no cæcum in the *armadillos*, but the great inteftine is thicker and wider than the reft of the canal, from which it is feparated by a contraction: the fmall inteftines are much puckered and folded by the manner in which the mefentery is attached to them.

The *tardigrade* quadrupeds have the fmall inteftine gathered into irregular dilatations by the mefentery. There is no cæcum. The great inteftine is diftinguifhed from the fmall by a fudden dilatation, and a valve interiorly at the part where the colon commences. The irregular form and contractions of the fmall inteftines, in fome of thofe animals which have the colon fhort, and want the cæcum, are defigned apparently to anfwer the fame purpofes that a capacity in the great inteftines does in other animals.

The *Cape ant-eater* has a fhort oval cæcum.

The *hoofed* quadrupeds are remarkable for the capacity of their great inteftines. Amongft the *multungulata*, the *elephant* has the colon fo large as to cover a great part of the abdominal vifcera: it is folded from fide to fide, and lies in the front of the other inteftines: it is facculated in two rows on each fide. The cæcum is alfo very large, and thrown into facs or cells by three mufcular bands. The fmall inteftines have an uniform diameter. The ileum terminates by a circular valvular opening in the colon. The internal membrane of both the fmall inteftines and the colon is plicated tranfverfely: in fome places it projects fo as to form valves: in the rectum the folds are longitudinal. The furface of the internal membrane in the fmall inteftines is covered with fine fhort papillæ. The coats, more particularly the mufcular one, are very thick.

In the *one-horned rhinoceros* the cæcum is very wide, and divided into facs, as is the colon ftill more plainly, at leaft at one part; but the moft curious part of the ftructure of the inteftinal canal in this animal is to be obferved in the inner coat. In the firft portion of that part of the canal between the pylorus and the infertions of the hepatic and pancreatic ducts, the mucous membrane forms little projecting longitudinal folds, in the form of fegments of a circle: in the next portion of the fame part of the gut, thefe folds become more tranfverfe in their direction, and affume a triangular figure. A little beyond the infertion of the biliary ducts the laminæ become more numerous, compreffed, and irregularly lobed. Farther on there is upon the internal coat a kind of papillæ, lengthened into filaments, preffed the one againft the other, efpecially about the middle of the length of the fmall inteftine. The extremities of fome of thefe proceffes are bifid. The internal furface of the cæcum has only the rugæ that correfpond to the facs. The laminated ftructure is renewed in the colon; the folds are tranfverfe, and grow larger as they come nearer to the rectum, between which gut and the colon the laft lamina forms a valve.

The *Cape cavy* has very fingularly formed cæcum and colon: the firft of thefe is a large irregularly fhaped bag, which is puckered upon the fides by two longitudinal bands The ileum opens into it by a projecting contracted orifice, and near the fame place the colon arifes: there is a valvular fold at the aperture of the colon. This inteftine is at firft fuddenly and greatly dilated: the inner coat of this portion is fmooth, and irregularly plaited, as in the cæcum. The part of the canal fucceeding the dilatation is fmall, has thick parietes, and the inner coat with waving folds, which are at firft longitudinal, but afterwards become tranfverfe in their direction. Beyond this portion the colon grows wider, and then becomes irregular in its fhape and diameter: it has broad longitudinal folds internally. There next fucceeds another enlargement of the colon, from the fides of which arife two pyramidal or cone-fhaped proceffes, which pafs in the direction contrary to that of the reft of the gut, in the fame manner as the cæca of birds, to which they bear a confiderable refemblance. The colon, after furnifhing thefe two appendices, makes feveral fpiral turns upon itfelf, and fome convolutions in the belly, and terminates in the rectum. This laft inteftine has thicker coats than the colon, and has broad longitudinal folds internally.

Amongft the *bifulca*, the *ox* has no folds in the interior of the fmall guts, except in the duodenum, where there are fome tranfverfe rugæ or plaits. The villi have the figure of fine fcales, according to Cuvier; but we may obferve, this ftructure is by no means uncommon in mammalia. The cæcum is not large: it is firft contracted, then dilated, and terminates in a bulb. The inner coat is without rugæ, except where it is narrow, and there we find fome longitudinal rugæ: the colon is without folds of the inner coat: the rectum has thicker coats; and the internal furface furnifhes longitudinal folds, and, very near the anus, fome circular ones. The *goat* has a much larger cæcum in proportion than the *ox*.

The duodenum of the *lama* is wide at the commencement, forming an oval fac; the other fmall inteftines are puckered by the mefentery. The cæcum has a conical fhape, and no contractions: the internal membrane of the fmall inteftines has fome tranfverfe folds; that of the colon longitudinal ones. In other refpects the inteftinal canal of the *lama* refembles that of the *ox*, as does alfo the alimentary canal of the other *ruminants without horns*.

The great inteftines are much more capacious in the *horfe*, *afs*, &c. than in the *ruminating* quadrupeds; more particularly the cæcum, which is of a prodigious fize. This gut is nearly as wide as it is long; and when the excrementitious parts of the food are allowed to accumulate in it and the colon, the abdomen has that tumid appearance which is feen in *affes* and in *horfes*, that are fed only upon hay or ftraw. The colon begins with a dilatation, not much inferior in fize to the cæcum: it is doubled upon itfelf, and in its courfe through the abdomen it forms other curves or arches. The great inteftines are drawn up into facs: thefe are larger in the firft portions of the colon. For a more detailed account of the inteftines of the *horfe*, we fhall refer the reader to the anatomy of that animal in this dictionary.

It is faid, that in the *morfe* (*trichecus rofmarus*) the cæcum is fituated in the left fide of the abdomen. There is no other inftance of the kind in mammalia, except in cafes of tranfpofition of the vifcera. The cæcum in this animal is very inconfiderable, refembling a mere knob of the inteftine. Both the fmall and great inteftines have very nearly the fame diameter.

In the *fouthern lamantin* the cæcum has a very peculiar figure: it forms the fegment of the outfide of a circle, or has a crefcentic appearance. The ileum communicates with the middle, from which alfo the colon arifes. This inteftine is wider at firft than the cæcum, and forms fome clofe convolutions; it afterwards proceeds as a flightly twifted canal, and becomes again enlarged near the rectum, which laft gut is wider than the colon.

The *cetacea* are ftated by Cuvier to want the cæcum; Hunter, however, afferts that it exifts in the *piked* and *large whale-bone whales*. In the genus *delphinus* there is certainly no dilatation correfponding to the cæcum: the laft inteftines are diftinguifhed by their having a fmaller diameter, and thicker mufcular coats. In the *porpoife* the internal membrane forms fome longitudinal folds, which are not very eminent in the fmall inteftines, and decline in the colon and the rectum. The *grampus* has tranfverfe and longitudinal folds, which produce in fome degree the appearance of mefhes: thefe are moft plain in the duodenum, and gradually diminifh until they difappear. For about ten inches above the anus, the inteftine is lined with a thick white cuticle. All the *cetacea*, we believe, have the termination of the rectum covered with cuticle, and contracted in fize. In the *piked whale* the inner coat of the duodenum has longitudinal rugæ, at a diftance from each other, which receive lateral folds: thefe decline in the other inteftines, and appear to correfpond with the mefhes of the *grampus*. The duodenum in the *bottle-nofe whale* fwells into a large cavity, which might be called an additional ftomach, if it were not that the hepatic ducts terminated in it. The whole of the inteftinal canal in this fpecies nearly has the inner coat forming facs or cells, which are again fubdivided into fmaller cells. Thefe open, or have their mouths directed towards the anus, or in the courfe of the food through the canal.

The *cetacea*, as alfo all other animals that inhabit exclufively the water, never have any flatus in their inteftines. The *fpermaceti whale*, however, produces a curious excrement, which is called *ambergris*. This fubftance is fometimes found floating on the furface of the feas that are frequented by thefe *whales*, and at others is taken from their great inteftines. When *whales* are in a healthy ftate, their excrements are liquid, and of a black colour; but when fickly, the fæces are folid, and accumulate in fuch quantity in the inteftines as to produce a tumour of the abdomen. It is in thefe cafes that the ambergris is obtained from the *whales* themſelves: it is found in the great inteſtines, about from two to ſix or ſeven feet from the anus. When taken out, it has the ſame ſmell and the black colour of the fluid fæces; but after expoſure to the air, it becomes harder, whiter, and acquires its peculiar odour. The pieces of ambergris are of various ſizes, from half an ounce weight to 100 lbs. or more. Dr Swediar relates that one piece weighed 182 lbs., and another 130 lbs., which was worth 500*l*. The ambergris is found largeſt and pureſt in the *male whales*. Mr. Hornby found that human fæces, by being long digeſted, acquired ſo ſtrong a ſmell of ambergris, that the veſſel was obliged to be removed out of the laboratory.

Plate V. of the *Anatomy of Mammalia*, repreſents the moſt remarkable varieties in the form of the inteſtines. *Fig.* 1. is the cæcum and appendix vermiformis of the *ourang-outang: a* is the ileum; *b*, the cul-de-ſac, which takes the place of cæcum; *c*, the colon; *d*, the appendix vermiformis. *Fig.* 2. ſhews the ſame parts in the *phaſcolomys*. The appendix is ſeen to communicate with the gut by a valvular opening. *Fig.* 3. is the origin of the great inteſtines in the *lemur macaco: a* is the ſmall inteſtine; *b*, the colon; *c* is the long convoluted vermiform proceſs, correſponding to the cæcum. *Fig.* 4. is taken from the *ornithorhynchus paradoxus: a*, the ſmall inteſtine; *b*, the colon; *c*, the ſtraight appendix, which has been conſidered analogous to the vermiform. Upon the ſame ſide of the gut a number of black ſpecks are viſible, which are produced by the mucous glands, they appearing of a dark colour in this animal. *Fig.* 5. exhibits the cæcum and parts adjacent in the rabbit: *a*, the ſmall inteſtine; *b*, the cæcum: *c*, the colon. The figure being drawn from a dried preparation, the courſe of the ſpiral membrane is ſeen through the coats of the great inteſtines. *Fig.* 6. repreſents ſome coils of the ſmall inteſtine, and the commencement of the great inteſtine, with a portion of the latter in the *three-toed ant-eater: a*, the ſmall inteſtine, very irregularly formed; *b*, the great inteſtine; *c*, *c*, the two curious cæca peculiar to this animal. *Fig.* 7. is intended to ſhew the cæcum in the *Cape cavy: a* is the ileum; *b*, the ſac, correſponding to cæcum from which the colon ariſes; *c*, the colon doubled upon itſelf at its origin. *Fig.* 8. repreſents the two additional proceſſes which are produced by the great inteſtine of this animal: *a*, *a*, are ſome of the ſpiral turns of the colon at this place; *b*, *b*, the two ſharp proceſſes, reſembling the cæca of birds; *c*, the continuation of the gut, after it has furniſhed theſe two cæca.

Liver.—This viſcus is, in proportion, rather leſs bulky generally in mammalia than it is in man. It is uſually divided more deeply into lobes, and theſe are alſo, in many ſpecies, more numerous. The diviſion of the liver into ſeveral, almoſt diſtinct lobes, has been chiefly obſerved in the beaſts of prey, and an opinion has been entertained by ſome, which was firſt advanced, we believe, by Monroe, that it was neceſſary, on account of the ſudden and extenſive flexions of the ſpine in theſe animals when running. Cuvier has inſerted the number of lobes that are found in a great many ſpecies, from which we have compoſed the following table.

Animals.	No. of Lobes in the Liver.
Ourang-outang	Two large and one ſmall, as in man.
Simia paniſcus	Five.
S. pates	Three.
S. ſabæa	Three.
Simia cynomolgus	Four large and one ſmall.
Howling monkey	Four.
Lemur macaco	Two large and one ſmall.
L. mongooz	The ſame.
L. tardigradus	Four unequal ſize.
L. tarſius	Three large and one ſmall.
L. catta	Two large and one ſmall.
Galeopithecus variegatus	Two, the left is again ſubdivided into five lobes.
Vampyre bat	Four large and one ſmall.
The other bats	Three.
Brown bear, *Racoon*, *Coati*, *Hedge-hog*	Five.
Badger	Four.
Mole	Three.
Water ſhrew, *Otter*, *Weazels*	Five.
Cat genus	Five to ſeven generally.
Jaguar	Four.
Lynx	Eight.
Dog kind	Five, ſometimes ſix.
Muſk animal (*viverra zibetha*)	Four.
Viverra genetta	Five.
Opoſſums	Three to four.
Porcupine	Four large and three ſmall.
Ditto of Hudſon's Bay	Four large and two ſmall.
Hare	Three large and two ſmall.
Pika, *Lepus tolaï* of Pallas	Five.
Lepus ogotona	Seven.
Beaver	Four.
Paca, *Agouti*	Three large and one ſmall.
Cavy	Four.
Guinea-pig	Two large and one ſmall.
Common ſquirrel	Five.
Palm ſquirrel	Three.
Flying ſquirrels	Five
Bobac	Three.
Marmot	Five.
Water rat, *Short-tailed rat* (*M. arvalis*), *Hamſter*, *Black* and *Norway rats*, *Mouſe*, *Sand rat*	Six.
Lemming, or *Lapland marmot*, *Mus lagurus*	Four great and one little.
Mus agrarius	Three.
M. œconomus	Seven.
Dormouſe	Five.
Ondatra, or *muſk rat*	Four.
Kanguroo	Five large and one ſmall.
Phaſcolomys	Four.
Ant-eaters	Three.
Ornithorhynchus	Three large and two ſmall.
Echidna	Four.
Armadillo, *Oryčteropus*	Three.
Hog, *Pecari*	Four.

Elephant

Animals.	No. of Lobes in the Liver.
Elephant *Rhinoceros* *Horſe* *Stag* *Antilope* *Dolphin* *Porpoiſe*	The two lobes have only two notches.
Gazelle *Chamois* *Ram* *Goat*	Three.
Seal	Six.
Northern lamantin	Two large and one ſmall.
Whales	Two large and one ſmall.
Ruminants without horns	Reſemble the human ſubject.

The lobes of the liver in mammalia, from being more diſtinct, are thinner in their form, and have ſharper edges than in the human ſubject. Differences in the figure of this viſcus are, however, immaterial, as they do not affect its functions.

The intimate ſtructure of the liver is eſſentially the ſame in man and mammalia. The laſt branches of the vena portæ terminate in both in the ſame manner, and give origin to the excretory ducts.

The chief varieties in the biliary ſyſtem of mammalia are produced by the number and ſituation of the trunks of the hepatic ducts, and the abſence of the gall-bag.

The *gall-bag* is not found in the following inſtances; *viz.* many of the *ſaltigrade* order, as the *common rats* and *mouſe*; the *hamſter*, the *mus talpinus*, *mus minutus*, *mus agrarius*, *mus ſongarus*, *mus phæus*, *mus arenarius*, *mus acredula*; in the *Hudſon's Bay porcupine* (*hyſtrix dorſata*); all the *tardigrade mammalia*; amongſt the *many-hoofed quadrupeds*, the *elephant*, the *rhinoceros*, the *daman*, and the *pecari*. Of the *ruminants*, the *camel*, *dromedary*, and *ſtag*; all the *ſolipeda*; the *northern lamantia*; and the *cetacea*, according to Hunter, although Cuvier only ſtates the *porpoiſe* and *dolphin* as wanting the gall-bag.

In ſome mammalia there is a dilatation in the courſe of the bile to the inteſtine, which may anſwer ſome of the purpoſes of the gall-bag. This dilated part is moſt remarkable in the *elephant*, on account of the numerous diviſions in it. Upon the biliary duct entering the coats of the duodenum, it becomes enlarged into an oval ſac, which is irregularly divided interiorly: ſome of the ſepta are placed nearly tranſverſely, but in ſuch a manner as to produce the effect of a ſpiral valve. They create four principal apartments: two other ſepta placed at the ſeparation of the firſt, in the longitudinal direction, form as many more pouches. There is at laſt a ſmall cell which precedes the four principal ones, and which opens into the firſt of theſe. It receives the orifice of the pancreatic duct upon its ſide, and that of the biliary duct in the direction of its axis. This reſervoir of the bile and pancreatic juice opens into the inteſtine by a moderately ſmall orifice.

In the *horſe*, the *aſs*, &c. the biliary duct becomes very much dilated before it reaches the duodenum.

In the *northern lamantin* the hepatic duct likewiſe is greatly enlarged, and receives the pancreatic duct before it paſſes into the inteſtine.

We have obſerved that the biliary duct of the *grampus* enlarges, before its termination, in what has been called the fifth ſtomach. The ſame has been noticed by Hunter in the *cetacea* generally.

There are ſometimes dilatations of the common duct of the liver and of the gall-bag, even when the latter organ exiſts. In the *cat* genus, the ductus communis choledochus forms, in the parietes of the duodenum, a ſac, which is divided by a membranous ſeptum into two cavities, one of which receives the pancreatic duct.

In the *otter*, the common duct ſwells into an oval ſac on the outſide of the duodenum, and becomes contracted again to the original ſize before it penetrates the inteſtine.

In the *kanguroo*, the common biliary duct of the liver and gall-bag is large, and joined to the pancreatic before it reaches the duodenum. It is deſcribed by Cuvier as having thick glandular coats, and being furniſhed with ſtrong bands internally, which render its inner ſurface cavernous. The cells thus produced are deep, and have their mouths directed towards the inteſtine. The pancreatic duct, although conjoined for a certain diſtance with the other, is ſmooth internally. The orifice of theſe ducts in the duodenum has neither dilatation nor valve.

The ſituation of the *gall-bag*, with reſpect to the liver, appears to be the ſame in all mammalia. In ſome ſpecies, however, it is more imbedded into the ſubſtance of that viſcus than in others. Cuvier ſtates, that the gall-bag of the *opoſſum* is buried as far as the ⅘ths of its ſurface in the parenchyma of the liver.

The figure of the gall-bag is moſt commonly pyriform. Cuvier ſtates it to be elongated, and approaching a cylindric ſhape in the *badger*, *coati*, *otter*, *weaſels*, and *civet*. Although, in ſome others of the ſame order, it tends to a round figure, as in the *bear*, *hedge-hog*, *mole*, and *racoon*. It is alſo round in many *bats*.

The ſize of the bag varies alſo in animals that are allied to each other in other parts of their anatomy. Thus, it is large in the *bear*, *coati*, and *hedge-hog*, and ſmall in the *mole*, *porcupine*, &c.

The ducts which carry the bile from the liver, form a greater number of trunks on the outſide of that viſcus in many mammalia than in the human ſubject. This appears to be the neceſſary conſequence of the diviſion of the liver into a greater number of lobes than exiſt in man. In ſeveral mammalia theſe trunks do not unite to form a ſingle duct, but communicate ſeparately with the cyſtic duct.

In the *monkies with prehenſile tails*, the hepatic ducts form three trunks, which open in ſucceſſion in the cyſtic duct, and the ductus communis choledochus appears to be the continuation of the latter; although, in the human ſubject, the common duct is evidently, both in direction and ſtructure, the continuation of the hepatic duct.

In the *lemur tarſius*, there are alſo three hepatic ducts which unite with the cyſtic, in order to form a ductus communis.

In the *variegated flying lemur* there are ſeveral hepatic ducts, terminating in the cyſtic ducts.

The *mole* has two hepatic ducts; one, which comes from the middle lobe, receives the cyſtic duct. The two hepatic ducts afterward unite to form a ductus communis.

The *hedge-hog* has ſeveral ducts from the liver that join with the cyſtic.

In the *cat kind*, there are many hepatic ducts united to the cyſtic duct, which is ſmall. The ductus communis undergoes, in the parietes of the duodenum, the dilatation already deſcribed.

In the *dog genus*, the hepatic duct opens into the cyſtic, near the neck of the gall-bag.

The *armadillos* and *ant-eaters* have one trunk from the liver, which joins the cyſtic at a very acute angle. The common duct is the continuation of the hepatic.

In the *echidna* there are three hepatic ducts joined to the cyſtic, near the neck of the gall-bag. The cyſtic is large, and appears to form the ductus communis.

In the *ornithorhynchus* there are two hepatic ducts which end in the cyſtic in the ſame manner.

The *elephant* has nine or ten branches from the liver: theſe form three trunks, which unite again, and make but one. It is inſerted into the duodenum, and there ſuffers the remarkable dilatation previouſly deſcribed.

In the *ſeal* one hepatic duct joins the cyſtic near the neck of the bladder, the other at ſome diſtance from it.

In ſome ſpecies the hepatic ducts terminate directly in the body or neck of the gall-bag. This has been particularly remarked in the *ox* and *ſheep*, in which animals there are ſeveral ſhort ducts leading from the liver chiefly into the neck of the gall-bag, reſembling what is found in ſome fiſhes. A ſimilar ſtructure has alſo been deſcribed in the *wolf*, *dog*, *hedge-hog*, and *hare*; but in theſe animals the hepatic ducts rather ſhould be conſidered perhaps as entering the origin of the cyſtic duct than the gall-bag itſelf. In the *vampyre bat* there is but one hepatic duct. It terminates in the commencement of the cyſtic. In all theſe caſes the cyſtic duct muſt be conſidered as ſupplying the place of the ductus communis choledochus. The deſign of the hepatic ducts opening into the body or neck of the gall-bag, is obviouſly to produce a more concentrated ſtate of the bile by retarding its progreſs into the inteſtine; but it is difficult to explain why this effect ſhould be neceſſary to animals in whom the organs of digeſtion, and the quality of the food are ſo very different.

The exiſtence of a gall-bag, whether the bile be conveyed directly into it, or by regurgitation through the ſame duct that carries the cyſtic bile out again, has neceſſarily the conſequence of increaſing the peculiar properties of the bilious fluid; it being found that all ſecretions, when accumulated in reſervoirs, become more concentrated by having their aqueous parts abſorbed. It would ſeem that the preſence of cyſtic bile is required more eſpecially to carnivorous animals that have a rapid digeſtion, as the gall-bag is only wanting in vegetable eaters, if we except the *cetacea*.

The diſtance from the pylorus at which the bile is poured into the inteſtine, was formerly conſidered as determining the digeſtive powers of the animal, it being ſuppoſed that the biliary duct opened neareſt the pylorus in the moſt carnivorous quadrupeds. A further knowledge of comparative anatomy has ſhewn that no general concluſion of this kind can be drawn. There is great variety, even amongſt animals nearly allied in other circumſtances, with reſpect to the ſituation of the orifice of the biliary duct in the duodenum. Cuvier ſtates that it is nearer the pylorus in the *ſaltigrade* quadrupeds generally, than in other mammalia, and at the ſame time the fartheſt removed in the *kanguroo*, which belongs to the ſame order.

In *Plate* VI. of the *Anatomy of Mammalia*, *fig.* 1. repreſents the ſac into which the biliary and pancreatic fluids are poured in the *elephant*: *a* is the hepatic duct, formed by two branches, which are compoſed of nine or ten leſſer ones; *b*, the pancreatic duct which paſſes to the cellular receptacle of the bile; *c* is that receptacle laid open, in the cavity of which the ſepta and apartments already deſcribed are to be perceived; *d*, the parietes of the duodenum. *Fig.* 2. exhibits the receptacle of the bile and pancreatic fluids in the *otter*: *a*, the biliary duct; *b*, the pancreatic duct; *c*, the external form of the receptacle; *d*, a portion of the duodenum.

Pancreas.—In moſt mammalia this viſcus has lobes, branches, or proceſſes, which make its form different from that of the human ſubject.

In the *ourang-outang* the pancreas reſembles, in its figure, the ſame gland in man. It has an irregular form in the *Barbary ape*. In the other *monkies*, the end towards the right ſide is divided into ſeveral proceſſes.

In the *mole*, *hedge hog*, *racoon*, and *bear*, there are two branches or proceſſes in the right end of the pancreas. The *badger* has it bent into an arch. In the *ſhrew*, the left end is ſeparated into two forked proceſſes.

The *cat* genus has the pancreas compoſed of two irregular ſhaped lobes, the ſmaller one accompanies the duodenum from before backwards. The larger lobe is ſituated tranſverſely. The *dog* has the gland formed nearly in the ſame way. The *martin* (*muſtela foina*) has the pancreas doubled upon itſelf, ſo as to reſemble, according to Cuvier, an overthrown figure of 6, thus ∽. In the *viverra genetta*, and *viverra zibethica*, this gland is a thick, compact, broad band, which reaches from the duodenum to the ſpleen.

In the *beaver*, the pancreas is long and thin, and accompanies the convolutions of the duodenum. In the *water rat* the pancreas has three long thin branches.

The *echidna* has ſeveral branches or proceſſes.

The pancreas of the *elephant* is long and narrow, and without any offsets; it is ſaid to be 6½ feet long.

In the *ox* this gland has the figure of a lozenge.

The pancreas of the *horſe* has an irregular figure, and three proceſſes.

In the *ſeal* the pancreas has diſtinct lobes.

The *northern lamantin* has two branches to the pancreas.

In the *cetacea*, at leaſt the genus *delphinus*, there is an irregular ſhaped pancreas, conſiſting of ſome roundiſh lobes maſſed together. The gland is ſmall, in proportion to the ſize of the animals.

However the form of this gland may differ in the various genera of mammalia, the organization is uniformly the ſame in all, and does not differ from that of the human pancreas.

As the pancreas of mammalia has frequently branches or lobes, the excretory duct is often found made up of ſeveral others.

The *ourang-outang* has the duct formed as in man, and ending in common with the ductus communis choledochus. The pancreatic and biliary ducts are in the other *monkies* united in ſome ſpecies, and diſtinct in others.

The *dog* has commonly two pancreatic ducts, one unites with the common biliary duct, and the other paſſes into the duodenum, a little diſtance farther on. In the *cat*, the biliary and pancreatic ducts enter together. The *panther* has them ſeparate, and the duct of the pancreas penetrates the inteſtine after the other. The biliary and pancreatic ducts unite, however, generally in the *carnivorous* quadrupeds.

They are diſtinct in the *porcupine*, and enter the inteſtine at ſome diſtance from each other. They are alſo remote in the *hare*. In the *marmot* the ducts are ſeparate, but enter the inteſtine near each other. The *flying ſquirrel*, *kanguroo*, and many other *ſaltigrade* mammalia, have but one orifice for the biliary and pancreatic ducts.

In the *elephant* the pancreatic duct has two principal branches, one opens into the beginning of the dilated part of the biliary duct, and the other paſſes into the duodenum at a little diſtance.

In the *cloven-footed* quadrupeds the biliary and pancreatic ducts are commonly united.

In the *horſe* they are ſeparate, although cloſe to each other.

In the *northern lamantin*, and in the genus *delphinus*, these ducts are united.

If one may judge from the variety that is to be observed, with respect to the insertion of the biliary and pancreatic ducts, both as to their conjunction, and the distance of their orifices from the pylorus; these circumstances are unimportant in themselves, and have very little concern with the functions of the pancreas or liver.

In *fig.* 5. *Plate* IV. of the *Anatomy of Mammalia*, the letter *h* indicates the pancreas of the *porpoise*. In *Plate* VI. *fig.* 3. exhibits the curious form of the pancreas in the *martin* (*mustela foina*).

Spleen.—The situation of this organ is as nearly as possible the same in all mammalia. It is always attached to the great or left end of the stomach, when the latter is a simple cavity; and when it is composed of more than one cavity, the spleen is connected with the first stomach, or that in which the œsophagus terminates. Thus, in the *ruminating* quadrupeds, the spleen is placed on the left side of the paunch, and in the *cetacea* upon the first cavity, or that which is the receptacle of the food in those animals. It is retained in its situation by reflexions of its peritoneal coat, and is likewise connected by its blood-vessels with those of the first cavity, or of the great end of the stomach.

The form of the spleen is very various, and is likewise subject to a change of bulk, and, in a degree, of figure, according to the different states of the distension or fulness of the stomach; it being well known that the spleen, from its spongy structure, is easily compressed by the adjoining viscera.

Cuvier has inserted the figure of the spleen, as he found it in several species. We shall extract the following from his "Anatomie comparée."

The *monkey* kind differ much with respect to the shape of this organ; thus it is triangular in the *long-armed ape*, the *ribbed-nose ape*, the *baboon*, the *simia apella*, the *orange ape*, and the *sajou*, &c. It is broad posteriorly, and divided into two lobes in the *Chinese ape*, and *Barbary ape*. It is long and narrow in the *weeping monkey*, and in the *ring-tailed macaco*, the *lemur mongoz*, and the *lemur macaco*. It is broader posteriorly than before in the *tardigrade lemur*. It is very long, and has the figure of a triangular prism, in the *howling baboon*. In the *lemur tarsius*, the spleen has the shape of an irregular leaf, notched upon the edges.

The *carnivorous* quadrupeds generally have this viscus long and narrow, prismatic or flattened. It has a similar form in the *bats*, the *mole*, *chrysocloris*, *hedge hog*, &c.

In the *galeopithecus variegatus*, and *Virginian opossum*, it is triangular. In the *brown phalanger* it is in three lobes, and has a similar figure in the *Mexican opossum*, and the *marmose* (*didelphis murina*).

The spleen is large and oval in the *weasel*.

This organ is triangular, broad, and flat, in the *kanguroo rat*, *water rat*, and *guinea-pig*. Very long, narrow, and thin in the great *kanguroo*; long and narrow in the *marmot*, *common rats*, and *hare*. The figure of the spleen is said to vary in different individuals of the *porcupine*.

The *echidna* has three branches to the spleen. It is larger than the stomach in the *ornithorhynchus*, and square.

The spleen is very long in the *elephant* and *hog*; broad and flat in the *rhinoceros*; of a semilunar form in the *daman*.

It is round and flat in the *stag*; thin and oval in the *gazelle*; flat, large, and semilunar in the *lama*. It is broad and thin in most of the other *ruminating quadrupeds*.

The *horse* has a flat triangular spleen.

The most remarkable deviation of structure is found in the *cetacea*. The *porpoise* and *dolphin* have, according to Cuvier, seven small round spleens of various sizes, from the bulk of a chesnut to that of a grain of corn. We have counted but five spleens in the *porpoise*. It is probable they vary both in number and size. They are scattered over the first stomach in the course of its blood-vessels, from which they receive their branches. In the *grampus* we did not observe these small spleens, but found a long stripe of a spongy substance, which appeared to be the spleen. We do not wish, however, to speak positively, as it was paler and closer in its texture than the spleens of other animals, and the parts surrounding it were so much injured in being taken out of the animal, that we could not satisfactorily make out their connections. This stripe was two feet long, and about one inch broad for its greatest extent. Towards the root it becomes gradually wider, and where it appears to originate, it is three inches broad. Hunter states the spleen in the *whales* to be very small.

The variations as to bulk are not very material in the spleens of mammalia; the *herbivorous* quadrupeds appear to have the organ largest, and perhaps the *cetacea* should be considered as having the smallest spleen.

The colour of this viscus is generally deeper in mammalia than in the human subject.

No satisfactory account has yet been published of the intimate texture of the spleen in mammalia. As far as our observation extends, the organization is essentially the same in this class of animals as in man. In the spleen of the *ox*, *sheep*, *horse*, and *hog*, &c. the cellular structure described by Malpighi and Stukely is more apparent than in man, or the small quadrupeds; and the ramification of the blood-vessels upon these cells is discoverable. Mr. Home relates, that he saw these cells very distinctly when in a distended state. He says that the roots of the splenic vein arise from the outside of the cells at right angles to their circumference, like radii. When the injection has not been very minute, they are seen to arise at so many points of the capsule: but when the injection has got into smaller branches, their number is so much increased, that they appear to form plexuses round the cells. Mr. Home also found invariably that the grains described as glands by Malpighi, and called corpuscles by Cuvier, are distinct cells, which contain a fluid, when the stomach had received an unusual quantity of liquids. This fluid was evacuated by puncturing the cells when their membranous coat became visible. Mr. Home further ascertained, that the trunk of the splenic vein, compared with that of the artery, was in the proportion of five to one in its size, by which it appears that the veins of the spleen exceed the size of its arteries in a greater degree than is observed in the other organs of the body. Much, however, remains to be done in order to explain the anatomy of the spleen. To us the cells have appeared of different sizes, and to have a very free communication with each other, by which the organ, particularly towards the surface, resembles a good deal the texture of a sponge. We are doubtful whether the cells have coats proper to themselves, or whether they are not formed by the interspaces of the parenchymatous substance. The blood-vessels appear to communicate with the cells only by their ultimate and most minute ramifications. Cuvier states that the texture of the spleen is very loose in the *ornithorhynchus*, and that its vessels are much developed.

Fig 5. *Plate* IV. of the *Anatomy of Mammalia*, gives a view of some of the spleens of the porpoise upon the first stomach, as pointed out by the letters *i*, *i*, *i*, *i*.

Peritoneum and its Processes.—This membrane has the same structure in mammalia as in man; but the reflections of it, which form the omentum, and the envelopes of the intestinal teftinal canal, differ confiderably in their figure and extent in fome quadrupeds. The form and extent of the mefentery, mefocolon, and meforectum, depend upon the length and convolutions of the fmall and great inteftines, and may be in fome meafure calculated from the previous defcription of the inteftinal canal. The ufes of thefe parts are precifely the fame as in man.

The great *omentum* varies in length in different mammalia, but in moft of them it is longer than in the human fubject. In fome fpecies it not only covers the front of the inteftines, but extends into the pelvis, and is reflected forwards the length of the rectum. This reflection of the omentum is attached to the bladder, rectum, meforectum, and to the fides of the peritoneum. The omentum is thus extended in many fpecies of *monkey*, but the length of this membrane does not correfpond with the agreement of the animals in general ftructure. Species nearly allied have it very different; for inftance, in the *brown bear*, it does not pafs below the middle of the abdomen, and in the *racoon* and *badger* it reaches to the pubis.

The layers of the omentum have not always the fame origin and connections as in man, which arife from the want or the prefence of the tranfverfe mefocolon. There is no omentum to the colon, or appendices epiploicæ in the carnivorous mammalia.

The *ruminating quadrupeds* have the cavity of the principal omentum very large. It inclofes the four ftomachs, the duodenum, and the pancreas.

The fat, which is depofited between the layers of the omenta, is found in all mammalia, but in greater quantity in the *herbivorous* than in the *carnivorous* tribes.

Some of the *hibernating* quadrupeds; for inftance, the *Alpine* and *Polifh marmots*, the *fuflic* (*mus citellus*), the *fat fquirrel* (*myoxus glis* of Gmelin), and the *jerboa*, have lateral omenta in addition to thofe of other mammalia. Thefe arife from the loins, cover the fides of the abdomen, fometimes even coming as far as the middle of the belly. About the period of hybernation, thefe proceffes of the peritoneum become, as well as the other omenta, loaded with fat, which is expended during the time that the animals remain torpid. The ufe of the lateral omenta is, therefore, fufficiently obvious, and yet it is very extraordinary, that they fhould be wanting in other fpecies that fleep during the winter, fome of whom alfo are nearly allied to thofe above mentioned; as, for inftance, the *garden fquirrel* (*myoxus nitela*), the *common dormoufe* (*myoxus mufcardinus*), &c.

Abforbent Syftem.—This part of the anatomy of mammalia fo much refembles what has been difcovered in the human fubject, that there has been no inducement to inveftigate it minutely; we, therefore, poffefs no detailed account of the abforbent fyftem of this clafs of animals.

The chief varieties which have been obferved, relate to the number and fituation of the abforbent glands, and the form of the thoracic duct.

The *glands* are lefs numerous, generally fpeaking, in quadrupeds than man: they are alfo commonly larger. The *mefenteric glands* are perhaps in moft quadrupeds affembled together into one or more maffes; befides thefe maffes, there are often fome diftinct glands in the mefentery. It is at the root of the mefentery that the glands are congregated into the chief mafs. They are connected with each other by means of cellular fubftance, and prefent an unequal furface externally. The affemblage of the mefenteric glands was miftaken for a pancreas by Afellius, and have ever fince retained the name of *pancreas Afellii*. In the *bear*, the *mole*, the *brown phalanger*, &c. there is only one mafs. The *cat* kind, and perhaps all the *digitigrade* quadrupeds, have one principal mafs or clufter at the root of the mefentery, and near this fome fmaller ones. Cuvier ftates them to be the fame in the *dolphin*. The pancreas Afellii is very large, and of an elongated figure in the *feal*. There are two maffes of the mefenteric glands in the *weafel*.

In the *flying lemur*, the *common rat*, and the *cloven-footed* quadrupeds, the glands are difperfed over the mefentery. We have found them fo likewife in the *grampus*. It is probably the fame in the other *cetacea*. The cellular ftructure of the abforbent glands is very apparent in the *horfe*, *afs*, &c.

A very fingular ftructure has been defcribed in the mefenteric glands of the *whale* by Mr. Abernethy. He reprefented them as forming round bags, about the fize of an orange: thefe facs contained a flimy fluid, which was apparently a fecretion of their own. The lacteals not only terminated in thefe bags, but formed a plexus upon their furface. The blood-veffels likewife ramified upon the coats, and communicated with the cavity of the bags, fo that a waxen injection paffed into it. We feel inclined to confider the cyfts defcribed by Mr. Abernethy on the mefentery of the *whale* as a morbid ftructure, as we have found nothing of the fame kind in thofe *cetacea* we have diffected, and as it has not been obferved by Hunter, Cuvier, Blumenbach, or any other comparative anatomift, as far as we know.

The *thoracic duct* has generally in mammalia a confiderable dilatation of its origin, or a large *receptaculum chyli*. The bulk and courfe of the thoracic duct are liable to vary amongft individuals of the fame fpecies, more particularly in domeftic quadrupeds. Sometimes there is an annular dilatation at the upper part of the thoracic duct in the *dog*, which has been reprefented by Vans Bils as a conftant ftructure, which he called the *receptaculum tortuofum*. The thoracic duct is double in fome quadrupeds. It is fo in the *dog*. Cuvier defcribes the duct in the *dolphin* as being complicated, and at laft terminating in two branches, which open befide each other into the jugular vein. Mr. Home found in the *fea otter* the receptaculum chyli large, and the thoracic duct compofed of two tortuous branches, which make many convolutions and communications with each other, and terminate feparately.

Mr. Bracy Clarke has ftated, that he found the thoracic duct of the *horfe* forming feveral lateral communications at the lower part with the lumbar veins. (See Anatomy, *Veterinary*, in this dictionary.) We cannot, however, help doubting the accuracy of the obfervation, as this fact would form fo extraordinary an exception to the fyftem of abforption, as it has been proved to exift in all the higher claffes of animals.

Doubtlefs there are many varieties in the form of the thoracic duct, and the diftribution of the abforbent veffels in mammalia, which have not yet been obferved: but as they probably would not throw any light upon the function of abforption, they are but of little importance.

Heart.—This organ in mammalia correfponds in all material circumftances with the heart of the human fubject. It is in every inftance enclofed in a *pericardium*, notwithftanding Blafius, Peyer, Harder, Tozzetti, &c. have reported that this membrane is wanting in the *hedge-hog*. Blumenbach accounts for thefe anatomifts having made fuch a miftake from the thinnefs of the pericardium in the *hedge-hog*; but to us this membrane has appeared not to be unufually thin, confidering the fize of the animal.

The pofition of the heart in the body is rather different from that of man. It is fituated more in the direction of the animal's body, and refts rather upon the fternum than the diaphragm. We ought to except from this obfervation the

the heart of the *ourang-outang*, which is placed obliquely in the breaft, with the point turned towards the left fide, as in man. It muft have been from the diffection of quadrupeds, that the cavities of the heart firft received the names of *right* and *left*, which are not ftrictly applicable to their fituation in the human fubject.

There are fome differences in the relative fize of the cavities of the heart, and in the thicknefs of the parietes of the right and left ventricles in mammalia, which are pointed out by Cuvier. He has alfo defcribed fome varieties in the form of the valves. As thefe are unimportant, we fhall refer the reader to Cuvier's "Anatomie comparée," tom. iv. for the details. It is neceffary to ftate that the valve of Euftachius is not found to exift in certain fpecies; as the *lion*, the *bear*, and the *porcupine*. It is ftrong and mufcular in the *feal*. In the *elephant* this valve is fpiral, and is continued for the length of the fuperior parietes of the finus, with the left and pofterior extremity of another broad femilunar valve, that feparates the orifice of the right and anterior vena cava from the cavity of the appendix of the auricle.

There are two fuperior, or more properly fpeaking anterior, venæ cavæ in the *elephant*; one left, the other right. The firft opens into the finus of the auricle, near the mouth of the ventricle. The fame is obferved in the *porcupine*. The *kanguroo* has alfo two fuperior or anterior cavæ. Mr. Carlile ftates, that the *hybernating quadrupeds* have the fuperior cava divided into two trunks; the left paffes over the left auricle of the heart, and opens into the inferior part of the auricle near to the orifice of the inferior vena cava. In fome of the *ruminating quadrupeds*, and in the *pig*, there are two fmall flat bones at the origin of the aorta from the heart. It has been fuppofed that they fupported the aortic valves. See C. J. Keuchen de Officulis et Cordibus Animalium.

A very common error, with refpect to the anatomy of the heart, is the fuppofition that the quadrupeds which inhabit the water, and the *cetacea*, have the foramen ovale fo much unclofed, that the two auricles communicate. The opinion has received fome fupport from this communication being actually found to exift in a very few inftances. Blumenbach relates that he was prefented with the heart of a *feal*, in which not only the foramen ovale, but the ductus arteriofus remained unclofed. Seger found the ductus arteriofus open alfo in the fame animal. (Ephem. Nat. Curiof. dec. 1. an. 9.) The foramen ovale has been feen in an open ftate twice by Mr. Home, in the *fea otter*. In the other numerous diffections which have been made by the moft expert anatomifts of the *diving quadrupeds* and the *cetacea*, the heart has been obferved to poffefs the four cavities feparate, as in man and the other mammalia. Our own experience is amply fufficient to enable us to conclude that any communication between the cavities of the heart in thefe animals is not a natural or neceffary ftructure. That it may occafionally exift is not improbable, and that thefe animals may be particularly liable, from their habits, to fuch malformations of the heart, feems alfo not unlikely; but it would be abfurd to found an opinion upon the exceptions to what is fo well known to be the general rule. We might further add, that the foramen ovale is frequently found more or lefs unclofed in the human fubject, without having occafioned any embarraffment or peculiarity in the pulmonary circulation during the life of the perfon. We have obferved, that it is even more commonly imperfectly clofed than otherwife in the human fubject. In moft dead bodies that we have examined, we could at leaft pafs a probe obliquely from the right into the left auricle.

The *otter* has been reported to have three communications between the auricles; but thefe were nothing more than the foramina Thibefii, perhaps in an enlarged ftate.

The external form of the heart is in fome fpecies elongated, in others broad. The point is blunter or rounder in fome than others, but thefe varieties do not merit a particular notice. In the *lamantin* the figure of this organ is, however, very peculiar. It is much broader than it is long. The ventricles are actually feparated half way from their end, fo that there are two points or apices to the heart.

Arteries.—The ftructure of thefe veffels is perfectly fimilar in man and mammalia. They confift of the fame number of coats, and in general have a fimilar relation in their diameter and the thicknefs of their parietes. The quadrupeds that inhabit rivers or the fea, and the *cetacea*, are diftinguifhed by a large fize of their blood-veffels, in proportion to that of the entire bulk, or the fize of the other organs of the body. In fome *cetacea* the principal trunks have a diameter nearly equal to that of the inteftinal canal. The branches of the blood-veffels alfo in thefe animals are very large in proportion to the trunks from which they arife. The circulation appears to be much lefs free in aquatic animals than others, and hence the great fize of the veffels and the accumulation of blood in *fifhes*, which circumftances are alfo to be obferved in a lefs degree amongft thofe mammiferous animals that live in the water. It feems to us, that the arteries of the *cetaceous* mammalia have thinner coats than in other animals of the fame clafs, according to the fize of the veffels. The *pulmonary* artery in the *cetacea*, however, has nearly as ftrong coats as the aorta.

The chief varieties to be noticed in the arteries of mammalia are the different origins of the trunks; the greater fize of particular veffels; and the plexufes that are formed in certain fpecies.

The *aorta* in the *ruminating quadrupeds*, the *horfe*, the *rhinoceros*, the *hog*, the *pecari*, and probably in other inftances not yet difcovered, divides almoft immediately upon its origin into two large trunks. One of thefe, which is the fmaller, proceeds upwards, or more properly forward, in the body of a quadruped; and it correfponds to the arch of the aorta, and furnifhes the fame branches. The other trunk goes backwards, and takes the place of the defcending aorta.

The firft branches of the aorta have different origins in mammalia. In the *marmot* and *guinea-pig*, the arch furnifhes only two primary branches. One of thefe fends off the two carotids, and then ends in the right fubclavian. The other is the left fubclavian artery. Sometimes the firft of thefe branches very foon feparates into two others, one of which is the left carotid, and the other produces the right carotid and fubclavian. In other cafes, the firft of the primary arteries of the aorta furnifhes a branch which divides into the two carotids. The remainder of the artery is the right fubclavian. This laft mentioned diftribution exifts in the *lion*, *dog*, *cat*, and *bear*.

In the *dolphin*, each of the two primary branches of the arch of the aorta furnifhes the arteries of the head, and fuperior extremity, on its proper fide.

The *feal* has three principal branches from the arch of the aorta: the firft is the common trunk of the right carotid and fubclavian, the fecond the left carotid, and the left fubclavian.

The *elephant* has three branches from the arch of the aorta alfo. The lateral veffels are the two fubclavian arteries. The middle one divides into the two carotids.

The *goat* has the aorta divided, as already defcribed, into the afcending and defcending, or the anterior and pofterior, more properly called. The anterior divides into three branches:

branches: the left subclavian; the right; and a trunk that forms the two carotids.

The anterior aorta of the *horse* soon bifurcates into two branches; the trunk of the two carotids and the right subclavian arise from one branch: the other terminates in the left subclavian.

The *inferior thyroideal* artery is not commonly in quadrupeds a branch of the subclavian, but of the carotid higher up. This distribution arises from the length of the neck removing the thyroid gland so far from the usual origin of this vessel.

In the *opossums*, the *kanguroo*, and as it would appear in all the *marsupial* quadrupeds, the *brachial* artery divides very high up into the ulnar and radial arteries; in some instances as high as the middle of the humerus. The ulnar is a large vessel, and passes through a hole formed in the internal condyle of the os humeri, and proceeds from the back of the arm to the front, where it is distributed in the usual manner. Cuvier states that the brachial artery forms several branches for the supply of the portion of the fin corresponding to the *fore* arm in the *dolphin*. The very remarkable plexus which the brachial artery furnishes in the *tardigrade quadrupeds*, will be noticed hereafter, along with the other arterial plexuses.

Daubenton has described in the *descending* or *posterior aorta* of the *pecari* a large dilatation, which appears to have been an aneurism. Tyson found in the same animal three dilatations in the course of this vessel. They were divided interiorly into cells. These enlargements were probably also a morbid structure, as they have not since been observed by other anatomists.

There are some varieties to be noticed in the branches of the *cœliac* and *mesenteric* arteries. In the *cat* the cœliac sends off a branch to the right renal capsule, previous to its supplying the *hepatic*, the *coronary* of the *stomach*, and the *splenii*. In the *porcupine* the cœliac divides into two branches; one furnishes the artery of the spleen, and a large branch to the pancreas; the other gives the hepatic and coronaria.

The two *mesenterics* always are found; but when there is no marked distinction of great and small intestines, the one corresponding to the inferior mesenteric is very small. This vessel is almost exclusively distributed to the rectum in the *bear*. In the *ruminating quadrupeds* the primary branches of the superior mesenteric artery are numerous. They do not consequently form such frequent anastomoses as exist commonly. The *inferior*, or, as it should be called in quadrupeds, the *posterior mesenteric* artery, is small in these animals, and almost confined to the rectum. The remarkable anastomosis between the two mesenterics on the colon is not found.

In the *seal*, the left kidney receives two arteries from the aorta, and the right only one, according to Cuvier. This not improbably may have been a variety.

The *middle artery* of the *sacrum*, which is so inconsiderable in man, is often very large in mammalia, as it conveys almost the whole of the blood to the tail. In the *kanguroo, bear, lion, dog*, &c. it has been observed not to arise from the aorta, but to be furnished by a thick short trunk proceeding from the bifurcation of the aorta, which also in these cases sends off the *sacræ laterales* and the *hypogastric* arteries. The artery of the tail is as large in the *kanguroo* as the internal iliac. This vessel is of great magnitude also in the *cetacea*. It runs along the under surface of the tail, protected by a number of small bones, which are attached to the caudal vertebræ, to near the extremity of the tail, and form by their opposition a sort of triangular conduit, similar to that inclosing the termination of the aorta in the tail of fishes. The artery of the tail might properly be considered the continuation of the abdominal aorta in the *cetacea*; it sends off a great many branches which anastomose with each other, and unite again in a small branch under the two last caudal vertebræ.

The *primary iliac arteries* frequently do not exist in the *cloven footed quadrupeds*, the *cat* and *dog kind*, the *bears*, the *kanguroo*, &c. The *external iliacs* are formed by the bifurcation of the aorta, and the *internal iliacs* arise from a common trunk, as already mentioned. They are much smaller than the external iliacs, and separate into two principal branches, which send off the customary arteries of the internal iliac, except the *ileo lumbalis*, which comes in these instances from the external iliacs.

In the *seal* the ileo-lumbales arise from the aorta before the primary iliacs are produced.

In the *cetacea* there are no arteries analogous to the external iliacs. The aorta sends off arteries which correspond to the internal iliacs, but which only supply the bladder and genital organs.

We shall now notice the different plexuses which the arteries form in mammalia.

In the *digitigrade* quadrupeds, some of the *ruminants*, &c. the branches of the carotid, which go to meet the basillary, form so remarkable a plexus, that it was called by the elder anatomists *rete mirabile*. These branches of the carotid are suddenly dissolved into an immense number of small vessels, which are twisted and united together like a plexus of nerves. These plexuses fill up the sides of the sella turcica, and afterwards reproduce the two branches that, uniting with the basilliary artery, establish what is called the circle of Willis. It is not known in how many species the rete mirabile exists; it was formerly supposed to be universal in mammalia. The Parisian dissectors did not find it in the *monkey*, and Cuvier says it does not exist in the *elephant* and *beaver*.

Mr. Carlile has mentioned a similar plexus of the carotid artery near the jaws in the *lion. ox*, and *sheep*.

We have observed in the *grampus* a very intricate plexus of vessels around the articulation of the lower jaw. We did not ascertain whether the vessels were arterial or venous: they appeared to be both, and were lost in the apppearance of ligamentous cells.

The *intercostal* arteries in *cetacea* form a very remarkable plexus. It appears to be made by the convolution of one vessel, which measures several hundred feet in length.

The arteries of the spinal marrow also in *cetacea*, are converted into a close plexus throughout the greater part of the spinal canal. In the *grampus*, the section of the sheath of the spinal marrow exhibits a number of the orifices of these vessels all round it.

But the most interesting arterial plexuses, are those described by Mr. Carlile in the limbs of the *slow-moving animals*. In all these, as well as the *tardigrade lemurs*, as the *sloths*, the axillary and iliac arteries produce a plexus of undulating branches, which vary in number according to the species. Mr. Carlile describes the trunks of the arteries as being expended in the formation of the plexuses; but we have ascertained that the trunk of the vessel is continued beneath the plexus, in the same manner as in the plexus of the anterior tibial artery in birds where the trunk is scarcely diminished. The vessels composing the plexus in the anterior extremity of the *lemur tardigradus* amount to 23. In the inguinal fasciculus there are 17. These vessels have the same size throughout their course, and occasionally anastomose with each other.

The brachial and inguinal plexuses are larger in the *great American sloth* than in the *tardigrade lemur*. In the first Mr. Carlile counted 42 vessels, and computed from the bulk that there

there might have been above 20 more concealed in the middle of the fasciculus. He reckoned only 34 in the thigh, and those of the first series were larger than the rest. The plexus of the axillary artery in the *two toed sloth* is very inconsiderable, and disappears in the upper part of the humerus, although in the other instances it reaches to the elbow. The inguinal plexus also in this animal contains but eight vessels, which soon begin to ramify in the usual arborescent form.

In the *lori* (*lemur gracilis*) there are brachial and inguinal plexuses, the vessels of which appear to form fewer anastomoses than in the other animals. From the agreement in the distribution of the arteries in the limbs of the *slow-moving* animals, it is impossible not to admit Mr. Carlile's supposition, that this peculiar arrangement of vessels is necessarily connected with the slow operation of the muscles in those quadrupeds, although we cannot perceive why such a connection should exist.

The *rete mirabile* has evidently the effect of retarding the current of the blood to the brain, which may be more necessary to *quadrupeds*, from the frequent low position of the head, than in *man* and the *monkey*, where this plexus does not exist.

It is difficult to account for the intercostal, spinal, and maxillary plexuses of the *cetacea*, unless we suppose that they serve as reservoirs of the blood, or rather prevent an accumulation of blood in larger vessels, which might arise from their continual residence in the water, and frequent suspension of their respiration.

In *Plate* VI. of the *Anatomy of Mammalia*, *fig*. 4. represents the rete mirabile of the carotids in the *calf*, somewhat above the natural size: *a*, the sella turcica, a little pared away, to shew more plainly the plexus, *b*, on each side; *c*, *c*, are the carotid arteries; *d*, the basilar. *Fig*. 5, of the same plate, is to shew the axillary plexuses of the *tardigrade lemur*: *a* is the trunk of the axillary artery; *b*, the plexus; *c*, *c*, the arteries of the fore-arm resuming their proper form. *Fig*. 6. exhibits the plexus of the iliac artery in the same animal: *a*, the trunk; *b*, the plexus; *c*, *c*, distinct vessels for supplying the leg. *Fig*. 7. shews the axillary plexus in the *three-toed sloth*: *a* is the sub-clavian vein; *b*, the trunk of the artery behind the large veins; *c*, the remarkable plexus which the artery forms; *d*, the median nerve. *Fig*. 8. represents the brim of the pelvis and groin of the *three-toed sloth*, with the plexus of the inguinal artery: *a* is the bifurcation of the aorta into the two iliacs; *b*, a part of the internal iliac muscle; *c*, part of the bony margin of the pelvis, leading down to the pubis.

Veins.—These vessels agree in general exactly in mammalia with those of the human subject. Even where the arteries deviate in their origin from what is observed in man, the veins pursue the ordinary course.

We have already mentioned that there are two superior or anterior *cavæ* in the *porcupine*, *elephant*, the *kanguroo*, and the *hybernating mammalia*. Mr. Carlile has stated, that, in addition to the cavæ forming two trunks before approaching the heart in the quadrupeds that remain torpid during the winter, there are also two trunks to the *vena azygos*, which each open into the superior cava, on its own side of the thorax. He likewise remarks, that the intercostal arteries and veins are particularly large in those animals. Mr. Carlile wishes to infer from this distribution of the venous trunks, that it is necessary, on account of the languid circulation that is carried on when the animal is torpid; but we believe it is vain to attempt the explanation of the phenomena of hybernation by the anatomical structure of the animals concerned. The habit of retiring to rest during the winter is common to animals whose anatomy is extremely different, and if the diminished action of torpid animals were to depend upon any particular organization of their vascular system, it would interfere with their perfect circulation at other seasons. Hybernation is accompanied by a suspension of functions, not a different mode of exercising them.

In the *seal* the inferior vena cava is dilated into a large sinus, as it passes the liver, into which five large hepatic veins enter. This dilatation may be either the consequence of the animal living in an element in which its respiration, and consequently free circulation is so often interrupted, or it may be an original provision of nature, to relieve the right side of the heart, when the current of blood through the lungs is impeded during the moments the animal is under the water.

A similar contrivance seems to exist in the *horse*. There is a dilatation of the *jugular vein* behind the jaws in this animal, which may serve to relieve the brain from the pressure of the venous blood during the time this animal is feeding. The ruminating quadrupeds do not require a provision of this kind so much as the *horse*, as they often eat lying, and generally ruminate so.

The veins of the viscera appear to be provided with valves in some mammalia, like those of the members in man. According to Haller, there are valves found at the origin of the branches of the *mesenteric* and *hæmorrhoidal* veins of the *horse*; and they have been observed also in the *splenic* veins. They exist in the *pulmonary* veins of the *dog* and *sheep*. Most probably they may be found in many other instances, where they have not yet been observed.

The texture of the coats of the veins is apparently the same in man and in mammalia. Cuvier says he found the proper membrane to tear, like felt, into long silky filaments, in the axillary vein of the *elephant*, which he considers an example of the structure of this coat generally.

Vital Temperature.—That degree of heat which an animal sustains most commonly, or when not exposed to extremes of external temperature, we have called the natural *standard*. The standard heat of *mammalia* is several degrees higher than in *man*, although still below what is found to be the natural temperature of *birds*.

The thermometer, when introduced into the rectum or urethra of a man, (for the standard can only be ascertained in the cavities,) rises to 97°.

The following experiments were made by Mr. Hunter, and shew the difference in quadrupeds.

The ball of the thermometer [in every case we are to be understood as speaking of Fahrenheit's scale] being introduced two inches within the rectum of a healthy *dog*, the quicksilver rose to $100\frac{1}{2}$° exactly. The chest of the *dog* was opened, and a wound made into the right ventricle of the heart. Immediately on the bulb being introduced, the quicksilver rose to 101°.

A wound was next made into the substance of the liver, and the instrument being inserted into it, rose to $100\frac{3}{4}$°. It was next introduced into the cavity of the stomach, where it stood exactly at 101°.

The thermometer was introduced into the rectum of an *ox*, and the quicksilver rose to $99\frac{1}{2}$°.

When inserted into the rectum of a *rabbit* it stood also at $99\frac{1}{2}$°.

Doctor Martine, in his Essays upon Thermometers and Heat, states that the temperature of the surface of the body is from 100° to 102°, or sometimes 103°, or a little more, in ordinary quadrupeds, as *dogs*, *cats*, *sheep*, *oxen*, *swine*, &c. in which he is certainly incorrect. We have been led to ascertain the usual temperature of several quadrupeds, previous to making different experiments that would be irrelevant

vant to our prefent purpofe, if related here; but we may ftate that we have always found the heat of the cavities of the body to be about 99°, 100°, or 101°, when the quadrupeds were placed in a medium natural to them, and that of the furface of the body, two, three, or more degrees, according to circumftances, below that of the interior of the body. In quadrupeds, generally, we conceive the *ftandard* temperature fhould be ftated to be 100°.

The heat in *cetacea* we fhould fuppofe to be equal to that of quadrupeds, or perhaps higher. The quantity of oil interpofed between their internal parts and the water would feem to be fufficient to prevent the abftraction of heat, and that circumftance, joined with the want of evaporation from the furface, might even tend to exalt the temperature of the interior part of the body. Boerhaave confidered the heat of cetacea to be the fame as in quadrupeds, but he rates it in both too low. Mr Richer found the blood of the *porpoife* to be as warm as the blood of land animals. Du Ham. Hift. Ac. Sc. P. M. 157, and Mem. de l'Acad. des Sc. 1666—1668. Dr. Martine relates that he found upon trial the heat of the fkin of the *fea-calf* (*phoca vitulina*) to be near 102°, and in the cavity of the abdomen it was about a divifion higher.

We may fafely conclude from the facts before us, that the ftandard temperature in all mammalia furpaffes the human by a few degrees. In what manner can this fact be explained? fhould it be attributed to there being lefs evaporation from the fkin; or the natural integuments of mammalia being better calculated for retaining the vital heat? We do not pretend to anfwer thefe queries, but we fhall obferve that although the natural clothing of an animal evidently tends to preferve its temperature from the influence of external cold, it does not feem capable of giving a higher ftandard. We cannot believe that the ftandard of a *bear* could be altered by depriving the creature of its fur.

Mammalia have, both from their ufual coverings, and the high natural ftandard, great powers of refifting the effects of external cold. Many of them are expofed to great extremes of temperature in the northern climates, in which they fuffer more than birds, from fleeping on the ground. Mr. Hunter failed to freeze a *dormoufe*, when furrounded by a freezing mixture, until he wetted its hair with water. And in another experiment, a *moufe* which he had placed in an atmofphere as low as 13° above 0 during an hour, had not its heat diminifhed more than 16° at the diaphragm, and only 18° in the pelvis.

Like all other animals, however, which poffefs a high ftandard, when this is brought very low in mammalia they perifh. When in a torpid ftate they fuffer a great reduction of their natural temperature, with the fame impunity as the more imperfect animals. Thus, in an atmofphere of 26°, a torpid *hedge-hog* was only 30°, although the fame animal, when roufed, was expofed for two days to the fame atmofphere, and the internal heat, as tried by the rectum, did not fink below 93°.

Lungs.—Thefe organs have their general figure regulated, in fome degree, by the fhape of the thoracic cavity. In thofe fpecies which have the cheft fhort it is commonly wide in proportion, and the convexity of the diaphragm is not confiderable; and, on the contrary, where the thorax is long, it is often narrowed and diminifhed in the longitudinal direction, by the diaphragm being very convex, or projecting far into the cheft. In the *rhinoceros*, *horfe*, *elephant*, and *two-toed floth*, the diaphragm paffes up into the thorax, far beyond the margin of the ribs, fo that it receives a part of the abdominal vifcera. The volume of the lungs is, therefore, ftill preferved in due proportion to the fize of the animal, notwithftanding the external form of the cheft might fometimes make it feem otherwife.

The lungs of mammalia are commonly divided into a greater number of lobes than thofe of the human fubject, although there are fome fpecies which have them lefs fo, or even not feparated into lobes at all. The number of the lobes of the lungs is not conformable to any natural claffification of mammalia, but varies even amongft individuals of the fame fpecies.

Cuvier has given in his "Anatomie comparée," tom. iv. a very full table of the divifions of the lungs of mammalia by lobes and fiffures, from which we fhall felect the following account.

In the *ourang-outang*, there are three lobes in the right lung and two in the left, as in man.

The *long-armed ape* has four in the right, and only a fiffure in the left. The reft of the *monkey* genus have commonly four lobes in the right, and two in the left lung: in fome of thefe there are fiffures.

The *lemurs* have four or three lobes to the right, and two or three in the left lung.

The *flying lemur* and the *common bat* have the lungs undivided, except by fiffures. The *great* or *ternate bat* of Edwards, has four lobes in the *right*, and three in the *left* lung.

The *plantigrade* mammalia have generally four in the right, and two or three in the left. The *common hedge-hog* has, however, four in the right lung, and no divifion of the left.

In the *digitigrada* there are four lobes in the right, and three or two in the left.

The *marfupial* quadrupeds (except the *kanguroo-rat*) have the left lung undivided, or flightly fo, by one fiffure. The *phafcolomys* has no lobes, but two fiffures in the right lung. The *kanguroo-rat* has four lobes in the right lung, and two in the left. The *Virginian opoffum* has three in the right lung: the other fpecies of *didelphis* have either three lobes, or two and a fiffure to the right lung.

The *faltigrade* quadrupeds have moft commonly the right lung divided into four lobes, and the left is frequently entire. When the left lung is divided, it is ufually into two lobes; but in the *Hudfon's Bay rat* there are four lobes, and in the *jerboa* three. The *porcupine* has fix lobes to the right lung, and five to the left.

In the *edentata* there are two, three, or four lobes to the right lung, and either two or none in the left.

In the *elephant* and *rhinoceros*, both the right and left lungs are without lobes. The *daman* has two fiffures to each lung. The *wild boar* has three lobes in the right lung, and two in the left. The *Siamefe hog* has four in the right, and two in the left lung.

The *ruminating* quadrupeds have generally four lobes in the right lung, and two in the left. The *lama*, however, has the left lung only divided by a fiffure.

In the *folipeda* there are no lobes to the lungs of either fide.

The *feal* has two lobes in the right lung, but none in the left. The *lamantin* is without lobes.

The *cetacea* have not their lungs divided into lobes.

Some of the *mammalia* are faid to have the lungs adhering to the parietes of the cheft. The *elephant* is reported to be an inftance of this kind, and Tyfon has alfo ftated it to be the cafe in the *web-footed* and *cetaceous* mammalia. In thofe fpecies we have examined the lungs have been free, as in the human fubject. In the *cetacea* the coats are ftrong, and the lung altogether feels firm and flefhy. Hunter ftates, that the lungs of *cetacea* poffefs fo much elafticity,

city, that they are of themfelves fufficient to exprefs the air from their cells. He alfo reprefents the air-cells as being fma'ler than they are in quadrupeds.

The intimate organization, which confifts in the diftribution of the arteries, veins, and the air-tubes, is perfectly the fame in all mammalia and in man.

Bronchial Gland.—The ufe of this part not being eftablifhed by anatomifts, it cannot have a proper place affigned to it according to any phyfiological arrangement. We fhall, therefore, defcribe it next to the lungs, from its contiguity to thefe organs in the body, without endeavouring to fhew any connection between the functions of the bronchial gland and refpiration.

The fize of the bronchial gland is greater in the human fubject than in any other animal. In proportion to the entire bulk, there is very little difference obferved in mammalia, except in the *kanguroo*, which has a particularly fmall bronchial gland.

This gland is compofed of two lobes, as in man; but they are fometimes quite unconnected with each other, as in the *bat*, in fome fpecies of *rat*, the *elephant*, the *daman*, the *folipeda*, and the *feal*. Moft commonly the two lobes are conjoined by one or fometimes two thin ftripes, which pafs over the front of the trachea.

The form of the lobes varies in different fpecies. They are broader above than below in the *bat*, elongated in the *plantigrada*, long and flattened in the *cat* kind generally, ftill longer and cylindrical in the genus *viverra*. In the *faltigrada* the lobes are elongated, and not quite cylindric, being thicker above than below. The figure of the gland varies in the *ruminants*. It is round and tolerably large in the *lama*, longer in the *ox*, *fheep*, and *antilope*.

In the *folipeda* the gland is but little elongated, and fituated far below the larynx.

Hunter denied the exiftence of the thyroid gland in the *cetacea*, but Cuvier afferts that he found it very diftinctly in many *porpoifes* and *dolphins*, confifting of two parts fufpended to the trachea, oppofite to the fuperior, or rather anterior edge of the fternum. We have not perceived it in the *porpoife* or *grampus*, perhaps from not feeking it far enough from the larynx.

In *man* and the *monkey* the cellular fubftance connects the thyroid gland clofely to the fides of the trachea, but in the other mammalia this connection is loofer. It is fo much fo in the *rabbit*, *guinea-pig*, and fome other of the *faltigrade* quadrupeds, that the thyroid gland is moveable.

The internal ftructure of the thyroid gland appears to be the fame in man and mammalia. The obfervations that have been made upon it in the *elephant* have tended to explain its organization, as from the fize of the animal the gland is large. It is furrounded by a thick aponeurofis, in the fubftance of which the thyroid veffels divide before they penetrate the gland. Each lobe of the gland is compofed of about thirty lobules having a firm texture, and feparated by peculiar cells, which are made by an extremely fine membrane. Thefe cells are but flightly connected with each other, and with the lobules which furround them, fo that they appear to ferve only as the foundation for the fmalleft ramifications of the veffels that enter the gland. It is by means of thefe veffels, rather than the cellular tiffue, that the different lobules are joined together.

According to Steller, the *northern lamantin* has the thyroid gland very large; it contains two fluids, differing from each other in colour and confiftence. The external part of the gland is compofed of a number of very fmall grains, and of a fluid refembling milk in colour and confiftence, and having a fweet tafte. There is a membranous fac in the middle of the gland, containing a thick and rather bitter fluid. It feems to be fecreted by the grains, and depofited in the fac.

The exiftence of cells fo plainly proved in the thyroid gland of thefe large animals, feems to juftify the opinion entertained by fome anatomifts, that the cellular ftructure obferved in bronchocele is produced by the natural cells of the part becoming enlarged.

It is a remarkable circumftance, which may throw fome light upon the functions of the thyroid gland, that it only exifts in man and mammalia. Cuvier feems inclined to confider a round cellular gland placed before the heart in the *ferpents* as analogous to the thyroid of mammalia. It does not feem probable, however, that an organ fhould be wanting in *birds*, and re-appear in certain animals of a clafs one ftep farther removed from mammalia.

Kidnies and Urinary Bladder.—The pofition of the kidnies in the abdomen is different in man and mammalia, inafmuch as the latter commonly have the right kidney higher than the left.

The kidnies of mammalia ufually poffefs the figure of the human. In the *cat kind*, the *coati*, the *armadillo*, the *gazelle*, &c. they are more or lefs round. In the *ruminating* quadrupeds, the *paca*, the *hog*, and the *porcupine*, &c. according to Cuvier, they are long-fhaped. The *lama* has them nearly cylindric. They are fhort and triangular in the *horfe*.

In *man* and fome *mammalia* the kidnies before birth are in feparate lobules. In thofe mammalia that inhabit, or frequently vifit, the water, and in a very few others, thefe glands preferve the diftinctly lobulated appearance during life. The original lobules can, however, be always perceived, and reckoned from the number of their papillæ. They may be injected alfo with different coloured fluids, and not occafion any confufion, although they are confolidated into one mafs.

The *elephant* is one of the animals which have lobulated kidnies. They are, however, not much divided, there being only four lobes to each in this animal. The texture of the *elephant's* kidnies is foft, and the diftinction of the cortical and medullary fubftances is not plain. There are three papillæ, and as many infundibula, which join together without forming a pelvis.

The kidnies of the *ox* are ftill more divided than in the *elephant*, having from 23 to 30 lobes.

It is in the *otters*, *bears*, *feals*, and *cetacea*, that the lobulated ftructure is moft diftinct. The lobes are numerous and fmall in proportion, according to the fucceffion of thefe animals. Thus, in the *otter* there are ten lobes to each kidney; in the *bear* there are from 50 to 60; the *feal* has 120 to 140; and in the *porpoife*, *dolphin*, *grampus*, &c. there are upwards of 200. In the *cetacea*, the lobules or glands of which the kidnies are compofed, are particularly diftinct and fmall in proportion to the fize of the vifcus. They are connected almoft entirely to each other by means of their veffels alone, in the manner of a bunch of fruit, and have a good deal of motion upon one another. In the other animals they are more preferved in their proper fituation, and in contact with each other by means of their cellular fubftance. No fatisfactory phyfiological reafon has yet been given for the kidnies being divided into numerous diftinct glands in certain animals and not in all. It has been conjectured that this ftructure was in fome way connected with the habit of diving, on account of its being met with in all the aquatic mammalia; but, as we have before ftated, it is not

not peculiar to them. Like many other peculiarities of ſtructure it muſt remain unexplained, until it be inveſtigated by experiment.

The number of papillæ indicate both the original and the actual number of lobes that compoſe the kidney. There is but one papilla in the *tanrec* and the *coati*; in the *ſquirrel*, the *hare*, the *guinea-pig*, the *daman*, and many other of the *ſaltigrada*. There are two in ſome *rats*, three in the *elephant*, four in the *echidna*, and five in the *hedge-hog*. In the *otters*, *bears*, *fin-footed* and *cetaceous* mammalia, each ſeparate lobe has its proper papillæ.

The papillæ regulate in a certain degree the number of infundibula. When there is but one papilla the infundibulum is commonly abſent, being confounded with the cavity called the pelvis of the kidney. This is particularly to be ſeen in the *cat*, the *dog*, the *armadillo*, &c. in which the medullary ſubſtance that forms the papillæ does not project into the cavity, but is flat or ſometimes hollow: therefore, the cavity which receives the urine, and is the origin of the ureter, cannot ſend off any proceſſes or funnel-ſhaped reflections of its membrane. The pelvis of the kidney in theſe caſes is not viſible on the outſide.

The lobulated kidnies have a calyx or infundibulum to each of the glands that compoſe them. They unite to form trunks of veſſels, which make at laſt ſomething like a pelvis for the ureter to ariſe from in the *bears*, *otters*, and *ſeals*. In the *cetacea* there is no pelvis; the ureter is formed by the junction of ſome branches from the anterior infundibula, and receive the branches of the other infundibula afterwards, without forming any dilatation correſponding to the pelvis.

The *renal arteries* and *veins* do not enter at one place always: this is occaſionally ſeen in man. The *adipoſe arteries* alſo are of various ſizes, but in the lobulated kidnies, the veſſels penetrate the organ at the neareſt place, inſtead of paſſing in preference at the ſinus, or the part where the excretory ducts come forth.

The veins of the kidnies in the *cat* kind have their principal trunks and branches running in an arboreſcent form upon the ſurface. They receive the branches from the internal part of the gland, as the ſinuſes of the dura mater collect the blood from the brain.

The intimate ſtructure of the kidnies in all mammalia appears to be the ſame as in the human ſubject.

The chemical compoſition of the urine appears not only to vary conſiderably in animals reſembling each other, but even to differ in the ſame animal at different times. In this way one may account for the diſagreement in the analyſis publiſhed by the French and Engliſh chemiſts.

The urine in the *camel*, according to Mr. Brande's experiments, is compoſed as follows:

Water	75
Phoſphat of lime, Muriat of ammonia, Sulphat of potaſh, Urat of potaſh, Carbonat of potaſh	6
Urea	6
Muriat of potaſh	8
	95

Rouelle ſtates the *camel's* urine to be compoſed of carbonat of potaſh, ſulphat of potaſh, muriat of potaſh, urea, and water.

Mr. Brande found the following component parts in the urine of the *cow*:

Water	65
Phoſphat of lime	3
Muriat of potaſh, ——— ammonia	15
Sulphat of potaſh	6
Carbonat of potaſh, ——— ammonia	4
Urea	4
	97

But from Rouelle's examination, it conſiſts of carbonat of potaſh, ſulphat of potaſh, muriat of potaſh, urea, and benzoic acid. Both theſe chemiſts agree that potaſh is the only fixed alkali in the urine of the *cow*.

The urine of the *rabbit*, according to Vauquelin, is compoſed of the following parts: carbonat of lime, carbonat of magneſia, carbonat of potaſh, ſulphat of potaſh, ſulphat of lime; muriat of potaſh, urea, gelatine, and ſulphur.

The ſame chemiſt found that the urine of the *guinea-pig* depoſited carbonat of lime; that it changed the colour of ſyrup of violets to green; and that it contained carbonat and muriat of potaſh, but not any phoſphat, nor the uric acid.

From theſe examinations it would appear that ſoda and its combinations do not form any part of the urine of the *camel*, *cow*, *guinea pig*, and *rabbit*.

In the urine of the *horſe* the following component parts have been diſcovered by Fourcroy and Vauquelin:

Carbonat of lime	11
——— ſoda	9
Benzoat of ſoda	24
Muriat of potaſh	9
Urea	7
Water and mucilage	940
	1000

Mr. Brande found the urine of the *horſe* to contain the following ſalts, *viz.* carbonat of lime and of ſoda, ſulphat of ſoda, muriat of ſoda, benzoat of ſoda, and phoſphat of lime, which parts amounted to about ⅑th of the urine.

The urine of the *aſs*, according to the ſame chemiſt, is mucilaginous, but at the ſame time tranſparent. Like that of the *horſe*, it changes vegetable blues to green, but depoſits no carbonat of lime. It differs in compoſition from that of the *horſe*, by containing a much greater relative proportion of phoſphat of lime and urea: it alſo contains carbonat, ſulphat, and muriat of ſoda, and there appeared to be a ſmall quantity of potaſh, which is probably united to muriatic acid. He did not diſcover any benzoic acid.

It deſerves to be remarked, that the urine both in the *horſe* and *aſs* is deſtitute of ammonia.

The urine of quadrupeds appears to have generally more conſiſtence than in man. It feels particularly unctuous or mucilaginous in the *horſe*, *aſs*, and *cow*.

Fig. 1. *Plate* VII. of the *Anatomy of Mammalia*, exhibits the lobulated kidney of the *bear*.

The *urinary bladder* exiſts in all mammalia, and reſembles, in general very cloſely, that of the human ſubject. Its muſcular coat is particularly ſtrong in ſome quadrupeds: it is moſt ſtrikingly ſo in the carnivorous ſpecies, and a few herbivorous quadrupeds. The faſciculi of the bladder are,

 in

in these instances, very thick, and generally contract the bladder when the animals die; by which it is supposed to have a smaller cavity than it really possesses during life. In the large graminivorous quadrupeds the muscular coat is generally weak, and hence the great distention that the bladder admits in these animals by inflation.

The bladder of the *echidna* and the *ornithorhynchus* terminates in a long neck or tube, which opens by a small foramen into the cloaca, as in the *tortoise*. The ureters and vasa deferentia open close to each other into this tube, before the bladder. The urine, therefore, must return, or regurgitate into the bladder, in the same manner as in the *tortoise*.

This fact is displayed in *fig.* 5. *Plate* VII. of the *Anatomy of Mammalia*. The letter *g* indicates the tube; *i*, *i*, are the orifices of the ureters before the neck of the bladder; *h* is the opening of the tube into the cloaca; *k* is the urinary bladder.

Renal Capsules.—The French academicians have stated, that these parts are deficient in the *Canada stag*; but this appears to have been a mistake, as no instance of their being wanting in mammalia is mentioned by other writers.

The relative situation of the capsules to the kidnies is nearly the same as in man. Sometimes they adhere to the kidnies, but, almost constantly, the right is attached to the vena cava.

The magnitude of these bodies differs very much according to the species, besides the variations depending upon age, which seem to be less than in man; and in the *guinea-pig* the capsules are even larger in the adult than the fœtus.

The relative bulk of the renal capsules to the kidnies is as great in the *monkey* as in *man*. Cuvier found it to be as 1 to 16 in the *varied ape* (*simia mona*), and as 1 to 12 in the *simia patas*. He found it to be $\frac{1}{3}$d in a *young howling baboon*.

In the *digitigrada*, Cuvier found the renal glands to be $\frac{1}{15}$th the size of the kidnies in the *tiger*, and in the *lynx* the $\frac{1}{2}$th.

They are the $\frac{1}{16}$th in the *hedge-hog*; the $\frac{1}{40}$th in the *kanguroo*; but the other *saltigrada* in general have the renal capsules large. In the *guinea-pig* they are in the proportion to the kidnies of 1 to 5: they appear to be largest in some of the *rat* genus, in which they equal the $\frac{1}{4}$th of the kidnies during the whole life of the animal.

The *opossum* has them only amounting to the $\frac{1}{43}$th of the size of the kidnies.

In the *horse* they are the $\frac{1}{30}$th.

Cuvier found the renal glands smaller in the *seal* than in any of the whole class. This animal has them only the $\frac{1}{13}$th part of the size of the kidnies.

The form of the renal capsules is very various, but corresponds, in some degree, with that of the kidnies; thus, when the latter are lobulated, the capsules are commonly so also.

In the *ruminating* and *solid-footed* quadrupeds, these parts resemble the renal capsules of the human subject, being flat and triangular.

In the *elephant* they are long, conic, and have their base turned backwards, and divided into two round lobes.

In the *paca* and the *porcupine*, they are elongated and cylindric. In these, and a great many mammalia, they resemble very exactly the kidnies. In the *coati* and the *daman*, they have a sinus like the kidnies.

In the *seal* and the *cetacea*, they are flat and triangular, but divided into many lobes, which coalesce in the centre. The lobules are more separate in the *cetacea* than in the *seal*.

The structure of the renal capsules is the most interesting part of their history, but it is involved in some obscurity. The vein which collects the blood of the capsule commonly forms a dilatation in the centre, which seems to have been sometimes mistaken for a peculiar cavity. Cuvier, however, has described three little pouches in the renal gland of the *elephant*, which he found to be covered with a very delicate, smooth, white membrane, that exhibited no orifice of any blood-vessels. This membrane appeared to be moistened with a clear mucous fluid. The bottom of one of the pouches had a little hole, which communicated with a fourth pouch, occupying the internal and posterior lobe of the capsule.

The appearance of two substances composing these glands is generally the same in mammalia as in man. The external or yellow portion of the capsule appears to correspond with the cortical substance of the kidnies. It is of a brighter colour generally in animals than man, and is often so thick as to occupy more than the half of the gland. Cuvier says, that it is composed of fibres or tubes situated in a perpendicular direction with respect to the internal substance. This last is soft, and of a deep brown colour.

In the *coati* three substances have been observed: one grey, which forms the nucleus. It is encompassed by a stripe or thin layer of a brown coloured substance; and external to these there is another thin layer of a bright yellow colour.

The same distinctions of substances exist in the *guinea-pig*, the *rat*, and some other *saltigrade* quadrupeds, or rather a division into five substances, according to J. T. Meckel, who reckons every shade of colour as a distinct substance composing this gland.

It is remarkable that in the *elephant*, which has the cortical and medullary substances of the kidnies indistinct, the two substances of the renal capsules are so likewise, which marks the great analogy and connection which exist between the kidnies and these bodies. This is still further shewn by the renal capsules having an uniform colour and substance in birds, which want the distinction of cortical and medullary substances in their kidnies.

Plate VII. of the *Anatomy of Mammalia*, and *fig.* 2, shews the relative magnitude and form of the renal capsule and kidney in the *common rat*: *a* is the capsule to the kidney. *Fig.* 3, of the same plate, exhibits a section of the renal capsule of the *rat*, in order to expose its different coloured substances: *a* is the central substance; *b*, the intermediate one; *c*, the cortical or external substance. *Fig.* 4. is a section of the renal capsule of the *ox*, to exhibit the cavity in the interior; *a*, the vein of the capsule; *b*, the cavity.

Glands for peculiar Excretions.—The most of these in mammalia are situated in the neighbourhood of the anus, or the external parts of generation, and secrete an odorous fluid, the natural use of which appears to be that of a defence against hostile animals. Nevertheless, many of the products of the excretory glands are employed by mankind as perfumes, or as medicines. There appears to be a very considerable resemblance amongst these excretions of quadrupeds, not only in their colour and consistence, but their effects upon the sensations of other animals. The fœtid matter furnished by the *pole cat*, and the *civet* or *musk*, are equally offensive to many individuals of the human species, and are probably universally disagreeable to beasts, except those that furnish them. All these odorous excretions likewise have a similar effect upon the nervous system, though differing in the degree of that effect.

In several quadrupeds, besides the small follicles which furnish the sebaceous matter of the prepuce, the odour of which is rather calculated to invite the opposite sex than to disgust other animals, there are two glands of considerable

size

fize on the fides of the penis, which are conglomerate and formed of different lobules united together, and producing a common excretory duct, which opens within the prepuce either of the penis or the clitoris. Thefe are very remarkable in the *rat* tribe, in whom they are large, flat, oval maffes of granular bodies.

Cuvier ranks the apparatus which furnifh the *caftor* amongft the *glands* of the prepuce, but they are much larger than would be neceffary for the fecretion of a fubftance to be ufed merely on the penis or clitoris. They are fituated under the integuments, between the pubis and the common aperture of the anus and prepuce, which exifts in the *beaver*. The number of thefe glands is apparently four; but there are two others involved in the lower facs. The two firft glands are conjoined together, and have, when thus united, the figure of a heart. Their internal coat is fmooth, thin, and of an afh colour, ftreaked with fome white lines. They contain a cavity internally, the parietes of which are thick, and formed into irregular folds or wrinkles, upon which a grey odorous fubftance is found to adhere. The afh colour of the external coat is derived from the inner one. Thefe two glands or pouches meafure acrofs about two inches in each direction. Where they are applied to each other, there is an aperture of communication between them of an inch in fize. Both glands difcharge their contents into the prepuce by a fingle orifice.

Underneath thefe facs there are two others, which are diftinct, and have the figure of a pear, fomewhat flattened. They are two inches and a half long, and about ten lines broad. There are placed, between their coats, a number of fmall glandular bodies, each of which contains a cavity, in which there is a fluid fecreted, that is ftrongly odorous, yellow, unctuous, and combuftible.

At the lower part of thefe pear-fhaped pouches the third pair is found. They are about fourteen lines in length, and fix in breadth. They are full of a fluid, which is yellower than the contents of the other glandular facs, and has alfo a different fmell. Thefe pouches have likewife little glandular bodies on their furface, fimilar to thofe of the fecond pouches. The membranes of the two lower pair of pouches are intimately united to each other. Both thefe pair open into the common aperture of the anus and prepuce. An ancient error prevailed with refpect to the *caftor*: many of the old anatomifts believed that it was taken from the tefticles. Some abfurd ftories alfo are told of it; fuch as the *beaver* preffing this fubftance out with its paw, and eating it to create an appetite, &c.

The apparatus for the fecretion of the *mufk* in the *mofchus mofchiferus*, is perfectly fimilar in ftructure to that above defcribed in the *beaver*. The pouch containing the mufk is fituated under the fkin of the abdomen. Its figure is oval, and it is hollowed below into a groove, in which the penis comes forth; its parietes are apparently membranous, but the inner furface prefents many irregular folds. The pouch has a fmall orifice, which is at the fore-part of the prepuce. The membrane furrounding it contains fome febaceous follicles. Between the pouch and the fkin of the belly there is a flefhy fubftance, apparently glandular. The mufk does not exift in the females, nor in the young males.

The *antilope gutturofa* has alfo been defcribed by Pallas as poffeffing a fimilar membranous pouch to the foregoing, but it does not contain the mufk. Moft of the *antilopes* have a pouch at the fide of each nipple, formed by a fold of the fkin, which contains an oily, odorous matter.

The *inguinal* glands of the *hare* appear to belong to the clafs of thofe of the prepuce. They are fmall oval bodies; their orifices are on two femi-lunar fpots of the fkin, which are deprived of hair, and are fituated one on each fide of the prepuce of the penis, or of the clitoris.

Thefe glands, which Cuvier has called the *anal*, are capable of furnifhing the moft powerful of the odorous excretions. They are thefe which afford the fubftance called *civet*, and thofe offenfive difcharges of others of the *weafel tribe*, the effluvium of which fcarcely any animal can bear to approach. Thefe anal glands are two pouches of a round or pear-fhape, the coats of which are glandular. The interior of the facs is lined apparently by the continuation of the fkin. They are the refervoirs of the odorous matter which is difcharged by a large opening from each fac, ufually into a cell or cavity formed by the integuments either around the anus, or in the neighbourhood of it. There are peculiar mufcles for compreffing thefe bags. Bartholinus figured four mufcles; the French academicians found but three; one which paffed acrofs from one pouch to the other, and two mufcles which arofe from the ifchium: each came to be joined to its antagonift at the middle of the two pouches, and was faftened to the pouch over which it went to make this conjunction. Cuvier merely reprefents fome fafciculi, which crofs between and furround the pouches. The odorous matter found in the *civet* bags is of a yellow colour, and refembles oil in compofition and confiftence. It has the fmell of mufk.

Thefe kinds of anal glands are met with in many of the *digitigrade* and *faltigrade* quadrupeds, and *feal* tribe; Blumenbach alfo afcribes them to the *opoffums*. There are three of thefe pouches in the *marmot*, but fmaller than the ufual fize: they open upon the edge of the anus, in the centre of three papillæ which project from the anus when the animal is excited.

In feveral quadrupeds, befides the ftink bags above defcribed, there are numerous fmall glands placed in the parietes of a large cell or cavity, which the integuments form either around the anus or in the neighbourhood of it, or, in rare inftances, in other parts of the body. Thefe frequently make a part of the excretory apparatus already defcribed, but they exift alfo without the anal facs, or ftink bags.

In the *civet*, this cavity is fituated between the genital organs and the anus: it opens by a longitudinal flit, the edges and infide of which are furnifhed with long hairs, that ftand inwards. The inner furface of the cavity is grooved in the tranfverfe direction.

The glandular cavity of the *ichneumon* furrounds the anus: the internal furface of it exhibits a great number of foramina along the margin. Thefe are the orifices of the follicular glands, which are each about the fize of a fmall pea, and lie upon the external part of the parietes of the cavity. They furnifh a thick, yellow, oily fluid. On the fuperior part of the circumference of the anal cavity there is a triple row of little conglomerate glands, which fecrete a whitifh matter, and have larger openings than the preceding glands. This cavity further receives the contents of the large glandular facs above defcribed. The anal cavity is compreffed by the ufual fphincter ani.

The *guinea-pig* has a fquare fhaped cavity below the anus. It is much puckered internally, and receives the product of two febaceous glands, which has a peculiar fmell.

The anal cavity in the *hyæna* has a narrow tranfverfe opening. This flit, fays Cuvier, leads firft to two lateral pouches, which are the central cavities of two glandular maffes compofed of lobes and lobules. Thefe two pouches communicate with two other glands, of which the lobules are more detached, and are even affembled round a central cavity, in which their excretory canals terminate, and which opens

into

into the firft pouches, as we have mentioned. There iffued from the left anterior pouch a yellow-brown matter, although that in the right held a grey matter, as well as the two pofterior pouches.

In the *badger* there is a tranfverfe fiffure between the anus and tail, which is the mouth of a cavity, the parietes of which are furnifhed with a number of fmall glands, that fecrete into it an unctuous fluid. It is this which the *badger* mixes with its urine, and with its tail throws againft its affailants.

The *pecari*, or *Mexican hog*, has a large gland or pouch fituated under the fkin of the back. It is compofed of lobes and lobules, the excretory ducts of which terminate in a fingle orifice in the back. This gland furnifhes an odorous matter, and muft be removed immediately after the animal is killed, it is faid, to prevent the flefh being tainted with the fmell.

There is a gland under the fkin of the temple in the *elephant*, which fecretes a vifcid fœtid matter, and fhould be ranked with thofe juft defcribed, though placed in a different fituation. It has an oval fhape, and is interiorly of a red, fungous ftructure. The fluid it fecretes paffes off by a canal, which defcends obliquely from behind forwards, and opens midway between the eye and the ear. The parietes of the canal refemble the fkin. The fluid of this gland is lefs abundant in females than males ; in the latter it is very copious when the animal is in heat. After death it becomes like wax.

In the *antilopes* and *deers* there is a cell near the inferior and internal part of the eye ; it is covered internally by a continuation of the fkin, and is lodged in an excavation of the fuperior maxillary bone. The parietes of this fac are provided with febaceous follicles which fecrete a thick, black, unctuous fubftance. Thefe facs open by a flit. They have no connection with the lacrymal gland, or the tears, as has been fuppofed, but feem to belong, whatever may be their ufe, to the clafs of glands at prefent under confideration.

The *fheep*, and feveral of the *cloven-hoofed* quadrupeds, have glandular cavities in the feet. Thefe are covered with hair internally, and have an excretory duct, which opens at the junction of the toes. When this is obftructed from wet weather, it occafions difeafe in the fheep.

In *fig.* 6. *Plate* VII. of the *Anatomy of Mammalia*, there is a view of the three different kinds of anal glands in the *ichneumon*. The letters *o* and *p* indicate the pyriform facs ; *q*, *q*, are the fmall glands which are upon the outfide of the two-thirds of the cavity that furrounds the anus: thefe furnifh the yellow unctuous fluid: *r*, *r*, are the conglomerate glands, fituated farther in upon the anal cavity, and which fecrete the whitifh matter. Some mufcular fafciculi are feen to pafs between and furround the anal glands *o* and *p*, by which their cavities are compreffed, and their contents forced into the common cavity that includes the anus, and receives the fecretions of the three orders of anal glands in this animal.

Organs employed in the Exercife of the Generative Functions.

Male Parts of Generation.—The *penis* is a more complex organ in many mammalia than in man. The peculiarities in its formation do not correfpond with a fimilarity of general ftructure in different animals, but are often perfectly fpecific, which feems to be defigned, in fome meafure, to prevent that promifcuous intercourfe which the blind appetites of fome animals might lead to.

The penis has its figure and magnitude in many cafes determined by the prefence of a bone in it. The *os penis*, by giving firmnefs and fhape to the member, renders the corpora cavernofa and the glans lefs neceffary : we accordingly find thefe parts diminifhed in thofe fpecies which poffefs a bone in the penis.

The os penis has been found in fome fpecies of *monkey*, but not in others : in moft of the *bat kind*, in the *bear*, the *badger*, the *racoon*, the *weafel*, the *ichneumon*, the *otter*, the *dog kind*, except the *hyæna*, the *cat kind*, the *hamfter*, and feveral of the genus *mus*, the *feal*, the true *whales* amongft the *cetacea*. It is denied to the *lamantins* by Cuvier, but Blumembach ftates that it exifts in the *walrus*. We poffefs a preparation of an os penis, which we have every reafon to fuppofe belonged to that animal. It is two feet long, thicker than the thigh-bone of a man, and as folid as ivory, except at the root and where the glans is attached, at which places it is fomewhat fpongy in its texture. Camper is faid to have a preparation of this bone, which had been fractured, as he fuppofed, during coition, for the penis of this animal is not expofed to injury unlefs when erected.

The os penis is grooved in the lower furface for holding the urethra in the *dog* kind. It ends in a hook in the *weafels*. It is curved into the form of an S in the *racoon*. In the *fquirrel*, it is fpirally twifted at the extremity. It is large, rounded, and terminates like a club in the *whales*.

This bone forms the principal part of the penis in the *bear*, *otter*, *racoon*, *badger*, *dog*, and *weafel*; but in the *bats*, *cat*, *ichneumon*, and moft of the *rat* kind, it is fmall, and ferves as an acceffory part to the corpora cavernofa.

The direction and attachment of the penis are different from what is obferved in man ; none bu the *quadrumana*, the *cheiroptera*, and the *armadillos*, have the penis pendulous, or at all times projecting from the body, and covered with a fkin proper to itfelf. In the other genera, the penis, when employed, is concealed more or lefs in a fheath formed by the fkin of the abdomen. In the *carnivorous* and the *large herbivorous quadrupeds*, the fheath of the penis opens forwards, near the umbilicus. When the penis is long in thefe cafes, it forms curves or folds upon itfelf in the fheath. According to Cuvier, the penis of the *elephant* makes, when retracted within the fheath, the curves of a double italic *S*.

Thofe quadrupeds which have the penis fixed in this manner under the belly, have two *adductor* mufcles to the fheath : they arife from below the aponeurofis and the flefh of the abdominal mufcles by feveral fafciculi, and having joined their fafciculi, are inferted into the fides of the anterior part of the fheath. Thefe draw the fheath forwards upon the belly. There are alfo two mufcles for *retracting* or opening the fheath, which come from the firft caudal vertebræ : they terminate in the *digitigrada*, either upon the external part of the corpora cavernofa, or upon the os penis ; and in the *ruminants* they are inferted upon the fheath of the penis. In the former thefe mufcles muft bring back the penis itfelf.

In the *folipeda*, the retractor mufcles accompany the inferior part of the urethra, and are loft in fafciculi that are diftributed upon the mufcle which covers this canal. In thefe animals Cuvier thinks the retractor mufcles reftrain the elongation of the penis when it is erected, and contribute to withdraw it into the fheath.

Thefe mufcles appear to be fupplied in the *elephant* by the levators of the penis, to be defcribed hereafter.

In fome of the *faltigrade* quadrupeds, the penis comes firft as far forwards as the anterior brim of the pubes, and then turns back, the orifice of the prepuce being near the anus. But in moft of the *faltigrada*, and in the *opoffums*, the

the penis goes backwards from the time that it comes out of the pelvis.

Several quadrupeds have been obferved to void their urine backwards. It was, therefore, thought by the ancient naturalifts, that they alfo copulated in the fame direction, but later obfervations have proved the contrary.

The figure of the penis is very various in mammmalia. It is determined either by the fize and fhape of the os penis, when that bone exifts, or by the form of the glans, and the thicknefs of the corpora cavernofa. The penis is flender in the *boar* and *cloven footed* quadrupeds. It is thick and long in the *folipeda*, the *elephant*, and the *lamantins*; thick and conic in the *porpoife* and *rhinoceros*; thick, conic, and flat in the *dolphin*; nearly cylindric in the *monkies* and *lemurs*; fhort in the *opoffum*, and moft of the *faltigrada*, the *digitigrada* and the *feal*; long and cylindric in the *hedge-hog*; twifted like a fcrew in the *fquirrel*, and bent like an S in the *racoon*.

The corpora cavernofa are commonly formed of two diftinct branches arifing from the ifchium, as in man, and afterwards joined apparently into one body; but the interior divifion of this part of the penis by a feptum is often lefs diftinct in mammalia, and fometimes is wanting. It is incomplete in fome fpecies of *monkey* and in the *lemurs*. It is totally wanting in the *bear* and the *badger*. It is alfo abfent in moft of the *many-hoofed* quadrupeds: the *elephant* and *rhinoceros*, however, have it. The *folid* and *cloven-hoofed* quadrupeds and the *cetacea* want a feptum between the corpora cavernofa. In thefe cafes the ligamentous laminæ arife from within the circumference of the united cavernous bodies, and meet in the centre.

The corpora cavernofa in the *opoffums* arife by two long fmall branches, which are only connected to the ifchium by means of the mufcles called the *erectores penis*. They unite without any feptum, and then branch into two, in order to form the bifid penis of thefe animals.

In the *kanguroo* there are at firft four corpora cavernofa, which unite to form a conical-fhaped penis. The urethra runs in their centre. They are compreffed by a mufcular inveftment. The director mufcles of the penis, or *ifchio-cavernofi*, ferve to connect two of the roots of the corpora cavernofa to the ifchium. The two other roots are enveloped by a mufcle which takes the place of the *accelerator urinæ*, or *bulbo-cavernofus*.

The interior of the corpora cavernofa, during the erection of the penis, has been defcribed by Cuvier in the *elephant*, and other large quadrupeds, as being compofed of the branches of the veins anaftomofing frequently with each other, fo as to form a clofe and inextricable plexus, refembling cells. We have difcovered the fpongy part of the urethra to be compofed of ramified veffels in man and quadrupeds, but we have not been able to fatisfy ourfelves, that the corpora cavernofa are made in the fame way.

The firft membranous portion of the urethra is in proportion to the reft of the canal, commonly longer in mammalia than in man. The *monkey* kind have it fhort and almoft entirely enveloped in the proftate gland: it is particularly long in the *hedge-hog*, *opoffum*, *kanguroo*, *civet*, and the *cat kind*, in moft of which it is more than half the entire length of the urethra.

The part called *verumontanum*, on which the feminal ducts terminate, contains in the *elephant* and fome others a deep cell. There are frequently other folds of the membrane which form longitudinal eminences befides the verumontanum; and in the *marmots* there are twelve prominent folds, which go off on each fide of the longitudinal projection.

The fecond portion of the urethra in the *cloven-footed* quadrupeds and the *hog*, has a cul-de-fac at its origin, or at that part correfponding to the bulb. This cæcum receives the femen and the fluid of Cowper's glands. In the *fquirrel* and *marmot*, the dilatation in the bulb merely receives the ducts of Cowper's glands, and is continued into a narrow canal, which opens into the urethra as far forward as the middle penis.

The fpongy texture of the urethra in the *opoffum* and *phafcolomys*, all the *marfupial* quadrupeds, and in the *water rat*, arifes in two branches diftinct from each other, and inclofed in their proper mufcle. There is alfo fome appearance of two branches to the bulb in the *camel*.

There is a large corpus fpongiofum in the *large herbivorous* quadrupeds, and a fmall one in the *carnivorous*, more particularly the *otter*, *bear*, &c. It is fcarcely apparent at the part of the urethra which runs along the os penis.

The corpus fpongiofum, as already mentioned, is compofed of an intricate plexus of veins. This is very evident where it forms the glans penis of the *horfe*, in which the veffels are very plainly feen. They likewife communicate with a vaft mafs of veins upon the dorfum of the penis in this animal, which increafe the bulk of this member very much when they are diftended with blood during erection.

The *glans penis* varies very much in mammalia, both with refpect to form and the nature of its integuments: even the animals of the fame genus do not agree in thefe refpects.

The glans of fome *monkies*, as thofe with prehenfile tails, forms a large tubercle, like the head of a mufhroom. In the *baboons* and *apes* it is oval, and fplit into two tubercles at the end where the urethra opens. In the *Chinefe ape* there are feveral tubercles, which produce a fingularly formed glans.

In the *ring-tailed maucaco*, (*lemur catta*), the glans is thick behind, but merely covers the os penis at the end. It is covered with horny fpines, which have their points turned backwards.

The *vefpertilio ferotinus* has two tubercles or bulbs upon the fides of the glans. The inferior furface forms a fort of edge, and is clothed with ftiff hair-like proceffes.

The *hedge-hog* has a piece of cartilage upon the top of the glans.

In the *racoon* the os penis has two tubercles at the end, which give the fame form to the glans.

In the *cat kind* the glans is conic. The point is made by the os penis which projects beyond the orifice of the urethra. In moft of this genus, the glans is armed with reflected fharp hard fpines. Cuvier fays they are few in the *lion*, and moft numerous in the *Mexican cat* (*felis pardalis*).

In all the long-bodied or *vermiform* quadrupeds, and in the *badger*, *bear*, and *racoon*, the glans takes the form of the os penis.

In the *dog* genus, the back of the glans forms a very remarkable bulb of the fhape of a chefnut, the bafe of which is pofterior. It is compofed of venous cells, which are only diftended when the penis is erected, and is compreffed behind the glans, there being two large trunks of veins running backwards, which carry off the blood from the bulb. It is by means of this apparatus that the penis of the *dog* is retained in the female organs, feemingly againft his will. The fphincter of the vagina fuffers a fpafmodic contraction, and compreffes the veins behind the bulb, and thus maintains it in a ftate of diftention. To obviate the effects of compreffion upon the urethra, that part of the canal is lodged in a groove of the os penis. The femen of the dog paffes in jets for fome time after he has turned off, as it has been fuppofed, in confequence of his wanting veficulæ feminales.

In the *opoffum kind*, the glans is neceffarily bifid, as the corpora

corpora cavernosa are so which it covers. The two branches of the glans penis are short, and are directed outwards in the *Virginian opossum*, but in the *Mexican opossum* and the *marmose* (*didelphis murina*), they are long, and grooved upon the inner side so as to form a perfect canal when they are applied to each other. This canal forms a continuation to the urethra.

The *phascolomys* has the glans penis forming four lobes at the end: the urethra opens in the centre.

The *kanguroo* has a long, taper, sharp-pointed glans, formed chiefly by the corpora cavernosa. The urethra emerges near the end of the penis from the united corpora cavernosa, acquires the spongy coat, and ends in a kind of sac, which has its orifice under the point of the glans.

The formation of the glans, as well as all the other parts of generation, is singular in the *saltigrade* mammalia.

In the *guinea pig* the orifice of the urethra is under a flat os penis; and behind and below it there is a cell, in the bottom of which are attached by their base two long hooks of a horny substance: the glans and surface of this pouch are covered with hard scales. When the penis is erected, the pouch is turned inside out, carrying with it the horny hooks, and forming a projection preceding considerably the orifice of the urethra. The glans is drawn in again by two fasciculi of muscles, which arise from the two crura of the corpora cavernosa, and pass under the bulb of the urethra, to which they are also attached. They furnish two tendons that run along the under part of the penis, and are inserted on the outside of the sac or pouch already mentioned.

The glans of the *agouti* is still more curious. It has a pouch similar to that above described, and horny scales upon the surface; and in addition to these, two horny plates upon its sides, which adhere to the glans by one edge, and have the other edge notched like a saw.

The *alpine marmot* has the glans conical, and ending in a fine point, which is formed by the os penis. The urethra opens on the right side of this point, and on the left there is a small deep cell.

In the *common rat* there is the appearance of a second prepuce at the end of the glans, when the penis is not erected: this is produced by the edge of a cavity that encloses the os penis. This bone comes forth by pressure, and exhibits upon each side two little cartilaginous appendices, in the form of wings. The urethra opens under this extremity, and has upon the inferior edge a valve formed like a gutter.

The other species of the genus *mus* have the glans constructed upon the same plan: its surface is armed with papillæ, or with fine hairs, as in the *hamster*.

The *dormice* have a conical and sharp-pointed glans: the urethra opens at the end. There are two cells at its base.

In the *elephant* the glans is at first cylindric, as the rest of the penis: the lips of the orifice of the urethra open to each side.

The glans of the *rhinoceros* has a singular conformation: it is dilated at the end like the mouth of a bell, in the centre of which there arises a peduncle, shaped like a mushroom, with a broad, flat, oval surface, upon the inferior edge of which the urethra opens.

In the *boar*, and many of the *ruminating* quadrupeds, the glans is taper and pointed, and has a fissure upon its side, in which the urethra terminates. The *ram* has it oval, with a transverse fissure at the end. The orifice of the urethra is at the left side of the slit, and near it there is a long slender process of a tendinous substance. The glans of the *camels*, which is long and taper, ends in a hard appendix, which is bent transversely from left to right, by which its edge is turned forwards, and the point to one side.

The *solipeda* have a cylindric glans, which contains a cavity or large cell, that is found to have a quantity of a brown oily substance, for defending the glans from the irritation of the urine, and lubricating the end of the penis. This secretion appears to be similar to that of the glands surrounding the glans in other animals, but is in greater quantity in the *horse* than in them. There is a second cell, according to Mr. Clarke's description, which is smaller than the first, and separated from it by a membranous partition: it nearly surrounds the urethra, which opens at the end of a pyramidal eminence of the glans.

The *northern lamantin* has the glans and all the penis similar to that of the *horse*, according to Cuvier, except the existence of a bone; although he denies that the *lamantins* have an os penis in another place.

The glans of the *porpoise* is broad at the base, diminishes suddenly, and ends in a slender point, at which place the urethra opens. In the *dolphin* it is broad, conic, and flat. The canal of the urethra runs distinctly along its under surface, and opens at its extremity.

The *muscles of the penis* are commonly more numerous in mammalia than the human subject.

The *erectores penis*, or, as they are more properly called by Cuvier, *ischio-cavernosi*, do not materially differ from those of man, except in the *marsupial* quadrupeds: they, however, vary with respect to strength. Cuvier has observed them to be particularly thick in the *lion*; they are weak in the *horse*; and are divided in the *elephant* into four distinct slips. In the *opossum* tribe these muscles form an oval mass around the roots of the corpora cavernosa, which in these animals are not attached immediately to the bones of the pelvis. The bulbous enlargement of the muscles is made of several layers of concentric fibres, which surround and compress the long roots of the cavernous bodies. The origin of the muscles is from the ischium by tendon.

The *accelerator urinæ* (*bulbo-cavernosus* of Cuvier) varies generally in thickness, in proportion to the difficulty of ejecting the urine and semen, as depending upon the structure of the urethra. In the *horse* this muscle is not confined to the bulb, but forms a layer of transverse fibres, which cover the urethra the whole way to the glans.

The *bulbo-cavernosus* consists of two portions in the *rats*, all the *marsupial* animals, the *elephant*, and the *camel*. In the two first tribes, these cover the branches of the bulb, and also extend to the corpora cavernosa and pelvis: they are, therefore, not strictly muscles of the urethra in these animals. The bulb of the urethra is single in the *elephant* and *camel*, notwithstanding its muscle is double.

The *bulbo-cavernosus*, in some instances, has no effect upon the urethra; the contents of that canal being expelled by a strong layer of muscle that surrounds the first portion of the urethra. Thus in the *marmot* and *squirrel*, the *bulbo-cavernosus* compresses the cul-de-sac of the urethra, into which the fluid of Cowper's glands is poured; and in the *ichneumon*, this muscle constitutes rather a thin layer, which surrounds both the glandulæ Cowperi, and performs no other office than that of expressing the fluid from these bodies.

Many mammalia have a muscle for raising and sustaining the weight of the penis. It has been described in the *baboons* as composed of two thick fleshy portions, arising from the arch of the pubis: its tendon is extended along the back of the penis; and towards the extremity it becomes incorporated with the corpora cavernosa. In the *hare*, *marmot*, *cavy*, &c. it is twisted backwards, in order to give the

the proper direction to the penis during coition. This muscle is remarkably large in the *elephant:* it is attached to the pubis by two distinct fleshy portions, and partly to the roots of the corpora cavernosa; they proceed upon the dorsum of the penis, and their tendons uniting into one, it runs in a strong ligamentous sheath to the end of the penis. There is no muscle of this kind in the *horse*, which is the reason that manual assistance is given to that animal in coition.

In the *bear*, *racoon*, the *dog*, &c. there is a small muscle arising from each of the roots of the corpora cavernosa, and conjoined by a middle tendon, which is inserted into the back of the penis under the pubis. This muscle compresses the dorsal vein in the *simia callitrix*, in which animal the middle tendon is not found.

In the *bisulca* there is a muscle on each side, which arises from the tuberosity of the ischium, and ascends obliquely inwards, and is inserted into the bulbous part of the urethra. It brings the bulb downwards and forwards, and contributes as Cuvier thinks, to elongate the penis.

The *arteries* and *veins* of the *penis* are similar in mammalia and man, except where there are plexuses formed, as already described.

The *nerves* of this member are stated by Cuvier to be very large. He discovered that they formed in the *elephant* a net-work upon the veins of the back of the penis, in the same manner as they have been observed to do on arteries.

The *ornithorhynchus* and *echidna* seem to form a link between mammalia, birds, and reptiles, with respect to their anatomy. Their alliance with the two last mentioned classes is decidedly shewn in the structure of the organs of generation.

These two animals have a spur upon the heel of the male, for the purpose of holding the female during copulation. The spur contains two small bones or phalanges: one is very short, flattened, and joined to the astragalus; the other is long and pointed, and serves as the mould of the horny spur, in a manner similar to the spurs of *cocks*. There is no other instance in mammalia of the male possessing any prehensile organ, exclusively designed to be employed during coition.

The *penis* of the *ornithorhynchus* and *echidna* is attached to the margin of the cloaca, as in birds and reptiles. It is covered with the continuation of the lining of the cloaca, and is composed interiorly of a plexus of blood-vessels, which become more close and intricate towards the extremity of the penis. This plexus makes up the whole bulk of the organ: it is only surrounded by a fibrous sheath, and the integuments already mentioned. There is no urethra in the penis of these animals; that canal terminating short of it, as will be presently shewn. The penis is nearly cylindric in its form, and short: it terminates in the *echidna*, in four eminences or processes, which are hollowed out in the centre, like cups. These correspond to the glans of other mammalia, and no doubt are endowed with a greater sensibility than the rest of the organ. Cuvier thinks the concavities of these eminences or papillæ are unfolded during erection. In the *ornithorhynchus paradoxus* the penis terminates in two papillæ, which have denticulated edges; and the surface of the penis is more rough and wrinkled than in the *echidna*.

The erection of the penis in these animals is accomplished by the distension of the vascular structure of the interior part of the organ, and by the contraction of the sphincter muscle of the cloaca. The penis is retracted by a particular muscle, which arises from the *sphincter* ani, and passes along the under surface of the penis, and is attached to its extremity. When retracted, it is received into a sac.

The urethra in these animals is simply a muscular canal, continued from the bladder to the under part of the cloaca, into which there is a small round hole, not quite at the extremity of the urethra; that canal terminating in a sort of cul-de-sac. The *vasa deferentia* open into this canal at the neck of the bladder. There is a layer of muscular fibres arranged obliquely, and meeting upon a middle line, like the constrictors of the pharynx, which encompasses the rectum and urethra together, and assists the muscular coat of the urethra in ejecting the semen and urine into the cloaca.

There are two small oval bodies, containing each a cavity, from which there departs a long excretory duct to the side of the cloaca when it opens. These *glands* appear to correspond to *Cowper's*.

The margin of the anus is furnished with a row of well marked *follicular glands*, similar to those described in *birds*.

The *testicles* are originally formed and situated in the lumbar region, next the kidnies, in all mammalia, and in man. In some of the former they remain in that situation during life, as instances of which we may mention the *ornithorhynchus*, the *echidna*, the *elephant*, the *daman*, the *nectopodous* or *seal* tribe, and the *cetacea*. These animals are consequently without a *scrotum* and *cremaster* muscles. The testicles are retained in their proper situation by peritoneum, in the same manner as the other abdominal muscles.

In a number of mammalia the *testicles* leave the loins, and are placed behind the opening of the abdominal ring, which is so large that these bodies can easily pass backwards and forwards through it, as occasion may require. The testicles have been observed to come out of the abdomen in this manner, particularly in the season for pairing, in the *bat*, *mole*, *shrew*, *hedge-hog*; in many of the *murine* tribe, as the common *rats*, *hamster*, *musk rat*; and in the *guinea-pig*, *porcupine*, *beaver*, *squirrel*, &c. In these animals the passage from the abdominal cavity to the tunica vaginalis is permanently open, and of great width.

The situation of the testicles is subject to vary in mammalia, when they are on the outside of the abdomen: thus they are suspended in a single bag or *scrotum*, behind the penis, in the *quadrumana*, the *digitigrada*, and many *plantigrada*. The *scrotum* is long, and suspended before the pelvis, and wants the *septum scroti*, in the *opossum* kind, the *kanguroo*, and *phascolomys*. The scrotum forms two distinct pendulous bags in the *hare*, *jerboa*, and most of the *cloven-footed* and in the *solid-hoofed* quadrupeds.

The figure of the testicles varies but in a few species from that observed in man. The *racoon*, *badger*, and *elephant*, have these glands of a globular form; and in the *nectopodous* and *cetaceous* tribes they are very much elongated.

The magnitude of the testicles is remarkably great in the *mole* and in the *saltigrade* quadrupeds, being even more considerable than that of the kidnies. In these, and in several other quadrupeds, the testicles become much larger at the season for procreation than they are at other periods.

The interior structure of the testes in man and *mammalia* is essentially the same. In most of the latter that have been examined, the *tubuli seminiferi* are in separate packets. In the greater number of the *saltigrada*, however, they are distinct from each other, and are very large. In the *ram*, the seminiferous tubes have been observed to be very distinct, and to have a serpentine or undulating course.

In several quadrupeds the real structure is clearly seen of the part called *corpus Highmori*. It is not a canal, nor does it it poffefs the ftructure defcribed by the older anatomifts; but is formed by the *tunica albuginea*, and paffes like a ligamentous ftripe or band along the tefticle, from which the laminæ or fibres that pafs downwards and feparate the seminiferous tubes of this gland arife. The principal arteries alfo of the tefticle are fuftained by this band.

The *epididymis* is very large in the *faltigrada* and the *echidna*; in moft of the former and in the *opoffum* tribe, it is not attached along the back of the tefticle, but is free, except at its origin.

The *vafa deferentia* have thinner parietes in thofe animals that retain the tefticles always in the abdomen, than in thofe inftances where they occafionally pafs into the fcrotum, or are always outfide the belly. They likewife proceed lefs directly to their termination in the urinary paffage; thus in the *elephant*, the *echidna*, the *daman*, and the *ant-eaters*, their courfe is very tortuous.

Very frequently the vafa deferentia become thicker, or are dilated before their termination. In the *otter* and *feal*, and in many of the *faltigrada*, as the *hare*, *cavy*, *beaver*, *hamfter*, and the *rat* tribe, thefe tubes acquire ftrength, and in the *faltigrada* juft mentioned, they are alfo wider as they pafs behind the bladder. In the *bear*, *badger*, and *racoon*, their coats are much thicker, and the two vafa deferentia touch each other, and appear as one canal, but do not really communicate. In the *elephant*, the *vafa deferentia*, where they pafs befide the veficulæ feminales, are dilated into globular facs, the furfaces of which adhere to each other. The vafa deferentia of the *horfe* are dilated to about the fize of the human thumb, for five or fix inches before their termination. This dilated part confifts of a number of cells, refembling thofe of the corpora cavernofa of the penis, which, when preffed, pour out a milky fluid. Mr. Bracy Clarke ftates, that the vafa deferentia run in the centre of thefe cells, with each of which they communicate by fmall pores. See ANATOMY *of the Horfe* in this dictionary.

There is a fimilar dilatation in the vafa deferentia of the *ram*, in which there are tranfverfe laminæ that form a mefh work.

The vafa deferentia are ftill more dilated in the *buffalo* than in the *ram* or *horfe*. They are not divided into cells or mefhes, but there are little cavities that fecrete a fluid. They are dilated alfo in the other *ruminants*. The defign of this ftructure feems to be to add a peculiar fecretion to the femen before it paffes into the urethra.

Cuvier mentions a curious variety in the courfe of the vas deferens, from the fcrotum into the pelvis, in the *Chinefe monkey* (*fimia finenfis.*) In this animal, that canal does not pafs through the abdominal ring, but through the crural arch, and afcends between the internal and external oblique mufcles to join the *cremafter* mufcle near the ring.

In a very few inftances, the two *vafa deferentia* have but one opening into the urethra. In the *badger* they terminate in a cul-de-fac, which contains the verumontanum.

The *veficulæ feminales* are wanting in the following mammalia, *viz.* in all the *plantigrada*, except the *coatis* and the *hedge hogs*; in all the *digitigrada*; the genus *didelphis*, the *ornithorhynchus*, and *echidna*; the *cloven-hoofed* quadrupeds; in the *feal* tribe, and the *cetacea*.

The veficulæ feminales are nearly fimilar in the *monkey* and the human fubject.

In the *vampyre bat* they are large, and form three convolutions. The firft third of their canal is without cells or reticulation, and opens into a round body which is fituated upon the neck of the bladder, and has the interior divided by membranous laminæ into a great number of cells, which are found filled with a feminal fluid. This cellular refervoir alfo receives the vafa deferentia, and has two fmall openings into the urethra. The remainder of the tube of the veficulæ is cellular, as ufual.

In the *common bats* they are round white facs, with a fimple cavity: their coats are glandu'ar.

In the *hedge-hog*, the veficulæ appear as bundles of convoluted tubes; ufually four in number on each fide of that part of the urethra which contains the verumontanum: each of thefe bundles of tubes ends in one tube, which either opens feparately, or conjointly, with that of fome of the other bundles or parcels in the verumontanum. Thefe different bundles or veficulæ, when taken together, exceed in bulk that of the two tefticles of the *hedge-hog*.

The veficulæ of the *guinea-pig* are two long conical tubes, becoming much thinner towards the extremity: they have fome dilatations in their fecond half.

In the *agouti* they are alfo large tubes, and have fome fmaller branches.

In the *marmot of the alps* the veficulæ are fmall; their cavity is very intricate, and their coats glandular. They are fimilarly formed in the *bobac*, according to Pallas; but he defcribes the veficulæ of the *fuflic* (*mus citellus*, Pall.) as being compofed of a little puckered tube, which adheres to a mafs formed of fmaller tubes.

The *rat* tribe have the veficulæ feminales enormoufly large, particularly during the feafon of procreation. They project even beyond the pelvis. They are membranous bladders, conical in their figure, but twifted, and having their cavity rendered unequal by dilatations on their convex edge.

The *common hare* and *rabbit* have one fac in place of the veficulæ feminales. This is of a confiderable fize, and of a rectangular figure. The external corners are fometimes extended from the body of the fac, and reprefent the two veficulæ. The coats of the fac are membranous, except in the two-thirds of their fuperior fide, which are very thick and glandular, and fimilar to the fubftance of the proftate gland. The opening of this fac into the urethra is fingle. In the *lepus pufillus*, *ogotona*, and *alpinus* of Pallas, the veficulæ are two, and feparate, as in other animals.

In the *fquirrel* the veficulæ are fmall, wrinkled, convoluted tubes, with glandular coats.

In the *daman*, according to Cuvier, the veficulæ are very large and ramified.

The *rhinoceros* has the veficulæ making two tolerably large bladders: their cavity is irregular, from a number of dilatations on their external fide.

In the *boar*, the veficulæ are remarkably large, and compofed of lobes and lobules which contain cells interiorly, that communicate with each other. All the lobes pour out their contents through a common canal, which opens in the verumontanum.

The veficulæ feminales of the *elephant* are very large. Their figure is nearly oval, there being a contraction which feparates the top from the reft of the fac. The internal furface of the top and middle portions is provided with irregular columns or projections of the internal membrane of the veficulæ, which is much thicker towards the top or end of the facs than elfewhere. The veficulæ are furnifhed with a mufcle for expreffing their contents in this animal. It arifes from the neck, and extends as far as the middle part of the fac, its fibres fpreading as they proceed.

In the *horfe* and *afs*, the veficulæ are two long membranous bladders, like portions of an inteftine. They are wider at the end or fundus than the neck, which ends in a large excretory canal, that opens into the urethra by a common orifice with the vas deferens.

Some anatomifts have fuppofed that the proftate glands of the *cloven-footed quadrupeds* were the veficulæ feminales. The only part correfponding to the veficulæ in thefe animals, is a ligamentous bridge extending between the ends of the two vafa deferentia, and ferving to unite the bafes of the proftate glands. This ligament has been obferved in the *ram*, the *axis*, &c. But in the *fallow deer*, the place of the ligament is taken by two little capfules, which appear to be glandular, and their cavity to lead to the verumontanum, by the fame orifices with the vafa deferentia.

The parts fupplying the place of the *proftate gland*, are very different in their ftructure and number in different genera of mammalia. The termination of the proftatic duct or ducts alfo is various; they are found to open into the origin of the urethra, or throughout its extent, or towards the end of that canal. In fome of the *faltigrada*, in the *hedge-hog*, and in the *mole*, the parts correfponding to the *proftate* glands are defcribed by Cuvier as a diftinct feries of glands, which he, calls *veficules acceffoires*, on account of their having a ftructure fimilar to that of the veficulæ feminales, and becaufe they are obferved to enlarge during the feafon of procreation; but their being found in thofe animals which have not proftate glands of the ufual ftructure, and yet are remarkable for the magnitude of all the genital organs, would lead us to receive thefe veficular bodies as analogous to the proftate glands of other mammalia; we fhall therefore defcribe them as fuch in the proper order of the animals to which they belong.

The proftate gland in the *monkey* tribe is fimilar to that of the human fubject, except that it is fomewhat different in fhape. In the *mandril*, there are fome additional lobes to the proftate.

This gland in the *lemurs* has two offsets, which furround the excretory ducts of the veficulæ feminales. There are two in the *lemur tarfius*, which form diftinct tubercles before the veficulæ upon the fides of the urethra.

In the *vampyre bat*, the proftate is fimple, as in *man* and the *monkey*; but in the *common bats*, this gland confifts of a great number of lobules.

In the *bear*, the fubftance of the proftate appears to be confounded with the enlargement of the united vafa deferentia.

In moft of the *vermiform quadrupeds*, as they are called, fuch as the *weafel*, and in the *otter*, this gland appears like a layer upon the urethra. In the *ichneumon*, however, it is of a confiderable fize.

The *hedge-hog*, as before obferved, is one of the animals which has the proftate formed of a number of tubes. It has four bundles of thefe tubes, which are fmaller than thofe of the veficulæ feminales, and arranged parallel to each other, branching into ftill fmaller tubes

In the *mole*, this gland is alfo compofed of a mafs of tubes, ramified and convoluted upon each other. During the feafon for copulation, thefe tubes enlarge fo much, that they form a bundle, according to Cuvier, of a greater bulk than the urinary bladder.

In the *agouti* and *guinea-pig*, the proftate is formed of ramified and convoluted tubes. The former animal has thefe tubes ending in veficular proceffes.

The *rat tribe* and *lagomys* have alfo tubular proftates, and in addition to them have two glands, which are attached to the inner furface of the veficulæ feminales. They are compofed chiefly of one tube.

In the other *faltigrada*, the proftate gland is a fingle mafs, often divided pofteriorly into two lobes.

The proftate is fingle alfo in the *digitigrade* and *pedimanous* quadrupeds, as far as they have been examined.

In the *boar*, it is divided into lobes, and there is befides a layer of glandular fubftance, which furrounds the origin of the urethra.

The *elephant* has four proftate glands, which are fmall in proportion to the other parts of generation. They are of different fizes with refpect to each other. Some mufcular fibres are fpread over them which ferve to prefs out their fecretion. Each gland contains one principal cavity, with which fmaller cavities communicate: thefe laft fill the indiftinct lobes that are feen upon the glands externally. The chief cavity of each gland produces a duct, and thefe ducts terminate feparately at the fide of the verumontanum.

The *cloven-hoofed quadrupeds* have two proftates poffeffing the fame cellular ftructure as thofe of the *elephant*. The lobes are ftill more diftinct in the *ram* and *bull*.

There are four proftate glands in the *folid-hoofed* order. The two firft are paler, and have larger cavities than the others. They are covered with mufcular and tendinous fibres, which are extended to them from the veficulæ feminales and the bladder. The ducts from this pair of glands have many orifices in the urethra. The fecond pair of proftates are fituated towards the end of the membranous portion of the urethra. They are enclofed by mufcular and tendinous fibres. They have each twelve ducts, which open by as many orifices, arranged in a row in the urethra.

The *feal* tribe have the fame fort of proftate as that defcribed in the *otter*.

The *cetacea* have the proftate in a fingle mafs, and cellular internally, as in the human fubject, &c. The mufcle which furrounds it is very ftrong.

The *glands* called *Cowper's* are much larger, and confequently of more importance, generally, in mammalia than in man. They are wanting in fome genera, and prefent in others clofely allied to them. Thefe glands, therefore, as well as the veficulæ feminales and proftate, are not fubject to any general rule, or regulated, either as to their exiftence or magnitude, by the anatomical rank or character of the animals. Cowper's glands are not found in the *bear*, *racoon*, *hedge-hog*, *mole*; and are wanting, according to Cuvier, in all the *plantigrade*, except the *ichneumon*; in the *dog* genus; the *vermiform* quadrupeds; in the *hare* and *rabbit*; in many other of the *cloven hoofed* tribe; the *horfe* and *afs*; in the *feal*, and in the *whale* tribe.

Thefe glands become larger than in man, in proportion to the fize of the animals, in the *quadrumanous* and *chieropterous* mammalia.

They are alfo very large in the *civet* and *cat*; of a ftill greater fize in the *hyæna*. The mufcle that furrounds them in thefe animals is very thick.

In the *ichneumon*, the glands of Cowper are very remarkable. They are covered by a layer of mufcle, and each of them is befides inclofed in a mufculo-tendinous fac. Each gland confifts of a number of veficles, which communicate with each other, and furnifh a fingle excretory duct, that runs along the lower part of the urethra, and terminates by a diftinct opening in the bottom of the cell at the end of the penis, in which alfo the urethra itfelf finifhes. Thefe glands have an egg fhape, and are of great fize.

In the *marfupial* animals there are feveral Cowper's glands, and it is remarkable that they are never wanting in this tribe, although the other glands are in fome of the genera. The *Mexican* and *Surinam opoffums* (*didelphis cayopollin*, *d. orientalis*), the *phafcolomys*, and the *great kanguroo*, have fix Cowper's glands. The *kanguroo rat*, and *Virginian opoffum*, have four. In all thefe animals they are compofed of tubes which lie in the longitudinal direction of the glands.

In the *echidna*, there is a gland analogous to Cowper's

on

on each side of the cloaca. They are small oval bodies, containing a narrow cavity internally, from which a long duct proceeds. It passes through the constrictor muscle of the cloaca, and goes to join the little canal by which the urethra opens into the cloaca. These glands are surrounded by a very strong muscle, which urges their fluid out when occasion requires.

The *squirrel* has two large vesicles, cone-shaped, and coiled upon themselves. The top of these has thick glandular coats, and is divided, interiorly, into a number of little cells. The glands both open into a cavity in the bulb of the urethra, which is continued into a canal that extends to the bend of the penis when it opens into the urethra. The *alpine marmot*, and the *bobac*, resemble the *squirrel* in the structure of their Cowper's glands.

The *boar* has these glands in the form of long flattened cylinders. Their substance has a firm texture; it contains small cells, which open into larger ones, and they again join to form a common cavity, from whence a canal proceeds to open upon the side of the urethra, within the bulb. Their muscle has oblique fibres. The glands of Cowper are very large in the *elephant*, in proportion to the prostates, as before-mentioned. They have an irregular form, as if lobulated. There is a distinction of two portions to be observed: the first is situated next the bulb of the urethra, and is small: it is divided internally into cells, which are of different sizes, the smallest being external, and the larger opening at last into a common cavity in the centre of this part of the gland, which furnishes a duct to join the principal duct that comes from the rest of the gland. The larger portion of the gland contains two central cavities, which each give origin to a duct. These two ducts concur to form the principal duct above-mentioned. It proceeds, for some way, in the parietes of the urethra, before it opens into the canal. The glands of Cowper have a very thick muscle in this animal; the fibres of which are collected upon a tendon that is attached to each side of the corpora cavernosa.

In the *camel*, the glands of Cowper resemble, in figure and size, pigeon's eggs; their texture is close; and their single excretory duct terminates within the bulb of the urethra. The same structure is observed in the other *cloven-hoofed* quadrupeds which possess these glands. The muscle for compressing them in this tribe is very strong.

The figures which illustrate the *male organs* are found in *Plates* VII. and VIII. of the *Anatomy of Mammalia*.

Fig. 7, in *Plate* VII., exhibits the os penis of the *dog*: *a* points out the groove in which the urethra is inclosed for some distance. *Fig.* 8, of the same plate, is a view of the os penis in the squirrel. *Fig.* 1, in *Plate* VIII., shews a transverse section of the penis of the *kanguroo*, in which the canal of the urethra, as indicated by *a*, is seen in the middle of the united corpora cavernosa. *Fig.* 2, of the same plate, is a similar section of the *kanguroo's* penis nearer the end, in which the urethra is seen to be gaining the side of the penis. *Fig.* 3, of the same plate, is a longitudinal section of the penis of the *dog*, after the cellular structure had been injected with quicksilver, dried, and emptied: *a*, the glans penis; *b* is the bulb behind it; *c*, the trunks of the veins going backwards from the bulb, which are compressed by the sphincter vaginæ of the female during the coitus. *Fig.* 4. is a view of the penis of the *guinea-pig*: *a* shews the glans, armed with horny scales; *b* are the hooks that come forth from the pouch in which the urethra terminates; *e*, *c*, the muscular fasciculi that retract the pouch. *Fig.* 5. is the penis of the *cat*: *a*, the glans furnished with reflected horny spines. *Fig.* 6, of this plate, represents the male organs of the *kanguroo*; *s* is the urinary bladder; *q*, the ureters; *r*, the vasa deferentia; *p*, the first part of the urethra, which is inclosed in the prostate gland; *a*, *b*, and *c*, are the three glands of Cowper, on each side; *d*, *d*, are the two branches of the bulb of the urethra, each enveloped in its proper muscle; *e*, *e*, are the two branches of the corpora cavernosa, inclosed by their muscles; that on the right side is laid open longitudinally to expose its interior, and the section of the muscle; *g* is a portion of the sphincter; and *k* is a portion of the levator ani muscle; *i*, the rectum; *l*, the anus; *o* is the pointed glans of the penis. *Fig.* 6, of *Plate* VII. exhibits the male parts of the *ichneumon*: *a* is the bladder; *b b*, the ureters; *c*, *c*, their orifices in the neck of the bladder; *d d*, are the vasa deferentia; *e*, *e*, their orifices in the urethra; *f*, *f*, *f*, *f*, the different lobes of the prostate gland; *h* is Cowper's gland of the left side exposed, the muscular sac in which it is inclosed being laid open; *i*, the opposite gland, covered with its muscle; *k* is the excretory duct of the left Cowper's gland; *l*, an opening seen at the lower part of the glans penis, which leads into the cell where both the urethra and excretory ducts of Cowper's glands terminate; *m* is a part of the ischio-cavernosus muscle of the right side; *n n*, the rectum, at the lower part of which the anal glands are seen, which are already described and referred to under the head of the *excretory glands* in this article. *Fig.* 7, of *Plate* VIII. exhibits the male organs in the *phascolomys* (*didelphis ursina* of Shaw): *a*, the urinary bladder; *b*, *b*, the ureters; *c c*, the vasa deferentia; *d d*, the testes, of which the one on the left has the tunica vaginalis slit open; *k*, the first portion of the urethra; *l*, *l*, the branches of the corpora cavernosa enveloped in their muscles; *m*, *m*, the branches which form the bulb of the urethra, covered also by muscle; *n*, *o*, two of the glands of Cowper, seen on each side; the third are concealed by the branches of the bulb of the urethra; *q* is the glans penis; *r*, *r*, the retractor muscles; *s* is the rectum. *Fig.* 5, of *Plate* VII. is a view of the organs of generation in the male *echidna hystrix*; *a a*, the singular termination of the penis in this species; *b*, the body of the penis; *c*, the cloaca; *d d*, the rectum, slit open and divided, to shew the canal which conducts the urine and semen to the cloaca; *g* is that canal laid open; *f*, *f*, orifices of glands; *e*, *e*, Cowper's glands; *k*, urinary bladder; *i*, its opening into the urinary canal; *l l*, the vasa deferentia; *n n*, the epidydimis of each side; *m*, *m*, the two testicles. *Fig.* 8, in *Plate* VIII. represents one lobe of the vesiculæ seminales of the *hedge-hog*, which is seen to be composed of convoluted tubes. *Fig.* 9, of the same plate, shews the single vesicula seminalis of the *hare*; *a*, the penis; *b*, the urinary bladder; *c*, the vesicula, with its two horn-shaped processes. *Fig.* 10. is a view of one of the lobes of the prostate, or, as Cuvier calls it, accessory gland of the *hedge-hog*.

Female Organs of Generation.—The orifice of the *vulva* is not provided, in mammalia, with either the *external* or *internal labia*. It is a simple fissure in most cases, taking the direction of the body. The *hyæna*, however, has this slit placed transversely. In the *saltigrada*, the orifice of the vulva is circular, and in many of them, and in the *marsupial* animals, it is surrounded by a sphincter, common to it and the anus.

The *vulva* is not a mere entrance to the vagina, as in the human subject, but forms most commonly a canal of some length, preceding the true vagina. In the *prehensile-tailed*, and other American species of *monkey*, this canal is, according to Cuvier's observations, as long as the vagina. In the *bear*, it is even much longer. In some cases, however, the vulva is little more than the aperture of the vagina. It has been observed to be so in the *lemur*, the *agouti*, *paca*, and *guinea-pig*. In the *baboon* also, it is a very shallow cavity.

 The

The internal ſurface of the vulva has uſually ſlight rugæ, which diſappear upon the part being ſtretched. In the *tiger* they are oblique in their direction, and very ſmall. They are tranſverſe in the *biſulca* and the *hyæna*, in which they are numerous, fine, and undulating. The *daman* has the interior of the vulva ſmooth. There are glands analogous to thoſe of Cowper, the ducts of which paſs into the ſides of the cavity of the vulva. Theſe glands are remarkably large in the *cat* genus and *marſupial* tribe of mammalia. They are compreſſed by a muſcular inveſtment.

The *clitoris* of mammalia is of various figures, ſizes, and ſtructures.

Its ſituation in all quadrupeds is neceſſarily the reverſe of that in the human ſubject: the part of the vulva next the pubis being the loweſt in all animals whoſe ſtation is on four legs.

The clitoris is ſituated farther in where the vulva forms a canal, than in other caſes. In the *bear* it is incloſed in a pouch, which opens into the vulva by a ſmall orifice. In the *baboon*, and in the *rat* tribe, the clitoris is ſituated externally to the vulva: in the latter animals, the ſkin before the vulva forms a projection, which ſerves as a ſort of prepuce to the clitoris, at which place alſo the urethra terminates; there are, therefore, in the *rats* three apertures in ſucceſſion; the orifice of the urethra, the opening of the vulva, and that of the anus.

The clitoris of quadrupeds ſo generally reſembles the penis of the males in the ſame ſpecies in form and ſtructure, that it has been ſuppoſed they were ſimilarly conſtructed in every inſtance. There are, however, exceptions to this rule: the clitoris in the *quadrumana*, the *civet*, and the *dog*, wants a bone, although there is an os penis in theſe animals.

The ſize of the clitoris is frequently greater in proportion than in the human ſubject: it is particularly ſo in the *monkies*, *lemurs*, moſt of the *digitigrade* and *ſaltigrade* quadrupeds. It is very long, and curved upon itſelf, in the *bear*. In the *marſupial* mammalia, which have a bifid penis, the clitoris is alſo double.

The prepuce of the clitoris ſometimes forms a deep ſac, in which the latter is nearly concealed, as in the *dog* genus. This prepuce is furniſhed with numerous ſebaceous glands, like thoſe of the penis, and in the *rat* kind they are extremely large.

The *orifice of the urethra* is found pretty uniformly upon the extremity of the inferior part of the vulva; it is, conſequently, often much deeper ſeated in mammalia than in the human ſubject.

In the *prehenſile-tailed monkies*, and ſome others of the new continent, the urethra opens in the ſubſtance of a ſtrong fold, extended from the hymen. Sometimes this canal is found to open in a ſlit between two tubercles, or folds, of the inner membrane of the vulva, which are ſometimes extended upon the ſides of the groove on the back of the clitoris, to conduct the urine out. In other caſes, the urethra opens in the middle of a papilla. This orifice is in the baſe of the clitoris in the *agouti* and *paca*; but in the *lemurs*, properly ſo called, and the *lori*, the urethra paſſes along the back of the clitoris, and opens near its end.

A general opinion has prevailed that the *hymen* is peculiar to the human ſubject, which ſeems to have ariſen from ſuppoſing this part to be formed for the ſole purpoſe of proving the virginity, and, conſequently, the purity of the mind in the female of the human ſpecies. Similar obſtacles, however, to the congreſs of the ſexes, are found in a conſiderable number of mammalia, and probably exiſt in many other ſpecies that have not yet been examined for this circumſtance.

In the *ſimia paniſcus*, and *ſtriated ape* (*ſimia jacchus*), the *hymen* conſiſts of two ſemi-lunar folds of membrane, the pointed corners of which unite, above and below, on two columns of the ſuperior and inferior parietes of the vulva. Theſe folds were found to be nearly effaced in an *old monkey* (*ſimia paniſcus*).

The *northern lamantin* has been deſcribed by Steller as having a ſtrong ſemi-lunar membrane ſituated at the inferior part of the opening into the vagina from the vulva.

Cuvier found a very decided membranous partition of the vulva from the vagina in a young *daman*. It was a circular fold of thin membrane, nearly of equal breadth at every part. The ſame author diſcovered in the *brown bear* a thick fold of the internal membrane, which projects in ſuch a manner from above, as to convert the aperture of the vagina into a ſimple tranſverſe fiſſure.

In the *hyæna* there is alſo a thick broad fold of membrane, which forms two ſinuoſities, the one above the other, projecting from the ſide of the vulva, and having the figure of a beak, between which there is a narrow tranſverſe ſlit, that leads from the vulva into the vagina.

The *otter*, the *bitch*, the *cat*, and the *cloven-hoofed* quadrupeds, have been obſerved to have the vulva ſeparated from the vagina by a membranous circle, which approximates, or unites, either directly, or by means of little tranſverſe bands, the longitudinal folds of the vagina that ariſe from this circle.

The *vagina* varies very much with reſpect to its ſize. This is chiefly regulated by the length of the vulva, and the magnitude of the fœtus.

It is uſually leſs wide than the vulva in thoſe mammalia which have not had any young.

The length of the vagina, in proportion to that of the vulva, varies in different ſpecies of the ſame genus: thus, in the *prehenſile tailed monkies*, and ſome other *ſimiæ*, it does not exceed the vulva in length, but in the *baboons* it is much longer.

The vagina is about half the length of the vulva in the *brown bear*. It is twice the length in the *cat* and *dog* genera. In the latter there is a remarkable dilatation, which is adapted to hold the bulb of the *dog's* penis.

There are generally longitudinal rugæ to be obſerved upon the internal ſurface of the vagina. The ſtructure of the vagina is very curious in the *bears*. The longitudinal rugæ are interſected by deep fiſſures, which divide them into ridges. There is one circular fold that entirely conceals the *os uteri*. It has a crucial opening, or one in the form of a T, which does not altogether correſpond with the orifice of the uterus. This ſtructure, added to the form of the hymen already mentioned, muſt produce great obſtruction to the reception of the male *bear*, and to the paſſage of the ſemen into the uterus.

The rugæ of the vagina are tranſverſe in the genus *delphinus*, and in the *hyæna*, although Blumenbach denies that any of the mammalia have the rugæ tranſverſe, except the *monkey* and the *mare*. He ſeems to have miſtaken the folds of the vulva in the *mare* for the rugæ of the vagina.

In the *whales*, the vagina is deſcribed by Hunter as being ſmooth upon the internal ſurface for the firſt half of its length, and afterwards valvular. He ſtates the number of theſe valves to be from ſix to nine; to be directed outwards, and each of them to reſemble an *os tincæ*. At firſt they do not go quite round, but afterwards make complete circles.

The *hyæna* has alſo tranſverſe rugæ in the firſt half of the vagina.

The vulva and vagina ſeem to be confounded with each other

other in the *tardigrada*, and in the *edentata*, the canal which conducts to the uterus in thefe orders being extremely fhort.

The *uterus*, in a few tribes of mammalia, poffeffes the fame triangular form as in the human fubject; fuch is the cafe in the *tardigrade* quadrupeds, the *ant-eaters*, the *pangolins*, and the *armadillos*. It is nearly fimilar in the *monkey* kind, but in thefe the body is more round, and the neck is diftinguifhed from the reft of the uterus by a contraction.

In all the remaining orders of mammalia, except the *marfupial* animals, the body of the uterus is more or lefs prolonged on each fide, and forms what have been called *cornua*. The extent of thefe lateral divifions is, in many inftances, very confiderable; they often reach into the loins, in which cafes the *broad ligaments* of the uterus are much fpread out, and in the large quadrupeds there are mufcular fibres placed between their laminæ. According to Cuvier thefe form different fafciculi in the *cow*, one of the ftrongeft of which extends from the ovary to the neck of the uterus. It approximates thefe parts, but for what purpofe is not known. Befides thefe there are fome tranfverfe fibres, which go from one horn of the uterus to the other, in the firft third of their length. The round ligaments alfo poffefs, in general, mufcular fibres. The divifion into cornua is lefs marked in the *lemurs* than any other genus. They have the uterus rather formed into two lobes than cornua.

The neck of the uterus is very fhort in fome fpecies; in the *agouti*, the *paca*, and the *guinea-pig*, it can fcarcely be faid to exift, and in the *hare* and *rabbit* there is no part correfponding to the neck, but the two branches or cornua of the uterus open immediately by two diftinct orifices into the vagina.

In the *ornithorhynchus* and *echidna* there is no neck or body, properly fpeaking, to the uterus. The organ confifts merely of two large convoluted tubes, which terminate by two diftinct orifices in a common canal, which leads from the bladder to the cloaca, and appears to ferve alfo the purpofe of the vagina. The firft portion of thefe tubes is the wideft. This correfponds apparently to the cornua uteri. The fucceeding part is the moft contracted; but terminates in a wide mouth that feems to fupply the place of the Fallopian tube, which is wanting in thefe animals.

The plan on which the uterus is formed in the *marfupial* animals is very peculiar. There are parts correfponding to the cornua, and to the body of the uterus, and in addition to thefe, two lateral canals. The cornua are oval cavities continued into fmall canals that extend to the ovaries, and are the Fallopian tubes. The oval cavities have been generally confidered as the dilatations of thefe tubes, but Cuvier afferts that they are very diftinct from the fmall parts of the canal which are really the Fallopian tubes. The openings of the cornua into the part correfponding to the body of the uterus are feparate from each other, and are guarded by valvular folds. The body of the uterus is a ftraight canal, which is wideft at the fundus, or the part that receives the horns, and becomes gradually lefs capacious as it approaches its termination, which is in the vagina, clofe to the orifice of the urethra. The body of the uterus is a fingle cavity in the *kanguroo*, *phafcolomys*, and the *phalanger*; but in the *Virginian opoffum*, the *wombat*, and *koala*, the uterus is double, or confifts of two cavities. Mr. Bell has defcribed thefe in the *wombat* as having a pyramidal form. The right was confiderably the largeft, being about the fize of a pullet's egg. It fhould be obferved, however, in this inftance, that the right uterus was gravid. From the fundus of each of thefe uteri there was a Fallopian tube, nearly three inches long, which terminated at the ovarium. This tube had no dilatation at its junction with the uterus, which appears to confirm Cuvier's opinion of the dilatations in the *kanguroo*, &c. anfwering the purpofes of the cornua uteri. The double uterus of the *wombat* had a common neck half an inch long, and of confiderable breadth and thicknefs, which however had two orifices in the vagina. In the *Virginian opoffum*, the two cavities of the uterus are formed by a longitudinal feptum of the part correfponding to the body, and each of thefe cavities has a feparate opening into the vagina. In the *kanguroo*, *phafcolomys*, and *phalanger*, there is but one opening from the uterus into the vagina, which is ftated by Mr. Home to be fo fmall in the virgin *kanguroo* as to be fcarcely difcernible.

By comparing the number and fituation of the communications of the uteri in the vagina, with the form of the male organs in the *marfupial* mammalia, it will be fufficiently plain that the femen paffes, as in other cafes, into the uteri directly, and not by the circuitous courfe of the lateral canals, as fome have fuppofed.

The *lateral canals* arife in the *kanguroo* from the fundus of the body of the uterus where the cornua terminate, and in the *wombat* from the pofterior furface of the common neck of the two uteri, near its junction to thofe uteri. The canals defcribe a femicircular curve, and terminate in the vagina, on each fide of the orifice or orifices of the uterus.

The ufe of thefe lateral canals it is difficult to explain. It has been obferved, that the ovum of the *marfupial* animals had no connection with the parietes of the uterus, but were involved in a fpecies of jelly, which has been fuppofed to fupply the nourifhment of the fœtus. Mr. Home has conjectured that the jelly is fecreted by the lateral canals, becaufe they become fhut towards the vagina, enlarged throughout, and maintain a free communication with the uterus after impregnation. We are not, however, fufficiently acquainted with the hiftory of geftation in thefe animals, to determine whether the changes in the canals fubfequent to impregnation, may not be required for other purpofes than the fecretion of the jelly found in the uterus.

The uterus has but rarely, in mammalia, that projection around its orifice which is called the *os tincæ* in the human fubject. Moft commonly the os uteri is a tranfverfe flit at the end of the vagina, and fo much on the lower part of that canal, that the fuperior parietes form a cell or cul-de-fac above it. In the *porcupine* the os uteri has fo flight a prominence, that it appears as an opening of the inferior part of the vagina. In the *bear*, *cow*, and others, the vagina makes a projection which tends to obftruct the paffage into the uterus.

The *ftructure* of the uterus is the fame in the *monkey* and the human fubject; but in the other mammalia the parietes are thin, and generally compofed of layers of red mufcle, fuperadded to the internal membrane, and external coat in the fame manner as the alimentary canal is formed. Thefe mufcles are particularly plain in the double uterus of the large quadrupeds. There is a tranfverfe layer of mufcle upon the cornua covered by a thin layer of longitudinal fibres. The neck of the uterus has commonly the tranfverfe layer only. The principal thicknefs of the neck of the organ in the *cow* is, however, compofed of a white hard texture, refembling the fubftance of the human uterus.

The internal membrane of the body of the fingle uterus, and of the cornua of the double uterus, ufually exhibits longitudinal folds, but in the *civet* they are tranfverfe, and inferted into each other.

The changes of ftructure which the uterus undergoes after impreg-

impregnation will be defcribed under the head of OVUM, *Hiftory of, in viviparous animals*, in the fubfequent part of this dictionary.

The ufes of thefe changes will be more eafily underftood, by being contemplated in conjunction with the parts immediately connected with the embryo. We fhall alfo referve the account of the *mammæ*, and *marfupia*, or *fuckling pouches*, for the fame head, as thefe organs are likewife fubfervient to the dependent ftate of exiftence of the young animal.

In *Plate* IX. of the *Anatomy of Mammalia*, the ftructure of the unimpregnated female organs is exemplified. *Fig.* 1. reprefents the uterus, vagina, and vulva of the *bear*, a portion of the parietes of the two latter parts being removed, to expofe their internal furface: *a* is the mouth of the vulva; *b* is the clitoris, half concealed in its prepucial pouch; *c*, the internal furface of the vulva; *d*, the valvular fold correfponding to the hymen, under which the orifice of the vagina is feen; *e*, the vagina laid open; it is fhorter than the vulva, and its longitudinal folds are croffed by grooves; *f*, the crucial flit that leads to the uterus; *g*, the body of the uterus; *h*, *h*, the two cornua. *Fig.* 2. fhews the double uterus of the *rabbit*: *a* is the *vulva* opened; *b* is the clitoris; *c*, the vagina laid open; *d*, *d*, the orifices of the two uteri or cornua in the vagina. *Fig.* 3. exhibits the female organs of the *ornithorhynchus paradoxus*: *a*, the *cloaca* laid open; *b*, the vagina, or canal which receives the urine, and the two lateral tubes or oviducts; *c*, the opening into the bladder; *d*, *d*, the two orifices of the oviducts; *e*, *e*, the dilated parts of the ducts, which apparently correfpond to the cornua uteri; *f*, *f*, the contracted portions of the ducts which reprefent the Fallopian tubes; *g g*, the termination of the ducts, which probably fupply the place of the infundibula of the Fallopian tubes. *Fig.* 4. is a view of the female parts in the *kanguroo*: *a* is the fhort canal correfponding to the vulva and vagina laid open; *b* is the clitoris; *c*, the meatus urinarius; *d*, *d*, the lateral canals arifing at the fundus of the body of the uterus, and terminating in the vagina; *e*, the middle canal which correfponds to the body of the uterus in other mammalia; *f*, *f*, the dilated parts which Mr. Home has confidered as belonging to the Fallopian tubes; but which Cuvier, more correctly, in our opinion, calls the cornua of the uterus; *g*, *g*, the parts of the tubes which really reprefent the Fallopian; *h*, *h*, the ovaries; *i*, *i*, the ureters.

If we except the formation of the tubes which correfpond to the *Fallopian* in the *marfupial* mammalia and the *ornithorhynchus*, and the *echidna*, there is fcarcely any peculiarity to be remarked in the *Fallopian tubes* in mammalia. Blumenbach ftates that they are found to be convoluted, fometimes fo as to form a knob, as in the *pygmy* (*fimia fylvanus*), and in the *opoffum*. The fimbriated extremity of the tube is conftructed like a funnel in the *rabbit*, &c.

The *ovaries* of mammalia poffefs the fame ftructure, as to all material circumftances, with thofe in the human fubject. The figure of thefe bodies is frequently more round in their fhape than in woman. In general, the veficles containing the ova are buried in the fubftance of the ovaries, as in thofe of the human fpecies; but in fome quadrupeds they are found near the furface, fo that the ovaries appear tuberculated: this has been obferved in the *pig*, the *civet*, and in the *opoffum*, the ovary of which laft is entirely made up of the veficles. The moft unufual form of the ovary is in the *hedge-hog*. The *veficulæ Graafianæ* are contained in capfules, which are diftinct externally, but connected together by their footftalks, fomewhat like the *racemus vitellorum* of birds.

The *corpora lutea* grow much larger than the cells of the ovary from which the veficles have been expelled, at leaft in fome quadrupeds. We have obferved them, in the *fheep*, to be compofed of a folid, firm, flefhy fubftance, interfected by membranous lines, fomewhat like a carcinomatous tumour, and to be about the fize of a fmall cherry.

Fig. 5. *Plate* IX. of the *Anatomy of Mammalia*, exhibits the ovary of the *hedge-hog*, which appears like a clufter of ova bound together. *Fig.* 6. reprefents a portion of the ovary of the *fheep*, from which an ovum had been recently difcharged: *a* is the vacant cell. *Fig.* 7. is another portion of the ovary of a *fheep*, in which the depofit above defcribed had been made in a cell, after the ovum had left it: *a* is the fection of the fubftance of the ovary; *b* is the fection of the new fubftance, or, as it is called in other cafes, the *corpus luteum*.

Bones.—The fkeletons of mammalia exhibit many important peculiarities, not only as compared with that of the human fubject, but with each other. This clafs has great varieties in the modes of locomotion; and confequently in the organs by which thefe are effected. In all the deviations in the mechanifm of the fkeleton, the *quadrumanous* tribe feems to be the model. Thus, the parts which conftitute the arm and hand, or are neceffary to make a prehenfile member, are found in thofe that employ the extremities for walking, flying, or fwimming, in a greater or lefs degree obliterated, changed, or concealed; although the members have fo different a form externally. The long tail alfo feems to be the model from which the fhort coccyx of fome mammalia and of man is the deviation.

The interior compofition of the bones of mammalia is generally the fame as in man. Their texture is moft clofe and denfe in the fmall quadrupeds. We have obferved the bones to be particularly hard and fragile in the *kanguroo*, but this might have been from the manner in which they had been prepared. The bones of the *cetacea* exhibit very plainly the fibrous ftructure, it being more loofely arranged than in the *terreftrial* mammalia. In the long bones, the offeous fibres can be eafily feparated, and the cells of the fpongy bones are exceedingly evident. Both in the *feals* and the *cetacea*, there are no large medullary cavities in any of the bones. The texture of the bones in thefe animals has the effect of rendering them lighter than thofe of other mammalia; and therefore better fuited to locomotion in the water. The vertebræ of the *whale tribe*, efpecially thofe towards the end of the tail, are much more denfe in their ftructure than the other bones. All the cells of the bones in thofe animals are filled with fluid oil.

It has been attempted to eftablifh a regular gradation in the proportions of the magnitude of the cranium to that of the face amongft the different mammalia, with the view of fixing the relative fize of the brain, and confequently the degree of intelligence poffeffed by the animal.

Daubenton and Camper propofed meafuring the relative fize of the cranium, by fuppofing two ftraight interfecting lines to be drawn upon the cranium and face. The angles which they exhibit in different fpecies determine the relative bulk of thefe parts. Camper's method was the moft accurate. He drew one line upwards, which touched the incifor teeth of the upper jaw below, and the greateft projection of the forehead above; this he called the *facial line*. The other line was fuppofed to pafs along the loweft part of the cranium. It was taken in the plane correfponding to the external meatus auditorius and the floor of the noftrils, and was called the *bafilar* line. The angle formed between thefe two lines determines, according to Camper, the differences of the crania of animals, as well as the national phyfiognomy of the various races of mankind.

It

It is obvious, however, that the projection of the frontal ſinuſes in many of the large quadrupeds, eſpecially the *elephant*, muſt, in a degree, interfere with the accuracy of this mode of meaſurement. The great ſize of the naſal cavity in ſome ſpecies, and the prolongation of the jaws in others, will alſo form exceptions to a rule founded upon this principle of meaſurement. Blumenbach ſtates that about three-fourths of all the ſpecies of quadrupeds with which we are acquainted, whoſe crania differ extremely in other reſpects, have the ſame facial line.

Nevertheleſs it muſt be admitted, that the proportions which the cranium (as indicating the bulk of the brain) bears to the face, ſerve in general to determine the mental endowment of animals. It is ſtrikingly proved by the *monkey* tribe, which moſt nearly approach the human ſubject in the form of the head, poſſeſſing ſo much more of the mental character of man than any other animal in the claſs.

The following table will ſhew the number of degrees of the facial angle in ſeveral ſpecies of mammalia.

Young ourang-outang - - -	67°
Sapajous, or *prehenſile-tailed monkies* -	65
Talapoin monkey - - - - -	57
Young mandril - - - - -	42
Coati - - - - - -	28
Pole cat - - - - - -	31
Pug dog - - - - - -	35
Maſtiff dog, the tangent taken at the external ſurface of the cranium - - -	41
Ditto, at the internal ſurface - -	30
Hyæna, at the external ſurface - -	40
Ditto, at the internal - - -	25
Leopard, at the internal ſurface: a tangent cannot be drawn to the external ſurface, on account of the convexity of the noſe -	28
Hare - - - - - -	30
Marmot - - - - - -	25
Porcupine - - - - -	23

Theſe three laſt are meaſured by the internal ſurface of the cranium, it not being poſſible to bring a tangent to the external.

Pangolin - - - - - -	39°
Barbirouſſa - - - - -	29
Ram - - - - - -	30
Horſe - - - - - -	23
Dolphin - - - - - -	25

According to this table, the facial angle of the *ourang-outang* does not differ materially from the human, the adult *negro* having it only 70°. In the *European head* it is 85, a difference generally conſidered as accompanying a gradation of the intellectual powers in theſe races of mankind. This opinion is not a modern one, but ſeemed to have been entertained by the ancients, who always made the cranium, in the ſtatues of their gods and heroes, project more than is obſerved in any human head. The facial angle of many of the antique ſtatues is 100°

Another method of arriving at the relative bulk of the cranium and face, is to meaſure and compare the area of each, after there has been a vertical and longitudinal ſection made of them. The area of the ſection of the European human cranium is four times as large as that of the face; the lower jaw not being included. In the *negro*, the cranium remaining the ſame, the area of the face is increaſed about $\frac{1}{5}$th. In the *Calmuc* only $\frac{1}{10}$th. In the *ourang-outang* the proportion of the face is further increaſed. It is nearly equal to the half of the cranium, in the other *monkies* and the *digitigrade* quadrupeds.

In the other orders, the area of the face is generally larger than the cranium. The *hare* and *marmot* have it $\frac{1}{3}$d larger. It is nearly twice as large in the *cloven-footed* quadrupeds; ſtill more than double the ſize in the *porcupine*; nearly three times in the *hippopotamus*, and almoſt four times the ſize in the *horſe*.

The *cetacea* have the face ſo much flattened, in conſequence of wanting the naſal cavity, that it does not admit of a fair compariſon with the cranium.

Theſe modes of meaſuring the cranium only indicate the extent of its circumference in one direction. In order to arrive at the real bulk of the cranium, or of its contents, it would be neceſſary to make a vertical ſection from one ſide to the other, and a tranſverſe ſection, ſo as to detach the upper half of the ſkull from the lower, as is done for the diſſection of the brain; or, what would be ſtill more ſatisfactory, to weigh the brain, firſt having aſcertained the variations in the weight of a given bulk of brain in different ſpecies, if any do exiſt.

The number of bones compoſing the cranium in mammalia is frequently different from what is found in man. In ſome ſpecies certain bones remain during life in ſeparate pieces, while in others, the ſutures that are always found in the human cranium are ſo early obliterated, that two, three, or more bones are conſolidated into one.

The *quadrumanous*, and all the *hoofed* mammalia, have frequently the ſphenoid bone in two parts. The ſuture of the middle of the os frontis is found in the *digitigrada*, *ſaltigrada*, the *hog*, *tapir*, *hippopotamus*, *rhinoceros*, *ſeal*, and *morſe*. In the *cloven* and *ſolid-footed* quadrupeds it exiſts for a conſiderable time. The bone containing the cavity of the tympanum is divided by a ſuture from the reſt of the temporal bone in the *cat*, *dog*, and *civet* genera; the *ſaltigrada*, the *ruminants*, *ſolipeda*, *ſeal*, *lamantins*, and *cetacea*.

The oſſa parietalia are united into one bone in the *chiroptera*, *digitigrada*, *hare*, *cavy*, *porcupine*, *marmot*, *rat*, and *ſquirrel*; the *hog*, *tapir*, *hippopotamus*, *rhinoceros*, the *ruminants*, the *ſolipeda*, and *lamantin*.

In the *cetacea* the parietal, occipital, and temporal bones are united together; although the ſphenoides is long, diſtinct, and even divided into ſeveral pieces.

All the ſutures of the cranium are very ſoon obliterated in the *elephant*.

The bones of the cranium in mammalia have not always the ſame connections with each other as in man. Even the *ourang-outang*, whoſe head bears ſo ſtrong a reſemblance to the human, does not agree in this reſpect. This animal, as well as many other ſpecies of *monkey*, has the temporal wing of the os ſphenoides very narrow, and not extended to the parietal bone: the temporal bone is partially joined to the frontal. The *jocko* has the temporal bone articulating by its ſquamous portion immediately with the os frontis, the temporal ala of the ſphenoides not being connected with either the frontal or parietal bones. In the *ſapajous*, or *monkies* with *long prehenſile tails*, the parietal bone is articulated with the os malæ. In the *howling baboons*, and the *digitigrade* quadrupeds, the bones of the cranium have the ſame connections as in man.

In all the *ſaltigrada*, the *armadillos*, *pangolins*, and *ſloths*, the ſphenoid does not articulate with the parietal bone; but in the *ant-eater* theſe two bones are extenſively connected.

In the *ruminants* the os ſphenoides has the ſame connections as as in man, but in many of the *many-hoofed* quadrupeds the ſphenoides is not joined with the parietalia.

The *ſutures* of the cranium of mammalia, in general, are apparently leſs marked than in man. Their denticulations are, however, very plain in the *ruminating* quadrupeds. The *oſſa triquetra* are not often met with. Blumenbach reports that he poſſeſſes ſpecimens of them in the *ourang-outang* and the *hare.* All the ſutures in the *cetacea* are ſquamous.

There are conſiderable varieties in the form of the different bones of the cranium. In the *ourang-outang* the *os frontis* has a more irregular outline than in man; its proceſſes are more eminent, and the orbitar arches are more elevated. This bone is triangular in the *monkies,* with long prehenſile tails; but in the other ſpecies of *ſimia* it is oval, and the arches of the orbits are flattened ſuperiorly, and prominent. The orbits of the *monkey* tribe, although opening anteriorly like the human, are much cloſer together.

The orbits are firſt obſerved to incline outwards in the *lemurs.*

In many of the quadrupeds which have the orbits directed to each ſide, the os frontis has a ſquare figure.

The *ſaltigrada* and the *hog*, however, have a notch or vacancy in the orbitar arch, which gives, in a degree, a rectangular figure to their frontal bones. The orbits of the *beaver* look upwards. In the *digitigrada*, the *cloven* and *ſolid-footed* quadrupeds, the orbitar arch has alſo a deficiency at the poſterior part.

The frontal bone forms a vault over the orbits in the *hippopotamus*, the *ruminants*, and the *horſe.*

In the *mole*, *ant-eaters*, and *cetacea*, the orbits are ſo ſhallow, that they can hardly be ſaid to exiſt. There are alſo no orbitar arches, properly ſpeaking, in the *hedge-hog*, *ſhrew*, *ſeal*, *morſe*, or *rhinoceros.* In the *cetacea* the frontal bone is narrow from before backwards; the proceſſes corresponding to the orbitar deſcend below the maxillary bone.

The *parietal* bones of the *ourang-outang* have the inferior anterior angle very prominent, on account of the ſmall extent of the ſquamous portion of the os temporis. It is the ſame, or more ſo, in the other *monkies.*

This angle of the parietal is ſtill more prolonged in the *lemurs.* It is very broad and much extended in the *ant-eater*, the *ſquirrel*, &c.

There is a ſeparate piece of bone ſometimes found in the *ſaltigrade* mammalia, between the parietal and occipital bone. It has been deſcribed in the *common mouſe* by Meyer, under the name of the *os tranſverſum.*

The ſingle parietal bone of the *ruminants* has the occipital creſt before it in the *antilope bubalis*, and reſembles a ribbon ſurrounding the back part of the head.

The *occipital bone* departs more from the form and poſition it has in the human head, than any other bone of the cranium.

The occipital ridge or creſt is not more marked in the *ourang outang* than in the human ſubject; but in the other *monkies*, eſpecially thoſe with elongated jaws, the os occipitis begins to form the angle at the creſt, which is ſo ſtriking in moſt quadrupeds. The tranſverſe occipital ridge is very prominent in the carnivorous quadrupeds, whether *digitigrade* or *plantigrade*, making the upper part of the occiput angular, and beneath this the cranium flat or concave. The longitudinal occipital ridge is very ſtrong in the *badger.*

The *ruminating* quadrupeds, likewiſe, have a very projecting occipital ridge, and the *beavers* are remarkably ſo. In the *pig* the occiput has the figure at the upper and back part of a very acute angle.

The occiput is round in the *ant-eater* and *cetacea;* it is ſmooth and without proceſſes in the *mole.*

The *elephant* has the occiput nearly ſquare, and the condyles at the poſterior extremity. There is no occipital protuberance, but a depreſſion in place of it, containing a longitudinal ridge for the inſertion of the ligamentum nuchæ.

The *maſtoid proceſs* belongs to the occipital bone in all mammalia, except the *monkey*, in which it is an appendix of the os temporis, as in man. This proceſs in the *apes*, and moſt of the *monkey* kind, is nearly obliterated. Moſt of the *digitated* quadrupeds want the maſtoid proceſs, and merely have a ſlight protuberance from the projecting part of the cavity of the tympanum; or this cavity itſelf ſupplies the place of the maſtoid proceſs. The *cavy*, *hog*, *guinea-pig*, the *cloven* and *ſolid-footed* quadrupeds, &c. have a long maſtoid proceſs behind the cavity of the tympanum.

The poſition of the *foramen magnum* is remarkably different from that of the human ſubject; it removes from the under part of the head, even in the *monkey* tribe, and in the true quadrupeds is found at the poſterior part of the cranium, and ſituated ſo, that the edge, which is poſterior in man, is directed obliquely upwards. This edge is in ſome quadrupeds turned directly upwards, or, as in the *alpine marmot*, is even turned more forwards than the other edge of the hole. The relative poſition of the occipital foramen was employed by Daubenton to determine the gradations of the crania of different animals. He drew one line from the edge of the hole, which is poſterior in man, but ſuperior in moſt quadrupeds, as already mentioned, through the lower edge of the orbit: another line was taken in the direction of the foramen itſelf, beginning at its poſterior edge and touching the articular ſurface of the condyles. The angle formed by the interſection of theſe two lines, was conſidered by Daubenton as indicating the variations of form and magnitude of different crania. It has been objected to by Blumenbach, upon the ſame ground that he diſapproved the facial angle of Camper, namely, its not expreſſing all the variations that exiſt.

The *ſquamous* portion of the *temporal* bone, as already noticed, is much leſs extenſive in mammalia, even in the *ourang-outang*, than in man. The principal part of this bone, as it appears externally in many quadrupeds, is the zygomatic proceſs. The petrous portion of the os temporis will be deſcribed along with the other parts of the organ of hearing, to which it properly belongs.

The *zygoma* is not merely formed by the junction of the proceſſes of the temporal and malar bones, but has an intermediate piece of bone in the *otter*, *opoſſum*, *beaver*, *guinea-pig*, &c. Cuvier alſo mentions a particular bone which ſupplies the place of the zygomatic angle of the os malæ in the *green ape*, but which bone is ſoon anchyloſed with other malar.

The zygoma is remarkably broad in the *opoſſums* and the *kanguroo.*

In the *mole*, it is a ſtraight proceſs, not much thicker than a needle.

In the *cetacea*, at leaſt the genus *delphinus*, the zygoma is a very ſlender oſſeous bar.

In proportion to the extent and ſtrength of the maſſeter muſcle, the zygoma forms a curvature in an upward direction, and when this muſcle is leſs conſiderable, the zygoma is either horizontal, or makes a convexity downwards. The zygoma is univerſally arched upwards in the *carnivorous* quadrupeds. The *ſaltigrada* have the convexity downwards, and in the *cavy* and the *paca*, it even extends below the diſtance of the molar teeth.

The

The zygoma of the *sus æthiopicus* is nearly horizontal, but is extremely broad and thick, and forms all the broad part of the cheek under and before the eyes.

The curvature of the zygoma outwards, which gives it properly the name of an arch, depends upon the magnitude of the temporal muscle which passes under it. We, therefore, find the zygomatic arch very wide in all the *carnivorous* tribe of quadrupeds, and particularly so in the *cat* genus, upon which depends the round shape of the head of the *tiger*, *leopard*, *cat*, &c. in a great measure.

The large *herbivorous* quadrupeds, in general, have the zygoma but little arched outwards. It is the same in most of the *saltigrada*.

The zygoma is quite straight in the *mole*, and in the *cetacea*.

It is not found to form an arch outwards, of any consequence, in the *edentata*. In the *Cape ant-eater* it is perfectly straight.

In the *pangolins* and *American ant-eaters*, the zygomatic arch is incomplete; the latter animals have merely two tubercles in place of the processes, which usually form the zygoma.

The zygomatic arch, also, is not complete in the *sloths*. The os malæ terminates posteriorly in two angles; the one superior, which extends above the zygomatic process from the os temporis; the other inferior, which passes obliquely downwards, and is unattached.

We shall describe the *ethmoid bone*, more particularly, under the head of the organ of smelling, by which its uses will be more apparent.

The large *fossæ*, or depressions upon the inner surface of the base of the cranium, are shallow in proportion as the animal is removed from man.

Even the *howling-baboons* have the posterior and intermediate fossæ, and the sella turcica, in the same plane.

Many quadrupeds want the sella turcica, as the *digitigrada*, and most of the *saltigrada*. In the *cavy*, the *rhinoceros*, and the *cloven-footed* quadrupeds, the part having the situation of the sella turcica is even depressed, instead of being elevated.

Some of the spinous ridges on the internal part of the cranium, are often more eminent in mammalia than in man.

In the greater number of the *carnivorous* species, there is a thin projection of bone from the petrous portion of the os temporis, which strengthens the tentorium of the cerebellum. It is usual to say that these animals have a bony tentorium, and to suppose that it is necessary to defend their brain from concussion, during the rapidity of their motions, which does not seem probable, as something of the same structure is found in other species whose movements are slow.

The limits between the middle and posterior fossa of the cranium is formed in the *pangolin* by a large vertical osseous septum, with an oval hole in the middle.

In the *rhinoceros*, the part corresponding to the posterior clinoid processes is not attached to the base of the cranium, but extends like a bridge from one middle fossa to another, while the depression that is in place of the sella turcica communicates under this bridge with the cuneiform process of the occipital bone.

The *foramina* upon the inside of the cranium are often less distinct, and consequently less numerous in mammalia than in man.

The *optic foramina* are close together in the *agouti*, being only separated by a thin osseous plate. They are united into one hole next the scull in the *hare*, the *four-toed ant-eater*, and the *elephant*. The *chevrotin* (*moschus*) has but a single optic foramen, which is divided by the vomer.

The *spheno*, or *superior orbitar fissure* in the *ourang-outang*, is similar to that of the human subject; but in almost all the other mammalia it is nearly a round hole. In many of the *saltigrada*, and the *rhinoceros*, *elephant*, and *hippopotamus*, it is incorporated with the foramen rotundum. They are also confounded in the *cloven* and *solid-footed* quadrupeds.

The *foramen rotundum* in the *monkey* is marked with a furrow for some way before it leaves the cranium. This hole is very large, and more of an oval than a round shape in the *digitigrade* quadrupeds.

The *foramen ovale* of the *bear*, *cat*, *civet*, &c. is defended at the external edge by an osseous lamina.

The *bear*, *badger*, *seal*, and *vampyre bat*, have this foramen united into one with the foramen rotundum.

The foramen ovale is thrown into one with the *anterior foramen lacerum* in the *cavy* and *porcupine*. In the *ten-banded armadillo*, and the *four-toed ant-eater*, it is confounded either with the foramina lacera, which are united, or with the foramen rotundum, which is thus rendered very large, and of an oblong form. It is conjoined with the anterior foramen lacerum in the *elephant* and *hippopotamus*. It is very large in the *ruminating* quadrupeds, and does not exist as a separate hole in the *solipeda*.

The *foramen lacerum anterius* is not found in the *monkey* kind, the *digitigrade*, the *squirrel*, and the *ruminating* quadrupeds.

It is very wide in several of the *saltigrada*. It is confounded with the *posterior foramen lacerum* in the *armadillo*, the *hippopotamus*, and *solipeda*.

The *canalis carotideus* is much shorter and less tortuous in the *digitigrada* than in man. There is no canal in the *saltigrada*; the carotid passing immediately through the foramen lacerum. In the *hippopotamus* the carotid canals are lost in the foramina lacera.

The *foramen lacerum posterius* is a very small round hole in the *pangolin* and *sloth*; and in the *elephant* it is very large. In the two first of these animals the anterior condyloid foramen is remarkably large; and in the last there is no hole before the condyles, which shews the connection that exists between these two foramina.

The foramen lacerum posterius is confounded with the anterius in the *rhinoceros*; and the *anterior condyloid hole* is very large. There are sometimes two condyloid foramina on one side, which are united into one.

The two tables of the cranium are in general less distinct in mammalia than in man, or appear to be more perfectly ossified; but in the *elephant*, the magnitude of the cranium depends in a great measure upon the separation of the two tables, between which are interposed a number of large cells of a very irregular figure, which are filled with air instead of medullary substance, and communicate with the Eustachian tube, and by that means with the external air. The cellular structure of the cranium in the *elephant* is similar to that found in the head of the *owl*, and designed in both to produce an increase of bulk, without an additional weight.

The bones of the face differ very much in this class, both in their forms and connections, from those of man, in consequence of the great prolongation of the jaws, and the lateral position of the eyes, in most mammalia.

The form of the upper jaw arises in a great degree from the presence of two bones, which are placed between the two ossa maxillaria. These have received different names, such as *intermaxillary* or *labial bones*; or frequently they are called the *os incisivum*, from the circumstance of their holding the incisor teeth, when they exist: they are called also *os palati*

palati by Blair, and *os maxillaire interieur* by Vitel. The intermaxillary bones have been confidered by fome anatomifts as forming a diftinction between all mammalia and man; but they have not been found in feveral fpecies of *monkey;* and Fifcher, who wrote a treatife on this fubject, ftates that he did not find an intermaxillary bone in the *three-toed floth*, and in the *horfe-fhoe bat;* but he admits that the bone might have been broken off, at leaft in the *floth*. Cuvier fays that the *floths* have very fmall intermaxillary bones. Vic d'Azir has afcribed thefe bones to the human fubject, confidering the fmall tranfverfe fiffure, feen within the incifor teeth of the human fœtus, as the future connecting the intermaxillary bones or bone with the upper jaw; but all other anatomifts deny the intermaxillary bones to man.

Thefe bones vary much in different fpecies, with refpect to form and fize. They are fmall in fome of the *digitigrade quadrupeds*, in the *rhinoceros*, and in the *walrus*; although Cuvier ftates them to be large in the *lamantin*. They are particularly large in the *faltigrada*, in which they make the whole front of the upper jaw, and contain the large upper gnawing teeth of thefe animals. They are large alfo in the *elephant*, *hippopotamus*, *porpoife*, and *phyfeter macrocephalus*. In the *ornithorhynchus* thefe bones exift, although there are no incifor teeth; and the form of the jaws is fo very peculiar, refembling in this animal the bill of a duck. The intermaxillary bones confift of two hook-fhaped pieces, united by a broad cartilage.

The *proper maxillary* bones contain ftill in mammalia the pofterior teeth of the upper jaw. Thefe bones contribute more than any other to the compofition of the face: even in the *monkey* tribe they begin to be prolonged, and affume fomething of the figure they poffefs in the true quadrupeds.

In the *cheiropterous*, *digitigrade*, *plantigrade*, and *pedimanous* mammalia, the nafal proceffes of the maxillary bones become fo broad as to feparate the orbits fufficiently, to give them a lateral pofition. The *faltigrada* have thefe bones carried fo far back by the great fize of the intermaxillary bones, that they form a confiderable portion of the orbit, the palatine bones having but little concern in the compofition of it.

The maxillary bones of the *floths* alfo extend to the orbits.

In the *ant-eaters* thefe bones are very long and narrow, refembling a portion of a cylinder; but they do not contribute to the formation of the orbits.

The maxillary bones of the *tapir* pafs backwards, and make the floor of the orbits: they alfo extend to the orbit in the *rhinoceros*.

In the *hippopotamus* thefe bones have no fhare in the orbit; they are very ftrong inferiorly, in order to accommodate the fuperior tufks, which are placed in them, and not the intermaxillary bones.

The *daman* has the inferior furface of the orbit formed by the fuperior maxilla: it makes a fmall part of it on the *ruminants*.

In the *lamantin* the maxillary bones conftitute the bafe of the orbit, and afterwards extend a confiderable way behind it.

In the *cetacea* they are much elongated, and reach to the very end of the flattened fnout of thefe animals: they afcend upon the fide of the blow-hole, and cover that part of the os frontis which forms the arch of the orbit.

The *malar bone*, in a great number of mammalia, is lefs in proportion than it is in man, and does not articulate with either the orbitar procefs of the os frontis or the fphenoides, but merely forms a part of the zygoma and the lower margin of the orbit. In thefe cafes, the frame of the orbit is incomplete at the pofterior part, and communicates with the foffa for lodging the temporal mufcle. It is thus with the *cheiroptera*, *digitigrada*, *plantigrada*, *faltigrada*, *pedimana*, *edentata*, and *multungulata*. In the *faltigrade* the os malæ is placed in the middle of the zygoma; the fuperior maxilla fupplying the anterior zygomatic procefs, in place of the malar. The temporal foffa is completely thrown into one cavity, in the *rhinoceros* and *elephant*.

The frame of the orbit is completed externally by the union of the malar and frontal bones; but there is an opening behind this from the orbit into the temporal foffa.

In the *folipeda* the malar and frontal bones unite by a procefs of the latter, which defcends on the outfide of the orbit, and furnifhes the margin of this cavity; but it is open behind into the temporal foffa, as in the *ruminants*.

The *nafal bones* are commonly prolonged, in proportion to the other parts of the face in mammalia. In fome of the *monkey* tribe they are united into one bone, which is very narrow. In the *long-prehenfile-tailed monkies* the interfpace between the orbits is very narrow, and pofteriorly merely forms a feptum.

Thefe bones are longeft in the true quadrupeds, and moft fo in the *faltigrada*, whofe external nares open immediately above the incifor teeth.

In the *hog*, the *tapir*, *hippopotamus*, and the *rhinoceros*, the nafal bones are not conjoined with the jaw at their anterior extremity, but form a diftinct procefs, which ftands out above the intermaxillary bone. This procefs fuftains the probofcis of the *tapir* and *hog*, and the horn of the *rhinoceros*, or the anterior one when there are two, as in the *bicornis*.

The procefs which fupports the trunk of the *elephant* is ftill more unlike the common nafal bones.

The nafal bones of *cetacea* are two fmall tubercles implanted in the os frontis.

The *lachrymal bone* is fometimes wanting, as in the *elephant:* in other inftances it is remarkably large, in the *ant-eater*, the *opoffum*, the *ruminating quadrupeds*, efpecially the *antilope*. It advances a little upon the cheek in the *flying lemur*.

According to Cuvier, the *ethmoid* bone has no fhare in forming the orbit in the *cheiroptera*, *digitigrada*, *plantigrada*, and *pedimana:* its place is fupplied by the orbitar procefs of the *palatine bones*, which are very large in thefe animals.

The *palatine bones* alfo conftitute, in the *long-nofed edentata*, the lower part of the furface of the depreffion correfponding to the orbit. The *pterygoid* proceffes alfo are produced by two laminæ, which are continued with the offa palati, and which, having joined each other inferiorly, prolong the canal of the nares to the foramen magnum of the occiput.

In the above defcription of the bones of the upper portion of the face, we have anticipated moft of the circumftances refpecting the *nafal* and *orbitar foffæ*.

It fhould be mentioned, that the *hog* has two fmall peculiar bones, fituated between the point of the offa nafi and the correfponding intermaxillary bones. Thefe ferve to ftrengthen the fnout, and are therefore called by Cuvier the *bones of the fnout*.

The *nafal foffæ*, although always opening nearer the front in quadrupeds than in man, are liable to vary with refpect to their fituation. In the *faltigrada* the external nares are quite at the end of the fnout, as already mentioned. In the *elephant*, the nafal foffæ are at about an equal diftance from the top of the cranium and the edge of the alveoli. In the *feal*, they are directed upwards. They are far forwards in the *morfe*. In the *cetacea*, the openings into the blow-hole, which

which correfpond with the nafal foffæ, are immediately before the os frontis, and open upwards and backwards.

We have already mentioned the figure of the margin of the orbit in feveral fpecies. In the *cetacea* there is a foffa correfponding to the orbit, although the eye of thefe animals is furrounded only by the foft parts. This foffa has a femicircular roof, formed by the os frontis; but it is quite open below, down to the lower jaw.

The *spheno-maxillary fiffure* is fhorter in all the *monkey* tribe than in man: it is contracted to the fhape of a hole in the *long-prehenfile-tailed monkies*, and is clofed altogether in the *howling baboon*. In the other mammalia, which have the orbitar and temporal foffæ united, it does not exift.

The *fub-orbitar foramen* is fingle in moft mammalia, as in man; but in fome there are two, or three, or more holes under the orbit; in which cafes they are fmall. There are, according to Cuvier, two in the *ourang-outang* and the *prehenfile-tailed monkies*, three in the *common monkies* and *Barbary ape*, four or five in the *ribbed-nofed ape* and *hair-lipped ape*. There are three or four holes in the *cetacea*. From the pofition of the orbits in thefe animals being fo low, the maxillary bones are above them, and contain the holes correfponding to the fub-orbitar.

The fub-orbitar foramina are large in moft of the *whifkered* quadrupeds, for the tranfmiffion of the great nerves that are diftributed to thofe parts. In the *cavy*, *agouti*, *porcupine*, and many of the *rat* tribe, they are prodigioufly wide; and in the *jerboa*, nearly equal in fize the orbits themfelves.

The greateft deviation from the human fubject, with refpect to the foramina of the face, is to be obferved in the *foramen incifivum*. This hole is fmall and fingle in the *ourang-outang* and *chimpanfee*, but enlarges a little in the other fpecies of *fimia*. There are two foramina very diftinct from each other in almoft all the other mammalia: they are remarkably large in the *faltigrade* and *cloven-hoofed* quadrupeds; in the *hare* they even exceed the extent of the folid part of the palate.

It is fingle and large in the *tapir*, *rhinoceros*, *horfe*, and *lamantin*; it is nearly obliterated in the *morfe*; fmall and far from the alveolar procefs of the jaw in the *dugong*; and wanting altogether in the *cetacea*.

Peculiarities of the *lower jaw* are to be found in its compofition, general form, direction of its afcending ramus, and the figure and relation of the condyloid and coronoid proceffes.

The inferior maxilla remains, during life, in two pieces, united by cartilage or ligament at the front, in moft mammalia. Thefe are anchylofed together, as in man, at an early period, in the *monkey* kind, the *vampyre*, and feveral other *bats*, the *phatageri* (*manis tetradactyla*), and the *elephant*. The two inferior maxillary bones are united into one very foon; alfo in the *many-hoofed* and *folid-footed quadrupeds*, and in the *morfe* and *lamantin*.

The general figure of the lower correfponds ufually with that of the upper jaw, already defcribed. In the *faltigrada* it is commonly a little fhorter than the upper jaw, on account of the inferior incifor teeth being fo long. In the *armadillo* and *four-toed manis*, the two fides of the jaw approach each other, and form a very acute angle at their fymphyfis.

The *ornithorhynchus* has the two pieces of the jaw joined to each other before their termination, and then bifurcate again In the *echidna* the extremities are again joined; they are thin, flat, and round, or fpoon-fhaped.

The lower jaw of the *elephant* is rounded in the front, and refembles the human jaw more than could be fuppofed, from the general outline of the head in each.

The *afcending ramus* of the lower jaw forms nearly a right angle with the body of that bone as in man, in the *lemur*, *cat*, *hedge-hog*, *fquirrel*, *hare*, *beaver*, *kanguroo*, and moft of the *faltigrada*, *rhinoceros*, *elephant*, &c.; in fine, in moft mammalia: but the mechanical operation of the jaw depends upon the fituation of the condyle on which this bone moves, and the coronoid procefs by which it is chiefly moved, with refpect to the body of the bone.

The *condyle* projects commonly back beyond the line of the angle formed by the body, and the afcending branch of the jaw. The more it is out of this line, or, in other words, the more the condyloid procefs approaches to the continuation of the body of the jaw, the more difadvantageous is the lever which this bone forms. The condyle, therefore, departs leaft from a right angle with the body of the bone in the *carnivorous* quadrupeds; a very little more in the *graminivorous*; and ftill more in the *monkey kind*. In the *ant-eater*, *manis*, *armadillo*, *ornithorhynchus*, and the *whale tribe*, the condyle does not form an angle, but is nearly in the fame line with the body of the jaw, thefe animals not having any afcending branch to the lower jaw.

The nature of the lever, and the force of the moving power, depend chiefly upon the fituation of the *coronoid* procefs, and the height and extent of this part.

This procefs is fmall in the *monkies*. In the *lemurs* and the *digitigrada* it is large, and paffes up into the temporal foffa, its point ftanding higher than the zygoma, and than the condyle, confequently the power of the temporal mufcle is diminifhed, but the difadvantage of the pofition of the coronoid procefs is more than counterbalanced by the enormous fize of the temporal mufcles in the *digitigrade* quadrupeds.

In the *faltigrada*, the coronoid procefs, in many inftances, is fhort, and fo far from the condyle, that it paffes before the pofterior grinding tooth, which is thereby placed between the moving power, and the point on which the jaw moves. The defign of the force of the temporal mufcle being carried fo far forwards in the *faltigrada*, is to increafe the power of the gnawing teeth. The *hare*, *fquirrel*, and *kanguroo*, however, have the coronoid procefs lefs advantageoufly fituated, but they do not employ their teeth, like the *rats* and the *beaver*, as mechanical inftruments.

In the *elephant*, the coronoid procefs advances upon the molar tooth, and paffes on the outfide of it as far as the one-third of the length of the tooth. It is a broad and very fhort procefs. In the *rhinoceros*, this procefs is at an equal diftance from the condyle and laft molar; and in the other animals of this order, it is generally nearer the back teeth than the condyle.

The *ruminating quadrupeds* have the coronoid procefs afcending into the temporal foffa, and its point paffing nearly into a line with the condyle.

The *folipeda* have it nearly the fame: its point is not fo far removed from the molar teeth.

In the *edentata* it is obferved to approach very nearly to the condyle in the *armadillo*. It is directed outwards, in place of upwards, in the *echidna* and the *ant-eaters*. In the *four-toed manis* it is not to be perceived.

There is a fhort coronoid procefs in the genus *delphinus*, and the true *whales*, which is directed backwards, and only forms the fuperior angle of the long triangle which each fide of the jaw prefents in thefe animals. There is no trace of the coronoid procefs in the *cachalots* (*phyfeter*.)

The kind of motion of which the lower jaw is fufceptible, is determined by the figure of the *condyles*, and the *cavities*, called *glenoid*, which receive them.

In the *carnivorous mammalia*, the condyle is longeft in the tranfverfe direction, and the glenoid cavity is adapted to it in fhape and fize: in many of thefe animals the articulation

 of

of the lower jaw forms a perfect hinge, and only permits the feparation of the lower from the upper jaw in the direction downwards. This is particularly to be obferved in the *badger*, where the glenoid cavity has a projection before and behind, by which the condyle is partially inclofed in the joint: it even remains fo after the parts are macerated, and the ligaments and cartilages are deftroyed.

In the *monkies*, the condyle is tranfverfe, and a little oblique: the glenoid cavity is wide and fhallow, and permits a degree of retraction, protrufion, and lateral motion of the lower jaw.

The freedom of motion in different directions is increafed in the other quadrupeds, and is moft fo in the *ruminating* and *gnawing* tribes. In the latter, the figure of the condyle is exactly oppofite to that of the *carnivorous* quadrupeds. It is a very thin oval tubercle, the length of which is from before backwards. The glenoid cavity is larger than the condyle, and fo little concave, that the jaw has a very free lateral motion.

In the *elephant*, the condyle is fhort and round: the glenoid cavity, in place of being concave, is elevated in the middle. There is another condyle formed by the bafe of the zygomatic procefs: a joint, thus conftructed, enables the animal to protrude and retract the jaw in a peculiar manner.

The glenoid cavity of the *hippopotamus* is fituated behind the zygomatic procefs, in fuch a way as would feem to prevent any protrufion of the jaw.

In the *rhinoceros*, although the furface of the glenoid cavity is nearly flat, it is bounded pofteriorly and internally by a long procefs, which muft reftrain its horizontal motion.

The articular cavity of the *tapir* has pofteriorly an oblique procefs which oppofes the lateral motion of the jaw.

The condyloid furface in the *ant-eater* is plane, and fituated at the pofterior extremities of the jaw. There is no glenoid cavity, but an articular furface correfponding to that of the jaw. In the other *edentata*, the condyle is a diftinct eminence, fmooth upon the furface, and applied to a fimilar furface of the zygomatic procefs, which fupplies the place of the glenoid cavity.

The condyle of the *cetacea* is round, and very little eminent. The furface correfponding to the glenoid cavity is adapted to the figure of the condyle; they are united together, not merely by ligaments externally, but the articulating furfaces furnifh many ligamentous bands, which confolidate the joint, and preclude every other motion of the jaw except that downwards.

The *os hyoides* of mammalia differs from that of the human fubject with refpect to the figure of the body of the bone, the relative magnitude of the cornua, and the exiftence of an additional offeous piece in place of the ftyloid ligament. This laft is found in all the genera, with the exception of the *monkey* tribe: it is ufually a long, flender bone, and is fometimes articulated in a particular depreffion fituated at the place correfponding to the ftyloid procefs of the os temporis. In other cafes it does not reach fo far as the cranium, but is connected to it by ligament or cartilage. The cornua, which are called the large, in the human fubject, are often confolidated with the body of the os hyoides, and thofe called the fmall cornua are fometimes very large. Cuvier has treated of all the varieties of the os hyoides, at great length, as he has of all the parts connected with the organs of deglutition or of voice. We fhall notice fome of the moft remarkable deviations in the conformation of the os hyoides, from its ftructure in the human fubject, and refer the reader to Cuvier's "Anatomie comparée" for details of the lefs important circumftances.

The os hyoides of the *ourang-outang* and *chimpanfee* refembles, almoft exactly, the fame bone in man. In the other *monkies*, the body of the bone is broader, and either fquare or triangular. In the *common monkies* with *long tails, not prehenfil*, the *hare-lipped monkey*, and the *baboon*, it is convex in the front, and forms a fort of cavity upon the internal furface.

In the *howling baboons* this bone is very remarkable: it forms a bony fac under the root of the tongue. The parietes of the fac are thin and very elaftic; they furnifh a number of thin projections interiorly, by which the fac is divided into feveral irregular fhaped apartments. This fac communicates pofteriorly by a canal with the larynx. It is, therefore, fubfervient to the functions of that part, and enables the animals that poffefs it to produce that loud cry for which they are fo diftinguifhed.

The os hyoides of the *digitigrada* is compofed, in general, of flender pieces: the body is cylindric, and nearly ftraight. The anterior cornua are longer than the pofterior: they are formed of two pieces; the fecond is fuftained by the ftyloid bone. This laft is ufually larger than all the other parts of the os hyoides; the end next the temporal bone is broad, and covered with an articular furface.

The os hyoides of the *opoffums* is flat, and nearly fquare: the cornua are joined to the angles: the large cornua are very broad at their bafe, and bent anteriorly, and end in a point: the fmall cornua are longer, cylindric in their form, and enlarged at the pofterior extremity.

In the *faltigrada*, the figure of the os hyoides and its branches vary in their fhape; in fome genera they are broad; in others, narrow and flender. The *beaver* has a ftrong long oval procefs defcending from the inferior edge of the body of the os hyoides. The anterior cornua are fmall and cartilaginous. Several of the other *faltigrada* have alfo a procefs or projection from the body of the bone.

The os hyoides has a peculiar ftructure in the *echidna hyftrix*. The body is formed of a flat, ftraight piece. The extremities of its anterior edge fuftain the anterior cornua, which are cylindric, directed forwards, and compofed of but one piece. The *ftyloid* bone defcends almoft perpendicularly to meet thefe cornua. The pofterior cornua are arched before: they are broad, flat, and articulated upon the fides of the body of the bone. The end of the pofterior edge is convex, and is attached to a fecond piece, which defcends parallel to the firft as far as behind the body of the os hyoides, where it is joined to the one of the oppofite fide. Two other pieces are added to thefe, about the place of their junction, and feparate from them upon the fides.

In many of the *multungulata* and *bifulca*, the pofterior cornua are confolidated with the body of the bone. In the *elephant* this bone has the figure of a flattened lamina, a little arched upwards. The pofterior branches are alfo flat, afcend obliquely backwards, and bend a little inwards. The ftyloid bone is bifid. Its pofterior branch is arched, long, and ends in a point. The anterior is ftraight, fhorter, and is articulated with the anterior cornna.

The os hyoides of the *cetacea* is both peculiarly fituated and formed. The ftyloid bone is long; it proceeds very obliquely forwards and inwards, under the bafe of the tongue, where it is joined to the anterior corner of the fame fide. The anterior cornua are fhort; they pafs directly backwards, to articulate with the middle of the convexity on the body of the bone: this laft is flat and anchylofed with the pofterior cornua, and reprefents the figure of a crefcent, the points of which are turned backwards, and are not attached by ligaments to the thyroid cartilage.

 The

MAMMALIA.

The number of vertebræ that compoſe the different regions of the ſpine of mammalia are ſubject to great variety, with the exception of thoſe of the neck, which are the ſame number in man and all mammalia, beſides the *three-toed ſloth*, which has nine cervical vertebræ. When the neck is remarkably ſhort, as in the *whale* tribe, the bodies of the cervical vertebræ are very thin, and a certain number of them conſolidated by anchyloſis into one bone, in which the diſtinctions of their original number and their proceſſes can barely be ſeen.

The following table of the number of the vertebræ in the other parts of the ſpine, beſides the cervical, is extracted from Cuvier's "Comparative Anatomy," and will render any further obſervations upon the numbers unneceſſary.

TABLE of the Number of Vertebræ in mammiferous Animals.

Species.	Dorſal Verteb.	Lumbar Verteb.	Sacral Verteb.	Caudal Verteb.
Man - - -	12	5	5	4
Ourang-outang - -	12	4	3	4
Jocko - - -	13	5	4	5
Long-armed ape -	14	3	6	0
Coaita or four-fingered monkey -	14	3	2	32
Weeping monkey -	14	7	4	25
Silky monkey - -	12	7	1	26
Red monkey - -	12	7	3	more than 16
Rib-noſed ape - -	12	7	1	13
Hare-lip monkey -	12	7	1	5
Chineſe monkey - -	11	7	3	20
Baboon - - -	12	7	1	31
Magot or Barbary ape	12	7	1	3
Mandril - - -	12	7	3	13
Pongo - - -	12	4	3	4
Howling baboon -	14	4	5	25
Maucauco - -	12	7	3	18
Lori - - -	15	9	1	9
Tarſier or woolly jerboa	14	5	3	more than 17
Vampyre or ternate bat	12	4	1	0
Common bat - -	11	5	4	12
Noctule or great bat -	12	7	3	6
Horſe-ſhoe bat - -	12	6	3	12
Flying lemur - -	12	6	1	22
Hedge-hog - -	15	7	4	12
Tanrec - - -	15	6	3	8
Shrew - - -	12	7	3	17
Mole - - -	13	6	7	11
White bear - -	13	6	7	11
Brown bear - -	14	6	5	more than 4
Badger - - -	15	5	3	16
Glutton - - -	16	5	3	18
Coati - - -	14	6	1	more than 10
Racoon - - -	14	7	3	20
Otter - - -	14	6	3	21
Martin - - -	14	6	3	18
Weaſel - - -	14	6	3	14
Civet - - -	13	6	3	20
Lion - - -	13	6	3	23
Tiger - - -	13	7	4	19
Panther - - -	13	7	3	24
Couguar or American lion - - -	13	7	3	22
Cat - - -	13	7	3	22
Dog - - -	13	6	3	22
Wolf - - -	13	7	3	19
Fox - - -	13	7	3	20
Hyæna - - -	16	4	2	more than 8
Cayenne opoſſum or crab eater - - -	13	6	5	more than 16
Marmoſe or murine opoſſum - - -	13	6	1	29
Phalanger or Surinam opoſſum - - -	13	6	1	30
Porcupine - -	14	5	4	more than 8
Hare - - -	12	7	4	20
Rabbit - - -	12	7	2	20
Cavy - - -	13	6	2	more than 4
Guinea-pig - -	13	6	4	more than 6
Paca or ſpotted cavy -	13	6	5	7
Agouti - - -	12	8	4	7
Beaver - - -	15	5	3	23
Flying ſquirrel - -	12	8	3	13
Marmot - - -	13	7	6	22
Field mouſe - -	13	7	3	15
Water rat - -	13	7	4	23
Black rat - -	13	7	3	26
Norway rat - -	13	7	4	23
Common mouſe - -	12	7	4	24
Field or harveſt rat -	12	7	3	23
Hamſter - -	13	6	4	15
Fat dormouſe - -	13	7	2	18
Garden dormouſe -	13	7	4	24
Ant-eater - -	16	2	4	40
Pangolin - - -	15	5	3	28
Long-tailed manis -	13	5	2	45
Armadillo - -	11	4	3	30
Two-toed ſloth - -	23	2	4	more than 7
Three-toed ſloth - -	14	4	3	13
Elephant - - -	20	3	4	24
Hog - - -	14	5	3	more than 4
Tapir - - -	20	4	3	12
Rhinoceros - -	19	3	4	22
Camel - - -	12	7	4	17
Dromedary - -	12	7	4	18
Stag - - -	13	6	3	11
Camelopard - -	14	5	4	18
Antilope - - -	13	6	5	15
Gazelle - - -	13	5	5	11
Chamois - - -	13	5	4	more than 7
Goat - - -	13	6	4	12
Sheep - - -	13	6	4	16
Ox - - -	13	6	4	16
Horſe - - -	18	6	2	17
Couaga - - -	18	6	7	18
Seal - - -	15	5	2	12
Dolphin - - -	13	In all 66		
Porpoiſe - - -	13			

The *cervical vertebræ* of the *monkey* tribe reſemble thoſe of the human ſubject, except that their ſpinous proceſſes are ſtronger and not forked. They are very long in the ſpecies of *baboon* called *pongo*, in conſequence of the large projecting face of this animal requiring an extenſive attachment for the muſcles, which raiſe and ſupport the head.

In the *digitigrada* the ſpinous proceſs of the ſecond vertebra is very high, and extends upwards, or rather forwards, upon the atlas, and backwards upon the third vertebra. The tranſverſe proceſſes of the atlas are very large and flat on the front and back. Theſe two vertebræ are altogether large. The pendent poſition of the head, in moſt of the *digitigrada*, makes the exiſtence of ſtrong muſcles neceſſary for its ſupport; the ligamentum nuchæ not being large in this family of quadrupeds. The ſhort muſcles at the back of the head contribute to the opening of the mouth of quadrupeds, and therefore ſhould be ſtrong in this carnivorous tribe.

The cervical vertebræ have no ſpinous proceſſes in the *mole* and *ſhrews*. They appear, eſpecially in the middle of the neck, as ſimple rings of bone, which admit of as free a motion upwards as in any other direction; their ligamentum nuchæ is oſſified in parts.

In the *ant-eaters* and *armadillos* the bodies of the laſt ſix cervical vertebræ are large and compreſſed. They are conſolidated to each other by anchyloſis. All the *edentata* have a gutter in the anterior part of the bodies of the cervical vertebræ, in which the œſophagus is placed.

In the *camel*, *camelopard*, and other quadrupeds with long and flexible necks, the ſpinous proceſſes are ſmall, or almoſt obliterated. In the ſhort-necked *ruminants*, as the *common cattle*, the tranſverſe proceſſes form two angles or double tranſverſe proceſſes. In both the *ruminants* and *ſolipeda* the bodies of the cervical vertebræ have a longitudinal ridge along their front.

The large quadrupeds, in conſequence of the great weight of their heads, have that peculiar elaſtic ſubſtance which is called ligamentum nuchæ of a great ſtrength. In the *horſe*, the attachment of this part to the dorſal vertebræ is two hands broad. It is alſo connected by proceſſes to ſome of the cervical vertebræ. In the *elephant* it is of an enormous ſize, and is inſerted into a foſſa at the back of the occipital bone.

In the *porpoiſe* and *dolphin*, the two firſt vertebræ are oſſified together. In the *grampus*, the firſt three or four are anchyloſed, and in the *cachalots* (*phyſeter*), the ſix laſt are united into one maſs, and the bodies of the five middle vertebræ are reduced to an extreme thinneſs.

The *dorſal vertebræ* want ſpinous proceſſes in ſome ſpecies of *bat*, and in others there are little tubercles in the place of the ſpinous proceſſes. In all this genus the canal for lodging the ſpinal marrow is very wide where it paſſes through the dorſal vertebræ.

In all the long-necked and heavy-headed quadrupeds, the ſpines of the dorſal vertebræ are remarkably large and long, particularly in the *elephant*, *camel*, *camelopard*, and *horſe*. The ſize of the ſpinous proceſſes in theſe animals is neceſſary for the attachment of the ligamentum nuchæ.

The dorſal vertebræ of the *whale tribe* have at firſt the articular proceſſes at the root of the tranſverſe, but towards the ninth vertebra there are only the ſuperior ones; for at this diſtance theſe articular proceſſes turn backwards to the baſe of the ſpinous proceſſes next the head, and form a kind of groove, which receives the preceding ſpinous proceſs.

In the *lumbar vertebræ* there is great variety with reſpect to number, as is ſhewn by the foregoing table. When a quadruped is diſtinguiſhed by a long body, it is uſually found to be occaſioned by the number of the vertebræ of the loins. The ſpinous proceſſes are long in the *dog* and *cat* genera, and have an inclination towards the head. This likewiſe takes place in ſome degree in the *monkey* kind.

The motion of the lumbar vertebræ is more or leſs reſtrained in moſt quadrupeds, by the external ſide of each poſterior articular proceſs having a point directed backward, ſo that the anterior articular proceſs of the next vertebræ is received between two prominences.

The tranſverſe proceſſes are very large in the *ox*, *horſe*, &c.; but are particularly ſo in the *whale* tribe, for the purpoſe of affording a ſurface for the attachment of the great muſcles which move the tail, and give theſe animals the figure of fiſhes. There is a gradual change of form and ſize in the vertebræ of the poſterior portion of the ſpine in the *cetacea*, but no marked diſtinction into the lumbar, ſacral, and caudal vertebræ.

The breadth of the *ſacrum* in man evidently ariſes from the erect poſition of his body. The few mammalia that occaſionally ſtand upon the poſterior extremities, as the *monkies* and *bear*, have it broader than quadrupeds in general. In theſe laſt it is an elongated triangle, and is the continuation of the ſpine. This bone has large lateral proceſſes at its anterior extremity in the *horſe*.

The ſpinous proceſſes are uſually more eminent upon the ſacrum in quadrupeds, than in man or the *monkey*. They nearly join to form a high ſharp ridge in the *rhinoceros*, and many of the *biſulca*. This creſt is very remarkable in the *mole*.

The *vampyre bat* is the only example in mammalia of a total want of *tail* or *caudal vertebræ*. The ſacrum of this animal terminates in a long point.

The *vertebræ of the tail* are uſually very numerous in mammalia. Thoſe next the ſacrum have the ſame proceſſes as the vertebræ of the other portions of the ſpine, and alſo a canal for holding the medulla ſpinalis. The vertebræ towards the extremity of the tail want the ſpinal canal, and have only ſmall eminences or tubercles in place of the tranſverſe or ſpinous proceſſes. Thoſe animals that employ their tail in ſwimming, as the *cetacea*; in building, as the *beaver*; or for progreſſion by leaping, as the *kanguroo*, have the proceſſes of the caudal vertebræ large and ſtrong. The *beaver* has the breadth of the tail increaſed by the ſize of the tranſverſe proceſſes, and has alſo inferior ſpinous proceſſes, which are larger than the ſuperior, for the purpoſe of giving attachment to the great muſcles by which this animal's tail is ſo forcibly depreſſed. The tranſverſe proceſſes only diſappear very near the extremity of the tail in the *cetacea*.

In thoſe quadrupeds that make much uſe of the tail, there is generally found a ſeries of ſmall double bones upon the under ſurface of the joints of the vertebræ, from the third or fourth to the ſeventh or eighth. In the *cetacea* they are very remarkable, and deſigned to perform the ſame offices as the inferior ſpinous proceſſes of fiſhes' tails. They are ſometimes anchyloſed in pairs; but, generally, their edges touch, and each pair forms a ſort of inverted Gothic arch ſomewhat ſimilar to the inferior caudal ſpines of fiſhes.

Thoſe that have prehenſile tails, as one diviſion of *monkies*, have upon the inferior ſurface, and at the baſe of each body of the caudal vertebræ, two little tubercles, between which the flexor muſcles of the tail paſs.

The *ribs* of mammalia, both the true and the falſe, are very various with reſpect to number. They appear, however, to be not fewer in any inſtance than twelve, the number found in the human ſubject: as will appear by the following table, extracted from Cuvier's "Comparative Anatomy."

Table of the Number of Ribs in mammiferous Animals.

Species.	Total.	True.	Falſe.
Man	12	7	5
Sai, or weeping monkey	13	9	4
Ourang	12	7	5
Pongo	12	7	5
Ternate bat	13	7	6
Common bat	12	7	5
Mole	13	8	5
Hedge-hog	15	7	8
Bear	14	9	5
Seal	15	10	5
Glutton	14	9	5
Racoon	14	9	5
Otter	14	9	5
Lion	13	9	4
Cat	13	9	4
Wolf	13	9	4
Opoſſum	13	7	6
Hare	12	7	5
Guinea-pig	13	6	7
Three-toed ſloth	16	8	8
Long-tailed manis	13	6	7
Elephant	20	7	13
Hog	14	7	7
Rhinoceros	19	7	12
Dromedary	12	7	5
Camelopard	14	8	6
Ox	13	8	5
Stag	13	8	5
Horſe	18	8	10
Dolphin	13	6	7
Porpoiſe	13	6	7

The ribs are thick and broad in the large herbivorous quadrupeds, which are employed as beaſts of labour; the ſtrength of the ſpine, and its capability of ſuſtaining great weights, depending very much upon the ſize of the ribs, and the figure they give to the trunk of the body.

In all the quadrupeds that protect themſelves by rolling the head and extremities under the belly, when attacked by other animals, the ribs are remarkably ſtrong, and cloſely ſet together. This conformation is to be obſerved in the *common hedge-hog*, but much more in ſome of the *edentata*, as the *armadillo* and the *ant-eaters*. The two firſt ribs of the *armadillo* are exceſſively large in proportion to the others, and in the *two-toed ant-eater* the ribs are ſo broad, that they overlap or reſt upon each other, which gives this animal a greater ſecurity than it could derive from having the parietes of the thorax formed of one piece of bone.

The ribs of the *ornithorhynchus paradoxus* and *echidna hyſtrix* are curiouſly formed. The ſix true ribs are each compoſed of two pieces united by an intermediate cartilage, like the ribs of birds: the piece connected with the ſpine is longer than the other. The falſe ribs of theſe animals terminate in broad, flattened, oval plates, which are connected together by elaſtic ligaments.

The ribs have leſs curvature upon their ſides in thoſe quadrupeds that want clavicles than in the others. Thoſe with clavicles have a cheſt ſhaped more nearly like the human, but in the quadrupeds which never uſe the anterior extremity as a prehenſile member, the cheſt is flattened or narrowed upon the ſides, eſpecially towards the ſternum. The *cetacea*, however, notwithſtanding they have no clavicles, have a cylindric thorax, or one rather wider from ſide to ſide, than from above downwards.

The *ſternum* in mammalia differs from the human generally in being longer in proportion to the body, being a rounder and narrower bone, and compoſed of a greater number of pieces.

The *ourang-outang* and the *pongo* have a flat broad ſternum like man, but in all the other *monkies* it is narrow, and compoſed of ſeven or eight bones.

In moſt quadrupeds it projects a little forwards beyond the line of the firſt rib, but in the *mole* this projection is very extraordinary; it paſſes forwards for almoſt as great a diſtance as the bone makes a part of the cheſt. This anterior portion is compreſſed upon the ſides; is like a ploughſhare, and ſuſtains upon its ſides the clavicles: by this ſtructure the anterior extremities of the *mole* are carried forwards under the neck, occaſioning the appearance of a want of neck, and the animal is enabled to excavate the earth for the admiſſion of its body by the fore feet with extraordinary rapidity.

The anterior end of the ſternum is curiouſly formed in the *bats*; it is enlarged into the figure of a T, the ſuperior branches of which paſs over the ribs and are joined to the clavicles.

The *hog* has the ſternum narrow anteriorly, and large behind.

In the *cetacea*, the ſternum is ſhort, thin, and even broader in proportion to its other dimenſions, than in man.

The *clavicle* is a bone required for the motions of the anterior extremity in the outward or inward direction. It exiſts neceſſarily, therefore, in all animals that employ the arm as a prehenſile or mechanical member, or as a wing. There is a perfect clavicle in all the *monkey* tribe, the *cheiroptera*, the *opoſſum* family: in the *mole*, *ſhrews*, and *hedgehogs*, amongſt the *plantigrada*: in the *ſquirrels*, *rats*, *beaver*, *porcupine*, and *kanguroo*: in the *armadillos* and *ant-eaters*: in the *ſloths*, &c.

The *digitigrada*, and ſome of the *ſaltigrada*, have an imperfect clavicle, (*os claviculare* of Vic d'Azir.) This is a ſhort bone ſuſpended merely by the muſcles, and not attached either to the ſternum or the ſcapula.

The clavicle is entirely wanting in the quadrupeds which employ their anterior extremities for progreſſive motion, as all the *hoofed* quadrupeds, the *daman*, the *cavy*, the *pangolins*, and in all the *cetaceous* tribe.

The clavicles of the *ourang-outang* reſemble thoſe of the human ſubject.

In the *bat*, they are remarkably long and ſtrong.

The clavicle has an extraordinary thickneſs in the *mole*. It is nearly ſquare, being more broad than it is long.

In the *two-toed ant-eater*, this bone has the figure of a rib.

In the *ſloths*, the clavicle has a proceſs from the extremity next the ſternum, which forms nearly a right angle with the axis of the bone.

The *ſcapula* exiſts in all mammalia, but its poſterior angle is moſt elongated in thoſe ſpecies which have the moſt complicated motions of the anterior limbs or the arms.

It is in the *monkies* and *lemurs* a triangular bone, of which the inferior or poſterior edge, and that next the ſpine, are larger than the anterior ſide, but not ſo much larger as they are in man.

The *cheiroptera* or *flying mammalia*, have the edge of the ſcapula next the ſpine very long, and the poſterior very acute.

The body of the ſcapula in the *hedge-hog* is narrow, and the edge next the ſpine not extenſive, but the whole is conſiderably elongated.

In

In the *mole*, the ſcapula is a long narrow bone, which does not exhibit the diſtinction of ſupra-ſpinous and infra-ſpinous ſurfaces upon the back; there being no ſpine except near the poſterior margin, and before the tubercle which correſponds to the acromion. The ſcapula of the *mole* lies parallel to the vertebræ, and reſembles a good deal both in form and poſition the ſame bone in *birds*.

In quadruped, generally, the edge of the ſcapula next the ſpine is rounded, and the poſterior angle thus rendered blunt. The ſpinous proceſs of the bone is ſituated about the middle of the body, or even lower.

In thoſe quadrupeds that want clavicles, the acromion ſcapulæ is not ſo prominent as when theſe bones exiſt, and there is another proceſs which points backwards almoſt perpendicular to the ſpine. This proceſs is alſo found in the *hedge-hog* and *opoſſums* which have clavicles. In the *hare* the recurrent proceſs is very long.

The coracoid proceſs of the ſcapula is commonly wanting in thoſe that have only the rudiments of clavicles, and more conſtantly where theſe bones do not exiſt.

In the *ruminants* and *ſolid-footed* quadrupeds, the ſcapula has neither acromion, coracoid, nor recurrent proceſs.

The *cetacea* have a thin flat ſcapula. The edge next the vertebræ is round and broad, ſo that the whole bone has much the figure of a ſaw. In the genus *delphinus* the ſpinous proceſs is near the cervical edge of the bone, and does not form an angle with the infraſpinous ſurface, of which it ſeems the continuation. The ſupraſpinous foſſa has a deep concavity, which appears to ariſe from a deficiency in oſſification. Above the humeral angle, there is a projecting plate continuous with the ſpinous proceſs, which appears to correſpond with the acromion. In the other genera of the *whale* tribe, the ſupraſpinous foſſa is ſtated by Cuvier as being leſs diſtinct.

The *humerus* of mammalia varies in length and thickneſs, and in the elevation of its proceſſes.

This bone is longer in the *bat* and the *tardigrade* quadrupeds, in proportion to the reſt of the anterior extremity, than the humerus of the human ſubject. In quadrupeds, generally, however, it is much ſhorter. Thoſe that have the metacarpal bones long, have the humerus ſo ſhort, that it is concealed in a great meaſure by the muſcles of the limb and the ſkin of the thorax, from whence the ancient anatomiſts fell into the error of ſuppoſing, that the elbow was turned forwards in quadrupeds, the joint of the carpus being miſtaken for that of the elbow. It is cuſtomary with people ignorant of comparative anatomy, ſtill to miſcall the part correſponding to the waiſt in quadrupeds the elbow.

This bone is alſo very ſhort in the *cetacea*, and has a large ſpherical head.

The ſhorteſt humerus, and the thickeſt with reſpect to its length, is found in the *mole*, which animal is diſtinguiſhed by many peculiarities in its ſkeleton. It has beſides a very ſingular form. The two ends of the bone are ſo much expanded and changed from the uſual appearance of theſe parts, that they are with difficulty recognized. There is a ſmall proceſs which takes the place of the head of the bone, and is articulated with the ſcapula. There is another articular ſurface, apparently correſponding to the great tuberoſity, which alſo forms a joint with the clavicle: between theſe two the top of the humerus is deeply hollowed. The creſt of the little tuberoſity is ſo large, that it reſembles a ſquare placed vertically, with the linea aſpera at top. The body of the bone is bent towards the top, ſo that the part which forms the joint with the ulna points directly upwards; by which means the elbow of this animal ſtands above the ſhoulder, and the palm of the hand is turned outwards. This formation of the arm enables the *mole* to throw the earth to each ſide when it buries itſelf.

The humerus of the *beaver* is conſiderably enlarged at the condyles. It has alſo a large tranſverſe proceſs, at about the diſtance of one-third from the top.

In the *hog*, *tapir*, and *rhinoceros*, the humerus has the great tuberoſity divided into two parts. The linea aſpera alſo of the *rhinoceros* terminates in a very high tubercle. Something ſimilar exiſts in the *horſe*.

The *biſulca* generally have the great tuberoſity very high, and the linea aſpera prominent.

In moſt quadrupeds, the great tuberoſity is elevated above the head of the humerus.

In thoſe mammalia that employ the upper extremity for other purpoſes than walking, the *bones of the fore-arm* exiſt diſtinctly, and preſerve nearly their proper proportions, as in man. But in the true quadrupeds, the *ulna* declines in ſize, and becomes in ſome a mere appendage to the *radius*, which is the principal bone of the fore-arm in moſt quadrupeds. The exiſtence of two bones in the fore-arm is only neceſſary on account of the motion of ſupination. Where the ſupine ſtate of the member would be inconvenient in the progreſſion of the animal, we find the ulna either anchyloſed to the radius, or entirely abſent.

The *ulna* in the *ourang-outang* reſembles that of man In the *monkey tribe*, generally, the coronoid proceſs of the ulna is narrower, and the bone is more compreſſed than in man. The articular ſurface of the radius alſo is deeper. There is often a hole found in the cavity at the back of the humerus, which receives the olecranon.

In the *digitigrada*, the olecranon is compreſſed, and projects more backwards; and the coronoid proceſs is diminiſhed before. In the *dog* there is a little cavity in the end of the radius, for the reception of the external proceſs, or leſſer head of the humerus, and a ridge for the furrow that divides it from the anterior part of the pulley, by which the rotation of the radius is a good deal reſtrained.

In ſome of the *ſaltigrada*, as the *cavy*, the *hare*, the *rat*, and others, the coronoid proceſs of the ulna is entirely obliterated, and the radius covers the front of the articulation. The head of the latter bone forms a hinge-like joint, having a cavity for the leſſer head of the outſide of the humerus, and a ridge for the anterior part of the pulley, that is occupied in man by the coronoid proceſs of the ulna.

In the *rhinoceros*, the *tapir*, and *hog*, the ulna is entirely behind the radius. They move as one bone upon the pulley of the humerus. The leſſer head of the latter bone is quite effaced inferiorly. The ulna and radius of theſe animals are notwithſtanding diſtinct, but ſtill are incapable of rotation.

In the *elephant*, the coronoid proceſs is divided into two ridges with hollow ſurfaces, which revolve upon the projecting parts of a ſingle hinge. Between theſe the head of the radius is placed. It is ſmall, and ſuſtained by the external ridge, and the middle channel of the hinge or pulley: for as it is oblong, it cannot turn upon it. The lower part of the radius is directed towards the inner ſide of the leg, which is therefore always in the pronated poſition. The inferior head of the ulna is larger than that of the radius, which Cuvier ſays does not occur in any other animal in this whole claſs.

In the *cloven* and *ſolid-footed* quadrupeds, the ulna is united immoveably to the radius almoſt throughout its whole length. This union is oſſeous after a certain period, ſo that they might be conſidered as one bone. They form together a hinge-like joint, with the pulley on the end of the humerus, which does not admit of any rotatory movement.

Where the anchyloſis is incomplete of the two bones in theſe
