Mr. Douglas, gr. to F. Whitbourn, Esq., Loxford Hall, Ilford, was the only exhibitor of new *Hyacinths* in the class devoted to varieties which have not before been exhibited, and he took the 1st prize with *Diana*, single dark blue; *Prince Imperial*, single parplish blue; *Alice*, single red; *Oxford*, single dark blue; *Helen*, single pale rose; *Starlight*, single blue. In the class for twelve *Hyacinths* (amateurs), Mr. Douglas was again 1st with an excellent group, including fine spikes of *Von Schiller*, single red; *L'Innocence*, single white; *Grand Lilas*, single blue; *Grandeur à Merveille*, single white; *Koh-noor*, single red; *Ida*, single yellow; *General Havelock*, and *King of the Blues*. Mr. G. Tomes, gr. to H. Wetenhall, Esq., The Poplars, Seven Sisters' Road, N., was 2d. The same exhibitors also occupied similar positions in the class for twelve *Tulips*,

so large a variety of plants been introduced; never, perhaps, have there been more of the description styled "new," which term, however, must be admitted to hold a very different sense than the best and the most successful. And upon few occasions has the general effect been so lively and pleasing. This came principally from the abundance of bulbous flowers, Hyacinths in particular, and of the beautiful phalanxes of Cyclamens. The gay and cheerful colours of these last made the visitor forget the dulness of the day, which, unhappily, though fine, was not blessed with a single sunbeam, and nowhere else in the world could we more clearly than on the first floor front of the Manchester Town Hall. Hyacinths, however, like the lady in Spenser's *Entry Queen*, are gifted with the pleasant power that "makes a sunshine in the shady place," and their presence in fair plenty was thus most opportunely useful as well as contributive to the excellence of a display in many respects exceptionally meritorious. The long-continued severity of the weather, the imminent danger of rain and sleet and reduction of temperature, naturally had the effect of keeping away several of the principal local amateurs who is accustomed to give welcome to at the Manchester shows. Their place was well supplied, however, by nurserymen—two or three coming in strength. Amateurs grow plants simply for pleasure, nurserymen grow them for sale; they cannot afford to wait for fine days, and, somehow, by a kind of instinct, they seem to stand back and make way for the non-professional. Such, at least, is observable on the occasion of the minor shows in the provinces. The pre-eminent features of the show on the 16th inst. consisted in a group of ten Orchids from Dr. R. F. Ainsworth, which received the Society's Gold Medal; and in a conspicuously well-filled table set out by Mr. B. S. Williams. As a very effective among the former may first be named a couple of plants of *Dendrobium crassinode*, loaded with bloom, and wanting only foliage in order to be perfect. Were it not that the *Mezereon*, the *Almond-tree*, the *Forsythia*, and scores of the *Amentiferae*,—pleasing enough in their way, have the same fancy for blooming on leafless stems, one might almost suppose it congenious with the oddity of the archibulous race in regard to structure and habitations. But the circumstance is too common, and is illustrated in plants belonging to orders too widely different, to allow of its being regarded as anything more or less than one of Nature's fixed, though inconsistent, manners and customs. We have only to remember that *Flora* is of the feminine gender, and waywardness is the very thing to be expected. The Orchid, however, which most attracted the attention of the *connoisseurs*, was the owner's hybrid, *Dendrobium Ainsworthii*, a very pretty plant, exhibited a year ago, and described and figured in the *Gardener's Chronicle*, but then only a rudiment; now it is tall and elegant, and clothed with bloom from head to foot, with green leaves in abundance. After these a very noticeable plant was a beautiful example of *Odontoglossum marmoraceum*. The brownish amber centre of its otherwise pure white flower is very remarkable, being constituted of many broken concentric rings. *Lycastes* and *Cypripediums* made up the ten. Mr. B. S. Williams' plants were at once referable to "new and rare," and to highly finished among the relatively old. Such, perhaps, is the division that all collections admit of, or ought to admit of, for high finish is by no means universal; but on the present occasion it was very marked. Among the novelties the grand attraction was a promising plant of the *Echmea Marie Regina*, from Costa Rica, of which, we believe, Mr. Williams holds the entire stock in Europe. Its appearance is certainly very imposing. The foliage, as would be expected in a Bromeliad, is of the Pine-apple type; the solitary flower-shaft is clothed at the upper part with large and brilliant magenta-coloured bracts, erect at first, but subsequently pendulous, and at the top of the inflorescence, the bracts are before the expansion of the corollas, creamy white, but in due time to be tipped at every point with violet-purple. *Geonoma gracilis*, in this collection, reminded one of *Cocos Weddelliana*, for which *Palm* it will form an excellent companion. Alongside of it were several hybrids, reckoning, of course, as "new" plants, the principal being *Amaryllis Mendelii*, species all in the head-stone. *Agus*, curious in its green and chocolate several very engaging varieties, counting also as "new" plants, which, of course, they must be allowed to be, so long as difference of structure is not insisted on as passport to the title. Very beautiful in this class were Mr. Williams' examples of *Abutilon Sellowianum marmoratum*, an immense improvement on the old *A. striatum* Thomson, in its more advanced stage; whether the combination will be preserved in the adult plant of course remains to be proved. Very inviting, also, as a good dinner-table plant, was Mr. Williams' *Anthericum* (what species?) variegatum, understood to be a rival of the *Pandanus Veitchii*, with which it may certainly contend in elegance of form and in

coloration, with the advantage, upon its own side, of smooth-edged instead of spinous leaves; *Ficus Parcellii*, *Adiantum gracillimum*, *Dendrochium glaucum*, the racemes of tiny flowers looking like sheaflets of Wheat ears; *Tillandsia Lindeni*, reminding one of a blue Iris or Marica; *Masdevalla Lindeni*, the best specimen ever shown in the North of England. *Calamus ciliaris*, *Dendrobium Jamesianum*, and *Odontoglossum Roezlii* likewise held their own among the new and rare; while of *Odontoglossum Alexandræ* there was a raceme so grand and luminous that no one at the show could speak could say he had ever beheld the like of it. Mr. Williams came well to the front also with Cyclamens, a bank of about fifty, with a dozen besides of the strain *giganteum*. To those who remember what the Cyclamen persicum was only thirty years ago, the advance made in the development of this lovely plant is almost incredible. It speaks very plainly for the potentiality of improvement that lies hidden away in floral Nature. If flowers were made for the pleasure and solace of man, it is very certain that man in turn was made for the flowers, just as he was made for the cereals, the vegetables, and the fruit trees, none of which would ever have assumed the forms under which they are now familiar had not the ingeniously constructive animal we designate the human race been introduced upon the scene as workmen on their behalf. How many more flowers are to be expected to follow in the wake, first of the ancient *Auricula* and *Carnation*, now the modern Cyclamen, we do not know; but certainly our florists need not fear that we are approaching even the beginning of the end.

From the Royal Nurseries, Ascot, there were sent up, by Messrs. Standish, some good new varieties of Clematis and Azalea, again very interesting of their kind. We should like to be informed, however, whether this singular basket of great white stars of Clematis, and that other of great lilac stars, placed the plant before the public in the way that it grows naturally, or can even be made to grow. If not, is it quite legitimate so to exhibit such plants? The charm of a lovely plant consists not more in its intrinsic beauty than in its upright and downright honesty in every part. Nothing is more painful than insincerity, or even the suggestion of it, and floriculture, when such things should never give occasion for the least thought of an untruth. Although suggested by the Clematises referred to, the above remark has far less reference to them as individual examples, which, after all, perhaps they were not, than to incomparably more fragrant ones, alas! only too common, bedding-out, so to speak, in pots. A plant that is really good will always speak for itself, and needs none of the ingenuities of "making-up." Mr. T. Perkins, of Leamington, sent forth the beautiful double-flowered Chinese Primula. No doubt the variety is interesting, but as a matter of personal taste we would fifty times rather see the sweet and simple flower of five petals and yellow eye. Mr. R. S. Yates sent some capital trays of cut Camellias and Rhododendrons, and, better still, half-a-dozen beautiful demi-arches of Solomon's Seal, a flower that belongs by birthright to the time of the year, and which he manages to improve "before the swallow dares." From Messrs. J. & W. Yates came a nice little collection of Conifers, and another of the "sculpturesque" section of plants, Alocas, and so forth. Mr. Thomas Studd, of Heaton Nursery, followed creditably with miscellaneous plants, and gave also quite a new feature to a town-hall show, and more particularly to an early spring one, in the shape of six or eight choice bouquets. We have so often had to look with sorrow upon the floriferous "Mushroom" and its lace-petticoat, that it was quite refreshing to note the taste which in Mr. Studd's designs came to the rescue. Mr. S. Cooper, of Timperley (amateur), sent a very pretty lot of early and accelerated spring flowers, chiefly bulbous. Mr. Sherratt brought from Knypersley a grand branch of the *Kumquat*, loaded with its miniature Citrons; and, lastly, the Society's gardens at Old Trafford came in a showy and in the most creditable contribution, outsiders, in the shape of a bank of tropical and greenhouse evergreens, with foreground of the never-too-highly-valued *Hyacinth*.

The following awards were made by the Committee:—

Collection of Orchids: The Society's Gold Medal, Dr. R. F. Ainsworth.

First-class Certificates for new plants:—*Adiantum gracillimum*; *Abutilon Sellowianum marmoratum*; *Echmea Marie Regina*; *Amaryllis Mendelii*; *Cypripedium Argus*. Mr. B. S. Williams, Holloway. *Primula sinensis*, Prince Arthur, Mr. Perkins, Leamington; hybrid Clematis, Mr. Quilter; hybrid Clematis, Mr. Badger; and hybrid Azalea indica, Sigismund Rucker, Messrs. John Standish & Co., Ascot. *Cypripedium Harrisonianum*, Mr. Robert Ayles, Whalley Range. *Oncidium cucullatum*, Mr. W. Leach, Edgemoor.

First-class Commendations:—Miscellaneous collection of plants, Mr. S. Cooper, Timperley. Miscellaneous collection of Palms, Mr. George Toll. Floral Bouquets, Mr. Thomas Studd, Grange Nursery,

Heaton Mersey. Cut Orchid Blooms, Mr. S. Barlow, Stoke Hill, Middleton. Cut Camellia and Rhododendron Blooms, Mr. R. S. Yates, Brocklands. Collection of Miscellaneous Plants, Messrs. G. & W. Yates. Grapes, Lady Downe's, Mr. John Rylands. Cultural Certificates:—Grapes, Mr. John Downe's, Mr. John Potts, gardener at Manley Hall; *Odontoglossum Alexandræ*, Mr. B. S. Williams.

East London Amateur Floricultural Society. — This highly successful amateur floricultural society held its Spring Flower Show—and it is the only amateur society that ventures upon such an exhibition around London—on the 17th, 18th, and 19th inst. The exhibition was held at the Bow and Bromley Institute, and consisted of a stage of nearly 400 feet in length, embellished by between 400 and 500 pots of Hyacinths, and nearly as many Tulips, &c. As regards Hyacinths, Tulips, forced Azaleas, Rhododendrons, Spireas, Solomon's Seals (huge specimens of which were very imposing), &c., it was superior in point of merit to the display at South Kensington on the 17th. Messrs. Hill and Parker staged some remarkable Hyacinths, Tulips, and Narcissis. The spikes of the former averaged 15 inches in length, and had generally ten to twelve tiers of bloom. Narcissis were remarkably fine also, averaging twelve to fourteen blooms to the spike on the generality of the spikes. The special classes were variously well contested, and the arrangements neat and effective. *W. E.*

The Villa Garden.

KITCHEN GARDEN.—As soon as the weather is in keeping with the traditional character of that which should distinguish the time of year, a period of busy, even of restless activity will have set in for gardeners. If any vacant pieces of ground from which green crops have been cleared require to be dug over, let them be manured and dug at once. The drying March winds will penetrate the soil and pulverise it, and render it fit for working for crops when required. Such necessary work as this cannot be got through too quickly.

Peas.—If some early Peas are already sown, then follow on with successive crops of this most popular vegetable. Such moderate growing varieties as James' Dwarf Prolific, Premier, Veitch's Perfection and Omega, with a new dwarf variety of Mr. Laxton's raising, are best adapted for small gardens. In large gardens, where space is not so circumscribed, such fine types as Champion of England and Ne Plus Ultra may be sown, and require to be in good soil. All the varieties of Peas here refer to the middle class of wrinkled marrows, which have a branching habit of growth, and consequently should not be sown so thickly as the early-round-seeded varieties that branch but very little. The last-named kinds pod mainly at the top of the haulm; the former, or wrinkled marrow type, nearly the whole length of it. The sorts named above can be strongly recommended for exhibition as well as table purposes, if the show takes place from the middle of July to the middle of August. Dishes of Peas form classes in all local shows now-a-days, and this custom serves the excellent purpose of bringing into cultivation in village and cottage gardens the bestermost sorts of Peas of recent introduction. For exhibitions held at the end of June and the beginning of July, and which are somewhat early in relation to outdoor crops, one of the best and most reliable sorts is Laxton's William the First. Peas must have rich ground to produce large and continuous crops, and it is a good plan to sow them in the old Celery trenches; these are generally well manured, and the crop does not exhaust the whole of the manure so liberally applied. Sow Peas in drills about 2 inches in depth, or even less; they strike their main roots down into the soil, and some soil can be drawn up to the rows when required, in the same manner in which gardeners earth up Potatoes.

BROCCOLI, CABBAGES, &c.—Numerous other seeds should now be sown, or at least directly the ground is in a fit state to receive them; such as Broad or long-pod Beans to succeed the early ones. The Broccolis, Cabbages, Kales, Cauliflower, Carrots, Lettuce, Onion, Parsley, Parsnip, Radish, and Spinach should all be got in as quickly as possible. It is of great advantage to get seeds of the Brassica tribe—Broccoli, Cabbage, Brussels—sown early in Winter Greens, the two last especially—soon early in the season, as the stronger the plants are when put out at mid-summer and the weeks following, the better. On the other hand, small plants are often checked by spells of drought, and fail to grow into size by the autumn. The Brassicas can be sown in small beds, the seeds being scattered broadcast, and then, at the proper time, planted out in their winter quarters. Beet, Parsnips, Carrots, and Spinach should be sown in shallow drills, a foot apart, at least. Sow thickly, which will tend to reduce the

labour of thinning out by-and-by. Onions may be sown either broadcast or in shallow drills, 8 or 10 inches apart. All successful cultivators recommend the liberal manuring and deep digging of soil intended for Onions. The ground should be trampled or rolled down fairly hard, before the seed is sown. Place it thinly in shallow drills, only just covering the seed with soil. Onions are now much grown for exhibition purposes, and those who make a point of showing them sow very early in the season—in January or early in February—so as to get a good start of the season, as they say. In cases where ground is scarce, Lettuces and Radishes may be sown sparingly over the Onion beds, as they can be removed before they can do material injury to the Onion crop. The Reading or White Spanish Onion is the best for a general crop. Of Lettuce sow that fine Cabbage variety, the Leyden White Dutch, which is unsurpassed for summer culture, and is extremely crisp and sweet and pleasant to the palate; and the Paris White Cos where the upright Cos Lettuces are preferred to the Cabbage type. It is always well to sow some of each.

POTATOS.—Potato planting must also be proceeded with; the earliest kinds in blast should be sown in the ground by the first week in March, if the weather permits at all. For the best results, the weather the planting might be carried right through, from the earliest to the latest varieties. As a general rule the ground should be forked over, and the planting proceeded with as the ground is dug. Break the soil well to pieces immediately about the Potato sets. It is not desirable for manure to be put in with the tubers as the work proceeds, but far preferable that ground intended for Potatoes should be manured in the autumn, and allowed to settle before the time for planting. For the early crop plant Veitch's Improved Ashleaf, and follow on with Rector of Woodstock, Yorkshire Hero, and Excelsior Kidney; these, or some such well-known high-class varieties, will yield almost all that is required where gardens are small. If nice clean samples are wanted for exhibition—and it is now as much the practice to grow Potatoes for this purpose as anything else—it will greatly assist the production of fine show samples if a light mixture is made up to put in with them, such as some old turf, decayed vegetable refuse, leaf-mould, and a little soot and lime, or wood ashes; and this will also tend to invigorate the crop, and, by reason of its nourishing quality, yield a larger return. Early Potatoes, and in fact all varieties of moderate growth of haulm, should be planted about 12 inches apart in the rows, and the rows should be about 2 feet apart from each other. The teachings of experience have shown that wider intervals tend only to waste of ground, and closer ones serve to check the perfect growth and maturation of the crop by overcrowding. Later and stronger growing varieties should be planted 15 inches apart in the row, or a little nearer or farther according to the size of the tubers. The rows should be 2½ feet apart, or should the soil be rich, this distance may be extended with advantage.

Law Notes.

OLDROYD v. MYTTON: Feb. 22.—This was an action brought by Messrs. Oldroyd & Son, nurserymen and seedsmen, Shrewsbury, in the Shrewsbury County Court, against Captain Mytton, of Garth, for the sum of £110, alleged to be due for shrubs and seeds. The case for the plaintiffs was to the effect that on February 27, 1874, Miss Ann Jane Jones, and Evans, Captain Mytton's gardener, visited their nursery and purchased some trees and shrubs. Evans told the senior partner that Miss Jones was Captain Mytton's housekeeper, and that the plants were for him. They were sent with the invoice to Trefany Court, and the bill was forwarded in the autumn. Some time afterwards they had a letter from Captain Mytton, in which he stated that he did not consider himself liable. In this letter the defendant said he had not the slightest idea that the plants had been put down to him. The idea of his allowing a woman to order trees and shrubs was too preposterous for him to entertain for a moment.

The plaintiffs and defendant, Miss Jones and the gardener Evans, were examined at some length. His Honor (Judge Smith, Q.C.) on giving judgment in this case had to consider the text-books on the law of trade, but at the same time he thought it was a very objectionable way of doing business. If tradesmen liked to run the risk of servants pledging their masters' credit, they must do so at their own peril. The old adage was, "All's well that ends well," and tradesmen sometimes ran the risk, hoping it would all

turn out right. As the plants were there, he had hoped that Captain Mytton would have paid a certain price for them. Whether he would do so or not he could not say. If he did so, it would be as a present from himself or as an equivalent for any benefit he might have derived, or would derive, under his order. He should give judgment for the defendant. The only question he hesitated about was that of costs.—Mr. Redman: We don't ask for costs.—His Honour: That relieves my mind. The only reason why I might not have made Messrs. Oldroyd pay the costs was this—that Captain Mytton has had the shrubs and trees, and I should have been sorry if they had also had to pay the costs. I should be glad to hear that Captain Mytton had (notwithstanding what has happened) in a spirit of magnanimity said, "Oh, I'll overlook it, and give you a cheque for—say £10."

ACTION AGAINST A SEED MERCHANT BY THE AGRICULTURAL AND HORTICULTURAL CO-OPERATIVE ASSOCIATION.—This was an action tried in the Westminster County Court on Thursday last, before Mr. Judge Bailey and a jury, to recover the sum of £21 11s. 11d. from the defendant, Mr. Kopfel, a seed merchant. Mr. Simpson, the chief clerk of the Company, proved the invoice for the goods sold to Robert Simpson, the seed department of the Association, proved the correctness of the invoice of the Company. Mr. Merriman, the solicitor, called upon the defendant, who said he had been formerly seed buyer to the Company; further, that he had a set-off of £19 against the Company, but in cross-examination he showed such an indisposition to reply that the learned Judge, considering him, in the position of a defendant, as an adverse witness, said he could not be subjected to the ordinary rules of cross-examination.

Mr. Alsop, the defendant's solicitor, combated this, which was overruled by the learned Judge, when witness stated that the set-off was the cost price of the goods, that he had 50 per cent. profit on the goods, and that the goods were supplied to him as agent for the Company, and had charged as much as 100 per cent. for goods sold by the Company. Several items, the amount of which were disputed by the defendant, were submitted to the jury.

By the defendant's solicitor, the witness said that there was an agreement between himself and the Company, but it was not produced. It was for commission on all goods sold at 2½ per cent., and on all purchases of seeds. The agreement was not stamped, therefore not admissible in evidence. The learned Judge thought it was a question whether the defendant was or was not a buyer when the debt was contracted. By Mr. Merriman: The defendant said he had purchased plants for the Company, and that his commission on sales formed the amount stated in his set-off. He gave notice to the Company to leave, but there was no settlement of accounts at the time, and he had not received £67 for commission when in the Company's service. At this stage of the case the Judge ordered a non-suit to be entered, as the balance was not proved.

The Weather.

STATE OF THE WEATHER AT BLACKHEATH, LONDON, FOR THE WEEK ENDING WEDNESDAY, MARCH 17, 1875.

MONTH AND DAY.	BAROMETER.		TEMPERATURE OF THE AIR.		Hygrometrical Data from Glaisher's Tables 5th Edition.	WIND.	RAINFALL.

Mar. 11.—Fine, mild, brisk wind, and partially cloudy all day.
 12.—Overcast, dull, cold, and sleet fell during the morning.
 13.—Overcast, dull, cold, and brisk wind throughout. A little rain about 9 P.M.
 14.—Overcast, dull, and cold in morning. Fine, and mild in afternoon and evening.
 15.—Overcast, dull, and cold in morning. Fine, and mild in afternoon and evening, nearly calm throughout.
 16.—Overcast, dull, mild, and next prevailed throughout.
 17.—Overcast, and dull throughout. A little rain in early morning.

In the vicinity of London the reading of the

barometer at the level of the sea increased from 29.69 inches at the beginning of the week to 30.08 inches by the afternoon of the 8th, then turned to decrease to 29.85 inches by the early morning hours of the 9th, increased rapidly to 30.45 inches by the morning of the 10th, decreased to 29.94 inches by the afternoon of the 12th, and again increased to 29.99 inches by the end of the week. The mean reading for the week was 30.08 inches, being 0.24 inch higher than that of the preceding week. The mean readings were alternately above and below their averages throughout the week, the greatest amount in defect being 0.22 inch on the 7th, and in excess 0.31 inch on the 10th.

The highest temperatures of the air at 4 feet above the ground ranged from 57° on the 7th, to 37½° on the 12th, the mean value for the week being 50°. The lowest temperatures of the air varied between 51½° on the 8th, and 33° on the 11th, the mean daily range for the week being 39½°. The mean daily range of temperature in the week was 10½°, the greatest range being 19½° on the 10th, and the least, 3½°, on the 12th. The mean daily temperatures of the air, and the departures from their respective averages, were as follows:—March 7, 50° 2', + 0° 2'; 8th, 53°, + 12° 5'; 9th, 48° 8', + 4° 3'; 10th, 43° 5', + 1° 9'; 11th, 39° 8', - 0° 9'; 12th, 35° 5', - 5° 3'; and 13th, 37° 8', - 3° 2'. The mean temperature for the week was 43° 9', being 3° 3' above the average of sixty years' observations.

The highest readings of a thermometer with blackened bulb in vacuo, placed on grass in the sun's rays, were 119½° and 115½° on the 10th and 11th, but on the 13th 167° was the highest reading. The lowest readings of a thermometer on grass, with its bulb fully exposed to the sky, were 22° and 27½° on the 10th and 11th, but the lowest reading, on the 8th, was 48½°. The mean for the seven low readings was about 34°.

The direction of the wind during the week was S.W. and N.E., its strength gentle.

The weather during the week was somewhat fine, and very mild, except on Friday, which was overcast, dull, cold, and sleet fell during the morning.

Rain fell on three days, the amount being 0.39 inch.

In England the extreme high day temperatures ranged between 62° at Sunderland and 52° at Newcastle-on-Tyne, the general average over the country being 57° nearly. The extreme low night temperatures varied from 34° at Sunderland to 26° at Hull, with a general average of 30½°. The mean range of temperature in the week from all stations was 26½°, the extremes being 32° at Hull and 20° at Newcastle-on-Tyne. The mean high temperatures observed by day varied between 52½° at Sunderland and 46½° at Newcastle-on-Tyne, the general average being 48½°. The mean low temperatures observed by night ranged from 39½° at Blackheath to 34½° at Newcastle-on-Tyne, with an average value of 36½°. The mean daily range of temperature in the week was 12°, the greatest range being at Sunderland, 15½°, and the least at Bristol, 10½°.

The mean temperature for the week was 41½°, being 6½° higher than the value for the corresponding week in 1874, the highest recorded in the week was 44½° at Sunderland, and the lowest 39½° at Newcastle-on-Tyne. The fall of rain at the different stations varied from 1 inch nearly at Bristol, to rather more than one-tenth of an inch at Sheffield, the general average fall over the country being twenty-sixths of an inch.

The weather during the week was fine and very mild, except on one day, viz., Friday, which was dull, cold, and sleet fell during the day; the sky was for the most part cloudy.

Fog prevailed at Liverpool and Bradford on Wednesday, March 10.

In Scotland the highest temperatures by day ranged from 58½° at Aberdeen to 52° at Paisley. The lowest temperatures by night varied between 33° at Aberdeen and 29° at Paisley and Perth, their respective averages being 54½° and 39½°. The mean range of temperature in the week was 23½°. The mean temperature for the week was 41°, being 2½° higher than the value for the corresponding week in 1874, and, therefore, the excess of mean temperature this week was marked in Scotland as well as in England. The highest in the week occurred at Edinburgh, 42½°, and the lowest at Paisley, 39½°. Rain fell at each of these stations, and varied in amount from 2½ inches at Aberdeen to three-quarters of an inch at Leith; the average fall over the country was 1½ inch nearly.

At Dublin the highest temperature was 57½°, the lowest 27°, the mean 43°, and the fall of rain 0.56 inch.

JAMES CLAWSON.

Garden Operations.

(FOR THE ENSUING FORTNIGHT.)

PLANT HOUSES.

ORCHIDS.—March is the commencement of the growing season, and a greater degree of heat and moisture will now be required. The temperature for the East India-house should be kept at 70° by night and 80° by day, when a few degrees more may be allowed by sun-heat; the Mexican-house 60° by night and 65° by day; the cool-house 48° by night and to 58° by day. A strong degree of moisture must be maintained for the East Indian plants. The evaporating pans must be kept full of water; water must be poured over the floors and benches morning and evening; and the pipes may be syringed in the evening, so that the house may become charged with vapour. After a sunny, drying day the plants that have commenced their growth will be all the better with a light syringing in the afternoon; this should be done as soon as the external heat begins to decline. Plants on blocks will now require frequent syringings, and those that are in a growing state will be all the better for a drier atmosphere twice a week. The water for syringing should always be a few degrees warmer than the house, and rain-water should always be used for the purpose. But little ventilation will be required for another fortnight, except on very hot days; it should then be admitted with caution through the bottom ventilators. The wind this month is generally drying and cold, and if allowed to enter the house in a heavy stream it dries up the plants' food. It is advisable to allow the floors to dry up once a day, which will keep the atmosphere of the house sweet.

Calanthe vestita and *C. Veitchii* must be shaken out, have the old roots cut away, and be repotted into a compost of three parts fibrous peat and one of old cow-dung or horse-droppings and turfy loam, with broken potsherd or pieces of charcoal, the whole being well incorporated together. These plants require large supplies of water during their growing season, so that good drainage is indispensable. The pot should be filled with soil up to the brim of the top with the compost, on which the bulbs should be placed; water very sparingly until the young shoots begin to root, after that they will require a good supply, in fact the soil must not be allowed to become dry until the growth is finished. *Calanthe Masuca*, *C. veratrifolia*, and *Sobralias* should have copious waterings with weak manure-water; *Cypripedium* and *Cymbidiums* will also be the better for a little weak manure-water if the pots are full of roots. *Odontoglossum novium* and *O. Phalenopsis* should be syringed pretty freely, they will also require a good supply of water at their roots. This is a very good time to report any that require it. The above two varieties should never be in a temperature below 55°. The small yellow thrips are very troublesome to the *Odontoglossos*, especially to the small leaved-varieties; and frequent sponging must be resorted to by the grower. The young growths of the *Macodvallias* are frequently disfigured by them. The sponging must be done by a very careful hand, as being succulent they are easily broken. Where tobacco smoke can be blown into the young growth the thrips is easily killed. *G. Baker*, *Clapham Common*.

FLOWER GARDEN, &c.

PARTERRE AND MIXED GARDEN.—The winter weather prevailing of late will have retarded operations in this department, and unless alterations that may be in hand are now pushed on vigorously to a close, there will be some difficulty and much labour in getting fresh-laid turf, Box edgings, &c., properly established before dry weather sets in. It is best to avoid transplanting deciduous trees late, but it may in some cases still be necessary to do so, to complete alterations already in hand. In such cases the plants should be removed from place to place as extensively as possible, so that the roots may not suffer from unnecessary exposure, as at this season a slight check in this way soon causes the bark to become contracted, and when this takes place it is a long time before the plants make satisfactory progress. In planting at this late season, care should be taken to wash the earth well in amongst the roots, as success in a great measure depends on this. This should be done when the roots are only partially covered, and the water should be thrown in in quantity, and with some force, so as to wash the earth well into the interstices. Water used in this way will do more in settling and consolidating the soil about the roots than any amount of treading, especially if the ball of the plant is large. Plants heavily watered in this way before being finally covered in will be independent of the water-pot for months after, provided they receive a good mulching of some kind, as all newly transplanted stuff should. The broom and roller should be in almost constant use at this season to keep both grass and gravel walks in first-rate order.

Where large breadths of lawn or greensward have

to be laid down, and the necessary quantity of turf cannot be obtained, measures should at once be taken to prepare the ground, and to sow it down with a suitable mixture of grass seeds. These should be obtained from some of the large and reliable seed-houses, and not, as is frequently the case, from the mangers, cribs, and other feeding-places of cattle. Such seed as is thus obtained is totally unfit for the purpose, containing as it does many seeds of weeds and coarse inferior grasses, that never form a close velvetly piece of turf. Before sowing, the ground should be made perfectly level and firm, so as to prevent any after settling. The margins should then be laid with turf, a foot or so wide, before sowing the seeds. Choose a still day for the latter operation, to prevent the seed from being blown about, and to insure regularity in its distribution. After sowing, scatter some fine soil over it, then rake it well in, and roll down.

Push on with the pruning and training of all kinds of *Wall Creepers*, *Roses*, and trellis plants. See that the shoots are not overcrowded, and make choice of the longest and best-ripened for the purpose of protection round *Vitis Rotunda* may now be removed, and the weak branches should be pruned entirely out, leaving only the strongest and best situated. These should be slightly shortened back, as, on account of their less vigorous growth, *Vitis* *Roses* do not bear such severe pruning as the perpetual and other varieties. Even these are often pruned too severely, and if treated as advised for the above, shortening back the strong wood more or less according to the strength of the plant, much more fine and fine blooms may be obtained than by cutting hard back to a bud or two. The stems of standards that have become mossy should receive a scraping with some blunt instrument, or be well scrubbed with a stiff hard brush, so as to get the bark thoroughly clean and healthy, without which satisfactory results cannot be obtained. After pruning, the beds should be heavily mulched over with good rotted manure, making choice of that from the cow or pig, in preference to any other, especially if the soil is at all light. Roots of *Briars*, *Manetti*, and other *Rose* stocks may still be grafted with success. Select strong pieces of root or young plants of *Manetti*, which should be shortened back so as to leave only an inch or so of stem. To this attach the graft in the usual way, tie tightly, and plunge in close propagating boxes in a temperature of 75° to 80°. Keep them totally dark for a fortnight or so till they begin to unite or start into growth, when light should be gradually admitted. Cuttings of *Pot Rose* that have been forced and have tolerably firm wood, strike freely if placed in brisk moist heat, and these may be put in as the plants go out of bloom, should it be desirable to increase the stock in this way. Many *Roses* do best on their own roots, and are preferable in other respects, as the suckers from stocks are often troublesome. *F. Sheppard*, *Woolverstone Park*.

FRUIT HOUSES.

PINES.—Take advantage of suitable occasions for prosecuting any operations which may have been deferred on account of unfavourable circumstances. If important matters, such as starting fresh plants and potting, and that attention has recently been drawn in this Calendar, are now completed, constant watchfulness over the state of heat in the beds where plants are plunged will be essentially requisite. A temperature of 95° is to be recommended as the most suitable standard for promoting proper root-action in the case of such Pine plants as those alluded to, and for this purpose no means which are employed to generate heat equals that which is obtained from fermenting materials, and that from tan in particular. The directions given in recent Pine Calendars upon this subject should be carried out, the chief object being to induce root-action; until this be accomplished, growth in the plants is undesirable, and more detrimental to future prospects than otherwise; therefore, by all means avoid maintaining a high temperature in the plants, and shade effectually from sunshine when it is powerful, which will not only obviate growing in abundance of air, but will materially assist in preserving a more genial condition about the plants, which under these conditions is so much required. Any plants which have severely suffered from the invasion of worms or drip, or from other causes which have brought the soil into an unhealthy condition, should be examined in all bad cases it should be entirely taken away, and the plants re-started and treated in the same manner as rootless suckers. Maintain a brisk bottom-heat of from 85° to 90° in those beds wherein plants are plunged which have recently been transferred to fruiting pots; by so doing the roots will soon take hold of the new material, and growth will follow, which, as the season advances, with the aid of sunshine and light confined, can be encouraged by making available as far as possible the natural means—solar heat—for the purpose. Ventilate these plants at about 80°, and keep on a liberal supply while the internal temperature does not fall below 85°; close the house at this

degree, and lightly sprinkle the plants overhead occasionally. Natural advantages will now materially assist in Pine cultivation. The plants under proper treatment will quickly make growth, and come into fruit, and give most satisfactory results. *G. T. Miles*, *Wycombe Abbey*.

FIGS.—The early forced crop of Figs in pots will now be rapidly swelling, and syringing them twice daily, and attending to watering the roots, will be the routine till the ripening period arrives. If the pots are well drained, there is little danger of over-watering them at this stage of their growth. The night and day temperature lately advised may still be maintained, and when the weather is favourable plenty of ventilation will be required to make the foliage and young fruit look healthy. In the house where the Figs are planted out, the tying-in and regulating of the terminal shoots, and stopping the spurs at the fifth or sixth joint, will now be required. Keep the house as moist as possible by daily syringings and by damping the paths at shutting-up time, so as to keep the red-spider from attacking the foliage. This is a good time to propagate young plants in cuttings, should it be necessary to increase the Fig collection. The shoots should be selected from 5 to 6 inches in length, with a heel of last year's wood attached. Such cuttings will strike roots readily in bottom-heat. *William Tillery*, *Wlbeck*.

CUCUMBERS.—However much artificial heat we are able to command, it is but a poor apology and substitute for a bright and genial sun-heat—the great lack of which for the past few weeks has not been quite favourable to the growth and fructification of Cucumbers. In such weather as we have lately experienced, it is only by dint of a close and regular attention that a good and continuous supply is secured. Where plenty of heat is at command, however (as it always should be, and nobody can have a perpetual supply without), there should certainly be no lack of Cucumbers at this season. As the days lengthen, and the power of the sun increases, increased vigilance on the part of the grower will also be necessary to guard against red-spider and other pests, for if these now get a strong foothold they will occasion serious trouble and loss, it may be, all through the season. The market grower well knows the importance of maintaining a clean growth; let the amateur imitate the example. The work of cutting over the plants every week must from henceforth never be omitted, for it is the reverse of good practice to cut out large quantities at one time; moreover, there is no saving of time attending it, as well as the danger of removing that which it is desirable to retain. Increase the night temperature to 72°, and that by day to 85°–90°, with sun-heat, and employ a little more atmospheric moisture. For pits and frames, see this week's *Melon Calendar*. Make further sowings as occasion requires, and prepare more fermenting material for frames, as fast as they become cleared of Potatoes, Carrots, winter salads, and the like. Frames never need be uncropped. *Thomas Simpson*.

KITCHEN GARDEN.

If forthcoming requirements in regard to new plantings of *Asparagus* which may be necessary have been considered, and due provision made by manuring and trenching an already well-enriched plot of ground, the plants may now be transferred to the beds at almost any suitable time; we, however, perform the operation when the shoots are just emerging from the soil, and prefer two-year-old plants for the purpose. The long existing character of this plant when subject to even ordinary good treatment is such as does not render a removal of beds often necessary, excepting under certain circumstances. In those places where a part of the stock is annually destroyed in the forcing operation, provision must annually be made to maintain a supply of suitable roots for the purpose. The main object in the cultivation of this delicious and wholesome vegetable—which is doubtless more universally esteemed as being the best of the choice kinds of vegetables—consists in securing large clumps of healthy root and crowns, which, as a natural consequence, produce fine "grass" in abundance. For this purpose we have abandoned the old method of planting three rows in the ordinarily-sized bed of 4 feet 6 inches wide, and now have substituted two rows instead, thus affording considerably more space for the extension of the roots; the plants are considerably diminished in number, although practically more satisfactory results are obtained, both in regard to the quality of the roots for forcing, and the superiority of the "grass" for use. In connection with the cultivation of *Asparagus* a great mistake is committed (not by practical men generally) in tolerating the existence of seedling plants on the surface of properly planted roots in beds; it is a sure means, sooner or later, of frustrating the object in view, if not of ultimately sacrificing them altogether. In planting, we know the soil to be about 3 inches wide, and about 3 inches deep, so that the roots can be put evenly on a flat surface 2 feet apart from plant to plant, and 1 foot on each side from the centre of the bed. We have some planted out on the French

system, single rows, in rows 4 feet apart, the plants being 3 feet asunder, and treed accordingly; so far these promise to give very satisfactory results. Asparagus seed should now be sown thinly in drills about 18 inches apart.

If it has not been already done, a part of the supply of *Horsradish* should be lifted by trenching the ground and clearing it of all waste pieces of roots, selecting that which is fit for use, which should lie laid at the back of a north wall, where it will be ready to hand throughout the whole of the busy period, and retaining the thin long clean pieces of from 18 inches or more in length for transplanting. After the ground intended for it has had an addition of manure, and has been trenched, it should be planted its entire length in rows 18 inches wide and about 3 inches apart. This useful root, which is always in request, is now having more attention given to its cultivation by private growers than it had formerly, which its usual command at all places, considering its importance for many uses. Let the ground which is allotted for new plantings of *Globe Artichokes*, *Khubarb*, and *Seakale* be got ready, so that planting can be effected at the end of this or the beginning of the following month. Do not be hasty in removing the ashes from about the collars of *Globe Artichokes*, as severe frost are still very tender from the effects of the protecting materials. All work, such as sticking Peas, stirring the soil about growing crops, &c., should be kept well in hand, as every week at this season will multiply various warts.

FORCING DEPARTMENT.—Shift *Capsicums* and *Tomat* into larger pots when they need them. 8-inch pots will be ample to obtain strong plants of *Tomato*; out of these they should go into the prepared borders or pots, as the case may be; 12-inch pots are suitable for fruiting these. Put them rather firm into turfy loam, with an admixture of decomposed manure—a third, and mulch the surface with it, to encourage roots there. Another sowing of these plants should be made about the end of the month, for cultivation on the walls outside. All plants which are being raised in heat for outside purposes should be well ventilated on every favourable occasion, to check their being drawn up weakly. Now is a good time to make a sowing of French Beans in a pit, which will come in just before those from outside. *G. T. Miles, Wycombe Abbey.*

Enquiries.

He that questioneth much shall learn much.—BACON.
43. FIGUS PARCELII.—I shall be obliged if some of your correspondents will inform me if they consider the fruit of this plant edible. We have a good-sized fruit swelling on a plant growing in an 8-inch pot. *G. B.* [It is not likely to be good eating, and you had better be cautious in trying the experiment. Eds.]

Answers to Correspondents.

BLANDFORDIAS: *F. J. H.* These should be potted in turfy peat, and grown in a rather warm greenhouse.
FUNGI: *Neto*, 1, 3, and 4, all Polyporus vesiculosus; and 2, *P. lucidus*.
FOUR FOR SANDY SOILS ON THE SEA-COAST: *E. N. K.* If the sand be a drift sand, add some *Elymus arenarius* (Upright Sea Lyme-grass), and *Ammophila* (or *Psamma*) arundinacea, 4 lb. or 5 lb. of each, mixed with clay and straw ropes cut into small pieces and dibbed into the sand. In addition to this, or if the soil have sufficient stability to resist a storm of wind) without it, sow the following seeds per acre. We take this list, with some alteration, from Lawson's *Aerographia*.—

Table with 3 columns: Plant name, With a crop, Without a crop. Lists various plants like Alepeurus pratensis, Avena flavescens, Dactylis glomerata, etc.

ANTHRUM SCHIERZIANUM: *C. W. S.* The seed should be sown in 8000 as it is ripe in Sphagnum moss, and must not be covered over. Your other query shall be answered next week.
CARTES DE VISITE: *X.* We have given no authority to the gentleman in question to use the name of the *Gardener's Chronicle* on his visiting card, and he has no right so to use it.
CONFÈRE: *Seedling.* We do not undertake to answer such questions as yours. Consult our advertising columns.

GRAPES IN WATER: *Old Subscriber.* With care Grapes will keep good in water for three or four months.
HOLLYHOCKS: *E. J. W.* Your Hollyhocks are infested with a fungus—*Puccinia malvacarum*, which was figured and described in our columns, p. 767, 1874. You may try bluing compound and flowers of sulphur, but the safest plan would be to burn them.

INSECTS: *A. B.* The aphid which attacks your Melons and Cucumbers is the same which is found upon several other plants, including the Poppy, hence named *Aphis papaveris*. Perseverance in the plans you have already adopted is the only means of checking the evil which once established in your frames. Better still, destroy the infested plants and get fresh ones. *I. O. W.—H. M.* The insects which have appeared by thousands in your newly made tan-bed for Cucumbers is one of the many species of *Acanthoides* found in decaying vegetable matter. It is not improvable they would attack also the young fibres of the roots of the Cucumber. Soak the beds well with gas-tar and lime-water; soot and strong soapsuds may be mixed with the fluid. *I. O. W.*

MONSTERA: *H. W. C.* *Monstera* was growing against an open wall at Lisbon a few years since. *H. A.*

NAMES OF FRUITS: *W. R. F.* We regret that we cannot name your Apple; it was too much bruised.

NAMES OF PLANTS: *Self.* 1, *Hymenophyllum tunbridgegense*; 2, *Cheilanthes hirta*; 3, *Neprolepis exaltata*. The *Dendrobie* is *D. Pierardii*.—*H. O. P.* *Dendrobium nobile*.—*H. G. S.* *Eranthum albiflorum*.

PEACHES: *F. & S. A.* We are equally at a loss to account for your *Peach* trees refusing to grow; your soil may not be of the best character, or very suitable for Peaches; and, of course, it could be analysed. The simplest plan would be to try some other soil; you need only have adopted this quantity at first to plant each tree in to see how they may succeed. But we can scarcely attribute your failure altogether to the soil.

VIRGINIAN CREEPER: *J. Morison.* The plants bearing the names you quote are no doubt the same—*Ampelopsis hederacea*.

Correspondents are specially requested to address, not paid, all communications intended for publication to the "Editors," and not to any member of the staff personally. The Editors would also be obliged by such communications being posted as early in the week as possible. Letters relating to Advertisements, or to the supply of the Paper, should be addressed to the Publishers, and not to the Editors.

Markets.

COVENT GARDEN, March 18.

[The markets remain much the same as they were last week, very little change having taken place either in home-grown or foreign produce. *Thos. Taylor, Wholesale Apple Market.*

Table with 3 columns: Plant name, s. d. s. d., s. d. s. d. Lists various plants like Azaleas, Camellias, Carnations, etc.

Table with 3 columns: Plant name, s. d. s. d., s. d. s. d. Lists various plants like Begonias, Bougainvillea, Cineraria, etc.

Table with 3 columns: Fruit name, s. d. s. d., s. d. s. d. Lists various fruits like Apples, Chestnuts, Currants, etc.

Table with 3 columns: Vegetable name, s. d. s. d., s. d. s. d. Lists various vegetables like Artichokes, Asparagus, Beans, Beet, Broccoli, etc.

Potatoes.—Early Shaw's, 12s.; Early Myatt's 14s. 6d.; Early Regents, 12s.; and Early Downs, 12s. per ton.

LONDON: *March 17.*—An active demand, as might be expected, is now felt for Clover and other seeds. Prices, generally, have been the exception of American Red, which is slightly easier, keep very steady. Choice home-grown samples are now become rare. In Trefoils there is a good trade going at full rates. Alsike is dull at a better decline, but White Clover is in improved request. In foreign Trade a good quantity is selling at enhanced currencies. Fine Linseed is scarce and dearer. In bird seeds there is no quotable variation; Canary seed, however, is in diminished request. A large business is passing in spring Tares, at an improved occasion. The Ber quarter Stocks in London seem now about used up. Blue boiling Peas are steady in both value and demand. Of the larger descriptions very few are offering. Fine white Mustard and Rape seed are tending upwards. *John Shaw & Sons, Seed Merchants, 57, Mark Lane, E.C.*

CORN.

At Mark Lane on Monday business was dull, but prices were generally supported. Wheat was in small supply, but, being in excess of the demand, higher rates were not established. Barley was inclined to weaken, and malt was almost neglected. Oats were steady, and the value of Malt was unaltered. Beans and Peas changed hands at the rates of Monday last, and flour tended in buyer's favour.—At Wednesday's market there was no improvement in the demand for Wheat, but prices were in most instances supported. Barley was very dull, and scarcely an inquiry prevailed for malt; but Oats were in moderate request at the rates current on Monday. Maize was rather heavy, and very few sales were effected in either Beans, Peas, or flour. Average prices of corn for the week ending March 13:—Wheat, 41s. 4d.; Barley, 29s. 4d.; Oats, 29s. 6d. For the corresponding week last year:—Wheat, 6s. 8d.; Barley, 48s. 4d.; Oats, 28s. 10d.

CATTLE.

At the Metropolitan Market on Monday there was a fair trade in beasts at, on the average, higher prices. The demand for sheep was good, with no quotable alteration in price. Calves sold freely at higher rates. *Keightons*:—Beasts, 25s. 4d. to 45s. 6d.; Oats, 29s. 6d.; 6r. 2d.; calves, 5s. to 6s. 6d.; sheep, 5s. 4d. to 5s. 8d., and 6s. 4d. to 6s. 10d.; pigs, 4s. 4d. to 5s. 4d.—On Thursday trade in beasts was not brisk, but Monday's prices were freely given, and occasionally an advance was realised. Sheep were readily disposed of at from 5s. 4d. to 7s. A few good lambs found purchasers at about 8s. per stone. Choice calves were scarce and dear, and for milch cows prices were decidedly lower.

HAY.

From Whitechapel we learn that, arrivals having been short, demand for fodder had proved good, at improving prices. Prime Clover, 100s. to 120s.; 100s. to 125s.; prime meadow hay, 90s. to 115s.; inferior, 55s. to 75s.; and straw, 35s. to 40s. per load.—Cumberland Market quotations:—Superior meadow hay, 116s. to 126s.; inferior, 90s. to 108s.; superior Clover, 120s. to 130s.; inferior, 100s. to 110s.; and straw, 40s. to 45s. per load.

POTATOS.

From King's Cross it is reported that there has been a better demand, at the following prices:—York and Lincoln Victorias, 100s. to 130s.; do. Flukes, 100s. to 140s.; York Regents, 100s. to 130s.; Lincoln do., 90s. to 120s.; East Lothian do., 80s. to 110s.; Peas, Flukes and Montrose do., 60s. to 80s.; do. Rocks, 60s. to 65s.; Kent, Essex, and Cambridge Rocks, 60s. to 80s.; do. Regents, 80s. to 120s.; French, 50s. to 55s.; do. seedlings, 65s. to 70s.; Belgian Kidneys, 65s. to 70s. per ton.—The Borough and Spitalfields reports are to the effect that moderate supplies have been on sale, and that for all good and prime qualities a steady trade has been experienced, prices having had an upward tendency. Inferior qualities showed very little change. Regents, 75s. to 115s.; Victorias, 100s. to 135s.; Flukes, 100s. to 145s.; Kent, 60s. to 75s. per ton; 200s. week's imports into London consisted of 4188 bags from Antwerp, 630 from Ghent, 1214 sacks and 233 tons from Dunkirk, 13 bags from Rotterdam, 1096 sacks from Boulogne, 4 from Hamburg, and 188 tons from Dant.

Carnation, Picotees, and Pinks.
ISAAC BRUNNING AND CO. beg to announce that they have this Season a very fine and extensive Collection of the above to offer, strong plants of which are now ready for sending out. **LIST of Varieties and Prices, together with Illustrated SEED CATALOGUE,** on application. Our **ONE GUINEA COLLECTION of CARNATIONS,** contains six or seven choice Show Carnations, six pair of choice Show Picotees, twelve pair of Show Pinks, and twelve choice mixed Carnations and Picotees for borders.

Cartage and packing free on receipt of Post Office Order. Half of the above quantities, 12s.

Belgrave, Queanstown, County Cork, Ireland.
 "Mr. W. E. Gunlinton has this day received the Carnation and Picotee Plants, with which he is much pleased, and would like another dozen of either the same or other varieties of **ISAAC BRUNNING AND CO.,** Great Cornmouth Nurseries.

THE LONDON MANURE COMPANY
 (ESTABLISHED 1840.)
 Have now ready for delivery, in fine dry condition—

CORN MANURE, for spring sowing.
 PURE DISSOLVED BONES.
 PURSER'S BONE MANURE.
 PURSER'S BONE TURPIN MANURE.
 SUPERPHOSPHATE.
 NITROPHOSPHATE.
 NITRATE OF SODA, SULPHATE OF AMMONIA,
 Genuine PERUVIAN GUANO, &c. PURSER, Secretary,
 116, Finchurch Street, E.

ODAMS' MANURES,
 FOR ALL CROPS.

Manufactured by the NITRO-PHOSPHATE and ODAMS' CHEMICAL MANURE COMPANY (LIMITED), consisting of Tenant-Farmers occupying upwards of 150,000 Acres of Land.

Chairman—ROBERT LEEDS, Castle Esq. Norfolk.
 Managing Director—JAMES ODAMS.
 Sub-Managers—JAMES ODAMS & T. MACADAM.
 Chief Office—109, Finchurch Street, London, E.C.
 WESTERN COUNTIES BRANCH—Queen Street, Exeter.
 Particulars will be forwarded on application to the Secretary, or may be had of the local Agents.

MILLER AND JOHNSON
 (ESTABLISHED 1859.)

Manufacture the highest quality of ARTIFICIAL MANURES FOR ROOT, CORN, and GRASS CROPS.
 36, Mark Lane, London, E.C.

GISHURD COMPOUND. Used by many of the leading Gardeners since 1859, against Red Spider, Mildew, Thrips, Greenfly, and other Blight, in solutions of from 1 ounce to 2 ounces to the gallon of soft water, and of from 16 ounces as a winter dressing for Vines and Fruit Trees. Has outlived many other preparations, and is superior to all. Sold Retail by Seedsmen, in boxes, 15s., 3s., and 10s. 6d. Wholesale by PRICE'S PATENT CANDLE COMPANY (LIMITED).

SIMPSON'S RED SPIDER, THRIP, and GREENFLY ANTIDOTE is now extensively used, and may be had through all Seedsmen and Chemists. Pronounced a "valuable discovery." Sufficient for the worst case of Red Spider dilute the rate of one quart to 65 gallons of water. Price per quart, condensed, 6s.
 Prepared by JOHN KILNER, Wortley, near Sheffield.
 Important Testimonials on application.

GRAVEL FOR SALE.—Wandsworth Common Gravel, suitable for Road and Path-making, in large or small quantities. Prices on application to ROBERT NEAL, Nurseryman and Contractor, Wandsworth Common, S.W.

SHAW'S TIFFANY AND ELASTIC NETTING for Shading and Protecting. Sold by all respectable Seedsmen. For particulars apply to JOHN SHAW & CO., Tiffany Manufacturers, 29, Oxford Street, Manchester.

RUSSIA MATS.—A large stock of ARCHANGEL and PETERSBURG, for Covering and Packing—Second sized ARCHANGEL, 100s.; PETERSBURG, 60s. and 80s.; superior close Mat, 45s., 50s., and 60s.; PACKING MATS, 20s., 30s., and 35s. per 100; and every other description of MATS at equally low prices, at BLACKBURN. ANDERSON'S, Russia Mat and Sack Warehouse, 4 and 5, Wormwood Street, E.C.

RUSSIA MATS, for Covering Garden Frames.—ANDERSON'S TAGANROG MATS are the cheapest and most durable. Price List, which gives the size of every class of Mat, forwarded post free on application. JAS. T. ANDERSON, 7, Commercial Street, Shoreditch, London, E.C.

E. T. ARCHER'S "FRIGI DOMO."—Patronised by Her Majesty the Queen for Windsor Castle and Frogmore Gardens, the late Sir J. Paxton, and the late Professor Lindley, &c. &c.

MADE OF PREPARED HAIR AND WOOL. A perfect non-conductor of heat or cold, keeping a fixed temperature where it is applied. A good covering for Pits and forcing Frames.

PROTECTION FROM COLD WINDS AND MORNING FROSTS.
 "FRIGI DOMO" NETTING, 2 yards wide, 15s. 4d. per yard.
 "FRIGI DOMO" CANVAS—
 2 yards wide 15s. 10d. per yard ran.
 3 yards wide 18s. 0d.
 4 yards wide 22s. 10d. per yard.

ELISHA T. ARCHER, only Maker of "Frigi Domo," Scamstead and Brockley Roads, Forest Hill, London, S.E.; and of all Florists and Seedsmen. All goods cartage paid to London. NOTICE.—REMOVED from 3, CANNON STREET, CITY.

MILDEW.—Ewing's Infallible Cure. ("The finest of all antidotes." WM. EARLEY.) Retail of most Seedsmen, at 1s. 6d. per bottle—12s. 10d. per bottle, if packed for travelling, of the Manufacturers, at 10s. per bottle.
 EWING AND CO., Norwich.

Genuine Tobacco Paper, Cloth and Cord.
J. GEORGE can supply Nurserymen and Seedsmen with the above. Price, very low, on application to J. GEORGE, Wholesale and Retail Dealer in Tobacco Paper, Putney Heath, London, S.W.

RALPH WALLER AND CO.,
 45, Dale Street, Manchester, MANUFACTURERS of all kinds of GARDEN NETTING, &c.

The serious injury done every spring to Fruit Crops by frost has proved to every Gardener the absolute necessity of providing some Protection to the Trees early in the year. If the blossom in its earliest development be but slightly weakened by frost, the vitality of the fruit-germ is destroyed, and the fruit lost. In this climate, on the average of a century, there is not more than one year in nineteen when the protection is unnecessary. Many fabrics have been tried for this purpose of protection, with more or less success; and we may now say, without fear of contradiction, that we have succeeded in manufacturing the only fabric which is altogether unobjectionable for this purpose. Without unduly nursing, it effectually protects the young germ, and does not impede the action of light and due circulation of air. Some other fabrics do this, and thus weaken the vitality of the tree altogether. Almost every large grower in the three Kingdoms can testify to these facts.

HOTHOUSE SHADING of various thicknesses, superior to any other yet discovered for lightness, strength and durability, standing, as it does, all weathers.
 Testimonial from ROBERT WARNER, Esq.
 "I have had the netting No. 6 on my Orchard-house for eighteen months, and I find it now in very good order, and likely to last as many more months, and I intend to use it on all my houses in future, being well satisfied both as to its lasting qualities, and also as to the shade it gives, which is sufficient to prevent burning, and yet not thick enough to keep out the light, as the ordinary strong shading stuffs do; indeed, it is suitable for shading any kind of plants."—Broomfield, Feb. 13, 1871.

PICES of various kinds always on hand. NETTING and SHADING, in pieces 20 yards long, 16 yard wide, TIFFANY, in pieces 20 yards long, 35 inches wide. For prices, &c., apply to the above address—
 45, Dale Street, Manchester.

SPECIAL NOTICE.

ANNUAL EXHIBITION OF HYACINTHS, TULIPS, &c.

WM. CUTBUSH & SON

Beg to announce that the whole of their superb Collection of HYACINTHS and TULIPS, with CAMELLIAS, AZALEAS, and other Spring Flowers, will be in full perfection on Easter Monday (Bank Holiday) and for ten days after; and they hope to be honoured with a visit from all Horticulturists and the general Public who take an interest in such subjects.

Open on MONDAY, the 29th inst., and ten following days, from 10 A.M. till dusk.

SOLE WHOLESALE VENDORS OF PHOSPHO-GUANO.

FUCHSIA PROCUMBENS (NEW ZEALAND).

THE CREEPING FUCHSIA, WITH ERECT YELLOW FLOWERS.

FRANCIS R. KINGHORN

Has much pleasure in offering this distinct and elegant novelty, which created so much interest among botanists and horticulturists when exhibited by him at the meeting of the Royal Horticultural Society on August 5, 1874, when it was awarded a Botanical Certificate. An excellent coloured representation, by the late Mr. J. T. Moggridge, with description by Dr. Hooker, appeared in the December number of the *Botanical Magazine* for 1874. Its prostrate free-growing habit, and numerous brilliant-hued flowers, continuously produced, renders it particularly suitable for baskets or rockwork. It will certainly prove of great value to the hybridiser, and botanists are of opinion that it may possibly give rise to a race of Fuchsia of totally different habit from what we have now in cultivation.

Plants of this extremely desirable novelty will be ready for distribution on April 20, at 10s. 6d. each; six plants, 60s.; twelve plants, 110s. The usual allowance to the Trade.

Orders are now being Booked, and will be executed in strict rotation.

Coloured Illustrations from the "Botanical Magazine" can be had, post free, at 1s. each.

FRANCIS R. KINGHORN, SHEEN NURSERY, RICHMOND, SURREY.

SAVE YOUR COAL BILLS,

BY ADOPTING

COWAN'S COMPENSATING SYSTEM OF HEATING.

THE COWAN PATENTS COMPANY, LIMITED,
21, WHITEHALL PLACE, LONDON, S.W.

BOULTON & PAUL (LATE W. S. BOULTON & CO.), NORWICH, HORTICULTURAL BUILDERS AND HOT-WATER APPARATUS MAKERS.

Improved Steam-power Machinery for working wood enables us to supply first-class Horticultural Buildings of every description at very low prices. Only the best materials used. Houses designed to suit any situation. Estimates given Free. Gentlemen are respectfully invited to have price from us before ordering elsewhere. Ladies or Gentlemen requiring advice as to the Situation, Style, Dimensions, &c., of proposed Horticultural Buildings, waited upon in any part of England, Ireland, or Scotland. Our NEW ILLUSTRATED CATALOGUE of HORTICULTURAL BUILDINGS, containing upwards of 60 Engravings of Conservatories, Greenhouses, Peach Houses, Forcing Houses, &c., Free by Post for 12 stamps.

BOULTON & PAUL'S PATENT UNIVERSAL PLANT PRESERVERS—GREAT IMPROVEMENTS for 1875.

The Judges at the Royal Horticultural Society's Great Meeting lately held at Birmingham, pronounced these to be by far the best and most useful articles of the kind they ever saw, and awarded them the ONLY PRIZE.

Now Ready, our NEW LIST of PRICES, containing full description and a number of Woodcuts clearly showing the uses to which these handy articles may be applied. Free by Post. **PATENT UNIVERSAL PORTABLE PLANT PRESERVERS and GROUND VINERIES.**—Instead of having to remove or slide loose glass every time it is necessary to attend to the plants, we attach the glazed lights (21-in.) with hinges to the frame of each light, thereby doing away with continual breakage of glass and loss of time. Two men can instantly remove a complete length, 12 feet by 3 feet wide; thus proving them to be really portable. **PATENT UNIVERSAL PLANT PRESERVERS, Large Sizes to Build on Brick Walls,** for use as Span-roof Pits, suitable for Forcing, Propagating, Growing Cucumbers, Melons, and a variety of other things too numerous to mention. *Far superior to anything of the kind yet offered.*

OPINIONS OF THE PRESS.

GARDENERS' CHRONICLE, February 6, 1873.
The uses to which such frames can be put are fully recognised by practical gardeners, and if any notice can be taken of the great demand arising for such contrivances amongst amateurs, it would appear that they too are not ignorant of their great value.

FLORAL WORLD.
The Ground Vinery which has the greatest advantages is unquestionably that manufactured by W. S. Boulton & Co.

MELON OR CUCUMBER FRAMES.

All sizes glazed with 21-in. ready for immediate delivery.
Height at back, 24 inches; at front, 13 inches; sides, 1½ inch thick; lights, 2 inches thick. All made of very best red deal. Painted three coats. Every pane of glass is nailed as well as puttied in. Each light is provided with an iron strengthening rod and handle.

Glazed with 21-ounce.

GARDENERS' MAGAZINE, May 25, 1872.
Considering their substantial character, portability, and the many ways in which they may be employed, we anticipate a very large demand when they become generally known.

THE GARDEN.

Every convenience is provided to save time in cases of removal, planting, watering, and giving air. The glass is firmly fixed and puttied—an essential point. They are complete and ready for use the moment they are received, &c.

Cash Prices, carriage paid to any station in England when orders amount to 60s. and upwards.

VIENNA PRIZE WIRE NETTING.

CAUTION TO BUYERS OF WIRE NETTING.

The great reputation and success of Messrs. J. B. BROWN AND CO.'S VIENNA PRIZE WIRE NETTING seem to have induced certain Dealers in Wire Netting to advertise an inferior article at reduced prices, specifying the mesh, gauge, &c., as if such were the same in quality and value as the Price Wire Netting of which Messrs. J. B. BROWN & CO. are the SOLE MANUFACTURERS.

Messrs. BROWN & CO. would suggest that, before ordering quantities, one roll of their Wire Netting should be ordered and one roll of that advertised at reduced prices. The size and shape of the mesh may then be examined, the thickness or strength of wire, the weight of the rolls and the exact measurements, the general finish of the manufacture, and the quality of the galvanising.

This examination will prove the respective qualities of the Netting.
99, Cannon Street, London, E.C.—March 22.

THE FRENCH SYSTEM OF WIRING GARDEN WALLS, &C., FOR TRAINING FRUIT TREES.

Prices on application to
J. B. BROWN AND CO., 99, Cannon Street, E.C.

Garden Wall Wiring.

R. HOLLIDAY, PRACTICAL WIREWORKER,
2A, Portobello Terrace, Notting Hill Gate, London, W., begs to call the attention of all Gardeners who are about to have their Garden Walls wired to his system of Wiring Walls, as being superior to all others for neatness, strength, and durability.

For Neatness.—Because all the Wires are kept perfectly tight, without the use of the Raddisseur.
For Strength.—Because very much stronger Wire can be used, therefore not liable to be drawn out of the horizontal line by the branches of trees.

For Durability.—Because, being able to use the strong Wire, it is not so likely to be eaten through with the galvanism as the thin Wire, as used in the French system.

The above Engraving is an Example of our system of Wiring Garden Walls. We have recently completed the Wiring of the New Garden Walls for the Marquis of Salisbury, Hatfield House. The Walls are 12 feet high and 753 yards long, wired on both sides; making a total length of 1506 yards,—our system being chosen in preference to any other.

Illustrated Catalogues of Garden and Conservatory Wirework, Rabbit Proof Hurdle Fencing, &c., may be had on application as above.

NETTING FOR FRUIT TREES, SEED BEDS, RIPE STRAWBERRIES, &C.

TANNED NETTING for protecting the above from Frost, Blight, Birds, &c., 2 yards wide $\frac{1}{2}$ per yard, or 100 yards, 20s.; 3 yards wide, 6d. per yard, or 50 yards, 20s.
NEW TANNED NETTING, suited for any of the above purposes, or as a Fence for Fowls, 3 yards wide, 6d. per yard; 4 yards wide, 1s. per yard; $\frac{3}{4}$ inch mesh, 4 yards wide, 1s. 6d. per yard.
TIFFANY, 6s. 6d. and 7s. 6d. per piece of 20 yards.
EATON and DELLER, 6 & 7, Crooked Lane, London Bridge.

Superior' Pea and Seed Guards.

SUPERIOR QUALITY. GALVANISED AFTER MADE.
NEW PATTERN with Diagonal Stays.

3 feet long; 6 inches wide; 6 inches high.
9s. 6d. per Dozen.
Two end-pieces included with each dozen.

THOMAS' Fittings for Wiring Walls ON THE FRENCH SYSTEM.

PRICES OF MATERIALS. Per dozen—s. d.

Galvanised Raddisseurs for tightening the wires (one required for each line of wire)	4 0
Galvanised Terminating Holdfasts (two required for each line of Wire)	3 0
Galvanised Wall Eyes	11 0
Galvanised Wire, 2s., 2s. 6d., and 3s. per 100 yards.	0 6

Illustrated Lists, with full particulars of the above and Fittings for Expansor Trainers, on very economical principles, free on application.

Five per cent. discount allowed for prompt cash on orders amounting to 20s. and upwards.

Special quotations for larger quantities.

Popular Elementary Scientific Botany.

In Fcp. 8vo., with 155 Woodcuts, printed in a less technical style than any other work of the kind. It is hoped more useful and interesting sketch of the natural orders of plants, indicating the source of many useful, economic, ele- mentary, or medicinal sub- stances—though necessarily Elementary in its nature, it will go far to give a more adequate view to making its condensed but introduced.

LONDON: LONGMANS and CO.

THE GARDENER'S MONTHLY.—One of the most popular and best edited of American Horticultural and Advertising Monthly Journals. Editor: THOMAS BRIDPORT, Philadelphia.

Subscriptions for Great Britain—½s. 4d. per annum, in advance. It was for Europe—A. M. C. JONGKINDT CONINCK, Tottenham Nurseries, Dedemsvaart, near Zwolle, Netherlands.

WANTED, as UNDER GARDENER, a Man who understands every part of the business, sitting particularly, to G. S., Brunswick Terrace, Brighton.

WANTED IMMEDIATELY, by a Clergymen, a WORKING GARDENER, married: Wife must be willing to undertake the Washing, Cows, Pasture Land, Pigs, &c. Church people, and without children preferred. Wages 20s. a week, with board and rent free.—Rev. H. L., The Cottage, Halford, Middlesex.

Under Gardener. WANTED IMMEDIATELY, where two are kept, an active, industrious young MAN (not under 23) for General Garden-work. Good character indispensable. Wages 20s.—Mr. A. RUMBOLDS, Gardener, Frogna Rise, Hampstead, N.W.

THE AGRICULTURAL GAZETTE ALMANAC, 1875.

The best Illustrated Agricultural Almanac.

OPINIONS OF THE PRESS.

"It is an excellent and useful work for farmers and all interested in rural pursuits. Beyond the matter usual in such compilations are many good serviceable hints on fattening cattle, growing of root crops, &c. The illustrations are admirably executed, many being engraved from photographs."—Weekly Dispatch, Jan. 31, 1875.

"The 'Agricultural Gazette Almanac,' which deals with matters of interest to farmers, has reached a second edition."—Lancet, Jan. 17, 1875.

"It is a very cheap threepennyworth of information of interest and utility to farmers, and contains numerous illustrations."—The Field, Jan. 16, 1875.

"In addition to the usual matter to be found in an almanac, we have here useful information to the farmer, as to stock and crops, with illustrations of prize animals."—Glostershire Chronicle.

"This is a cheap and useful almanac and diary, well illustrated. Its contents will be found interesting to the agriculturist, and adapted for daily use."—Farmer's Herald.

"The Calendar contains all the fixtures for cattle shows, races, &c., space for diary and memoranda by the side, and various useful information of an agricultural character."—Oxford Times.

"The 'Agricultural Gazette Almanac' is a cheap quarto almanac, comprising information on agricultural topics and a series of portraits of the Prince of Wales, Dr. Voelcker, and Viscount Bridport, and engravings of recent prize cattle, reproduced from the 'Agricultural Gazette.'"—Daily Express.

"To farmers, cattle dealers, and others interested in agriculture, this work will be found invaluable. It contains a deal of information relative to cattle, crops, land, and miscellaneous matters, and is profusely illustrated with engravings chiefly taken from photographs."—Deansbury Chronicle.

"This almanac, which appears to be carefully compiled, and the contents judiciously selected, may be commended to the notice of agriculturists generally. It is issued in a low figure, and contains a large variety of information. There are numerous illustrations, and the likeness of the Prince of Wales, which forms the frontispiece, is especially deserving of mention."—Grafton Journal.

"To all persons interested in agriculture in this neighbourhood 'The Agricultural Gazette Almanac' for 1875, price 3d., will be worth obtaining. It contains a fund of information, as well as a variety of advertisements on topics especially connected with the interests of the community which it is intended to serve."—Halfpenny Guardian.

"Although this almanac comes rather late it is none the less welcome; as containing a mass of information, both interesting and valuable to any person connected with agriculture, it is to be welcomed. In addition to the usual calendar it contains a diary, supplies us with authentic portraits and verbal descriptions of prize cattle, sheep, and pigs, a list of the members of both Houses of Parliament and of the Chambers of Agriculture, another of County Agricultural Societies, besides hints as to practical farming. Such a combination of information most recommend itself to every agriculturist."—Western Daily Mercury.

"Though it is rather late to be noticing an almanac for 1875, we make an exception in favour of the one before us, which, owing to its great merits and low price, ought to be purchased by every agriculturist in the kingdom. The illustrations of prize cattle, implements, &c., are a valuable feature in the Almanac."—Prescot Reporter.

"Considering the valuable information for the farmer and stock breeder to be found in this publication, no wonder the first edition has had to be followed by a second. In addition to the usual calendar it contains a good paper on 'Crickets in the Houses in 1874,' and alphabetical lists of the members of the Houses of Parliament. It is besides admirably illustrated with notable prize-winning stock. The diary is well adapted to the requirements of agriculturists."—East Anglian Daily Times.

"It contains a lot of information useful to farmers and breeders."—Cornish Times.

"It contains a mass of information which will be found exceedingly useful to all who are engaged in agriculture."—The Prince of Wales, and several other engravings."—Gloster Mercury.

"It is a wonderfully good threepennyworth, containing, as it does, in addition to the calendar specially arranged for agriculturists, some of the beautiful portraits of stock which have appeared in the columns of our contemporary within the last year and a-half. Among others, there are portraits, from photographs, of the Duchess of Devonshire's prize pig, the Duke of Devonshire's prize pig, and the Prince of Wales' Champion Short-horn Heifer—among the Short-horns, and a biographical portrait of a Jersey cow. There are also illustrations descriptive of noteworthy American 'wrinkles' for farmers."—Norwich Mercury.

"It contains much interesting matter for the farmer, who may get a new wrinkle from this unpretentious little publication. As may be imagined, the notes relate to matters of purely farming interest, such as rotation of crops, manure, and the like. These are worth consulting, and the writer they contain being sound and practical."—Land and Water.

DINNEFORD AND CO., 172, New Bond Street, London, W.; and of all Chemists throughout the World.

PARR'S LIFE PILLS.—The warm Balsamic and Invigorating Powers of this Pure Herbal Medicine are wonderful. A trial of a single dose will produce conviction that they invigorate the feeble, restore the invalid to health, and do good in all cases. Sold by all Chemists.

DR. LOCKOCK'S PULMONIC WAFFERS. Give instant Relief to Coughs, Colds, Bronchitis, and Disorders of the Breath and Lungs. In hysterical, nervous, and heart complaints they are unfailing. In rheumatic and neuralgic pains they give a charming relief. They give such a sound, refreshing night's rest. They taste pleasantly. Sold by all Druggists at 12. 1/2d. per box.

THE "ARCHIMEDEAN" AMERICAN LAWN MOWER

HAS BEEN AWARDED
GRAND DIPLOMA OF HONOURABLE MENTION, Vienna, 1873.
SILVER MEDAL, Vienna, 1870. SILVER MEDAL, Hamburgh, 1869.

NOTE.—The "Archimedeon" was specially selected from the Mowers exhibited at Vienna for constant use in the Exhibition Grounds, and gave great satisfaction; and we have pleasure in calling attention to the following Testimonial, received from the Inspector of the Royal Gardens, Schönbrun, Vienna :—

"Your 'Archimedeon' Lawn Mowers have been used for some time past at the Imperial Gardens, and I have great pleasure in stating that they have given perfect satisfaction. Their quick and good work prove them to be the best and most efficient machines of the kind."

PATRONIZED BY

HER GRACIOUS MAJESTY THE QUEEN,
HER IMPERIAL MAJESTY THE EMPRESS OF GERMANY,
THE LATE EMPEROR OF THE FRENCH,

HIS ROYAL HIGHNESS THE PRINCE OF WALES,
HIS IMPERIAL MAJESTY THE EMPEROR OF AUSTRIA,
THE VICEROY OF EGYPT,

And many of the Nobility and Gentry of Great Britain.

CHIEF ADVANTAGES.

They are extremely **LIGHT IN DRAUGHT**,
SIMPLE IN CONSTRUCTION, WELL
MADE, and **NOT LIKELY TO GET**
OUT OF ORDER.

They cut **LONG** or **SHORT**, **WET** or **DRY**
Grass, and do not clog.

They have no **ROLLERS** in **FRONT** of the
Cutters, and therefore cut the Grass as it
GROWS, and do not miss the **BENTS**.

They work well on **SLOPES**, **STEEP EM-
BANKMENTS**, **UNDER SHRUBS**, and
close up to **Trees**, &c.

They can be **USED** either **WITH** OR **WITH-
OUT GRASS BOX**, as may be desired.

TESTIMONIALS.

From **A. F. BARRON, Esq.**, *Royal Horticultural Society, Chiswick Gardens, W.*

"**GENTLEMEN**.—We have now had your 'Archimedeon' Lawn Mower in use for several months, and without hesitation I can truly say it is the best and most efficient implement of the kind we have ever used."

From the late **Mr. GEORGE WYNESS**, *Royal Gardens, Buckingham Palace.*

"**GENTLEMEN**.—I beg to say that we have had your Patent 'Archimedeon' Lawn Mower at work in Her Majesty's gardens at Buckingham Palace for some time past, and I have much pleasure in testifying that it has given every satisfaction, as it does its work well and quickly."

From the **Rev. J. H. WHITE**, *Hemingford Grey, St. Ives, Hants.*

"I am much pleased with the working of your 'Archimedeon' Mowing Machine. I think it superior to others which I have used in previous years."

OPINIONS OF THE PRESS.

"The quickest, most simple, and most efficient Mower ever used."—*Gardener's Chronicle.*

"Far superior to any of ours."—*The Field.*
"Remarkably easy to work."—*Gardener's Mag.*

"We feel bound to recommend it to our readers as one of the best Mowers we have as yet made acquaintance with."—*Floral World.*

EVERY MOWER IS WARRANTED TO GIVE AMPLE SATISFACTION,
And if not approved of may be returned within a Month, and the amount paid be refunded.

 Exotic and Vanxhall Nurseries, Canterbury.

New Roses—Strong Plants now Ready.
JOHN FRASER, of the Lea Bridge Road
 Nurseries, Essex, has much pleasure in offering strong
 plants of the following carefully selected varieties of **NEW**
ROSES for 1875, which may be relied on as being the best of
 this year:—
HYBRID PERPETUAL ROSES.
 Adanson Hippolyte Jamin
 Arthur Ozer La Souveraine
 Antoine Mouton Madame Rougier
 Colonel de Sarsel Mademoiselle Hono de Adoajan
 Casimir Perier May Turner
 Comtesse de Sereny Mons. E. V. Teas
 Duchess of Edinburgh Princess Armetine
 Gonoli Gaellone Souvenir du Baron de Semur.
 Henry Ward Beecher

TEA-SCENTED ROSES.
 Aline Sisley Marie
 Duchess of Edinburgh Mademoiselle Thérèse Genevay
 Jean Ducher Perle des Jardins.

PERPETUAL MOSS ROSE.
 Souperet Notting.

LIST, with full descriptions of above, may be had on
 application.

Planting Season—Avenue Trees.
LIMES, 12 to 16 foot high, straight stems,
 girthing 4 to 8 inches at 4 feet from the ground, with
 well-balanced heads, and splendidly rooted. A stock of
 more than 2000 of these fine Trees to select from.
PLANES, OCCIDENTAL, 12 to 16 feet.
HORSE CHESTNUTS, 10 to 12 feet.
SCARLET HORSE CHESTNUTS, 10 to 12 feet.
NORWAY MAPLES, 10 to 16 feet.
 All being stout, straight stemmed, and finely rooted. Every
 tree has been removed within two years.
POPLAR, CANADENSIS NOVA, 15 to 20 feet.—This new
 variety of Poplar, far exceeding in rapidity of growth any
 tree I am acquainted with, is strongly recommended as a
 Town Tree, especially in smoky districts. There are
 hundreds in this Nursery three years old, measuring 18 to
 22 feet high, and stout in proportion.

PAUL'S NURSERIES, WALTHAM CROSS.

SEED POTATOS.

H. & F. SHARPE

Invite the attention of the Trade to the following varieties of SEED POTATOS, which they have grown from the finest selected stocks especially for Seed purposes, viz:—

RIVERS' ROYAL ASHLEAF,
 MYATT'S PROLIFIC KIDNEY,
 LAFSTONE KIDNEY,
 BERKSHIRE KIDNEY,
 FLUKE KIDNEY,
 WALNUT-LEAVED OXFORD (for Forcing),
 EARLY FORTYFOLD,
 " ROBSON'S CHALLENGE,
 " DALMAHOY,
 " FLOURBALL,
 WALKER'S IMPROVED REGENT,
 YORKSHIRE REGENT,
 PATERSON'S VICTORIA,

RED-SKINNED FLOURBALL,
 LATE FORTYFOLD,
 WHITE ROCK,

AMERICAN VARIETIES.

EARLY ROSE,
 BRESEE'S KING of the EARLIES,
 CLIMAX,
 EARLY GOODRICH,
 AMERICAN WONDER,
 BRESEE'S PEARLESS,
 BRESEE'S No. 6,
 EXCELSIOR.

For Prices (which are very moderate), and further particulars apply to
H. AND F. SHARPE, SEED GROWERS, WISBECH, CAMBRIDGESHIRE.

**THE HANDSOMEST AND BEST NEW POTATO IS
 CARTER'S AMERICAN BREAD-FRUIT.**

Indispensable as one of the best Potatos for Exhibition.

CARTER'S
AMERICAN
BREAD-FRUIT.

FOR MAIN CROP.

This is a grand Potato in every respect. Handsome in shape, with very shallow eye. Flesh of fine texture and superb quality, whether baked or boiled. It is a first-rate keeper, and extremely prolific.

An invaluable acquisition to Hotel Keepers, for Public Institutions, &c.

CARTER'S AMERICAN BREAD-FRUIT POTATO.
 Per Peck, 6s.; per Bushel, 21s.; per Cwt. 35s.; per Ton, £30.

**THE POTATO THAT BEST
 RESISTS DISEASE**

**CARTER'S
 IMPROVED RED-SKIN
 FLOURBALL.**

Price per Peck, 2s. 6d.; per Bushel, 9s.;
 Per Cwt. 17s.;
 Per Ton, for not less than half a ton, £14.

We again offer a very fine selected stock of this invaluable Potato, which continues to resist the ravages of the disease in a most surprising manner. We have at all times avoided the statement published by some Houses, "that the Red-skin Flourball Potato is the only disease-proof variety." We, however, repeat that our Improved Red-skin Flourball resists the disease to a far greater extent than any other variety in cultivation.

CARTER'S Improved Red-skin Flourball was one of the varieties in the great Trial of Potatoes made by the Royal Agricultural Society of England last year, and we believe we are justified in stating that it fully maintained its disease-resisting reputation, whilst other varieties were nearly consumed by the disease.

Carter's

THE QUEEN'S SEEDSMEN, 237 & 238, HIGH HOLBORN,
 LONDON, W.C.

FUCHSIA PROCUMBENS (NEW ZEALAND).

THE CREEPING FUCHSIA, WITH ERECT YELLOW FLOWERS.

FRANCIS R. KINGHORN

Has much pleasure in offering this distinct and elegant novelty, which created so much interest among botanists and horticulturists when exhibited by him at the meeting of the Royal Horticultural Society on August 5, 1874, when it was awarded a Botanical Certificate.

Plants of this extremely desirable novelty will be ready for distribution on April 20, at 10s. 6d. each; six plants, 60s.; twelve plants, 110s. The usual allowance to the Trade.

Orders are now being Booked, and will be executed in strict rotation.

Coloured Illustrations from the "Botanical Magazine" can be had, post free, at 1s. each.

FRANCIS R. KINGHORN, SHEEN NURSERY, RICHMOND, SURREY.

Open on MONDAY, the 29th inst., and ten following days, from 10 A.M. till dusk.

HIGHGATE NURSERIES, LONDON, N.

LOBELIA PUMILA MAGNIFICA.

THE PINE APPLE NURSERY COMPANY

Are now sending out this fine Lobelia.

Price 2s. 6d. each, or 24s. per dozen for not less than half a dozen.

It received the Floral Certificate at the Royal Botanic Society, and a First-Class Certificate at the Royal Horticultural Society. It has been favourably noticed by all the gardening papers, and the Gardeners' Magazine of July 18 says of it:—"This dwarf bedding Lobelia, exhibited by the Pine-Apple Nursery Company, is unquestionably the most important of the many bedding Lobelias introduced of late years. The colour of the flowers is a deep indigo-blue, and as there are no conspicuous eyes to mar the general effect, a solid mass or band will tell in a wonderful manner."

MAIDA VALE, LONDON, W.

White flowered, silver-leaved, price 3s. each, 20s. the set of five varieties.

Descriptive CATALOGUE of the above, including also the General COLLECTION of GERANIUMS, is now ready, and will be forwarded post free on application.

WILLIAM PAUL,

PAUL'S NURSERIES, WALTHAM CROSS, N.

New Double Zonal Pelargoniums for 1875.
 First-class Certificate Royal Horticultural Society.

Emily Laxton.

MESSRS. W. AND J. BROWN have again been entrusted by Mr. Laxton with the distribution of the following set of New Double ZONAL PELARGONIUMS raised by him, viz.:

- EMILY LAXTON.—First-class Certificate Royal Horticultural Society. The largest flowered and most remarkable Scarlet Pelargonium, either double or single, hitherto sent out. Individual flowers upwards of 3 inches in diameter; full, but not crowded; truss enormous. Free-flowering, and suitable for winter work. Figured in the *Floral Magazine* for October last. Strong plants, 12s. each.
 - GUIDING STAR.—The most shrubby and dwarf Double Pelargonium yet raised. Foliage pale green, and partaking somewhat of the character and habit of the Show Pelargonium. Flower very pretty purplish pink, and double; quite unique and distinct. Strong plants, 10s. 6d. each.
 - ILLUMINATOR.—A striking and distinct purplish carmine-coloured variety of the Emily Laxton type, but darker in colour; semi-double, but full; petals large and stout. Strong plants, 7s. 6d. each; the set for 51 10s.
- Prizes will be offered for the above in 1876. To be sent out in May next. Coloured Plates of Emily Laxton post free for 1s. 6d. Electors of Single bloom 2s. 6d. each.

NEW STRAWBERRIES.

Messrs. W. & J. BROWN are also now sending out Mr. Laxton's fine firm-fleshed New Strawberries—TRAVELLER and ENQUISITE; the flavour of both these is distinct and unequalled. Traveller has received a First-class Certificate from the Royal Horticultural Society, and is undoubtedly the most suitable Strawberry for transmission yet raised. Strong plants of last season.—Traveller, 4s. per 25, 4s. per 100. Enquisite, 12s. 6d. per 25, 2s. 2d. per 100. Early struck runners of each, in 60 sized pots, 7s. per 25 extra. Prizes for fruits of these will be offered in 1876. Trade terms on application to—

W. AND J. BROWN, Nurserymen and Florists, Stamford.

Suttons Sons

CHOICE FLOWER SEEDS,

FREE BY POST OR RAIL.

Suttons' Collections of Choice Flower Seeds, to produce a beautiful and continuous display during Summer and Autumn.

No. 1 Collection, Free by Post or Rail	.. £2 2 0
No. 2 Collection 1 11 6
No. 3 Collection 1 1 0
No. 4 Collection 0 15 0
No. 5 Collection 0 10 6

Small and Useful Collections can also be had, from 2s. 6d. to 7s. 6d. Free by Post.

Complete Instructions as to the Cultivation of Suttons' Choice Flower Seeds will be found in

"SUTTONS' AMATEUR'S GUIDE,"

The most practical work on gardening yet published, beautifully illustrated with 300 engravings.

Price 1s., Post Free. Gratis to Customers.

ROYAL BERKS SEED ESTABLISHMENT, READING.

FERNERIES.

The annexed cut shows a Section of our IMPROVED GLASS ROOFS for FERNERIES, as erected by us at Eastwood Park, (see *Gardeners' Chronicle*, page 434, 1873); also at Maryfield, Glasgow; Benmore, Argyleshire, &c.

By means of strong Wrought Iron Girders Buildings of any length can be roofed in with a clear span of from 30 to 35 feet, without pillars or tie-rods of any kind.

JAMES BOYD & SONS,

AMERICAN CRANBERRY PLANTS.—There are doubtless many thousands of acres of Swamps, Docks, and Marshes throughout the United Kingdom, which are now comparatively useless and unproductive, that may be made to yield a handsome income by cultivating this delicious fruit. We are now prepared to furnish strong and well-rooted Plants, in any quantity, carefully packed for transportation, at the following prices, which includes cost of packing and delivery on board steamer, with full directions for planting and subsequent cultivation. 10,000 plants are required for an acre.
Prices: 1000, 20s.; 5000, £4 10s.; 10,000, £8.

WHITE'S CRANBERRY CULTURE, 120 pages, illustrated, sent post paid upon receipt of 6s.
Cash or satisfactory reference to accompany the orders. No orders accepted for less than 1000 plants. Remittances can be made by Draft or Postal Order on New York. Address—
B. K. BLISS and SONS, Seed Merchants, 34, Baring's Street, New York.

ROYAL AGRICULTURAL BENEVOLENT INSTITUTION, for the relief of decayed Farmers, their Widows and Orphans.
Patron—HER MAJESTY THE QUEEN.
President—HIS GRACE THE DUKE OF RICHMOND.
Allowances to Pensioners.
Married £40 per annum.
Male £20 ..
Widow and unmarried Orphan Daughters £20 ..
Every information to be had of the Secretary, by whom Subscriptions and Donations will be thankfully received.

ROYAL AGRICULTURAL BENEVOLENT INSTITUTION—THE FIFTEENTH ANNUARY FENCIBLES, to be held at the FENCIBLE INSTITUTION, will take place at Will's Rooms on SATURDAY, June 5, at 6 o'clock.
H.K.H. THE PRINCE OF WALES, K.G., is the Chair.
Dinner tickets, 2s., application for which should be made to the Secretary not later than May 22.

ROYAL AGRICULTURAL BENEVOLENT INSTITUTION—THE ANNUAL GENERAL MEETING will be held at Will's Rooms, St. James's, on WEDNESDAY, June 16, at 11 o'clock precisely, and the ELECTION OF PENSIONERS will take place on the same day at half-past 11 o'clock.
All Subscriptions shall be deemed payable on January 1 in each year; and no Contributor shall vote in respect of an Annual Subscription until the same is in arrears.
Officers of the Institution—
No. 26, Charles Street, St. James's, London, S.W.

SATURDAY, MARCH 27, 1875.

PALM SUNDAY.

THE lingering of old customs, and the slowness of their extinction, is a fact patent to every observer. We imagine that a belief, superstition, or tradition—the names vary, but they represent the same thing from different points of view—has died out, and suddenly we find it in full force and vigour at our very doors. We are, of course, too civilised to believe in witches—yet the drowning of a poor old man at Sible Hedingham on the plea of witchcraft was not an act of the "dark ages," but of the middle of the present enlightened century. We have abandoned the superstitious religious observances of bygone days; and yet, walking through Covent Garden a few days before Palm Sunday, and noticing the members of the "costermonger" class in our London streets, we observed bunches of Willow twigs with their fluffy yellow catkins exposed for sale in the one, while a spray of the same tree formed part of the "outward adornment" of the other. On enquiry we learnt that they were "Palms," and this reminded us of "Palm Sunday," with which these Willow twigs may perchance have something to do.

Palm Sunday itself is at any rate no mediæval invention, but dates back to very early times. Ecclesiastical writers tell us that in the fourth century the Palms from which the people cut the branches when they went out to meet our Saviour were still to be seen in the valley of Cedron. It was at the beginning of the seventh century that the "Procession of Palms" at Angers, which may be said to have become historical, took place. The late Dr. Neale, in one of his charming little books, gives the narrative of the events which occurred on this occasion; and tells how Bishop Theodolph, having been imprisoned by the king—for Church and State conflicts arose even in those days!—composed for his choir-boys the hymn which is still in use in the Catholic Church upon this day. The dramatic character of the service of the day was well calculated to fix it upon the minds of the people; and so it is that, after 300 years' disuse, the Spitalfields weavers, to quote Mr. Timbs, "to this day emerge from their murky dwellings into the open country of Essex to gather Palm," as many Willows, and especially *Salix caprea*, are called; while in mining districts the Protestant miners crowd the Catholic churches on Palm Sunday to obtain a "blessed Palm," believing that it will preserve them from danger at their work.

Reference has been made above to a Palm Sunday, which has become historical. Some may be inclined to refuse the term to the event to which we have applied it, but they will not deny it to the discovery of Florida by the Spaniards, under Juan Ponce de Leon, on the Palm Sunday (April 2) of 1513. Both Gulf and peninsula owe their name to the day on which the latter was discovered, which was known as "Pascha Floridum."

It would not be easy to ascertain how long the golden catkins of the Willow have been connected in the popular mind with Palm, and have borne the same name, but the use of them is certainly ancient, and appears to have been in a great measure confined to our own country. Hampson quotes an old sermon for Palm Sunday from the Cotton MS., in which occurs a passage saying that, as "we have non only

that bereth grene leves we [have] taken in stede of hit Hew [Yew] and *Palmes wyth*, and broth abowte in procession; and so this day we callen *Palme Sonnenday*." Barnaby Googe speaks of the "hallowing" of Willow branches, "that they *Palmes* do use to call;" and Coles, in *Adam in Eden* (1657), says of the Willow blossoms that "divers gather them to deck up their houses on Palm Sunday, and therefore the said flowers are called *Palme*." It is the Willow which is sold as "Palm" in Covent Garden Market, and which is placed in the porches of churches; while in Kent and other counties, "going a Palming" is a popular custom on the Saturday before Palm Sunday. In Germany also the Willow is gathered, and blessed by the priest in the ceremonies of Palm Sunday, and Goethe records its use in the lines—

"More northern climes must be content
With the sad Willow"

as a substitute for the "true Palms," which are used in Rome upon this day. It would appear that in Turner's day Willow only was used in England, and in his *Libellus* (1538) he has a characteristic protest against the "mendacity" of the clergy who used the prayer beginning "Benedic etiam hos palmarum ramos," when only "salignas frondes" were present. According to Sir Walter Scott's novel, *Castle Dangerous*, Willow and Yew are carried even in Scotland upon Palm Sunday; and Brockett says that in the North of England the flowers of Willow are gathered early in the morning of that day, and with them "small pieces of wood formed into crosses, called Palm crosses," are decorated, which are then "stuck up or suspended in their houses." According to Pallas, as quoted by Martyn, it is a species of Willow (*Salix vitellina*) that is used as a substitute for Palm in the Greek Church of Russia. Among ourselves, *S. cinerea* and *S. caprea* are the species chiefly used; and of these waggon-loads from the marshy banks of the lower Thames region are sent to London every year.

So far as ecclesiastical use is concerned, however, it would appear that Yew, rather than Willow is nowadays the chosen representative of the Palm. In most of the London Roman Catholic churches it is branches and sprays of this tree that are blessed and distributed upon Palm Sunday. We have already given an early reference to this employment of Yew, but it seems to have come into more general use of later years than formerly. In the accounts of St. Martin Outwich, London, for 1525, there is a payment for "Yow" on Palm Sunday, but as there is also an entry for "Palme" and "Box floures" on the same date, we may conclude that Willow was at any rate the most common substitute for the tree of which it had appropriated the name. Some have supposed that the planting of Yew trees in churchyards originated in the necessity for obtaining a supply of their branches for the ceremonies of Palm Sunday; but this is an improbable theory.

On the Continent, and especially in France, Box is the favourite representative of the Palm. Any one who has walked through the churchyard of a French village must have been struck by the somewhat unsightly appearance of withered or withering Box branches upon most of the graves; these are placed there on Palm Sunday. A very good account of the use of Box in France upon this day will be found in our volume for 1870 (p. 560), to which it is only necessary to add that it is occasionally, though not frequently, employed in England at the present day as a substitute for Palm. In former times, however, its employment was more general; there is an entry in the *Domesday Boke* of a tenure of land in Shropshire being held on payment of a bundle of Box twigs upon Palm Sunday; and Newton, in his *Herbal to the Bible*, gives an account of the serious effects upon "a certain young man" of the ashes of

Box which had been blessed upon that day, and were administered to him as medicine.

A notice of the ecclesiastical use of the real Palms will also be found in our volume above referred to, where other substitutes for it are also mentioned. Among these, however, there is no reference to the Hazel, which is used with the Willow in Lincolnshire. A writer in the *Stanford Mercury* for April 15, 1870, says:—"Long after the Reformation the common people were tenacious of their belief that such branches gathered on Palm Sunday had peculiar virtues, the old Pagan demons or spirits of evil having no power on that and the two preceding days. I have seen bunches of Hazel and Willow twigs so gathered preserved in constant verdure the year round by placing them in pots of water in cottage windows, and was once told by an aged granddame in South Lincolnshire that they were 'good against thunder and lightning.'"

The ashes which are used in the ceremonies of Ash Wednesday are made from the "Palms" of the previous year, which are preserved until then, and used for that purpose. This notice may be concluded by the following quotation from Mr. Conway, who does not specify to which representative of the Palm his notes refer:—"In Germany, the might of the Wild Huntsman was conquered by a leaf of Easter Palm. In Slavonian regions it is supposed to be especially endowed on Easter Day to protect the field in which it is planted from bad weather. In Germany it is naturally the chief banner of Palm Sunday, on which day—like the Mistletoe before it—there is hardly any good result that may not be secured by it. If as many Palms as there are members of a family be thrown on a fire, each with a name on it, he or she whose leaf burns first will die first. In Bavaria, one who, during an eclipse of the sun, throws an offering of Palm with crumbs on the fire, will never be harmed by the sun. In a storm, Palm switches laid cross-wise on the table procure safety. In Bohemia the charm against fleas is this: During Passion Week put a leaf of Palm behind a picture of the Virgin. At the first stroke of the resurrection bell—i.e., on Easter morning—take down the leaf, swing it twice, saying, 'Depart, all animals without bones!' There will be no more fleas in the house for that year. Palms are thrown on the fire on All Soul's Day, for the poor souls are that day free from purgatory." *E. M.*

New Garden Plants.

ODONTOGLOSSUM RAMOSISSIMUM, Lindl.*

A species of that very interesting group of Odontoglossa which Dr. Lindley called "Isanthium sepals et petals anthesi longe distantibus," which do not make a *favore* by their single flowers, but by the masses of those organs, just as in the case of some of the Epidendras, Calanthes, &c. The panicles are very large, with very numerous stellate white flowers. If I may guess from my very copious wild specimens, there are many varieties, among which—to my taste at least—I would prefer to all others those with deep violet spots on all parts of the flower. Others must have had flac, others purplish spots, and these I regard inferior, though they may be very pretty. The crests are, alas! subject to variation. Dr. Lindley found them serrate in *Odontoglossum angustatum*, and entire in *ramosissimum*. The first he described from Colonel Hall's specimens, the second from Mr. Linden's, n. 61. I took no notes at Dr. Lindley's, possessing Hallian and Lindenian specimens. Now, one may guess my trouble when my Lindenian plant

* *Odontoglossum ramosissimum*.—Pseudobulbus ovalibus compressis; foliis linear-ligulatis acutis elongatis; panicula maximam ramosissima divaricata; bracteis triangularibus longe longioribus, sepalis cuneatis ligulatis acutis crispis; tepalibus brevis latioribus crispis; labello rhombico acuminate vixto basi cordato subcordato integre trifido trilobato hinc crispulo disco velutino; carinulis basibus oblongo semihiruto elongato integre, carinula humilissima mediana, falcibus appositis acutis utrinque termit; columnae apertae.—*Odontoglossum angustatum*, Lindl. Orch. Lindl., No. 90; Bateman, *Odontoglossum*, xxvi. *Odontoglossum ramosissimum*, Lindl. Folia, i. n. 47.

showed toothed crests, and the good Colonel's plant entire ones! And yet, having examined no doubt the richest materials accumulated in one man's hands, and having studied Dr. Lindley's types, I am persuaded he was very right in separating the two.

Odontoglossum angustatum (late observed by Dr. Spruce, whose No. 6069 it is) is a narrow spider-like thing, quite easily recognised by the narrow base of the lip, as Dr. Lindley has very well pointed out. It will never be able to match *Odontoglossum ramosissimum*, having a poor inflorescence of tiny flowers. Dr. Spruce kindly informed me that the sepals are brownish purple, with yellow margins; petals yellowish, with brownish blotches; the crest of the lips whitish. That would not be very tempting for a modern amateur.

Odontoglossum ramosissimum has flowered in Europe in Mr. Linden's establishment, who obtained it from his keen traveller (call him botanic or horticultural, just as you like), Wallis. It has been very beautifully represented on plate xxvi. of Mr. Bateman's splendid work. This author says it "does not exactly answer to the descriptions in the *Folia Orchidaceae*, either of *O. angustatum* or *ramosissimum*." This is decidedly true, yet the base of the lip makes it a go to *O. ramosissimum*, as well as the broad petal; and I plead guilty of having then regarded it an anomalous *O. angustatum*. *O. ramosissimum* was also discovered by Colonel Hall, then gathered at Meride by Mr. Linden, no doubt under the helping assistance of his half-brother, Mr. Schlum. In the *Folia Orchidaceae* it

FIG. 77.—ADIANTUM SEEMANNI (FERTILE AND BARREN PINNÆ AND FRUIT).

is called, according to Mr. Linden, "a magnificent species;" and Mr. Bateman says, i.e., "it was universally admired at South Kensington." For my part I should like the dark violet-spotted varieties. May they be included in the importation Mr. Bull appears to have made. *H. G. Rehb. f.*

ONCIDIUM ANNULARE, Rehb. f., n. sp.*

This is a curious species, that may probably prove a good acquisition, though not just of the very first class. It is a Cystochiloid *Oncidium*, very near *Oncidium serratum* and *æmulum*. The callus of the lip is the chief and peculiar ornament. The crisp toothed, plaited and folded petals are coherent at their top, and form a ring, whence the name. They would rather appear to be of a warm yellow, with cinnamon dots, and with a cinnamon disk. It is of New Grenadan origin, one of the numerous discoveries of Mr. Wallis, who dried a branch I possess. I have also specimens from M. Roehl and Chesterton, the latter a present of Mr. Harry Veitch. It is now at hand from Mr. Bull, who would appear to have introduced living plants, since he is impatient to have its name. The plant should be recommended to Austrian amateurs, at least the blackish variety, as it

* *Oncidium annulare*, Rehb. f., sp. n.—Bene affine *Oncidium falcatipetalum*, Lindl. sepalo summo transverse uniforme crispulo bene unguiculato basi auriculato; sepalis lateralibus subangulatis paulo longioribus, tepalibus unguiculatis, angustis utrinque auriculatis; laminae utrinque oblongis complicatis crispulis annulato coherentibus; labello utrinque basi auriculata ligulato a basi contracto; callo basibus interno utrinque obtuse tridentato, medio obtuse callosa, extus utrinque lamella, incumbente serrata; columnae auriculari triangulis retibus ascendebus.—A simili *Oncidium æmulum* recedit tepalis annulatis, a simili *Oncidium falcatipetalum* tepalis multo latioribus ac callo toto celo diverso,

bears the Austrian national colours, black and yellow. *H. G. Rehb. f.*

ADIANTUM SEEMANNI, Hooker.*

Though not a new name amongst our garden Ferns, this is in reality a new garden Fern; at the same time it is not new to science, having been described by Sir W. J. Hooker so long since as 1851. This seeming anomaly is thus explained. When publishing his *Species Filicum*, Sir W. Hooker described under the name of *Adiantum Seemannii* a remarkably fine pinnate species, gathered by Seeman in 1853 in Central America. Some four or five years ago, on the occasion of one of his subsequent trips to Central America, Dr. Seemann gathered fertile fronds of a pinnate *Adiantum* which he supposed to be the same as that just referred to, and these were either sent or brought home by him, and handed to Mr. Bull, who raised from them a crop of plants, which in the juvenile state passed unchallenged as *A. Seemannii*, for which Seemann had gathered them. The error was not discovered until Messrs. Veitch & Sons exhibited, under the provisional name of *Adiantum Zahnii*, a fine pinnate Maidenhair, collected also in Central America by their collector, Zahn, when a closer examination showed that the plant introduced by Seemann was really *Adiantum Wilsoni* and not *Seemannii*, while the supposed new *A. Zahnii* was not strictly new, but the already described *A. Seemannii*. The mistake was one that might easily be made, since both species have pinnate fronds with large oblique long-pointed pinnae, and it was only when fructification was produced by the young plants that any tangible materials for their identification were available,

and even then they were overlooked until the advent of Zahn's plant led to their closer scrutiny.

Adiantum Seemannii, as will be seen from our illustrations (figs. 77, 78), is a noble species. We are indebted to Messrs. Veitch for fronds from their specimen plant represented by fig. 78, which are fully 2 feet long, with fertile pinnae 3 inches long and 2 inches broad at the base, while some of the sterile pinnae are nearly 4 inches long and 2 inches broad. They have a comparatively slender glossy black stipe, bare on the lower part, and bearing towards the top from four to eight of the magnificent pinnae already noted, which are attached by a slender petiole an inch long, and are prominently rounded on the anterior base, and sloped off on the posterior side, the colour being a deep olive-tinted green, slightly glaucous beneath. The sori in the more perfect fronds occupy the whole margin except the sloping portion of the base and the acuminate point, which latter, as well as the sterile pinnae, is incisely toothed; they are very large and prominent, in some places oblong, a quarter of an inch long, sometimes more sometimes less, in other places cohering for a length of an inch or more, chiefly at the upper base.

When shown at the Royal Botanic Society's *file* in June last under the name of *A. Zahnii*, the plant was awarded a certificate. The specimen represented at fig. 78 measures 2 feet 2 inches across. *T. Moore.*

* *Adiantum Seemannii*, Hooker.—Caudex creeping knotted, sending down copious woolly roots; fronds ovate, pinnated; pinnae long large, 4-6, on long slender petioles, obliquely and broadly deltoid-ovate-acuminate, not lobed, coriaceous-membranaceous; sterile ones closely and deeply incise-serrated, striated with the copious veins; dark brown-green and glossy above, glaucous and opaque beneath; sori contiguous, short oblong or linear-oblong and elongated, or less continued or continuous, hard and contractile; stipes and petioles black, ebrious and very glossy.—*Species Filicum*, ii. 5, t. 8, A.

EASTER FLOWERS.

It is no unnatural instinct which prompts the decoration of churches with flowers at Easter; and it is a pity that so pleasing and in itself innocent a custom should be regarded among Church people as the badge of a party. It would probably, however, be easy to show that the custom of church decoration at Easter is no innovation, as some have supposed, but rather a restoration of a custom which was once general and has never really become extinct. Thus, at Berkeley, a village near Frome, the church has always been decked with Yew on Easter Day.

But it is rather with the popular than the ecclesiastical history of Easter flowers that we have now to do, although the one and the other are in the present instance "somewhat mixed." We devoted some space last year (Sept. 19) to a notice of "Easter Mangians," as *Polygonum bistorta* is called in the North of England; and some notes upon "Tansy pudding," an Easter dish of repute in former days, will be found in the same paper. In addition to

and all things that is foul with fume and smoke shall be done away, and then the fyre shall be gayly arrayed with fayre flowers, and strewed with grene tyssles all aboute;" and it is still the custom in some homes to leave off fires on Easter Sunday. In Ireland Easter bouquets are carried about, formed, when the weather will permit, of a round ball of Primroses, with an Anemone or other flower in the centre. Similar bouquets are made in Warwickshire, save that the "Palm" or Willow there enters into their composition.

In France the Daisy is the Easter flower, being known as Paquerette, or Paquette. In Upper Bavaria the peasants make garlands on Easter Day of the sweet-scented Calt's-foot (*Nardosmia fragrans*) and such other flowers as they can find, and cast them into the fire; this is doubtless the modern form of some pre-Christian ceremony. The great Stithwort (*Stellaria Holosteia*) is known in some parts of England by the pretty name of Easter Bell.

A curious superstition with regard to planting flower seeds, especially of Stocks, about this time of year prevails, not only in some parts of England, but also in France. In Bohn's edition of Brand we read that

well planted with bulbs, which are just peeping through the soil; they will be very effective when in flower. In the centre of one of the beds I noticed some fine specimens of *Thuja aurea*.

Adjoining the house is a large conservatory for foliage and flowering plants, which are looking well. There is here a grand pair of *Areca Bauerii*, a fine Palm, and one of the best for a cool house, also a pair of the graceful *Seaforthia elegans*; under these was the noble *Latania horbonica*, with its shining fan-like green leaves, and at each side of the entrance was a stately *Draecena indivisa*. These foliage plants were all in pairs, which produces a grand effect. Underneath are flowering plants of different kinds, such as *Camellias*, *Ericas*, &c.; this house is kept gay all the year round. On the west side of the dwelling-house is a fine fernery under glass; in it are some grand specimens, also in pairs. I noticed *Cyathea Smithii*, 12 feet high; also *Cyathea dealbata*, the Silver Tree Fern; *C. medullaris*, 20 feet high, and fronds 15 feet across; also *Dicksonia antarctica*; below these were *Todea superba*, *T. pellucidia*, and many other good Ferns. The soil and rocks were covered with *Lycopodium*. After leaving these fine Ferns you arrive at a corridor of

FIG. 78.—ADIANTUM SEEMANNI (SPECIMEN PLANT).

what was there published regarding the *Bistorta* and its curious name, the following note, from the *Peonies of England and Wales*, may be given. Speaking of Westmoreland the writer says—"Till about the middle of the last century garden vegetables, except Onions and a few savoury herbs, were little known, but a mess made of the tender leaves of a fine *Bistorta* (called here Easter Ment-gions, i.e., sprouts of the Easter month) and groats, mixed with a small portion of young Nettles, leaves of the giant Bellflower, and a few blades of Chives, all boiled together in a linen bag with the meat, was accounted a delicacy to eat with veal in the spring."

Another plant which commemorates Easter in its name is the Pasque-flower (*Anemone Pulsatilla*), pasque or pask being an old word for Easter, which is the equivalent of the Jewish Passover; indeed, the word which is rendered "passover" in the authorised translation of the Bible, stands as "pasch" in the Douay version. This name was bestowed upon the *Anemone* by Gerarde, who says he was "mooved" so to name it because it "flowers for the most part about Easter." This was before the revision of the Calendar, and all Easters are not as cold and wintery as the present one bids fair to be.

In *The Festival*, published in 1511, we are told that "it is the maner at this [Easter] daye to do the fyre out of the hall, and the blacke wynter brondes,

in Gloucester it is, or was, believed that if sown on Palm Sunday the blossoms would "be sure to come double." A similar belief attaches in some places to the sowing of Stock seed on Good Friday; while in some parts of France it is customary for the women to take to church on that day in their pockets seeds of Stocks mixed with earth, which they shake up during the singing of the "Stabat Mater," believing that by this means double flowers will be ensured! *E. M.*

STOKE PARK, SLOUGH.

THIS fine domain, the seat of J. C. Coleman, Esq., is celebrated for its large timber, consisting chiefly of Oaks and Elms, &c., and which have a grand appearance in this extensive park. The mansion, a large well-built structure, overlooks a fine stream of water in the hollow below, which has the park sloping down on either side of it, and there are also about 1000 head of deer, some of a very large size. These add very much to the grandeur of the park, as they bask under the fine old trees and parade the spacious grass carpet. I noticed some fine specimens of *Conifers* on one side of the mansion, also a large collection of *Rhododendrons*, which when in bloom must produce a very good effect; the flower garden is

glass, which is heated, and in it are the finest specimens of *Chamaerops excelsa* that I ever saw. There are two rows of fine specimens of different kinds with mirrors at each end, on each side of which are pairs of grand Palms, *Draecenas*, &c. The *Seaforthia elegans* are very effective, the stems being 12 feet high; also the *Chamaerops arborescens*—they have good heads on tall stems. Mr. Coleman has great liking for these fine plants; no other class of plants can produce the same grand effect. In May and June the large specimen *Azaleas* are brought in full bloom, and intermixed with the various foliage plants. I also noticed a fine specimen of *Imantophyllum minimum*, just coming into bloom; it is a showy plant and produces a good effect with its orange-scarlet flowers; it will grow well in any cool house. On leaving these houses I walked through part of the park, which, on a hot summer's day, must be pleasant, owing to the shade afforded by the grand trees, and the cool and refreshing appearance of the lake, the rising ground on one side, and in the distance a church spire, which always forms a kind of finishing touch to the landscape. Some of the trees are covered with *Mistletoe*.

In the kitchen garden my attention was at once taken by the men's bothies. Mr. Coleman deserves great credit for his consideration of the comfort of the young gardeners; the bothies are quite model apartments; there is a bedroom for each

man, a good dining-room and kitchen, and every other convenience; a woman is provided to cook and do all that is required. Mr. Simpson, the steward, was kind enough to show me over these bothies, and explained to me what pleasure and interest Mr. Coleman felt in providing such accommodation for the young men.

After leaving here we met Mr. Stocking, the gardener, who was kind enough to show me round the houses. The first were a range of span-roofed houses, chiefly for Orchids; there were many in bloom, the most noticeable being two rows of *Dendrobium nobile* and *Wallichianum*, with as many as 500 expanded flowers on one plant, all of a good colour. There is no Orchid so useful for decorative purposes as this, and to see it in such perfection is a grand sight. In the same house was *Vanda tricolor* and *suavis* with strong spikes; also *Phalænopsis amabilis*, *grandiflora* and *Schilleriana*, with their white and mauve-coloured flowers and drooping spikes; *Vandæ gigantea*, *Calanthe Veitchii* and *C. vestita*, all help to make a good display. I was glad to see a few good Ferns intermixed with the flowering Orchids, as they enliven the scene.

The next house was quite gay with *Cattleya Triana*, which was one of the finest varieties I have seen. The colour was good and the flower large, the lower part of the lip being fully fringed. *Cypripedium villosum*, *Cattleya amethystoglossa*, *Coleogyne cristata*, with its pure white flowers appeared with its graceful foliage, is a most useful Orchid, and very effective in ladies' hair and bouquets; *Anthurium Schzerianum*, with its showy scarlet spathes, also took part in this house; and near this was the beautiful *Adiantum Farleyense*. On the whole the Orchids look well, and I have no doubt that they are the foundation of a good collection, as they seem to be appreciated by Mr. Coleman.

The next is a foliage-house, consisting principally of *Maranthus*, *Dracæ*, *Crotons*, &c. These are grown for decorative purposes, and they are very useful, especially when they are well coloured, as they are here. We next come to a range of Pine-houses, in which the plants are showing well for fruit; and there are also many good succession plants which are strong and vigorous. In the next houses there is a fine display of Orchids, especially of *Phajus grandifolia*, of which there were some large plants with numerous spikes of showy flowers. I noticed a fine upper part of the flower, and the flowers were very large. With these were some fine specimens of *Dendrobium nobile*, in full bloom, and others coming in succession; also a grand plant of *Dendrobium Dalhousianum*, showing thirty spikes of bloom. When this is in flower it will be a grand sight, for we seldom see a well-grown specimen of it. Mr. Stocking succeeds well with it, and deserves great credit for its cultivation.

After leaving this house we come to a large span-roofed house filled with fine specimen Azaleas. *Azalea Gem* is a grand specimen, A. *Stanleyana* is also large, and well set with buds; A. *punctata rosea* is a fine showy kind; A. *Barkeleyana* is a splendid specimen; A. *Criterion* one of the best show kinds; *Rhododendron Gibsoni*, also a fine plant, and of *Rhododendron Edgeworthii*, that has ever come under my notice. It is 5 feet high, in robust health, and produced about 1000 flowers last year. An illustration of this plant, when in bloom, deserves a place in the *Gardener's Chronicle*. There is another span-roofed house, filled with *Pelargoniums* and *New Holland* plants. The collection of *Ericas* seem to be well managed; they are thriving well, and tied out to make fine young specimens. I noticed a fine plant of *Pimelia spectabilis*, which we seldom see grown well. This we seldom see for exhibition purposes. The *Camellia-house* is gay with flowers, and many fine bracts are in blossom.

The fruit houses are a good range. Peaches form a prominent feature here; the crops promise well. Some are set, others coming on. There is also a good range of vinerias. The first house was taken up last year, and it is promising well for a good crop now. Mr. Stocking informed me that the same year they were replanted the Vines bore a fair crop of fruit; the rest of the Vines are coming on in succession. Strawberries are grown large for forcing, and, according to the appearance of the crops, there will be an abundance of fruit. B. S. Williams.

FUNGI.

A REVIEW, A GOSSIP, AND A CONFESSION.

UNDER the name of *Fungi, their Nature, Influence, and Uses*, Messrs. King & Co. have recently issued one of the volumes of their "International Scientific Series." The author of the book is Mr. M. C. Cooke, and it is edited by the Rev. M. J. Berkeley: it contains 294 pages, is furnished with an index, and is fully illustrated.

In a recent number of the *Gardener's Chronicle* Mr. Berkeley was happily compared with Agamemnon, the great commander-in-chief of the Greeks and King of Mycæne (a fungus). Now we all know that Mr. Berkeley is not one of the acknowledged "King of Mycæne," but the honoured commander-in-chief of every other sub-genus (and genus) of fungi. For the time being Mr. Cooke takes the part of a trusty lieutenant recommended to the publishers (says the preface) by Mr. Berkeley himself, the latter having "merely suggested such additions as seemed useful, subjoining occasionally a few notes." "I have no doubt," says Mr. Berkeley, "that the same high character will justly apply to this as to Mr. Cooke's former publications, and especially to his *Handbook of British Fungi*."

When the great Agamemnon thus introduces his officer, anything that may fall from the lips of Achilles (mere King of the Myrmidons) may seem more or less invidious, but as for many years there has been a great want felt for a good and trustworthy introductory text-book of fungi, and now that this want seems for the present to have been supplied, a few words from one who has tried with success for nearly twenty years may perhaps be not altogether out of place.

The work is divided into fourteen chapters, which treat of the nature, structure, classification, uses, and notable phenomena of fungi; on the spore and its dissemination; germination and growth, sexual reproduction, polymorphism, influence and effects of fungi, their habitats, cultivation, geographical distribution, and their collection and preservation: a sufficiently extensive and exhaustive programme, but one that appears to be fully and well carried out. All the best authorities on the various subjects treated of appear to have been consulted, and their observations generally transcribed (often at considerable length), and the source duly acknowledged. The production of a work like the one now under review represents a large amount of laborious, difficult, and critical work, and one in which a serious slip or fatal error would be one of the easiest matters possible; and as far as we are able to judge the new handbook seems in every way to be well suited to the requirements of all beginners in the difficult and involved study of fungology.

In a future edition will probably soon be called for, we think it extremely desirable (if possible) to attach the scale to which all the figures are drawn. Some data of magnification are indeed present, but in too many instances the number of diameters to which the figures are enlarged is omitted. The scale to which things are drawn is often of the utmost importance, for no one (unless well acquainted with fungi) would believe the gigantic sporidium of *Sphaeria putaminum* on p. 135 to be only enlarged 400 diameters, especially after comparing it with the upper figures to the same scale. It reminds one of Dickens' humorous description of the toy "Noah's Ark" in *Our Mutual Friend*, where "the elephant" is described as "leading, and the fly, with difficulty and some hissing, bringing up the rear." *Morchella rimolipes*, referred to on p. 99 as occurring in France and America, has also been known as a British plant for the last year or two, though its name may possibly have escaped publication, or been overlooked. The paragraph beginning p. 235, which says—"Of special habitats, we may allude to *Nyctalis*, of which the species are parasitic on dead fungi belonging to the genus *Russula*"—is far from correct, as a glance at the figures will show. Berkeley, in his *Outlines* (p. 217) correctly says, "often parasitic on other fungi;" and the fact is that even the British species of *Nyctalis* grow parasitically on several *Agarics*, including *Lactaria*, and in certain species (one British) they grow on the naked ground, or on rotten trunks—"ad terram nudam" and "in truncis arborum," *Fries, Epic.*, nov. ed., p. 463. It is true *Nyctalis* is defined in the *Micrographic Dictionary* as "a genus of one or two species parasitic on *Russula*;" but this is by an oversight of the writer of the paragraph.

We regret to see the statement again repeated (p. 95) that the late Mr. Salter at one time lived almost entirely on different species of Boleti, without using much discrimination," because we know that, before Mr. Salter died, he greatly regretted that such words had ever obtained publicity. Mr. Salter was unacquainted with fungi, and during the latter years of his life he made (to say the least of it) some very almost entirely a racy and searching philippic. "Why we should not eat funguses," was written because "my good friend" (*i.e.*, Mr. Salter), "who really seemed well-versed in the subject, and who found at every turn some well-known test of wholesomeness or otherwise to guide him, wound up the day by very nearly poisoning a member of my family, for he had, it appears, mistaken *Boletus flavus*, a violent poison, for the very similar but wholesome and excellent *B. tuberosus*." Further on Mr. La Touche says, "I saw with my own eyes my scientific friend eat and swallow an entire *B. flavus* raw without any apparent bad effects; whereas, a small portion of the same kind, cooked,

produced violent sickness in another individual;" and "my friend assures me that he has eaten the highly poisonous *Boletus Satanas* with no worse effect than a little indigestion the next morning." We think all reasonable people, after reading of Mr. Salter's exploits, will exclaim with Mr. La Touche, "One man has, to use a vulgar expression, the stomach of a horse; can I, an average mortal, calculate on possessing such a treasure?"

Under "cultivation" (p. 253) no mention is made of *Coprinus atramentarius*, which has now become under cultivation in London for some years, as fully reported in a former volume of the *Gardener's Chronicle*. We believe specimens were displayed at one of the London fungus exhibitions at South Kensington, and were awarded a prize. We have never been able to appreciate the correctness of the statement (p. 139) that "in the cultivated species we proceed on the assumption that the spores have passed a period of probation in the intestines of the horse, and by this process have acquired a germinating power." Elsewhere (p. 254) Mr. Cheswold's experiment is referred to, in which *Mushrooms* are developed from spores merely sown on glass. We have constantly repeated this experiment with success, not only with the spores of the *Mushroom*, but with other species of *Agaricus*. Neither, we imagine, do any of the other dung-borne *Agarics* require the intestines of a horse, for if the fresh spores of *Coprinus radiatus* or *C. niveus* be sown upon fresh dung they will in a day or two produce a dense crop of plants and quite exclude the *Mushroom*; so that these experiments have, we believe, been reported in the *Gardener's Chronicle*. The cultivated *Mushroom* being a very common species, it is reasonable to suppose that its spores are abundant everywhere in the air, and horse-dung being also everywhere, too, the spores at once find a suitable nidus, and infest the dung; but if we once admit that the "intestines of a horse" are necessary to the *Mushroom*, then we must conclude that all the other "dung-borne fungi" require the same equine apparatus to "acquire a germinating power."

A few typographical slips require correction, as *Cortinariis violaceus* (p. 91), *Agaricus geotropus* (p. 86), &c. Before taking leave of an excellent book we will make a few remarks on the last chapter, and on the study of fungi in general. Under "collection" of fungi (p. 287) Mr. Cooke describes the outfit of a collector, which must include, says the author, "an ordinary collecting box," or "open shallow basket; a large clasp knife, a small pocket saw, and a pocket-lens." "A great number of the woody kinds," says Mr. Cooke, "may be carried in the coat pocket and foliaceous species placed between the leaves of a pocket-book. It is a good plan to be provided with a quantity of soft bibulous paper. In collecting moulds (p. 286) we have found it an excellent plan to go out provided with small wooden boxes corked at top and bottom," and the "pill boxes" are afterwards not forgotten. "Some of the most precious objects never go out without a pair of forceps, a small axe and hammer, even a ladder; when these items are added (together with a hank of string) the enthusiastic fungus collector stands confessed. Some of our readers may exclaim, "Then, thank Heaven, I am not a Fungologist!" But Mr. Cooke says on his last page, "The prospects of new discoveries for the industrious and persevering are great. All who have as yet devoted themselves with assiduity have been in this manner rewarded. The objects are easily obtainable, and there is a constantly increasing infatuation in the study." As regards this study and its "infatuations" it is satisfactory to know that (p. 266) "Ireland is comparatively unknown, no complete collection having ever been made, or any at least published;" so that there is a good chance for any enthusiast who feels inclined to pass a year or two in the woods and bogs of the Emerald Isle—he need only take a simple list of his incursions to his friends, and he will have done. Of the indications we may say they are generally good, though very unequal in merit—some are new, whilst a good many have been before published elsewhere, as in Mr. Cooke's *Handbook*, &c.

Of late years we have come to the conclusion that the blamings of fungi are dangerous, the "infatuation" referred to by Mr. Cooke, we know, is strong, and, like the sweet song of the Sirens, it too often (like that song) makes the hearer forget all else and die of hunger. Therefore our advice would be, especially to young men, if the force is once upon you, stick to one section of fungi only, or for a certainty you will be inundated. It is all very well for men of leisure and ample means, for the clergy, and for professors and doctors at museums and universities, to study the whole family, but the number of species is so large that no one can hope to master all unless he devotes the whole of his time to the subject. The general literature of fungi is very extensive, and there are in too many instances carelessly compiled, so that for a beginner to do any real work he must go over the ground himself. Here is an instance. There are two *Agarics*—one *Agaricus murinaeus*, the other *Hygrophorus murinaeus*, Fr. Berkeley (*Outlines*, p. 100 and p. 203) states they are "quite different"

(as we know them to be), and says the first is figured by Sowerby (t. 106); but Fries (*Epis.*, p. 333) says the last is Sowerby's plant and not the first. Now if we turn to Cooke (*Handbook*, p. 27), he says the two plants are "very different," and quotes Berkeley's reference to Sowerby for the first, and Fries' reference to the last; so that, if we follow the latter author, the plants are "very different," and yet *quite the same*, for the reference is not confined to Sowerby, but there is another to Bulliard (t. 520), under both plants. With one other instance we will conclude. Berkeley, describing *Agaricus clypeolarius* (*Eng. Bot.*, p. 8), says it is *inodorous*, but in the *Outlines* (p. 94) it is described as *sweet-scented*. Now, as odours are often of great importance in fungi, we naturally turn to Cooke (*Handbook*, p. 15), and we see under *A. clypeolarius*, first line, it is described as "fragrant" in the ninth it is "sweet-scented," whilst in the last line of the same description the same species is said to be "inodorous."

When it is remembered that there are so many other useful occupations which bring "reward" of a different nature from the "reward" of merely finding some minute fungus, because nobody ever looked for it before, or perhaps ever will again, that it becomes a question whether fungology is not better as it is—confined to the attention of a few. When one looks over "Outlines" and "Handbooks" of "fungi," and observes the vast number of minute species, and the involved and distracting terminology, one might almost be excused for saying, "Well, if this is fungology I'll go fox-hunting;" and the worst of it is that, countless as are the numbers of species already described, yet every month other armies come into the field, till one almost exclaims with Macbeth in his despair, "The cry is still, 'They come.'" They are nearly all pygmies, and come in innumerable whole armies of whom might be held in the hand as Hercules held the dwarfs of the Upper Nile; they come in such shoals that, to use Chancer's words in "The Millere's Tale," "Half so gret was never Noes flood." They are so similar in size and habit that one has to use all sorts of powers of the microscope to distinguish their differences; they are like the "Ghost Melody" in the "Corsican Brothers" played for a week, or Beethoven's "Turkish March" from the "Ruins of Athens," played without ceasing for a fortnight. We must confess that after many years' study of fungi our feelings are very much the same with those expressed by Goethe's *Faust* in his opening soliloquy—that the "reward" is in no way commensurate with the labour of the study. Berkeley, indeed, well says that "few exercises of the mental powers can be more improving than a diligent study of such a genus as *Agaricus*." The same may be said of whist and chess. But apart from the vital phenomena of fungi, and a knowledge of those species which decidedly affect our health or food, we confess that we consider the knowledge of the plants themselves (as mere species) to be little more than a difficult "mental exercise." W. G. Smith.

THE VIOLA,

FOR TOWN AND SUBURBAN GARDENS.

It may rightly be assumed that the proper degree of importance attached to anything depends wholly upon the amount of benefit derived therefrom. Applying this rule to the subject of the following remarks—and we presume that it would be difficult to touch upon a vein more interesting, or indeed prolific of blessings appertaining to the temporal enjoyments of those whose lives are spent in towns and cities than the delight these gardens, both small and great, afford—just suppose what a wilderness London would be deprived of its splendid parks and public gardens, without mention of the countless multitude of green spots which afford relief to its vastness of stone, brick, and plaster facings. Magnificent buildings it has in abundance, and many of them moulded in architectural completeness, which are both the wonder and admiration of all who have the judgment and taste to admire such, but were those multiplied to a number comprehending examples of all the master conceptions displayed in the art that the world ever knew, and those grand monuments were reared on the spaces now devoted to pleasure ground and garden purposes, they would supply but poor compensation for the loss of the healthful pleasure derived from the city gardens and parks, however unpretending they may be.

Such being the writer's estimate of the importance of town and villa gardens—the floral furnishing of these may be left in the hands of those who would prove themselves well qualified to manage the matter—that the writer proposes doing at present is to draw the attention of those concerned to the *Viola* as a genus well suited for garden embellishment, in towns or elsewhere, and for certain purposes we are safe in asserting they stand unequalled by any

other plants. For edging beds or borders, filling in scroll-work, and forming a ground in dwarf plants, they are indispensable, especially when distinct bright colours are wanted. Where the garden is damp and shaded, and therefore ill-adapted to the perfect flowering of Pelargoniums and other more tender popular favourites, the *Viola* ought to have a place in quantity. Unfortunately with the *Viola*, as with most other kinds of plants, a great number of worthless varieties exist. Although honoured with high-sounding names and testimonials calculated to lead the most alert astray by this dishonest practice, we have looked on all new sorts with suspicion until time and trial prove their qualifications. The following sorts we commend in confidence to our readers—*V. cornuta* Magnificent: this is a deep mauve, furnishing large handsome flowers of the true *Viola* type, and an abundant bloomer. *V. cornuta* Perfection is a bright mauve, as a bloomer unsurpassed by any all through the summer. *V. Sensation* is one of the very finest darks in all respects, and *V. Admiration* will long sustain a good character as a deep mauve. Amongst whites *Purity* ranks high, forming dense regular tufts of foliage smothered with well-formed white flowers. *Nor* is *V. White-begger* a shade behind, only it shows more blue in its eye. Amongst yellows, to form a deep shade, all the yellow *Violas* are good, but are not approached, but its flowers must not be compared to those of *V. lutea* major, which also forms a dense uniform line. *V. Lady Susan* claims attention also when displaying her golden petals; but we consider the greatest novelty among the selfs to be *Princess Teck*, as it is so distinct from all in colour, which is a very pale violet suffused with mauve; this is a most abundant flowerer, of vigorous compact habit of growth, seen in flower early and late. *V. Tory* is a very dark sort, and I have it from good authority that it is one of the best of new kinds. Speaking of fancy varieties there are a few worthy of notice, and *V. Batterfly* numbers amongst them. It is a gaily marked sort, and produces a sparkling effect alongside of others: ground colour yellow, the superior petals stamped or blotted shining bluish purple, surrounded by a border band of orange-yellow. *V. Magpie* is equally dissimilar and novel, its ground colour maroon-purple, showing large and lengthy angular spots of white filling the centre of each segment of the corolla, and with a deep clear orange eye; a profuse bloomer, of dwarf compact growth. *V. Lothair* is a fine hybrid cross with a fancy Pansy, the colour dense blue, bearing indigo, furnished with a faint dark centre blotch; habit good and profuse, and continuous in its production of flowers. *V. Lady Mathison* must not be forgotten; though not a fancy, it is peculiar in its shade of mauve, and altogether first-rate. *A. K.*

PLANT GOSSIP.

REOEL'S *Gartenflora* for January contains, among other things, not the promised revision of the species of *Rheum*, but a figured description of, and some historical notes on, *RHEUM PALMATUM* V.A.R. *TANGUTICUM* (to which we have alluded before, p. 179), by Maximowicz. Although he does not dispute the fact that *Rheum officinale* of Baillon, figured in the December number of the *Botanical Magazine* of last year, yields a commercial Rhubarb, he contends that the drug known in England as Turkey Rhubarb, which came to us through Siberia by way of Kiachta, was the produce of the plant he describes. We say came, because the trade from that source has been destroyed, not, as Maximowicz says, in consequence of the attempt of some of the tribes to overthrow Chinese rule, but, as related in Flückiger and Hanbury's *Pharmacographia*, in consequence of the very strict supervision exercised by the Russian Government. In the work just named a very full history of medicinal Rhubarb is given. Maximowicz's plant was collected by Przewalski, in 1873-4, in the vicinity of Lake Koko Nor, North-West China. It is, or was, extensively cultivated in that district, and the wild plant was also collected. An account is given of the method of its cultivation and preparation, but this part adds little to our knowledge of the requirements and conditions necessary for the profitable cultivation of Rhubarb. The plant figured agrees in all respects with a specimen in the Kew Herbarium labelled "*Rheum palmatum*, from Tallas," and also with another from Dr. Siebeck; and there seems little doubt that the account given in the previous introduction about 125 years back is correct. The Russian officials stationed on the frontier were instructed to obtain seeds or plants of the genuine Rhubarb, if possible; and in 1740 they succeeded in obtaining a quantity of seed, though they had to pay a high price for it. But the "heathen Chinese" was too crafty for them, the plants raised from this precious seed proving to be nothing more than the well-known Siberian *R. undulatum*. However, in 1750 the true plant was procured, and from Russia it spread over various parts of Europe, including Britain, so that after all we have, according to Maximowicz, been seeking for a plant we already possessed. He goes on: "Let it be admitted

that we now possess two species which furnish a superior quality of Rhubarb, still *R. palmatum* has the advantage of being the genuine plant that produced the drug whose reputation dates from the time of the Arabian and Greek physicians." Speaking of the cultivation in Europe of Rhubarb for medicinal purposes, Maximowicz says that *R. palmatum* has proved rather unprofitable on account of the principal root decaying, and thus leaving only the less valuable lateral ones; and he adds that to a certain extent this has been the case with other species. So far as this country is concerned, we do not think these remarks are applicable. There is certainly a difference in the hardness of the species. *R. officinale* was rather severely injured by frost at Kew last spring. We know nothing respecting the constitution of *R. palmatum*, but *R. kraponticum*, *undulatum*, and others are harder than *R. officinale*. In Otto's *Hamburgers Gartenzeitung* for February, a writer, referring to the article from which we have gleaned the preceding notes, gets into a sad confusion with *R. officinale* and *R. palmatum* Tanguticum, which he speaks of as the same thing. Through getting hold of this journal first, we were very near doing the same thing; but the figure in the *Gartenflora* being so unlike the *R. officinale* we had seen, we looked further, and discovered that the illustration did not suit the two plants; and that what we had corrected was the first notice of his plant which we reproduced at p. 179.

— In the *Hamburgers Gartenzeitung* for February there is a short article entitled "Die Köstritzer Georginen," Köstritz Dahlias. The writer complains that a certain Dahlia grower of Altona, named Ammann, enumerates in his catalogue of 194 varieties only nineteen of Gervey's. From this he observes it would almost appear that German gardeners had paid little attention to this flower, and that the varieties raised were far inferior to the English and French ones, whereas it is not so. The two principal German cultivators and raisers of Dahlias are Christian Deegan and J. Lieckmann, both of Köstritz. These gentlemen, we are informed, have succeeded in raising a strain of varieties equal, and in some respects superior, to the best English variety. Whether our author writes with authority we know not, but we only extract a few of his remarks in consideration of those specially interested in this flower. We are told that a careful examination of the English and French Dahlias reveals the fact that the raisers' principal aim has been largeness of size. It is admitted that our Dahlias are well filled, and many of them marvellously pretty in colour. German gardeners, on the contrary, have striven more especially to improve the shape of the flower, and the result is they have surpassed everybody else in this particular. Coming to colour, great purity and decided tints are claimed for the German varieties. From the diversity of form displayed by German varieties it has been found desirable to classify them as *Ranunculus*, *Aster*, *Chrysanthemum*, *Rose*, &c., flowered. Only one English variety, *Keynes' Crimson King*, in respect of shape, was worthy to take a place by the side of its German sisters! Is this really true? If so our raisers must be sadly deficient in enterprise and taste. Another desirable result has been attained—a dwarfier more compact habit, and with it the property of earlier flowering. Thus we are told that the English varieties do not flower in the climate before the middle of July or beginning of August, whereas the best German varieties are in full flower by the middle of June. Doubtless the Germans are able to raise, and have raised perhaps, as good varieties as some of our best; but it appears to us that the writer of the article from which we have quoted has rather overshot the mark in his unbounded admiration of German, and depreciation of foreign varieties. True, we do not know what English varieties he selected for comparison.

We learn from the *Bulletin de la Société Botanique de France* that M. Roumeguère has published a paper on the origin of the flowers which are distributed by the Academy of Lyons, named at Toulouse. It contains an unpublished letter by Lapeyrouse, who protests against the long established error of distributing the flowers of *Columbine* under the name of *Eglantine*. Gouan is the only author who gives this name for the *Aquilegia*, and it is thought that he may have done so from having seen the flower distributed by the Academy under that title. The true plant to which attention is directed is the *Amaranth*, the plant representing this in most of our gardens being our "Love-lies-bleeding" (*Amaranthus caudatus*). Lapeyrouse thinks it more probable that the founders of these Games would have chosen the yellow everlasting (*Helichrysum Stuechias*), the *Amaranthus luteus* of some sixteenth century botanists, as a symbolic and poetical emblem. This plant is very common on the chalky soil of the mountainous regions of central France, and was used in pagan times for ornamental purposes, and is still in Portugal it is still employed in the decoration of churches. The Floral Games of Toulouse date from 1333, when they were founded by a lady of Toulouse,

named Clémence Isaire — at least so tradition affirms, although Murray says that her very existence is not a little doubtful, as, although her statue is preserved in the Capitole, there is no mention of her in the archives of the town. The Société des Jeux Floraux has, however, adopted her as its patron and founder, and on every 3d of May, after visiting the church of La Doucade, in which her tomb once stood, prizes are distributed for the best original compositions in verse and prose upon a given subject. The prizes consist of golden and silver representations of the Eglantine and Anaranth, as above mentioned; and also of the Violet, Lily, and Marigold. A golden Violet is the prize bestowed upon the author of the best poem. These Games were discontinued during the Revolution, but were revived in 1808, and are still celebrated with considerable splendour.

Some of the finest bulbs of *LILIUM AURATUM* now being imported to this country, previous to being packed for dispatch are thoroughly encased in moist clay, and then dried in the sun, or by some other means. This keeps the bulbs plump and fresh, and their value is enhanced on arrival in consequence. The bulk and weight of an importation is in consequence much increased, but it is stated the augmented value of the roots repays the trouble. Prices do not nearly rise so high as they did some time ago, though the larger bulbs go at fairly good prices. So many thousands of bulbs have been imported in recent years that it may be thought our cultivators must be nearly overdone in the matter of this splendid Lily; on the

Rhododendron arboreum and kindred forms, and large Camellias and Azaleas, being in full bloom, to say nothing of Acacias and the usual description of bulbous and other spring-flowering plants. A fine specimen of the South African Aloe *Salmijckiana* is also flowering on a six-branched spike. Its orange-scarlet flowers are very striking. The spring show to be held here on Wednesday next promises to be very successful.

The following Orchids were in flower a few days ago in Mr. William Bull's houses:—*Dendrobium litiflorum*, *Odontoglossum Roezlii*, *Oncidium sacrodes*, rather scarce, and distinguished by its handsome branching spikes of yellow and crimson flowers; *Dendrobium infundibulum*, *Cypripedium Harrisianum*, *Odontoglossum ramulosum*, *Pulma fragrans*, *Oncidium cucullatum*, various *Lycastes*, including *L. Skinneri* var. *rubella*, the flowers of which are more deeply tinted with rose than the typical plant, and several forms of *Phalenopsis*, which we shall notice more fully hereafter.

It has sometimes been objected that certificates should not be given to fine forms of the *CYCLAMEN PERSICUM*, on the ground that they cannot be propagated: the old practice of dividing the corms being well nigh abandoned by cultivators. On the other hand, cultivators like Mr. Henry Little state that any one variety, especially if artificially fertilised with its own pollen, will reproduce itself with almost unvarying exactness. The first position is unsound and impolitic, because it leads to the inference that

sonianum, *Roezlii*, *Phalenopsis*, and the new *O. madrense*, a very beautiful introduction in the style of *O. maxillare*, and originally sold for it at Stevens'.

From our advertising columns it will be seen that the remarkably fine collection of Azaleas, stove and greenhouse plants, &c., formed by the late J. Philpot, Esq., Stamford Hill, and so successfully grown by his gardener, Mr. J. Wheeler, are about to be sold at Stevens' Rooms.

Many persons are now found cultivating the charming *CYCLAMEN PERSICUM*, and as the best way to keep up a yearly succession of plants is to raise a batch of seedlings every year, the importance of fertilising with a view to gain improved types is at once seen. The best time to fertilise the blossoms of the *Cyclamen* is during the early part of the month of March, but it may be done as late as April. The later it is done, however, the less the chance of obtaining the desired result, as all flowering plants are more or less fertilised by the agency of insects during the late spring and summer months, and the access of any of these to the flowers may upset all the calculations of the operator. Crossing should be done when the sun shines, and the first business is to select the parent flowers. The pollen parent should possess undoubted good qualities, that it is desirable to transmit to the progeny—such as large blossoms, fine shaped, or vividly-coloured flowers. The operator should take hold of the stem between the thumb and forefinger of the left hand, just below the flower, with the thumb-nail of the

FIG. 79.—*ENCEPHALARTOS VILLOSIUS*.

other hand it is asserted that 70 per cent. of the bulbs perish: some have put the loss even higher.

OROBUS VERNUS is now an attractive object in the flowering plant-house at Kew, growing in pots and forced into bloom. Treated in this way it forms a nice shrubby habit of growth, and flowers as freely as in the open border. The flowers are most charming in hue when they have aged somewhat, then the purple and rose tints become suffused with blue, and yield a pleasant aspect of colour. It does especially well in a warm south border where the soil is light, rich, and deep, and there is some shade at times during the day.

One of the finest specimens of *ACUCUA JAPONICA* we have seen stands in a sheltered corner of a small garden attached to the residence of W. Sowerby, Esq., in the Royal Botanic Society's Garden, Regent's Park. It measures about 50 feet in circumference, and about 8 feet in height; and is beautifully clothed with foliage to the ground. At the present time it is a most attractive object, being thickly studded, especially on the exposed side, with its rich coral-red berries. Mr. Sowerby has a small male plant in a pot, which, when in flower, he stands on a wooden post almost in the centre of the bushes, and so causes an abundant fertilisation with very little trouble.

RHODODENDRON COUNTESS OF HADDINGTON may now be seen in great beauty in the large conservatory in the Royal Botanic Society's garden at Regent's Park. The plant is not a large one, but has between eighty and ninety trusses of its beautiful white and delicately rose tinted flowers fully expanded; and is an object of great interest. This same conservatory is very gay just now, the large specimens of

new plants and flowers should be recognised only so far as they possess a commercial value and can be put into circulation. The second position is mainly a correct one, but it is not always reliable, unless great care can be taken to isolate the plants to be propagated by seeds, and then not to be absolutely depended on. An illustration in point was furnished in Mr. H. Little's fine collection of *Cyclamens* at the last meeting of the Royal Horticultural Society. Mr. Little fertilised with its own pollen a pure white variety of excellent qualities, and obtained from it some sixteen or so seedlings. All but one were reproductions of the seed parent, with slight variations, and this was of a pleasant pale pinkish rose hue, in other respects an exact counterpart of the seed parents. Mr. Little supposes some fugitive pollen from another variety with coloured flowers affected the colour of this member of the progeny, but it is perhaps open to doubt whether such a surmise is correct.

The Orchid-houses at Messrs. Veitch & Sons' Nursery are fast becoming interesting to visitors on account of the many species coming into flower. Passing through them a few days ago, we noticed already in flower two remarkably strong plants of *Phajus grandiflorus*, *Dendrobium litiflorum*, with over 100 flowers; *Vanda Cathartii*, *Dendrobium fimbriatum oculatum*, *D. Wardianum*, two plants with ten spikes of flowers, mostly three in a bract, a sight in itself; *Cymbidium eburneum*, a fine variety; *Cypripedium Argus*, a very free-flowering plant; *Dendrochilum glumaceum*, a very fine specimen; *Angreicum sesquipedale*, with five flowers; *Vanda suavis*, Veitch's variety, with sixteen flowers on one spike, ten on another; *Vanda coccinea*, *Dendrobium crassinode*, various *Phalenopsis*, and *Odontoglossums Alexandræ*, *triumphans*, *gloriosum*, *Ander-*

right hand rap against the side of the bloom, and the pollen will be found lodged on the thumb-nail of the left hand. The seed parent should possess a good habit of growth and well-marked foliage; these qualities are indispensable, and the pollen should be applied to the blossoms, fertilising not more than six, which are ample to produce seed — probably Mr. Little would not impregnate more than two or three. The operation of applying the pollen is one requiring to be done with some care — the stigmatic organs are extremely delicate, and will not admit of any rough usage. The pollen should be gently applied to the stigma, and it will be found that at least a small portion has adhered, which is all that is required. Some growers are of opinion that it is not advisable to cross the ordinary white form of *C. persicum* with a deeper-coloured flower, except to obtain variety; the aim should be rather to keep them distinct, and improve each variety separately. If a flower combines good shape and high colour, but an indifferent habit, it may be used as the pollen parent, crossing with it another coloured flower possessing good dwarf, regular foliage; and the result will be, in most instances, an improved habit, combined with fine quality of flowers in shape and colour. Flowers emitting an agreeable perfume should be crossed one with the other, in order to increase and perpetuate this desirable property. The seed parent should not be overladen with pods — not more than six blossoms on a large plant should be allowed to seed; if a greater number are retained there is danger of the seed being small, and the plants obtained from it, in all probability, will be found wanting in that vigour which is at all times an important item in obtaining seedlings. After fertilising the flowers intended to carry seed, all others should be removed, and the plants placed in a rather shady part of the greenhouse, still having as much light as possible.

THE GENUS ENCEPHALARTOS.

The following conspectus of the known species of this genus is abridged from a recent pamphlet published by Dr. Regel, and kindly forwarded by the author. The references are to De Candolle's *Prodromus*, xvi., part ii., pp. 530 et seq., where the synonymy of the several species is given.

- A. Leaf-segments linear, revolute at the margins, acute and spiny at the apex.
 - 1. E. CYCADIFOLIUS, *Lehm.* (*D.C. Prodr.* l. c. 531): leaf-segments quite entire, 3—4 inches long, about $\frac{1}{2}$ inch wide, 3-5-nerved.
 - α *glaber*: trunk glabrous; petiole and rachis slightly tomentose, ultimately glabrous = E. cycadifolius, *Lehm.* *Cycad.*, p. 13; *Zamia cycadifolia*, *Jacq. Fragm.*, t. 25, 26.
 - β *Friederici-Cattilini*: trunk woolly at the top; petiole and rachis at first covered with dense tomentum, ultimately subglabrous = E. Friederici-Guillemi, *Lehm.* *Cycad.*, p. 8, tab. 1—3; E. Ghelinkii, *Lemaire*, in *Ill. Hort.* 1867, p. 80, and 1868, t. 567.
- B. Leaf-segments linear, flat, acute, and spiny at the apex.
 - 2. E. PUNGENS, *Lehm.* (*D.C. Prodr.* 533).—Not known by Dr. Regel.
- C. Leaf-segments linear-lanceolate, acute, and spiny at the apex.
 - (α) *Leaves dark green.*
 - 3. E. VERSCHAFFELTII, *Reel.*: leaf-segments quite entire, seven times longer than broad.
 - 4. E. ELONGATUS, *Miq.*: leaf-segments entire, or 1-toothed near the apex, fourteen times longer than broad (*D.C. Prodr.* 533).—Not known by Dr. Regel.
 - 5. E. VILLOSUS, *Lehm.*: leaf-segments spinous-toothed, fourteen times longer than broad; teeth subulate, erect, or slightly appressed; *Ill. Hort.* 1867, p. 80, and 1868, t. 557. Trunk covered with ash-coloured tomentum at the apex; petiole and rachis at first loosely tomentose, ultimately glabrous; leaves bright green, about 8 inches long, and $\frac{3}{4}$ inch broad.
 - (β) *Leaves glaucous.*
 - 6. E. LEHMANNI, *Lehm.* (*D.C. Prodr.* 531). α *typicus*: leaf-segments entire. β *spinulosus*: leaf-segments spine-toothed.
- D. Leaf-segments lanceolate or elliptic-lanceolate.
 - (α) Lower leaf-segments spine-pointed, upper ones obtuse or hooked.
 - 7. E. LONGIFOLIUS, *Lehm.* (*D.C. Prodr.* 531). α *typicus*: leaf-segments lanceolate, flat = E. longifolius, var. angustifolius and var. Honeri, *D.C. Prodr.*—*Zamia longifolia*, *Jacq. Fragm.* t. 20, —E. caffer, *Hook. Bot. Mag.*, t. 4903. β *revolutus*: leaf-segments lanceolate, revolute at the margin.
 - γ *latifolius*: leaf-segments elliptic-lanceolate, revolute at the margins, and 1—2 toothed, rarely quite entire; about 3 inches long, $\frac{1}{2}$ inch wide = E. Almasianus, *Hort. Paulovsk.*
 - (β) Leaf-segments all spine-pointed.
 - * Leaf-segments green, entire, or bluntly toothed.
- E. CAFFER, *Miq.* (*D.C. Prodr.* 532).
 - α *integrifolius*: leaf-segments glabrous, quite entire. β *unidentatus*: leaf-segments glabrous, usually one-toothed.
 - γ *brachyphyllus*: rachis and under surface of the leaves covered with cobweb-like pubescence.
 - ** Leaf-segments green, acutely lobed and toothed.
- 9. E. LANUGINOSUS, *Lehm.*: leaf-segments 1—4 lobed, and acutely toothed at the lower margin, oblong or elliptic-lanceolate = E. lanuginosus, *Lehm.*, *Cycad.* p. 14.—*Zamia lanuginosa*, *Jacq. Fragm.*, t. 20, 31.—E. horridus, β *lanuginosus*, *Miquel*.—E. horridus latifolius, *Miq. Monog.*, p. 59.
 - *** Leaf-segments glaucous.
- 10. E. HORRIDUS, *Lehm.*: leaf-segments prickly-lobed and toothed, lobes frequently spreading; *D.C. Prodr.* 532.—*Zamia horrida*, *Jacq. Fragm.*, t. 27, 28.—E. horridus trispinosus, *Hook. Bot. Mag.* 5371.
 - *** Leaf-segments green, lanceolate, spinous-toothed, teeth subulate, erect.
- 11. E. ALTENSTEINI, *Lehm.*
 - α *typicus*: leaf-segments dense, spinulose on both sides, 1—3 toothed, rarely entire, about 6—7 inches long, $\frac{1}{4}$ inch wide = E. Altensteini, *Lehm.* *Cycad.*, tab. 4 and 5.—*Zamia spinosa*, *Lodd. Cat.*
 - β *paucidentatus*: leaf-segments 1—3 toothed, or entire = E. Murrai, *Vriese*.
 - γ *distans*: leaf-segments 3—4, distant = *Zamia veniosa*, *Hort. J. Versch.*
 - δ *parvifolius*: trunk glabrous, leaf-segments about 3 inches long, scarcely $\frac{1}{4}$ inch wide, 2—4 toothed on each side = *Zamia elegantissima*, and *Z. Van den Hecke*, *Hort. J. Versch.*—*Encephalartos Vroomii*, *Hort. J. Versch.*
 - ε *eriocephalus*, *Vriese*: trunk woolly above, otherwise as in the type.

Excluded Species.

E. TRIDENTATUS = MACROZAMIA MIQUELII, A. D. C.

BRITISH GARDENERS.—XIV.

JOHN HALLIDAY.

MR. JOHN HALLIDAY, whose portrait accompanies this notice, though occupying one of the more prominent positions filled by the gardeners of Scotland, is one of those quiet, unassuming, but worthy men of whom comparatively little is heard by the outside world, but who yet contrive to plod on successfully, absorbed in the duties of their avocation. Different circumstances may in different cases conduce to this end, and what these may be in the present instance we need not stay to inquire. Suffice it to say that the visitor to the gardens at Scone Palace in Perthshire, the seat of the Earl of Mansfield, and which are under Mr. Halliday's management, will find in the good example of North Country gardening.

Mr. Halliday was born on December 27, 1806, at Craigielands, Moffat, Dumfriesshire. In 1826 he entered as an apprentice in the gardens at that place, and remained as a journeyman until March, 1831. He then became a journeyman in the famous gardens of the Duke of Buccleuch at Drumlanrig, in the same county, where he remained for about two years, and then went South; and after having been employed for a few weeks in the Duke of Devonshire's garden at Chiswick, he entered as a labouring gardener in the Horticultural Society's garden at Turnham Green,

which was then in its heyday. Here he remained until July, 1837, when he was appointed head gardener to Lord Sondes at Elmham Hall, Norfolk, and which situation was held by him till July, 1842, when he left, and was employed in Messrs. Lee's nursery at Hammersmith for about a year.

The next situation upon which Mr. Halliday entered was as head gardener to General Lord Lynedoch and Heers, Lyndoch, Perth, which situation he held for about two years, when he left to take charge as gardener and forester at Fortham Hall, Bury St. Edmunds, the seat of Lord Manners, with whom he served in these capacities until the close of 1857; and from thence he went to his present situation, Scone Palace, Perth, the seat of the Earl of Mansfield, on January 1, 1852, where he occupies the posts of gardener and park forester, and is besides manager of the gasworks, clerk of charities, &c.

Nearly forty years ago Mr. Halliday invented a flower-pot, designed so that a trellis could be more expeditiously affixed to it than to an ordinary pot. For this Mr. London marked him amongst the inventors of improved horticultural appliances, and the pot was, we believe, figured in *London's Gardener's Magazine*, though we have not that work at hand to refer to. It appears that on lately asking a Glasgow potter to make a few for him he was met by the objection that the plan was patented.

A very successful Peach and Fig house, erected at Scone in 1860 by Mr. Halliday, from "a walking-stick and gravel sketch" by his noble employer, and which is the subject of an illustration at p. 1293 of our volume for 1871, still continues to answer perfectly. It is an elliptical quadrant, 8 feet 4 inches wide, and 15 feet 9 inches high, furnished with planted-out trees on the back wall, and otherwise furnished with trees

in pots; and usually the crops are so plentiful that Peaches at Scone are "nothing accounted of," like the gold in Jerusalem in the days of King Solomon. The entire skeleton of the roof of this house is of cast iron, a point on which Mr. Halliday claims some originality, and the advantages of which he considers to be that when once erected and finished it is too firm to be swayed or shaken by any hurricane ever likely to bear upon it. Mr. Halliday mentions that there have been several imitations of this house in the adaptation of materials, if not in structural form, and as one of the outgrowths from this nucleus, he points to Messrs. Downie & Co.'s Winter Garden in Edinburgh.

THE BIRCH ROD.

"By breathers, besoms, fie, buy them noo; Fine Heamer risers, better never grew."

THE London stable besom is a wisp of Heather tightly bound with a sort of wooden hoop, and it has, moreover, a rustic handle some 3 or 4 feet long secured by a cotten-pipe driven through the hole of the besom and through the handle, so that no amount of drying or shrinking can ever allow the besom to get loose upon the handle, or in the least degree to turn, still less to tumble out, which, without this cotten-pipe, it certainly would. When the besom is worn to the stump the little faggot still remains as a well-seasoned fire-lighter, and the besom's tail or handle, when not wanted for fuel, becomes a useful prop or stake for any drudgery where such a truncheon is wanted. The London garden besom is composed of birch rods, and those gardeners who buy their besoms ready made seldom buy handles, but only the faggots of birchen twigs, and content themselves with one handle for fifty or a hundred brooms.

Everyone thinks he could dig if he only tried, and even plough with very little practice, but surely anybody could use a besom and sweep; and who ever heard of any rehearsing his or her part in getting grass or withered leaves into a wheel-barrow to make "his garden" "a more expressive term used in the North to denote the absence of loose litter." The mowing machine has lessened the labour of the birchen besom, but there are many other items besides mown grass that still need the birch rod in gardens. When lawns or pleasure grounds have been neglected, and the grass got coarse and tall, with rotten twigs from overhanging trees littering about, it is needful to mow it with the scythe and gather the swathes with a wooden rake, and thoroughly brush the stubble with the birchen besom to prepare it for the mowing machine. Now we have in Manchester a regiment of professional sweepers who turn out very early in the morning when the streets are empty, dressed in sober blue gowns, a sensible sort of livery well calculated to hide poverty as well as dust and mud. When these men attack a street they do it boldly, beginning in the middle. A., armed with a brush about 18 inches wide, sweeps about 3 feet wide, and leaves the issue for B., who does the same for C., and by the time that the fourth has reached the water table, the sweepings will have reached the water table, and half the street will be swept; but the swathe is still in the gutter, and not swept into heaps, which is done by a fifth man, E., and eventually the dust-cart, with its driver and his assistant, comes and clears the street. We had years ago brushing machines, and have some now that sweep the dust, &c., into iron carts, but these threw the sweepers out of employment, and were abandoned. Our streets are now well swept, and our iron carts on lofty wheels are still in use, and attest to all the world that we have not left that scheme untried. Now this style of sweeping is just what would be done in a garden if no system were adopted to do it with less than half this labour, for it must be evident to any one that the filth in the middle of the street will certainly make every step dirty between the centre of the causeway and the gutter, whereas if it could be dealt with as our sweepers do, the greater part of the street would be cleaned by a right-and-left stroke, and this is the great difference between street sweeping and lawn sweeping. A nice slender handle is got, 9 feet long, and on this is mounted a birchen besom, not a round faggot, but, as it were, five little wisps of Birch twigs laid side by side like the fingers of one's hand; and when these come out of the hands of the maker they are kept pressed flat by a door and heavy weights, so as to be ready for use when wanted, and with this kind of besom a man strikes right and left, and lays bare a swathe about 20 feet wide—that is to say, he alone sweeps clean the whole width of a street, and those that follow sweep the swathes into heaps ready for the hand-cart or grass-barrow. The sweeping at Alton Towers in my time was done by women, who on "red letter days" wore a Swiss dress to hide anything like poverty, and in this livery

* Old Scotch ditty.

they took up a position for effect; and on one occasion, when a scion of Russian royalty visited the Towers, these sweepers received him with open besoms, meaning the birch, as he passed. I never thought besoms, but always made them, and the tools for this kind of manufacture, though simple, are little known. A common stirrup for the foot is attached to a cord, and this cord is tied overhead, so that when the cord is put once round the loose Birch twigs it confines them tightly by means of the stirrup with the maker's foot straining on it, and now is the time to make one tie to the besom. I found tar cord best for binding, but some prefer wire, as being cheaper; either will do; but when the besom is worn out, the cord is easily cut, that it may be used as a fire-lighter, whereas the rusty wire is troublesome to get rid of.

Many years ago it was the fashion to make baskets as well as besoms in the foil weather of winter, but this branch of the industry in the craft seems to have died out, and I question if I am not one of the one hundred that could make a vegetable basket of peeled Willows fit to be seen. I may mention here that the best way to get at the better style of basket-making is to buy a neat basket, and quietly take it to pieces, and replace the twigs a few times. Nothing ever set up my boyish pride so much as when I saw my abilities in the art of basket-making; and, although besom-making may be useful and profitable, no one could glory in it—it never could be respectable. *Alexander Forsyth.*

CONIFERS FROM COLORADO.

SOME good cones and foliage of an interesting Conifer (*Abies concolor*) have recently been received at the Kew Museum. Its history has been given by Mr. Andrew Murray at p. 105 of the present volume of the *Gardeners' Chronicle*, and Mr. Murray's opinion as to its close resemblance to P. grandis we rely on. The cones referred to above were sent by Dr. Engelmann, some from the gorges in the foot-hills of the mountains in Southern Colorado, and the others from Southern Utah. Of these Dr. Engelmann thinks there are two forms, differing in shape of cone—one described as pointed, and the other retuse, and also differing in their bracts and scales. One of these cones had fallen to pieces on its journey, therefore we are not able to speak on that point; but so far as the bracts and scales are concerned we must confess ourselves as being unable to distinguish between them. With regard to the "question of which is Douglas' *Abies grandis* and which *amabilis*?" quoting from Dr. Engelmann's letter to Dr. Hooker, he says, "I should like to know whether any of the different forms have yet borne fruit in England?" and he states that a tree with very dense, dark green foliage, white on the lower side, which he saw in the Edinburgh Garden under the name of *amabilis*, and another at Dropmore, where it was called *gravis*, are undoubtedly the true *amabilis*. It is singular, Dr. Engelmann says, that none of the forms of *grandis* should have fruited in England, while in Colorado it fruits at the age of twenty-five years.

The following list of Colorado Conifers, with the altitude of each species, from the pen of such an authority as Dr. Engelmann, may be valuable to some readers of the *Gardeners' Chronicle*—

Abies grandis.—Altitude from 8500 feet to the tree limit.

A. concolor.—Between the waters of the Platte and Arkansas; between 6000 and 7000 feet.

Tsuga Douglasii.—6000 to 10,000 feet.

Picea Alvestrii.—In valleys near mountain streams; 6000 to 8500 feet; never forming forests.

P. Engelmannii.—In valleys, and especially on mountain slopes, scattered, or in extensive tracts; 8500 feet to timber line 11,500 feet.

Pinus contorta.—Extensive forests on mountain slopes; 9000 to 10,500 or 11,000 feet; in valleys running down, scattered as low as P. Engelmannii.

P. ponderosa.—Lower down at the base of the mountains than other Pine; at an elevation of about 5000 to 9000 feet.

P. aristata.—9000 and, more especially, 10,000 feet to timber line, and in scraggy bushes even above it, up to 11,500 and 11,800 feet.

P. edulis.—Only in Southern Colorado, from Pike's Peak southward to between 6000 and 7000 feet.

P. flexilis.—9000 to 10,500 feet, probably not up to 11,000 feet, in valleys coming down to 8500 feet.

Thuberias communis.—Up to 9000 or 10,000 feet elevation.

T. virginiana.—Up to 9000 or 9500 feet; over the territory in the southern part (Colorado Springs to the Arkansas) in very unusual forms, short trunks, broad flat heads, &c.

T. occidentalis.—Only from Pike's Peak southward, with *Pinus edulis*, especially on the Upper Arkansas River.

Foreign Correspondence.

BANGALORE.—The following notes may serve to give some idea of our horticultural work:—

Canna indica.—There are two kinds that grow to perfection at Bangalore, and attain a great height. Planted in ordinary soil, it is quite usual to see them from 5 to 6 feet high, and if carefully grown in rich soil it is not unusual for them to attain a height of 9 to 10 feet; a few have been correctly measured as just exceeding 11 feet to the top of the free-growing spike of flower. The dark bronzed leaf variety is perhaps the quickest and strongest grower, and the freest seeder. Massed together against a blank wall, they make an excellent screen, and have been used extensively in this way with great effect. The green and bronzed varieties were alternately planted in this manner to hide a newly-erected stone wall 8 feet high. They were put in about five months ago as divided roots, the plants being then on the average only 1 foot high. The growth during the rainy season in the new soil was most rapid, and at the end of five months they ranged generally from 8 to 9 and 10 feet in height, and magnificent undergrowth, and with single specimens 11 feet as above. One variety has a bright green leaf, and the other a dark olive-green leaf, with a bronze fringing and reflection, and with markings down the veins of the same colour. The back of the leaf is a lighter and more decided green, and the deep fringing or edging is of a brighter and warmer bronze, while the back of the petiole is of a sorrel colour, as attempted to be shown in the accompanying nature-printed specimen. The plants show a disposition to sport, which will be carefully encouraged, and there appears to be every probability of a new and distinct variety being produced. They are so common in Bangalore, and grow so freely, that when the Lal Bagh (which up to about two years ago had been allowed to become greatly overgrown) was being cleared out, it was found that the *Cannas* had increased so much that, after giving away as many as would be accepted, the remainder were carted to refuse heap. A few of the amateur gardeners who grow them in the plea that they were "so common," and it took a long time to make known their real value as foliage plants. The flowers are formed on long upstanding spikes, many of them being distinct in colouring. Four kinds are particularly recommended, the orange, the deep yellow, the glowing crimson, something after the colour of a freshly-opened *Géant des Batailles*, and the pale primrose. The last may be readily understood, is from the plants with the light green foliage.

Colours.—These foliage plants are now in great plenty at Bangalore; they are in leaf all the year round, and with care make the most effective beds of good and varied colour even in the hottest weather. There are many distinct varieties, and in addition to this, leaves of different colours and shape may often be seen on the same plant, as their disposition to sport is most noticeable. A few years ago there were only two ordinary kinds, but since the introduction of new seed all the best varieties have become thoroughly acclimatised, and are propagated without any trouble whatever. Massed in well selected colour in flat raised beds, or in groups arranged around some old stump, or effectively placed in some ugly re-entring angle, or in long lines staged up one behind the other, and interspersed with other foliage plants, are now quite common, and make a brilliant show. The native gardeners have learned the value of a display of this kind, and arrange them with considerable taste. "The Golden Bedder" and the "chryso-purpurea," as they are locally called, are among the most effective and large beds of these, intermixed with *Iresine Lindeni* and *Herbstii* and *Cineraria maritima*, and backed up again with the green and white *Graptophyllum* and the free-flowering *Cannas*, have an imposing appearance. In the very hot weather—viz., March, April, and May—the growth is a little stunted, but with plentiful watering, and with care that they shall never be alternately wet and dry, the plants appear to revel in the sunshine, and certainly display their colouring (though somewhat different to that of the wet season) in a charming manner. Many of them suffered from the late extremely wet season, but this was due rather to ill-drained ground than to anything else, for in better drained localities the growth was very luxuriant, and during any break in the monsoon the dark purple and the deep crimson varieties apparently took a fresh start. In the case of the first-named this was especially noteworthy, for the young leaves that were pushed forth so abundantly were covered with a light plum-coloured down that gave them a most velvety look. I endeavoured to dry some of the leaves, but gave it up after many failures, as I found the colour faded completely out after a few days, though at first it seemed to be permanently fixed. The figured leaves that accompany this were nature-printed in green ink and then roughly coloured, but they do not seek justice to the originals. Advantage has been

taken of the disposition of the plants to sport, and the best kinds of the most distinctive colours have been closely grouped together in the hope that some new varieties may be raised from the seed which has been carefully saved from this rough group-hybridising process.

Grevillea robusta.—This tree has been introduced into Bangalore within the last eight years or so, and appears to have become fairly established. Its habit of growth and Fern-like foliage, with its Aspen-like colouring, make it a desirable acquisition in landscape gardening, where the generality of the indigenous tree foliage assumes such a compact dome-like shape. This is specially noticeable in the Mango and Ippé (*Mangifera indica* and *Bissia longifolia*), that are so abundant everywhere. Besides being ornamental the wood of the *Grevillea* is hard and good, and, if properly trimmed when young, the tree grows up in a comparatively short time, tall, straight, and shapely; but it is very necessary to attend to the pruning, otherwise the leading shoot is apt to bifurcate. They are very easily raised from seed, and have been freely distributed throughout the province. To give an idea of their growth the following facts will be found interesting to any one seeking information on the subject.

Exactly three years ago three hundred seedlings, varying from 1 to 2 feet in height, were transplanted from the pot nursery into pits prepared for them in the park attached to the Government House at Bangalore. They made very rapid growth the first year, not so much the second, but again appeared to recover and to thrive better during the present year. They were planted rather too closely at first, and have had to be thinned out a little, and those remaining are, in consequence, now looking well and vigorous; their average height is 20 feet, with an average circumference of stem of 11 inches, computed from 100 measurements of trees of all sizes one year from the ground line. The little plantation forms a distinct feature in the grounds, which have been greatly improved and modernised within the last three or four years by the present Chief Commissioner of Mysore, who takes a great interest in the matter. When the tree was first introduced from Australia it was called the Silk Oak, but considering this to be a possible misnomer, and with reference to the silvery colour of the back of the leaves, the name of "Silver Oak" was gradually substituted, and is that by which it is now locally known. At the same time the word Oak is equally a misnomer. From their graceful foliage when young they would answer well for any decorative purposes, and would be admirably adapted for a change in table ornamentation. A young *Araucaria Cunninghamii* or A. Cookii looks also very well, and the beauty of the *Poinciana regia* for a similar purpose is very striking. The *Tinian Pine*, *Casuarina muricata*, makes a suitable novelty. *N. P., Dec. 8, 1874.*

Forestry.

THE cutting and clearing of timber and all kinds of underwood should now be proceeded with as expeditiously as possible. All Larch required for posts and other rustic work with bark on, should at once be cut off the tree, because a few mild days the sap will be up after which it becomes daily less applicable and suitable for such purposes. The sap rises sooner in the Larch than in any other species of forest tree, and also continues in it longer in the liquid state than in any other. It is, therefore, the first tree that can be properly peeled, and also the last in the season that permits the operation being performed. With some circumstances of posts in certain situations readily acquiring a mouldy coating, the above precaution is of itself sufficient recommendation for their general adoption. Palings and fence-posts of all descriptions, which are desired to maintain their rusticity for a protracted period, with the bark in its natural and perfect state, should be cut before the sap expands the bark; for if the latter result occurs before the tree is cut, the bark in a short time separates from the wood, thereby destroying the very effect that was wished to be preserved in the appearance of the posts. If, however, it is at any time imperative to use posts, cut while the sap flows, the best means of preventing the bark from falling off, or becoming ragged, is to make an incision in the bark longitudinally, deep enough to reach the sapwood underneath. This, with due precaution to lay the posts in a drying position for a short time before using them, induces the bark to adhere with considerable tenacity for many years. I would here mention that my own experience for many years confirms the opinion that posts of any kind of wood endure much longer when put into the ground in the round state with the bark unbroken, than they do with the bark taken off, charred, and otherwise artificially treated by tarring, &c. It would be well for such as are interested in the maintenance of telegraph posts to make the experiment of putting in each alternate post with the bark on, and the other charred, tarred, &c. This, if done with the

some kinds of wood through a long line of telegraphic wire, would do more to convince those who have only limited opportunities of proving the case than many pages of printed matter would, however well authenticated or forcibly written. All wood to be used as fuel should be cut before the rise of the sap. Those who burn wood solely as fuel testify that it burns stronger, clearer, and brighter when cut in winter than in summer. In the county of Sussex, where some parts are well wooded, wood as fuel is extensively used, and comparatively cheap. It is all cut in the winter season, in the form of cord-wood, stacked up to dry, and kept free from rain till about twelve months old, when it is considered in its best state for fuel, and of the highest value for such purposes. What applies to one does so to all descriptions of wood—Pine, Fir, and hard woods, not even excepting Oak; while it burns very bright and clear after being pulled or flayed (as it is) for the sake of the bark, it is nevertheless true that Oak burns with stronger heat, and is more durable, when cut in winter, and dried as other woods are for fuel, without peeling. The spray of Birch is extensively used in some parts of the country for lighting fires, but more generally for brooms for streets, stables, and other purposes of sweeping. For these and most other purposes it is necessary that the Birch be cut before the sap rises, at least to such an extent as to swell the bark of the young shoots. All descriptions of wood, for whatsoever purpose, and when the beauty and smoothness of the bark is to be maintained after it is dry and dressed, should specially be cut before the sap rises. Any one who duly appreciates a good Hazel walking-stick, and can discern its marks of beauty, will know that unless cut before the sap rises the bark on being seasoned so far contracts and shrinks as to detract greatly from its richness and beauty. Hazel, therefore, Sloethorn, Holly, Bird Cherry, and Birch, all of which as walking-sticks have their bark preserved on, and which constitutes one of their greatest features of beauty, should be cut before the sap rises. Holly, which is extensively used for whip-handles, and Elder for tops of fishing-rods, together with the two common varieties of Heath, which are used for brooms and general purposes, should all be cut before the flow of the sap; and even Broom for thatching houses, and Whins for heating ovens, or burning lime, tiles, bricks, &c., should, in order to produce the best results respectively, be all cut before the rise of the sap. C. Y. Michie, Cullin, March 15.

Notices of Books.

The Pinetum. By George Gordon, A.L.S. Second edition. H. G. Bohn, Henrietta Street, Covent Garden. 1875.

In laying down Mr. Gordon's new edition of the *Pinetum*, after as careful perusal as one can be expected to give to a book of reference, we can find no triser terms which to condense our judgment than those used by Sir Walter Scott in concluding one of his novels—"There are many things here for blessing and ever good for banning, like Rob Roy." It is impossible to give it unqualified praise, and still less can we refrain from giving it a great deal. It is too late in the day to recommend it as a book of great usefulness and convenience to practical men. It has been in their hands for upwards of fifteen years, and the best proof of its answering its purpose is that it is now out of print and a new edition has been called for. This second edition is the answer to the call. The volume is considerably augmented, more so, indeed, than the mere increase in thickness would indicate, for a considerable amount of space which was occupied in the first edition by descriptions of Roelz's pseudo-species, and which it was one of the chief objects of the little supplement (published in 1862) to cancel or correct, has been freed from them, and the space thus acquired has been left free for other matter. Other improvements in the way of omission might be pointed out. We are glad to see that age has sobered the sharpness of Mr. Gordon's pen, and that the little

exhibition of temper in the supplement at *Abies Alcocquiana*, where we were told in a note that the specific name was "botanical pedantry for Alcock, a man's name," is now removed. Dr. Lindley's title to name a species after Sir Rutherford, or Sir Rutherford's title to have a species named after him, in the only way that scientific custom allows botanists to do it, is no longer sneered at. The edition is distinctly a record of horticultural varieties, besides the few novelties which have been described since 1862. The work also being arranged in alphabetical order, although its scientific appearance is thereby detracted from, is especially handy and convenient for those who rather desire a speedy reference than an elaborate and careful diagnosis.

Putting aside minor blemishes, which may be more differences of opinion than actual errors, the great faults of the book seem to us to be two—one of principle, and the other of execution. The former can hardly be charged against Mr. Gordon as a crime, seeing that it is one that is shared by every author who has yet written upon Conifers, and by most monographers in general. It is the fault of leaving the reader to do the most important portion of the author's work. The author gives a succession of stereotyped descriptions of species all according to the card, so like each other that, with the exception of two or three words, the description of one would apply as well to another, but his help is distinctly lacking is given by another, the reader is guided to the distinguishing points of difference between them. Let the reader turn to any part of the *Pinetum* and he will find that if he means to find out any species by the description he must go over every description in the group to which it belongs and compare it with his plant, going over time after time exactly the same characters common to them all. We thought of giving an example or two, but it is unnecessary: every reader knows the grievance of which we complain. We maintain that the author who pours out such descriptions pell-mell by tilting up the shafts, as it were, leaving the reader to sort and select the contents of the cart for himself, is guilty of a serious wrong, which he has no right to inflict. To save his own time and labour he wastes the time of who can say how many men in the future whose time, in all probability, may be more valuable than his own, and we should hail with enthusiasm any device by which every author should be obliged to do his own work, and sort his own rubbish. If Mr. Gordon had made his descriptions clear and easily comparable with each other it would in some degree have atoned for his following this too general plan, but we can scarcely say that they are, and this arises from the other fault to which we alluded, viz., the mode of execution.

To understand this it may be necessary to premise that Mr. Gordon appears to unite two curious and somewhat inconsistent attributes. He is eminently a practical man, and appears to have a thorough knowledge of the plants that he has had the opportunity of studying when growing in the open ground; and on what he so knows we can place the most entire reliance, at all events as to the fact of their being distinct or otherwise; although even then we are not always sure of the soundness of his acumen in discovering what are the essential points of difference in species or varieties which he yet can perfectly and truly recognise as distinct; but this sort of *stair horticolæ* seems wholly to fall him when he comes to books or dried specimens. Now one of the great faults we find in his descriptions is that he jumbles up together these two different kinds of knowledge all in one lump, and gives out the whole as of equal value, and to all appearance from his own knowledge, and without the slightest hint as to the sources or value of the different pieces of information on which it is founded; so that while on one part of it (that within his own knowledge) we would place the most implicit confidence on his statement, on the other (what he has got from books or other sources) we would not place any reliance at all. Whatever be the cause, he seems to be totally destitute of the faculty of weighing or comparing evidence, or estimating the respective value of authority. The reader may say, how can we tell thus confidently that he has worked up different things together in this way? It is very easy. The authors who have written upon Conifers are not very numerous, and it is easy to trace back the phrases used to their original authors. There is necessarily a great deal of compilation in it. Whenever a species has not been introduced the author must go back to the describer, or to the most recent compiler who has taken his materials from him, and so the repetition goes on until the plant is introduced and then we have fresh information, and if Mr. Gordon gets it he sticks it in among the original description, even although it be contradictory. A contemporary last week, in noticing this work, seems to have been puzzled by the contradictory statements regarding the Stone Pine (*Pinus Pinaster*), where in one line it is described as "a low tree with a round bushy appearance, from 15 to 20 feet high," and in another as attaining in Greece "a height of 50 to 60 feet;" the fact being, that in the former line he is giving the result of his own observation on the tree in this

country (which is exactly as he puts it), and in the other the information he has got from books or at second-hand.

There is another point on which we find ourselves often at variance with him. It reckons many so-called species as distinct which we consider only varieties or synonyms of other species. But this is matter of opinion, on which he is as well entitled to hold his own opinion as we are, and we only allude to it to caution his readers against assuming that every species that appears in his book is necessarily to be taken as a good one. The book being obviously more intended as a practical one than a scientific one, it can scarcely be reckoned a disparagement to it to say that its scientific merit is not great.

There remains to be noticed a new feature in this edition, viz., an index of popular names, compiled by Mr. Henry Bohn, the publisher. We have gone through this index with some care and more curiosity to see how it really was, and fairness compels us to say that we only found one trifling slip in the application of the names (*Morinda* for *Picea Pinifera* instead of *for Abies Smithiana*), and that we found a great deal of learning, especially in Chinese and Japanese names, which we confess ourselves quite incompetent to criticise. Mr. Bohn's is nothing more than a mere index of popular names. A portion of it is composed of translations—as, for instance, *Bal-four's Pine* for *Pinus Balfouriana*, *Menzies' Spruce* for *Abies Menziesii*, the funeral Cypress for *Cupressus funebris*, the tetragonal Libocedrus for *Libocedrus tetragona*; and the same is carried into other languages, as *Dicht blätterige Kiefer* for the recently introduced Japanese *Pinus densitata*. The advantage of giving the names in their own language with those who either at home or abroad do not understand Latin, will amply make up for the somewhat too restricted title of "popular names."

—In Mr. Markham's *Progress and Condition of India* we are candidly told that the Government farms have failed to effect the objects for which they were established. That they would show little if any profit is no more than might have been expected, and it might have been supposed that the natives would learn something from their management. But the natives understand the climatal conditions and soils of their country much better than we assumed, and successfully raise crops where their would-be teachers fail miserably. True, their practice is based upon empirical experiments, and is wasteful, and therefore they must be taught by some means. Hence it is now suggested that their system should be mastered in the first place, and for that purpose intelligent natives should have the management, under superintendence, of the farms. It is as well to acknowledge it when we are wrong, though rather humiliating to have to change places, and after going to teach, remain to be taught. Doubtless many other lessons in Indian administration might have been learnt in a similar manner. The following anecdote, related by Mr. Markham, gives some idea of a native's view of the question. When the commissioner visited one of the model farms devoted to Cotton-growing experiments, he got the old head of a village on one side and said, "Now, Pateljee, tell me really what you think of all this." The Pateljee replied that the English farmer was an intelligent young man; that he worked hard, and was not quarrelsome, and that, considering that he knew nothing about it when he came, his Cotton was no much worse than theirs. In this country we frequently hear the remark, when practical matters are under discussion by farmers, "Ah! that may answer very well with you, but it won't do on my land." And those who could teach the routine of cultivation from the experience of a lifetime, if under the same conditions were engaged in the same work, would manage their neighbour's adjoining farm so well as he whom they have censured. True, there are certain fundamental principles to be observed, but all the rest must come by actual practical experience. This fact is too often lost sight of by writers, and the practical reader throws aside a book that professes to teach the most minute details of all operations on a general plan, without reference to local conditions.

THE FIRST PRIMROSE.

A sweet little Primrose has bloomed since last night,
Unfolding its charms at the first ray of light;
A tear-drop just rests on its bosom so fair;
Methinks 'tis because it is all alone there!
The sun with its warmth will soon dry up such tears,
And bring some companions to chase away fears.
Ah! I dear little flower, thou art welcome to me,
I've watched for thee daily, thy blooming to see;
And now thou hast shown thy bright innocent face,
Thou'lt not remain long, but to others give place.
And why should we sigh at things fleeting away,
That their own duty as long as they stay
I speak now of mortals, as well as of flowers,
These give us pure pleasure, the duties are ours.

M. A. Baines, in "Charing Cross Magazine."

HORTICULTURAL EXHIBITIONS, 1875.

APRIL.

- 4.—Special Exhibition of the Royal Horticultural Society of Amoy.
- 7.—Royal Horticultural Society, South Kensington. Meeting of Fruit, Floral, and Scientific Committees.
- 21.—Royal Horticultural Society, South Kensington. Meeting of Fruit, Floral, and Scientific Committees.
- 22.—Royal Horticultural Society of Ireland. Spring Exhibition. Sec., A. Balfe, 28, Westland Row, Dublin.
- 27.—Manchester Botanical and Horticultural Society. Exhibition of Auriculas, &c., in the Town Hall. Manager, Bruce Findlay.
- 28.—Royal Botanic Society, Regent's Park. Spring Show. Sec., W. Sowerby.
- MAY.
- 1 to 70, inclusive.—Royal Botanic Society, Regent's Park. Mr. William Paul's Special Show of Roses, Pelargoniums, &c.
- 10 to 24.—Royal Botanic Society, Regent's Park. Special Exhibition of Clematis, by Mr. G. Jackman.
- 7 and 8.—Exhibition of Plants and Flowers in the Kibble Conservatory and Royal Botanic Garden, Glasgow. Manager, Robert Bullen.
- 12.—Royal Horticultural Society, South Kensington. Meeting of Fruit, Floral, and Scientific Committees. Pot Rose Show.
- 14 to 21.—Manchester Botanical and Horticultural Society's Annual National Exhibition, at the Garden, Old Trafford. Manager, Bruce Findlay.
- 17 and 18.—Hull and Floral and Horticultural Society's Annual Exhibition. Sec., Leonard Kettle, 20, Gladstone Road, West Hill Park.
- 30.—Royal Horticultural Society of Ireland. Early Summer Exhibition. Sec., A. Balfe, 28, Westland Row, Dublin.
- 22.—Crystal Palace Great Flower Show. Sec., F. W. Wilson.
- 26.—Royal Botanic Society, Regent's Park. Summer Exhibition. Sec., W. Sowerby.

THE

Gardeners' Chronicle.

SATURDAY, MARCH 27, 1875.

APPOINTMENTS FOR THE ENSUING WEEK.

- MONDAY, Mar. 29. Show of Hyacinths, Tulips, Azaleas, Camellias, &c., at Messrs. Cubash & Son's Nurseries, Highgate, London, N. (eleven days).
- WEDNESDAY, Mar. 31. Mr. W. Paul's Special Show of Hyacinths, Tulips, Roses, &c., at the Royal Horticultural Society's Gardens, South Kensington (six days).
- THURSDAY, April 1.—Royal Botanic Society, Regent's Park. Exhibition of Spring Flowers.
- Meeting of the Linnean Society, at 8 P.M.

IT is a healthy sign of the times that the project of establishing an INDIAN INSTITUTE in London should once more be brought forward for discussion. No one can doubt that such an Institute, properly organised, would prove very beneficial, not to the mere handful of students only, but to the toiling millions of India also. WALLICH and ROYLE, WIGHT and FALCONER, CLEGHORN and BRANDIS, and a host of others (botanists whose names shined as great a lustre on our rule in India as those of the astutest statesman or the ablest soldier), have, and some continue to do so, laboured with the view of making known and of developing the products of India, to an extent which is little short of marvellous.

When people talk of the enervating effect of the Indian climate, they overlook the fact that as hard or harder work is done in India as is ever accomplished at home. The field is, indeed, ample—it offers opportunities and inducements of no ordinary kind to men of energy and talent. The establishment of an Indian Institute at home would go far towards systematising and co-relating the efforts of individuals, and it may be, of neutralising the effects or loosening the bonds of red tape.

One of the most important departments of the proposed Indian Institute would be the Museum. There are some of us who have watched the fortunes of that Museum with much interest, whether, as of yore, in dingy rooms in Leadenhall Street, or as now, or lately, at the very top of the new India Office in Whitehall, access to which involved a journey comparable without much hyperbole with that to India itself! When reached, however, the adventurous visitor was pretty sure to be amply repaid, and pretty sure to wonder why so excellent a collection should be starved in the manner it was.

The publications, too, which have issued from this department, though we suspect but

little known to the general public, sufficiently attest the importance of the Museum and the desirability of extending and improving it.

The vegetable products capable of being turned to good account in India are numberless. But a small fraction of them are developed to anything like the extent they might be. Some indeed, as Indigo, Cotton, Tea, and lately Cinchona, have assumed commercial importance, but the gums, the resins, the oils, the caoutchouc, the fibres, and other matters alluded to in Dr. COOKE'S recent list, all require fuller knowledge on the part of our own manufacturers and on the part of the native and European cultivators.

The India Museum should be the centre where all desirable information on the commercial products of India should be readily accessible, just as the museums and herbaria at Kew are the centres of scientific knowledge in all matters relating to foreign, Indian, and colonial vegetable products. The Museum is only one of the departments, the value of which would be increased by an Indian Institute, such as is proposed, though naturally it is one which primarily interests us. Our gardeners and farmers might possibly learn somewhat from their Indian brethren, quite independently of the natural products.

We may give a curious illustration of this, but it is only one out of many—in the case of a drill for field use, simpler, and as efficient, all things considered, as the more elaborate and far more costly implements turned out as novelties by our manufacturers centuries after the native farmers had adopted the simple contrivance just alluded to.

The India Museum is designed to represent as fully as may be the various aspects of India in a manner most convenient for reference, study, and research, by the student, the scientific man, the merchant, the manufacturer, and the artist. The idea is, that each class of visitors should have the opportunity of seeing and studying that class of articles, and of acquiring that kind of information, which they would seek out in the country itself if they had the opportunity of visiting it. The main heads of arrangement, then, are, first, the country and its resources, and next the people and their material condition. Under the former head, physical geology, natural history, agriculture, forestry, and manufactures would be comprised; under the second, ethnography, history, legislation, and domestic and social economy. The library, to a large extent, should be classified in a similar manner, and, of course, also with special reference to its rich stores of manuscripts and other literary treasures. To secure the extension of, and the full benefit from, Museum and library is one of the main objects of the proposed Institute. While the Museum would be as a specimen or a diagram, and the library as a text-book, the Institute would be the lecturer or demonstrator to explain and show the proper way to use the Museum and library to the best advantage. Any reader desirous of further information on this important subject should peruse a pamphlet of Dr. FORBES WATSON'S lately published, and he will then not be surprised to learn that the Chambers of Commerce of the United Kingdom are memorialising the Government to provide proper accommodation for the housing and extension of the India Museum, now temporarily lodged at South Kensington, but which it may be hoped may find permanent accommodation nearer to the India Office.

— THE following letters have been sent to us for publication:—

“Royal Horticultural Society, South Kensington, S.W., March 12, 1875.
“Sir,—I have the honour to make an application to your Excellency on behalf of this Society with reference to the colony of Fiji.

“It is obvious that the territory newly annexed to Her MAJESTY'S dominions must possess plants of great importance to horticulturists, and on behalf of this Society, which has long been engaged in the acquisition of foreign specimens, I have to submit to your consideration the great service which would be rendered to science if an association could speedily be formed there for the purpose of collecting such plants.

“I have further to state that it would be esteemed a great favour to the Society if your Excellency would afford facilities for the transmission to it of specimens of indigenous plants, should any collection be made.

“I feel certain that the importance which the subject has for those engaged in the study of natural history will be considered by you sufficient excuse for this communication.—I have the honour to remain your Excellency's most obedient servant,
“W. A. LINDSAY, Sec.”

“His Excellency the Hon. Sir ARTHUR H. GORDON, K.C.M.G., Governor of the Fiji Islands, &c.”

[Copy.] “4, Mount Street, March 8, 1875.
“Sir,—I beg to acknowledge the receipt of your letter of the 12th instant in behalf of the Royal Horticultural Society.

“It will give me much pleasure to afford every facility in my power for the furtherance of their views, and I hope at no lengthened period after my arrival in Fiji to have the honour of again communicating with the Society on the subject.—I have the honour to be, Sir, your obedient servant,
“ARTHUR H. GORDON.”

“To W. A. LINDSAY, Esq., Secretary to the Royal Horticultural Society.”

— We have received the first of a series of bulletins concerning the proposed INTERNATIONAL EXHIBITION OF HORTICULTURE AT AMSTERDAM in 1876, containing an account of the steps taken in Holland and elsewhere, and from which we extract the following particulars:—

1. That the exhibition be held in the spring of 1876, about the month of April, on a much vaster scale than was taken as the basis for the previous exhibition in 1865.

2. That besides the usual horticultural productions and appliances, an exhibition of colonial vegetables be added, which would secure for the same the importance of the display, especially to foreigners.

3. For the adequate realisation of this idea, to call in the energetic aid of Government to bring together such a collection, and to endeavour to gain the assistance of scientific men, to secure for the collection the intended completeness and importance.

4. To invite foreign Governments to send in, on their own account, similar collections from their respective colonies.

5. To arrange the display in such a manner as, by combining the floras of various countries, to offer as clear a view as possible of the vegetation of the whole globe.

6. To give as accurately as possible a full survey of the species of plants and of the varieties proceeding therefrom, and also the modifications to be observed in these varieties, in order to illustrate the progress of horticulture.

7. To hold a congress simultaneously with the exhibition.

Moreover the relations were determined between the Exhibition Commission and the Palace of Industry Company.

9. The financial concerns were regulated, and—
10. A provisional plan was projected for erecting extensive supplementary buildings to the Palace of Industry, and for preparing the adjacent grounds.

The managing committee was further charged with all the necessary preliminaries for the exhibition, especially with the drawing up of a provisional programme or prospectus, and also with the care of issuing bulletins in the Dutch, French, German and English languages, and distributing the same as widely as possible, in order to give the greatest possible publicity to the cause of the exhibition.

It has been further determined that the articles to be exhibited should be distributed under the following heads, not exceeding ten in number, comprising:—Cotton, madder, indigo, gutta-percha and india-rubber (Caoutchouc), ætherial oils, fatty oils and fats, materials for paper manufactures, Dutch cereals, Tobacco and Peruvia Bark.

The committee opines that the limited number of these articles will conduce to the completeness and perfection of the display; while not only a number of sorts, probably from various regions, might be required, but that, moreover, the sending of plants of the objects, as also of drawers, tools, or implements, books, &c., relating to the articles displayed, might be insisted on.

In this way a collection might be brought together well worthy the attention of professional men, offering an opportunity of exchanging opinions and diffusing the results of their researches.

Besides the exhibition of such chief articles, secondary ones might be added, such as vegetable wax, cachou, sarsaparilla, resin, copal, vanilla, grass-plaiting (Marrum grasses), &c., which though of minor importance, might be made of considerable interest.

The Commission for the regulation of the exhibitions of vegetable productions consists of the following gentlemen:—C. A. J. A. Oudemans (Chairman), F. W. Van Eeden, H. F. R. Hubrecht, W. F. K. Suringar. The managing committee comprise the following persons:—J. H. Krelage (Chairman), C. G. J. J. A. Oudemans, C. J. Van der Oudermetulen, G. A. V. Westerman, H. Gronewegen (Secretary).

Professor REICHENBACH'S address for a short period is Herbarium, Royal Botanic Garden, Kew.

— At the end of September next a GREAT FRUIT SHOW will be held at GHENT, on which occasion the Pomological Society of France will, as an exceptional thing, cross the borders of France and join its forces with those of Belgium. English pomologists have also been invited.

— The accompanying illustration (fig. 81) of *GLEICHENIA RUFESTRIS* gives an admirable portrait of a specimen measuring 7 feet through, grown by Mr. THOMAS BAINES, and sketched by Mr. SMITH before it was sold—we believe, to Mr. WILLIAMS—at the dispersion of Mr. MICHOLL'S collection last year. Mr. WILLIAMS, in his *Select Ferns*, states that the species is rare in cultivation. It has a dense and symmetrical habit; the fronds are from 2 to 6 feet in height, dichotomously branched; the branches pinnate; the pinnae broad and pinnatifid, not pouched, rich deep green in colour above, very glaucous

600 francs a year. Thanks to Messieurs the barristers, the thing grew into a scandal; at that point the Club thought fit to interfere. ISABELLE, in consequence, has lost the privilege of flowering the gentlemen riders' buttonholes. "Eh! dame," said one of them, "the Jockey Club did right to show her how firm is its seat on principles of duty." This shooting star, now extinguished, was one of the prominent figures of the day. At La Marche or Anteuil spy-glasses were pointed at ISABELLE, as an acknowledged celebrity. She has her place in the *Dictionnaire des Contemporains*, being a sort of approach to a great man. The *demi-monde* took note of her looks; the tip-top dressmakers studied her toilettes; the chronicles recorded her sayings—for the *bouquetière* had her witty moments, neither more nor less than Mdlle. SUZANNE BROHAN. Another item of her originality consisted in showing herself in the weighing inclosure adorned with the colours of the last

— We are informed that the VINEYARD NURSERIES, GARSTON, near Liverpool, were purchased at the sale on Tuesday last by the Cowan Patents Company, Limited, who intend to use the property for the purpose of exhibiting their system of heating in full working order, while at the same time endeavouring to maintain the well-earned fame of the Vineyard, and, if possible, to increase its reputation.

— In the *Journal of Botany* for March is given an extract of a paper, published by NORSTEDT in a recent number of the *Botaniska Notiser*, entitled "DO THE LEAVES OF DROSEERA EAT FLESH?" In this essay the negative side of the question is taken up, and the results of a chemical examination of the mucus of *Drosera* leaves are given, the author considering that this mucus is "analogous to the slime resulting from change of the external parts of cellular membranes in some Algae, and not a secretion from

FIG. 81.—GLEICHENIA RUFESTRIS (7 FEET 1 INCH THROUGH).

beneath; the stems of a reddish purple. It is an evergreen species, and very handsome. A native of New South Wales.

— In *L'Illustration* for March 20, M. PHILIBERT AUDEBRAND announces that the famous ISABELLE has ceased to be THE OFFICIAL BOUQUET-GIRL of the Paris Jockey Club. They first *blackballed* (black-balled) her, and then sent her about her business. The fall of a queen would not have made more ado. Of course you know why. One year with another, ISABELLE made an income of 10,000 francs by selling Roses and Carnations to the handsome gentlemen of the horsey world. Living amongst flowers, and coming in contact only with persons the most *comme il faut* possible, one would fancy that she could not help having her heart in the right place. But it so happened that her aged mother, now past work, asked her prosperous daughter for a morsel of bread, that is, for a trifling money allowance. On the flowerist's refusal there was an appeal to justice, and ISABELLE was condemned to pay her poor parent an annuity of

winning sportsman. Persons given to superstitious fancies could not help covering their eyes with their hands the last time she made her appearance on that stage. She wore a scarf of sinister aspect—black and yellow—the colours of Saltarella, M. EDOUARD FOULD'S mare, colours which are also those of Prussia. "Take care, ISABELLE," they said to her; "that unlucky scarf will bring you into trouble." Ye sensitive souls, who always pity the unfortunate, do not, nevertheless, bestow too many tears on the dismissed flower-girl's mournful fate. If we may believe the rumours which circulate in the side scenes of sporting life, the Jockey Club's *bouquetière* retires to a country house with some 200,000 francs of savings—a fortune sufficient for ten philosophers. Mention is also made of a well-filled casket, containing divers brilliants, presents received in the evenings of grand Derby days. There should also be a ring bearing in form of device the almost prophetic words, taken from *Les Saltimbanques* (the part of ODRY), *Tout n'est pas Jasmin dans la vie*—"All is not Jessamine here below."

the cells." The paper is well worth the attention of those who are investigating the phenomena presented by "carnivorous plants." The following explanation of the disappearance of meat placed upon the leaves of *Drosera* will give a good idea of Professor NORSTEDT'S method of treating the subject—"If a living insect settles on the leaf the mucus will adhere to its body, and be mostly disentangled from the glands. It is thus in no way surprising that insects cause the hairs to converge. But what is the effect of a dead insect or a bit of raw meat? If you take a little slice from the middle of a large piece of fresh meat and place it immediately on a leaf of *Drosera* on a warm day in summer, after an hour or less you will see that the hairs have converged around it. On examining the meat and the hairs with the microscope you will find that a numerous swarm of bacteria are already present; the meat has begun to decompose. During the putrefaction ammonia is formed, and it is not surprising that the cells in the knob and upper part of the stalk are already influenced. If, however, the meat be previously placed in septin or amyco-septin

[What are these?] to impede putrefaction, it remains unaltered, and the hairs do not converge. That the meat mostly disappears when it becomes rotten is not very surprising: the bacteria consume it; but that the leaf has absorbed it through the cells of the glands, whose contents are contracted and dried, must be considered to be out of the question. The author considers one cause of the deflection of the stalk of the plant to be found in the fact that the spiral vessels usually, if not always, lie nearer to the inner side of the stalk.

— THE PRESTON FLORAL AND HORTICULTURAL SOCIETY will hold an exhibition of plants and cut flowers, fruits, and vegetables, in the Miller Park, Preston, on July 28 and 29.

— Among plants suitable for culture in a sitting room the CYCLAMEN stands in the foremost rank, and as this is the season of the year when this valuable decorative plant is at its best, it is well to call attention to the fact. One of our leading amateur cultivators of the Cyclamen, Mr. B. HOOKE, of Bradford, Berks, thus writes respecting its value for house culture:—"One property of the Cyclamen consists in its being one of the most easily grown of any of our winter-flowering compact habit, lively marked foliage, exquisite fragrance in the flowers of some of its varieties, long continuance in bloom, and to these must be added its greatest recommendation, viz., that of being, of all flowering plants, the best adapted for indoor decoration. I have frequently had it in my sitting-room, and with most ordinary care it will flourish as well, or almost as well, as in a conservatory. The only attention it demands is to have its leaves brushed over every morning with a soft camel-hair brush dipped in a little lukewarm water." We ourselves, as also many indoor gardeners, can endorse this statement; and, on the other hand, neglect will not affect it injuriously as quickly as it will many other plants cultivated indoors. The simple process of the daily washing of the leaves works wonders in the way of preserving plants in living-rooms; it is but a small attention, but the necessity of constantly paying it cannot be too strongly insisted on.

— We lately received from Mr. W. PARKINSON, of Ripon, Yorkshire, one of his PATENT STUDLEY KOVAL LAWN-MOWERS, with a request that we would try the same, and report the results. We have done this, and are enabled to say that on a piece of lawn that had not been mown since last autumn it made exceedingly good work, cutting close, evenly, and without ribbing. It was a 10-inch machine, the knives, on the Archimedean principle, being very close, and the driving power in the centre of the drums or hind rollers instead of at the side. It is a very compact machine, and strongly made, but required more muscular exertion than some other machines of a similar size. The wicker-work basket which does duty for a collecting-box is not substantial enough for the ordinary treatment which mowing-machines receive, and the single handle may be objected to by those who have hands and slopes to keep in order, inasmuch as that it is always a difficult operation to steady a machine when the operator is too far from his work.

— We have before us the first part of a new edition of the *Deutschlands Flora*, a work in quarto, to contain 500 coloured plates with letterpress (in German) descriptive of wild plants of Central Europe. The edition is to be revised by Dr. ERNST HALLER, of Jena. The figures are good, but with few botanical details, and no scale of magnitude.

— THE LEEDS HORTICULTURAL SOCIETY'S twelfth annual summer exhibition will be held on June 9, 10, and 11.

— The staple article of export from SWEDEN AND NORWAY is TIMBER—the produce chiefly of coniferous trees. The wood is sent out of the country in various states of preparation—sometimes in the form of mauls, and even complete joiner's work. A large proportion of the whole exports is sent to England under the name of "planned goods." The average annual quantity of wood exported from Sweden and Norway during the ten years ending in 1874 amounted to 881,500 tons, but in the year 1873 it rose to 1,250,000 tons, of the aggregate value of £3,050,000 sterling. Besides the timber exported in bulk, a very large quantity is reduced to pulp for paper-making, several thousand tons of which are now annually exported.

— In the Island of Key West, Florida, an important industry has become developed during the past seven or eight years, namely, the MANUFACTURE OF CIGARS. In 1867-68, when the manufacture was first introduced, about eighty persons were employed, who turned out in the course of the year about 150,000 cigars. At the present time there are seventeen manufactories in full work, in which 1200 men,

and children are employed making, picking, stripping, counting, labelling, and boxing. The makers, who are nearly all Cubans, are paid by the ton, the average earnings of an ordinary workman being from three to four dollars per day, but some of the best hands earn as much as nine dollars. The number of cigars manufactured during the year 1874 amounted to about 21,144,075.

— Until recently the PRINCIPAL PRODUCE OF SYRA, one of the islands of Greece, has been bread-stuffs and wine; recently, however, other branches of cultivation have made rapid strides, for it has been found that the soil and climate are eminently suited to the cultivation of vegetable. Consequently most of the vineyards and a large proportion of the corn-fields have been converted into gardens, which now produce a great quantity of vegetables, which are chiefly exported to Constantinople, where a very good market is always found. In 1872 the value of vegetables so produced amounted to £15,500, which, it was anticipated, would have been doubled in succeeding years had the country not been visited by severe drought.

— We are glad to learn that the authorities of the British Museum have secured by purchase Mr. W. G. SMITH'S unrivalled collection of drawings of BRITISH FUNGI.

— One of the CURIOSITIES OF COMMERCE is the growth and traffic in Oranges. The thought frequently occurs to many how the fruits can be sold at the low price they are to be remunerative to the growers, when the gathering, packing, and expenses of freight are considered. In St. Michael's, Azores, an island always noted for its Orange crops, a large company has been formed, consisting of many of the principal proprietors of plantations; and this company is shipped in the year as many as 36,000 mule boxes. The island suffered from a severe drought in 1873, so that in some parts the fruits dried up and were worthless. Many trees perished for want of moisture, and were consequently cut down, and it was found that not more than half a crop would be produced. These fears, however, were not confirmed, for during the season from November, 1873, to April, 1874, upwards of 270,000 boxes of Oranges were exported to Great Britain.

— The cultivation of CAROLINA RICE IN INDIA, which was commenced in 1863, seems at present to be only partly successful, that is, it has succeeded moderately in some parts and less satisfactorily in others. Nineteen barrels, containing 1725 lb. of seeds, were sent out as a first experiment; and in 1872 200 barrels were received by the India Government, and the seed was widely distributed. The superiority of the Carolina over the native Rice is generally acknowledged, but it is said to require a higher system of cultivation and a deeper surface-soil, as it throws its roots to a much greater depth. A fair crop of native Rice may be obtained off land with a surface-soil of 3 feet deep, but Carolina Rice requires deep ploughing, plenty of manure, and good drainage. The question is, whether the extra expense of cultivation can be covered by the increased value of the crop.

— A very voluminous and interesting report, elsewhere alluded to, on the MORAL AND MATERIAL PROGRESS AND CONDITION OF INDIA during the year 1872-73, has recently been issued. As might be supposed from its title, the matter comprised in its pages is very varied, ranging from legislation, finance, taxation, education, cultivation of useful plants, forest conservancy, meteorology, &c. Under the head of agriculture we learn a good deal about the natural resources of the country; the cultivation of indigo, for instance, has, it appears, increased in Bahar, while its area has diminished in Bengal. In Malddah alone there are twenty working indigo factories. More than half the exported product is from Bahar, and almost entirely from the districts on the north side of the Ganges—Feroz Churn, and Sirgan. In 1872-73 the export of indigo from Calcutta amounted to 162,860 maunds, of the value of £2,704,408. The cultivation of Tea and Coffee has been extended in the hill districts, many hundreds of acres of tangled underwood and forest trees having been cleared for planting Tea and Coffee plants. A special chapter is given to forest conservancy and the training of forest officers, both of which are being well looked after by a systematic administration; though we are reminded that forest conservancy has had to struggle against numerous difficulties, arising from the immemorial practices of the natives, as well as from natural causes. The two worst obstacles to progress are jungle fires and the cleaning and burning the jungle for cultivation. In the spring the leaves and grass of the deciduous forests dry up, and everything becomes inflammable. The smallest spark is sufficient to create a conflagration, and fires are intentionally made every year either for cultivation or to cause fresh tender shoots of grass to spring up as fodder for cattle. The report, which

occupies some 236 pages, is worth the perusal of those interested in the welfare of India.

— A new publication is before us in the form of a monthly sheet, entitled *Revue des Jardins et des Champs*, edited by ANATOLE MASSÉ, nurseryman, of La Ferté-Macé. We find in one of the numbers a recommendation of *Bambusa mitis* as an ornamental plant, which is quite hardy in the north of France.

— JABORANDI, the newly-introduced diaphoretic and sialagogue, has been a source of interest lately both to the botanist and to the chemist—to the botanist on account of its source being comparatively unknown, and to the chemist on account of recent experiments as to its physiological action. Both these subjects have been discussed in the two numbers of the *Pharmaceutical Journal* for the 16th and 23d of January, from whence we learn that the term Jaborandi is given to several plants in South America which possess somewhat similar properties. These seem to be little or no doubt, however, that the drug recently introduced into this country consists of the leaves of a species of *Pilocarpus*; but two forms are said to have been received in Europe, one of which comes near *Pilocarpus pennatifolius*, Lem., and the other, though only belonging to the same genus, has not been identified with regard to its species. From a quantity of Jaborandi recently received from Pernambuco by a large firm of London druggists, Mr. E. M. HOLMES has been enabled to publish a description, and to give a figure of a leaf and fruits in the *Pharmaceutical Journal* for January 23. With regard to its physiological action a very interesting account is given in the same journal for January 16 by Mr. MARTINDALE, of experiments made upon himself, which fully bear out the efficacy of the drug.

— We are glad to learn from the *Builder* that it is proposed to construct a PUBLIC GARDEN at the east end of the churchyard of St. George's-in-the-East, London, a district where such a garden would be a great boon.

— We understand that Mr. LAWRENCE, late gardener at Farnham Castle, is still open to an engagement, but we may hope soon to hear that so good a practical gardener has met with an appointment worthy of his high character and ability.

— THE CARDAMOM (*Elettaria Cardamomum*), a plant belonging to the Ginger tribe, is well known on account of its aromatic seeds being used medicinally in this country. The spontaneous growth of the plants in the Indian forests is very well described in a recent report on the products of India. In the hill districts, chiefly on the western slopes of the mountains of Coorg and Mysore, at an elevation of from 2500 to 5000 feet above the sea, the Cardamom forms an important product. In February the largest trees on the steep slopes are marked out, and the tree is felled at about 12 feet from the ground. It falls down the side of the mountain head foremost, carrying a number of smaller trees with it in a great crash. Within three months the Cardamom plants begin to show their heads all over the cleared ground. During the rains they grow 2 or 3 feet, and twenty months after the felling of the tree, when the Cardamom plants are the height of a man, the ground is thoroughly cleared of weeds. In the following April the fruit-bearing branches shoot forth, and become covered first with clusters of beautiful flowers, and then with capsules. In the following October the first crop is gathered, and the harvest continues good for seven years, when they fall off. Then another giant of the forest is felled, and the process is renewed. The gathering in, entailing a walk of several miles through wet underwood covered with leeches, is very hard work. In Coorg the Cardamom forests are rented out for 30,000 rupees a year. In Mysore the yield is valued at £17,000. Instructions were given in 1871-72 for the demarcation of such tracts of jungle as were favourable for the growth of Cardamoms, and coffee planters are beginning to turn their attention to its cultivation.

ORNAMENTAL PIECES OF WATER.

AMONGST the various adaptations of natural scenery which may be brought into play in landscape gardening, a well-managed piece of water is always effective. Some care, however, is requisite, or the result is anything but desirable. It would not be difficult to find an instance where years of attention and much outlay have only produced a series of stagnant ponds, closed in with thick masses of bushes and overhanging trees, the effect on the visitor is gloom and depression rather than any enjoyment, and in all probability a thorough chill also from the permanent shade and damp.

Another beautiful, but often very objectionable, arrangement is a Water Lily pool quite close to the residence. The pool is all very well in the early summer—the flowers expand, and their silver or golden cups are charming amongst the dark green leaves; but as summer goes on, with it comes decaying vegetation, and a falling surface of water, and with them smells from the uncovered surfaces, that, if not always dangerous, at least are better away, and in some cases where (possibly without the knowledge of the neighbouring resident) the ornamental pool is also a portion of the course of the house drain, the mischief may be very serious. Similarly (in a flat country) a stream of varying height allowed to meander about close to a house too often brings fever in its train, and a small quantity of water wandering in this way gently on past the outskirts of a town, and then through garden and pleasure ground, where the owners and their friends stroll or sit on the brink, is more likely than not to affect the health seriously. A very beautiful effect, depending in part on the extreme purity of the water, may be given by the adaptation of a small disused limestone quarry. Here I have seen a little pool of clear water of a deep sky-blue lying at the foot of the surrounding rocky walls, rising sheer up out of it in sharp, clean-cut cliffs, and surrounding the pool so as to give in miniature the appearance of a rocky lake, and in reality as lovely a little bit of scenery as could be desired, with the advantage that through some of the water was necessarily always in shadow, the observer on the brink might enjoy the sunshine at pleasure. In this case the pool was only occasionally depending on wet seasons, but a small outlay in stopping cracks between the stones through which the water escaped would have secured it as a permanent ornament. Where the limestone crops out on the surface an imitation may easily be made of the large workings, having an excellent picturesque effect even on the smallest scale, from the sharpness of the rock and the clearness of the water (perfectly free from weeds) contrasting with the rich vegetation around.

Where the very tiniest stream is attainable on sloping ground, it gives scope for almost endless variety of arrangement. To give a single example—with the aid of a little masonry at distances, it may be backed up so as to form a succession of pools, with the waterfalls for perhaps in one place just the water falling over a few large stones placed across the stream, with a few water plants above them; in another, a higher wall, with the top row of stones projecting, so that the spray of the dropping water might keep some specimens of Ferns, or whatever might be preferred, in constant luxuriance. A small cascade, falling into a natural basin fringed with appropriate plants, is always a beautiful object; and where the water is required for domestic as well as ornamental purposes (if the basin can be overflowing by picturesque bushes or Ferns), it is almost as pleasing to the eye if it is surrounded by a border of neatly trimmed and squared stones as with vegetation, the formal lines contrasting well with the picturesque surroundings, and at the same time securing a neat, clean edge to the little pool.

In a very shallow piece of water, a row of large stones, apparently placed as stepping-stones, look well—the stones, of course, being so placed as not in any reasonable probability to cause an accident, for however shallow the water may be, it is anything but agreeable to be suddenly wet through and very dirty. One may know the pond is not deep, nevertheless the moment of immersion seems endless, and by the time the luckless sufferer has struggled to land with sodden dress, boots full of water, and a general sprinkling of duckweed, he is apt (judging by what I am thankful to think is a solitary experience) to wish very sincerely that safety as well as beauty had been studied in the arrangement of ornamental pieces of water.

In small naturally formed pools much might be added, both to their beauty and interest, by introducing many of our wild flowers in appropriate situations. The Trollius europæus, or Golden Ball, is very ornamental for a growth close to the edge of the water, so are a few clumps of the very common *Caltha palustris* or Meadow Bouts in spring, and the tall purple Loosestrife in summer or autumn.

In the water itself there is no reason that the Water Lilies, as is often the case, should hold sole possession. The *Nymphaea umbellata*, or flowering Rush, with its rich umbels of rose-coloured blossoms rising high above the water, is very beautiful. The *Sagittaria sagittifolia*, or common Arrowhead, is striking from its peculiarly shaped leaves, and the white water Crowfoot, and little white Frogbit, with its fairy cups floating on the surface like a Water Lily in miniature, are all ornamental additions. The large Forget-me-not hardly needs to be recalled to memory, but Snowdrops are less commonly adopted as ornamental growths in such situations, and they will thrive to perfection planted on the very tiniest islands a few feet across in a small running stream. The Giant Campanula is another wild flower of great beauty, when seen in full luxuriance of its native growth, as on the

Greta banks near Rokey, or many years ago in the neighbourhood of Clestow; and the kind of mixture of low bush and tall grass often seen by a small pool, is just the locality in which its purplish blue bells show to great advantage.

Sometimes, from the accidental grouping of old timber and thick bushes, rough bank and smooth sward, the banks of a pool chance to be so arranged as to be a favourite resort of birds, reptiles and insects, delightful to the naturalist as well as the lover of the picturesque, and such a pool once destroyed is so difficult to replace that a description of one, which for years was a favourite resort, may be acceptable to some naturalist readers.

The pool was placed in a row of old Oaks, standing on greensward in front of a plantation, and was of small size, and almost square in shape, but so varied by surroundings as not to convey the idea of a formal outline. One side was merely used as an approach for fetching water; another was chiefly overgrown, even into the water, by tall and thick-tangled bushes, making an almost impenetrable shelter for birds or small animals, above or below; and a third side, which had been somewhat infringed on by a field-road, had been protected by a quantity of large logs, formed of useless stumps sawn off the butt end of trees, which, rolled into the water, gave hiding places for the newts, and foundation for a lovely growth of Forget-me-not.

The fourth side, however, was the head-quarters of the visitors—here a hollow old Oak, over-hanging the pond, gave sheltering nooks, as the case might be, to an owl, a hornet's nest, or any other object of interest or alarm to be expected in such a place, and a shady recess in the bank beneath gave room for a tiny back, where a hamper sunk in the water brought up endless matters for inspection. On the sunny side of the tree, on the dry hot smooth bank, was a basking place for snakes, and a nesting ground for wasps, and the broken bank, running irregularly into the water, was exactly to the taste of the water-insects for an occasional airing, and the water-scorpion would bask and unfold in the sunshine till the reddish under-wings would glow with almost tropical colouring in its enjoyment of the heat. With the addition of the luxuriant growth of the water plants, the vigour of the fish, and the occasional four-footed visitors which might be surprised there by a quiet watcher, the pool was of unending interest; and when pool, and trees, and plantation all were cleared away Cowper could hardly have regretted his Poplars more than the old Oaks and their sheltered pool were longed for by some of those who had known them. O.

Home Correspondence.

Home-grown Tobacco.—Tobacco is one of the gardener's greatest aids to successful cultivation, and is an article almost indispensable in every garden in some form or other. Insecticides we have in any quantity, all good and useful enough in their way, but none can take the place of Tobacco, or compare with it for expiating green-fly. For destroying the various forms of scale, mealy-bug, &c., the insecticides are more efficacious, but, unfortunately, even weak solutions of most of these disfigure and injure paint if sprayed on, and their use in this way should therefore be avoided. Infusions of Tobacco are much the safest and cleanest, and if mixed with any of the insecticides for spraying fruit trees on the open walls it will be found much better than using entire solutions of insecticides containing such a large amount of alkaline matter, a slight overdose of which often causes injurious effects on the tender foliage. As yet we have no substitute for Tobacco for fumigating purposes, and it is in this way it is found of so much value, as its fumes insinuate themselves into every curled leaf and crevice, carrying destruction to the insect pests lurking therein. Its use in this way entails a very considerable outlay in most places, and is often one of the heaviest items for garden requisites. Having used large quantities of home-grown Tobacco, I can strongly recommend it as the best substitute for the manufactured article, and but little inferior to it if properly grown and harvested. If more attention were paid to its cultivation in gardens we should be able to furnish less egregiously than is done now supplies are obtained at a dear rate from the tobaccoist. The best variety to grow for the above purpose is *Nicotiana virginica*. This is a very large-leaved variety, much resembling those of the Jerusalem Arti-

choke in colour and form, but considerably larger and longer. The seed should be sown towards the end of April, and be placed in slight heaps to induce it to vegetate. As soon as the plants are up and sufficiently large to handle, they should be pricked out about 2 inches apart and replaced in gentle heat for a few days, after which they may be gradually hardened off for planting out towards the end of May. A rich open piece of ground should be chosen for this purpose, and the plants should be placed in rows a yard apart and 2 feet plant from plant. When sufficiently high to require support they should either be staked singly or tied to a line of string or thin rods run down the row and supported at intervals for that purpose. No more attention will be required beyond a watering now and then, and keeping the ground clean till the lateral shoots begin to show themselves. These should be pinched out from time to time, so as to concentrate the whole energies of the plant in a limited number of main leaves. These should be confined to ten to fifteen, according to the strength of the plant and the quality of the ground. As soon as they show sufficient leaves they should be stopped, and not allowed to flower, or the leaves will become impoverished and not attain a large size. By the end of September they will be fit for harvesting, and should then be gathered from the stalks and hung in an open shed or in a room where the air is free to circulate, the leaves dry too rapidly and become sunburnt and crumble to pieces. As soon as the midribs have lost all moisture they should be packed away in boxes, and stored in some nice dry place for use. Treated as above, there can be no reason why home-grown Tobacco should not be nearly as good for fumigating purposes as that which is imported. The fermentation and sweetening process undergone by the manufactured article can in no way add to its efficacy for garden use. J. Sheppard.

Seedling Lilies.—Can any of the readers of the *Gardeners' Chronicle*, who have been successful in raising Lilies from seed, oblige me with one or two-year old seedlings of the following species, as I wish to figure them in the first part of my *Monograph of the Lilies*—*L. Humboldtii*, *Washingtonium*, *canadense* (of any of its varieties), *virginicum*, *Phoeniceum*, *gigantum*, *tigrinum*, *caudatum*. The last two are so easy to increase by other means and so rarely ripen seed, that I am afraid the seedlings may be difficult to obtain. It is not generally known how much the different kinds of Lilies differ in the early stages of their existence. Several may be distinguished when in their first year's growth, and it has been shown by Professor Duchateaux of Paris that distinctive characters can be found in the seedlings of such allied species as *L. giganteum* and *cordifolium*. I should also be glad to know if *L. testaceum* ever ripens seed in England, and if so, whether it comes true from seed, as it is supposed to be a plant of hybrid origin. I believe Lilies might be hybridised much more easily than is supposed, and though it is a tedious process to raise most of them, it would be well worth trying experiments on such species as *monadelphum*, *tenuifolium*, *Brownii*, or *gigantum*. R. J. Ehors, *Mitlen House, Cirencester*.

The Royal Horticultural Society.—There are two facts which somewhat affect Mr. Bull's arguments in your issue of March 20. Mr. Jas. Veitch and Mr. Lee were on an old Council (but this is long, long ago. Ens.), and no one can deny that they were excellent representatives of the class of "professional horticulturists." On looking at my photograph of the members of the committee of the memorable "International Horticultural Exhibition," I find that the seven more central figures in the front-rank were not professional horticulturists, in the sense used by Mr. Bull. I had not the opportunity of seeing the working of that committee, which certainly carried a great exhibition and Congress through very difficult circumstances to a thorough success, and, therefore, I should like to ask whether the two most central front-rank figures in the picture (Sir John Cooper and the late Sir John Wood Dike) had not very much to do with the success achieved. I make these remarks only that we may keep on sound ground—not to say a word against professional horticulturists being on the Council. I have long thought that one or two representative nurserymen, selected by their brethren, would much strengthen the Council. As I am writing, would you allow me to air a notion which I think might be useful when the Society is being reconstituted, as it will have to be. I am the more anxious to do so as the opinion of an old, experienced, practical, friendly adviser is adverse, in the fear of its causing the introduction of desultory conversation and reconsideration of matters already about settled. The notion is that, in addition to the present members of Council (not too many to ensure a quorum at all seasons), we should have four or six extra members from the country, say more than fifty miles from London, and that one attendance of these should count as two of the nearer town ones. The effect would, I think, be to strengthen our tie to the country, and to bring in the services of some first-class horticulturists who cannot afford the time or cost of

regular attendance. *George F. Wilson, Heatherbank, Weybridge Heath, March 20.* [Those on the spot would naturally carry their views of the above more than of non-attendant members of Council, if they happened to be opposed; and therefore we think the addition proposed would be of no practical advantage so far as securing better management. Eds.]

Since I had the pleasure of last addressing you I have informed myself of the numerical strength of the several classes or parties, so to speak, who, divided against each other, and, indeed, against themselves, have been, and are working on the ruin of that great Society which it was their bounden duty to support. I was happy to find that the number of those who remain attached to a Legitimist policy, and ready to support the few leaders of horticulture proper which are left to us, is greater than I expected; indeed, I cannot otherwise account for the singular transaction which occurred with regard to the report at the anniversary meeting when that document was virtually condemned, together with the framers thereof. On that occasion the Council were saved from resignation, not upon the merits of the case, but by the charming manner and high gentlemanly bearing of their chairman. After this occurrence I own to having cherished a hope that the form of a hope that something of the following kind might have been effected—to wit, that a fusion between the old independent horticultural party and that of the local Fellows might result in the formation of a Council containing a good proportion of the former. That these two parties (in Council) having agreed to act honestly together might have together gone to the Commissioners and so entered into arrangements of such a nature (upon the basis of cancelling the lease) as to leave all parties in the possession of their desired privileges. The thing is, I believe, still possible in some shape or another. Should anything feasible of this kind turn up, I and my friends will be ready to give it our support. If not, and the Council stick to their policy of making use of the usurper's power to retain the lease and starve the Society, then I counsel, on the part of my brother horticulturists, a firm, compact, and persistent opposition to an evil and a serious influence. *R. Trevor Clark, Welton Place, March 23.*

The "50 per Cent." Reduction at South Kensington.—The total amount of the money offered as prizes in the Society's schedule for the recent spring show was £126 6s.; the total amount actually awarded in accordance with the prize list, owing to the smallness of the competition, was £25 5s., exclusive of medals. This would represent a clear saving of £100 on this show alone, and if the same average saving is to be the case all through the season, it will certainly not be less than £1000. As it is not, then, really hard, indeed I may say absolutely mean, towards the few exhibitors who, under much discouragement, came up to the scratch so well on the 17th, to reduce this small amount by one half, that is, making it the ridiculously small sum of £12 12s. 6d., thus making a total saving on the show of £113 13s. 6d.; for without doubt, had things been more prosperous, medals would still have been awarded. So far from any reduction being made, I think the Council ought to mark its approval of the spirit of the few exhibitors of the 17th by adding at least 50 per cent. to their prize money, instead of making a large subtraction from it. *One Concerned.*

Lee's (Hammersmith) Early Kidney Potato.—Now that the season is at hand for planting, I would strongly advise all who have not yet given this variety a trial, to do so. I have grown it now two seasons, and have no hesitation in pronouncing it the best early Potato I know. I consider it much superior to the favourite Ashleaf, inasmuch as it is with me quite ten days earlier than that variety, of equal if not better quality, and far excelling it in productiveness. I feel sure one trial will suffice to place it high in the estimation of those who value a really good early Potato. *John Brown, Gr. to Earl Howe, Gosnell Hall, Atherstone.*

The Culture of the Verbena.—This once popular plant, sharing the fate of many other florists' flowers, has become much more neglected than it should be, for its adaptability to greenhouse decoration, and the ease with which it could be grown in small pots, with a close net habit, was clearly demonstrated by the late Charles J. Perry, Mr. S. Hyde, of the Alma Nurseries, Farnham, is a very successful cultivator of Verbenas, and his plan of propagating is this:—The cuttings are taken in September from clean planted-out plants, and are struck either with a little indoor bottom-heat or in a dung bed. They are wintered in stores, with a cold bottom, in narrow span-roof houses, with only sufficient heat to keep out frost. Spring cuttings are taken off early in February, being given a little, and the stock pots to be planted in the plants to grow. Moderate drainage is used, with ordinary good potting soil, and a little sand on the surface. Care is taken both in September and February to use clean cuttings from a healthy

stock, and then but little fumigation becomes necessary. There is a disease peculiar to the Verbena, called by some "black top," which should have immediate attention. This is the discoloration of the top of the cutting or young plant, and it should be immediately pinched out, as it is a contagious disease, and of a destructive nature. The store pots of spring cuttings are plunged in sand and sawdust mixed—sufficient of the former to give more solidity to the sawdust, underneath which is tank bottom-heat. The admirable health of a very large stock of Verbenas shows that this treatment is efficacious. Another variety, the Centaurea candidissima, is cultivated extensively here, and with little trouble. Cuttings are taken off in September, slipping them off with a bit of heel, only removing the ragged part. These go into 60-pots singly, or three in a larger size, and are placed in a cold frame under a north wall until December, when they are removed into a cold frame with a south aspect. *D. H.*

Double Cinerarias.—No doubt many, like myself, would be glad to see the double Cinerarias, for they have been persistently advertised and figured, and their fine, perfectly and evenly double qualities, and their beautiful colours, strongly praised. I was tempted to purchase a 5s. packet of seed from a large London house last autumn, and I send you a sample of the flowers I have had. A worse strain of singles I never saw for a very long time. *George Pain, Holland House, Weston-super-Mare.* [The flowers we received were simply stretched, but still better than the Cauliflower-like monstrosities shown by Mr. Bennett. Eds.]

The Fruiting of Young Pine-apple Plants.—For Mr. Bond's information, as sought at p. 375 in your last week's issue, I give you the shortest instance which I have of records of suckers fruiting here. Amongst a batch of strong ones which were started the last week in February, two Charlotte Rothschilds and one Smooth Cayenne showed fruit in June, and were cut on November 28 following—the Charlotte Rothschilds weighing 7 and 7½ lb. respectively, and the Smooth Cayenne 8½ lb. These were grown in pots, and had one shift out of the sucker-pot into 12-inch ones. *Geo. Thos. Miles, Wycombe Abbey.*

Sulham Prize Pink Celery.—It may be of interest to some of your readers to know that Celery can be kept good in the ground till the end of March, if they only get the right sort to grow for that purpose. For years I have been trying to get a good Celery that would stand good all through the winter. I have succeeded in getting one to my mind until now that I have grown Sutton's Sulham Prize Pink. I find it to be all I could wish for in a late Celery; it has stood this very severe winter without any protection whatever, and is now good and fit for table. I believe it to be the very best pink Celery in cultivation. It is of medium growth, stiff close habit, remarkably solid, crisp, and juicy, and of fine flavour. This is a desideratum that has been long wanted, and I think Messrs. Sutton & Sons deserve great credit for having given us a valuable late Celery. With this I send a few heads for your inspection. *Alex. Ingram, Alwick Castle Gardens, March 22.* [The specimens received were remarkably good for the time. We have heard other growers highly praise this variety. Eds.]

Wild Dafodil.—I suppose difference of soil is the cause of the differing experiences of Messrs. Crewe and Barr and of "C. W. D." My own experience, I regret to say, accords with that of "C. W. D." I have repeatedly transferred to my garden bulbs of the wild Dafodil, some from Devonshire and some from this neighbourhood (North Wilts), and have found them turn double after a couple of years. Two clumps only, out of half a dozen each, remain single out of the lot; these have been planted some six or seven years. *R., March 22.*

Orchids at Rangemore.—In walking through the fine gardens of M. T. Bass, Esq., M.P., of Rangemore, I was very much struck with a few specialties which I think worth mention in your correspondence column. The first was a fine plant of *Halenopsis Schilleriana* with leaves a foot long, having two spikes fully 3 feet long, beautifully branched and flowered to the half their length. This had been in bloom since the middle of January, and the blooms were (March 12) without spot or blemish. I counted one hundred flowers, with four spikes, on which I counted six hundred flowers, the others over fifty each. *Dendrobium Pierardi*, with growths 6 feet in length, in a basket suspended from the roof, being one mass of flowers the full length of the growths, making one of the prettiest sights I had seen for a long time. In the cool house, in a 6-in. pot, was a specimen of *Leelia acuta*, with seven spikes of three blooms each, all open—a beautiful sight. Also, in a 7-in. pot, *Lycaste Skinneri*, with twenty-five fully expanded blooms, as perfect a model as a well-trained *Polygonatum*. I never saw so fine a speci-

men before in so small a pot. Of *Odontoglossum*, *Alexandra*, and *pulehiense* were good. Of the former I measured one bloom 4½ inches across; one had fourteen beautiful flowers on one spike, and on another, not quite open, I counted eighteen flowers on one spike, the largest number I remember having seen. I was the more pleased at seeing these fine examples of cultivation, as when I passed through this fine establishment three years before they had only begun to get a few imported Orchids together, and how remarkably well they have done the above will testify. Those I have mentioned were only a few among many beautiful things. *G. L. Burton.*

Manchester and South Kensington Contrasted.—At Manchester we have a schedule, at South Kensington a squabble. But—no, I will not follow out the contrast, but leave it for each reader to fill in at his leisure. On reading the sayings at South Kensington—for, be it noted, there have been no doings—and the schedule of the Manchester Society for their forthcoming Whitsumtide show, it is impossible not to exclaim, Look on this picture and on that, but especially on that! And yet there are those with both pictures before them that invite growers from Manchester to Kensington in aid of horticulture. Well, Kensington has coolly cut 50 per cent. off the prize of exhibitors. Allow me to set in contrast what Manchester is doing. In round numbers it is offering over a thousand pounds in prizes to the Whitsum-week show. But to descend to particulars:—For twenty plants, ten foliage and ten in flower, there are three prizes, one of £30, a second of £20, and a third of £12. For sixteen Orchids the prizes are £16, £12, and £7. For eight stove and greenhouse plants in flower the prizes are £10, £6, and £4. For eight stove or greenhouse Ferns, £8, £5, and £3. For twenty-five hard Rhododendrons in flower, £15, £10, and £5. For ten Roses a flower in pots, £25, £18, and £10. For eight show *Polygonatum* in flower, £8, £5, and £3, and the same prizes for the same number of *Fancies* and *Zonals*. For collection of Clematis, £12 and £8. For twelve new or rare plants, £12, £7, and £5. And so on throughout the schedule. And be it noted these liberal prizes and the spirited management that has lifted the Manchester Society out of its financial difficulties, has established its prosperity and enabled it to do what such splendid service to horticulture. *D. T. F.*

Madresfield Court Grape.—I can fully endorse the high recommendation Mr. Smith has given at p. 375 of the Madresfield Court Grape. I can also add to its good qualities, that I kept it in this way, and sent it to table in good form on February 1, and after our Black Hamburgs were cut at the end of November it succeeded them in splendid condition. It certainly requires closer and more constant attention with regard to damp in the bunch than thicker-skinned varieties, such as Lady Downe's, Gros Colman, and others; but for its superiority of flavour it is well worth all the extra attention it may require. I know of some places it has proved troublesome through cracking, but I liberally supplied with water until it has nearly done colouring, and after that the roots are protected from wet and the air of the house is kept as dry as possible, the complaints of its cracking would be very few. I consider it and Venn's Black Muscat (which I have once tasted at South Kensington) the two finest Black Grapes with Muscat flavour at present grown. I would not advise Mr. Martin (p. 312) to graft it on the Frontignan, it being a very free-growing kind, whereas the Frontignans are not. *F. Ridout, Woodhatch Lodge, Reigate.*

Some Remarks upon the Fickleness of a British Climate.—Where so much of the success or failure of a British gardener in his cultural efforts depends on the state of the weather, it naturally forms an important part of his duties to make the atmosphere his study, and take observations of local signs of coming changes, in addition to that of marking the ups and downs of the mercury, for to be forewarned is to be forearmed. Such signs of rising storms and sudden changes of temperature as are common to the observation of shepherds and others accustomed to be much in the open air, are not unfrequently better guides as to what is coming than the best regulated barometers. To prognosticate the weather, it is to take place in this country at any stated period, is only like leading the weak-minded and uncautious on to rotten ice. Meteorologists, by their constant observations, have assisted science to a certain extent in deducing periodical changes that our climate is subject to, such as the cold atmospheric dips that take place about the beginning of February, March, and May, &c. These falls of temperature are more or less severe according to the position of the wind in the locality at the time in various parts of the kingdom, and more especially in such places as are low and moist, or what may be properly termed within the hoar-frost level. It is now pretty well understood that our climate has its periods or cycles of heat and

cold, running generally in successions of two and three years at a time, rarely extending to a fourth—hence the general impression formed that the present winter was to be one of no ordinary severity, the three previous winters being all remarkable for their mildness, and no less remarkable for the varied characters of summers which followed them. The first, 1872, will be long remembered for its heavy rainfall and low temperature; while 1873, although greatly exceeding in average of rainfall, was a warm, growthy, and productive summer; whereas its successor, 1874, was one of great drought and extreme heat. Thus we see that these three mild winters were followed by summers differing very much in character and results. It is, therefore, evident that no one can foretell what sort of a summer it is to be by the winter preceding. Some faint and obscure light as to the sort of weather that may be expected to prevail through the spring months—that is, from the end of March to the longest day—may be gathered from noticing the position of the wind a week before and a week after the vernal equinox. This is no new theory, as from a number of years' observations I have found the prevailing winds to come from the same direction during that period; but as regards the state of the weather during that time it can only be guessed at by its usual character when the wind has been out of the same quarter at the corresponding period—thus an east wind in March and

hibited at a flower show as an instance of the earliness of the season; early purple Plums ripe on east aspect the last week in July; Walnuts also ripened sufficient to send in for dessert, April 12; Damson and other standard Plums white in blossom, April 25; Lilacs and Horse Chestnuts in flower, do.; Common Hawthorn on May 2; cuckoo heard on April 24, and swallows seen on April 25. *J. Webster, Gordon Castle.*

Diseased Palm Roots.—Some time since I was requested by the Editors to examine and report on some diseased Palm roots supposed to be affected with lungus. On examination, however, I was unable to detect any fungus but an hypertrophy or overgrowth of the cellular tissue bursting through the rind and producing the appearance shown in the figure (fig. 82.) The tendency of the enlarged cells to form a stellate growth, similar to that of the well known star-shaped cells of the Rush, is also shown in the drawing—the cells in the centre of the figure being those of the Rush. The cause of this unusual formation is at present unknown. *W. G. S.*

The Eccentricity of Growth.—I enclose a sketch of a section of an Oak tree that grew over an orchard, shooting out of the hedge nearly horizontal. The pith is very much out of the centre, as is usual in horizontal growth; but the curious part of the sec-

tionally administered? Like Mr. Barron, with his pretty fringed Petunias, which considerably enhances their decorative value, I mean to originate a race of large, bold, fringed common Primroses; and whether the Floral Committee recognises them or not will be a matter of small moment to me, or to those who love these beautiful spring flowers for their own sweet sakes. I cannot be one of those who seek to limit the improvements in natural productions according to the ideas of an uninteresting and shackled uniformity. *Richard Dean, Ealing, W.*

Abies Douglasii.—If this valuable free-growing Conifer were only better known it would, I think, be much more sought after for planting extensively both for ornamental purposes and for the production of timber than it at present appears to be. It is seldom one meets with it in any quantity, and this is to be regretted, taking into consideration the highly ornamental character of the plant, and the excellent quality of its timber. Many of the Fir tribe, such as Spruce, and others comparatively worthless, are still planted to the exclusion of one possessing every good quality. This fine Fir ought by this time to be plentiful in this country, having been discovered as far back as 1796, but to Douglas must be accorded the merit of having introduced it to England, and his name could not have been associated with a more

FIG. 82.—DISEASED PALM ROOTS, NATURAL SIZE; AND TRANSVERSE SECTION, SHOWING DISEASED TISSUE, ENLARGED 100 DIAM.

April is generally dry and cold from blowing over the continent of Europe. A north wind here is a good deal softened by the influence of the Gulf Stream washing our northern shores, and in consequence of which we have frequently a moist atmosphere from that quarter; whereas in the South of England a north wind through the spring and summer months is commonly a dry and cold one, unless counteracted by the sun shining through a cloudless atmosphere. The varied effects of the north wind at the opposite ends of our island are accounted for by its blowing over a large tract of land, and thus giving strength in its dry and arid course. I am not one of those who believe that our summers are fixcely growing colder and the winters warmer, although the seasons are liable to great fluctuations, often following each other in cycles, influenced by causes not yet ascertained. Contrast, for instance, the summer of 1874 with those of 1872, 1866, and 1860, and again the winter of 1873-4 with that of 1860-1. With such a wide range of temperature in so short a time, it is easy to conceive that all the extremes hitherto reached in our island climate will recur again. This place is situate on the south shore of the Moray Frith, in latitude 57° 38', and the subjoined jottings, taken out of my pocket-book, 1874, will serve to show what our climate is in the far north. Roses flowering nearly all the winter; Mignonette lived through the winter unprotected and flowered through the following summer; Apricot blossom, on south aspect, fully expanded on February 6—some fruit on same wall perfectly ripe on July 22, and ex-

tion is that the heart has been formed without reference to the rings of growth, and has a kind of independent rings of its own. The black pencil marks give some of the rings of growth, the black ink spot representing the pith. The red lines show the rings of the bark, *H. R.* [Similar instances are often seen. *Eds.*]

Fringed Petals versus Rounded Petals.—At the meeting of the Royal Horticultural Society on the 17th inst. I exhibited a box of seedling Primroses before the Floral Committee, and one of them, a large sulphur-coloured variety, with an orange centre, was remarkable for the dimensions of its blossoms. I think perhaps it might have obtained an award but for the unhappy Primrose—beautiful in spite of its defect—having imbricated edges to the petals; at least, I inferred as much from a remark I heard come from a member of the Floral Committee. The rule laid down by the speaker was, that a common Primrose must have smooth edges to the flowers to entitle it to a Certificate. By the side of my box were some Chinese Primroses, and here, in order that the flowers should possess properties that would commend them to the attention of the Floral Committee, the petals must have imbricated edges. Are not these artificial distinctions too slavish and intolerant in their character for the present day?—and must they continue to bind the Parliament of Horticulture to the observance of laws as unalterable as those of the Medes and Persians, and often very capri-

worthy representative of the many choice things among Coniferæ introduced by that enterprising traveller. The tree is of free and rapid growth, keeping pace with the Larch in that respect where it has slight shelter and the same favourable conditions as to soil, &c. In growth it always assumes an upright conical form, sending out its branches horizontally. These are set very thickly with foliage of the most healthy green colour, forming a dense mass if the tree is growing where it obtains plenty of light and air. The colour of the young shoots is of a light silvery green, thus contrasting very favourably with those of older growth, affording a glow of light and deep green at once striking and beautiful. The wood of the Douglas Fir is very firm, heavy and solid, containing an abundance of resinous sap, indicating at once the lasting qualities and value of the timber. Now that we hear so much of disease in Larch plantations, it may be worth while to give more attention to a plant that has all the good qualities of the Larch, and may ultimately in a great measure supersede it. Here it does not appear at all particular as to soil, as one planted in stiff clay about eighteen years back is now 50 feet high and in the most luxuriant health, while others in soil varying from this to a loose gravelly mixture are equally healthy and robust, quite keeping pace with the Larch with which they are planted. As to the Larch disease, I am of opinion that it is often brought about by the careless manner of planting in ground containing dead roots of fallen timber, and by burying the *Abies* and rubbish of old plantations when trenching the land previous to planting. This prac-

tice is very faulty and injudicious, as vegetable matter buried in this way is sure to lead to the formation of fungus, and once this attaches itself to the bark or roots of plants, be they small or large, their fate is soon sealed; as it will kill the giant of the forest as well as the puniest plant. Too much care cannot be taken in grubbing up any roots that may have been left in the soil after felling the timber. The practice is too common among planters of leaving these in, and this cannot be too strongly condemned, as it is a sure source of disease and decay. As to the leaves, dead sticks, and other vegetable matter, so long as they remain on the surface they can do no harm; indeed in that position they are a positive benefit, forming, as they do, the mulching plants stand so much in need of. In summer they are great conservators of moisture, as the ground is never dry if roots are attracted to the surface to feed on the rich decomposing matter, and take up the moisture they would search for in vain at a lower level. In winter, what can more effectually protect the roots of plants from frost than a layer of leaves? Nature is very wise and bountiful, and by following her teaching we shall not err; but if we reverse the order of things, and bury beneath the soil the material which on the surface is a train of evils will be sure to follow. On the surface this accumulation of vegetable matter is subject to all the atmospheric changes, and the conditions are not favourable while in that position for the development of fungus spawn. Buried beneath the soil it is soon robbed of the moisture that hastens decay, by the absorption of the surrounding soil, and being away from the influence of air and atmospheric changes the conditions are directly favourable; and, once the fungus starts, it spreads with the greatest rapidity, seizing hold of every root and atom of vegetable matter that comes in its way. As soon as it fastens itself on the roots and bark of plants their growth is impeded, their energies become paralysed, till at last they sicken and die. For years we have had a continuation of dry summers exactly suited to develop fungus on all decaying vegetable matter buried beneath the soil, as the conditions required are a certain amount of dryness, accompanied by the necessary warmth; and the result has been wholesale destruction among valuable trees from a cause little suspected or credited. Elms, and such like trees, that have always a quantity of loose decomposing bark on their roots and round the collar, have been the most affected; and every tree I have seen taken down that had died previously, or was on the point of doing so, showed unmistakable evidence of having been brought to that state by fungus on its roots, as they were white with it. No doubt the scorching seasons hastened their end, but the real cause has, in my opinion, been the debilitating effect of this insidious and little suspected enemy working quietly beneath. May not this have been the cause of the decrepitude and decay going on with the trees in the London parks, and to which you called attention some time back? Water is inimical to the spread of this pest, and had it not been for the excessive dryness little harm could have resulted, as it would not have had time to spread itself over the roots before being checked or killed. *F. Sheppard.*

The Hardiness of Fuchsia Riccartoni.—Last summer I planted out against a low west wall, in a very cold, exposed, and sunless position, a plant of this Fuchsia, some forms as the Gum Cistus, and Clematis. As the Fuchsia had no protection during the severe wintry weather in December, I concluded it was hopelessly destroyed. Certainly all the forms of the Gum Cistus, excepting the common one, were hopelessly destroyed; Clematis patens (azarea grandiflora) was cut down to the ground, but the Fuchsia not only survived but is rapidly breaking into flower almost from every part of the wood left from last year. I am of opinion that this Fuchsia might be much more generally planted for its hardiness, either to grow in the bush form or against trellises and walls; in either case it would be a beautiful object during the summer. *R. D.*

Dendrochilum glumaceum.—Has any one noticed the singular change in perfume of this plant? I enclose you spikes cut some days since, when they had their usual perfume. Now you will notice that they smell like curry-powder. *H. T. P.*

Drosera capensis.—When the collection of plants at Manley Hall was disposed of just two years ago, among the East Indian Orchids there was a number of plants of a *Drosera*, which we knew under the name of *capensis*. It is very possible, however, that there are many very distinct collections in different parts of the country, and others may have noticed the peculiarity and short duration of its flowers. I have been fortunate in again getting one or two of them with some Orchids, purchased from a local nurseryman, and last summer one of them threw up a spike of flower. It is certainly very interesting to watch this as it gradually develops itself, growing about 8 inches high before any flowers appear, and then one morning at about

7 A.M. a bright rose pink flower would burst, which would keep very pretty till 10 A.M., then gradually fold itself up again and be seen no more. Generally one flower would open on each successive morning, remaining open just about three hours, but sometimes two flowers would be out together, and at other times it would be two days before one opened. I have had one of these things in flowers on a spike, which would represent about as many days it would be flowering. Without any artificial aid the flowers were fertilised, and by the time all the flowers had opened a quantity of small black seed would be found enclosed in the majority of the dried flowers. By sowing these as soon as ripe, I have succeeded in raising a quantity of young plants. I have also increased it by cutting the stem through as it grew, and each piece, with a root to it, would always throw up one or more young plants. *W. Swan, Fallowfield, March 22.*

Lisianthus princeps.—There exist some plants in the rich stores of Nature which have the privilege of an extraordinary and peculiar beauty, such as *Lisianthus princeps*, and *Lisianthus grandiflorus*. This is an anthurus princeps, and grows fully in their native country. The traveller who beholds such an extraordinary sight forgets for a moment his troubles, his fatigue, and sacrifices; everything around him breathes delight and satisfaction—the rich spot that has attracted him from afar appears sacred, and when he leaves it he goes blessed with the precious remembrance, feeling himself encouraged on his painful pilgrimage. I wish to speak more at length to meet the note, not only in a full flowering state, but also with abundance of seeds, the latter being the more pleasant and important to me, as I knew the difficulties which had hitherto been experienced in growing this plant, so long known (about twenty-five years) and aspired after: various efforts to establish it from roots, from stems, and even from seeds, having proved without result. The plant grows in the Cordillera of the State of Santander, Republic of New Grenada, at an elevation of 10,000 feet above the sea level. It displays in June and sometimes in frosty temperature a magical aspect, an ornament contrasting strongly with the desert-like regions around. The plant differs in several ways from the general character of *Lisianthus*. It is rather a climber than a shrub, and its flowers are so particularly elongated as not to permit an easy comparison with its congeners. The fruit, too, shows a special variation, being a dry one, while all others known to me are invested nearly throughout with a glutinous substance, which has a smell very much like that of Apples. The plant, it seems, does not prefer any particular soil; any, being a good fertile one, will suit it. The atmosphere is laden often by thick fogs, and rough winds prevail; the position was never a sheltered one—I always found it in open places. The flowers are irregularly funnel-shaped; and the great multitude of them (several hundred at a time), profusely spreading, produce an indescribable effect. The time of flowering is December and January, a time that will best suit growers of cold-house plants. In regard to colour, I have to acknowledge here the existence of two different forms, the one being a variety of the other, and each produces the same high effect. The one originally known is bright orange-tinted red, changing towards the ends into yellow and dark red; the other variety was found in a distinct locality, and about 80 miles distant from the former; it is vermilion-coloured, with the base clear white. The five-lobed limb of each is green, on the first one clear, and on the second one dark green. *G. Wallis.*

SPRING FLOWERS.

MESSRS. JAMES VEITCH & SONS' show of spring flowers, no view at their Chelsea nursery, is, we think, the most attractive they have had. To be displayed will be found in a large span-roofed house, the outside staging of which is devoted exclusively to Hyacinths, Tulips, Crocus, and Narcissi, one side holding Hyacinths only, while at the entrance is a charming group of Clematis. Amongst the new Hyacinths we noted the following as being the best:—*Duchess of Edinburgh*, single, flesh-pink; *Disraeli*, single, lavender-blue, fine; *Masterpiece*, similar, nearly black, a close compact spike—the best of all the dark varieties; *Princess of Wales*, semi-double pink, and a tall spike; *Queen of Naples*, single, and of a bright shade of rose, a close compact spike; and *Gladstone*, single, lavender-blue. Of the older sorts there will be found excellent specimens of (single reds) Charles Dickens, La Joyeuse, Garibaldi, Linneus, Macaulay, Fabiola, Von Schiller, Princess Alexandra, Prince Albert Victor, and Vuurbaak. Single whites: *Snowball*, Grandeur à Merveille, Mont Blanc, and La Grandesse. Single blues: *Blondin*, Leonidas, Lothair, King of the Blues, Grand Lilas, Charles Dickens, Princess Mary of Cambridge, and Baron von Tuyl. Single yellows: *Ida*, Bird of Paradise, and Grand Duc de Luxembourg. Single lilac or mauve: *Czar Peter*, *Adelina Fatti*, *De Candolle*, and *Haydn*. Double reds: *Lord*

Wellington, Noble par mérite, and Koh-i-noor. Double white: *La Tour d'Auvergne*. Double blue: *Lauren Kosters*. The best Tulips as exemplified by Messrs. Veitch's collection are *Proserpine*, *Wanverman*, *Vermilion*, *Biliani*, *Fabiola*, *Kelzerkroon*, *Rose Lusitanie*, *Belle de Lyons*, rectified; *Chrysolira*, one of the finest pure yellows; *Mollire*; *Rose aplatie*, *Roi Pepin*, *Pottbakker* *White*, finest of pure whites; *Joost van Vondel*, dark crimson, with a few white pencillings; *Bride of Haarlem*, cerise-red, with white stripes, forces well; *Rose à Merveille*, rectified; *Cottage Maid*, pink, with white featherings, excellent for pot culture, but not so good out-of-doors; *Cerise Grésidien*, crimson, edged with sulphur; and *Salvator Rosa*, double rose. Of new Polyanthus Narcissi the most prominent varieties are *La Magnifique*, creamy yellow, with orange cup; and *Bontes*, white, with citron-yellow cup. Of the older forms, Queen of the Netherlands, Lord Canning, Bazelman major, Gloriosa, Golden Era, Newton, and Sulphurine will be found in admirable order.

Amongst the Crocuses not yet in general cultivation are *La Innocence*, pure white; *Dandy*, blue, with light edge, dwarf and good; *Grand Alexander*, blue, very fine; *General Havelock*, fine deep blue; *Mr. Peabody*, very dark blue; *Mrs. Beecher Stone*, pure white; *Miss Nightingale*, white, faintly striped with mauve; and *Princess of Wales*, closely resembling *Sir Walter Scott*, white striped with lilac. We have by no means exhausted the list of varieties worthy of cultivation as shown by Messrs. Veitch, but can say no more now than that visitors to the nursery during next week will find, in addition to the bulbs, a fund of interest amongst the Orchids, Cyclamens, Camellias, &c.

On Monday next Messrs. James Cutbush & Son, Highgate, will open their annual exhibition of Hyacinths, Tulips, Crocus, and Narcissi, &c., at the home establishment on the top of Highgate Hill. They have an excellent stock of all sorts of spring flowers well forward into bloom, and we may be sure the exhibition will not be allowed to blush unseen during the Easter holidays. The exhibition will be open for eleven days.

—On Saturday (this day) Mr. William Paul, of Waltham Cross, will open his annual exhibition of spring flowers in the western arcade adjoining the conservatory in the Royal Horticultural Society's garden at South Kensington. The show will remain open until April 3, and will be well worth visiting, if we may judge from Mr. Paul's previous achievements in this direction.

Natural History.

OUR COMMON TOAD.—The gardener has few better friends than the poor despised toad. A friend fond of Rose culture had a favourite Tea Rose, but he was constantly plagued with the greenfly, so much so that two years since the handsome bush was almost destroyed; last year they again began to appear in a few of the lower branches, but in a few days, to his great joy, as suddenly disappeared, and the Rose afterwards was very healthy. This was soon explained by his finding, close to the stem, a large toad embedded in the soil, his head only above ground. Many naturalists have been puzzled to account for the strange assertion of these reptiles being found in solid blocks of stone alive, and when discovered, apparently in a vigorous state, but dying soon after they were liberated from their "living sepulchre." Jesse records one as having been found in a mantelpiece. "A Wet spot had always been observed in a freestone mantelpiece, which afterwards cracked at that place, and, upon its being taken down, a toad was found in it dead." Recently the workmen in a saw-mill near Liverpool are stated to have found one in an old Elm trunk, and I have a record in my notebook of one being discovered in the stem of an Apple tree, but this was just beneath the bark. Several instances can be cited where brickmakers have dug them out of clay-beds several feet below the surface soil, though these are not so well authenticated as those of toads found in red sandstone blocks.

It is not an unusual occurrence for them to climb up the boughs of aged fruit trees, in damp or rainy weather—probably they do so in search of insect food; they may thus be often tempted to secrete themselves in some decayed crevice, and, in the course of time, be completely imbedded—first in the bark, afterwards, as they roll on, in the wood. In dry seasons they are almost torpid. But how do they live when entombed in either solid stones or wood. Dr. Townsend, by many careful experiments, clearly demonstrated the fact that the amphibia do not receive liquid nourishment by the mouth only, but have the power to absorb water through the skin. He found that a frog placed on a sheet of blotting-paper absorbed nearly its own weight of water in an hour and a half. This

might account for their living, probably, in some instances, for centuries, until they were again brought to light, and, in the case of the one found in the mantlepiece it must have been killed by the gradual drying of the stone, when placed so near the fire, as was proved by its cracking & so on.

This theory seems to have been confirmed by the experiments of a gentleman who placed a toad in a flower-pot, securing it so that no insect could enter, and buried it sufficiently deep in the soil to protect it from frost; after the lapse of twenty years he took it up, and found the toad much larger and healthy. On the other hand, Dr. Buckland conducted a series of experiments by enclosing toads in plaster of Paris, trees, &c., but found they all died within two years; he came to the conclusion that it was simply impossible for them to live without food for a longer period than two years. In the experiments by this celebrated naturalist it is just possible that they might have, by the glass, &c., by which they were enclosed, been deprived of all moisture, for it is proved, beyond doubt, that they cannot live without moisture.

We have still lingering amongst us the foolish notion that this despicable reptile is poisonous; some believe they can bite, although I have never yet met with any one who asserted this positively who had seen their teeth; agricultural labourers believe they have the power to spit poison. They are certainly not a pleasant looking reptile [Look at their beautiful eyes]; this may cause them to be shunned, more than the more highly-favoured frog. They can secrete an acid liquid from the large tubercles scattered over the skin; from this dogs do not care to bite them, but, beyond this, they are as harmless and inoffensive as frogs.

In old medical works we have an antidote for the poison of the toad, which is remarkable for the number of its ingredients.—I wonder whether any of our modern pharmacists would undertake to prepare it? This wonderful remedy is to be compounded as follows:—"Take of Plantain and Black Hellebore

the cast-off clothes of the toad, for the simple reason that our friend is ashamed to let others see his worn-out garb, and quietly puts it out of sight—not in the garret or chest, but where it is never seen again, so that he can never be criticised for his miserly habit of wearing his suit so long, even until it is actually torn and threadbare, like many more of his much more intelligent fellow creatures. Do not, however, think any the worse (it has a fearfully bad character already) of this much maligned reptile, because it rolls up its cast-off coat and forcibly pushes it down its throat, like a big pill. I am not aware if it is proud of its new suit; most likely it is, for it seems to be more lively just at this time, and it is anything but an easy matter to get rid of the old one. It first splits down the centre of the back, then down the belly; by means of its mouth, together with much twisting and turning of its legs and body, it gradually pulls off the incumbrance. R.

The Villa Garden.

THE lengthening days, slightly warmer weather, and occasional glimpses of sunshine, even though cold drying winds are their habitual accompaniment, are turning the attention of villa gardeners to the plants they have wintered, and on which they depend to some extent for spring and summer decoration. Nearly every one who has the slightest convenience for wintering plants endeavours to keep a few through the winter, and a great deal of trouble is expended in the attempt, often with but sorry results. Sorry results have rewarded many an attempt put forth during the past winter, and not only did the owners of a cold frame or a few hand-lights find out what destruction could be wrought during a spell of severe frost and snow, weather like that which attended on the closing days of the past year, but those having houses affording better, though not a perfect or even reliable means of artificially warming the same, saw many plants destroyed that would survive an ordinary winter. We have before stated that there is a certain amount of risk in wintering plants in unheated or imperfectly heated structures, and, naturally enough, attention is being turned to those plants which can be preserved without fear of harm, and which flower in spring and early summer. He that loves flowers for their own sakes will grow something, and if he cannot succeed with tender plants during the winter months because of liability to injury during severe weather will devote his attention to plants of a more certain character, because hardy. We know several villa gardeners who have done this, and they bear witness to the great pleasure they derive from the new pursuit. Not long since we paid a visit to one of these gardeners, a man daily engaged in business, but passionately fond of his garden, in which scarcely a tender plant found a place even during the summer months, because of the difficulty of wintering them. As a lover of hardy plants he had so selected the subjects he cultivated as to possess something of interest all the year round. That he should have this perennial pleasure he had constructed a small span-roofed house, the floor of which rested on a good bed of rubble, and its surface was some 18 inches to 2 feet below the ground, and he had constructed on each side and at the farther end of the house a pit, by building up a 4-inch brick wall, 2½ feet from the wall of the house all round. This was filled up to within 1 foot or 15 inches of the top with rubble, and the remainder with Cocoa-nut fibre; and the last-named being used to plunge the pots of the plants in. Not a day passed during the autumn and winter months without something representing itself to gratify the eye. In early spring many pleasant flowers that in the open air would be tardy to bloom, or else the fragile blossoms would be seriously damaged by cold winds, have been or are in their full beauty, unharmed and protected.

Autumn Crocuses, especially the pretty *C. speciosus*, Violets, Snowdrops, Early Primroses, Iris reticulata, Saxifraga oppositifolia, Myosotis dissitiflora, and some Hyacinths, Narcissi, Crocuses, &c., alternating with a few plants noticeable for their variegated or attractive foliage, have been especially noticeable during the winter. The plunging material seems to assist Nature in inducing precocity. There is the necessity for keeping the plants clean, shifting them, dividing them, potting off of sets, &c., all of which gives occupation and enhances the interest felt in his pots by the cultivator.

Some such method as this can be applied, in part, at least, in every cold house or glass structure where fire-heat cannot be constantly supplied in severe weather sufficiently to keep out frost. During the past winter, and in such a house, Zonal Pelargoniums that in the winter of 1873-74 were uninjured, the frost being kept at bay by means of a good-sized paraffin lamp, were, during the Christmas season, every one

destroyed, established plants and cuttings alike; and with them went *Draena australis*, *Agapanthus umbellatus*, *Cinerarias*, *Acacia lophantha*, *Fuchsias*, and other things that invariably survive an ordinary winter in a cold house. Had it not been for certain hardy plants, our shelves would have been very bare at this season of the year; and several of them are now getting very interesting. Foremost among them is the pretty snow-white *Primula nivea*, generally known as *nivalis*, now in charming bloom, with large trusses of pure white flowers. This plant is not more than 4 or 5 inches in height, and several examples of it are quite hidden by the snowy flowers. Of all the hardy Primroses this is one of the prettiest, and the earliest to flower. It grows well in a gritty loam, with which is mingled some leaf-mould; and this gritty loam is obtained by mingling with it a little fine siftings of mortar rubbish. This gives a free porous soil, one that this Primrose likes; and it grows quite freely in it. Another beautiful species, just coming into flower, is *P. intermedia*. This has larger flowers than *P. nivea*, and of a purplish rose hue, and when the trusses of flower are developed is very handsome. Two more bewitching flowers to cultivate in pots at this season of the year can scarcely be imagined; and though the soil in the pots were frozen hard several times during the winter, no harm was done to the plants. *P. denticulata* is also in bloom, and though the flowers are not nearly so showy as those of the other two just named, it is worth growing because of the white mealiness spread over the handsome leaves. All three of these are managed with the greatest ease; and soon after they have done flowering, and even during the time of blooming, they throw up side shoots from the stem of the plant. A little fine soil should be placed on the surface as a top-dressing, and this will induce the shoots to root into it. They should then be taken off and potted into very small pots, using a light sandy soil, and put in a shady part of the house, or plunged in coal ashes in a shady cool place in the open air. They will soon make growth, and in this way a stock can be obtained in a short time. *P. cortusoides amena* and its varieties are making a robust growth, and the leaves are quite handsome. Unlike *P. nivea* and *P. intermedia*, *amena* and its varieties die down during the winter; they are what is termed deciduous, but are perfectly hardy. The flower-stems of this are being pushed up rapidly, and their blossoms, large and of great beauty, will succeed those now in bloom. This type should also be divided as soon as the foliage begins to decay, so that the roots may become thoroughly established in pots by the blooming season the following year. Too much cannot be written in praise of the hardy Primroses for spring flowering.

Of the other members of the Primrose family now flowering in pots we have the splendid double crimson, the purple lilac, and white double varieties also which do well in pots, but which ought to be planted out as they have done blooming. There are a few single varieties also among them, the rich maroon-crimson *auriculata*, which seems too beautiful to be a common Primrose, and likely to suffer for want of appreciation in consequence; and there are also some of the gold-laced *Polyanthuses*, and a few of the showy fancy or modern varieties, that are most valuable for spring decoration. Some of these are fantastically marked, all are very attractive, and they can be cultivated with the greatest ease, and with scant accommodation. Add to these the *Snowdrops*, *Trachelium uniflorum*, just coming into bloom, and the charming blue *Myosotis dissitiflora*, now getting into fine condition in pots under glass, and there is ample materials out of which to make a button-hole or a pretty posy of spring flowers worthy the acceptance of the fairest lady in the land.

Law Notes.

DOM LUIS I., KING OF PORTUGAL, v. CARRUTHERS AND ANOTHER (Vice-Chancellor's Court, Lincoln's Inn, before Vice-Chancellor Sir C. Hall): *March 22*.—The object of the plaintiff in this suit was to obtain a declaration that he, in right of his Crown, and as part of the public property of the kingdom of Portugal, was entitled to some collections of botanical specimens and other natural objects, made by the late Dr. Friedrich Welwitsch, in the course of his employment in Africa by the Portuguese Government, including, as part thereof, the notes and descriptions from time to time made by Dr. Welwitsch explanatory thereof, or in reference thereto; that the defendants might be ordered specifically to deliver the collections, &c., whole, undefaced, and uninjured, to the plaintiff, or to whom he should appoint; that, if necessary, an inventory might be directed to ascertain of what the collections consisted; that in the meantime some proper person might be appointed to receive and take due care of the collections; or otherwise, that the same might be duly deposited as the Court should direct; that the defendants might be restrained from selling or disposing of, and from

FIG. 53.—THE COMMON TOAD (RANA BUFO).

roots, with powdered crabs' eyes, mingled with the blood of the sea tortoise, dissolved in red wine, the salks of three dogs' tongues, the right horn of an hart, cummin seeds 1 oz., the vermet of an hare, and 1 oz. of oil of scorpions." A dairymaid was so terrified by a toad crawling over her foot, as reported lately in a provincial paper, that she had fited severely, afterwards causing her death, but to the last she persisted in declaring that she was poisoned.

This poor creature, filled with poison as it is often supposed to be, has, however, its redeeming qualities, for it has the power, when dried and applied either to the nose or any wound, to "assuage bleeding." A diamond is also said to exist in its head, but which can only be extracted by the "seventh son of a man who was also the seventh son."

It is noticed above as the gardeners' friend, for it destroys, if allowed to ramble at will over the borders, an immense quantity of snails, slugs, grubs, and insects. The base of its tongue is attached at the entrance of the mouth, and the lip or point is, when not in use to catch its prey, pointing down the throat. For a moment watch it: as a worm crawls a few inches before its head, not suspecting any danger, the eyes glisten as they rest upon the morsel—perhaps it is hungry; however, in much less than a second the tongue darts from its mouth, and the worm has disappeared, being safely deposited in the toad's stomach; but it still sits in the same position, never having moved during its meal, as unconcerned as if nothing had occurred.

I have often been told of colonies of the Natterjack being found in various parts of the country, as if they were exceedingly common, but any one at all acquainted with this species will never again confound it with the common toad—it is a much handsomer reptile, with bright green and yellow bands. The reason why the common toad is thus confused is because the person reporting the discovery in good faith has seen a specimen in a new suit of clothes, or new skin. It has the power of changing its skin at certain intervals, but the old cast-off garment is never found. I frequently come across the skins of the slow-worm and serpents, yet I was never so fortunate as to find

parting with the possession (save to such receiver or otherwise, as aforesaid) of the collections, &c., or any part or parts thereof, respectively; and for such future or other relief as the nature of the case might require. The bill in the suit stated that Dr. Welwitch, a native of Carinthia, in Austria, held under her late Majesty Dona Maria II., Queen of Portugal, an office in the Royal Botanical Gardens at Lisbon, and was Curator of the Museum of the Polytechnic School in that city. In 1852 he was appointed by the Queen to explore as a naturalist the African provinces belonging to the kingdom of Portugal. It was to receive a certain salary, and was to furnish to the Governor-General of the province of Angola notes, observations, and experiments made in foreign countries by competent persons relating to the agricultural industry of that province. He was also to inform the Governor-General upon the collection, preparation, packing-up, and transport of the samples of the natural products of the province, which he might have to send to the Portuguese Colonial Council; to which he was also to send samples of the natural products which might be remarkable in any way, as well as specimens of herbs fit for collections. The plaintiff alleged that it was part of the Doctor's duty, in the execution of his appointment, and part, also, of the terms on which he held it, that he should collect in the African provinces botanical specimens and other natural objects, and make the necessary notes and descriptions explanatory of them, on his behalf and for the use of Her Majesty Dona Maria and her successors, and that all such collections, including the notes and descriptions, should become and be her and their property, in right of the Crown of Portugal, and as part of the public property of that kingdom. Dr. Welwitch accordingly left Lisbon in August, 1853, reached Loanda, the capital of Angola, in October of that year, and continued his explorations till 1866, collecting many botanical and other specimens, and illustrating them with notes. In January, 1867, he returned to Lisbon. In 1867 he obtained permission from the Portuguese Government to come over to this country with his collections, in order to get further scientific assistance for their arrangement, from our museums and institutions, and particularly from the officials at Kew Gardens. He continued to reside here, classifying and arranging his collections, and reporting thereon to the Portuguese Government. In February, 1866, that Government, deeming that ample time had been afforded to Dr. Welwitch for completing his operations, suspended the salary of which, until then, he had been in the receipt. He remained, however, in this country till 1872, in which year he died, having by his will assumed to treat the whole of his collections as his own. He disposed of various parts of them to different persons and bodies, and directed that "the Study Set," called in his work "the Study Copy," of African plants, the most valuable part of the collection, should be offered to the Botanical Department of the British Museum, which the defendant, Mr. Carruthers, was the keeper, at the rate of £2 10s. per century (100 species), and bequeathed some portion of the collections to the Portuguese Government, and the Royal Academy of Sciences at Lisbon. He concluded his will by stating that he made the dispositions thereinbefore appearing of his collections, in the hope that all the bequests made to museums might be considered as made to them by the Portuguese Government, through whose assistance and liberality some of the collections had been made; and he appointed Mr. Carruthers and the other defendant, Mr. Frederick Justes, and others, his executors. In that state of things a considerable amount of correspondence passed between the solicitors to the parties interested, and several interviews having been held in reference to the matters in dispute, the bill was filed in this suit, stating the facts, and praying for an above-mentioned relief. The defendants put in an answer, and the cause now came on for hearing.

Mr. Lindley, Q.C., Mr. Chitty, Q.C., and Mr. W. Phillimore, for the plaintiff, having explained the nature of the suit,
The Vice-Chancellor asked whether there were no means of settling it equitably and reasonably without a decree of this Court. He had read the pleadings, and thought that with the aid of a scientific person some arrangement could be arrived at which would satisfy both parties.

Mr. Lindley, Q.C., said the plaintiff's claim to the whole of these collections was disputed by the defendant. The plaintiff attached the greatest importance to "the Study Set." It was a collection of standard specimens, with the names and other particulars affixed, in the handwriting of the Doctor, and no second or other set of duplicate specimens ever had the same authority upon botanists as these, which were called "the Types." The "Study Set" of African plants was not complete, but so far as it went it was the most complete, but so far as it was his duty to the Portuguese Government, who, if the defendants' claim to that set was allowed to prevail, would be deprived of the most valuable result of an

expedition sent out at the expense of the Portuguese nation.

The Vice-Chancellor was aware of the importance attached to the possession of that set, but thought it hardly required a decree of this Court with respect to it.

Mr. Dickinson, Q.C., Mr. D. Jones, and Mr. Gregory Walker, for the defendants, said "the Study Set" was of the greatest consequence to both parties. But there were other matters of a pecuniary nature in dispute between them.

The Vice-Chancellor said the negotiations for an arrangement might include all those matters. The defendants were only desirous of doing their duty as executors of the Doctor, who appeared to have directed them to offer some of the collections to the British Museum.

Mr. Dickinson, Q.C., said the defendants had a double duty to discharge—one as executors of the Doctor, the other with reference to the British Museum.

Mr. Lindley, Q.C., said the British Museum had no more to do with the matter than Kew Gardens had.

Mr. Dickinson, Q.C., admitted that; but said that both institutions had something to do with it. There was a balance said to be due for salary to the Doctor's estate. He thought if the matters were considered, perhaps, with the assistance of the Court, the delivery of "the Study Set" to the plaintiff might be waived, and some arrangement come to.

Mr. Lindley, Q.C., said that any suggestion of the Court would be, of course, attended to; but there could be no arrangement without the delivery of "the Study Set."

The Vice-Chancellor said that, having regard to the parties to the suit and the nature of the questions raised in it, it was certainly one which, he thought, should be arranged. After some further discussion, he directed the cause to stand over generally for the consideration of the parties. Either of them might apply to have the cause put on the paper, and neither of them was to be in any way compromised by what had now occurred.—Times.

The Weather.

STATE OF THE WEATHER AT BLACKHEATH, LONDON, FOR THE WEEK ENDING WEDNESDAY, MARCH 24, 1875.

MONTH AND DAY.	BAROMETR. INCHES.			TEMPERATURE OF THE AIR.			HYGROMETRIC DEGREES.	WIND.	RAINFALL.

- Mar. 18.—Fine, bright, mild, and nearly cloudless throughout.
- 19.—Overcast, and dull throughout.
- 20.—Fine, partially cloudy, mild, and brisk wind all day.
- 21.—Fine, cold, and cloudless in early morning; partially cloudy, and mild afterwards.
- 22.—Overcast, dull, and mild throughout. A few drops of rain fell in the morning.
- 23.—Fine, bright, mild, though light clouds were present throughout.
- 24.—Overcast, dull, mild, and nearly calm throughout.

In the suburbs of London the reading of the barometer at the level of the sea increased from 30.08 inches at the beginning of the week to 30.17 inches by the morning of the 15th, decreased slowly to 30.14 inches by the afternoon of the same day, rapidly increased to 30.16 inches by the morning of the 18th, and then decreased to 30.12 inches by the afternoon of the 19th, and was 30.14 inches at the end of the week. The mean values throughout the week were above their averages, that for the 18th being 0.53 inch in excess. The mean reading for the week was 30.23 inches, being 0.15 inch greater than that of the preceding week.

The highest temperatures of the air at 4 feet above the ground ranged from 43° on the 14th to 41° on the 16th and 17th, the mean value for the week being 44°. The lowest temperatures of the air ranged between 35° on the 14th and 17th and 31° on the 15th; the mean for the week was 33°. The mean daily range of temperature in the week was 10°, ranging from 17° on the 15th to 6° on the 17th.

The mean daily temperatures of the air were as follows:—1st March 14th, 40°; 2nd, 15th, 38°; 3rd, 16th, 36°; 4th, 17th, 37°; 5th, 18th, 36°; 6th, 19th, 38°; 7th, 20th, 37°; 8th, 21st, 40°. The departures in defect of their respective averages—1°, 2°, 2°, 4°, 6°, 4°, 3°, 5°, 4°, 5°. The mean temperature for the week was 37° 8, being 3° 7 below the average of sixty years.

The highest readings of a thermometer with blackened bulb in vacuo, placed on grass in sun's rays, were 106° and 118° on the 14th and 18th, but on the 16th it did not rise higher than 53°. The lowest readings of a thermometer on grass with its bulb fully exposed to the sky were 27° both on the 15th and 19th, but on the 17th 32° was the lowest reading. The mean for the several low readings was 29°.

The direction of the wind was generally E. and N.E., and its strength gentle. The weather during the week was for the most part dull, and the mornings and nights cold, although there was an appearance of fine and bright weather at intervals each day.

Rain fell on one day; the amount measured was 0.09 inch.

Slight fog prevailed on the morning of Friday the 19th.

In England, the extreme high temperatures observed by day ranged from 56° at Bristol to 45° at Norwich, Hull, and Newcastle-on-Tyne, the general average over the whole country being 49°. The extreme low temperatures observed at night varied between 33° at Sunderland and 24° at Wolverhampton, the general average being 29°. The extreme weekly range of temperature was 10°, the extreme being 27° at Bristol, and 14° at Newcastle-on-Tyne. The mean high day temperatures varied from 47½° at Bristol to 41° at Newcastle-on-Tyne, with an average value of 43°. The mean low night temperatures ranged between 34½° at Sunderland and 30½° at Wolverhampton and Eccles, with a general average of 32½°. The mean daily range of temperature was 11½°, ranging from 15° at Eccles to 8° at Newcastle-on-Tyne.

The mean temperature of the air for the week was 37°, being 9° lower than the value for the corresponding week in 1874; the highest was 39° at Bristol, and the lowest 33° at Norwich, Hull, and Newcastle-on-Tyne.

Rain fell on one or two days in the week at most stations, and the amounts measured were very small; they, however, varied from two-tenths of an inch at Newcastle-on-Tyne to one-hundredth of an inch at Nottingham and Liverpool; at Sheffield no rain fell, the average fall over the country was five-hundredths of an inch.

The weather during the week was somewhat fine, but dull and cold, and the sky generally cloudy.

A lunar halo was seen at Bristol on March 14. In Scotland, the highest temperatures ranged from 48° at Aberdeen to 45° at Leith, the general average being 46°. The lowest temperatures varied from 32° at Dundee to 23° at Paisley, with an average value of 28°. The mean range of temperature in the week was 18°. The mean temperature for the week was 37½, being 9½ lower than the value for the corresponding week in 1874, the highest being at Edinburgh and Aberdeen, both 58½, and the lowest at Perth, 36½. The amounts of rain measured at the stations ranged from one-tenth of an inch at Greenock to three-hundredths of an inch at Aberdeen and Perth. At Dundee, Paisley, and Leith no rain fell. The average fall over the country was three-hundredths of an inch.

JAMES GLAISHER.

Garden Operations.

(FOR THE ENSUING FORTNIGHT.)

PLANT HOUSES.

PLANT STOVE.—Trained specimens of *Allamandas* that have been hard cut back, and partially disrooted sometimes break weakly and with an insufficiency of shoots; instead of stopping the points to increase their numbers and strengthen them, it is much better to allow the first breaks to grow until they are some 3 or 4 feet long, and then train them round the trellis, with the points a little lower than where the base of the shoots spring from: by this means several shoots will start from the bottom of each first growth, that will grow vigorously and be in every way more satisfactory than the results of the usual stopping process. Be particularly careful to keep regularly trained as they advance the young shoots of all rapid-growing stove twiners, such as *Stephanotis*, *Dipladenia*, *Aristolochia*, *Ipomoea Horsfallii*, &c.: the latter is an excellent plant for training lengthways over the paths of the house, as it does not need a number of shoots as many kindred subjects, but runs to a considerable length in the course of the season, and in such a position looks well and economises space, requiring little shade itself but imparting such to any plants placed under it that may be benefited by a little. By a judicious arrangement of those

climbing plants that do not require shade, grown thickly over a portion of the stove, the sun's rays will be sufficiently broken for some plants that cannot bear full exposure to them, without the application of much outside shading. Syringe overhead freely every afternoon sufficiently early for the plants to get dry before nightfall. This is not only necessary to promote growth, but to keep insects in check. This operation should be performed with judgment, so as not to wet the soil of delicate or sparse-rooted plant too much. All the *Atmanidas* are exposed to the feet of a very small species of thrips, which gets into the points of the shoots, and effectually prevents growth. Where these insects exist, unless the points are thoroughly well wet once a day their cultivation can never be satisfactory. These gross-growing plants, so different from the delicate-rooted *Dipladenias*, are not likely to be injured at the roots by this copious syringing. *Gloxinias* may now be moved into larger pots. To keep them stout, and short in leaf and flower, place them near the glass. Cuttings should at once be put in, or seed sown, of *Solanum Capsicastrum* and *S. Pseudo-Capsicum*. Let *Geranias*, *Bilbergias*, *Tillandias*, &c., have a good light position, otherwise they will not bloom so satisfactorily. No collection of stove plants should be without the lovely blue free-flowering *Tillandia Lindenii*. It occupies little room, and is a nice habitant plant, independent of its very copious flowers.

CAMELIAS.—Plants that bloomed early will now be commencing to grow. These should be placed where they can receive shade and a temperature of 55° in the night, with a rise of 10° or 15° by day. Let them have plenty of moisture both at the roots and in the atmosphere. Those that are in comparatively small pots will be benefited by the use of clear manure-water.

SOFT-WOODED GREENHOUSE PLANTS.—*Calceolarias*, both herbaceous and shrubby varieties, should be treated as the more delicate plants in a light and airy atmosphere. The most useful sibs for general decoration are such as are in, say, 6 or 7 inch pots; but if desirable some may be grown larger by moving on into 8 or 10 inch pots. The most suitable for this growing on are plants that are vigorous, and not yet showing flower; when they have got well hold of the new soil assist them with liquid manure.

Chenariars are always useful, and never more so than early in the winter, particularly the different shades of blue so essential for cutting. These plants cannot bear forcing, half their value being destroyed if they are submitted to heat. To have them in bloom at the above season the seed must be sown early: there is no better time for doing it than the present. *T. Batesii*.

FRUIT HOUSES.

VINES.—Energy, method, and determination are requisite to keep pace with the work in this department, for now that all the vinerias are started one will require thinning, another disbudding, another pinching down to the second joint, operations that can be put off without in some measure injuring the Vines. As soon as the fruit is set determine the number of bunches to be left on a Vine, and then cut off those that have not set well or are small and badly placed. The desire inherent in most of us to have a grand show of fruit generally leads to the error of overcropping, but this should ever be avoided. Greediness is at all times to be deprecated, and especially so when evils follow in its train, as they certainly do if Vines are overcropped. Our solace should be that what we lose in the number of bunches we gain in size of berry, higher finish, and quality. Pinch out the point of the shoots one joint beyond the fruit, or, if space will admit of more foliage being exposed to light, pinch out at the second or third joint, as the more foliage the more roots. Care should be exercised in tying out the shoots, as when growing vigorously they are apt to snap. It is best to go over them two or three times in the course of the winter, and get them down gradually. Keep up a supply of moisture in all houses, but those where the fruit is ripening; this is particularly necessary this season because of the bard firing consequent on the cold sunless weather we have had so long. Where Grapes are colouring a comparatively dry atmosphere should be maintained, and air given regularly, even though firing be necessary to keep up the temperature. A free circulation of warm dry air is indispensable to perfect colour and firm of Young Vines that were planted last season, and in the winter cut back to the bottom of the rafter, should have the points pinched out of all laterals they make to a length of 6 feet; this will help to plump their fruit buds for next season, but all growth made above this point should be allowed to grow at random at the in the manufacture of roots. *W. Wildsmith, Hockfeld.*

MELONS.—We may shortly hope for a more favorable condition of the weather, which (March 24) is still winterly; meanwhile, let everything ripen quietly, and now that the days are lengthening a slight increase in the temperature, both day and night, may

safely be permitted. Our first batch are this year later than usual, nevertheless they are advancing nicely up the trellis, and with half the batch we shall endeavour to secure a good set on the first laterals. To facilitate this end the plants should not be stopped until they have advanced up the trellis quite two-thirds of the distance they are intended to travel; after which, in many kinds, a few fruits may be expected to show at the second or third joint on these first laterals, and by securing which a few extra early fruits will result. The remainder of the batch may be stopped once or twice to keep them a little later. Do not earth up the roots till the fruits begin to swell off; a very small quantity of soil will suffice to grow the earliest batch, and especially if in boxes or pots. Maintain a moderately moist atmosphere in bright weather, with an occasional gentle syringing over-head. In pits and frames, if the fermenting materials have generated a good heat (and if not turn them and add fresh material) the plants may be planted out forthwith, pressing down the soil fairly tight in the operation. After turning out, the plants should receive a fair watering; afterwards use water very moderately for a few weeks. Be careful to allow the escape of rank heat and steam, and especially when the sun shines, and employ a good night covering of hay, straw, or Fern litter, or other good non-conducting material. *Thomas Simpson, Broomfield.*

ORCHARD-HOUSE.—In most localities *Apricot* trees in these structures will now be in full bloom, and air should be admitted in abundance whenever the state of the weather will permit this to be done. Should dull, damp weather happen to set in during the time that any of the fruit trees cultivated in the orchard-house are in flower, more particularly the *Apricot*, the *Peach*, and the *Cherry*, it is always advisable to facilitate the setting of the fruit by the use of a camel-hair pencil, which should be repeatedly filled with pollen from the anthers, and which should be deposited upon the stigmas. As yet, however, this operation has not been necessary, on account of the prevalence of east wind, and the somewhat arid state of the atmosphere, which has also made it advisable to close the ventilators somewhat early in the afternoon, so as to retain as much as possible of the solar heat; otherwise an injurious depression of temperature might occur during the night. Syringing the trees must, of course, be discontinued until the fruit is fairly set, when it must be resumed; and in order to keep down insects it may be necessary to have recourse to the syringe, or rather to the more powerful garden engine, mornings and evenings, but this should not be done on evenings when there are any indications of frost, or of a very low temperature. Let the trees, whether in pots or planted out in the borders, have abundance of water at the roots whenever this is required. To allow the soil in which the trees are growing to become too dry, at any stage of their development, is very injurious, but never more so than while they are in bloom, the result of this being, very frequently, the dropping off of the flowers, without setting and the consequent loss of the crop. For some weeks to come all spare space in the orchard-house, as well as in other glass structures, will be found useful in affording shelter to bedding plants, &c., which are in no degree injurious to the legitimate occupants of this structure; but which may, on the contrary, be so arranged or grouped by the sides of the paths and elsewhere as to give increased interest and attractiveness to the same, while to all such plants the protection afforded by an orchard-house will generally, after this time, be found to be sufficient. *P. Grieve, Culford, Bury St. Edmund's.*

Answers to Correspondents.

BOOKS. G. T. Get Ewart's *Land Improver's Pocket Book*, 4s., and Horton's *Complete Measurer*, 5s. Both are published by Lockwood & Co., 7, Stationers' Hall Court, E. C. 4. *C. A. T.* You will probably find what you want in *Lady's Garden* by *John Gorton* (Brabray, Agnew & Co.); Thomson's *Handy Book of the Flower Garden* (Blackwood & Co.); or a cheaper book of garden plans published at 17r, Fleet Street, E. C.

HEATING. *PT.* A. B. C. If we understand your question, we do not think any danger can arise, but to avoid any risk, why not work both top and bottom systems, keeping the Vine well in check? If you have the superabundance of piping your note seems to indicate, you need keep up much less powerful fires.

HYACINTHS. *A. H. D.* We will bear your request in mind, and give the list in a week or two.

NAMES OF PLANTS. *W. S. Worthing.* *Cotyledon umbilicus.*

SOPHORONIS. C. IV. S. The two plants—coccinea and grandiflora—have been a good deal mixed up. Dr. Lindley, in Paxton's *Flower Garden*, does not distinguish them, but gives the *Catleya* coccinea a synonym of *S. grandiflora*. The *S. grandiflora* of the *Botanical Magazine* is, however, different. They are distinguished thus: the *S. coccinea* of Reichenbach (*S. grandiflora* of Lindley) has the lip ovate undivided cuculate at the base; "something like the *S. grandiflora* of Leguminosae flower inventor of *S. S. militaris* of Reichenbach (*S. grandiflora* of *Botanical*

Magnolia) has the lip three-lobed, with the lateral lobes incurved, and the middle one flat and acuminate. INSECTS: *H. S.* The ring of eggs around the Apple twig sent are those of the Lacey Moth, *Bombyx Neustria* (fig. 84). The eggs will produce about the beginning of May, or earlier, small, black, hairy caterpillars, which immediately cover the ring of eggs with an exceedingly fine web, and thus they keep extending

FIG. 84.—BOMBYX NEUSTRIA.

until they change their skin the third time. Into this web they retire at night, and remain secure in web weather, continuing to feed until they become full grown, about midsummer. 1 is the ring of eggs; 2, the full-grown caterpillar; and 3, the perfect moth. * * * Correspondents are specially requested to address, post-paid, all communications intended for publication to the "Editors," and not to any member of the staff personally. The Editors would also be obliged by such communications being posted as early in the week as possible. Letters relating to Advertisements, or to the supply of the Paper, should be addressed to the Publisher, and not to the Editors.

FOREIGN SUBSCRIBERS.—We are requested by the Publisher to desire Foreign Subscribers sending Post Office Orders, to be good enough to write to the Publisher at the same time.

ERRATUM.—At p. 365 ("The Islands of Finistère"), close of first paragraph, for "island horses" read "Iceland horses."

Variorum.

"WHERE ARE THE POLICE?"—Messrs. James Carter & Co., seed merchants, High Holborn, write to complain of the absence of police supervision in a leading thoroughfare. They say that between 10.30 and 2.30 on the night of Friday last their seed warehouse, situated in a most prominent position in Holborn, and opposite to a cab rank, was broken into from the front door, the heavy padlock having been wrenched off, and the lock of the door forced. The burglars broke open twenty-eight desks, ransacking the contents, and the police believe that this must have taken them between two and three hours. There was moonlight; and, as the front of the warehouse almost entirely consists of windows, the lights moving about must have been plainly visible from the opposite side. *Times.*

Markets.

COVENT GARDEN, March 24.

The supplies have fallen off in most descriptions of rough goods both here and at the other markets, consequently some articles have improved in price. We have also experienced a better demand for late sorts of culinary Apples, such as Wellington, Northern Greening, and the Gooseberry Pippin, ranging from 5s. 6d. to 8s. per bushel; dessert varieties from 7s. to 10s. per bushel. Some new Grapes have been offered; but, having got good late ones yet, the dealers have not made much inquiry for them. *Thos. Taylor, Wholesale Apple Market.*

FRUIT.

s. d.		s. d.	
Apples, per 1/2-sieve	2 3	Nuts, Cob, p. 100	2 0

VEGETABLES.

Table listing various vegetables such as Artichokes, Asparagus, Beans, Beet, Broccoli, Brussels Sprouts, Cabbages, Carrots, Cauliflowers, Celery, etc., with prices per bunch, dozen, or ton.

CUT FLOWERS.

Table listing cut flowers such as Azaleas, Camellias, Carnations, Cineraria, Cyclamen, Daisies, Euphylliums, Eucharis, Fuchsias, Heliotropes, Hyacinths, etc., with prices per dozen or bunch.

PLANTS IN POTS.

Table listing plants in pots such as Azaleas, Begonias, Edwardias, Gesnerias, Cypripedium, Daisies, Ficus, etc., with prices per dozen.

SEEDS.

LONDON: March 25.—A very brisk demand now prevails for agricultural seeds. The first of the market of course, closed on both Good Friday and Easter Monday, threw a good deal of extra business into the early part of this week. Red Clovers generally maintain their value with great steadiness; the knowledge of the comparative smallness of the stocks remaining in London inspires holders with confidence, no wish to sacrifice goods being shown. For yearling red we have more inquiry. A fair quantity of white Clover seed has recently changed hands at rather more money. Alsike is again cheaper. Santolin, being exceedingly scarce, must be noted at 2s. to also quarter dearer. Crenal grasses and imported Italian are in better demand at full prices. Spring Tares show no change. Large Scotch Gores, being now nearly exhausted, realise an advance of 2s. to 3s. per quarter. In bird-seeds there is no noteworthy alteration. Large Peas, such as about 20 lbs. of Mustard, Rape, and Linseed kept fully dry, John Shaw & Sons, Seed Merchants, 37, Mark Lane, E.C.

CORN.

At Mark Lane on Monday trade was in no degree influenced by the firmer tone prevalent in the provinces, the probable arrival at an early date of a large quantity of produce tending to create caution on the part of millers. The show of Wheat was very moderate, and its condition quality variable, but factors evinced little disposition to press sales, though offers of less money were not generally refused. Barley was very dull, and the quotations of the previous Monday were not supported for all descriptions. Malt was slow of sale, and cheaper in some instances. Oats were steady, but not easily disposed of. Maize being abundant, and difficult to move, declined in price to some extent. Beans and Peas were purchased sparingly at about late rates. Flour met with a limited inquiry, and barely realised the rates previously current, and with the exception of Prime Clover, with a quiet but steady aspect. The supplies available were only moderate, and quotations remained generally steady. English and foreign Wheat cleared off slowly, at late rates. Flour was dull, Barley remained without improvement, and Maize was neglected.

CATTLE.

At the Metropolitan Market on Monday there was rather a larger supply both of English and foreign beasts. Trade was not quite so brisk as last week, owing to milder weather, yet choicest qualities were very little cheaper. Sheep were more plentiful, but there was a fair demand at late rates. The milder weather has caused more trade for shorn sheep and choice lambs. Choice calves were very scarce and dear. Quotations:—Beasts, 3s. 6d. to 4s. 6d. and 5s. 4d. to 6s.; calves, 5s. 4d. to 7s.; shorn, 5s. to 5s. 6d.; lambs, 7s. 4d. to 8s. 6d.; pigs, 4s. 4d. to 5s. 4d.

HAY.

The supplies of fodder on sale at Whitechapel market have been rather large, but a good inquiry prevailed previously classes, and with the exception of Prime Clover, rose to 125s.; inferior do., 85s. to 95s.; prime meadow hay, 60s. to 117s.; inferior do., 55s. to 75s.; and straw, 35s. to 40s. per load.

COALS.

There was a large supply of house coals in the market on Monday, and the price for "best" tons was lowered 3s. per ton, and for "seconds" 6d. per ton.

THE LONDON MANURE COMPANY

(ESTABLISHED 1840) Have now ready for delivery, in fine dry condition—CORN MANURE, for spring sowing. PURE ASSOLVED MANURE. PURSER'S BONE MANURE. PURSER'S BONE TURNIP MANURE. SUPERPHOSPHATE. NITROPHOSPHATE. NITRATE OF SODA, SULPHATE OF AMMONIA, Genuine PERUVIAN GUANO, &c. 116, FENCHUR STREET. E. PURSER, Secretary.

ODAMS' MANURES

Manufactured by the NITRO-PHOSPHATE and ODAMS' CHEMICAL MANURE COMPANY (LIMITED), consisting of Tenant-Farmers occupying upwards of 150,000 Acres of Land. Chairman—ROBERT LEEDS, Castle Acre, Norfolk. Managing Director—JAMES ODAMS. Sub-Manager and Secretary—T. MACADAM. CHIEF OFFICE—101, FENCHUR STREET, LONDON, E.C. WESTERN COUNTIES BRANCH—Queen Street, Exeter. Particulars will be forwarded on application to the Secretary, or may be had of the Local Agents.

MILLER AND JOHNSON

(ESTABLISHED 1859) Manufacture the highest quality of ARTIFICIAL MANURES for ROOT, CORN, and GRASS CROPS. 36, MARK LANE, LONDON, E.C.

GISHURST COMPOUND.

Used by many of the leading Gardeners since 1859, against Red Spider, Mildew, Thrips, Gravidity, and other Blights, in solutions of from 1 to 2 ounces to the gallon of soft water, and of from 4 to 16 ounces as a winter dressing for Vines and Fruit Trees. Has outlived many preparations intended to supersede it. Sold Retail by Seedsmen, in boxes, 1s., 3s., and 6d. Wholesale by PRICE'S PATENT CANDLE COMPANY (Limited).

SIMPSON'S RED SPIDER, THRIP, and GREENLY ANTIDOTE

is now extensively used, and may be had through all Seedsmen and Chemists. Pronounced a "valuable discovery." Sufficient for the worst case of Red Spider diluted at the rate of one quart to 65 gallons of water. Price per quart, condensed, 6s. Prepared by JOHN KILNER, Wortley, near Sheffield. Important Testimonials on application.

GRAVEL FOR SALE.—Wandsworth Common

Gravel, suitable for Road and Path-making, in large or small quantities. Prices on application to ROBERT NEAL, Nurseryman, and Contractor, Wandsworth Common, S.W.

SHAW'S TIFFANY AND ELASTIC NETTING

for Shading and Protecting. Sold by all respectable Seedsmen. For Circulars and Prices apply to JOHN SHAW AND CO., Tiffany Manufacturers, 29, Oxford Street, Manchester.

MILDEW.—Ewing's Infallible Cure.

The finest of all antidotes. (Wm. EARLEY.) Retail of most Seedsmen at 1s. per bottle, or 12d. per bottle, if packed for travelling, of the Manufacturers, EWING AND CO., Norwich.

Genuine Tobacco Paper, Cloth and Cord.

J. GEORGE can supply Nurserymen and Seedsmen with the above. Price, very low, on application. J. GEORGE, Wholesale and Retail Dealer in Tobacco Paper, Purney Heath, London, S.W.

The Royal Pottery, Weston-super-Mare.

UNDER ROYAL PATRONAGE.

JOHN MATTHEWS (late C. PHILLIPS), Manufacturer of TERRA COTTA VASES, FOUNTAINS, ITALIAN BASKETS, RUSTIC FLORAL ARBORETTES, STATUARY, GARDEN POTS from 2 to 30 inches in diameter, of superior quality, withstand frost, and do not become green; EDGING TILES, &c. See specimens in the Royal Horticultural Gardens. Price List free. Books of Drawings, 7d. each.

JOHN MATTHEWS, Royal Pottery, Weston-super-Mare.

THE CELEBRATED GRANITIC PAINT.

Manufactured Solely and Only by the Silicate Zopissa Composition and Granitic Paint Company. For Prices Lists, Testimonials, and Patterns of Colours, apply to THOMAS CHILD, Manager, 39a, King William Street, London, E.C.

 3, Westminster Chambers, Victoria Street, S.W.

BOTANICAL DRYING PAPER.—For
 Drying Flowers, Ferns, Seaweeds, &c., for the Her-
 barium. Perfectly preserves Form and Colour. Requires no
 change of sheets whilst the Plants are being dried. "All I have
 to say is in its favour. It is the best paper for the purpose I
 have ever employed."—*The late Sir H. J. Hooker.*
 SIZES:—16 by 20 inches, 15s. per Ream, 1s. 10d. per Quire; 20
 by 24 inches, 23s. per Ream, 1s. 9d. per Quire; 20 by 32 inches,
 30s. per Ream, 2s. 2d. per Quire.
EDWARD NEWMAN, 9, Devonshire Street, Bishopsgate.

Labels—Labels.
PARCHMENT or CLOTH LABELS,
 TREE or PLANT LABELS. Punched Parchment,
 4 inches long, 32. 6d. per 1000, or 30s. per 10,000; if cyriled,
 4s. per 1000. Vellum Cartridges, 4 inches long, 3s. per 1000 for
 10,000. Sample Labels sent on receipt of Postage Stamp.
 Orders delivered free in London.
JOHN FISHER AND CO., Label Works, Boston.

E. T. ARCHER'S "FRIGI DOMO."—
 Patronised by Her Majesty the Queen for Windsor
 Castle and Frogmore Gardens, the late Sir J. Paxton, and the
 late Professor Lindley, &c. &c.
 MADE OF PREPARED HAIR and WOOL.
 A perfect non-conductor of heat or cold, keeping a fixed
 temperature where it is applied. A good covering for Pits and
 Forcing Frames.
 PROTECTION FROM COLD WINDS and MORNING
 FROSTS.

"FRIGI DOMO" NETTING, 2 yards wide, 1s. 4d. per yard.
 "FRIGI DOMO" CANVAS—
 2 yards wide 1s. 10d. per yard run.
 3 yards wide 3s. per yard.
 4 yards wide 3s. 10d. per yard.
ELISHA T. ARCHER, only Maker of "Frigi Domo,"
 Stanstead and Brockley Roads, Forest Hill, London, S.E.; and
 of all Florists and Seedsmen. All goods carriage paid to London.
 NOTICE.—REMOVED from 3, CANNON STREET, CITY.

RUSSIA MATS.—A large stock of
 ARCHANGEL and PETERSBURG, for Covering
 and Packing—Second sized ARCHANGEL, 100s.; PETERS-
 BURG, 60s. and 80s.; superior close Mat, 45s., 50s., and 55s.;
 PACKING MATS, 20s., 30s., and 35s. per 100; and every
 other description of MATS at equally low prices, at
J. BLACKBURN AND SONS, Russia Mat and Sack
 Warehouse, 4 and 5, Wormwood Street, E.C.

RUSSIA MATS, for Covering Garden
 Frames.—ANDERSON'S TAGANROG MATS are
 the cheapest and most durable. Price List, which gives the
 size of every class of Mat, forwarded post free on application.

 Cox's Quay, Lower Thames Street, London, E.C.
 Retail of the principal Seedsmen. Prices on application.

THE BEST TWO POTATOS.

VERY HEAVY CROPPERS.—LEAST AFFECTED BY DISEASE.

SUTTONS'
Red-skin Flourball.

Three Hundred Pounds
 of Seed planted produced
 Two Tons Fourteen Cwt.
 One Quarter.

Originally introduced by
SUTTON & SONS, in 1869,
 and considerably improved
 by them since that time.

From Mr. JOHN PULLIN, Gardener
 to E. St. Paul Chaplin, Esq., Los-
 borough Park Gardens, Sept. 26,
 1874.

A very Heavy Cropper.

"I have just had the Red-skin
 Flourball Potatoes lifted, and again
 found it free from disease. Having
 grown it now three seasons, I can
 speak confidently to its being disease-
 proof, a heavy cropper, and of the
 best quality for table use."

Excellent Cooker.

Unequaled for Late Use.

SUTTONS' RED-SKIN FLOURBALL POTATO.

Remarkably Free from
 Disease.

From Seven Pounds
 planted in 1874, One
 Hundred and Eighty-five
 Pounds weight were
 raised.

Excellent Cooking
 Qualities.

A very Heavy Cropper.

From Mr. WM. PATERSON, Gardener
 to Her Majesty the Queen, Bal-
 moral, Oct. 25, 1873.

From Mr. A. TUCKER, Gardener to
 the Rev. H. Brice, Gouthurst,
 Sept. 17, 1874.

"Your New Hundredfold Fuke
 Potato is of good size and flavour, and
 quite free from disease."

"The Hundredfold Fuke is the best
 kidney Potato I have ever grown. A
 splendid crop, and not one diseased."

SUTTONS' NEW HUNDREDFOLD FLUKE KIDNEY POTATO.

Lowest Price per Bushel, Sack, or Ton on application.
Suttons' Priced Descriptive List of Choice Seed Potatoes Gratis and Post Free on application.

SUTTON & SONS, The Queen's Seedsmen, READING, BERKS.

FOR SALE, a Handsome Modern CONSERVATORY, standing on 2 feet of Panelled Brickwork with Stone Sills, above which it measures 26 feet in length by 17 feet in width. Height inside, from floor to glazed dome, which is supported by Iron Columns, 15 feet 6 inches. Hot-water Apparatus with Fittings complete. The inside fittings consist of two tiers of ornamental Cast-iron Shelves all round, with Wooden Stages for Plants in centre, &c. Capital York Stone Floor. The above is standing in the grounds of the late Joseph Sharpley, Esq., at Hitchin, and may be viewed on application to **ARTHUR RANSOM, Esq., Encoft, Hitchin.**

HEATING and VENTILATING ENGINEERS TO THE SCHOOL BOARD.

VIENNA PRIZE WIRE NETTING.

Awarded *At* The Medal *Vienna,* For Merit *1873.*

CAUTION TO BUYERS OF WIRE NETTING.

The great reputation and success of Messrs. J. B. BROWN and CO.'S VIENNA PRIZE WIRE NETTING seem to have induced certain Dealers in Wire Netting to advertise an inferior article at reduced prices, specifying the mesh, gauge, &c., as if such were the same in quality and value as the Prize Wire Netting of which Messrs. J. B. BROWN & CO. are the SOLE MANUFACTURERS.

Messrs. BROWN & CO. would suggest that, before ordering quantities, one roll of their Wire Netting should be ordered and one roll of that advertised at reduced prices. The size and shape of the mesh may then be examined, the thickness or strength of wire, the weight of the rolls and the exact measurements, the general finish of the manufacture, and the quality of the galvanising.

This examination will prove the respective qualities of the Netting.
99, Cannon Street, London, E. C.—March 12.

6 in.	8 in.	10 in.	12 in.	14 in.	16 in.	18 in.	20 in.
Prices, 25s.	50s	70s.	£4 10s.	£5 10s.	£6 6s.	£7	£8 10s., Carriage Paid.

SOLE MAKERS: **JOHN CROWLEY & CO., Meadow Hall Ironworks, near SHEFFIELD.**

JONES'S PATENT "DOUBLE L" SADDLE BOILER

These Boilers possess all the advantages of the old Saddle Boiler, with the following improvements—viz: the water space at back and over top of saddle increases the heating surface to such an extent that a "PATENT DOUBLE L SADDLE BOILER" will do about twice the amount of work with the same quantity of fuel; the cost of setting is also considerably reduced, and likewise the space occupied: at the same time these Boilers are simple in construction, and being made of wrought iron, are not liable to crack. They are made of the following sizes—

Sizes.			To heat of 4-in. Pipe.	Price.
High.	Wide.	Long.	Feet.	£ s. d.
22 in.	18 in.	18 in.	300	7 0 0
20 "	18 "	24 "	400	8 0 0
20 "	18 "	30 "	500	9 0 0
24 "	24 "	24 "	700	12 0 0
24 "	24 "	30 "	850	14 0 0
24 "	24 "	36 "	1,000	16 0 0
28 "	24 "	48 "	1,400	20 0 0
28 "	28 "	60 "	1,800	25 0 0

Larger sizes if required.

From Mr. CHARLES YOUNG, *Nurseries, Batham Hill, S.W.*, May 29, 1873.

"Having given your Patent 'Double L' Boilers a fair trial at my Nurseries, I beg to say that they are most satisfactory. I consider them the best in use, and without doubt the most economical of all boilers; they will burn the refuse of other tubular boilers I have in work."

PRICE LISTS OF HOT-WATER PIPES and CONNECTIONS, with Boilers, of all sizes and shapes; or ESTIMATES for HOT-WATER APPARATUS, erected complete, will be sent on application.

J. JONES and SONS, Iron Merchants, 6, Bankside, Southwark, London, S.E.

When ordering Boilers please refer to the above advertisement.

FOWLER'S PATENT STEAM PLOUGH and CULTIVATOR may be SEEN at WORK in every Agricultural County in England.

For particulars apply to JOHN FOWLER and CO., 71, Cornhill, London, E.C.; and Steam Plough Works, Leeds.

GEORGE'S PATENT CALORIGEN, for

Warming and Ventilating Small Conservatories.

COAL CALORIGEN, £6 6s
Height, 36 inches; diameter, 21 inches.
GAS CALORIGEN, £3 3s
Height, 28 inches; diameter, 14 inches.

The only Gas Stove in which the product of combustion is entirely excluded from the Conservatory, while a constant stream of warmed, not burnt, fresh air is introduced. The "Coal Stove" consumes the smallest amount of Fuel—2¢ per diem being the average cost. It will be found very valuable in the Nursery or Sick Room, Damp Buildings, Conservatories, Offices, &c. Exhibited at the Exhibition of 1871 (Department of Scientific Inventions).

Illustrated Prospectuses and Testimonials on application.
J. F. FARWIG and CO., 36, Queen Street, Cheshire, E.C.
This Stove introduces a strong current of warmed (not burnt) fresh air.

STEVENS' TRENTHAM GREENHOUSE BOILER,

After long experience, has proved the most Simple, Economical, Efficient, and Lasting Boiler extant; recently much improved. For Illustrations, with full particulars, apply to the Sole Makers, F. and J. SILVESTER, Castle Hill Foundry, Engineering and Boiler Works, Newcastle, Staffordshire.

CONSERVATORY FLOWER STANDS.

Address, The Editor of the Cultivator, St. Michael's, Azores. Second Edition, Price 3d., Post Free 4d.

THE AGRICULTURAL GAZETTE ALMANAC, 1875. The best Illustrated Agricultural Almanac.

OPINIONS OF THE PRESS.

"It is an excellent and useful work for farmers and all interested in rural pursuits. Beyond the matter usual in such compilations are many good serviceable hints on fattening cattle, growing of root crops, &c. The illustrations are admirably executed, many having engraved from photographs."—Westly Dispatch, Jan. 31, 1875.

"The 'Agricultural Gazette Almanac,' which deals with matters of interest to farmers, has reached a second edition."—Lloyd's, Jan. 17, 1875.

"It is a very cheap threepennyworth of information of interest and utility to farmers, and contains numerous illustrations."—The Field, Jan. 16, 1875.

"In addition to the usual matter to be found in an almanac, we have here useful information to the farmer, as to stock and crops, with illustrations of prize animals."—Gloucestershire Chronicle.

"This is a cheap and useful almanac and diary, well illustrated. Its contents will be found interesting to the agriculturist, and adapted for daily use."—Farmer's Herald.

"The Calendar contains all the fixtures for cattle shows, races, &c., space for diary and memoranda by the side, and various useful information of an agricultural character."—Oxford Times.

"The 'Agricultural Gazette Almanac' is a cheap quarto almanac comprising information on agricultural topics and a series of portraits of the Prince of Wales, Dr. Voelcker, and Viscount Bridport, and engravings of different prize cattle, reproduced from the 'Agricultural Gazette.'"—Daily Express.

"To farmers, cattle dealers, and others interested in agriculture, this work will be found invaluable. It contains a deal of information relative to cattle, crops, land, and miscellaneous matters, and is profusely illustrated with engravings chiefly taken from photographs."—Dewsbury Chronicle.

"This almanac, which appears to be carefully compiled, and the contents judiciously selected, may be commended to the notice of agriculturists generally. It is issued at a low figure, and contains a large variety of information. There are numerous illustrations, and the likeness of the Prince of Wales, which forms the frontispiece, is especially deserving of mention."—Grantham Journal.

"To all persons interested in agriculture in this neighbourhood 'The Agricultural Gazette Almanac' for 1875, price 3d., will be worth obtaining. It contains a fund of information, as well as a variety of advertisements on topics especially connected with the portion of the community which it is intended to serve."—Litcham Guardian.

"Although this almanac comes rather late it is none the less welcome, as containing a mass of information, both interesting and valuable to any person connected with agriculture, it is to be commended. In addition to the usual calendar it contains a diary, supplies as well with authentic portraits and verbal descriptions of prize cattle, sheep, and pigs, a list of the members of both Houses of Parliament, another of the Chambers of Agriculture, another of County Agricultural Societies, besides hints as to practical farming. Such a combination of information must recommend itself to every agriculturist."—Western Daily Mercury.

"Though it is rather late to be noticing an almanac for 1875, we make an exception in favour of the one before us, which, owing to its great merits and low price, ought to be purchased by every agriculturist in the kingdom. The illustrations of prize cattle, implements, &c., are a valuable feature in the Almanac."—Preston Reporter.

FARM BAILIFF.—A GENTLEMAN wishes to recommend his Farm Bailiff, who has lived with him for fifteen years. Leaving on account of employer giving up his Farm.—R. HALL-SAV, Esq., St. 106's Place, Maidenhead, Berks.

KINAHAN'S L.L. WHISKY. This celebrated and most delicious old mellow spirit is the very CREAM OF IRISH WHISKIES, in quality unrivalled, perfectly pure, and more wholesome than the finest Cognac Brandy. Note the Red Seal, Pink Label, and Cork branded "Kinahan's L.L." Whisky. Wholesale Depot, 20, Great Titchfield Street, Oxford Street, W.

Grateful-Comforting. E P P S S C O C O A BREAKFAST.

By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected Cocoa, Mr. Epps has provided our breakfast-tables with a delicately flavoured beverage, which may save us many heavy doctors' bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up until strong enough to resist every tendency to disease. Hundreds of subtle maladies are floating around us, ready to attack wherever there is a weak point. We may escape many a fatal shaft by keeping ourselves well fortified with pure blood and a properly nourished frame."—See article in the *Critic* & *Review* *Gazette*.

Made simply with boiling water or milk. Sold in packets (in tins for abroad) labelled—JAMES EPPS & CO., HOMOEOPATHIC CHEMISTS, 48, Threepenny Lane, and 170, Piccadilly, W. Works:—Luton Road, and Camden Town, London, N.W. Makers of Epps's Glycerine Jubjubes for Throat Irritation.

In consequence of Spurious Imitations of LEA and PERRINS' SAUCE, which are

calculated to deceive the Public, LEA AND PERRINS have adopted a New Label, bearing their Signature, thus— which will be placed on every bottle of WORKS. LEA AND PERRINS' SAUCE, after this date, and without which none is genuine.—Sold Wholesale by the Proprietors, Worcester; CROSS & BLACKWELL, London; and Export Offices generally. Retail, by Dealers in Sauces throughout the World.—No. 10, 1874.

DINNEFORD'S FLUID MAGNESIA.

The best remedy for Acidity of the Stomach, Heartburn, Headache, Gout, and indigestion; and the best mild Aperient for delicate Constitutions, especially adapted for Ladies, Children and Infants. DINNEFORD AND CO., 172, New Bond Street, London, W.; and of all Chemists throughout the World.

THE "ARCHIMEDEAN" AMERICAN LAWN MOWER

HAS BEEN AWARDED
GRAND DIPLOMA OF HONOURABLE MENTION, Vienna, 1873.
SILVER MEDAL, Vienna, 1870. SILVER MEDAL, Hamburg, 1869.

NOTE.—The "Archimedeon" was specially selected from the Mowers exhibited at Vienna for constant use in the Exhibition Grounds, and gave great satisfaction; and we have pleasure in calling attention to the following Testimonial, received from the Inspector of the Royal Gardens, Schönbrunn, Vienna:—

"Your 'Archimedeon' Lawn Mowers have been used for some time past at the Imperial Gardens, and I have great pleasure in stating that they have given perfect satisfaction. Their quick and good work prove them to be the best and most efficient machines of the kind."

PATRONIZED BY

HER GRACIOUS MAJESTY THE QUEEN,
HER IMPERIAL MAJESTY THE EMPRESS OF GERMANY,
THE LATE EMPEROR OF THE FRENCH,

HIS ROYAL HIGHNESS THE PRINCE OF WALES,
HIS IMPERIAL MAJESTY THE EMPEROR OF AUSTRIA,
THE VICEROY OF EGYPT,

And many of the Nobility and Gentry of Great Britain.

CHIEF ADVANTAGES.

- They are extremely LIGHT IN DRAUGHT, SIMPLE IN CONSTRUCTION, WELL MADE, and NOT LIKELY TO GET OUT OF ORDER.
- They cut LONG or SHORT, WET or DRY Grass, and do not clog.
- They have no ROLLERS in FRONT of the Cutters, and therefore cut the Grass as it GROWS, and do not miss the BENTS.
- They work well on SLOPES, STEEP EMBANKMENTS, UNDER SHRUBS, and close up to Trees, &c.
- They can be USED either WITH OR WITHOUT GRASS BOX, as may be desired.

TESTIMONIALS.

From A. F. BARRON, Esq., *Royal Horticultural Society, Chiswick Gardens, H.*

"GENTLEMEN,—We have now had your 'Archimedeon' Lawn Mower in use for several months, and without hesitation I can truly say it is the *best* and *most efficient* implement of the kind we have ever used."

From the late Mr. GEORGE WYNESS, *Royal Gardens, Buckingham Palace.*

"GENTLEMEN,—I beg to say that we have had your Patent 'Archimedeon' Lawn Mower at work in Her Majesty's gardens at Buckingham Palace for some time past, and I have much pleasure in testifying that it has given every satisfaction, as it does its work well and quickly."

From the Rev. J. H. WHITE, *Hemingsford Grey, St. Ives, Hants.*

"I am much pleased with the working of your 'Archimedeon' Mowing Machine. I think it superior to others which I have used in previous years."

OPINIONS OF THE PRESS.

"The quickest, most simple, and most efficient Mower ever used."—*Gardeners' Chronicle.*

"Far superior to any of ours."—*The Field.*
"Remarkably easy to work."—*Gardeners' Mag.*

"We feel bound to recommend it to our readers as one of the best Mowers we have as yet made acquaintance with."—*Floral World.*

EVERY MOWER IS WARRANTED TO GIVE AMPLE SATISFACTION,
And if not approved of may be returned within a Month, and the amount paid be refunded.

LEIGH, Sandy Lane Nursery, Loxton, near Newton-le-Willows.

Verbenas for Sale.

S. BIDE can now supply, for cash, Verbenas, spring-struck, strong, and free from disease of any kind, including Purple King, Scarlet, White, Pink, and many other varieties (of which a list may be had on application), at 8s. per 100, or 7s. 6d. per 100, in pots. Also, in quantity, of the best varieties, 40s. per 100. **GERANIUMS**, plain and zonal, strong autumn-struck plants, 10s. per 100. **CENTAUREA CANDIDISSIMA**, struck last autumn, and well established, 40s. per 100. **FLORIBUNDA** and other **CALCEOLARIAS**, 8s. per 100. **HELIO-TROPES**, light and dark, 8s. per 100.

S. B. would particularly wish to draw the attention of his numerous customers to his fine stock of **VERBENAS** for this season, which are the admiration of all who see them; and would request that all orders should be sent to him as early as convenient, as he was unable to supply many who applied late last season—general satisfaction being expressed by all those who favoured him with their orders.

S. B. **BIDE**, Alma Nursery, Farnham, Surrey.

The Only Really and Thoroughly Distinct LOBELIA OF THE SEASON.

BLUESTONE—hitherto a hidden gem.

Strange that this, by far the best of all the Lobelias, should have been kept back from the public by a "crotchet," and it is only within the last few days that the seed has been placed in my hands. The darkest blue, no eye, strong compact pumila habit; foliage, strange to say, is a most peculiar purplish green, and its whole character far exceeds any other Lobelia. Five hundred seeds, post free, 1s. 1d.; plants sent post free 1s. 2d. each, 1s. 2d. to 7s. 1d. p. 94 *Gardener's Magazine*, February 20. "Challenging the whole of the floricultural community to produce a better."

FORGET-MÉ NOT

H. CANNELL, F.R.H.S., begs to announce that his **FLORAL GUIDE** for 1875 is now ready, and will be sent, post-free (cost paid), in ten stamps. It is beautifully illustrated with 200 splendidly executed engravings. It also contains particulars and correct descriptions of all the correct descriptions of all the novelties, and the best new and old varieties of soft-wooded plants.

TRADE MARK.

in cultivation, and it is highly important to amateurs and gardeners that they should procure it continually, for it contains invaluable and practical information on Florists' Flowers and Bedding Plants, and their Seeds, and the best and correct manner in which they are supplied and forwarded to any part of the world cannot fail to be a great advantage and highly appreciated by all who are really fond of the choicest flowers.

NEW FUCHSIA, "MRS. H. CANNELL."

This magnificent variety justly bears out even more than the high character previously given it, and is by far the best double white corolla variety; foliage and flower even an advance on the good old dark Malanche. Fine half-specimen plants, 2 feet high, in 6-inch pots, 7s. 6d. each; small 10s., 5s.; nice plants in thumbs, 1s. 6d. each; small rooted little plants, or cuttings, 1s., post free.

TO OBTAIN THE

Best Garden Lawns and Croquet Grounds

SUTTONS' LAW GRASS MIXTURE,

LAWN GRASS MIXTURE,

Which forms a close velvety turf in a very short time. For making New Lawns or Croquet Grounds 3 bushels or 60 pounds is required per acre, or 1 gallon to every 6 rods (or perches) of ground.

For improving those already in turf, 20 pounds should be sown per acre.

March, April, and May are the best months for sowing.

Price is. per lb.; 20s. per bushel.

From Mr. J. MERRICK, Gardener to S. Forster, Esq., Le Court.

"The Seed you sent me last year turned out uncommonly well. Several gentlemen who came to Le Court could scarcely credit the appearance of the lawn, in August it was as fine and thick as I have seen some lawns that had been laid down for three years."

that it was only sown in May.

Instructions on the Formation and Improvement of Garden Lawns and Croquet Grounds. Gratis and Post Free.

"LITTLE TROT"

W.M. POTTER is **LOOKING ORDERS** for the above. For particulars see advertisement in *Gardeners' Chronicle*, January 30. A very favourable report of it may be seen in the *Journal of Horticulture*, November 19, 1874, by Mr. Robson, and February 5, 1875, by Mr. Luckhurst, Camden Nursery, Sissinghurst, Staplehurst, Kent.

CRANSTON'S NURSERIES, Established 1785.—The following CATALOGUES are just published, and will be forwarded on application:—

DESCRIPTIVE CATALOGUE OF ROSES (1874 and 1875).
DESCRIPTIVE CATALOGUE OF FRUIT TREES.
DESCRIPTIVE CATALOGUE OF CONIFERS, SHRUBS, and FOREST TREES.
DESCRIPTIVE CATALOGUE OF BULBS. Address, **CRANSTON and MAYOS**, King's Acre Nurseries, near Hereford.

NEW ROSES.

SIR GARNET WOLSELEV (Cranston's).
CRIMSON BEDDER (Cranston's).
CLIMBING JULES MARGOTTIN (Cranston's).
 All the new Continental Roses for 1875—upwards of forty varieties.
 Descriptive LIST on application to **CRANSTON and MAYOS**, King's Acre Nurseries, near Hereford.

Vines.—To the Trade.

S. BIDE will supply good strong **PLANTING VINES**, in Pots, of the undermentioned varieties, at 30s. per dozen (a special price for a large quantity will be given on application)—**Tynningham Muscat**, **Madreseld Court**, **Black Hamburg**, **Mrs. Pince's Black Muscat**, **Lady Dove's Seedling**, **Burchar's Prince**, **Seaciffe Black**, **Frankenthal Hamburg**, **Ferdinand de Lesseps**, **Black Morocco**, **Primate's Frontignan**, **Black Barbarossa**, **Sweetwater**, **Troveron Muscat**, **Bowd Muscat**, **Muscat of Alexandria**, **White Nice**, **Duchess of Buccleuch**, **Rasin de Calabre**.
S. BIDE, Alma Nursery, Farnham, Surrey.

Planting Season.—Avenue Trees.

LIMES, 12 to 16 feet high, straight stems, striking 4 to 8 inches at 4 feet from the ground, with well-balanced heads, and splendidly rooted. A stock of more than 5000 of these fine Trees to select from.
PLUMS, **OCULATA**, 12 to 15 feet.
HORSE CHESTNUTS, 10 to 12 feet.
SCARLET HORSE CHESTNUTS, 10 to 12 feet.
NORWAY MAPLES, 10 to 16 feet.
 All being strong, great stemmers, and finely rooted. Every Tree has been removed within two years.
POPLAR, **CANADENSIS NOVA**, 15 to 20 feet.—This new variety of Poplar, far exceeding in quality of growth any tree I am acquainted with, is strongly recommended as a Town Tree, especially in smoky districts. There are hundreds in this nursery, three years old, measuring 18 to 25 feet high, and stout in proportion.
ANTHONY WATERER, Knapp Hill Nursery, Woking, Surrey, S.W.

ISAAC BRUNING AND CO. beg to

announce that they have this season a very fine and extensive Collection of the above to offer, strong plants of which are now ready for sending out. **LIST of Varieties and Prices**, together with **Illustrated SEED CATALOGUE**, on application.

New Double Zonal Pelargonium for 1875.
First-class Certificate Royal Horticultural Society.

Emily Laxton.

MESSRS. W. AND J. BROWN have again been entrusted by Mr. Laxton with the distribution of the following set of **New Double Zonal PELARGONIUMS** raised by him, viz.:

EMILY LAXTON.—First-class Certificate Royal Horticultural Society. The largest flowered and most remarkable Scarlet Pelargonium, either double or single, hitherto sent out. Individual flowers upwards of 2 inches in diameter; full, but not crowded; truss enormous. Free-flowering, and suitable for winter work. Figured in the *Floral Magazine* for October last. Strong plants, 15s. each.

GUIDING STAR.—The most shrubby and dwarf Double Pelargonium yet raised. Foliage pale green, and partaking somewhat of the character and habit of the Show Pelargonium. Flower very pretty purplish pink and double; quite unique and distinct. Strong plants, 10s. 6d. each.

ILLUMINATOR.—A striking and distinct purplish carmine-coloured variety of the Emily Laxton type, but darker in colour; semi-double, but full; petals large and stout. Strong plants, 7s. 6d. each; the set for £1 10s.

Prizes will be offered for the above in 1876. To be sent out in May next. Coloured Plates of Emily Laxton post free for 1s. 6d. Electros of Single bloom 2s. 6d. each.

NEW STRAWBERRIES.

Messrs. **W. & J. BROWN** are also now sending out Mr. Laxton's fine firm-fleshed New Strawberries—**TRAVELLER** and **EXQUISITE**: the flavour of both these is distinct and unequalled. Traveller has received a First-class Certificate from the Royal Horticultural Society, and is undoubtedly the most suitable Strawberry for transmission yet raised. Strong plants of last season—Traveller, £1 per 25, £3 per 100. Exquisite, 12s. 6d. per 25, £2 per 100. Early struck runners of each, in 6s. sized pots, 7s. per 25 extra. Prizes for fruits of these will be offered in 1876. Trade terms on application to **W. AND J. BROWN,** Nurserymen and Florists, Stamford.

Hollies.

ANTHONY WATERER respectfully invites the attention of Holly buyers to the very fine Stock to be seen growing at Knapp Hill. It comprises upwards of Thirty Thousand Plants, from 3 to 10 and 12 feet high, of the finer Gold, Silver, and Green-leaved kinds, affording a choice in size and variety such as can be met with in no other Nursery in Europe. Every Plant has been recently removed, and will be guaranteed.

The Stock of Common Green Hollies alone occupies 5 acres of land, and Purchasers will find them in large numbers of all heights up to 15 feet.

Knapp Hill Nursery, Woking, Surrey.

WILLIAM POTTEN'S PLANT LIST for 1875 is now ready, which contains one of the largest and choicest collections of Geraniums and other Bedding Plants, and will be sent to all applicants post free.

W. BARRON and SON, Elvaston Nurseries, Borrowash, Derby.

CHRYSANTHEMUMS.—12 new varieties

of 1874, 2s. 12 older sorts, 2s. 100 Chrysanthemums, including new varieties of 1874, for 18s.; 50s. for 100.

FUCHSIAS—6 new varieties of 1874, for 4s.; 12 varieties of 1874, for 4s.; 10 Fuchsias, in 30 sorts, for 14s.; 50, in 25 sorts, for 8s.; 12 varieties, 2s. 6d.

LOBELIA, pumila grandiflora, 1s. 12 **IRENINE,** Lindeni, 1s. 6d.; **MESEMBRYANTHEMUM,** cordifolium variegatum, 1s. 6d. per dozen.

The above sent post free for cash with order.

L. LEIGH, Sandy Lane Nursery, Louton, near Newton-le-Willows

THE HANDSOMEST AND BEST NEW POTATO IS CARTER'S AMERICAN BREAD-FRUIT.

Indispensable as one of the best Potatos for Exhibition.

CARTER'S AMERICAN BREAD-FRUIT.

FOR MAIN CROP.

This is a grand Potato in every respect. Handsome in shape, with very shallow eye. Flesh of fine texture and superb quality, whether baked or boiled. It is a first-rate keeper, and extremely prolific.

An invaluable acquisition to Hotel Keepers, for Public Institutions, &c.

CARTER'S AMERICAN BREAD-FRUIT POTATO.

Per Peck, 6s.; per Bushel, 21s.; per Cwt. 35s.; per Ton, £30.

THE POTATO THAT BEST RESISTS DISEASE IS CARTER'S IMPROVED RED-SKIN FLOURBALL.

Price per Peck, 2s. 6d.; per Bushel, 9s.; per Cwt. 17s.; Per Ton, for not less than half a ton, £14.

We again offer a very fine selected stock of this invaluable Potato, which continues to resist the ravages of the disease in a most surprising manner. We have at all times avoided the statement published by some Houses, "that the Red-skin Flourball Potato is the only disease-proof variety." We, however, repeat that our Improved Red-skin Flourball resists the disease to a far greater extent than any other variety in cultivation.

CARTER'S Improved Red-skin Flourball was one of the varieties in the great Trial of Potatos made by the Royal Agricultural Society of England last year, and we believe we are justified in stating that it fully maintained its disease-resisting reputation, whilst other varieties were nearly consumed by the disease.

Carters THE QUEEN'S SEEDSMEN, 237 & 238, HIGH HOLBORN, LONDON, W.C.

NEW PLANTS.

MR. WILLIAM BULL

Intimates that the following will be sent out for the first time in the beginning of May:—

NEW FUCHSIAS.

ADMIRATION.—A beautifully-formed flower. Tube and sepals rich crimson, the latter completely recurved; corolla well expanded, and of a purplish crimson colour; a showy and attractive variety. *10s. 6d.*

BARONESS.—A very pretty and attractive flower with long tube, white sepals well-reflexed, and violet-rose corolla; an extremely pleasing and distinct colour. *10s. 6d.*

CAIYPSO.—An extremely fine variety, with large well-formed flowers; tube and sepals rich crimson, the sepals completely reflexed; large expanded bell-shaped corolla, of a rich crimson-purple colour. *10s. 6d.*

CHARMER.—A magnificent variety, producing fine large flowers, with extremely rich and bright reddish crimson tube and sepals; tube short, and sepals immensely broad and well reflexed; fine rich purple-pink corolla; the blossoms are of excellent quality and wonderful substance. *10s. 6d.*

GEORGE FREDERICK.—Tube and sepals rich scarlet-crimson; tube short; sepals broad and thick, and nicely reflexed; large scented corolla, of a rich purple-crimson colour; a fine and handsome variety, of free branching habit, and a profuse bloomer. *10s. 6d.*

HIGHLAND CHIEF.—Tube and sepals bright crimson; tube short; sepals elegantly reflexed, leaving completely exposed the large bell-shaped corolla, which is of a deep purple colour, expands as the flower acquires age, and retains its deep colour to the end; the plant is a free bloomer, and of good habit. *10s. 6d.*

NYSA.—Bright scarlet-crimson tube and sepals, the latter beautifully marked with a tinge of a rich purplish crimson colour; very fine. *10s. 6d.*

NEW CHRYSANTHEMUMS.

AGATHA.—A beautiful dwarf Pompon variety; flowers very full and double, of a blue-pink colour; the petals tipped with gold; very pretty. *5s.*

ARISTO.—A fine Pompon flower, of an attractive amaranth-crimson colour, slightly shaded with yellow; very dwarf and pretty. *5s.*

CLEMENTINE.—A first-rate hybrid variety, producing medium-sized flowers of a rich lemon-yellow colour. *5s.*

EXQUISITE.—A fine variety belonging to the large-flowering section. The blossoms are very full and double, and of exquisite incurved form. Colour a bright golden-yellow, the outer petals shaded orange and reflected salmon. *7s. 6d.*

JASPER.—Bright clear amaranth, a beautifully formed medium-sized hybrid flower, distinct and attractive, of dwarf habit and very free-flowering. *5s.*

OLIVAR.—A fine hybrid, extremely dwarf and floriferous, clear light brown, flowers of excellent form; very distinct and pretty. *5s.*

PROSPERINE.—A very dwarf Pompon variety, of a bright yellow colour. *5s.*

THERMOS.—A very pretty Pompon variety, producing extremely double flowers of a bronzy cinnamon colour shaded with yellow. *5s.*

NEW ZONAL PELARGONIUMS

WITH VARIETAL FLOWERS.

BEAUTY.—This splendid variety produces fine large white flowers, beautifully striped and flaked with rose and salmon; extremely distinct and attractive. *7s. 6d.*

CHARM.—Pure white, striped, flaked and splashed with rose; a very pretty flower. *5s.*

FAIRY.—A novel and distinct flower of a beautiful blush colour, richly flaked with white, striped with deep salmon; exceedingly striking and effective. *7s. 6d.*

SPANGLE.—A charming flower; white, attractively striped, flaked and splashed with bright rose. *5s.*

NEW ZONAL PELARGONIUMS.

ADAIR.—A magnificent variety, producing large trusses of very fine flowers, with thick wax-like petals of a rich cinnamon colour shaded with scarlet. *5s.*

CAMERON.—Magenta-purple marked with vermillion in the upper petals; a most beautiful, novel, and distinct shade of colour; flowers of large size and excellent form; extra fine. *7s. 6d.*

ERNESTINE.—A very pretty and distinct flower; colour blush shaded with salmon-rose towards the centre. *5s.*

EUROPA.—This variety is of remarkably good compact habit and a profuse bloomer; the flowers are of exquisite form and good substance; rich deep scarlet shaded with crimson in the upper petals; white eye; very attractive. *7s. 6d.*

HEBE.—An exceedingly pretty and distinct variety; the flowers are very pure white, shaded and irregularly marked with salmon-blush, all the centre of the flower being of a rich salmon-pink colour. *5s.*

JUANITA.—Salmon-pink; deeper towards the centre of the flower, which has a white eye; the blossoms are of large size, and beautifully round in form. *5s.*

JUBILEE.—This variety produces immense trusses of fine large flowers of a soft rose-lake colour; distinct and pretty. *5s.*

METIS.—A first-rate flower of excellent substance and shape, and of an intensely bright and vivid shade of rich scarlet, with conspicuous white eye. *5s.*

PALLAS.—A splendid variety, of good habit, freely producing enormous trusses of flowers of an extremely rich and brilliant shade of deep rosy pink, slightly marked with white in the upper petals. *7s. 6d.*

POTAMOS.—Light bright scarlet; in the upper petals shaded with crimson; a very fine large flower. *5s.*

THETIS.—Pure white, with a distinct rosy pink zone around the centre of the flower, which is also white; this is a most novel and charmingly pretty variety. *7s. 6d.*

URANIA.—Fine large flowers, of a beautiful rosy cerise colour, borne in enormous trusses; extremely effective. *5s.*

SATURDAY, APRIL 3, 1875.

PLANES.

FROM the first year of the existence of the *Gardeners' Chronicle* discussions have periodically arisen respecting the comparative hardness, identity with wild types, &c., of the forms or species of *Planes* cultivated in Britain. The result of all this writing, it appears to me, is greater confusion than ever; but I will not venture to affirm that I shall succeed in clearing it up. From the time of the earliest introduction of *Planes*, the greatest uncertainty has prevailed respecting their specific origin, and the most contradictory descriptions and attributes have been assigned to the same name by different writers—whether they had different species in view, I cannot tell. Continental writers seem to have been equally in the dark, unless it should turn out, as some suppose, that there really is no specific difference between the American and Eastern *Planes*. I am of the opinion that they are distinct species or races, and that the real *Platanus occidentalis*, or American *Plane*, was unknown to many of the writers on this subject. Though this is my opinion at the present moment, I am quite open to conviction, and shall not be surprised if some one should prove me wrong. But I must have real, unanswerable proofs, not statements based upon what are believed to be facts, otherwise the question will still remain, practically speaking, unanswered.

At the last meeting of the Linnean Society I exhibited fruiting specimens of *Platanus orientalis*, *P. orientalis* var. *acerifolia*, and *P. occidentalis*; but being prevented at the last moment from attending, I requested my friend, Mr. Baker, to read a short note on one of the most marked characteristics (as I believe) of *P. occidentalis*. It was objected that this character was equally valueless with all others put forward as distinguishing this or that species. Mr. Baker, of course, was not prepared to discuss the question, and I believe I had the worst of it, though nothing beyond words was adduced against my specimens. Under the circumstances, I think I cannot do better than state my case here, especially as it is rather a lengthy one, and a subject that concerns gardeners as much as botanists. Perhaps, too, after reading what I have to say, some planters may be able to confirm or refute my statement beyond dispute.

As there is some doubt respecting the correctness of the dates of the introduction of the Eastern and Western *Planes* given by Loudon and others, and as I shall have occasion to refer to a considerable number of books, I will in the first place relate what I have been able to gather respecting their history in this country. Turning to *Le Grete Herball*, 1526, I find no mention of the *Plane*, and as this book was translated from the French, it was probably unknown in France at that time. In the second part of Turner's *Herball*, 1568, is the first mention I have been able to find of the Eastern *Plane*, though Loudon says it was cultivated in England before 1548. Possibly he may have found evidence to that effect somewhere, but I imagine 1548 to be a misprint for 1568. How little it was known at the latter date may be learnt from the following quotation from Turner:—

"Although Dioscorides writeth of the vertues of the *Playn* tre yet he describeth it not, wherefore very many in England and Germany have erred in takyng of divers

trees for the *Playn* tre, whereof none of them all was the right *Playn* tre in dede. Sum take ye *Lynd* tre (which I and many others take for the right *Tilia*) for *Platanus*, because it shetteth forth long branches and boughes, and is able to cover a grete number of men under it. Sum take the tre which seemeth to me to be a kinde of *Acer* to be a *Platanus*, and that tre is called in *Dach Ahorn*. . . . For these and diverse other lyke causes I reken that tre called in *Dach Ahorn*, or *Wild Asshorn*, can not be *Platanus*. I have seen the leaves of that *Platanus* that groweth in Italy, and two very young trees in England, which were called there *Playn* trees, whose leaves in all payntes were lyke unto the leaves of the Italian *Playn* tre. And it is doubtles that these two trees were either brought out of Italy or of some far countrie beyond Italy, where onto the trees and monkes went a pilgrimage."

Gerarde, 1635, only mentions *P. orientalis*, which was still very rare in his day. A quaint and amusing passage is worth quoting, for it would almost seem that England retrograded between the time of Turner and Gerarde. Speaking of the *Plane*, the latter writer says it will flourish if "cherished and watered with wine; and it is found by experience that the same is very comfortable to the roots, and we have already taught that trees desire to drink wine." He adds below that he sent his servant, William Marshall, to the Mediterranean, and he brought seeds from *Morea* "whereof one or two are growing with *Tradescant*." Parkinson, *Theatrum Botanicum*, 1640, gives figures and the history of both *P. orientalis* and *P. occidentalis*, the latter, we are told, having been recently brought from *Virginia* by the younger *Tradescant*. The figure seems to have been made from the true American *Plane*, and is much better in its way than that of the Eastern species. Parkinson appears to have been the first to go wrong respecting the constitution of the Eastern *Plane*, of which he says, not "enduring our winter without extraordinary care." It is true that this species is, like many other trees, liable, when quite young, to be injured by frost. Ray (*Historia Plantarum*, 1706) knew apparently very little respecting one or the other of the two, for he alludes to them as *Platanus orientalis pilulis majoribus* and *P. occidentalis pilulis minoribus*. There is probably little difference in the size of the fertile spikes or catkins, but those of the true *occidentalis* are usually larger than those of *orientalis* in authentic specimens. Miller (*Gardeners' Dictionary*, 1731) states that *P. occidentalis* is much commoner than *P. orientalis*, and that *P. acerifolia* is a seminal variety of *orientalis*, as he knows from personal observation. Evelyn, in his *Sylva*, figures *acerifolia* for *occidentalis*; at least, such is my conclusion after consulting authentic figures and dried specimens.

I may here mention the particular character to which I alluded in the beginning of this article. In all the undoubtedly North American specimens that I have seen labelled *P. occidentalis* the fertile heads are solitary. In Michaux's *Arbres de l'Amérique du Nord* the plate of this tree exhibits the same character; and Dr. Asa Gray (*Flora of the Northern States*) mentions the same thing in his description. It is, therefore, quite evident that, if not an absolutely constant character, it must, at least, be commonly so, otherwise we make the specimens in the *Kew Herbarium* and at the *British Museum* wrong, as well as (probably) the only authentic figures (Michaux). The plate in the *American Dukemans* is also correct, but possibly that is simply a copy of Michaux. I have not the two works at hand at the time I am writing, and, therefore, I cannot decide this question. Why I suspect this to be the case is because all the other plates, with the exception of Parkinson's mentioned above, that I have seen called *occidentalis*, are most likely nothing more than *acerifolia*. Among others I may mention Watson's *Dendrology*, Schntzlein's *Iconographia*, and Schkuhr's *Handbuch*. I do not wish to appear too confident and positive of the accuracy of my views, but I think I have shown sufficient to justify myself in re-opening the question. I find that different writers have disagreed entirely in their description of the botanical characters, rate of growth, hardness, &c., of what they term *occidentalis*. For my own part, I have no experience whatever of its hardness; and the largest specimen actually known to me

is quite young, and only about 25 feet high. It was from this specimen in Kew Gardens that Mr. Smith kindly furnished me with the specimens exhibited at Burlington House. I ought not to omit to mention that here and there on this tree two heads may be seen on the same stalk, but that I think does not affect my position; solitary heads are occasionally seen on *P. orientalis*. It is labelled *P. pyramidalis*, whatever that may mean. I believe, however, that this name belongs to a cultivated variety of orientalis. A large tree at Kew bearing the name of occidentalis is doubtless acerifolia, as suggested by Dr. Hooker some years ago. Messrs. Decaisne and Naudin, in their *Manuel de l'Amateur des Jardins*, vol. iii., give it as their opinion that the greater part of the

degree of constancy there is in the character I have particularised. I believe I recognise Mr. Thomas Rivers in the "T. R." of the *Gardeners' Chronicle*, about the year 1856, if I remember right; perhaps he can say something decisive. I feel pretty sure that he had the true *P. occidentalis* at that time. The dried specimens and portraits of *P. occidentalis* are so distinct in appearance, that I have ventured to dilate at some length on this subject. There are several other instances of closely allied species or races separated by the Atlantic Ocean. In some cases the American species or race, as the case may be, is confined to the eastern side of the continent, and the Old World form stretches eastward to Japan. With the Planes it is otherwise; in America two or three species occur, and one or

forms, their geographical distribution, and the opinion of Heer that the fossil Plane of the miocene beds of Italy is more like the American than the Oriental form. Plane leaves have also been found in Greenland. If it should turn out that a Plane tree is native to Japan, we should consider our surmise well nigh established. EDS.]

New Garden Plants.

ANTHURIUM CUSPIDATUM.* (FIG. 85).

An Anthurium, somewhat resembling *A. aeranthe*, but, as it seems, distinct from it, and from any described in Schott's *Prodrromus*. It is a handsome stove foliage plant, of tufted habit, and with bold bright green foliage, the leaves measuring about 1 foot 7 inches in length, by 12 inches in breadth. The

FIG. 85.—ANTHURIUM CUSPIDATUM. LEAVES 1 FT. 7 IN. LONG, 1 FT. BROAD.

large Plane trees, both on the Continent and in England, are the American *P. occidentalis*, although they were perfectly aware of what had been published in this country on the subject, satisfactorily identifying our park Plane with *P. acerifolia*. I do not feel so confident that *P. acerifolia* is simply a seminal variety of *P. orientalis*; but possibly there may be an authentic specimen among the dried plants which the Chelsea Botanic Garden was bound to deposit at the Royal Society. If it really be so, there is perhaps very little more difference between the Western and acerifolia than there is between the latter and *P. orientalis*. The true orientalis is a far handsomer tree, and of more majestic habit than acerifolia, and, I believe, of much slower growth. I think even now it will turn out that *P. occidentalis* possesses characters by which it may readily be distinguished from *P. orientalis*, but I should be glad to hear from some of our American colleagues what

two of them down the western side from California to Mexico; whereas, in the Old World, the Plane does not appear to occur eastward of Kashmir. I have only to add, that possibly some of the characters reported to have broken down in attempting to discriminate the species have not been tried with the true *P. occidentalis*. *W. B. Hemsley*.

[Mr. Hemsley admits that *P. orientalis* has sometimes only a solitary female catkin while *P. occidentalis* has sometimes more than one, and so far concedes the point in dispute. We do not think that the evidence furnished by tenderness or hardihood is any better, for we have seen seedling varieties from the same tree, some cut by frost, others uninjured, though growing side by side in the same nursery quarter. In an article in these columns, 1869, p. 940, we lean to the view that all the forms of Plane had a common origin, founding our surmise on the known variability of existing

petioles are perfectly cylindrical, and not at all sulcated; a character by which it may be distinguished readily from any species with which we are acquainted. The spathe is reflexed much shorter than the elongated purplish spadix. The plant is, we believe, a native of Colombia, whence it was introduced to the Veitchian nurseries by Mr. Gustav Wallis. We had, however, previously seen it in the collection of Mr. Wilson Saunders, under the name of *A. cordatum*, from

* *Anthurium cuspidatum*, Mast., sp. nov.—Caudice abbreviato; petiolis 15–24 poll. long., viridibus, teretibus, nec sulcatis, rigidis crassitate, penne gulfinescae, geniculis $\frac{1}{2}$ poll. long. subtortibus, antice vix appianatis; foliis arcte approximatis 20–25 poll. long. 7–12 poll. lat., membranaceis, glabris, superne saturate viridibus, infra pallidioribus, cordatis ovato-oblongis, longe gradatim acuminatis, lobis basalibus distantibus rotundatis sinu lato separatis, nervo medio subtus prominente, nervis lateralibus secundariis 17–18, e quibus 6 basalibus e basi folii utroque latere radiantibus, ceteris a sese basi parum remotis pinnatis ad apicem pauloque intra marginem folii cum pseudo-nervo continuis, venulis arcuatis reticulatum ramulosis; pedunculis teretibus longitudo-aliter sulcatis, pallide puniceis; spathe demum reflexa oblonga obtusa apice apiculata, membranacea subpinnata glabra, vix 2 poll. long., circa $\frac{1}{2}$ poll. lat.; spadibus 6–8 poll. long., teretibus pallide brunneo-purpureis.

which it differs greatly. It is also in the Aroid subgenus at Kew. *M. T. M.*

ANTHURIUM WALLISII, Mast., sp. nov.* (Fig. 86.)

A very distinct Anthurium, remarkable for its peculiar cordate, elongate oblong leaves, quite different from those of any Anthurium we find in collections or herbaria. The leaves are of a deep green colour; the spathe is revolute, nearly as long as the greenish yellow spadix.

The plant is a native of Colombia, where it was found by M. Gustav Wallis, and by him introduced into the nurseries of Messrs. Veitch & Sons.

CYMBIDIUM ELEGANS, Lindl.†

It is very surprising that some very interesting Indian Orchids found their way to England so very slowly, when in a short time the inhabitants of India, as far as they are Orchidologists, may make pilgrim-

the name of the elegant *Cymbidium elegans*. It cannot be very rare. I have specimens at hand from Nepal, Wallich; Khasia, Griffith, T. Lobb, Hooker, and Thomson; Darjeeling, Griffith. It is a highly curious thing, not quite a first-class beauty, but quite apart, something totally unlike any plant seen before. The great raceme of long sulphur-yellow flowers, all nearly shut, is very striking, and decidedly must be acknowledged as very peculiar. It came to the collections of Lord Lovelace, East Horsley Towers, Ripley, Surrey, in spring, 1869, from Lady Lovelace's brother, and I am informed by Mr. Robert Miller, the skilful grower of the plant, that it flowered each year from 1871 to 1874; and I have at hand a beautiful inflorescence I obtained in February. It flowered during three weeks in my room. I also obtained it from the same place last autumn, in September. It flowered at that same period, I believe the first time, in the Royal Exotic Nursery of Messrs. Veitch. The plant would

by Mr. H. Low. The flower has not a single dot or blotch at all. Now the callus is pure yellow. The lateral lacinia of the lip are pure white, with a violet border, which looks exceedingly pretty. The plant is owned by J. T. Barber, Esq., of Spondon, near Derby, who selected it from the plants received last summer at Clapton Nursery, from the Philippines. *H. G. Rehb. f.*

MASDEVALLIA SPECTRUM, n. sp.*

Once more a *Masdevallia* of the Chimaroid group, very near *M. severa*, but very distinct in its very narrow sepals, which have yellow tails as long as the sepal bodies, which appear quite dark, being mottled over and over with blackish purple or violaceous dots. There is no doubt that it has three-flowered inflorescences, but whether those three flowers are developed at the same time, I cannot say. The plant may soon appear in the nursery of Mr. W. Bull, who

FIG. 86.—ANTHURIUM WALLISII IN FLOWER. LEAVES 2 FT., 2 IN. LONG, 10 IN. BROAD.

ages to England to see where their most distinguished Orchids decayed. I expressed that surprise I just alluded to when speaking of *Cymbidium longifolium*, and I have just the same opinion now when writing

* *Anthurium Wallisii*, Mast., sp. nov.—Caudice abbreviato; foliis arcte approximatis 2 poll. long., 11 poll. lat. subcoriaceis glabris superne saturate viridibus subtus pallidioribus oblongis basi profunde cordato-bilobis, lobis rotundatis seu subangulatis parallelis, sinu ovato utriusque attenuato separatis, pedatinervis nervo medio utrinque prominente carinam acutam superne efficiente, suturis costam validiorem subteretem constante nervi basales pedatis, caeteri pinnatis sub arcuati cum pseudo-nervo paulo intra marginales continuo, venulis arcuatis reticulatis; petiolis 20 poll. long. subteretibus antice leviter sulcatis viridibus glabris crassitie pennae anserinae, geniculo crasso sulcato ½ pollicari; pedunculis 4–5 poll. long. teretibus glabris crassitie pennae cynege; spathe demum revoluta, coriacea oblonga acuta apudice vix brevior; spadice 8–9 poll. long. flavo-virente; pollinis granis oblongis; ovula non vidi.

† *Cymbidium elegans*.—Caulisescens, caule basi tumido; foliis ligulatis acuminatis valde elongatis; pedunculo vaginis ligulatis acuminatis scariosis distichis vestito; racemo mutante; bracteis triangulis minutissimis; floribus hinc glutinosus, clausis, mento valde parvo; sepalis ligulatis acutis; tepalis sursum latioribus; labello a basi late ligulato concavo dilatato; antice trifido; lacinia atheralibus triangulis; lacinia media subrhombica; callis geminis

appear to improve much in Europe, its leaves, as well as its flowers, exceeding by far those of the wild specimens. I also made an astonishing observation. The two small angular lamellae at the base of the lip were very inconspicuous and orange-coloured last autumn, both in all flowers of the Lord Lovelace's as in those of Messrs. Veitch's plant. Those lamellae in fig. 1 of Lindley's *Sertum*, 14, appeared very superior; now this time all the flowers I examined have the same lamellae much larger than those represented in the *Sertum*, purplish and toothed. Let us hope to see it soon represented in the *Botanical Magazine*. *H. G. Rehb. f.*

PHALENOPSIS SCHILLERIANA, Rehb. f., var. IMMACULATA, n. var.

I have just been favoured with this splendid variety

semirhombis seu subfalcatis denticulatis in basi; pillis quibusdam circumspersis; carinis linearibus contiguis antepositis usque in basin laciniae antice, ibi abruptis velutinis; columna semitereti apice curvata, basi pilosula, rostellis trifido.—*Cymbidium elegans*, Lindl. G. and Sp. Orch. 163 Sertum, tab. 14.

sent me dry specimens, gathered by one of his collectors, Mr. Shuttleworth. *H. G. Rehb. f.*

DANIEL HANBURY.

THE death of this accomplished gentleman, on Wednesday the 20th inst., has come upon us as a most painful surprise. Amiable, accomplished, profoundly versed in his own special department, still in the prime of life, having done excellent work, capable and willing to do good service to science and to his fellow creatures, he has been suddenly removed from

* *Masdevallia spectrum* (Saccilabiata).—Racemosa, sepalis ligulato triangulis caudatis sat angustis; caudis corpora sepaliorum subaequantibus; limbo ac disco interno parce hispidulis atque tuberculatis; tepalis ligulatis abbreviatis apice obtusangulo bivalvibus, tumore hispido papuloso interjecto; labelli lacinia lateraliibus postice obtusangulis parvis; lacinia media oblonga calceata obtusa; carinulis angulata in quavis auricula basilarum; carinis membranaceis erectis tereti per totam laciniam mediam subrhombicis approximatis; columna apice acuta denticulata.

us, leaving behind him an example to be followed and a memory to be cherished.

Mr. Hanbury was one of those who raise their business and themselves to a higher level than that of mere money getting. Pharmacy to him was a means of serving, not only his own interest, but those of humanity and of knowledge. His original investigations into the nature and history of drugs and of the plants producing them were minutely accurate, and his record of them was as judiciously terse. Little was left doubtful, nothing, we may say, that it was within his power to clear up. At the same time not a word was wasted, not an irrelevant remark added. His *magnus opus*, the *Pharmacographia*, published in conjunction with Professor Flückiger, of Strasburg, and quite lately noticed in our columns, amply justifies our remark. It is the work of no mere compiler, but of one who brought judgment, penetration, and original research to bear on his self-imposed task. We mention this as his chief work, but the publications of the Pharmaceutical Society and of the Linnean Society, yield many evidences of his diligence and thoroughness. He was not content to examine and study dried specimens of the plants producing various drugs, he cultivated them whenever he had the opportunity. His brother's garden at La Mortola (see *Gardener's Chronicle*, 1874, p. 35, fig. 7) afforded him ample opportunity for indulging his gardening tastes, and for introducing to that genial climate plants that cannot be cultivated here in the open air.

The garden at La Mortola is a veritable garden of acclimatisation, in which the most interesting, the most useful, and the most attractive of plants find a home. In the formation, stocking, and management of this garden, Mr. Hanbury took the greatest interest. His catalogue of plants cultivated, and his notes on their progress, attest the zeal and devotedness he bestowed on furthering his brother's plans of establishing a garden of interest as well as of beauty on the lovely shores of the Mediterranean. Mr. Hanbury was a Fellow of the Royal Society, Treasurer of the Linnean Society, and a most active member of the Pharmaceutical Society. He was an occasional contributor to these columns, and was the means of introducing several plants of great interest to our gardens.

THE SOUTHPORT WINTER GARDEN.

WHEN, in 1865, Sir James Edward Smith, then simply M.D., wrote his notice of the evening Primrose, (*Enothera biennis*, for the original *English Botany*, he stated that his specimen of the plant (the same from which the drawing was prepared) had been gathered upon the "dreary sandbanks" on the coast of Lancashire, a few miles north of Liverpool. "Millions" of this plant, he goes on to say, had been noticed there by Dr. Bostock and Mr. John Shepherd, "perfectly wild," though possibly, he adds, the progenitors might have come "from the opposite shores of the Atlantic." This is now generally acknowledged to be the true history of the *Enothera*, as regards its apparently wild existence in England. It is clearly one of the New World plants which, after crossing the water, at once took kindly to the soil of Europe. So completely indeed has it become established in our continent that it is included and figured not only in the *English Botany*, but in the *Flora Danica*. The seeds were first brought to England designedly in 1629, and there can be no doubt that at some very early period afterwards accident conveyed seeds ripened in England to these Lancashire sandhills, where, as in our gardens, if not subdued, the multiplication would be as rapid as that of fishes. Had it been possible for the seeds of the Oil Palm, *Elais guineensis*, to germinate as readily, the margin of Lancashire at that part might now have held a young forest of it, for a few years ago they were strewn upon the sands by thousands, the result of some shipwreck or other disaster to a vessel trading to the coast of Africa, and homeward bound to the Mersey. Very interesting would it be to observe that the posterity of the old immigrants, the *Enotheras* of a century and a-half ago, are still in many parts quite thick upon the ground. They occur at intervals all along the shore from Waterloo, just above Liverpool, nearly to the mouth of the Ribble, and now probably will never disappear. Many and very lovely are the *bona fide* Southport wild flowers. The Southport people, who are wild-flower-minded, have still nothing more worthy of attention than the naturalised evening Primrose. Various little particulars give it a rare and permanent charm. The flower-buds, for example, that open so curiously—not as others do, at the top, but from the bottom upwards, the petals creeping out through a gap in the side—the easy and *nonchalant* way in which they allow us to watch their expansion, if we will but wait a moment; the large and beautiful cruciform stigma, laced to the anthers

by threads finer than gossamer, and beaded with pollen of the same clear yellow as the flower in general—with these, no one who loves the "little things of Nature" can be pleased, I say nothing of the romantic hour when the perfume commences, which is just about sunset in the calm warm evenings of mature summer, when the sweet lustre of the first planet is seen in the sky. In England we have only one or two really indigenous evening flowers. The prettiest and most abundant of them all, the milk-white evening Lychnis, is itself a Southport plant. That one of the first of their "American cousins" to arrive should have settled upon the sandhills of this now celebrated watering-place is really a sort of floral compliment to the neighbourhood, and one which should be fittingly acknowledged.

The sandbanks of the Southport of 1865 have long since ceased to be "dreary." Adjacent to them, occupying large areas of the ancient wilderness, there is now a town remarkable for its neatness, and with a history that is perfectly astonishing. When Dr. Smith received his *Enothera* there the name had not been even beginning to be celebrated, and the name is now Southport was simply "The Hawes," a bathing-station in the parish of North Meols—"Meols" being of ancient Saxon extraction, and signifying "sandhills"—while the people all dwelt at Churchtown. The first house of the present thousands was built only about 1792, and of course has long since disappeared, though the name of the old foundation is extant in that of "Duke Street." Two or three different railways lines now converge towards it, rendering access from Liverpool, which is only 18 miles distant, and from Manchester, which is 32, a very easy matter. Seven or eight well proportioned spires imply as many places of worship. High-class hotels abound: there has recently been opened a very handsome new public hall; there is a promenade half a mile long along the shore; and there is a pier nearly a mile in length, the visitors walking to and fro on a steamer. A long pier must be confessed, and indubitably on account of the distance to which the sea retires over the level sands, which do but correspond, either as regards flatness or breadth, with the inland country for a distance of many miles. The extent of these sands, and the rapidity with which high water changes to low, recommended them some years ago as the practising ground of the now famous Whitworth artillery. They contribute in no slight measure to the salubrity which has won for Southport, with its special patrons, the title of the Montpellier of the north. Within the last fifty years changes almost incredible have been made. Lord Street, a mile in length, was laid out soon after 1825; the promenade was commenced about 1835, and the pier soon after 1860. Since then immense breadths of marshy ground, the home of the Buck-bee and the Mare's-tail, have been drained, the surface brought into elegant and ornamental suburbs.

Tasteful and well-appointed villas have become hundreds, especially at fair-complexioned Birkdale; and where only the other day there was nothing but shifting sand and the multitudinous and speary Matragas, *Ammophila arenaria*, the haunt of the green lizard, now there is the spacious and remarkably well-kept Hesketh Park. The schools at Southport and Birkdale have earned themselves a reputation that has travelled all over England, and now, though fast by no means least, there has just been established an aquarium and winter garden, which will sustain the challenge of anything of the kind in England. This bit of local history, it is hoped, will not have been tiresome. Horticulture is itself so thoroughly a thing of progress—the *Gardener's Chronicle* may so rightfully assume the same word for its enduring motto—that a record of progress of any description that is honest and true needs to be genuine and in its own spirit, especially when the record begins to deal with such objects as flowers. Such is my apology for the guide-book details.

Of the aquarium, strictly so called, it is not our province here to speak. Let it suffice to say that in every particular, whether of extent, fittings, or contents, it appears to be everything an intelligent people can desire. The examples of *Anthonozia*, or "flower-animals," seemed to us, when we saw them, to be singularly beautiful, and among these were the feathery ones which in tenderness surpass even the Sea Anemones and the Sea Marigolds. Neither is it our province here to speak of the arrangements in the splendid building, which includes the aquarium proper, for entertainments of a popular character, music in particular. That which the readers of the *Gardener's Chronicle* are more nearly concerned with is the winter garden, a section of this great complex which is calculated as the first seeing to fill every eye with astonishment. A notice recently appeared in the *Gardener's Chronicle* of the great hall at the Pomona Gardens, Manchester, the scene of Mr. Kelly's flower and fruit show. In its way, the winter garden at Southport is quite as remarkable to all who enter it for the first time. It has the great merit also of improving upon acquaintance. Lancashire is

evidently determined not to be left behind as regards the construction of splendid edifices. The county of the red Rose long since won for itself celebrity in regard to huge cotton-mills; now it is equally well to the front in the buildings of every description that gratify Art. The total cost of this immense place has been not less than £100,000, and the winter garden may perhaps have consumed about a fifth of the money. Of course it is to be understood as a sort of immense cold greenhouse. The length is 180 feet; the width 80 feet; and along the centre, which is an exact miniature of the transept of the Crystal Palace at Sydenham, it is 80 feet high. The architects, Messrs. Maxwell & Tuke, of Bury, did very wisely in taking the latter for their model. It is warmed by means of Messengers's hot-water apparatus; the temperature maintained in winter being 50° by day, and 50° to 60° by night. Looking out upon the contiguous pleasure-grounds, and beyond these, upon the Irish Channel, the western extreme of the building bids fair to become a very seductive resort. Here, in addition to the plants and flowers, we have the aviary, and in the evening the full beauty of the western sky, and the moonlight, and extending the whole length of the edifice are two plant galleries, the lower one 5 feet wide, the upper one a yard. These are already furnished with pots holding *Passion-flowers*, *Cobæa*, *Clematis*, and various other plants of climbing and trailing habits, so that before long there will be a perfect veil of vegetation. In front, at suitable distances, there are hanging-baskets, while the floor is provided with beds and cages that are already well stocked with specimens in good variety—Palms, Tree Ferns, and Conifers not omitted, and the aggregate amounting to 5000 or more. Many of the plants were procured from London and the Continent. Besides those in view, the curator has plenty more in preparation in the nursery-houses, and will doubtless keep up a nice succession of bulbous flowers, and of other attractive and popular sorts as the seasons come round.

It is, however, a very large and important consideration with such a magnificent opportunity as the members of the executive have now provided themselves, it is to be hoped that designs and notions of mere prettiness of effect will be laid aside, and that in place of them there may be a determination to let the building become worthy of its contents, and, *pari passu*, to let the contents become worthy of the building. They are already very commendable, as regards the merit of the species they are only the nucleus of what they ought to be, and easily may be. See, in the first place, what admirable spaciousness! It is often quite lamentable to see how plants of aspiring tendency, and of the most exquisite forms and outlines, are confined and imprisoned, to their serious injury, if not ruin, in places no doubt cheerful enough to the owner, but which, regarded horticulturally, are nothing more than glass boxes. To give such plants an opportunity to display their beauties we regard as only honest and fair. In many cases it would be a genuine charity, and though the Humane Society could scarcely bestow a medal for it, the deserving would be none the less. What a grand potentiality for good lies accordingly in this Southport winter garden, in regard to the innumerable splendid plants which may be introduced into it, or those which require only a medium temperature. There will be no need or hindrance to their acquiring and retaining the graceful figures natural to them. Any quantity of such plants may be got together, and at a cost that never need be an impediment. Out-of-doors, in the floral "lathroving" of the garden, which Mr. Baines so happily terms the current or "bedding-out" system of floriculture, we have quite enough of the tinsel demanded by colour-worship—the great affliction of the age. Those whose plans it may be to devote to the curator what shall be done in his winter garden, if it is any facilities, will not desire, it is to be hoped, that their hall shall be simply "pretty." They have a splendid opportunity for showing themselves superior to childish preferences for mere finery, like a little girl's for a doll decked with ribbons and beads. Let them by all means have bright and fragrant flowers in constant plenty, but let them remember also at the same time that the true interests of the place demand for it a specific and æsthetic character. This is never incompatibly with "prettiness," and, on the other hand, there is no need for it to be made only a shelter for evergreens, though a simple fernery well-contrived is undoubtedly "a joy for ever." We desire only to see that the present first-rate chance shall not be ignored; and that botany, as a noble science, shall be accredited to the almost possible extent. To descend to mere colours, or the sake of the inorganic and the feeble, may be of good-natured; but Southport is a rapidly-rising place, and the executive of the aquarium will unquestionably promote their best interests by rendering their winter garden a spot that science as well as excursionists shall delight to visit. There is money enough to procure all that ought to be there; and it will scarcely be a credit to the town if with such a promise as this

building implies, the performance should lag behind. A very good beginning has been made. Note, for example, that handsome specimen of the Bidwill Araucaria, the famous Banyu-Banyu tree, from the banks of the Brisbane River. Is it nothing to have daily access to a tree like this? In its native country the Banyu-Banyu rises to the height of 100 feet, the cones—one of which was figured in these columns in 1873, p. 364—which stand erect on the loftiest branches, are nearly a foot in length, and contain seeds which, when roasted, resemble Chestnuts, and constitute the harvest of the aborigines. The different tribes of the latter possess each their own grove of trees; they pass, like estates, from generation to generation, and are the only kind of hereditary property they comprehend. We take it, moreover, that the getting together a collection of plants of this quality, especially economic ones, would render the Southport winter garden a first-rate place for practical botany lessons. Ready at all seasons, and in all weathers, how delightful would it be for the hundreds of young people in the schools to come hither, instead of cramming hard words from books, and receive from some competent teacher the lessons that in the presence of life become so charming. We beg leave to commend this idea to the directors. It is for them to choose whether they will do their best to enrich and elevate, or rest satisfied with providing a lounge for idlers.

One word more. Once quite renowned for their indigenous flora, the sandhills to the south of the town are still the abode of countless numbers of that lovely flower, the Pyrola, the Lily of the Valley of their quiet little plateau. Blending with it are myriads of the snowy *Parnassia*, *Orchids* in three or four kinds, the purple *Gentian*, the seaside *Spargelia*, *Euphorbia Paralias* and *E. portlandica*; the *Clorua*, the *Erythraea*, the blue *Eryngium*, many rare mosses, and fifty more of Nature's *bijouterie*. No more, therefore, than in kindly keeping with the gifts of wild Nature would be a winter garden well stored with choice exotics. These wild and wayward sandhills, so rich in indigenous botany, possess at the same Our English seedlings are few, but excellent in their merit, and the features of the present ones are such. A sort of *Andes* in miniature, at every turn there is something new, and ordinarily they are tranquillity itself.

It is but right to add that the curator, trusting in "a good time coming," has already secured some nice plants of *Phoenix*, *Rhopala*, *Chamerops*, and the like; but, looking to the capabilities of the winter garden, to rest in these, and for the future to think only of show and colours, would be most tasteless. G.

NEW AND LITTLE KNOWN PEARS.

If we are to judge from the remarks made in horticultural journals, and the lists authoritatively (more or less so, at least) given to inquirers after the "best dozen" of Pears to plant, we should conclude that the English mind had succumbed under the number of new introductions, and had fallen back in despair on old favourites, or that the novelties themselves were really of no value.

It would be a curious question, but one which it is fair to ask, where and how these arbiters of our future Pear culture have obtained their knowledge of the new varieties? Not at nurseries, for that is hardly fair to expect. Not in their own gardens, for their employers would scarcely enjoy the trial. Not in our public gardens, for these do not devote space for such things. Where, then, shall we go? We must even travel as far as the countries whence they come as seedlings, and then afterwards learn of those who devote their time especially to test which novelty is really adapted to our climate. Foreigners are very well aware of our weak points, and one of these is Pear culture, and another, knowledge of sorts.

As long, too, as a trial is confined to the training of trees on walls in largely developed forms it is impossible to spare sufficient space to grow varieties side by side, in exactly similar conditions, which is the only fair test.

The cordon system, originating abroad, has considerably contributed towards a speedier and more accurate determination of sorts, while the splendid climate of mid-France and the summers of Belgium have enabled observers to try how these answer as standards. America has also sent us valuable fruits, kind.

Not to dwell on these matters, however interesting, I shall endeavour to indicate a way by which English amateurs can, without much real trouble, ascertain for themselves exactly what Pears, new and old, will suit their local climate and soils. The difference these cause in Pear culture is immense. If in such cases

there be added a few scientific protections in the spring, a little more knowledge of pruning, no encroaching on the Pear borders, and general constant attention, in a few seasons our progress would surpass all others.

In the first, indeed the only way to test Pears is to use the diagonal cordon. Vertical cordons require too lofty walls; horizontal cordons give results which neither indicate what is right in wall culture nor in open borders. Fan-trained trees take too much room, and do not bear so quickly.

Let then the amateur take, if his space allow—and it will, in many cases—say 100 varieties, singly, or in pairs (which is far better), and plant these at 18-inch intervals, against a good wall, in a well cared for border. If possible, these same varieties should also be planted as standards close by.

In two seasons he will see a little fruit; by waiting three he will see abundance of the finest quality. Let the fruit on these 100 sorts be thinned out very freely and equally, and where can a better test be found, or a fairer comparison be made? As soon as the merits of any sort are considered as well-established, let the tree be removed, either for a standard or for another position, or say, for some distant locality. Destroy any trees which are found unprofitable; the expense is trifling, the time employed not much; and its place can be at once filled in by any novelty. I do not despair of seeing public gardens attached to horticultural societies for these purposes, and one grand national central garden devoted to some similar use, for Pear culture is of great importance.

Diagonal cordons I have found, after many seasons of experience, to be most suitable for Pears. Apples, except rare and tender American sorts, hardly need it, while Plums and Cherries grow too strongly for such small development, unless grafted accordingly; and there might be many interesting experiments made with new sorts in this way also. In short, it is marvellous to me that this system of training, now a quarter of a century established, and perhaps double as old, is so little known.

I also speak from experience, having for a long time tried nearly every new Pear of any repute, and some common numbers. My friends, seeing the good results, have also adopted the cordons, and some amateurs think nothing of training and pruning their thousands of trees, entirely by themselves. Can any one teach these which sort is the best? When they read the lists so often given of the "best trees to plant," they must smile at the retrograde and stunted ideas which prevail.

Such persons would exclude *Souvenir du Congrès* and *Beau de l'Assomption*, and adhere to time-honoured *Bon Chrétien* and *Louise Bonne*. But are not these two last inferior to *Beurré Superfin*? And yet we see it excluded in the "orthodox half dozen" far too frequently. The other day I read the name of *Beurré Capiaumont* among a list of six; let us hope M. Baltet will not hear of it.

A capital Pear, which is new to most people, but, thanks to cordons, several years well fruited here, is *Olivier de Serres*—moderate size, round shaped, melting, may keep well to March. *Marie Guise* is a new one, but also large, firm, flesh, good aroma, and requires high cultivation. *Beurré d'Espéren* is not very new, but deserves notice; early in December, pyriform, russety, melting. *Emile d'Heyst* is excellent here, considered first-rate abroad; rich and juicy, in season in November. *Nouvelle Fulvie*, like *Passé Colmar*, but not so cloying in flavour, and larger; ripe here at Christmas. *Prince Napoleon* is another new Pear of good augury. It is a very model cordon, of just the right quality; a seedling from *Passé Crassane*, having the fine flavour of this old Pear, and ripe in March. *Marie Benoit* is new, large and good, so is the *Brookworth Pear*. These I do not know so much of yet. *Grégoire Bourdillon* would also have many rivals in September. *Anna Nelis*, a very late Pear, has not fruited these two years. *Duchesse de Mouchy*, also immensely late, I cannot speak of yet. *Président Deboutteville*, and *Quintin*, also doubtful here. *Professor Barral*, more than a quarter of a century in culture completely, though yet on the best French lists. *Président Magy*, a fair Pear only, but *Beurré Bachelier* is too like it. *Marshal Vaillant* varies much; some years it is a grand Pear, and a late one too. *Jacques Molet*, large, melting; very hopeful, and has the merit of keeping from November to March. Among others, *Pitmans Duchessa* is a showy and very promising Pear, late in November. *Beurré d'Amalins* (striped) is also a fine-looking Pear. *Summer Beurré d'Arenberg* is a great acquisition; fruited here for years. *Calabasse* (*Boisbunel*), new and extraordinary, but not to be trusted.

Many more names could be given, but, although possessors of small gardens would probably not require one of the above—not even *Souvenir du Congrès*—still, we need not quite exclude—and there are also numerous large gardens—any variety simply because it is new. Some will ultimately hold their ground, our best old sorts were once novelties also. The thing to be ascertained is the relative merit

of recent introductions, and not to wait till we have forgotten their names, when, very likely, they will be re-introduced under another designation. Another matter deserving of consideration among gardeners is a trial of many sorts double worked *versus* single worked on the Quince. How can we expect to do this except by means of diagonal cordons? It is now certain that what succeeds on them will also do so in larger forms. Wall cordons give results for walls; espalier cordons show what is fit for the borders. I am not so much an admirer of these espalier cordons as some of my friends are, for they need protection by mats, &c., in the blossoming season. However they, too, have their use. As was said already, the horizontal cordon gives results appropriate to itself only, being neither wall nor border. With a fair wall, nothing equals the diagonal cordon for trial purposes; and, as to quality, I think it has been shown before this. *Thomas C. Brkhat, Guernsey.*

ELEMENTARY LESSONS IN BOTANICAL GEOGRAPHY.

ON THE BOTANICAL CHARACTERISTICS OF THE ZONES OF HEAT.

(Continued from p. 367.)

THE gradual lessening of the average number of plants in a given area which begins as soon as this zone is entered on its equatorial side, and goes on in proportion to the decrease in the time of vegetation, is one of its most important and noteworthy characteristics. France, including Corsica, is about the same size as Sweden, and the former yields 3600 and the latter 1160 flowering plants; Naples, with 3130 species, is about the same size as Iceland, with 400; Germany, as limited in Koch's *Synopsis*, with 3568 plants, is about the same size as the whole of Scandinavia, including Denmark, with 1677; Tuscany, with 2366 species, is about the same size as Yorkshire, Northumberland, and Durham taken together, with 1000; Silesia, with 1288 plants, is about the same size as Spitzbergen, with 107. Except in the heart of Asia the botany of this zone has been explored very thoroughly, and although it includes a third of the earth's surface we cannot estimate its total flora as sea-level at more than 15,000 species, to which, however, a large addition must be made for the plants that ascend into it on the mountains that rise from the countries of the two warmer zones.

The principal marks which give the general tone to the physiognomy of its vegetation are—1. The components in plant-form of a real winter, a great proportion of the trees with deciduous leaves, standing bare and leafless for half the year or more, according to latitude; and the few evergreens organised so as to resist severe cold, principally Pines with long needle-like leaves, in which the evaporating surface is reduced to a minimum; and plenty of herbaceous perennials that die down in winter to an underground root-stock. 2. Fewness of shrubby climbers, and total absence of the tropical types of form, such as Palms, Figs, Peppers, Tree Ferns, Grubers, Bauhinias. 3. The small number of trees and shrubs in proportion to the total number of plants, and the way in which single kinds (e.g., *Pinus*, *Fagus*, *Betula*, *Quercus*, *Calluna*, *Ulex*) often grow together in vast quantity. 4. The low floral type of the trees, which are usually achlamydeous or monochlamydeous, and incomplete sexually, with small obscure flowers in dense clusters, which appear in spring before the leaves are fully formed, thus offering a great contrast to the trees of equatorial regions. 5. The abundance and persistence of the greensward-producing grasses, and presence of a constant general covering of grassy verdure. 6. Ferns in the insular climates in the same way as the trees and shrubs, a small number of kinds growing in great quantity. 7. Relative preponderance as compared with the two former zones of terrestrial mosses, and large foliaceous and fruticose lichens, such as *Cladonia*, *Peltigera*, *Parmelia*, and *Collema*.

The orders or sub-orders, which have a decided maximum in the cool-temperate zone, are very few. The principal are *Alsinaceae*, *Amentaceae*, *Saxifragaceae*, *Grossulariaceae*, *Primulaceae*, *Polemoniaceae*, *Hydrophyllaceae*, and *Sarracenaceae*—the three last mainly or entirely American. Amongst orders and sub-orders that may be considered as characteristic of this and the warm-temperate zone taken together, are *Ranunculaceae*, *Fumariaceae*, *Cruciferae*, *Sileneae*, *Troiliceae*, *Grossulariaceae*, *Umbelliferae*, *Stellatae*, *Cichoraceae*, *Campanulaceae*, *Valerianaceae*, *Gentianaceae*, *Labiatae*, *Borraginaceae*, *Coniferae*, *Chenopodiaceae*, *Cupuliferae*, *Juncaceae*, *Phalaridaceae*, and *Festuceae*.

Amongst striking generic types that have their head-quarters here are *Anemone*, *Ranunculus*, *Aqui-*

legia, Corydalis, Cardamine, Arabis, Draba, Erysimum, Viola, Acer, Geranium, Astragalus, Vicia, Lathyrus, Stellaria, Arenaria, Lupinus, Prunus, Spiraea, Rosa, Pyrus, Crataegus, Cotoneaster, Potentilla, Fragaria, Ribes, Saxifraga, Chrysosplenium, Parnassia, Heuchera, Sedum, herbaceous Sempervivum, Philadelphus, Deutzia, Heracleum, Angelica, Cornus, Lonicera, Sambucus, Viburnum, Epilobium, Valeriana, Aster, Solidago, Chrysanthemum, Helianthus, Hieracium, Lactuca, Crepis, Leonodon, Vaccinium, Rhododendron, Kalimeris, Azalea, Pyrola, Primula, Lysimachia, Pedicularis, Pentstemon, Mentha, Phlox, Gentiana, Asclepias, Fraxinus, Rumex, Rheum, Chenopodium, Atriplex, Ulmus, Fagus, Corylus, Carpinus, Betula, Salix, Populus, Pinus, Juniper, Luzula, Gagea, Lilium, Allium, Scirpus, Carex, Eriophorum, Alpeocarpus, Phleum, Anthoxanthum, Agrostis, Calamagrostis, Glycyrrha, Poa, Festuca, Bromus, Triticum, Elymus, Avena, and Hordeum.

The principal plants grown in this zone on a grand scale for the use of man are the common cereal grasses, Wheat, Oats, Barley, and Rye; of fruits, the Plum, Apple, Pear, Peach, Apricot, Cherry, Strawberry, Gooseberry, Red Currant, Black Currant, Quince, Medlar, and Logquat; of garden esculents, the Potato, Cabbage, Turnip, Beet, Bean, Kidney Bean (*Phaseolus vulgaris* and *coccineus*), Onion, Leek, Chives, Mustard, Cress; of fibre-yielding plants, Hemp and Flax; and of forage plants, Vicia sativa, Lolium italicum, Clover (*Trifolium pratense*, repens, hybridum, and incarnatum), Lucerne and Sainfoin.

One of the most remarkable points about the zone is the wide and dissevered dispersion of many of its characteristic species. Of the 2100 flowering plants of the Northern United States 300 are European; and out of 577 Ferns, Mosses, and Hepaticæ, 355 are European; and the plants of this zone may be reached within the arctic circle about 100 species also inhabit cool-temperate areas in the southern hemisphere.

4. *The Arctic-Alpine Zone* includes at sea level all the country from the arctic circle northward to the perpetual snow-line, and upon the mountains of the warmer zones the belt between the upper limit of practicable cultivation and the perpetual snow.

The number and height of the Ferns that grow within the arctic circle does not exceed 800 species, of which not more than 25 per cent. can be regarded as all characteristic of this particular climate, the other 75 per cent. being plants of the cool-temperate zone, which are flexible enough in constitution to grow here also. The number of plants which inhabit the zone where it occurs as a belt upon the mountains is far greater. We cannot count the characteristic alpine plants of the Alps, Pyrenees, Apennines, Sierra Nevada, and other European ranges at less than 1000 species, and there must be three or four times as many that ascend into the zone from below, and the characteristic plants of this zone within the tropics and in the southern hemisphere are very rarely the same species as the arctic-alpines of the north.

There is, in fact, a wide difference in the period of vegetation of the plants of this zone near the poles and upon an equatorial hill, and similarly in the place of the one of perpetual snow, which is fixed, not by the average temperature of the year, but by the heat of the summer months. In high latitudes there is a great elevation of the temperature of the summer above that of the winter, with a proportionately higher snow-line as its result, and there is a very short period of vegetation. In Spitzbergen the plants to live need to flower and perfect their seed within six weeks or a couple of months, and the whole island does not yield much over 100 plants of the higher orders. On the equatorial mountains, on the contrary, there is very little difference between the temperature of the different seasons, and consequently no additional heat in summer to melt the snow above where the average annual temperature is at freezing-point. The snow-line is therefore here proportionately lower, and there is a much longer period of vegetation for the plants of this zone, and a much richer alpine flora. The plants known in this zone from the Andes cannot be fewer than 2000 or 3000 species. There is quite as much difference between the climates to which the different parts of this zone are exposed, as between the different climates, insular and continental, more polar and more equatorial, of the cool-temperate zone.

The general *facies* of the vegetation of this zone is not dissimilar from that of the cool-temperate. It is the flora of low herbaceous perennials, with a considerable scattering in its lower levels of trees and bushes, but the former fast disappearing after its lower bounds are passed, and all the few really characteristic shrubs dwarf and low-growing. The two negative general characters that stamp it most forcibly as compared with the cool-temperate zone are the absence of the plants cultivated on a grand scale for the use of man, and the almost entire absence of fannals.

Within the arctic circle, out of its 800 plants

there are nearly one hundred that are trees and shrubs. Of these about one-fourth are really characteristic, the other three-fourths being species that ascend here from further south. The following are those that may be considered as characteristic of the zone, viz.:—*Rubus arcticus*, *R. Chamæmorus*, *Vaccinium uliginosum*, *Andromeda hypnoides*, *A. tetragona*, *A. calciculata*, *Arctostaphylos alpina*, *Diapensia lapponica*, *Azalea procumbens*, *Rhododendron lapponicum*, *Osmorhiza fragrans*, *Phyllocladus taxifolia*, *Betula nana*, *Salix lanata*, *S. lapponicum*, *S. arbuscula*, *S. glauca*, *S. arctica*, *S. myrsinites*, *S. reticulata*, *S. herbacea*, and *S. polaris*.

There are not any orders characteristic of the arctic-alpine zone in the northern hemisphere, unless we count as such *Diapensiaceæ*. The characteristic genera are all either monotypic or very small, such as *Braya*, *Entrema*, *Kernera*, *Sibbaldia*, *Dryas*, *Homogyne*, *Adenostyles*, *Svevicia*, *Wulfenia*, *Fozzia*, *Soldanella*, *Koenigia*, *Oxyria*, *Chamaeorhiza*, *Kobresia*, *Vahlodea*, *Knipitza*, *Lloydia*, *Pleuropogon*, and *Woodsia*.

Out of the 800 arctic plants only eight are absolutely restricted to the arctic regions; the other species occurring, which are characteristic of the zone—about 200 in number, are many of them spread widely upon the mountain summits of the northern hemisphere. A very large proportion of the most characteristic alpine of the northern hemisphere are high-climbing species of the large characteristically cool-temperate genera. Of the genera, which include several characteristically alpine species, the following are the principal, viz.:—*Ranunculus*, *Arabis*, *Draba*, *Thlaspi*, *Silene*, *Alsine*, *Dianthus*, *Potentilla*, *Saxifraga*, *Senecio*, *Achillea*, *Erigeron*, *Hieracium*, *Crepis*, *Campanula*, *Phyteuma*, *Gentiana*, *Veronica*, *Pedicularis*, *Primula*, *Androsace*, *Salix*, *Juniper*, *Luzula*, *Carex*, and *Poa*.

Under the tropics, as already stated, hardly any of the characteristic arctic-alpines are the same species as those of the northern hemisphere. Many of them belong to characteristically cool-temperate genera, and others are high-climbing species of the genera that belong specially to the countries round the base of the mountains. We find, for instance, that in the Andes of South America there are 473 species of *Compositæ* which grow in the arctic region, and belong to sixty-one genera. Not one of these species is known in the northern hemisphere; 182 species belong to eight genera, which in the northern hemisphere have other species which are characteristic of the arctic-alpine zone. Fifty-four species belong to seven genera, which ascend into the cool-temperate zone of the northern hemisphere, but do not climb its mountains, and 237 species belong to forty-nine genera which are not north-temperate at all, but peculiarly South American. Of arctic-alpines of the northern hemisphere which pass down the Andes into the southern hemisphere, we have examples in *Draba incana*, *Lychnis apetala*, and *Phleum alpinum*.

It is scarcely needful to point out that these four zones of heat correspond to our four plans of garden treatment. We provide, for instance, at Kew, for the plants of the intertropical zone in the Palm-house, the large Fern-house, and the central compartments of the new range, and our imitation of a tropical climate must be of necessity a very imperfect and clumsy one. We cannot transfer to England the regular rainy and dry seasons, the equal day and night, the trade winds, and, above all, the clear cloudless skies and bright light and burning sunbeams of the equatorial zone. We provide for the plants of the subtropical or warm-temperate zone in the new-temperate house, the Cactus-house, the lesser Fern-house, and the ends of the new range, and it is a valuable elementary lesson for a young gardener to store up in his memory that a large proportion of the 40,000 plants of this zone are in danger of being killed if frost gets fairly at them. Our principal difficulty with the plants of this zone is with those from the southern hemisphere. These have been accustomed as a rule to bloom in their summer, which is our winter, and refuse when brought here to change their habits. The 20,000 plants of the cool-temperate zone we can accommodate without difficulty in the open air in our herbaceous ground and shrubberies, and arboratum. For the characteristic plants of the arctic-alpine zone we build rockeries and shelter them from the sun, but our long warm summers and dry sandy soil try their constitution severely, so that they need careful watching over and watering, and require that great pains should be taken to imitate their natural stations as closely as possible.

M. Alphonse De Candolle has given names to plants of the different degrees of heat-constitution, which it is sometimes convenient to use, and which, with a modification which I venture to make, by using four stages instead of three, are as follows:—

1. Macrotherm, characteristic of the intertropical zone, and requiring stove-heat with us for its cultivation.

2. Mesotherm, characteristic of the sub-tropical or warm-temperate zone, and therefore needing to be natively protected from frost.

3. Mesotherm, characteristic of the cool-temperate zone, and therefore quite hardy in the open air in England.

4. Microtherm, characteristic of the arctic-alpine zone, and therefore needing protection from drought and full sunlight at sea-level in England. *J. G. B.*

THE POUCE MOUNTAIN, MAURITIUS.

THE Pouce is a lofty mountain with a sort of thumb-shaped summit (hence its name), which rises immediately behind Port Louis; and the two illustrations (figs. 87, 89) accurately represent its appearance from front and rear. The ascent of this mountain from the Port Louis side is a favourite excursion, and the varied flora of the whole mountain range affords ample field for the botanist. The base is wooded, and the well-beaten path steep, but not difficult, affording good halting places, with openings in the trees, through which are obtained most charming views of the rich valley, with its villas, cottages, and gardens; the citadel, town, and port, with the forts William and St. George, which guard its entrance; the lines of shipping, and the wide blue ocean beyond. On the other side of the path is the bold steep pile of dark ferruginous volcanic rock, diversified along its different strata by tufts of grass and stunted shrubs rises, perpendicularly. Amongst these rocks the monkey can occasionally be seen springing from branch to branch, whilst overhead the Tropic-bird, or *pulli-en-guene*, sails along in the clear and cloudless sky. Along this route are constantly to be met small parties of creoles from the Moka district, carrying on their heads vegetable produce for the Port Louis market. The path crosses the mountain at what is called the shoulder, and passes to the cultivated plains on the further side. From hence the way to the summit lies through a thickly-wooded region, and innermaner plants greet the eyes of the enthusiastic collector, and claim examination and comparison. The collecting case is soon full to overflowing.

Orchids generally form the chief object of the collector's search, but so many new and beautiful plants of other species present themselves, that one hardly knows which way to turn, bewildered with botanical enjoyment. Attention is speedily attracted to two kinds of *Draacenas*—*D. mauritiana* and *tessellata*—besides, various elegant Ferns. Here grows that curious plant so like an *Anæthochilus*, viz., the Monkey-apple, *Mithridata Tambriciss*. Leaving the wooded cover, the track now emerges upon the bare steep side of the thumb or summit; when this is gained, a flatish space is attained 2847 feet above the sea, from which the whole island appears spread out like a map beneath the spectator. A grand panorama is here exhibited. By the time one has descended, the coolies are overloaded with specimens. Among the Ferns are to be found lovely specimens of *Asplenium macrophyllum* and *Adiantum pallens*. At the base of the mountain is the *Agrocyum elatum*, whilst the ravine is filled with masses of rock covered with trees, and overgrown with creepers and Ferns. Some of the fronds of *Asplenium Nidus* are at least 6 feet long and 8 inches across, covered with lovely fructification. Here also is the lovely *Lomaria circinata*. The fragrant *Erythrospermum* and the *Amaranthus-like* *Gnaphalium multicaule*, and others, abound in the higher parts of the mountain. The Orchids are simply innumerable. The accompanying sketches were made on the spot—one from a sugar estate in the Moka district, and the other from an avenue of *Casuarina filio*, leading to the old cemetery of Port Louis. *S. P. Oliver, Captain 22^d Brigade Royal Artillery.*

THE TEA PRODUCE OF CHINA.

THE Adulteration Act, which has in many cases weighed so heavily on innocent dealers in this country, is beginning to make itself felt in countries far beyond the limits of its actual operation. The inferior quality and the adulteration of tea has within the last few years become so notorious, that we are glad to learn from the official reports of our Consuls in China that the matter is causing a stir among the tea producers, who find that the demand is falling off; therefore, as their interest is affected, it becomes a question whether it would not be a better policy to produce a purer article, and not to be supplanted in this most important traffic by the Indian produce. The principal cause of the adulteration is, of course, the competition in prices:—

"Teas," we are told by the Consul at Canton, "are hastily and imperfectly prepared to meet the demands of the market; they are loaded with iron filings and refuse matter to give them weight, and mixed with Cactus or

other leaves; and in some, well known to the trade, there is scarcely a tea leaf in the whole composition."

So far as the leaves of the Cactus are concerned, it is the first time we ever heard of their application for such a purpose, and we do not certainly understand how such a succulent leaf or, as we suppose, joints of the stem, could be incorporated with true tea. The writer of the above sentence, however, speaks the truth when he says:—

"It is hopeless to expect a remedy for the evil will be found in China, and to lay the blame upon the Chinese producers and tea-men, the fact being that the Chinese producers and tea-men care no more for the genuine quality of their goods, so that they can sell them, than the English merchant does at home, and the blame, if any, attaches to each side pretty equally; but perhaps the reasonable view to take of the deterioration is, that it is a fault of system rather than individuals, and the correction must be found in the first instance at home. Questions of this kind are open to arguments of a very wide range, and must be so in all cases where people lay the blame on each other; but there is one which admits of no doubt of fact, and

the flavour of the tea in its voyage across the sea. If the tea were sifted, and all the dust extracted—which, however, is never done—the price would be considerably higher, and the dust would have to be sold by itself." The inland duty on the dust amounts to the same as that on whole tea, therefore no inducement is held out to separate the dust carefully from the tea; were the duty lowered the Russian firms in China engaged in making brick tea for exportation would consume a much larger quantity; as it is, not only the dust of the tea itself, but other refuse of the factories, such as the sweepings, &c., are made into a consolidated form.

A great deal of anxiety always exists in getting off as quickly as possible a few cargoes of the new seasons' teas to England, latterly a similar interest has sprung up in dispatching new teas to Australia. Writing on this subject the British Consul at Foo-chow-foo says:—

"It is conjectured that in future steamers of a large class will be put on to carry the teas which the colonies require, and that this change will supersede the small

demand for which during the year showed a considerable falling off, which was attributed to the unfavourable light in which green teas have been held in England of late. The artificial colouring of teas is stated to be carried on only in obedience to the European demand, the uncoloured leaf being absolutely unsaleable; the quality of the tea so coloured is exactly the same, but the appearance in its natural state does not please the merchant's eye. Should a demand for these artificially coloured teas die out, and the natural teas become more in favour, some good will have been done by the Adulteration Act both to the consumer and to the manufacturer. The colours mostly employed for artificial green teas are cobalt or indigo, according to the shade required. The soapstone or China clay which has been detected by analysts is used for giving a gloss or finish to the rolled leaf, while the iron which has been characterised as "iron filings" is said to be derived from the pans in which tea is fried or roasted. These pans are usually made of soft, rough iron, which by the continual trituration of the tea wear smooth.

FIG. 87.—THE POUCE MOUNTAIN, MAURITIUS, FROM NEAR THE OLD CEMETERY, PORT LOUIS.

that is, conviction by a magistrate, the effect of which has already made itself apparent in the Chinese market, and would, if frequently repeated, seriously damage the interests of spurious tea, and give the home consumer something like a pure article for his money."

The depression of the market at Canton in consequence of these proceedings at home has caused a circular to be issued by the tea-men to the producers, notifying that they will not purchase spurious teas in future. The yield of tea in Foo-chow-foo during the season of 1873 was quite satisfactory. Its reception, however, in London was from the first discouraging, owing to a large admixture of dust, which is a prominent feature of the Foo-chow teas, though nothing in the form of adulteration is attributed to them. The crops of 1873 were better made, cleaner and more free from dust than usual, and it is hoped that the manufacturers will maintain the high reputation of these teas by using their best endeavours to prepare them as cleanly as possible. "On the side of the native dealers it is contended, however, that no outside dust is mixed with the tea, and that no tea can be free altogether from dust, and while it is the dust of the tea itself, and not of another quality, it helps to preserve

sailing vessels, or the most part under the German and Danish flags, which now almost monopolise the carrying trade. The tea will be less exposed to damage by seawater in large steamers than is at present the case in sailing vessels of 260 and 300 tons in the heavy China seas.

"Tea for the Australian market has to be repacked into packages or small chests of uniform weight, say in packages of 80 lb. nett (38 to 40 lb., with boxes), which process necessitates additional expense through the cutting down of the tea-chests from the country into packages of the desired size, no matter the quality of the tea. It results from this, that on the whole the tea costs the consumer in Australia from 1d. to 2d. per pound more than the consumer in England. The Australian consumer is beginning to appreciate a better class of tea, and doubtless soon a demand will arise for first-class Congous. Up to the present time it has been supposed that the knowledge of tea in Australia was in a limited degree, and that purchasers for the interior stations in the colony were in the habit of choosing their supplies by appearance only, without regard to flavour, but a gradual change is taking place, and very shortly the fine teas of Foo-chow are likely to find a profitable market in the great markets of the colonies."

In Ningpo the staple trade is in green tea, the

From Tamsay and Kelung we learn also that the export of tea during the past season had considerably decreased, nevertheless the tea shrub is being planted in larger numbers every year; almost everywhere the Chinese are uprooting their other crops, such as sweet Potatoes, and in some places even the indigo plant, to make room for more tea plantations.

From the foregoing notes, which are the condensed opinions of those best able to speak on the subject, namely, the British Consuls at the various Chinese ports, it would seem that opinions are somewhat divided as to the wilful and systematic adulteration of tea, or that such a practice prevails in some districts, and not at all in others. On the other hand, it would seem that a general depression in the tea trade existed during the season of 1873; but that it is thought that the ultimate effect of our legislation would be to produce a more carefully prepared article, so that the general purity of Chinese teas would ultimately be much enhanced. From several of the consular districts good crops were anticipated during the season just closed. *John R. Jackson, Kew.*

THE GARSTON VINEYARD.

We learn from the *Liverpool Daily Courier* that the sale of Mr. Meredith's vineyards at Garston took place by the instructions of the mortgagees, the trustees under Mrs. Meredith's marriage settlement, and the trustee in liquidation, Mr. Bolland. The auctioneer was Mr. Morris, of the firm of Protheroe & Morris, 98, Gracechurch Street, London. A large company assembled to witness the sale, but the number of intending purchasers of such a concern was necessarily limited:—

"In commenting upon the property, Mr. Morris said he estimated it as worth £21,000 for a going concern, but taking the land for breaking up for building purposes, he reckoned the freehold worth £6,500. There was 50,000 feet of glass, which he estimated to be worth £3125. The dwelling-house was worth £1400, the piping £702, and boilers, bricks, and sundry other items £250, making a total of about £12,250. The plants, trees, and in pots, he said, were not included in this, and these would either be sold separately or could be taken at a valuation by the purchaser of the concern. The biddings commenced at £7500 by Mr. Ingfield on behalf of a client, and the competition lay mainly between him and the gentleman who eventually became the purchaser, although a third competitor, whose name did not transpire, made a few bids. The biddings proceeded by £50 a time till £8150 was reached, when £7500 was added, and the bidding proceeded till £8650, when Mr. Ingfield's opponent offered £9000, then £500 again became the rule till £9300, when a jump of £500 was made, and thereafter the biddings relapsed into fifties, until, after much patient and persuasive eloquence, the auctioneer's hammer fell on £10,000 (this being the reserve). The purchaser was Mr. John Cowan, of the Cowan Patents Company (Limited), London. The price realised is for the concern as it stands, and does not include goodwill; and the figure, though inadequately representing the skill and labour of money expended, and the business considered a fair value for an establishment so peculiarly situated. Much sympathy is felt for Mr. Meredith in the circumstances that have led to a change of proprietary, and it is hoped that the new owners will confine the vineyards in their present flourishing state, and maintain as interesting an establishment which has brought so much repute to Liverpool and to English Grape growers."

Foreign Correspondence.

COLLIURE, PYRENEES ORIENTALES.—I should like to bring under the notice of your readers the splendid varieties of *Canna* raised by MM. Huber & Co., of Hyères. Nowhere in Europe is there so rich and varied a collection, a circumstance easily accounted for by the climate, and by the skillful culture bestowed on the plants. Your correspondent, Dr. Henry Bennet, who has so well described for us the Mediterranean gardens, seems to have overlooked the little town of Hyères, which, nevertheless, enjoys an old-established horticultural reputation.

Adorned with numerous Palm trees, Hyères being an Algerian oasis, with this difference—that instead of being surrounded by the deserts and wastes of the Sahara, its surface and the neighbouring hills are clothed with an ever-green mantle of *Cistus*, *Kermes Oaks* (*Quercus coccifera*), *Arbutus*, *Lentiscus*, *Myrtles*, *Alaternus*; in fact, with all the shrubby vegetation of the South. On account of the clearness of the atmosphere and the mildness of the climate, Hyères is certainly the rival of Nice, with more verdure in summer, and greater quiet at all times.

I have known Hyères for many years, and revisited it in 1874, when I found it adorned with many handsome villas, new gardens and plantations, among which the *Eucalypti* made themselves remarkable for their rapid growth. Some trees, not more than fifteen to twenty years old, are already of enormous size.

The stranger arriving at Hyères, even if he knows a little botany, is surprised at the multitude of *Cactuses* of every size and shape, which grow there as freely as in their native clime; and at the gigantic *Agave Salmiana*, by the side of which even *A. americana* is dwarfed. He will be, moreover, specially surprised to see in 43° N. lat. the *Bambusa Thousartii*, a rival of *B. arundinacea*, and more handsome. *Livistona sinensis* flowers and fruits, but does not ripen its seed. Here, too, may be seen *L. australis*, *Sabal umbraculifera* (Hort., Huber), *Diplomethium campestre*, and many other Palms of recent introduction. *Yucca filifera* attains a height of nearly 12 feet, with a conical trunk nearly as thick as a man's body. Some years ago I saw in the garden of MM. Huber a magnificent specimen of *Jacaranda mimosaefolia*, covered with flowers, but which was unfortunately killed by the severe winter of 1874.

Either by local causes or by artificial fertilisation, the *Cannas* of Messrs. Huber & Co. have been wonderfully multiplied, so that the collection consists of many hundreds of varieties, of which I shall content myself with enumerating some of the best and most novel.

Ernest Denary.—A superb plant, 6 to 7 feet high,

with broad erect leaves, of a deep green colour; flowers compact, red bordered with carmine.

Henry Vilmarin.—Large tuft, 4 to 5 feet high, leaves large and stiff, of a deep green, erect; flowers large, of a bright red.

Jean Sisley.—A majestic plant, of 8 to 9 feet high, resembling in its habit and the size of its bright green leaves the beautiful varieties named *Imperator* and *Gigantum*: a shy bloomer, but the flowers are large and of a deep red.

Crozy.—Stems numerous and in a large tuft, 6 feet, leaves of moderate size, lanceolate, bright green; flowers straw-coloured, spotted with carmine.

Christen.—Height 4 to 5 feet, leaves lanceolate, bright green, free flowerer; flowers large, and of a fine orange-purple.

Nardy.—Seedling from C. Bihorelli, stems numerous, in vigorous tufts, 3 to 4 feet; leaves large, deep green, veined with purple; flowers compact, of a bright red.

Souvenir d'Hyères.—Stems tufted, from 3 to 4 feet, leaves lanceolate, erect, clear green; flowers orange-red, bordered with yellow.

Dr. Livingstone.—In 1874, stems 4 to 5 feet, leaves lanceolate, deep green, striped with purple, free flowerer; flowers very large, of an orange-carmine.

Gloire de Provence.—Stems 4 to 5 feet high, leaves green and erect; flowers very large, clear yellow, spotted with carmine.

Gustave Dippa.—Stems 3 to 4 feet high, leaves lanceolate, shining, glaucous green; flowers-spikes short and compact; flowers very large, and of a pure yellow.

Victoria.—Stems 3 to 4 feet high, leaves broad, lanceolate; flower-spikes numerous and compact; flowers very large, saffron-yellow, with a salmon-coloured centre; a superb variety.

Not to make the list too long, I merely mention the names of a few others, which are not inferior to the preceding, though older varieties—*C. compacta*, *Daniel Houbraken*, *Edouard Morren*, *Gloire de Lyon*, *Gabonensis*, *Jacques Plantier*, *Jean Bart*, *Jean Vandael*, *Madame Celler*, *Madame Schmidt*, *Prince Imperial*, and *Tricolor*. *C. Naudin*.

Forestry.

PLANTING having been unusually obstructed by frost, more of it yet requires to be done than is commonly the case at this advanced season of the year, and it is very fortunate for those who, like myself, are behind with the work, that vegetation is also late. The term "planting" comprehends much more than the simple operation of breaking the surface of the soil and inserting the roots of plants. Instead, however, of going into details at this time, I would rather call attention to a few general practical matters which are not unusually overlooked to a less or greater extent.

1. Where deaths have occurred either in forests, large or small plantations, shelter belts, ornamental groups, hedgerows, &c., no time should be lost in making up all such blanks, and these should generally be attended to before extending the area or extent of new ones.

It is a common practice, though by no means universal, to go on, year after year, adding to the acreage of the woodlands without paying due attention to the health and condition of what is already planted by way of making good all failures as they occur, and thereby producing such favourable results as to satisfy and encourage those interested in tree culture. In making choice between the two evils of over-thick and over-thin planting, I would unhesitatingly prefer the former; and if, in making up blanks in plantations, some plants are unavoidably planted too close together, the evil is speedily and inexpensively cured by timely attention to thinning.

2. Too much care and attention cannot be bestowed in strengthening or earthing the plants into the ground, either in the nursery or in the forest, after being lifted. Exposure of the roots for a short time to a strong hard wind will completely destroy the vitality of the plants. Drying winds are found to be much more injurious to the vitality of plants than hard frosts. I once knew of a quantity of Larch plants which had accidentally fallen from a cart about the month of November, and lay exposed to intense frosts and other elements till February, when they were discovered and carried home to the nursery from whence they were taken, and then again proved the vitality of experiment, when in due time it was found that not one of them had died, notwithstanding having lain quite exposed nearly four months on the open moor.

3. As much of the future success of plants depends upon the treatment they receive between the time of lifting and that of transplanting, I would strongly recommend attention to the following points—*1st*. Avoid packing or confining (especially evergreens) in any way so as to produce heating. *2nd*. Scotch Pine is perhaps the most liable to suffer in this way, while hard-woods, unless lifted early in autumn, seldom suffer much. In singling-in plants, whether Conifers or hard-woods, they should never be put into rich loam or cold soils of any kind if they are to remain for any considerable time. I have had more failures from

planting Birch and Oak that had been earthed into rich black loam, and had stood about three months, than from all other causes. Of the same sample of Beech, from 20 to 30 inches high, treated every way alike, such a respect of the soil that was singled-in fully one-half of those in the black loam died after being planted into hedges, &c., while those that stood in light sandy loam, with very few exceptions, grew and succeeded well. If the soil is light and open, it matters little at what depth the plants are singled-in if only the leaves are all above-ground, and they are removed before the move of the sap; but in permanent planting too much attention cannot well be paid to keeping the plants well up on the surface. That particular part of the plant where the stem and roots unite, termed the neck, is evidently a very sensitive and vital part, and should never be far excluded from the air and light. Plants, whether small or large, but especially the latter, should never be planted so deep that the swell of the roots is below the natural surface of the ground. In planting where hares and rabbits abound, either extra large or extra small plants should be used; by large I mean plants not less than 3 feet high, and by small plants not over 6 inches. The leading shoot and upper branches being above their reach (except in snowstorms) usually escape with impunity, or comparatively little injury. This class of plants, however, being too expensive, cannot be recommended except for small groups and ornamental purposes. It is, therefore, only small plants that can be recommended for such purpose. My own system is to plant all rabbit-infested ground with Larch or Scotch Fir (according as soil and situation are adapted), two years old from the seed, or what are now pretty generally known amongst planters as bedded plants, which are one-year-old plants lifted out of the bed and thickly laid in lines for one year, with the result of producing more roots in proportion to the top-growth of the plants than they would otherwise have had if allowed to grow on without transplanting. In planting I studiously avoid barring the ground, by paring off the turf or even cutting the rank herbage. The instructions to each spadesman simply are, hide the plants and plant close, say 3 feet apart or even less in some places. In tufts of heath or grass hide them as well as possible, and though many plants thus perish, and others struggle for existence amongst the choking herbage, yet by the use of small plants, thick planting, and careful concealing the plants amongst the herbage, many plantations can be reared at comparatively small expense, that under any other known practice would either fail or cost an unwarrantable sum of money. *C. Y. Michie, Cullen House, Cullen, March 29.*

Florists' Flowers.

THE FANCY, or, as it has been termed, the MOTTLED POLYANTHUS, because of the fantastic markings found in many of the flowers, is rapidly becoming a popular favourite because of its great decorative value, despite the protests of those who look upon the old-fashioned gold-laced Polyanthus as the only one deserving of culture, and regard other types as usurpers of its rightful domain.

It is difficult to state how this race of Polyanthuses first originated; and probably no single individual can claim the exclusive right of having originated them. They may be said to be a product of the necessities of the times, and when such a fine one compels a new departure, or originates and then develops in solid form new ideals, protests are futile in whatever department of life or branch of science such activities are brought into play. The growing taste for spring flowers led to the forms of the Polyanthus being looked after, and their improvement followed as a natural result. What Major Trevor Clarke did in the way of crossing the common Primrose into excellent results in excellent results, and of a continental form and improved these, and a concurrent action produced pleasing results. Some of these results have come before the Floral Committee of the Royal Horticultural Society, and gained the highest award it is in the power of that body to bestow on seedling flowers.

One result of improving the gold-laced Polyanthus by the florists' nurserymen, or so-called, was the certain deterioration of the race by breeding in-and-as it is termed, in order to get the desired quality in the flowers. This led to many giving up their culture on the ground of want of constitution in the breed. On the other hand the fancy Polyanthus has a remarkable vigour of habit, the growth being very robust, the flower-stem stout and erect, the trusses large and bold, the colours bright and striking, and most effective. They are characterized by great hardihood, and stand exposure to the severest wintry weather without injury, thus rendering them well adapted for planting out in beds for winter and spring decoration. One most acceptable characteristic is that of flowering very early—in mild weather very soon after Christmas, from the growth of the previous

autumn, and again most profusely in early spring from the young growths. By offering prizes for these Polyanthuses when grown in pots, the Royal Horticultural Society is doing something to encourage their cultivation for exhibition purposes; and there is reason to believe that, if the classes for hardy Primroses are continued, several cultivators will be ready to compete for the prizes offered by the Society.

For the information of those desiring to learn something of the fancy Polyanthuses in cultivation, I may state that the following have been distributed:—The *Bride*, pure white, with deep orange centre; very fine orange rays, fine pip, and bold truss. *Viceroy*, sulphur, with deep orange centre, very large round pip, and a splendid truss; remarkably free. *Warrior*, rich shaded magenta, yellow centre, rayed with deep orange, fine bold pip and truss; showy and striking. Contemporary raisers have announced other varieties, but those named have occasionally come before the meetings of the Royal Horticultural Society, and from an inspection of the same their characters can be attested to.

Beautiful as these showy flowers are when grown in beds or borders in the open air, their decorative value appears to be much enhanced from the fact that they are admirably adapted for culture in pots, and in this respect they are well fitted for the attention of those who are compelled to cultivate hardy plants during the winter and spring owing to lack of accommodation for tender plants. I grow some in this way every year, and they are beautiful objects, just now, mingled with spring-flowering bulbs, *Spirea japonica*, &c., and they serve to supply hues not found among the bulbs.

As soon as the plants have done flowering in pots, they are planted out in the open ground in some fine rich soil, without disturbing the balls in the slightest degree, and here the plants ripen any seed it is wished to get from them, and they also mature their growth. Early in October the plants are lifted and divided; the strongest crowns, which should be well rooted, are placed in 48-pots, or, if extra strong, in 32-pots, using a good soil made up of loam, decomposed manure, and leaf-mould, with some sand to keep it a little open. There should be a layer of drainage, and over this a piece of decayed turf; the roots should be nicely spread out, and the soil pressed firmly about them. The soil should come just above the collar of the plant, and for this reason—that the Polyanthus in the lowest level, which should be at the base of the plant, in order that they may fully root into it. It was for this reason that the old Polyanthus growers used to top-dress these plants in February, and the plan was to take out an inch or so of the surface soil, and replace it with a compost, of which thoroughly decomposed cow-dung formed an important part.

When potted, they can be placed in a cold frame on a bottom of cinders-ashes, and have air given them on all suitable occasions; or, failing a cold frame, the pots can be plunged in an ash-bed a foot or so in depth, well-drained at the bottom with brick rubbish, under a sheltered wall. In severe frosty weather a little light litter can be thrown over the plants, and in times of heavy rain some boards might be so arranged as to throw it off the plants. By the beginning of March the plants begin to throw up their flowering stems, and they soon become charming decorative objects, and a cold greenhouse, or any suitable place in which they can develop their flowers without harm from ungenial elements. R. D.

Notices of Books.

Introduction to Experimental Physics, By A. F. Weinhald. Translated by B. Loewy Longmans.

This is a thick and bulky volume, but one which will be valued by a number of physics as well as by students. Physics, or what used to be called natural philosophy, imperatively demands to be taught practically, by means of experiment and demonstration. So far as possible the student should carry out for himself, and by himself, all the experiments requisite to give him a clear idea of the subject. Without this he will be quite unable to make any practical use of what little knowledge he may pick up.

Professor Weinhald's work, of which we have here an excellent translation, is exceedingly well-adapted for a text-book for use in the laboratory. The directions are clear, precise, and minute. No one who has had practical experience of the apparent trifles which

make an experiment successful or not, will question the importance of attention to minute particulars. We must content ourselves with recommending this volume, the subject-matter of which is good, while the illustrations are numerous, and the typography all that could be desired. One remark we may make in view of a second edition, and that is as to the desirability of giving the ordinary measurements as well as those of the decimal system. Although we are firmly convinced of the immense advantage of a uniform system of weights and measures such as is afforded by the decimal system, yet we do not think the abrupt introduction of it is likely to tend to their more speedy adoption, nor, indeed, in the present transition state, is it fair to students to use either system alone. For a similar reason we should counsel the editor to append a full series of conversion tables to any fresh edition which may appear.

Die Rationale Spargelzucht. Von Franz Göschke. Berlin: Schotte & Voigt. (Asparagus Culture.) 8vo. Pp. 93. Williams & Norgate.

This is a little work treating on the cultivation of Asparagus according to the L'Herault system. Written, as it is, in German, it is not likely to have many readers in this country. It is a complete treatise on the cultivation and management of Asparagus, and is preceded by a short botanical history of the species.

Apiary.

YATES' ROUND-TOPPED HIVES.—Mr. Yates, seedsman, of Manchester, has acquired celebrity for his hives, and many Lancashire bee-keepers, especially those who follow Pettigrew's theory, are almost compelled to purchase their skeps (hives) from Messrs. Yates, because no dealer in apianian requisites can furnish straw skeps of the size required.

FIG. 88.—YATES' ROUND-TOPPED HIVE.

The illustration (fig. 88) will give our readers a tolerable idea of the shape of the hive; but to look at a hive 20 inches in diameter, and 14 inches high, both inside measure, is enough to astonish an old-fashioned apianian.* It certainly is an enormous hive, and, best of all, when it comes to be taken off the stand in autumn it means something for in average seasons we may expect to glean 80 lb. of honey from each stock. Then to watch the entrance of one of these monster hives, with a large colony tenanted it, on a warm, sunny day, the flight of the busy inmates going to and fro is not unlike the steam from a kettle spout, and is a sight seldom witnessed except in these hives.

We, however, draw our readers' attention to Yates' hives, not only for their size, but their workmanship. We believe they are manufactured in Scotland. This does not signify; yet we honestly confess we never saw any straw hives so strongly made as these. To show their strength and durability, we have had one in operation now for four years, and it seems as if it would last four more; but if a common skep lasts two seasons, it is thought to have done its duty.

Another feature about these hives is the improvement in the movable wooden top worked in the straw; the plug we have found very convenient both for supering and feeding. Hives of Pettigrew's pattern are also sold by Mr. Yates. These differ in having a flat top with straw plug in the centre. We do not recommend the flat-topped hive, for the simple reason that when ordinary sized swarms are introduced they commence the formation of the combs at the side, or rather in the corners; thus the combs are all irregular and unevenly built, which hinders both the breeding and honey-storing; in other respects they are excellent skeps, but in Yates' or the round-topped hives, the bees are compelled to build exactly in the centre.

Mr. Yates would confer a benefit on his rustic bee-keeping friends if he would introduce the common sized, or cottage skeps, as strongly made and bound

* This may seem impossible to some of our readers, but last year I took 70 lb. from one of these monster hives in my own garden, and Mr. Reid of Carlisle, took one up containing 200½ lb.; however, the latter is, in Old England, unfortunately, an exception; but from 60 lb. to 70 lb. may with ease be gathered by a strong stock, with a vigorous and healthy queen at their head. A.

with cane like the "monster hives" he now sends out. Cottage skeps bound with Briar or Blackberry stems are far from being as economical as the cane-bound skeps. A.

Natural History.

SLUGS.—Most people are only too well acquainted with slugs, but it is not quite so generally known where to look for their eggs, so as to destroy the coming pests in embryo, and a little attention directed to this point just now might save a deal of future trouble and loss. For those unacquainted with the appearance of the eggs it may be as well to mention that they exactly resemble small, slightly opaque round white glass beads, about the sixteenth of an inch in diameter. The most sure lurking ground in which to find what may be described as the nests, is in an old neglected Cabbage-bed, where the leaves have been allowed to remain lying on the ground, so as to form at once an attraction and a shelter from weather to the old slugs. Here there would probably be found a number of cavities, looking, at first glance, merely like holes in the ground, about the width of one or two fingers. On a closer examination these will be found to be little pits about 2 inches or more in depth, with edges overhanging at the top, and inside them (sheltered by earth and slime so as to look more than ordinarily disgusting) will probably be from two to five full-grown slugs. By carefully inserting the fingers, so as to remove the earth at the bottom of the hole, the deposit of eggs may be brought to light, usually well covered over with a slight deposit of soil and varying in number from six or ten upwards, according to circumstances.

The nests—eggs, slugs, and all—might be easily removed with a small trowel, and the whole collection should be completely destroyed. The slug egg is, in some cases, gifted with almost incredible vital powers, and no means short of burning or crushing can be regarded as sure destruction to those of which the eggs of one species can, as mentioned in Jeffrey's *Conchology*, vol. I, p. 135, stand being eight times dried in a furnace and yet retain their vitality and develop the young.

Another favourite hiding place for deposit of eggs is at the bottom of Box borders, which, however ornamental in kitchen gardens, are apt to detract very much from the usefulness of the ground, by the network of shelter they afford throughout the whole year and over the entire area of the garden, to slugs and other garden pests. There is a popular idea that slugs cease to be destructive during the winter, which is, unfortunately, very far from being correct. During the severe cold of last Christmas the slugs in a piece of rich garden ground which had been greatly neglected, discontinued their ravages at the very height of the frost and snow, but were out again in legions as briskly as ever, directly it abated, and the only plan which appeared really serviceable in diminishing their numbers was, to lay traps of five or six good sized Cabbage leaves one on the other. Here they fed at their pleasure, and then, partially burying themselves for shelter under the earth beneath, might be hand-picked and thoroughly got rid of.

In this case, which was the very worst instance of slug possession of ground that I ever met with, all the usual ways of meeting the evil seemed worse than useless. It appeared as if the renewed processes of culture of the garden, by destroying the neglected plants on which they fed, simply threw them quite unprepared for their sustenance on the new crops put in, and everything was swept before them. Lettuce, Spinach, and successive hundreds of Cabbage vanished rapidly and thoroughly, soon only acting as a prelude to a few days of most accurate sprinklings of lime clogging the leaves and the ground, and even (when laked) affording an extra shelter for the slugs, whilst the leaves, not being to their taste, they met the difficulty by gnawing the plant to death round the stem.

In such a state of things nothing but personal supervision by the owner or the head gardener can meet the evil; and here the Cabbage-leaf traps, with an eye to their daily clearance, brought down the quantities of slugs within common bounds from numbers which on the worst occasion would have covered about half one of the leaves they were on, if laid side by side.

In common cases soon answers excellently if laid round the plants to be protected, and where circumstances allow of its being placed so plant by plant its effect will well repay the trouble of laying it rather than broad-casting, where, unless carefully thrown, the leaves of the plant catch much of the falling powder, and thus leave unguarded the very part round the stem which requires the most protection.

Where gas-lime is easily procurable lines of it round specially attacked spots are said to be of much service, and possibly, where it would not cause damage to vegetation or otherwise, a watering with very dilute sulphuric acid might be of use, but those who are acquainted with any thoroughly well-working application would do their horticultural fellow-labourers a kindness in making it generally known. O.

HORTICULTURAL EXHIBITIONS, 1875.

APRIL.

- 21.—Royal Horticultural Society, South Kensington. Meeting of Fruit, Floral, and Scientific Committees.
 22.—Royal Horticultural Society of Ireland. Spring Exhibition. Sec., A. Balfour, Wickham Row, Dublin.
 27.—Manchester Botanical and Horticultural Society. Exhibition of Auriculas, &c., in the Town Hall. Manager, Bruce Findlay.
 28.—Royal Botanic Society, Regent's Park. Spring Show. Sec., W. Sowerby.

MAY.

- 1 to 10, inclusive.—Royal Botanic Society, Regent's Park. Mr. William Paul's Special Show of Roses, Pelargoniums, &c.
 1 to 24.—Royal Botanic Society, Regent's Park. Special Exhibition of Clematis, by Mr. G. Jackson.
 7 and 8.—Exhibition of Plants and Flowers in the Kibble Conservatory and Royal Botanic Garden, Glasgow. Manager, Robert Bullen.
 12.—Royal Horticultural Society, South Kensington. Meeting of Fruit, Floral, and Scientific Committees. Pot Rose Show.
 14 to 21.—Manchester Botanical and Horticultural Society's Annual National Exhibition, at the Garden, Old Trafford. Manager, Bruce Findlay.
 17 and 18.—Halifax Floral and Horticultural Society's Annual Exhibition. Sec., Leonard Kershaw, 50, Oldstone Road, West Hill Park.
 20.—Royal Horticultural Society of Ireland. Early Summer Exhibition. Sec., W. Sowerby, 10, Wickham Row, Dublin.
 22.—Crystal Palace Great Flower Show. Sec., F. W. Wilson.
 23.—Royal Botanic Society, Regent's Park. Summer Exhibition. Sec., W. Sowerby.
 26.—Royal Horticultural Society, South Kensington. Meeting of Fruit, Floral, and Scientific Committees.
 31.—Coventry and Warwickshire Floral and Horticultural Society's First Show of the Season. Sec., Thomas Wigston, 3, Portland Terrace, Lower Ford St., Coventry.

THE

Gardeners' Chronicle.

SATURDAY, APRIL 3, 1875.

APPOINTMENTS FOR THE ENSUING WEEK.

SUNDAY,	April 4	Royal Horticultural Society of Antwerp's Meeting of the Entomological Society, at 2 P.M.
MONDAY,	April 5	Sale of Orchids, <i>Lilium auratum</i> , and <i>Gladioli</i> , at Stevens' Rooms. Sale of Hollyhocks, Dahlias, Vines, Roses, &c., at the North Star Nurseries, Sloane's by Buckland & Sons. Sale of Poultry and Pigeons, at Stevens' Rooms.
TUESDAY,	April 6	Royal Horticultural Society's Meeting of Fruit and Floral Committees, at 11 A.M.; Scientific Committee, at 2 P.M.; General Meeting, at 3 P.M.
WEDNESDAY,	April 7	Sale of Caneless Palms, Roses, Fruit Trees, Shrubs, &c., at Stevens' Rooms. Sale of East Indian Orchids, at Stevens' Rooms.
THURSDAY,	April 8	Sale of Stove and Greenhouse Plants, the property of Mr. Wheeler, of Stamford Hill, at Stevens' Rooms.
FRIDAY,	April 9	

OUR Brussels friends take us to task for awarding the priority to Amsterdam as the *locale* for the next INTERNATIONAL HORTICULTURAL EXHIBITION. The Royal Flora Society of Brussels, we learn, claims the priority at once by right of birth and by priority of notification. We were of course aware that to Brussels belongs the honour of inaugurating that brilliant series of international gatherings which have done so much for the material interests of horticulture, and which have afforded opportunities for so many pleasant gatherings of botanists and horticulturists. To the splendid hospitality and cordial reception afforded to our horticulturists by the Belgians in 1864, and the Dutch in 1865, was due our own International of 1866. It was widely felt that we ought to reciprocate such good feeling, and we did our best to show we were not unmindful. Paris, St. Petersburg, Vienna, Florence, followed in turn, and now the cycle comes round again, and the only question arises, is Brussels, or Amsterdam to have the precedence? An amicable dispute is going on between the two capitals, which will, we trust, be speedily adjusted.

We are told that we were mistaken in attributing to the Dutch capital the first overtures for holding the International of 1876, and that as long since as May, 1872, the Belgians had taken preliminary steps—of which, however, no notice reached us. Certainly, last year at Florence we heard nothing official as to the intentions of the Bruxelles, but only of the proposals emanating from Amsterdam, and hence our statement. It appears, however, that Brussels really was the first in the field, and that there

are special reasons why the gay little capital of Belgium should be selected for next year. The most important of these is the fact that a special building of temporary construction, destined primarily for an exhibition of fine arts, will be at the disposal of the horticulturists next year, and that the Government, which is a kind of *Deus ex machina* in these affairs abroad, though not so in this country, will lend this building for the purpose, the said building to be demolished immediately after. The Amsterdam people have a splendid public building, somewhat like our Crystal Palace, always at their disposal. Moreover, next year the Flora Society of Brussels will celebrate its centenary, and it is naturally anxious to do so with *clat*. Brussels now says to Amsterdam, Wait till 1877; let us have 1876. Brussels informs us of these facts officially. From Amsterdam we learn privately that it is not unlikely the Hollanders will waive their claim, and postpone their exhibition and congress for a year.

To us Britishers it is of no particular consequence whether Brussels or Amsterdam should have the precedence. We hope they will adjust this matter for themselves. All that we know is, that we have the liveliest sense of the kindness and the hospitality shown to foreign horticulturists by both capitals. We should be thankful to accept the hospitality of either, "we're 'tother dear charmer away," and we shall be sorry if the success of both be imperilled by any attempt to hold an exhibition of such magnitude and importance in both capitals about the same time.

Should it be determined, as we hope it will, that the Congress shall meet in the one city in 1876 and in the other in 1877, our own exhibition—if we have one—must be postponed till 1878; a circumstance, in the present state of things here, not altogether to be lamented.

THE evils attending the DEEP PLANTING OF TREES, with the exception of those having the power to emit roots freely from their trunks, have so often been pointed out, that they must be familiar to most planters. "We recently saw a striking illustration of a case in point, or what amounted to the same thing, for the ground had been raised from 3 to 4 feet above the level of the water table. The roots, though severely crippled, Elms bordering the Thames opposite Kew Palace must have been familiar to thousands. The fall of one or two last autumn, and the dangerous appearance of several others, attracted the attention of the authorities, and their doom was sealed. Now they are already lying low. But the fact of an apparently healthy tree having broken off from the roots at its base puzzled us rather, especially as the roots were sound, or nearly so; and we have since examined several of the trees. In order to fell them from the base of the trunk, the workmen had to excavate from 2 to 4 feet of ballast, which must have been thrown in many years after the trees were planted. From the decayed appearance of the boles where the roots were given off and above, we believe that it has been going on slowly ever since the ground was raised; and if the soil had been of less open character, the decay would probably have been more rapid.

DR. GOEPPERT, the talented director of the Breslau Botanic Gardens, recently celebrated the fiftieth year of holding his degree, and congratulations and honours poured in upon him from all quarters. Festival memoirs (*Festschriften*) and addresses were numerous, and the Emperor of GERMANY honoured him with the Order of the Crown of the second class, the star bearing the number fifty. The city of Breslau made him a free citizen. But the best thing was done by a committee of scientific colleagues, who instituted a fund to create a foundation to be termed the GOEPPERT Foundation, with the gratifying result of obtaining 10,000 marks (£500). The interest of this sum is to be applied to the assistance of meritorious students of the natural sciences at the University of Breslau. This foundation is dedicated to Dr. GOEPPERT as a tribute of the highest esteem and an acknowledgment of his services to science and to his University. Truly these things are managed differently on the Continent; and we wish Dr. GOEPPERT may live many years to enjoy his honours.

THE freedom with which AUCUBAS set their fruits without any attention beyond planting a few plants in a nursery quarter of these highly ornamental shrubs, and the rapid growth of seedling plants,

promise well for a race of valuable varieties, such as scarcely any other class of evergreens are likely to afford. Several nurseries are raising large numbers of seedlings, which exhibit a surprising variety in the size, shape, and colouring of the foliage. We lately saw a fine bed of large examples of the common spotted variety in full fruit, the result, we were assured, of unassisted Nature. Adjoining this bed were two or three rows of seedling plants of great variety, including several males. Thus left to themselves, the females were impregnated, and here as fine a crop of berries as one could wish to see; and it was not only the females close by that had been fertilised—at a distance of 50 yards or more there were several large specimens in a mixed border that had also set fruit, though, it is true, less abundantly. We have heard complaints that birds frequently strip the bushes of their attractive fruit, but the nursery in which we saw the lot in question is situated in a district where birds are exceedingly numerous, yet they had not touched the berries a fortnight ago, and this winter has certainly been a severe one. The proprietor of this nursery informed us that he was agreeably surprised at his fine crop of berries, not having expected any, the late frosts last spring having caused the males to hang the berries as if all the vitality in the flowers had been destroyed.

WE learn from the *Gartenflora* that the Prussian Government has under consideration plans for the erection of a BUILDING IN THE BOTANIC GARDEN at Schöneberg, near Berlin, to house the NATIONAL HERBARIUM. Formerly it was deposited in a special building near the Botanic Garden, but it was subsequently removed to the University buildings in Berlin, and the garden authorities have in consequence experienced the greatest difficulty in determining and maintaining the correct nomenclature of the living plants. The herbarium has suffered, too, through being in a dark, unsuitable building, and through the duties of the officers being divided between the herbarium and botanic garden. Naturally little progress in the arrangement of the collection could be made under these circumstances; which makes as the more glad that the once threatened removal of Kew Herbarium is not to be carried into effect.

A NOVELTY IN PELARGONIUMS is announced in the French and German gardening journals. It is believed to be an accidental cross between *P. heterophyllum* and *P. zonale*, and, what is more, it freely bears seed. Mr. JEAN SISLEY describes it as near *P. heterophyllum* in its prostrate habit of growth, with leaves more like those of *P. zonale*. The flowers are of a dazzling red, and there are from fifteen to twenty in each truss. It was found in a garden at Nice, in a bed planted with several varieties of the zonal section, and a lilac-white variety of *P. heterophyllum*. Mr. SISLEY considers a great advantage, namely, that it is fertile on account of its fertility—a quality not possessed, he says by *Willisii*, *Willisii rosea*, *Emperor*, and *Dolly Varden*. He thinks it may probably give birth to a distinct new strain, in the hands of a clever hybridiser. It will be sent out this spring by Messrs. HUBER, of Nice.

IN the last number of the *Gardeners' Chronicle*, in an article by Mr. W. G. SMITH, there is a notice regretting the repetition of Mr. SALTER'S assertion "that he had lived almost entirely on different species of Boleti, without using much discrimination." As this assertion was made in a personal communication to myself, I feel bound to state as much, and from Mr. SALTER'S intimate knowledge of natural history, from a long apprenticeship and association with the late Mr. JAMES SOWERBY, I had not the slightest reason to doubt the correctness of his assertion, especially as an excellent naturalist informed me that he had eaten Boletus luridus with impunity, and even sent me specimens. It is true that late in life there were unfortunate symptoms of insanity in Mr. SALTER, which led ultimately to his death, but though there might even then have been such a tendency, it was, as far as my conversations with him went, on the subject of religion, and not of natural history. Indeed, about the time of his making the statement to me, I had the pleasure of hearing him at a meeting of the Geological Society, when nothing could be more luminous than his remarks. It is not aware that Mr. SALTER ever regretted that his words had gained publicity. He certainly never made such a statement to me. As the sheets of Mr. COOKE'S book passed through my hands, I am in some measure answerable for there are typographical errors, but every one knows how difficult it is to avoid them altogether, especially as it frequently happens that the process of correction at the press sometimes makes confusion worse confounded. *M. J. B.*

WE observe that Mr. R. A. PRYOR, of Hatfield—who is not to be confounded with Dr. ALEXANDER PRYOR, as has been the case with a host of other contemporaries—has in preparation a new edition of WEBB and COLEMAN'S *Flora Hertfordensis*, the

special features of which will be the incorporation of the various supplements, the more careful enumeration and investigation of segregates, and the omission of the irrelevant poetical and other matter which gave a somewhat *distant* tone and appearance to what was in other respects an excellent book. Mr. PRYOR has issued a pamphlet containing remarks and inquiries connected with the work, of which he will be glad to forward a copy to any one interested in the subject.

— The *Daily Telegraph*, as will be seen from the following characteristic extract, has been "gushing" about CASHMERE, and some of its statements are open to objection. We are told that "Cashmere is, indeed, the happiest spot in the world for the votaries of the goddess Flora. Nowhere are there more wonderful natural parterres or such novelties of botanical beauty, such luxuries of fragrance and grace. It is the chosen home of Roses, and some of the finest 'attar' in the world is manufactured from the delicious red and white blossoms which cover the thickets in summer. At another season the soil is draped, as it

tion in Burmah. This plant—the *Chavannesia esculenta*—is said to be very common in the Burmese forests, twining round the trees and sometimes forming a stem of from 9 to 11 inches in circumference. It is also cultivated by the natives for the sake of its fruit, which is of a pleasant acid taste, and is sold in the Rangoon markets. The rubber coagulates readily on exposure to the air, forming a solid and very elastic substance. The cultivation and conservation of this plant by the Forest Department for the purpose of yielding rubber has been advocated in a pamphlet on the subject recently published in Rangoon. It may be propagated, it is said, either from seeds or cuttings; the former, however, is recommended, "as natural reproduction is abundant wherever the creeper grows, and the results are certain if the plant lives; but not so with cuttings, which do not in every instance equal the parent tree—a phenomenon in vegetable physiology yet to be accounted for. Regarding the mode of planting, it is best for the present to follow the natural habit of the plant, which is to entwine itself round its more stalwart companions of

any large scale the system of tapping and collecting will no doubt be improved upon.

— We learn that the VILLA GARDENER is henceforth to be edited by Mr. D. T. FISH, already a frequent contributor to that and other journals.

— At p. 399 we noticed a German's complaint respecting the indifference of his countrymen to GERMAN RAISED DAHLIAS, and his estimate of their merits. He should be satisfied at any rate with the number of new varieties offered by German raisers this year. The total number sent out this year for the first time, according to the *Hamburger Gartenzeitung*, is 530! Of this number one grower, STECKMANN, furnishes no fewer than 405! If national vanity is to be satisfied with numbers, these should suffice, especially if the high standard of merit claimed for them is sustained.

— On the estate of the Duke of WELLINGTON at Strathfieldsaye, and immediately adjoining a small

FIG. 89.—MOKA DISTRICT, MAURITIUS: A SUGAR PLANTATION AT THE BASE OF THE POUCE MOUNTAIN.

seems, with cloth of gold, by reason of the wide fields of Crocuses, which are cultivated to produce the yellow dye erroneously called Cashmere saffron, which is known and sold in every market of Western Asia." The hue of saffron itself doubtless led the writer of this paragraph to state that the blossoms of the plant producing it were also yellow, but his notion of the extent of its cultivation does not correspond with that of the authors of *Pharmacographia*, who only say that "a very little is cultivated in Kashmir, under heavy imposts of the Maharajah." By the way, in the latter work the use of saffron in colouring cakes is specially noted as prevailing in Cornwall; we may add that it is very common also in Northamptonshire, especially in Northampton itself.

— Some more attention than has hitherto been given seems now to be directed by travellers and others to fresh sources of CAOUTCHOUC. With regard to East Indian plants, no doubt some impulse has been given to forest officers by the circulation of Mr. JAMES COLLINS' excellent report. A creeping plant belonging to the Apocynaceæ, not altogether unknown as a rubber plant, has recently occupied some atten-

tion, reaching from one to another in the most fantastic forms and shapes, until its trunk has gained sufficient strength to make it independent of its original support, which may long since have fallen a victim to its suffocating embrace." Such are the words of the writer of the pamphlet referred to, and he further proposes that seedlings should be planted at the base of every tree unsuited for every other purpose. Before leaving the subject, in the hope of soon hearing something more of the plant as a source of commercial rubber, it may be well to point out the manner proposed to be adopted for tapping these creepers. Three gashes in the shape of an arrow-head are made into the wood on three sides of the stem, each about 3 feet apart, not immediately over each other but alternately so as to form a spiral. At the point of the arrow, which is of course directed downwards, a kind of funnel formed of a leaflet of the *Butea frondosa* is fixed or rather temporarily attached by the aid of the glutinous milk of the *Chavannesia*. The *Butea* leaflet is selected on account of its size and non-liability to crack. Into these cups or funnels the milky juice flows and is afterwards amalgamated. If the rubber comes to be collected on

farmhouse, inhabited by Mr. DAVIDSON, the bailiff of the Hillfield property, there recently stood three large lofty Elm trees. These had of late shown symptoms of decay, and the huge limbs that occasionally fell rendered their vicinity dangerous, a portion of the house now and then getting damaged. After considerable delay, leave was at length given to have the trees cut down, and as the largest, which stood within 20 feet of the farmhouse, had a base of about 6 feet in diameter, instructions were given that a woodman should first open the tree round with an axe to the depth of several inches. This was done, when without warning the huge tree toppled over and fell, fortunately in a direction the reverse of the house, for had it fallen upon that it would have crushed it into ruins. Upon examination it was found that, with the exception of some 4 or 5 inches of the outer wood, all the rest was perfectly rotten, and much of it bore a close resemblance to furnace clinkers. The other two trees were also decayed, but in a lesser degree. Looking over the rings of growth, as shown when cut through by the saw, it was evident that the most robust growth was made when the tree was about fifty years of age. It is not improbable that if an

examination were made into the boles of large trees by means of an auger, similar evidences of decay would be found, and by at once felling such timber some possible disaster might be prevented.

— The CANTERBURY FLOWER SHOW is fixed for Thursday, May 12, and the management have been again successful in obtaining the permission of W. HOWARD, Esq., to hold it in his pretty grounds at Westgate.

— We understand that the plans for the laying out and planting of the NEW PUBLIC PARK at BARNSELY, submitted by Messrs. W. BARRON & SON, of Elvaston Nurseries, Borrowash, near Derby, and 16, Market Street, Nottingham, have been accepted. The park is the gift of Miss MCCREERY, of Richmond, Surrey.

— We are glad to learn that the NEW HORTICULTURAL CLUB has secured a club-house in a most suitable locality—viz., Adelphi Terrace. The site is excellent, being within three minutes' walk of Charing Cross, close to the Strand and Covent Garden, but removed from its noise and overlooking the Embankment garden, the river, &c. The Club offers its subscribers the conveniences of a West End Club at very moderate rates, there being handsome reading, dining, and drawing-rooms, as well as billiard-rooms and smoking-rooms; bedrooms for the accommodation of country members are also provided. The subscription at present is two guineas per annum, with an entrance fee of two guineas, but the terms will probably shortly be raised. The desirability of such a meeting-place for those addicted to horticultural pursuits has been so long felt, that we have no doubt, under proper management, that this Club will answer the expectations of its promoters. As so much turns on management, it may be well to mention that the caterer is proprietor of several hotels, and is manager of another similar Club. Members incur no responsibility beyond their entrance-fee and annual contribution, and from what we are assured in regard to the proposed arrangements we can confidently recommend the Club to the favourable notice of horticulturists in general. The secretary is the Rev. H. H. DOMBRAIN, Westwell, Ashford, Kent.

— We are requested to state that we were in error in stating in our last report of the Fruit Committee that certain Cucumbers were exhibited by Messrs. MONRO and WILKINSON. That firm has been dissolved, and Mr. JOHN MONRO was the exhibitor.

— *A propos* of the COLORADO POTATO BEETLE, an Englishman in America, writing from Pueblo, Colorado, U.S., March 12, says:—

"I have grown Potatoes in various parts of the Union, and have been bothered with the beetle since 1871. It is not necessary that the beetle should have pieces of haulm to support him whilst crossing the Atlantic; he can eat the tubers, though he prefers the haulm. In winter, when opening my Potato pits, I have seen the vermin eating greedily and moving briskly; several Potatoes were either wholly or partially destroyed, and I am sure it was beetle-work. I notice by the Parliamentary reports that the authorities are for taking time and seeing what other people in Europe are going to do about the beetle, but I wish to remark (and my language is plain) that if the English authorities don't wake up pretty mighty sudden and stop importation, they will soon have beetles pretty bad."

— The beautiful Forget-me-not-like OMPHALODES VERNA, termed by some the Creeping Forget-me-not, because of its peculiar habit of growth, is now very effective in cool, shaded spots, suitable to its well-being. Nowhere else perhaps is the *Omphalodes* more at home than on the warm, genial slopes in the almost uninvigil wild garden at Belvoir Castle. There Mr. INGRAM uses it with great judgment and remarkable taste, and it can be seen in large patches where it is overgrown and shaded during summer by deciduous shrubs, &c. It does well in a shallow soil in which decayed vegetable matter forms a good part, and it is by far the most useful and useful a spring plant to be stuck in the ground anywhere, as if anything like a tender care would be wasted on it. At Belvoir it has spread into large patches by reason of its creeping rhizomes spreading themselves underground, and pushing their way to remarkable lengths. If it lacks the rich profusion of flowers found on the highly fertile soil, its individual blossoms are of great beauty. The colour of the flowers is of a rich pale blue, and a raceme of blossoms greatly assists to make up a charming button-hole.

— In one of the plant-houses at the Chiswick garden of the Royal Horticultural Society *HEBELIUM TANTINIUM* and *HEBELIUM* are very attractive objects with their massive corombs of soft, pale mauve composite flowers. It is one of those plants that Mr. B. S. WILLIAMS considers should be in the choicest collections, because it flowers so freely during the

winter. The plant is of robust growth; the large leaves are ovate in shape, and contrast well with the masses of flower. It is a subject so easily managed that the wonder is it is so rarely seen in plant-houses during the winter. "The hardness of its constitution," states Mr. B. S. WILLIAMS, "allows of its being used in any situation under cover, while the flowers may also be used with advantage for bouquet making." In another plant-house *Clematis montana* is flowering freely on small plants trained in a spherical form, the pure white blossoms being produced in dense clusters. This species, together with *C. indivisa lobata*, are invaluable in a cool greenhouse at this season of the year, being so easily managed, and at the same time so prodigal of bloom.

— The well-known MANLEY HALL ESTATE, near Manchester, including the mansion, the conservatories, ferneries, and shrubs, and the 80 acres of freehold land on which they stand, has been sold by Mr. SAM MENDEL to Mr. ELLIS LEVER, of Spring Bank, Bowdon, who is well-known in Manchester as the principal agent of Midland Coal Company. The estate realised, we understand, nearly £150,000.

— We are informed that the total number of visitors on payment to the ROYAL HORTICULTURAL SOCIETY'S gardens on Easter Monday was 5175.

— Messrs. J. & C. LEE, of Hammersmith, have recently been removing from their Ealing nurseries to Hounslow some fine bushy Yews, from 8 to 12 feet in height, the diameter corresponding to their altitude. The plants are nearly half a century old, and were reared at what was once their Stanwell nursery; from thence they were transferred to Feltham, and from Feltham to Ealing, where they had become thoroughly established and perfectly at home in the strong clayey yellow loam there. The Yews were removed under the immediate superintendence of Mr. CHARLES LEE. In the first place, the lowermost branches were bent upwards, and secured in that position and from harm by means of mats, and so were safe from injury by breakage. Then a trench some 3 feet or so in depth was dug out all round the stem about a foot from it in each direction, and when it was sufficiently deep to be below the great mass of fibrous roots forming the huge ball, the latter was undermined till it was left standing on a kind of apex, some 6 inches or so in diameter. The next step was to bind old mats well about the ball of roots completely round it, which were securely fastened by means of strong cords, and which had the effect of preventing any of the soil from falling away. Then, by means of a tree lifter, the huge mass was lifted out of the hole and borne away to its destination. Treated in this way a plant can scarcely receive a check, and Mr. C. LEE states he has successfully transplanted many such specimens in the course of his experience as a planter.

— The eighth annual show of the CHEADLE FLORAL SOCIETY will be held in Cheddle, near Manchester, on August 6 and 7.

— Among HARDY PRIMROSES that flower at this season of the year is a beautiful one, the name of Messrs. BACKHOUSE & SON'S *Primula pulcherrima*. It is a most lovely species, taller and far more luxuriant than *P. denticulata*, and has deep lavender-purple flowers with yellow centres, and much larger trusses. The well-known Yorkshire Nursery firm who distributed it claim for it that it is perhaps the finest of the Himalayan *Primulas* of the denticulate section—"quite distinct," they say, "from the plant usually known as *P. purpurea*, though, judging by the colour, it has far more right to the name." A grand plant both for rockwork and well-drained borders, in stiff loamy soil, blooming in spring, and perfectly hardy (which the true *P. denticulata* is not with us.) It was originally received by them under the name of *P. denticulata nana*. It does well in pots grown in a cold frame, and under the protection of glass it comes into flower much earlier than in the open air.

— Judging from a letter recently received by Dr. HOOKER from a correspondent in MADEIRA, the climate of that island seems specially suited to the growth of *Cinchona succirubra*—a specimen originally from Coimbra in Portugal, and which he had in a half ago in a garden in Madeira at an elevation of about 500 feet above the sea, is now nearly 20 feet high, and blossoms freely. *C. condamina*, however, does not seem so satisfactory. Some plants sent from Kew six years back have been increased by cuttings, but these are said to make but little progress. From the same letter we learn that the fruits of the *Banana* are being exported from Madeira in large quantities, and that *Eucalyptus globulus* is being grown in some parts of the island simply for firewood.

— We are requested to state that the ground allotted for planting shrubs at the COLOGNE INTERNATIONAL HORTICULTURAL EXHIBITION is now at the disposal of intending exhibitors who care to commence to make use of it. No charge will be made for space.

— The Government of New Zealand has just issued a handy-sized volume of close upon 300 pages under the title of the "THE OFFICIAL HANDBOOK OF NEW ZEALAND, a collection of papers by experienced colonists on the colony as a whole, and on the several provinces." These papers are written by some of the best men in the colony, men whose names are well known in their various branches. Thus we have "Climate, and Mineral and Agricultural Resources," treated of by Dr. HECTOR; "Animal and Vegetable Productions," by Mr. TRAYERS; and an article on the "Native Race," by Sir D. McLEAN. After the whole colony of New Zealand is treated generally, each province has a separate notice, and besides its early history, geographical position, description of its institutions and similar matters interesting to the colonist or the historian, there is a great deal of interesting matter on the natural resources. Thus Dr. HECTOR tells us that in the whole colony there are about 12,000,000 acres of land suitable for agriculture, and about 50,000,000 more better adapted for pasture; 20,000,000 acres of this, however, is at present covered with forest, the value of timber from which is on the increase, for we learn from recently published statistics of New Zealand that the value of timber exported in 1873 was £43,697 against £27,373 in 1872, showing an advance of £16,324. Speaking of the fauna of New Zealand, Dr. HECTOR says that until its systematic colonisation it was very destitute of terrestrial or animal life suitable to the wants of civilised man, the only mammals being a small rat, a dog (which had been probably introduced since the islands were peopled by the present race), and pigs, the produce of some animals left by Captain COOK and the navigators who succeeded him. Domestic animals and poultry of various kinds have, however, been introduced during late years, thoroughly acclimatised and distributed over the colony. The seas around the islands abound with a great variety of valuable fish, crustacea, mollusca, and other mollusca and crustacea of excellent quality are also abundant, and require only proper systematic culture to become a source of wealth to the colony. With regard to vegetable productions, it is well known that the indigenous forest contains a large number of valuable timber trees, and many of the more important trees of Europe and America have been introduced and are now flourishing, as well as many of the best fruits, such as Oranges, Lemons, Citrons, Peaches, Apples, Pears, Grapes, Apricots, Melons, and numerous others, all of which produce their fruits in abundance, and ripen them to perfection. One of the most important indigenous plants is the New Zealand Flax (*Phormium tenax*). In Auckland a large quantity of rope and cordage is made from this fibre, amounting in one year to 1057 cwt., of the value of £2405.

— The SOUTH ESSEX, LEYTON, WALTHAMSTOW, WOODFORD, and WANSTEAD FLORICULTURAL SOCIETY will hold their annual show of flowers, fruits and vegetables, during the second week in June.

— A *Daily News* telegram from Paris on March 30 states that an official decree has been published prohibiting the importation into, and the transit through, France of POTATOS from the UNITED STATES or CANADA. Dead leaves, as well as sacks and barrels or other articles which have been used for the packing of Potatoes, are included in this prohibition.

— We learn from a correspondent that at Park-field House, near Worcester, the residence of Mr. LEA, a gentleman who has recently formed an interesting collection of Orchids, was to be seen a shot time since a remarkable specimen of *DENDROCHILUM GLUMACEUM*, in the finest possible condition, and bearing 117 spikes of bloom. Taking the number and vigour of inflorescence into consideration, it was by far the finest specimen our correspondent had seen, reflecting the highest credit upon the intelligent gardener, Mr. COX.

— A marble bust of the late Mr. WILLIAM MASTERS, executed in 1833 by his fellow townsman, H. WEBER, R.A., has been presented by the family to the CANTERBURY MUSEUM, of which the deceased gentleman was the founder, and for many years one of the most energetic supporters.

— Mr. G. WALKER, gr. to Mrs. HONEYWOOD, Mark's Hall, Essex, informs us that he has now commenced to flower a fine plant of *CHAMEROPUS HUMILIS*, with five spikes; and *VERSCHAFFELIA MELANOCYTES*, with one spike. We have not heard of the last-named plant flowering in this country before, and the event is the more interesting as the plant has only been introduced about four or five years.

— An influential meeting of the residents of RICHMOND and its locality was held at the Masonic Hall on Wednesday evening last for the purpose of establishing the proposed Horticultural Society. Colonel BURDETT, J.P., presided. Richmond is to

be the Society's centre, and it will include in operations the important parishes of Twickenham, Isleworth, Mortlake, Petersham, and Ham. Already the large sum of 160 guineas has been promised. A large committee—including the names of such well-known horticulturalists as Messrs. Kinghorn, H. Little, Bohn, Peel, James Clark, Steel, and Woodbridge of Syon—was elected, and they will proceed to arrange a schedule of prizes as early as possible. It is expected that whilst the major portion of the competition will be limited to exhibitors residing within the district, the committee will be enabled to offer some open prizes of such an amount as will induce growers from a distance to compete. The first exhibition will probably be held during the month of July, and no exertion will be spared to render it one worthy of the famous royal suburb.

A new substance has lately appeared in Germany in the form of an extract or ESSENCE of CHICORY, for use as a substitute or as an addition to Coffee. Chicory is very largely grown and used on the Continent, much more so than in England, and the residue of the root after the extraction of the essence makes an excellent food for cattle.

Home Correspondence.

The Wild Daffodil.—Calling on my son, Mr. G. Maw, who resides here, I have taken up the last number of the *Gardeners' Chronicle*, and wish to say with reference to a paragraph headed "Wild Daffodil" that a few years ago I transplanted a considerable number of the normal singly flowered bulbs from a meadow a few miles off, into my own meadow adjoining my house, and some also into my garden. On the second year after transplantation nearly all became double, and at the time not one of those in which I am free to confess I will give me as much surprise and pleasure as a blue Dahlia. I believe I am acquainted with almost all the great growers of Narcissus in this country, and I imagine every one of them would regard such an occurrence as more than passing strange. I have for years been endeavouring to obtain bulbs of Narcissus Pseudo-Narcissus fl. pl., but in vain. It was not to be heard of anywhere till last year, when Mr. Barr kindly sent me three bulbs, which, with a few others, he had succeeded in discovering after a world-wide search, in one single locality. "R." will find his bulbs most valuable if he has got hold of the genuine article. The great yellow Daffodil, so common in gardens, and so freely naturalised in meadows and orchards, has nothing to do with N. Pseudo-Narcissus: it is the double variety of N. major; but I think my hair would almost stand on end if some fine spring morning I were to visit one of the many naturalised clumps of this flower covering, after a world-wide search, in one single locality. "R." will find his bulbs most valuable if he has got hold of the genuine article. The great yellow Daffodil, so common in gardens, and so freely naturalised in meadows and orchards, has nothing to do with N. Pseudo-Narcissus: it is the double variety of N. major; but I think my hair would almost stand on end if some fine spring morning I were to visit one of the many naturalised clumps of this flower covering, after a world-wide search, in one single locality. "R." will find his bulbs most valuable if he has got hold of the genuine article.

Will your correspondent "R." do me the honour to send me a bloom of one of the double Wild Daffodils he has produced by two years' cultivation? I shall really esteem it a great favour. I am free to confess it will give me as much surprise and pleasure as a blue Dahlia. I believe I am acquainted with almost all the great growers of Narcissus in this country, and I imagine every one of them would regard such an occurrence as more than passing strange. I have for years been endeavouring to obtain bulbs of Narcissus Pseudo-Narcissus fl. pl., but in vain. It was not to be heard of anywhere till last year, when Mr. Barr kindly sent me three bulbs, which, with a few others, he had succeeded in discovering after a world-wide search, in one single locality. "R." will find his bulbs most valuable if he has got hold of the genuine article. The great yellow Daffodil, so common in gardens, and so freely naturalised in meadows and orchards, has nothing to do with N. Pseudo-Narcissus: it is the double variety of N. major; but I think my hair would almost stand on end if some fine spring morning I were to visit one of the many naturalised clumps of this flower covering, after a world-wide search, in one single locality. "R." will find his bulbs most valuable if he has got hold of the genuine article.

Eccentricity of Growth is probably much commoner than is generally supposed, and may often be traced to the injuries caused by boys climbing young trees time after time, and destroying the bark and young wood on the upper side of branches close to the trunk until decay sets in. I am speaking of lateral branches alone. I was much surprised one morning on going to Mr. Lawes' chemical laboratory at Harpenden, at seeing a large Elm tree, which was a few years old, more especially as it was a vigorous and not an old tree from which it had fallen. On examining the branch, I found that the growth was nearly all below the original centre,—that is, in a diameter of 18 inches 15 were developed below the pith. It had at length grown too heavy for the slender support afforded by the partially decayed 3 inches on the upper side, and pulled itself out from the trunk. Since then I have often mistrusted Elm trees. We frequently lounged on the grass immediately beneath this ponderous branch, which fell one fine still morning without the slightest warning. W. B. H.

The Victoria Regina Violet.—With this I send a few blooms each of Violets The Czar and Lee's Victoria Regina, gathered from plants growing side by side in the open ground, strong stools planted out last May. When Mr. Lee submitted plants of his Violet to the attention of the Floral Committee at South Kensington last February twelvemonths, it was mentioned that it did not present a sufficient advantage upon The Czar to make it deserving a certificate.

Now I have found that both under glass and in the open air the Violet Victoria Regina presents a considerable advance over The Czar in size of flower, breadth of petal, and depth of colour. The bloom sent for your opinion are the best to be found on either plant at all only represent each variety. They were gathered from a cold, dry east border, swept by the recent cold winds and very dry. Alex. Dean, Bedford.

Jaborandi.—Medicinal matters always had a general interest, especially if not well understood; hence these remarks about the Jaborandi plant, which you noticed at p. 406 in your issue of March 27. When travelling in Southern Brazil, in the provinces of Santa Catharina and Paraná (which are distant about 20° of latitude from Pernambuco, which you referred to), I took an especial interest in this particular plant, and learned that it came from Piper Jaborandi, Vell.; Ottonia anisim, Spreng.; Ottonia Jaborandi, Kunth. (in *Linnaea*, xiii, 250). It is used there as a diuretic and salagogue, and as a simple household drug. They administer a decoction to the dogs before starting out hunting, in order to animate them and make them more spirited and better suited for spying out and confronting the game—dogs in that country taking a great part in these pursuits. It would be well for European hunters to make experiments and state the efficiency of this drug, supposing it to be the true one as found in the province of Santa Catharina. The Jaborandi (with the accent on the first letter, pronouncing it as an *e* or German *ä*) is a small, insignificant-looking, thin-growing shrub. Its leaves are oblong, acuminate, shortly petiolate, about 3—4 inches in length and about 1½ inch broad; the texture is somewhat thin; the stem, or rather branches, generally as thick as a blacklead pencil or thinner; the height of the shrub not exceeding 2—3 feet, according to its position. The medicinal properties belong to the roots, these keeping for some length of time in a dry state. The taste is sharp, but exceedingly agreeable, reminding of the tongue and palate, but to be encountered in any other congener of the numerous family. Specimens which I collected will probably be found in the Museum of Berlin, where I sent the rest of my herbarium, which was unfortunately greatly reduced by the Cuppin (Termite or white ant). I believe there is a drawing of the Jaborandi in the *Flora Fluminensis*. The genus Piper, so richly represented throughout all South America, I believe, at present very partially known, but it will undoubtedly furnish new additions to medicine, especially on the western side, in Peru, where so many species occur of a particularly aromatic and acid, a true medicinal, taste. This supposition is enlarged by the circumstance of many Pipers growing in large and even compact masses, and the plants are generally content with a meagre stony soil, unprofitable for other vegetable culture, as especially concerns the Peruvian Corallines. Now, having an instance at hand in the Piper angustifolium in general use under the name of Matico. G. Wallis, Botanical Traveller.

Vegetables.—One of the most useful Lettuces in cultivation is the small Cabbage Lettuce, called Commodore Nutt. The most useful kind for winter use is the new Egyptian Turnip-rooted. Do not grow it so large, as I grew some of mine (10 inches across); they are too coarse when grown so large, but the small ones are very sound and of quick growth. I have some now as solid as cricket-balls. Sulham Prize Pink Celery kept first-rate with me: what I am now using is as firm and crisp as can be expected at this season of the year. Sandringham is a good white for early use. A good Pea, required to grow about 3 feet, is Maclen's Best of All, for exhibition, will do well to still grow Rollinson's Telegraph (true). Two useful dwarf Kidney Beans are Canadian Wonder and Black-seeded Negro. The most useful Turnip for use during February and March is Orange Jelly. C. Osman, S.M.D. Schools, Sutton.

Sulham Prize Celery, and Lee's Early Kidney Potato.—Let me endorse all that was said in last week's *Gardeners' Chronicle* of these two excellent vegetables; the latter I have grown for the last two years, and think it the best of all the very early Potatos. I look upon the Canadian Wonder French Bean, as really valuable additions to our stock of vegetables. D. Dast.

Summer Pruning.—In compliance with the solicitation of "W. T.," I was cheerfully proceeded to narrate the circumstances that led me primarily to believe that cutting or pruning certain descriptions of trees and shrubs in summer was attended with different and better results than by doing so in winter. There was an old Thorn hedge, very old, and very full of gaps, which the shepherd cut branches from at all seasons to fill up the gaps in it, and it required only a passing glance to see that from the snags or stools remaining and stronger than from those cut in early cutting or in winter. In forestry operations branches overhanging roads have to be lopped off whenever

they come in contact with the traffic, and, as is well known, the branches, when once cuffed, with foliage, and wet with rain or dew, yield to the weight, and this necessitates much summer lopping or pruning of all such species of trees and shrubs in winter. Under such circumstances it is often found desirable to cut the intruding branch at some considerable distance from the stem rather than close to it, not unfrequently leaving a bare arm projecting from the trunk—but no means a beautiful object for the time being—but encouraged by seeing many other bare arms by degrees gain spray, branches, and foliage, they were left in like manner, but doubt in some cases prevented their ever gaining branches and foliage again. On comparison of these summer-pruned roadside trees with others pruned in winter, it was quite evident that the former produced sory and branch much more certainly and abundantly than the latter. On pruning Birch trees in winter it very seldom happens that a large branch denuded of all its smaller branches will ever again reproduce them, while if cut during summer the second season will probably see it again well clothed with new sprouts. "W. T.," wishes to know how these results are produced, but that I cannot inform him. My own humble opinion, however, is, that a knowledge of the physiology of plants will enable any one to form a likely theory of it. The following is mine: The sap is attracted to the upper part and extremity of the branches, and after undergoing certain mysterious chemical changes, distributes itself over the whole structure of the tree, but most abundantly between the bark and the last or outer layer of wood. There are lying also beneath the bark, probably on the outer surface of the last-formed layer of albumen, latent buds, ready at any time, when stimulated by certain favourable influences, to start into life, and manifest themselves in the form of young shoots and branches. Now, in the case of old and comparatively dry and sapless stems, there is nothing to stimulate or provoke life in these latent buds; but when the sap has first ascended the tree, changed its properties, descended between the bark and sap, and in close connection with those latent buds, there is nothing unlikely, when the stem is severed, that a successful effort should be made to produce shoots below, which, but for the advantages the sap had gained in first ascending the tree, it would not have been able to produce. Hence the advantages of summer over winter pruning or cutting—over certain species or old age and weak constitution would not reproduce young shoots. I would not advise the leaving of Osiers upon the stool till the sap ascends, unless in case of very old stools which it is intended to reduce in height by cutting-over below the crown. Bleeding is certainly produced more profusely by spring cuttings than winter, but I am not certain that the plant is thereby more weakened, for the sap, while it almost pours for a short time from the wounds of Birch and Lycamore, also pours from the wounds in winter, though under the least mildness of weather prevails. I hope to make this subject more plain at some future time; meanwhile those having cutting or pruning of any old or weak kinds of subjects to perform, so that their growth may be most certainly and satisfactorily promoted, should do the work in summer rather than winter. C. Y. Michie, Cullen House, March 29.

Grape Rooms.—The Grape room is hardly yet become an important feature in all large garden establishments. Probably there is still considerable prejudice against that mode of storing cut bunches of Grapes, and in not a few places the stock of old Grapes, after the incoming of the new year, is not so abundant that a special store-room is needed; possibly, however, there would be a stronger disposition to hold over a stock of Grapes for late consumption if it were generally realised that they may be cut any time after Christmas, and be kept sound and almost perfect for four months stored. What is the best way of storing, and of straining upon the Vines, is obtained when the entire crops are cut and safely housed in a small and properly arranged store-room. It is nearly five years since I first drew attention in these pages to the admirable Grape room at Heckfeld; since that time it has been constantly used all through the winter months, and with the most satisfactory results, only one new idea being added to the original plan, and that is the simple one of allowing all the old wood beyond the bunch to remain when the bunches are bottled, as it is found that the berries are kept plumper in consequence. Mr. Wildsmith is not only a first-class Grape grower, but his advice is always read with interest as that of an eminently practical man. Readers who have not seen Heckfeld have, of course, to take all that Mr. Wildsmith may say for granted, but I may be bold to say that there are not too many prize establishments where the visitor could look into the Grape room and see in the most perfect state of preservation a hundred or more good bunches of Lady Downe's, all cut two months previously, and from which not half-a-dozen

berries in a decayed state have to be cut away in a fortnight. At a moderate computation these Grapes would have weighed 150 lb., and when it is remembered that high-class Grapes are quoted in the market at some 15s. per pound, it becomes obvious that this crop of Lady Downe's so preserved is rendered with the advance of the season of considerable value. I should think that our dining fruiters might make a good hit by establishing Grape rooms on their own premises, as they would then be enabled to buy up whole houses of Grapes at once and at a cheaper rate, and store them where they could be had at a moment's notice. Mr. Wildsmith holds that the great secret of successful Grape storing consists in the fact that the crop must be thoroughly ripened before being cut; the Grape is then much less liable to change, and maintains its good qualities for a longer period. With Kemp's Grape rats a large number of bunches may be stowed in a small space, but at Heckfield the shelves on which the bottles are placed are elevated in three tiers around the walls, and thus the Grapes are brought nearer to the eye line than if placed near the floor. A little ventilation and a very little fire-heat suffices to keep the atmosphere and the temperature all that can be desired. A. D.

Interpretation of Schedules.—On examining the schedule of prizes to be awarded at the horticultural exhibition to be held in Manchester in May next, I find there are two or three matters which seem to require explanation, and, as most horticultural societies are interested, it has occurred to me that the *Gardeners' Chronicle* would be the best source to apply for reliable information. In class 25 prizes are offered for three pots of *Lilium auratum*. Of course it is quite competent for one exhibitor to grow as many bulbs in each pot as he chooses; but to classes 35, 36, and 37 prizes are offered for sixteen, ten, and six Orchids in flower. Now suppose half a dozen plants are put together in a mass in one pot, as is very frequently the case—the result being that the lot is made up of double, triple, or even a greater number than is stated in the schedule—would such a collection be entitled to the prize, or ought it to be disqualified? Again, supposing a prize were offered for six *Pelargoniums* or *Cinerarias*, and the exhibitor, to make up a great show, introduced several plants in a pot, would that fact form a disqualification or not? Such practices are, unfortunately, becoming very common, to the great discomfiture of the honest exhibitor. If masses of plants, whether Orchids or other things, are desirable, why should it not be so stated in the schedule? But to offer prizes for six plants and allow a dozen to be exhibited to six pots seems an absurdity. *A Twenty Years' Subscriber*. [This is rather a difficult subject. As to the Lilies, the object is to secure a display, and therefore more bulbs than one are permitted. Orchids often grow in masses, which are more or less broken up when they are imported, and specimens are sometimes made up by putting together some of the separated pieces, but we do not think this is often done to such an extent and in such a way as to be a real grievance. *Pelargoniums* and such-like subjects would be assuredly disqualified if found to be made up. The conditions in this latter case are totally different from that of Orchids, though if these are too unscrupulously "manufactured" at the last moment we should be ready to disqualify them. Eds.]

Abies Douglasii.—I fully endorse all that is said by your correspondent, Mr. J. Sheppard, in favour of this magnificent tree, but it has one drawback—an utter inability to bear exposure to wind. I am acquainted with one of the original seedlings, now a fine piece of timber, which lost its head as soon as it was overtopped the neighbouring trees, and that appears almost invariably to be the rule. A large plantation might protect itself; but they so soon overtop other trees that, when scattered among them, their growth is cut short in a few years. I may add, that I have found seedlings from the tree above-mentioned to be far superior to any which I have purchased. H. K.

Seeding Lilies.—If your correspondent, R. J. Elwes, wishes specimens of two-year-old plants, *Lilium auratum*, I shall be very happy to supply him with them for the purpose he requires them. I may also state that I have raised seedling Lilies, but have not as yet been successful in obtaining decided crosses, although attempts have been made to fertilise them with other sorts. *Auratum* has in most instances come with slight variations, but the specimens amongst imported bulbs of that sort, *Lilium speciosum* (lancoifolium) rubrum? came pure white, and *L. giganteum*, which flowered with me last year raised from seed ripened in the open air, had no marked difference, although careful fertilisation was attempted. I find, however, that this latter sort seeds so freely when left to itself, that it is necessary to take it in a very early stage of its flowering for the process of manipulation. I have seen the petals before their expansion, and clipped off the anthers and fertilised the stigma as soon as it appeared shining and waxy, and have by this means gathered ripened seed, which is

now sown, and in due time should vegetate—the sorts *auratum* and scarlet *Martagon* being made the males. J. Webster, Gordon Castle, N.E.

Gardenia Stanleyana.—In your notice of the above plant (see p. 374) you observe that "at first there was evidence of its being a free-blooming plant, but subsequent experience has proved it the reverse," &c. As I live at Knowsley during the time *Whitefields* are under cultivation I have a vivid recollection of two varieties existing there, and designated the free *versus* the shy-flowering variety. I also remember that one of the plants known as the shy-flowering variety, and much the largest and oldest plant in the collection, did bloom, to the best of my recollection, once only, and it was remarked at the time that the blooms were of a paler colour throughout than the other. They do like bottom-heat and liberal treatment otherwise. I mention the above as an illustration of the fact that there are forms or varieties of certain species of plants which are more or less shy to bloom or fruit, neither is this peculiarity confined to any class or family of plants—it is, I believe, traceable to all. Robert Bullen.

Sulham Prize Pink Celery.—I quite agree with Mr. Ingram (p. 405) with regard to the keeping qualities of this Celery. I have some of it now in the ground alongside Sandringham White and Haywood's White Queen, and one and all are remarkably good for the season (March 29). H. W. Ward, Longford Castle Gardens, Salisbury.

Hardy Hybrid Begonias.—It may interest some of your readers to know that now is the best time of the year to procure tubers of these beautiful and most easily cultivated plants, which only require to be allowed to start into growth in small pots in a cold house (as they actually dislike and resent the kind of heat by artificial heat), and about the middle of May they should be turned out of the pots into a well-prepared bed in the garden filled with light rich friable soil, in which they will grow rapidly, and soon make nice bushy plants and begin to produce their bright showy blossoms about the middle of June, from which time till they go to rest about the middle of November they continue to produce flowers almost without intermission. The flowers are almost invariably produced on long foot-stalks from the axils of the leaves, in bunches of three, consisting of the large and handsome male flower in the centre, and a smaller but equally bright and longer lasting female flower on each side. About the commencement of September, when the nights begin to get chilly, the plants should be lifted with good balls and put into good-sized pots, when for the next couple of months or more they will form most acceptable ornaments for the conservatory or glass or drawing-room or elsewhere. The hybrids, to which the above remarks especially refer, are those raised by Mr. V. Lemoine, of Nancy, France; and as the parents from which all his seedlings originally sprang were the hardy variety B. Veitchii, and the beautiful foliaged B. Pearcei, nearly all his hybrids partake of the hardy nature of the one parent and the ornamental foliage of the other, while the blossoms are nearly all modifications of and most of them improvements on those of the first-named parent. I should especially recommend the following varieties, which I know to be really distinct and beautiful, and with which I may safely say none of your readers who invest in them can fail to be pleased—1, Camoens; 2, C. Glijm; 3, Coral Rose; 4, Mastodon; 5, Rubens; 6, Velours. The tubers travel quite safely in a tin box by post, and the very moderate prices at which they are offered by the raiser puts them within the reach of almost every lover of flowers. Mr. Lemoine also offers two new varieties for the first time this season, named respectively *Molière* and *Cornelle*, the latter often producing semi-double flowers. His fine double scarlet-flowered variety, named *Monstrous*, of which a woodcut and description were given in the fourth part of the *Revue Horticole* for last year, has not yet been sufficiently increased to enable the raiser to distribute them, he hopes, however, to have sufficient stock to be able to do so before the summer of next year. W. E. G.

Lee's Hammersmith Early Kidney Potato.—I can fully endorse the recommendation Mr. Brown has given at p. 408 of Lee's Early Kidney Potato. I have grown it for the last two or three years, and am perfectly satisfied with it. It forces well, I have been sending it to the market for the last three years, and it is spoken very highly of. It is very prolific, and nice and floury and of excellent flavour when cooked. But as a garden Potato in general I find very few, if any, to excel Myatt's Prolific. H. W. Ward.

Protecting Materials.—I was very much pleased with and, I hope, profited by reading your article (p. 372) on the protection of fruit trees. As to the material to be used, we do not appear to have much more choice than we had several years ago, though in almost every other department of textile manufacture there is a

great increase in the variety of choice, if not in improvement of quality, from the finest "Lyons" to the coarsest "shoddy." When will manufacturers turn their attention to an improved covering, not only for our walls but also for our frames? As to the material for our walls, the most efficient and easy to apply is canvas on rollers, the canvas to be secured to the wall under the coping, the roller to be drawn up by two cords run through two pulleys at the top. But an important question to be asked is, Why do we cover the trees? Because their growth is too early for the season. Then comes another question, When is the best time to begin to cover? I think the earlier in January the better, but until the blossom-buds are ready to burst I would reverse the order of general practice by keeping the canvas rolled up at night, also in the day unless the sun is shining—on every clear day keep the canvas down, to keep the sun from shining on the wall where there are any branches. By so doing you will have a considerably later spring for your trees, consequently much less danger of the flowers or fruit being injured by the late frost. Those who have no appliances ready to use and late frosts prevail, will find a substitute not to be despised by nailing to the wall flat branches of Yew, the common Spruce Fir, or *Abies Douglasii*. These will be of considerable assistance in saving the crop. They will want going over frequently with a pair of pruning scissors, to cut the weeds that are not wanted; this will give more light to the flowers and young shoots as they grow. David Walker, Gr. to B. H. Collins, Esq., Dunorlan, Tainbridge Wells, March 29.

DISA GRANDIFLORA.

This fine Cape Orchid is not nearly so often seen as its merits entitle it to be: any one who may have had the pleasure of beholding a good quantity of it in full beauty cannot readily forget the brilliancy of its large scarlet and yellow flowers, which are borne on tall leafy stems, something after the style of the herbaceous scarlet *Lobelia*, but the individual flowers of the plant in question are many times larger and much more brilliant, to which may be added a singularly grotesque form, which is at the same time extremely fascinating. One of the reasons, perhaps the main reason, why this most beautiful Orchid is not cultivated wherever a Chinese Primrose or a *Fuchsia* is grown is because it will only succeed under a special treatment, and either that treatment must be afforded by the natural conditions of the structure in which it is placed, or it must be procured by daily attention. It is a plant which will not forgive neglect. The soil most suitable for the *Disa* is a good sound peat, such as would do for Heather, but not so fibry as the peat usually used for Orchids, to which should be added a good quantity of good sharp river sand—silver-sand is not coarse enough, but will mix together, droppings, which should be well raked and thoroughly taken care not to break the peat up too fine. Select a broad pan in preference to a pot, and well and carefully drain by placing the crocks in such manner that they will not readily choke; if the drainage is thrown in in the careless slipshod manner so usual nowadays failure may be expected. Cover the crocks with a little sphagnum moss, and fill the pan to the rim with the above compost, on which place the plant, keeping it well raised up so that no water may lodge about the stems. The best time to pot these plants is about the beginning of November, after the shoots have nicely risen to the surface. After potting place in a cool, moist, but airy house or pit, not in too much sunshine, and syringe overhead six or seven times daily; it is better to syringe than to water—in fact, the *Disa* should never be watered with a pot during the stage, but be kept continually wet on the foliage by syringing; the soil by these means will be kept sufficiently wet without any additional watering. When the flower-buds are nearly ready for expanding the syringe should be laid aside and the water-pot called into use, commencing again with the syringe as soon as the young shoots make their appearance after the blossoming period is over. William Denning, *Norfolk*. [Our illustration, fig. 99, is of a plant 3 feet 6 inches high, grown by Mr. Denning, in Lord Lonsborough's collection. Eds.]

Reports of Societies.

Glasgow and West of Scotland Horticultural.—*March 25.*—The spring show of this Society, which was held in the City Hall, was publicly opened by Colonel Buchanan of Drumpellie, the President, who said he had been asked to inaugurate the spring show the first of the year, by a public opening. This was, he believed, a new thing in Scotland, but in England it had been very commonly done, and with the best results. He hoped that the public opening in Glasgow might create additional interest in the exhibitions, and tend to promote the success of the show that day, as

well as the general financial prosperity of the association. The Society had now been established for nearly a hundred years, and its funds had been increasing pretty steadily, although not in the ratio the directors desired. The annual revenue had been about £1000, but the expenditure had been nearly as much, about £420 being distributed in prizes. I was sorry to say that the number of yearly subscribers only amounted to 150—a fact which was the more to be regretted,

were very many to whom such a sum was the veriest trifle. It was not unproductive expenditure. The Society was doing real practical work, and he trusted it would no longer be possible to speak of its annual subscribers as limited to 150. Colonel Buchanan then formally declared the exhibition to be opened, and introduced the Lord Provost, who said he was glad to be able to stand on the platform of the City Hall and take by the hand his American cousin, Mr.

more eloquently than he could do on behalf of the association. All those whom he addressed, at least all such as had attained to years of discretion, remembered having at some period of their lives used the language of flowers, and perhaps made these exquisite productions of Nature give expression to thoughts which the tongue was too timid to declare. And so he might now safely leave the flowers to plead their own cause, or at least to furnish the spirit and essence of such an appeal. For himself, he should quit the flowery paths of speech and turn to practical matters, because, after all, a Lord Provost was nothing if not practical. Now, the practical counsel he had to give was, that they should all follow the advice of Colonel Buchanan and subscribe to the funds of the Society, which at present did not receive the support it was entitled to. He trusted that stigma would now be removed. One thing he would like to recommend, namely, the desirability of encouraging cottage gardening. All round Glasgow a great many houses were now being built for the industrial classes, and he thought it would be of great importance to encourage cottagers in giving their leisure hours to the cultivation of flowers and plants. There was also in the city—probably it was due to the climate—a great deal of the window gardening so common in London, Paris, and other large cities. The poor people living in very humble quarters in these busy communities, and shut out almost from the light of heaven, sought to overcome the depressing nature of their surroundings by growing a pot of Mignonette or a Geranium in the window-sill, with a canary overhead. His lordship concluded by again appealing to the citizens to give increased support to the Society.

The exhibition thus formally inaugurated was a highly attractive one. The favourable change in the weather from searching east winds and pressing cold to that of auspicious mildness brought out such a display as we have seldom witnessed in the City Hall. Moreover, the novelty of a public opening attracted many. There were not, it is true, so many of the productions of gentlemen amateurs as have occasionally been seen on the tables; but the lack of these was more than compensated by the superb display from the various nurserymen in and around the city. The principal hall was brilliant with everything that is rare and beautiful in flowers, and what with the rich tints of Azaleas and Rhododendrons, and Dutch bulbs of every description, commingled with the graceful foliage of Palms, Ferns, and these elegant coloured plants of which the Dracena and the Croton are the most distinguished representatives the tables seemed to groan with Nature's beautiful productions.

Mr. James Anderson, Meadowbank Nursery, Uddingston, was successful in taking first honours among the nurserymen for a collection of plants. Of those exhibited many were rare and beautiful—more remarkable, indeed, for their rarity and their beauty as individual flowers and plants than for their size. Mr. Anderson's table stretched across 30 feet of the hall, and among its chief attractions were the flowering plants of Azaleas, of which there was a very large assortment; Orchids, of which there was a marvellously fine white and yellow *Dendrobium thrysiflorum*, and a clear white species with a deep orange eye called *D. Jamesianum*; the *Amaris*, from Lima, which were very marked for their colours and prominent tints—the sorts called *Pardina grandiflora* and *Vivid*, the one spotted and the other bright scarlet, being highly attractive. The beautiful-leaved plants were very conspicuous, especially the young *Dracenas*, the *Crotons*, and the *Palms*, while not the least attractive were the upright *Pitcher*-plants, some of them in flower. One plant was particularly sought after, studded with tiny cactiform flowers and not a single leaf; this was a *Spiraea* (? *Deutzia*) which seemed to be new to most of the promenaders. Alongside of this table was one from Messrs. J. & R. Thyne, of the Great Western Nurseries, comprising large specimens of *Palms* and *Azaleas*, of which the striking amœna was the most beautiful. These, together with *Yuccas* and *Ferns* and choice foliage plants, rendered this table most interesting. On the other side was the bulbous collection of Mr. Peter Mackenzie, Gordon Street, better flowered and better put upon the table than we remember to have seen it; and on the platform was a very showy and fine collection from Messrs. Austin & McAsian, Coplawhill. The *Rhododendrons* and *Azaleas*, and indeed all the plants in this exhibit, were highly meritorious, and added much to the general attractions of the hall. This table was backed up by unquestionably the best flowered specimen *Camellias*, from Mr. Thos. Hill, Merryleek, and others, we have ever seen exhibited in Glasgow, and gave one a very favourable impression of the *Camellia* as an exhibition plant. We noticed that the pale carnation-striped variety called *Jubilee* was the best among light-coloured varieties, and the scarlet imbricated by far the best among dark ones. Messrs. Smith & Simons had an excellent table well arranged and filled with highly ornamental plants, among which were *Palms* and flowering plants, and the New Zealand Flax in splendid style, and

FIG. 90.—DISA GRANDIFLORA, AS GROWN BY MR. DENNING AT NORBITON.

because the Society was one which merited support as much as any institution in the city. In other large cities and in England organisations of this description were quite successful, and he knew of no good reason why Glasgow should not possess a flourishing horticultural society. A man who was fond of flowers could not be altogether a bad man, and if this taste were cultivated it must less or more purify his moral nature, and raise him above the desire for the baser pleasures and temptations of large cities. In this view of the matter he thought no one should grudge 10s. or 20s. a year for the Society, and in such a city as Glasgow there

Grant, son of the President of the United States. Of all countries in the world it was most desirable that we should be at peace with America, whose population was so largely recruited from Britain, and it might indeed be said that the amity of the civilised world depended upon the preservation of the *entente cordiale* between America and this kingdom. His lordship went on to say that he had been asked to make a few remarks in the way of commending the claims of the Society. And yet, after all, what need was there for doing so? Those flowers which brightened the hall so greatly, those children of Nature tended by man, spoke far

many other things suited for the general grower. Mr. William Montgomery had, as usual, a fine lot of small specimens, comprising most things in season at this time of year; and Mr. Wm. Paterson had a very good assorted lot, his *Roses*, *Palms*, bulbous plants, and *Lily of the Valley* being quite marked in character.

The private collections were limited, the best coming from Messrs. J. C. Wakefield, A. B. Stewart, Jas. Findlay, James Gordon, and Aitkenhead, the gardeners to these gentlemen distinguishing themselves both as culturists and as competitors. The *Coccyne cristata* and *Adiantum farleyense*, the most beautiful of Maidenhair Ferns, were splendid in the 1st prize collection, and the *Cocos Weddelliana* and *Odontoglossum Hallii*, a quite grotesque insect-looking plant, in the 2d prize lot, were of the highest excellence, and reflected much credit upon both Messrs. Fleming and Todd. The specimen *Cyclamens* exhibited by Colonel Buchanan, Drumpellier, were faultless as cultivated plants, and the highest meed of praise is due to Mr. Lewin, the gardener; while in the table plants from Rawcliffe Lodge, shown by Mr. Todd, the handsome outline of the plants and their rarity attracted the attention of all *connoisseurs*. The *Arabis Veitchii*, *Calamagrostis*, *Androsace gracilis*, and *Cocos Weddelliana* were simply superb. The *Hyacinths* from Mr. Peter Mackenzie were in greater force and finer than ever. The blue and white Lord Palmerston, the King of the Blues (a superb *Hyacinth*), the bright red Macaulay, the pale lavender Lord Derby (than which there was nothing finer exhibited), the rosy, close-headed Von Schiller, the blue General Havelock, the pure white *Aia maxima*, and many others nearly equally good, shown in almost all the collections. Mr. John Struthard had a very creditable lot. Mr. George Irvine, port Glasgow, and Mr. M. Miller, Bothwell, had really superb heads of bloom, the latter exhibitor having the finest foliage plants, and the former the largest heads of bloom. Both were highly meritorious exhibits. The *Narcissus*, the *Crocus*, the *Tulips*, and the miscellaneous bulbs were very fine, as also the *Deutzias* and the *Rhododendrons*, the latter particularly rising in the sale, from the gardens of Garscube, exhibited by Mr. James Graham, and from Mr. James Beveridge, who put up grandly flowered plants of *Rhododendron* Countess of Haddington, a sort comparatively new to commerce. Mr. D. Y. Stewart, of Barassie, exhibited an excellent basket of Black Alicante Grapes.

The amateurs were in strong force, and exhibited many articles that would have vied in excellence with gardeners. It was in this department of horticulture it is so well attended to by the promoters of the Society, as it encourages many gentlemen to give up somewhat of their spare time to flower cultivation. A silver cup is to be awarded for this department at the future shows of the Society. The secretary, Mr. F. G. Douglal, was untiring in his efforts to promote the comfort of all concerned, and not a little of the success of the show is due to his efforts, ably seconded as they were by Mr. M. Wilson, the treasurer.

The directors of the Society and their friends, with the judges, dined together in the afternoon, at Mr. C. Wilson's, West Nile Street, the chair being occupied by Mr. D. Duncan, and the duties of croupier discharged by Mr. Eadie.

Royal Botanic. *March 31.*—This Society's first spring show may be said to have been a little above the average merit of its predecessors, and favoured with comparatively warm, if not particularly bright, weather, there was an excellent attendance of visitors in the afternoon. There were only two competing collections of twelve stove and greenhouse plants, but both were very neat and fresh. The best came from Mr. J. Ward, gr. to F. G. Wilkins, Esq., of Leyton, who staged, amongst others, a specimen of *Cypripedium vilosum* with about three dozen flowers; *Phajus grandifolius*, with four spikes; a good *Lycaete Skinneri*, *Odontoglossum triumphans*; a nicely flowered *Eriosectum buxifolius*; *Cytisus racemosus* shown in a large and well furnished specimen; and a fine plant of *Anthurium Scherzerianum*, with four of the finest spathe we remember to have seen, and which measured 5½ inches in depth and 4 inches across. Mr. G. Wheeler, gr. to Sir Francis Goldsmid, Bart., Regent's Park, who took the 2d prize, had nicely flowered but not large examples of *Chorozeema Lawrenceanum*, *Cochlosystema Jacobianum*, *Imantophyllum minutum*, *Hederaema tulipiferum*, *Azalea Marie*, *Franciscea calycina*, *Cypripedium barbatum*, *Dendrobium nobile*, &c. The amateurs' class for six *Azaleas* was very well contested, and the specimens staged, while being of medium size, were beautifully flowered, and perfectly fresh. The prizes were awarded to Mr. J. Ward, Mr. G. Wheeler, and Mr. Coles, gr. to Mrs. Torr, Ewell, in the order named. In the nurserymen's class there was only one exhibitor—Messrs. William Cutbush & Son's. *Deutzias* were also fairly well represented, but not so well as we have seen them before. The half-dozen specimens shown by Mr. James Douglas, gr. to F. Whitbourn, Esq., Loxford Hall, Ilford, and which easily won the 1st prize, were remarkably good examples of

high cultivation, and differed in style from the plants ordinarily seen in being trained in the form of a hollow cylinder, which allows of the old wood being entirely hidden from sight. The 2d prize group, which came from Mr. Childs, included four standards, with bushy heads on clean stems, 3–4 feet in length, very useful plants in a large conservatory, no doubt, but not to be recommended for exhibition purposes.

The *Hyacinth* classes were well contested, and, on the whole, made a fair show, though we did not think the spikes were so fine, as a rule, as we have seen them in previous years. One class was for "twelve plants, any number of spikes," in which there were quite as many spikes which were simply fascinated as there were of plants with two and three spikes—proving the arbitrariness of the distinction which has been drawn. Every one knows that the finest spikes are those which come fascinated, and surely no one will claim that these should not be shown as single spikes. Fasciation being in a great measure the result of accident, which at present no grower can prevent or control except to a limited extent, it may reasonably be argued that if a bulb throws up two or three single spikes (by accident, which cannot be prevented) it cannot be fair to show the whole tier up as one spike. We are of those who believe that whatever number of spikes a single bulb may produce should be legitimately and fairly entitled to be shown in any class; and we believe that by drawing such lines of distinction as are now attempted to be drawn, future competition will be confined to growers of the greatest numbers—for small purchasers, who are the real supporters of the bulb trade, in not being able to select their *Tulips* for a definite purpose beforehand, will, as a consequence, be debarred from competing—with the result to bulb importers of something very like killing the goose that lays the golden eggs. Of the class for any number of spikes it may simply be mentioned that Messrs. Cutbush and Son were 1st, Mr. Douglas, 2d; and Messrs. Barr & Sugden, 3d; for it can serve no useful purpose to say that this variety had two spikes, that three and the other two, where accident at present plays such an important part, though we think it most probable if the production of these fascinated spikes be encouraged their production will soon become something more than accidental.

In the amateurs' class for twelve single spikes, Mr. Douglas came 1st, Mr. James Weir, gr. to Mrs. Hodgson, The Elms, Hampstead, 2d, and Mr. G. Potts, 3d—all showing well known varieties in very creditable order. In the corresponding class for nurserymen the prizes went to Messrs. Cutbush & Son, Messrs. Sugden, and Messrs. James Carter & Co., in the order named, the specimens shown being of the same average merit attained in the amateurs' class. *Tulips* were very attractive and good, Mr. James Douglas having the best twelve plants that were staged—a result especially creditable to an amateur in the presence of the larger growers. In the amateurs' class alluded to, next to Mr. Douglas came Mr. J. Ward, gr. to Mr. Torr, and Mr. G. Wheeler, the profusions in both cases being very creditable indeed. As in the nurserymen's class for *Hyacinths*, so in that for *Tulips*—the prizes went to the same firms, and in the same order of merit, viz., Messrs. Cutbush & Son, 1st, Messrs. Barr & Sugden, 2d, and Messrs. James Carter & Co., 3d.

For twelve *Cyclamens* there were only two competitors—H. Little, Esq., and Mr. James—who took the prizes in the order named. Mr. Little had the largest plants and the greatest variety in colour, while the smaller plants from Mr. James were a delightful *bonne bouche* to sticklers for floral formality, being so perfectly even in all points as to have the appearance of being cast in a mould rather than grown.

In the miscellaneous class, an all-important one at small shows, Messrs. George Paul & Son exhibited a very fine bank of forced *Roses* in pots, the plants being well furnished with foliage and in the best of floral reality. Mr. Turner, of Slough, contributed a striking group of *Lyces*, amply furnished and neatly trained on oval-shaped wire trellises; a still more attractive collection of standard plants of *Acucba japonica vera*, which were most splendidly furnished with berries, and a basket of plants of the semi-double lavender-blue *Violet*, *Lady Hume Campbell*. Groups being well shown in greenhouse to come from Mr. G. Wheeler and Mr. B. S. Williams—the latter showing amongst others a large and very fine plant of *Imantophyllum minutum*, the pretty blue *Tillandsia Lindeni*, *Puya Alstenheimii*, with white flowers enveloped at the base in scarlet bracts; *Aerides Fieidingeri*, *Trichopilia suavis*, *Lycaete Skinneri*, *Encholirion corallinum*, with a fine spike of very green flowers enclosed in dull crimson sheath; *Grenouze*, gr. to Mr. Aitkenhead, with a spike with white margin to its long green leaves; and an elegant *Aslophya Van Geertii*. From Mr. William Paul came a very attractive group of small but well furnished plants of *Camellias*, two boxes of cut blooms of the same flower, and examples of the fine Waltham White Primula. A fine batch of *Cyclamens* of the most approved type came from Mr. James, and

Messrs. Barr & Sugden and Messrs. James Carter & Co. each sent large collections of *Hyacinths*. The first-named firm were also contributors of a nice group of *Narcissis*, and the latter of *Tulips*. A choice group of seedling *Cinerarias* came from Mr. James, who also took the 1st prize for pine with admirably flowered specimens. From Mr. W. Stevens, gr. to G. Simpson, Esq., Reigate, came a specimen of *Dendrobium fimbriatum oculatum*, which measured 3 feet through, and nearly the same in height, evenly and regularly flowered all over—a wonderfully fine specimen.

MR. WILLIAM PAUL'S SPRING SHOW.—Mr. Paul's exhibition opened in the Western Arcade in the Royal Horticultural Society's gardens, South Kensington, on Saturday last, and closes to-day. To say that it has been very successful is only to repeat what has been previously said of other enterprising efforts of a similar nature which Mr. Paul has carried through, and it says much for the resources of the establishment at Waltham Cross that he should have been able to stage such an extensive and admirable collection of flowering plants, in spite of the extremely adverse weather he has had to contend against. *Hyacinths* and *Tulips* were shown in greater numbers than any other class, and being arranged in masses, with groups of *Camellias*, *Roses*, *Spiraeas*, *Silver Tricolor Pelargoniums*, *Azaleas*, *Clematis*, *Primulas*, *Narcissus*, *Deutzias*, &c., intervening—the whole had a very good effect. All the plants were of excellent quality, and the bulk of the *Hyacinths* and *Tulips* were quite up to Mr. Paul's high standard of excellence. Amongst the *Roses* we noticed the new *Star* of Waltham, which does but strengthen the good opinion which we formed of it when first shown last year. Amongst the new *Hyacinths*, Baron Jeau, single, porcelain-blue, with fine reflexed bells; Von Moltke, very dark single blue, with white centre; Admiral de Ruyter, with the back of the petals of a Cambridge-blue tint and large bells; and Snowspike, single, white, with petals of great substance, good bells and spike, were the best.

MESSRS. WILLIAM CUTBUSH & SON'S EXHIBITION at Highbate has been open all the week, and has deserved the attention which we have noticed it to. On Easter Monday no less than 2000 persons passed through the show-house, which, though small, was full of flowering plants, the *Hyacinths*, of course, having the lion's share of the space, as might be expected from the high reputation which the firm has gained for its culture. The front and one side of the house was most tastefully arranged with *Hyacinths*, broken up into groups by small masses of dwarf-flowering *Camellias*, *Deutzias*, *Lily of the Valley*, *Cyclamens*, *Azaleas*, *Cytisus*, and the usual *ceteras ad libitum*—the bright colours on these as on the other sides of the house, which were filled with *Narcissus* and *Tulips*, by a large mass of *Camellias* in the centre, the rich green foliage of which formed a striking and pleasing contrast.

Garden Operations.

(FOR THE ENSUING FORTNIGHT.)

PLANT HOUSES.

GREENHOUSE HARD-WOODED PLANTS.—In plants with variegated or handsome leaves that are used for the decoration of halls, rooms, &c., we are obliged to depend considerably upon such as require more or less heat to grow them; these answer the purpose very well during the warmer portion of the year, but in the chilly autumn and winter they are soon rendered useless. Provision should be made against this, by the timely preparation of a selection of the most appropriate plants for winter use, and that will grow and flourish in a greenhouse temperature. The number to select from is not nearly so large as it is to be found amongst the occupants of the stove; nevertheless there are many that will do good service for mixing with the usual flowering greenhouse subjects, forced or otherwise, in use at the dull season, and there is no better time than the present for laying in such as will be of use for the purpose under consideration. *Conatia leptophylla*, *Asplenium adnigrum*, *Asplenium robusta*, *longifolia* and *rosmarinifolia*; *Euryia latifolia variegata*, *Bambusa Fortunei variegata*, *Acacia lophantha*, *Avatia crassifolia*, *quinquefolia* and *trifoliata*; *Aspidistra lurida variegata*, *Farfugium grande*, *Rhopala corcovadensis* and *elegans*, *Ficus elastica*—all these plants will succeed with ordinary greenhouse treatment as to soil, air, and water, and a mixture of good fibrous loam and peat in equal proportions, with a moderate addition of sand, will answer for them. They should not be grown in pots larger than necessary to support them in a healthy growing state without over-luxuriance, as, for the purposes they will be required, this would render them less calculated to keep in good condition; moreover, in such places as they will be wanted to do duty in, the pots are often

required to be plunged in others of an ornamental character, or in vases; so that an advantage to grow them in pots as small as will be secured by, to assist which liquid manures may with safety and advantage be given to all subjects of this character. As a small plant for indoor decoration *Isolepis gracilis* is very useful. It is easily increased, for a plant that fills a 6-inch pot moderately, will divide into a score of bits that in a season will make nice plants; it should be grown in quantity, and is very effective when stood in front of, and as means of hiding, larger pots—it drooping habit fitting it for such a position. *T. Baines.*

KITCHEN GARDEN.

Remove the protecting material from about the crowns of *Globe Artichoke* plants, and replace it with a mulching of manure about 3 inches thick. If the dressing of this estimable kind of vegetable was more commonly understood, it would be generally more extensively cultivated. Artichokes, when properly prepared, if only plain boiled and seasoned, are very delicious. To secure large heads of tender quality, which is the chief object, the soil should be rich, yet not so rich as to be indispensable, and well enriched soil where moisture abounds at the roots is also necessary for the plants to make growth. We seldom retain plants more than two years without shifting them. For ordinary purposes a new plantation should be made every spring at about this time; these plants will give a limited supply of heads this autumn, and produce them abundantly next season. In dividing the plants, different modes prevail; some prefer the suckers entirely cut from the old roots, and use the latter out, singly or otherwise; we, however, retain a part of the old roots, to sustain vitality in the suckers during the period new roots are being emitted, and choose pieces with three or four offsets on them, and displace others above this number. Plant rather deeply, about 4 feet apart every way, and mulch at once to prevent evaporation. *Kilbarb.*—Plantations of this should be seen to now, and any deficiency of roots through being lifted, or partial decay, should now be made good. The most private establishments that their supply is maintained by having recourse to a division of those roots which have been forced; if such were laid-in in the manner indicated in this Calendar, they will now be fit for planting out, and should be divided and transferred to the space set apart for the purpose—about 4 feet apart every way. Those roots which will be required to give an early supply next winter should not be plucked at all this season, but unrestricted growth allowed, so as to insure a mature development at the earliest period. This remark is also applicable to *Asparagus* and *Seakale* roots which are intended for the same purpose. Seakale roots which were cut into lengths, as before directed, will not be callused over, and should be planted in well prepared ground in rows about 2 feet apart and 1 foot asunder. Where the soil is strong and heavy, a coat of ashes half an inch thick on the surface will be beneficial. Where planting is preferred, sow at once in drills about the same distance apart as recommended for planting. Prick the surface of the beds over where the roots have been forced under pots, and apply a surface dressing of well decomposed manure. If not already done, complete expeditiously the planting out of autumn-sown *Cauliflower*, *Cabbage* and *Lettuce*, and the *Triplot* section of *Onions*. Make another sowing of the *Braessica* tribe about the middle of the month, and include that superb variety of autumn *Broccoli*, *Veitch's Autumn Giant*, and other kinds for spring use, amongst which may be named *Snow's Winter White*, *Frogmore* and *Knights' Protecting*, *Penzance*, *Chappel's Cream*, *Wilcove*, and *Mayer's Gigantic*. Sow likewise *Turnips* and round *Spinach* occasionally, also *Radish*, *Lettuce*, and *Mustard and Cress*, and the *Australian Cress*, which is most useful for salading at this season.

Peas and *Scarborough*.—These roots are very much esteemed at some places; where such is the case extra attention should be given to them by affording a place for them where the soil is deep and rich in manure. In sowing the seed, scatter it thinly in drills 18 inches apart and 2 inches deep. *Chicory*, the roots of which will be required for blanching for salading in the winter, should be sown in the same manner as *Turnips*; a few dozens of good roots of this is generally ample for ordinary requirements. When the plants of a former sowing of *Broccoli*, &c., are large enough to be handled, they should be thinned out in the seed-beds, or otherwise be pricked out into prepared beds, to secure a sturdy habit. Choose a sheltered situation, and make a sowing of *Celery*; those plants which are raised under barely conditions are preferable for the general planting to those which under other circumstances frequently become drawn up weakly. *Spargrows* are sometimes very destructive to the *Onion* crop, pulling up the plants as fast as they emerge from the soil. If so, place a few strands of flimsy twine across the beds; this invariably checks, if it does not stop them altogether.

LATE FORCING DEPARTMENT.—Continue, as ad-

vised, to ventilate freely whenever favourable all growing crops of vegetables which are in frames or pits. If necessary, water *Potatos* before sowing them up; too much of this element under these conditions will, however, deteriorate the flavour. Thin out later crops of *Carrots*, and plentifully supply them with moisture. Prick out *Celery* from seed-pans, and sow *Tomatos*, *Capsicums*, *Sweet Basil*, *Knotted Marjoram*, and *Summer Savory*. Pot *Tomatos* into fruiting pots, and remove all side growths; one stem is enough for plants in pots. *G. T. Mizez, Wycombe Abbey Gardens.*

The Weather.

STATE OF THE WEATHER AT BLACKHEATH, LONDON, FOR THE WEEK ENDING WEDNESDAY, MARCH 31, 1875.

Mar 25.—Fine, bright, partially cloudy, and very mild throughout. 26.—Fine, mild, and partially cloudy in morning. Overcast, and dull in afternoon and evening. 27.—Fine, bright, mild, and light clouds prevailed throughout the day. Smart showers of rain fell at 6.15 P.M. 28.—Fine, dull, cloudy, and mild throughout. 29.—Overcast, dull, mild, and nearly calm throughout. 30.—Overcast, mild, though bright at intervals throughout the day. 31.—Overcast, dull, and mild throughout. Fog in morning.

—In the vicinity of the metropolis the reading of the barometer at the level of the sea increased from 30.14 inches at the beginning of the week to 30.18 inches by the afternoon of the 21st, decreased to 30.07 inches by the afternoon of the 22d, then turned to increase to 30.38 inches by the morning of the 25th, and decreased to 30.03 inches by the end of the week. The mean daily readings were above their averages throughout the week. The mean reading for the week was 30.23 inches, being the same as that of the preceding week, and 0.26 inch above the average.

The highest temperatures of the air at 4 feet above the ground varied from 41° on the 21st to 56° on the 25th, the mean value for the week being 50°. The lowest temperatures of the air ranged between 31° on the 23d and 45° on the 26th; the mean for the week was 36°. The mean daily range of temperature in the week was 14°, varying from 6° on the 21st to 18° on the 24th. The mean daily temperatures of the air, and the departures from their respective averages, were as follows:—21st, 37° 4', -4° 4'; 22d, 30° 5', -2° 4'; 23d, 38° 1', -3° 0'; 24th, 40° 7', -1° 4'; 25th, 47° 4', +4° 7'; 26th, 48° 8', +6° 3'; 27th, 46° 2', +3° 5'. The mean temperature for the week was 42° 5', being 0° 3 above the average, as deduced from sixty years' observation.

The highest readings of a thermometer with blackened bulb in vacuo, placed on grass in the sun's rays, were 111°, 105°, and 103°, respectively, on the 21st, 26th, and 27th; but on the 21st 54° was the highest reading. The lowest readings of a thermometer on grass, with its bulb fully exposed to the sky, were 27° and 27° on the 22d and 23d, but on the 26th 41° was the lowest reading; the mean for the seven low readings was 31° 0.

The direction of the wind was variable, and its strength gentle.

The weather during the week was generally fine, mild, and cloudy.

Rain fell on two days; the amount collected was 0.20 inch.

In England, the extreme high day temperatures ranged between 64° at Sunderland and 51° at Bradford, the general average all over the country being 55°. The extreme low night temperatures varied from 38° at Liverpool to 25° at Eccles, with a general average of 30°. The mean of the extreme ranges of temperature in the week was 25°, the greatest range being 32° at Sunderland, and the least, 14°, at Liverpool. The mean high temperatures observed by day ranged from 54° at Sunderland to 48° at Liverpool and Leeds, with an average value of 50°. The mean low temperatures observed by

night varied between 41° at Liverpool and 34° at Norwich, the general average being 37°. The mean daily range of temperature for the week was 13°, ranging from 16° at Manchester to 7° at Liverpool. The mean temperature of the air for the week from all stations was 42°, being 4° lower than the value for the corresponding week in 1874; the highest occurred at Sunderland, 45°, and the lowest at Norwich, 40°. The average fall of rain during the week was five-hundredths of an inch; the amounts varied from two-tenths of an inch at Liverpool to one-hundredth at Sunderland; and at Birmingham and Wolverhampton, however, no rain fell.

The weather during the week was generally fine, mild, dull and cloudy.

Snow fell on March 21 at Manchester.

In Scotland, the highest temperatures ranged from 56° at Edinburgh and Perth to 53° at Greenock and Paisley, the general average over the country being 54°. The lowest temperatures varied between 35° at Glasgow and Leith and 30° at Paisley; the general average was 33°. The mean range of temperature in the week was 21°. The mean temperature of the air for the week was 45°, being 1° lower than the value for the corresponding week in 1874. The highest was at Edinburgh, 46°, and the lowest at Aberdeen, 44°. The fall of rain varied from five-tenths of an inch at Greenock to one-tenth at Aberdeen and Leith. The average fall over the country was three-tenths of an inch nearly.

Dublin, the highest temperature was 58°, the lowest 38°, the range 20°, the mean 47°, and the fall of rain 0.20 inch.

JAMES GLAISHER.

Enquiries.

He that questioneth shall learn much.—BACON.
44. SWEET NANCY.—I shall be glad if some of your correspondents will kindly inform me if there is such a flower as the "Sweet Nancy," or whether it is a local name for any flower. *E. F.*

Answers to Correspondents.

ALOCASIA MACROCARPA VARIEGATA. *Notes.* Take off the top and strip it in the most heat, of course. If the roots are healthy you will also get cuttings from the old stem. As the plant has very fleshy stems, take care they do not rot.

BOOKS: *A Young Beginner*. Your first question is so vague that we cannot answer it. You may obtain a cheap gardeners' dictionary (Johnson's) from Messrs. Daldy & Sons, York Street, Covent Garden, W.C.—*W. T. E.* Write to Mr. E. H. May, 171, Fleet Street, E.C., for the book you want.

CAMELLIAS: *G. L. A.* Certainly, to be "always in the habit of cutting Camellia flowers freely especially in the case of young plants, injures them greatly. When the plants attain to some size and bloom sparingly, then only may the flowers be cut constantly. Why not have resort to the expedient practised by gardeners for market, viz., remove the blooms without cutting the wood, and wire the flowers, by fixing two wirecross-wires through all the petals and thus forming an artificial stalk with the four ends underneath? *W. E. CREEPER: Subscriber.* *Tasconia Van Volxemii*, or *Lagerania rosea*.

FROST-PROOF: *Fudge*. From your report we are inclined to believe that the tops or branches of your large trees are dead. The roots are somewhat on the move, and shoots may be produced from the bottom of the stem. It is this that has caused the bursting of the stem. Below the sap is still active, above it is dried up. The application of heat so soon after planting such large trees was injurious; they ought to have been allowed to break gently of their own accord; even now do not excite them too much until the roots have taken possession of the soil. You need not thin the young fruits on young trees; they generally do that sufficiently of themselves.

FROST-PROOF: *Fudge* raises some objections to a recent statement in a leading article. The expression "frost-proof" is, it is true, liable to misapprehension. The word of no particular import, but the object was never frost-secure under such copings as described in the article in question, while those not so protected were destroyed. This safety was reached through or by the copings, hence the expression "frost-proof." Doubtless the copings do moderate the energy of radiation, especially by when surrounded with white wash; and they likewise surround the blossoms with conditions more favourable for resisting cold. Putting together the cold they resisted, the heat they conveyed, and the increased power of endurance with which they furnished the blossoms, *Fudge* may easily discover the causes of the success of glass copings as protectors of fruit tree blossoms.

FUMIGATOR: *Notts.* Drescher's fumigator may probably be had of some of the London seedsmen who lay themselves out for the supply of horticultural requisites. We do not give prices, but we believe it is not a very expensive article.

FUNGI: *A. Hayter, Salisbury.* Your specimens belong to a coarse variety of the Horse Mushroom; there is nothing special about them, except that they are growing in a somewhat odd place and a little out of season.

HOW TO CLEAN CIDER BARRELS: *N. X.* The *English Mechanic* gives the following directions:—

Pour in lime-water, and then insert a trace chain through the bung-hole, remembering to fasten a strong cord on the chain, so as to be able to pull it out again. Shake the barrel until all the mould inside is rubbed off. Rinse with water, and finally pour in a little whiskey.

MUSHROOMS: Subscriber. How to Grow Mushrooms, by W. Earley (Bradbury, Agnew & Co.).

NAMES OF PLANTS: A. Bennett, 1, Veronica longifolia; 2, Centaurea, next week; 3, Sisymbrium Irioides; 4, Rumex pulcher, probably; 5, Valeriana officinalis; 6, Iberis pinnatifida, var.; 7, Atriplex patula, var. — W. Ingle. Echeveria fulgens, sometimes called E. retusa and E. splendens. — J. H. S. The white variety of Scilla bifolia. — Mrs. Charles Maynard, 1, Narcissus minimus; 2, Rhododendron dauricum; 3, Daphne Mezereum album. — E. G. Pinus Finaster. — T. H. Kennedy rubicunda (Australia). — A. Bennett. We are unable to name the Centaurea without better specimens. — Mrs. Bartlett. Polystichum angulare grandiceps; and a Diplazium which is too young for determination. — Gardner, Notts. Selaginella erythropus.

PAMPAS-GRASS: A Very Old Subscriber. — We cannot tell you how to clear out the old growth without pulling the plants to pieces. For our own part, we should most certainly let such a fine plant alone.

PARROT'S STRIP: A Very Old Subscriber. We know nothing about the stove you mention.

PAXTON'S CALENDAR: Cantab. Paxton's Cottagers' Calendar may be had from our publisher, for 4d., post free.

POTATO EXHIBITION: A Potato Grower writes to suggest that the intended exhibition should be held in the Royal Horticultural Society's Gardens, South Kensington, on the same day as the fungus show, — October 6. Our correspondent should have sent his suggestion to the committee of management, but we do not think that body would be likely to act upon it, as some at least of the promoters are not satisfied with the way in which the Society has treated the "noble tuber."

RABBITS INJURING YOUNG TREES: D. S. A mixture formed of coal-tar (three parts, laid one part, and flowers of sulphur one part, boiled together and applied, will deter these rodents from nibbling the bark. Why not stretch few Ash branches around the young plantations, as rabbits greedily prefer partly dried bark, and that of the Ash in particular. W. E.

Markets.

COVENT GARDEN, April 1.

Although we have a light supply, it is equal to the demand at present, business generally being quiet during the holidays. Another large cargo of St. Michael Pines of fair quality is to hand, and we hear of more to arrive during the ensuing week. Some new Grapes have been offered from Jersey, and a slight improvement has taken place in those supplied by our home growers. Thos. Taylor, Wholesale Apple Market.

FRUIT.

Apples, per 1/2-sieve 2 s. 0 d.
Oranges, per 100 2 s. 0 d.
Chestnuts, per bush, 10 s. 0 d.
Grapes, English, per bush, 4 s. 12 d.
— foreign, do. 1 s. 6 d.
Lemons, per 100 8 s. 12 d.
Medlars, per doz. 1 s. 6 d.
Nuts, Cob, p. lb. 2 s. 0 d.

VEGETABLES.

Artichokes, Fr., doz. 4 s. 0 d.
Asparagus, English, per bundle 8 s. 12 d.
Beans, French, p. 100 6 s. 0 d.
Beet, per doz. 1 s. 0 d.
Broccoli, p. bundle 9 s. 12 d.
Butter Beans, p. bush 9 s. 0 d.
Cabbages, per doz. 1 s. 0 d.
Carrots, p. bundle 2 s. 0 d.
Cauliflowers, per doz. 2 s. 0 d.
Celery, per bundle 1 s. 6 d.
Cucumbers, each 1 s. 6 d.
Endive, per doz. 1 s. 0 d.
Herbs, per bunch 2 s. 0 d.
Potatoes.—Early Shaws, 110s.; Early Regents, 120s.; and Early Downs, 120s. per ton.

SEEDS.

LONDON: March 31.—In consequence of the recent fine weather, we have now a very brisk demand for agricultural seeds. Considerable quantities of red Clover seed are being sold into the country at full prices, consequently stocks in London are getting into very narrow compass. Of large purple-horned red there is but little offering. White Clovers grow in steady request at last week's currencies. Alsike is neglected at a still further decline. A large business on former terms has been doing in Trefoil seed. For foreign Italian and Scotch Rye-grasses there is an improved demand. Spring Tares experience an active inquiry at hardening prices. In white Mustard and serving Rape seed quotations tend upwards. Taken Shew & Sons, Seed Merchants, 37, Mark Lane, E.C.

DAHLIAS.

JOHN KEYNES
Has the finest COLLECTION of DAHLIAS in the WORLD, Old and New.

Amateurs will be treated most liberally. CATALOGUES NOW READY. The NEW VERBENAS raised by ECKFORD now ready.

Dahlia will be sent out the first week in May. A VERY SELECT LIST OF THE NEW ROSES. Plants now ready. SALISBURY.—April 2, 1875.

New Roses.—Strong Plants now Ready. JOHN FRASER, of the Lea Bridge Road Nurseries, Essex, has much pleasure in offering strong plants of the following carefully selected varieties of NEW ROSES for 1875, which may be relied on as being the best of this year:—HYBRID PERPETUAL ROSES.

- Adanson Hippolyte Jamin
Arthur Oger La Souveraine
Antoine Mouton Madame Rougier
Casimir de Sansal Mademoiselle Ileana de Adorjan
Cosnel Perier May Turner
Comtesse de Seresoy Mons. E. V. Teas
Duchess of Edinburgh Princess Antoinette
Gonsoli Gaetano Souvenir du Baron de Samur.
Henry Ward Becher

TEA-SCENTED ROSES. Aline Sisley Marie Guillot
Duchess of Edinburgh Mademoiselle Therese Genevay
Jean Ducher Perle des Jardins.

PERPETUAL MOSS ROSE. ALICEA, Souvenir of Nottingham.

LIST, with full descriptions of above, may be had on application.

To Planters and the Trade. MESSRS. MASTERS AND KINMONT beg to call the attention of Planters and the Trade to their stock of the following trees, which can be furnished at low prices:—

- LIMES, 7 to 9 feet, clean grown.
THORNS, of sorts, Standard and Pyramid, including Double and Single.
ASH, Weeping, 6 to 10 feet stems, good heads.
WILLOWS, Weeping, American, Babylonian, and Kilmar-ELMS, of sorts, graded, 5 to 7 feet, including Huntingdon, distinguished, and cork bark.
BIRCH, 8 to 10 feet.
PHILADELPHUS, of sorts.
ALGEBRA, of sorts.
LILAC, of sorts.
OAK, Scarle, 6 to 8 feet.
YUCCA RECURVA, very fine.
ROSES, Standard and Half-Standard.
Dwarf, on Manetti.
CURRANTS, Black.
GOOSEBERRIES, of sorts.
ABIES CANADENSIS, 3 to 5 feet.
ALGEBRA JAPONICA, 2 1/2 to 4 feet.
CUPRESSUS SEMPERVERENS, 2 1/2 to 4 feet.
Exotic and Vauxhall Nurseries, Canterbury.

COCOA-NUT FIBRE REFUSE (newly made), 3d. per bushel, 20s. per 100 bushels, 45s. per 300 bushels. Larger quantities contracted for. J. STEVENS, Fibre Works, High Street, Battersea, S.E.

COCOA-NUT FIBRE REFUSE, 3d. per bushel; truck holding 300 bushels, 45s. free on rails from Messrs. Ewing & Co., Royal Norfolk Nurseries, Norwich:—"Your refuse is of first-rate quality." From Mr. E. Hollanby, The Nurseries, Groombridge, Tunbridge Wells:—"The five trucks refuse offered. It is highly satisfactory." For plunging and forcing your refuse is invaluable."—H. WRIGHT, Steam Fibre Works, Henagee Street, Brick Lane, London, E.

PEAT.—A few hundred tons of a SUPERIOR quality delivered at the Blackwater or Farnborough Stations for 17s. a ton. Apply to W. TARRV, the "Golden Farmer," Bagshot, Surrey.

Fibrous Peat. BROWN FIBROUS PEAT, best quality, for Orchids, Stove Plants, and Potting, 4/6 per Six-ton Truck-load. BLACK FIBROUS PEAT, for Rhododendrons, Azaleas, Heaths, New Holland Plants, &c., 4/6 per Six-ton Truck-load. Delivered on rails at Blackwater, South-Eastern Railway, or Farnborough South-Western Railway. WALKER and CO., Farnborough Station, Hants.

Sphagnum, or Peat Moss, for Orchids. FRESH SPHAGNUM MOSS, 10s. 6d. per sack. WALKER and CO., Farnborough Station, Hants.

To Propagators and Plant Growers. The most useful material for the attainment of successful and rapid culture is

COCOA-NUT FIBRE REFUSE.—Price 12s. per bushel, or 6d. per bushel for quantities of 20 bushels and over. DAGNALL and TILBURY, Steam Cocoa-nut Fibre Works, Farn Lane, Waltham Cross, S.W.

MILLER and JOHNSON (ESTABLISHED 1853) Manufacture the highest quality of ARTIFICIAL MANURES FOR ROOT, CORN, and GRASS CROPS. 36, Mark Lane, London, E.C.

THE LONDON MANURE COMPANY

(ESTABLISHED 1820) Have now ready for delivery, in fine dry condition— CORN MANURE, for spring sowing. PURE DISSOLVED SUPERPHOSPHATE, in solutions PURSER'S BONE MANURE. PURSER'S BONE TURNIP MANURE. SUPERPHOSPHATE, in solutions. NITROPHOSPHATE. NITRATE of SODA, SULPHATE of AMMONIA, Genuine FERROUS GUANO, &c. &c. Acres of Land. 116, Fenchurch Street. PURSER, Secretary.

ODAMS' MANURES

Manufactured by the NITRO-PHOSPHATE and ODAMS' CHEMICAL MANURE COMPANY (LIMITED), consisting of Teant-Farmers occupying upwards of 150,000 Acres of Land. Chairman—ROBERT LEEDS, Castle Acre, Norfolk. Managing Director—JAMES ODAMS. Sub-Manager and Secretary—C. T. MACADAM. CHIEF OFFICE—109, Fenchurch Street, London, E.C. WESTERN COUNTIES BRANCH—Queen Street, Exeter. Particulars will be forwarded on application to the Secretary, or may be had of the Local Agents.

GISHURST COMPOUND.—Used by many of the leading gardeners since 1859, against Red Spider, Mildew, Thrips, Greenfly, and other Insects, in solutions of from 1 to 2 ounces to the gallon of soft water, and of from 4 to 6 ounces as a winter dressing for Vines and Fruit Trees. Has outlived many preparations intended to supersede it. Sold Retail by Seedsmen, in boxes, 12, 3s., and 10s. 6d. Wholesale by PRICE'S PATENT CANDLE COMPANY (LIMITED).

SIMPSON'S RED SPIDER, THRIP, and GREENFLY KILLER is now extensively used, and may be had through all Seedsmen and Chemists. A "valuable discovery." Sufficient for the worst case of Red Spider diluted at the rate of one quart to 65 gallons of water. Price per quart, 6d. Prepared by JOHN KILNER, Wortley, near Sheffield. Important Testimonials on application.

RUSSIA MATS.—A large stock of ARCHANGEL and PETERSBURG, for Covering and Packing—Second stock ARCHANGEL, 200s.; PETERSBURG, 60s. and 80s. superior close Mat, 45s. 20s., and 55s. PACKING MATS, 20s., 30s., and 35s. per 100; and every other description of MATS at equally low prices, at J. JACKBURN and SONS, Russia Mat and Sack Warehouse, 4 and 5, Wornwood Street, E.C.

RUSSIA MATS, for Covering Garden Frames.—ANDERSON'S TAGANROG MATS are the cheapest and most durable. Price List, which gives the very latest and most superior class of Taganrogs, on application. JAS. T. ANDERSON, 7, Commercial Street, Shoreditch, London, E.C.

E. T. ARCHER'S "FRIGI DOMO." Patronised by Her Majesty the Queen for Windsor Castle and Frogmore Gardens, the late Sir J. Paxton, and the late Lord Lindesay. MADE OF PREPARED HAIR and WOOL.

A perfect non-conductor of heat or cold, keeping a fixed temperature where it is applied. A good covering for Pits and Forcing Frames. PROTECTION FROM COLD WINDS and MORNING FROSTS.

"FRIGI DOMO" NETTING, 2 yards wide, 12s. 4d. per yard. "FRIGI DOMO" CANVAS— 3 yards wide .. 12s. 10d. per yard run. 2 yards wide .. 12s. 2s. per yard run. 4 yards wide .. 13s. 10d. per yard.

ELISHA T. ARCHER, only Maker of "Frigi Domo," and of the "Brick and Iron Road," Brick Lane, London, S.E.; and of all Florists and Seedsmen. All goods carriage paid to London. NOTICE.—REMOVED FROM 3, CANNON STREET, CITY.

MARENDAZ and FISHER, RUSSIA MAT MERCHANTS, Importers of RAFFIA FIBRE, &c., Manufacturers of TWINES, TIFFANV, NETTING, &c., 9, Jubilee Street, Covent Garden, London, W.C. — A large quantity of Lined NETTING for Fruit Trees, &c., in stock.

MILDEW.—Ewing's Infalible Cure. ("The Finest of all antides.") Wm. EARLEY. Retail of most Packings at 12s. 6d. per bottle—12s. 10d. per bottle, if packed for travelling, of the Manufacturers. EWING and CO., Norwich.

SHAW'S TIFFANY and ELASTIC NETTING for Studding and Protecting. Sold by all respectable Seedsmen. For Circulars and Prices apply to JOHN SHAW and CO., Tiffany Manufacturers, 29, Oxford Street, Manchester. Labels—Labels.

PARCHMENT or CLOTH LABELS, TREE or PLANT LABELS. Punched Paper, 4 inches long, 1/2 inch wide, 2s. per 1000. If cycled, 4s. per 1000. Vellum Cartridge, 4 inches long, 3/4 inch wide, 10s. per 1000. Sample Labels sent on receipt of Postage Stamp. Orders answered in London. JOHN FISHER and CO., Label Works, Boston.

Indestructible Terra-Cotta Plant Markers. MAW and CO'S PATENT.—Prices. Printed Patterns, and Specimens, sent free on application; also Patterns of Ornamental Tile Pavements for Conservatories, Entrance Walks, &c. MAW and CO., Benthall Works, Broseley.

Reduced Prices. THE CELEBRATED GRANITIC PAINT. Manufactured Solely and Only by the Silicate Zopissa Composition and Granite Paint Company. For Price Lists, Testimonials, and Patterns of Colours, apply to THOMAS CHILD, Manager, 39A, King William Street, London, E.C.

THE SILICATE ZOPISSA COMPOSITION TO CURE DAMP in WALLS, and PRESERVE STONE, &c., from DECAY, at a very trifling cost. Manufactured Solely and Only by the Silicate Zopissa Composition and Granite Paint Company, Colourless, and in all Colours. For particulars and Testimonials, apply to THOMAS CHILD, Manager, 39A, King William Street, London, E.C.

SAVE YOUR COAL BILLS,

BY ADOPTING

MESSENGER & COMPANY, CONTRACTORS, MIDLAND HORTICULTURAL BUILDING AND HOT-WATER ENGINEERING WORKS, LOUGHBOROUGH,

Reg to inform their numerous Patrons and the Public generally, that since the recent disastrous fire they have erected new, more extensive, and commodious works, fitted with the best steam-power machinery, for the construction of Horticultural Buildings in wood or iron, plain or ornamental, of any required dimensions. I. G. MESSENGER & Co. are now, therefore, in a position, from their great facilities and experience, to carry out with dispatch and in the best manner, at moderate cost, the orders with which they may be entrusted. Glasshouses erected on Messenger's Patent principles are, owing to mechanical arrangements, very strong, most durable, light, elegant; perfect efficiency for purpose intended is guaranteed, are economical in cost and maintenance. Hot-water engineering in all its branches, Messenger's Patent Hot-water Boilers, Flexible Jointed Hot-water Pipes and Valves, are now in use in many thousands of instances, with the greatest success. Particulars on application. Plans and Estimates forwarded. Ladies and Gentlemen waited upon. The Plans of Architects and others carried out.

PRICE LIST on application; or, Six Stamps for DESCRIPTIVE CATALOGUE, 4th Edition;

VIENNA PRIZE WIRE NETTING.

Awarded The Medal For Merit

At Vienna, 1873.

CAUTION TO BUYERS OF WIRE NETTING.

The great reputation and success of Messrs. J. B. BROWN AND CO.'S VIENNA PRIZE WIRE NETTING seem to have induced certain Dealers in Wire Netting to advertise an inferior article at reduced prices, specifying the mesh, gauge, &c., as if such were the same in quality and value as the Prize Wire Netting of which Messrs. J. B. BROWN & Co. are the SOLE MANUFACTURERS.

Messrs. BROWN & Co. would suggest that, before ordering quantities, one roll of their Wire Netting should be ordered and one roll of that advertised at reduced prices. The size and shape of the mesh may then be examined, the thickness or strength of wire, the weight of the rolls and the exact measurements, the general finish of the manufacture, and the quality of the galvanising.

This examination will prove the respective qualities of the Netting. 90, Cannon Street, London, E.C.—March 12.

NETTING FOR FRUIT TREES, SEED BEDS, RIPE STRAWBERRIES, &c.

TANNED NETTING for protecting the above from Frost, Blight, Birds, &c., 2 yards wide 36. per yard, or 100 yards, 20s.; 4 yards wide, 6d. per yard, or 50 yards, 10s.

NEW TANNED NETTING, suited for any of the above purposes, or as a Fence for Poultry, 2 yards wide, 6d. per yard; 4 yards wide, 1s. per yard; 1/2-inch mesh, 4 yards wide, 1s. 6d. per yard. TIFFANY, 6s. 6d. and 7s. 6d. per piece of 20 yards. EATON and DELLER, 6 & 7, Crooked Lane, London Bridge.

Thomas' Pea and Seed Guards.

Reduced Prices for the remainder of this Season.

SUPERIOR QUALITY. GALVANISED AFTER MADE.

NEW PATTERN with Diagonal Stays.

No. 76. 3 feet long, 6 inches wide, 6 inches high.

THE DIAMOND PATTERN, With one Longitudinal and two Cross Stays.

No. 80. 3 feet long, 6 inches wide, 6 inches high.

Both of the above patterns 9s. per dozen. Two end-pieces included with each dozen.

Having a large Stock of the above, Orders can be executed on receipt.

Illustrated and Priced Catalogues of Horticultural Wire-work on application.

J. J. THOMAS & CO.,

PADDINGTON WIREWORKS,

285 and 362, EDGWARE ROAD, LONDON, W.

P. O. Orders to be made payable at 310, Edgware Road

RALPH WALLER AND CO.,

45, Dale Street, Manchester, MANUFACTURERS OF all kinds of GARDEN NETTING, &c.

The serious injury done every spring to Fruit Crops by frost has proved to every Gardener the absolute necessity of providing some Protection to the Trees early in the year. If the blossom in its earliest development be but slightly weakened by frost, the vitality of the fruit-germ is destroyed, and the fruit lost. In this climate, on the average of a century, there is not more than one year in nineteen when the protection is unnecessary. Many fabrics have been tried for this purpose of protection, with more or less success; and we may now say, without fear of contradiction, that we have succeeded in manufacturing the only fabric which is altogether unobjectionable for this purpose. Without unduly surmising, it effectually protects the young germ, and does not impede the action of light and due circulation of air. Some other fabrics do this, and thus weaken the vitality of the tree altogether. Almost every large grower in the three Kingdoms can testify to these facts.

HOTHOUSE SHADING of various thicknesses, superior to any other yet discovered for lightness, strength and durability, standing, as it does, all weathers.

Testimonial from ROBERT WARNER, Esq.

"I have had the netting No. 6 on my Orchard-house for eighteen months, and I find it now in very good order, and likely to last as many more months, and I intend to use it on all my houses in future, being well satisfied both as to its lasting qualities and also as to the shade it gives, which is sufficient to prevent burning, and yet not thick enough to keep out the light, as the ordinary strong shading stuffs do; indeed, it is suitable for shading any kind of plants."—Brookfield, Feb. 13, 1871.

TIFFANY of various kinds always on hand. NETTING and SHADING, in pieces 20 yards long, 1 1/2 yard wide. TIFFANY, in pieces 30 yards long, 2 1/2 inches wide. For prices, &c., apply to the above address. 45, Dale Street, Manchester.

SINGLE MACHINES ARE DELIVERED FREE.

Important to Market Gardeners and Others.
THE PATENT HAND GARDEN PLOUGH.

This effective little implement meets a long-felt want. It consists of one light but strong steel shovel, for marking out rows to plant, or for loosening up the ground after the plants are up. Also a small Steel Plough, to be used for hilling up the rows when desired; and a Cutter for exterminating weeds, and Rake for pulverising the ground. These pieces are made separate, and attached or detached in a moment by means of a simple fastening. Its construction enables the user to push it readily and easily through the ground, stirring the earth, if required, to a depth of six inches. It is exceedingly light, strong, and tasty, and fully adapted to the purposes designed. A large number have been sold, and are giving unqualified satisfaction.

Price, complete, with Shovel, Plough, Weed-Cutter, and Rakes, £2 2s.

FOLLOWS & BATE, Makers, Dutton Street Works, MANCHESTER.

BOULTON & PAUL (LATE W. S. BOULTON & CO.), NORWICH, HORTICULTURAL BUILDERS AND HOT-WATER APPARATUS MAKERS.

Improved Steam-power Machinery for working wood enables us to supply first-class Horticultural Buildings of every description at very low prices. Only the best materials used. Houses designed to suit any situation. Estimates given Free. Gentlemen are respectfully invited to have price from us before ordering elsewhere. Ladies or Gentlemen requiring advice as to the Situation, Style, Dimensions, &c., of proposed Horticultural Buildings, waited upon in any part of England, Ireland, or Scotland.

Our NEW ILLUSTRATED CATALOGUE OF HORTICULTURAL BUILDINGS, containing upwards of 60 Engravings of Conservatories, Greenhouses, Peach Houses, Forcing Houses, &c., Free by Post for 12 stamps.

BOULTON & PAUL'S PATENT UNIVERSAL PLANT PRESERVERS—GREAT IMPROVEMENTS for 1875.

The Judges at the Royal Horticultural Society's Great Meeting lately held at Birmingham, pronounced these to be by far the best and most useful articles of the kind they ever saw, and awarded them the ONLY PRIZE.

Now Ready, our NEW LIST of PRICES, containing full description and a number of Woodcuts clearly showing the uses to which these handy articles may be applied. Free by Post.

PATENT UNIVERSAL PORTABLE PLANT PRESERVERS AND GROUND VINERIES.—Instead of having to remove or slide loose glass every time it is necessary to attend to the plants, we attach the glazed lights (21-oz.) with hinges to the frame of each light, thereby doing away with continual breakage of glass and loss of time. Two men can instantly remove a complete length, 12 feet by 3 feet wide: thus proving them to be really portable.

PATENT UNIVERSAL PLANT PRESERVERS, Large Sizes to Build on Brick Walls, for use as Span-roof Pits, suitable for Forcing, Propagating, Growing Cucumbers, Melons, and a variety of other things too numerous to mention. *Far superior to anything of the kind yet offered.*

OPINIONS OF THE PRESS.

GARDENERS' CHRONICLE, February 6, 1873.

The uses to which such frames can be put are fully recognised by practical gardeners, and if any notice can be taken of the great demand arising for such contrivances amongst amateurs, it would appear that they too are not ignorant of their great value.

FLORAL WORLD.

The Ground Vinery which has the greatest advantages is unquestionably that manufactured by W. S. Boulton & Co.

MELON OR CUCUMBER FRAMES.

All sizes (glazed with 21-oz.) ready for immediate delivery.

Height at back, 24 inches; at front, 13 inches; sides, 1½ inch thick; lights, 2 inches thick. All made of very best red deal. Painted three coats. Every pane of glass is nailed as well as puttied in. Each light is provided with an iron strengthening rod and handle.

Glazed with 21-ounce.

GARDENERS' MAGAZINE, May 25, 1872.

Considering their substantial character, portability, and the many ways in which they may be employed, we anticipate a very large demand when they become generally known.

THE GARDEN.

Every convenience is provided to save time in cases of removal, planting, watering, and giving air. The glass is firmly fixed and puttied—an essential point. They are complete and ready for use the moment they are received, &c.

WANTED, TWO good NURSERY LABOURERS: state wages, reference, and age.—Also a CARTER.—**GEORGE J. WOOLLETT**, Nurseries, Cosham, Surrey.

WANT PLACES.

To Gardeners in Want of Situations, WHOSE CHARACTERS WILL BEAR STRICT INVESTIGATION. **THE PINE-APPLE NURSERY** has the pleasure to offer special attention to this important matter—proper Men to be put into Situations, or GARDENERS, or for a SITUATION, please send full particulars to Mr. JOHN BESTER, the Pine-Apple Nursery Company, Haida Vale, London, W.

B. S. WILLIAMS, having at the present time several very excellent GARDENERS upon his Register, is desirous of placing them in Situations where good experience and trust are required. B. S. W. would at the same time beg to intimate that when a Gardener is applied for that the filing of the situation should be left with him, so that he could prevent unnecessary correspondence and delay.—Victoria and Paradise Nurseries, Upper Holloway, London, N.

Head Gardeners. JOHN LAING can at present recommend several very creditable and practical Men, of tested ability and first-rate character. Ladies and Gentlemen in WANT of GARDENERS and BAILIFFS, or GARDENERS for first-rate Establishments or Single-land or Stands for Park and Rural Park Nurseries, Forest Hill, London, S.E.

Gardeners and Under Gardeners. W. M. CUTBUSH AND SON beg to state that they have at all times on their Books MEN of VARIOUS QUALIFICATIONS, whose characters will bear the strictest inquiry. Any Gentleman making application would save time by clearly stating the duties to be undertaken, wages offered, &c., so that suitable Men may be selected.—Highgate Nurseries, London, N.

GARDENER (HEAD).—Age 26, single; has a good practical knowledge of Flower and Kitchen Gardening, and Stove, Fruit, and Green Houses.—A. L., 18, Bedford Place, Old Dover Road, Blackheath, S.E.

GARDENER (HEAD).—Age 34, married; thoroughly practical, understands Gardening in all its various branches. Can be highly recommended. Twelve years' character.—**GARDENER**, Stoke Common, Slough.

GARDENER (HEAD).—Age 35, married; thoroughly competent. Would undertake Management of Land and good character.—G. L., Mr. Wm. Paul, Nurseries, Waltham Cross, N.

GARDENER (HEAD).—Age 38, married.—R. GRAY, Gardener to E. Tonks, Esq., is at liberty to engage with any Lady or Gentleman requiring a thorough Gardener of great experience in all Departments. First-class certificates from present and former employers.—R. GRAY, Puckwood Grange, Knowle, Warwickshire.

GARDENER (HEAD).—Age 40, married, Scotch; understands Vines, Pines, Early and Late Forcing of Fruit and Vegetables, and can take the Management of Land. Good character.—W. F., Post Office, Ascot, Staines.

GARDENER (HEAD).—Age 48, married, no incumbency; thoroughly understands the profession. Management of Land if required.—J. W., 2, Grove Cottages, Mill Road, Carshalton, Surrey.

GARDENER (HEAD), where two or more are kept, to any Lady or Gentleman requiring the services of a thoroughly competent Man.—Age 30, no incumbency; has had successful Exhibitions of Plants, &c. A comfortable and good situation is more desired than a high salary. Five years' good character.—S. H. R., Elneswood, Sevenoaks, Kent.

GARDENER (HEAD), where one or two are kept. Age 34, married, small family; thoroughly understands the profession in all its branches. Four years' good character. Wife no objection to the Management of Poultry or Fruit.—T. BARBEK, Bandon Hill, Beidington, Croydon, Surrey.

GARDENER (HEAD), to any Nobleman or Gentleman requiring the service of a good practical Man.—Age 30, married; understands the Growing of Fruits, Flowers, and Vegetables. Good references as to abilities, &c.—J. WILSON, Allington Hill Gardens, Grantham.

GARDENER (HEAD), to any Lady or Gentleman requiring the services of a thoroughly practical Man.—Age 30, married. Eleven years' good character from present employer.—B. W., Grove House, Twyford, Berks.

GARDENER (HEAD).—Married, one child; a good practical Working Man, of great experience in the Growing of all kinds of Plants, Grapes, Melons, Cucumbers, Kitchen Gardening, Pleasure Grounds, Stock, &c. Wife good Dairywoman. Good personal character from present employer.—D. H. RUSHETT, Faversham, Kent.

GARDENER (HEAD).—Scotch; thoroughly acquainted with the general routine of Hotheuses, Kitchen and Pleasure Grounds, Fruit, and Flower and Poultry and Fish Culture. Can produce first-class testimonials from leading places in Scotland, England, and Ireland.—I. M., 2, Henderson Place, Bonnington, Leith, Edinburgh.

GARDENER (HEAD, or good SINGLE-HANDED).—Age 31, married, two children; thoroughly understands all kinds of Greenhouses, Plants, and Flower and Kitchen Gardening. Good personal character.—**GARDENER**, Cromwell House, Havering, near Romford.

GARDENER (HEAD, WORKING).—Age 27, married; understands the Growing of Fruits, Flowers, Plants, &c., and the General Management of a Garden. Can be well recommended.—**GEORGE MORRISON**, 53, Trafalgar Street West, Scarborough.

GARDENER (HEAD, WORKING).—Age 30; understands Forcing, Vines, Stove and Greenhouse Plants, and the general routine of Flower and Kitchen Gardening. Good references.—R. T., 10, Swain's Lane, Highgate, N.

SHOPMAN, or TRAVELLER.—Has for many years travelled the Midland Counties, Lancashire, and Yorkshire, North and South of Scotland, and Ireland; is well known among Gardeners, Stewards, &c. would be glad to travel with any House to open up a connection over the above ground.—B. D., *Gardener's Chronicle* Office, W.C.

KINAHAN'S LL WHISKY. This celebrated and most delicious old mellow spirit is the very CREAM OF IRISH WHISKIES, in quality unrivalled, perfectly pure, and more wholesome than the finest Cognac Brandy. Note the Red Seal, Pink Label, and Cork Brand.—Kinahan's LL Whisky. Wholesale Depot, 20, Great Titchfield Street, Oxford Street, W.

Grateful-Comforting. E P P S C O C O A.

By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected Cocoa, Mr. Epps has provided our breakfast-tables with a delicately flavoured beverage, which may save many a life, and which will do more to make us healthy than any article of diet that a constitution may be gradually built up until strong enough to resist every tendency to disease. Hundreds of subtle maladies are floating around us, ready to attack wherever there is a weak point. We may escape many a fatal shaft by keeping ourselves well fortified with pure blood, and a properly nourished frame." See article in the *Civil Service Gazette*.

Made simply with boiling water or milk. Sold in packets (in tins) by **JAMES EPPS AND CO., HOMOEOPATHIC CHEMISTS**, 48, Threadneedle Street, London, W. **Wholesale**—**Easton** King, 17, Old Bailey, London, E.C. **Makers** of Epps's Glycyrrine Juleps for Throat Irritation.

DINNENFORD'S FLUID MAGNESIA.

DR. LOCKOCK'S PULMONIC WAFERS.

"I shall always consider it my duty to recommend them as a safe and effectual remedy for coughs and chest complaints (Scurvy) Croup, Hoarseness, Sore Throat, Manchester. In Asthma, Consumption, Bronchitis, Coughs, Colds, Rheumatism, and all Hysterical and Nervous Pains, instant relief is given.—Sold by all Druggists at 1s. 1/6d. per box.

GREEN'S PATENT "SILENS MESSOR" & "ROYAL,"

Or NOISELESS LAWN MOWING, ROLLING, AND COLLECTING MACHINES for 1875.

The Winners of Every Prize in all Cases of Competition.

PATRONIZED BY
HER MOST GRACIOUS MAJESTY THE QUEEN
On numerous occasions,

H.R.H. THE PRINCE OF WALES, The KING of the BELGIANS,
The Late EMPEROR of the FRENCH,
The EMPEROR of RUSSIA.
And most of the Nobility, Clergy, and Gentry in the United Kingdom.

Upwards of 75,000 of the above Machines have been Sold since the year 1856.

They have been submitted to numerous practical tests in Public Competition, and in all cases have carried off every Prize that has been given.

The following are their advantages over all others:—

- 1st. Simplicity of Construction—every part being free of access.
- 2d. They are worked with far greater ease than any other.
- 3d. They are the least liable to get out of order.
- 4th. They make little or no noise in working.
- 5th. They will cut either long or short Grass, and wet as well as dry.

SINGLE AND DOUBLE-HANDED LAWN MOWER.

To cut	8 inches	10 "	12 "	14 "	16 "
Can be worked by a Lady.	£ 2 10 0				
" 10 " Ditto.	3 10 0				
" 12 " Can be worked by one Person.	4 15 0				
" 14 " Ditto.	5 16 0				
" 16 " Can be worked by one Person on an even Lawn.	6 17 0				

To cut	18 inches	20 "	22 "	24 "
Can be worked by a Man and Boy.	£ 8 0 0			
" 20 " Ditto.	8 10 0			
" 22 " Ditto.	9 0 0			
" 24 " Ditto.	9 10 0			

Prices of Horse, Pony, and Donkey Machines, including Patent Self or Side Delivery Box; Cross-stay complete; suitable for attaching to Ordinary Chaise Traces or Gig Harness:—

DONKEY AND PONY MACHINES.

To cut 26 inches	£ 45 0 0
" 28 "	17 0 0
" 30 "	13 10 0
Leather Boots for Donkey	1 0 0
" " Pony	1 4 0

HORSE MACHINES.

To cut 30 inches	£ 22 0 0
" 36 "	25 0 0
" 42 "	30 0 0
" 48 "	34 0 0
Leather Boots for Horse	1 9 0

The 26 and 28 inches can easily be worked by a Donkey, the 30 inches by a Pony, and the larger sizes by a Horse; and as the Machines make little noise in working, the most spirited animal can be employed without fear of its running away, or in any way damaging the Machines.

GREEN'S PATENT "ROYAL" LAWN MOWER.

The special features of this Machine, which recommend it for universal adoption, are its novel construction and its extreme simplicity. It is composed of the smallest number of parts of any Lawn Mower extant.

The Framework is cast all in one piece, and therefore, is not liable to be twisted, or by any means get out of order.

The Cutters are fit in the cylinder without wedging or wiring, and yet they are so firmly fixed that they cannot be shaken, or in any way become loose.

The Fixings or Caps of the Cylinder are fitted together by two bolts and two screws only; and the cylinder itself can be adjusted or removed by the most inexperienced person in two or three minutes.

The Motive Power is given by the travelling wheels, into which a pinion fixed on the end of the cylinder shaft is geared, giving revolving motion to the cutters; and it will cut either short, long, wet, or dry grass, heath, &c. The Grass-box is placed in front of the cutters, and by removing it the Machine will cut grass close up to trees, seats, and underneath shrubs, &c. It is eminently adapted for Banks, Slopes, Flats, &c.

The Rollers fixed behind the cutters enable the Machine to cut over the edges of Flower Beds, Borders, Verges, &c., and close to any object.

The Handle of the Machine is self-adjusting, and will suit the height of the person using it at any angle.

The Mowers are of the strongest manufacture, simple in their construction, not liable to get out of order, and require the least repairing of any Machines of their kind extant.

WITH SINGLE GEARING.

To Cut 6 inches	£ 1 5 0
" 8 "	1 15 0
" 10 "	2 10 0
" 12 "	3 5 0
" 14 "	4 0 0
" 16 "	5 0 0

WITH GEARING ON EACH SIDE.

To Cut 18 inches	£ 6 10 0
" 20 "	7 0 0
" 22 "	7 10 0
" 24 "	8 0 0

Delivered, Carriage Free, at all the principal Railway Stations and Shipping Ports in England, Ireland, and Scotland.

Every Machine is Warranted to give entire satisfaction, and if not approved of may be returned at once unconditionally, without any expense to the Purchaser.

Green's Patent Lawn Mowers have proved to be the best, and have carried off every Prize that has been given in all cases of competition.

Our reason for bringing out the "Royal" Mower is to meet a want which has been repeatedly expressed by the purchasing public to have a good, useful, and efficient Machine CHEAP.

Green's Lawn Mowers are the only Machines used by the Royal Horticultural Society, South Kensington, London.

N.B.—Those who have Lawn Mowers which require repairing should send them to either our Leeds or London Establishment, where they will have prompt attention, as AN EFFICIENT STAFF OF WORKMEN IS KEPT AT BOTH PLACES.

SPECIAL NOTICE.

GREEN'S PATENT LAWN MOWERS possess (over those of all other makers) the advantage of self-sharpening: the cutters, being steel on each side, when they become dull or blunt by running one way round, the cylinder can be reversed again and again; and by bringing the bottom edge of the cutters against the bottom blade, the Machines will cut equal to new ones. Arrangements have been made so that the cylinder can be reversed by any inexperienced person in two or three minutes.

When Green's Lawn Mowers are used there is no ridgy or wave-like appearance left on the sward, but they leave the lawn with a smooth, even, and carpet-like surface, which is pleasing and delightful to the eye of the observer.

THEY CAN BE HAD FROM ALL RESPECTABLE IRONMONGERS AND SEEDSMEN IN THE UNITED KINGDOM; OR FROM
THOMAS GREEN & SON, Smithfield Ironworks, Leeds; and 54 and 55, Blackfriars Road, London, S.E.
ILLUSTRATED PRICE LIST FREE ON APPLICATION.

A VERY SELECT LIST of the NEW ROSES.

Plants now ready.

SALISBURY.—April 2, 1875.

CARTER'S

NEW NASTURTIUM RUBY KING (With dark-coloured foliage), per packet, 1s. 6d.

A seedling variety of that type of Dwarf Nasturtium originated by us—viz., the dark-folaged or King of Tom Thumb section—the popularity of which is now universal, from the fact of their bright colours contrasted with dark foliage, compact habit, and duration of bloom, rendering them quite equal in effect to bedding Geraniums. The colour of the new variety now offered is quite unique and distinctive—pure pink shaded with carmine—and forms an effective contrast with the varieties already in cultivation.

To Propagators and Plant Growers.

The most useful material for the attainment of successful and rapid culture in the open air.

COCOA-NUT FIBRE REFUSE.—Price 1s. per bushel, or 6d. per bushel for quantities of 20 bushels and over.

TO OBTAIN THE

Best Garden Lawns and Croquet Grounds

SOW

SUTTONS' LAWN GRASS MIXTURE,

Which forms a close velvety turf in a very short time. For making New Lawns or Croquet Grounds 3 bushels or 60 pounds is required per acre, or 1 gallon to every 6 rods (or perches) of ground.

For improving those already in turf, 20 pounds should be sown per acre.

March, April, and May are the best months for sowing.

Price 1s. per lb.; 20s. per bushel.

From Mr. J. MERRICK, Gardener to S. Forster, Esq. Le Court.

"The Seed you sent me last year turned out uncommonly well. Several gentlemen who came to Le Court who scarcely credit, from the appearance of the lawn, in August it was as fine and thick as I have seen some lawns that had been laid down for three years."

that it was only sown in May.

New Double Zonal Pelargoniums for 1875. First-class Certificate Royal Horticultural Society.

Emily Laxton.

MESSRS. W. AND J. BROWN have again been entrusted by Mr. Laxton with the distribution of the following set of New Double ZONAL PELARGONIUMS raised by him, viz.:

EMILY LAXTON.—First-class Certificate Royal Horticultural Society. The largest flowered and most remarkable Scarlet Pelargonium, either double or single, hitherto sent out. Individual flowers upwards of 2 inches in diameter; full, but not crowded; truss enormous. Free-flowering, and suitable for winter work. Figured in the Floral Magazine for October last. Strong plants, 1s. 6d. each, not crowded; truss enormous. Free-flowering, and suitable for winter work. Figured in the Floral Magazine for October last. Strong plants, 1s. 6d. each.

GUIDING STAR.—The most shrubby and dwarf Double Pelargonium yet raised. Foliage pale green, and partaking somewhat of the character and habit of the Show Pelargonium. Flower very pretty purplish pink, and double; quite unique and distinct. Strong plants, 2s. 6d. each.

ILLUMINATOR.—A striking and distinct purplish carmine-colored variety of the Emily Laxton type, but darker in colour; semi-double, but full; petals large and stout. Strong plants, 7s. 6d. each; the set for £1 10s.

Prizes will be offered for the above in 1876. To be sent out in May next. Coloured Plates of Emily Laxton post free for 1s. 6d. Electros of Single bloom 2s. 6d. each.

NEW STRAWBERRIES.

Messrs. W. & J. BROWN are also now sending out Mr. Laxton's fine firm-flashed New Strawberries—TRAVELLER and ENQUIRE, the favour of both these is distinct and unequalled. Traveller has received a First-class Certificate from the Royal Horticultural Society, and is undoubtedly the most suitable Strawberry for transmission yet raised. Strong plants of last season—Traveller, £1 per 25, £3 per 100. Enquire, 12s. 6d. per 25, £3 per 100. Early strong runners of each, in 6s. sized pots, 7s. per 25 extra. Prizes for fruits of these will be offered in 1876. Trade terms on application to W. AND J. BROWN, Nurserymen and Florists, Stamford.

FRANCIS & ARTHUR DICKSON & SONS.

106 Eastgate St. & The Upton Nurseries CHESTER.

Illustrated Catalogue of Vegetable & Flower Seeds.

Post free on Application. Quality—unsurpassed.

NEW ROSES.

SIR GARNET WOLSELEY (Cranston's). CRIMSON BEDDER (Cranston's). CLIMBING JULES MARGOTTIN (Cranston's). All the new Continental Roses for 1875—upwards of forty varieties. Descriptive List on application to CRANSTON and MAYOS, King's Acre Nurseries, near Hereford.

The Only Really and Thoroughly Distinct LOBELIA of the SEASON, BLUE STONE—

hitherto a hidden gem. Strange that this, by far the best of all the Lobelias, should have been kept back from the public by a "croton," and it is only within the last few days that the seed has been placed in my hands. The darkest blue, no eye, strong compact pinnatifid habit; foliage, strange to say, a most peculiar purplish green, and its whole character far exceeds any other Lobelia. Five hundred seeds, post free, 1s. 1d.; plants sent post free 1s. 6d. for 75. Trade price 9d. per 100. Catalogue, February 25. "Characterizing the whole of the Horticultural community to produce a letter."

FORGET-ME-NOT.

TRADE MARK.

H. CANNELL, F.R.H.S., begs to announce that his FLORAL GUIDE for 1875 is now ready, and will be sent, post-free (at price), for ten stamps. It is beautifully illustrated with 200 splendidly engraved engravings. It also contains particulars and correct descriptions of all the novelties, and the best new, and old varieties of two-folded plants in cultivation, and it is highly important to amateurs and gardeners that they should peruse it continually, for it contains invaluable and practical information on Florists' flowers and Bedding Plants and their Seeds; and the cheap, ready, and correct manner in which they are supplied and forwarded to any part of the world cannot fail to be a great advantage and highly appreciated by all who are really fond of the choicest flowers.

NEW FUCHSIA, "MRS. H. CANNELL."

—This magnificent variety last year bore out even more than the high character previously given it, and is by far the best double white corolla variety; foliage and flower even an advance on the good old dark Avochale. Fine half-specimen plants, 2 feet high, in 6-inch pots, 7s. 6d. each; small ditto, 5s.; six plants in the trade, 1s. 6d. fill to be a great advantage and highly appreciated by all who are really fond of the choicest flowers.

New Florist Flowers and Florist Flower Seed Merchant, Woolwich, S.E.

New and Genuine Seeds (Carriage Free).

B. S. WILLIAMS, Nurseryman and Seed Merchant, VICTORIA and PARADISE NURSERIES, UPPER HOLLOWAY, LONDON, N.

NEW AND CHOICE FLOWER SEEDS.

Table listing various flower seeds and their prices, including Almonsoa linifolia, Amaranthus hendleri, Auricula, Balsam, Blumebachia coronata, Calceolaria, Cyclamen, Cineraria, Gloxinia, Myosotis alpestris, Penta, Polyanthus, Pheolus drummondii, Primula, Ricinus gibsonii, and Stouck.

E. S. W.'s Illustrated CATALOGUE is now ready, post-free on application. VICTORIA AND PARADISE NURSERIES, Upper Holloway, London, N.

American Plants without Post.
W. M. MAULE and SONS beg to offer the choicest Hardy English and Continental RHODODENDRONS, with Belgic and other AZALEAS, at 30s. per dozen, 6/0 per 100.

The Plants are grown in a stiff Loamy Soil, on an exposed and elevated situation, and will thrive in any soil free from Lime, Iron, or Chalk. Large Bushes of the Potentilla and Cavendish varieties, 4 to 5 feet high and as much through, 60s. per dozen. April and May is the best time for planting. The Nurseries, Bristol.

HOLLIES.

ANTHONY WATERER respectfully invites the attention of HOLLY buyers to the very fine Stock to be seen growing at Knapp Hill. It comprises upwards of Thirty Thousand Plants, from 3 to 10 and 12 feet high, of the finer Gold, Silver, and Green-leaved kinds, affording a choice in size and variety such as can be met with in no other Nursery in Europe. Every Plant has been recently removed, and will be guaranteed.

The Stock of Common Green Hollies alone occupies 5 acres of land, and Purchasers will find them in large numbers of all heights up to 15 feet.

Knapp Hill Nurseries, Woking, Surrey.

DESCRIPTIVE CATALOGUE of BULBS. Address, CRANSTON and MAYOS, King's Acre Nurseries, near Hereford.

To Planters and the Trade.

MESSRS. MASTERS and KINMONT beg to call the attention of Planters and the Trade to their stock of the following trees, which can be furnished at low prices:—

LIMES, 7 to 9 feet, clean growth.

THORNs, of sorts, Standard and Pyramid, including Paul's new Double Scarlet.

ASH, Weeping, 6 to 10 feet stems, good heads.

WILLOWS, Weeping, American, Babylonian, and Kilmarels.

ELMS, of sorts, grafted, 5 to 7 feet, including Huntingdon, fastigiated, and cork-barked.

BIRCH, 8 to 10 feet.

PHILADELPHUS, of sorts.

VIBURNUM, of sorts.

LILAC, of sorts.

OAK, Scarlet, 6 to 8 feet.

VUCCA RECURVA, very fine.

ROSES, Standard and Half-Standard.

Dwarf, on Maresti.

CURRANTS, Black.

GOOSEBERRIES, of sorts.

ABIES CANADENSIS, 2 to 5 feet.

AUCUBA JAPONICA, 1 to 2 feet.

CUPRESSUS SEMPERVIRENS, 2½ to 4 feet.

Exotic and Vauxhall Nurseries, Canterbury.

ROYAL AGRICULTURAL BENEVOLENT INSTITUTION, for the relief of decayed Farmers, their Widows and Orphans.

Patron—HER MAJESTY THE QUEEN.

President—HIS GRACE THE DUKE OF RICHMOND.

Allowances to Pensioners.

Married £40 per annum.

Male £26

Widow and unmarried Orphan Daughters £20

Every information to be had of the Secretary, by whom Subscriptions and Donations will be thankfully received.

ROYAL AGRICULTURAL BENEVOLENT INSTITUTION.—The FIFTEENTH ANNIVERSARY FESTIVAL, in aid of the Funds of the Institution, will take place at Willis's Rooms on SATURDAY, June 5, at 6 o'clock.

H.R.H. THE PRINCE OF WALES, K.G., in the Chair.

Dinner tickets, 21s.; application for which should be made to the Secretary not later than May 22.

ROYAL AGRICULTURAL BENEVOLENT INSTITUTION.—The ANNUAL GENERAL MEETING will be held at Willis's Rooms, St. James's, on WEDNESDAY, June 16, at 11 o'clock precisely, and the ELECTION of PENSIONERS will take place on the same day, at half-past 11 o'clock.

All Subscriptions shall be deemed payable on January 1 in each year; and no Contributor shall vote in respect of an Annual Subscription while the same is in arrear.

Offices of the Institution—

No. 26, Charles Street, St. James's, London, S.W.

To the Trade.—Surplus Stock.

THOMAS IMRIE and SONS, Ayr, offer the following:—

BEECH, 18 to 18 ins., 10s. per 1000; 1½ to 2 feet, 15s. per 1000.

PINUS AUSTRIACA, 1½ to 2 feet, 10s. per 1000.

POPLARS, Ontario, 6 to 8 feet, 6s. per 100.

STRAWBERRIES, prepared runners, 10s. per 1000.

POTATOS, Victoria, 45s. per ton.

Milky White, 46s. per ton.

March, 1875.

Rhododendrons.

HENRY FARNSWORTH, Matlock, Bank, Derbyshire, has to offer a fine stock of the following, at a moderate rate:—

3-yr. Seedling, fine.

3-yr. Seedling and 2-yr. transplanted.

4 to 8 inches good stuff; 6 to 10 inches bushy.

For prices and samples apply as above.

New Fuchsia procumbens.

T. JACKSON and SON have much pleasure in introducing this exceedingly interesting Novelty, which they have purchased from the Gardener of T. C. Blackett, Esq., of Thorpe Lea, seeds of which he received from New Zealand. It is of a shrubby trailing habit, producing freely at the axils short erect flowers with orange-yellow tube and violet-black sepals. Strong Plants 5s. each, free by post 5s. 6d.; extra strong ditto, 10s. 6d. each.

Nurseries, Kingston, Surrey.

SAVE YOUR COAL BILLS,

BY ADOPTING

LOWAN'S COMPENSATING SYSTEM OF HEATING.

This System is suitable for Heating Horticultural and all other kinds of Buildings. A large number of Apparatus are in operation.

NEW SYSTEM of LIGHTING MANSIONS, PUBLIC BUILDINGS, &c.,
 Whereby a very large Saving in Fuel is effected.

By Combination of the Two Systems mentioned above a further and still more important Saving in Fuel is obtained.

THE PERFECT SUCCESS OF EVERY APPARATUS ERRECTED BY THE COMPANY GUARANTEED.

ILLUSTRATED CATALOGUE, WITH FULL PARTICULARS, SENT POST FREE ON APPLICATION.

PLANS AND ESTIMATES FREE OF COST.

THE COWAN PATENTS COMPANY, LIMITED,
 21, WHITEHALL PLACE, LONDON, S.W.

NEW PLANTS.

MR. WILLIAM BULL

Intimates that the following will be sent out for the first time in the beginning of May:—

NEW DOUBLE-FLOWERED IVY-LEAVED PELARGONIUM.

PELARGONIUM LATIFOLIOS, KONIG ALBERT.—This attractive and splendid novelty has been raised by Herr Oscar Liebmann of Dresden, from whom Mr. William Bull has purchased the half stock, with exclusive right of disposing of it in the United Kingdom, France, Belgium, America, and all other countries, Germany and Austria, excepted, the right of distribution in these two countries remaining with Herr Oscar Liebmann. The flowers of this beautiful Pelargonium are of a bright violet-pink colour, good shape, and double form. Each time this distinct novelty was exhibited in Germany it received a First Prize. 15s.

NEW NOSEGAY PELARGONIUMS.

ADMIRANDA.—One of the most remarkable and distinct varieties ever raised; the flowers are of a beautiful bluish colour, the base of the petals being marked with bright salmon-scarlet, thus giving the flower the appearance of having a ring of that colour with a light centre. 10s. 6d.

ALGERON.—Rich carmine-crimson; flowers large and fine; extremely effective. 5s.

CERES.—A splendid flower; violet-magenta, with scarlet marking in the upper petals; a most novel and distinct colour; one of the best varieties in its section. 7s. 6d.

COMO.—Bright rosy centre shaded with carmine; a very fine showy flower. 5s.

DORIS.—Very light pink, with white marking in the upper petals; an extremely beautiful and delicate shade of colour. 5s.

EUNOMIA.—Rich dark crimson shaded with scarlet; a remarkably fine flower. 5s.

JUNO.—A magnificent flower of a deep rose colour shaded with violet-lake; slight light marking in the upper petals; a very distinct variety, extra fine. 7s. 6d.

OSSIAN.—Rich crimson; all the petals edged with deep scarlet; a very effective flower of good size and shape. 5s.

PERIPLUS.—A remarkably fine large flower of a light rosy carmine colour; immense truss. 5s.

STREPHO.—Bright vermilion-scarlet; a fine large round well-formed flower; very showy and effective. 5s.

TAPOS.—A fine variety, producing large trusses of bright rosy centre flowers. 5s.

THAPTO.—This variety produces splendid large flowers of a rich deep magenta-crimson colour shaded with violet. 5s.

NEW BRONZE AND GOLD PELARGONIUMS.

ARBACES.—This variety has fine golden-yellow foliage richly zoned with dark bronze, and produces bright deep scarlet flowers of good form and size. 7s. 6d.

CAPELLA.—Pale yellow ground colour, with a very bright bronzy crimson zone; very rich and attractive. 7s. 6d.

EPIRUS.—A very fine variety; ground colour of leaves pale greenish yellow, ornamented with a very dark and broad bronze zone. 7s. 6d.

FIDES.—This distinct and effective variety has leaves with rich golden disc attractively banded with a rich bronzy crimson zone, and margined with pale yellow. 7s. 6d.

MARITANA.—A richly coloured variety; deep golden leaf-centre; surrounded with dark chocolate-brown zone, and margined with yellow. 7s. 6d.

PARTHENOPE.—A neat and attractive variety; small yellow leaf-disc; broad and distinct dark bronzy crimson zone; narrow yellow margin. 7s. 6d.

NEW IVY-LEAVED PELARGONIUMS.

PELARGONIUM LATIFOLIOS.

CORINTH.—An extremely distinct and pretty flower, of a deep pink colour, shaded with rosy violet; the upper petals barred and feathered with dark crimson. 5s.

HASTIA.—Under petals bluish-white; upper petals bluish feathered with light rosy violet; distinct and pretty. 5s.

LEDA.—Rosy pink with light centre, the upper petals richly feathered with dark violet-crimson; a very fine. 5s.

NEMANS.—An attractive flower, of a pinkish lilac colour; the upper petals feathered with deep crimson. 5s.

PHOCEA.—Blush-pink; a fine showy flower, with very long top petals, which are beautifully feathered and blotched with deep crimson; exceedingly attractive. 7s. 6d.

For Names and Descriptions of—

NEW FUCHSIAS,

NEW CHRYSANTHEMUMS,

NEW ZONAL PELARGONIUMS WITH VARIEGATED FLOWERS,

NEW ZONAL PELARGONIUMS,

Establishment for New and Rare Plants,

KING'S ROAD, CHELSEA, LONDON, S.W.

SATURDAY, APRIL 10, 1875.

THE APPLE OF LITERATURE.

NOTHING comes more naturally in the translations of the ancient authors of Greece and Rome, and in the Authorised Version of the Old Testament, than the word "Apple." Nothing at the same time is more unlikely than that the fruit so named is definitely intended, except upon rare occasions; and as for the scriptural allusions, with this fruit the Hebrews were probably not even acquainted. As a rule, the name appears after the same manner as "Rose" and "Lily," all three terms belonging to that beautiful class of poetical appellations to which people resort, almost by instinct, when a term at once intelligible and picturesque is wanted, either as a metaphor, or as a name for some new object, the general idea of which will be well covered by the name of an old and familiar one. With such terms language cannot dispense. They constitute part of the currency of human speech. There is a tacit understanding that they are not to be accepted too literally. Shakespeare's "Lilies of all kinds, the flower-deuce being one," might quite unobjectionably be paraphrased "Apples of all kinds, the Pomegranate being one." Popularly, we speak of the Pine-apple (which name, by the way, originally belonged to the cone of the Pine tree, still in certain districts called the Fir-apple); also of the Love-apple, the May-apple (Podophyllum), the Star-apple (Chrysophyllum), the Thorn-apple (Stramonium), and the Custard-apple (Annona). The Colocynth, in similar manner, goes by the varied names of the Bitter-apple, the Dead-Sea-apple, and the Sodom-apple. In this practice we simply imitate the practice of the ancients, who employed *μήλον* and *malum* in precisely the same way, calling the Quince the Cyprian *μήλον*, the Citron the Median or Assyrian *μήλον*, the Apricot the Armenian, and the Peach the Persian *μήλον*. These are the names by which the respective fruits are distinguished in Theophrastus and Dioscorides, and Pliny is content to translate them into Latin. To-day, accordingly, we only follow in a sort of reverent obedience to classical examples. Things of this description are like the bubbles on a stream—to find the originals we must go back to the fountain amid the hills. The Pomegranate, it should be added, was the Punic or Carthaginian *μήλον*.

That the veritable Apple was known and named in primeval times is likely enough. The philological fact is simply that what in the beginning may have been a term of special application, subsequently became a collective or poetical one, poetry being addicted to resemblances; or possibly the process was *vice versa*, the collective term becoming individualised. Whichever it may be, from ages immemorial *μήλον* and *malum*, or as we say in English, "Apple," have served for any description of fruit that is in any degree of Apple shape and Apple complexion, and that grows singly on the branch, or nearly so, as contrasted with clustered fruits, such as Dates and Grapes. When, in the ancient authors, a qualifying geographical adjective is prefixed, we may see that a particular fruit is intended; but in the absence of this it is impossible to know certainly what is meant; probably, when *μήλον* and *malum* stand alone, instead of "Apple," it would be safest, if we desire exactitude, to understand

"Quince," for this seems to have been the *μήλον* or *malum* *par excellence*. In the *Iliad* (ix. 538) *μήλον* appears to denote fruit in general.

In the *Odyssey* it may perhaps denote genuine Apples, as that charming passage where Ulysses reminds his aged father that when a little boy he had given him for his own garden "thirteen Pear trees, and ten Apple trees, and forty Fig trees." "I asked each of thee, being a child, following thee through the garden, and thou didst name and tell me each."* The original words are *ὄρχους, μήλας, and σκείλας*. In the presence of the exquisite picture, so simple and natural, one almost becomes careless of the question in hand. How tenderly it recalls to mind that little bit of early paradise—our own first little plot—where in the golden days of "lang syne" we learned how to feel to lose. Truly the great poetasters for all the ages—"the sun of Homer shines upon us still!" Apple trees, or *μήλας* rather, grew likewise in the gardens of King Alcinoüs, where "white-armed Nausicaä" was accustomed to pursue her daily walk.† In the verses of writers succeeding Homer the name soon becomes frequently recurrent, and now the fruit, whatever was intended, takes the picturesque and renowned place it has held ever since, being dedicated to the Goddess of Love and Beauty.

The dedication did not fade, as often supposed, from the thrice-famous judgment delivered on the summit of Mount Ida, when Paris received from Venus the fatal gift, remembered ever since in the phrase "Apple of Discord." The genuine reason is disclosed in a metaphor in Theocritus,‡ which, no doubt, well-pleased Boccaccio, and which has many parallels in the poets alike of his own age (B.C. 280) and of later times.§ It serves also to indicate that the Quince rather than the Apple was the *μήλον* pre-eminently, for the Apple, though smooth, is not downy, whereas the Quince is noted universally for its soft and velvety surface. Very pretty, indeed, are the associations under which, with the *prestige* in question, the Apple, so-called, now constantly appears; as when, for example, the shepherd in Virgil, giving an account of his first knowledge of Nisa, says it was while he was yet a boy, and he helped her to gather "Apples wet with dew," therefore in early morning. The picture, as a whole, is imitated from the Sicilian, in whose steps Virgil so often treads, only that while in the latter we have Apples, the earlier poet says "hyacinthine flowers."|| Take, again, the picture of the sprightly Galatea, whose practice was, figuratively, "to pelt with Apples," or, as the Greeks expressed it, *μηλοβόλευε*—Galatea never, with Olivia, letting concealment,

"Like a worm I' the bud,
Feed on her damask cheek."¶

Almost everywhere in the Virgilian poems the allusions to *mala* seem to point decidedly to Quinces—beautifully depicted, for example, in the epithet of "whitening" as they become ripe, and in the of "cana tenera lanugine mala;" and when we call to mind how greatly this fruit was esteemed among the ancient Romans, when converted, literally, into "marmalade," it is but reasonable that it should have acquired prominence in the literature of fancy and imagination. There is always, however, in all the poets, a certain amount of suggestion of the genuine Apple. The Quince, being austere, does not seem quite suited for a present to a favourite, which the *mala* elsewhere became in Virgil; and one is almost induced to think that here the word was employed in place of *poma*, which also, as at the present day, denoted Apple-formed fruits in general, and sometimes,

* *xviii.* 336—344. † *vii.* 124—120. ‡ *xviii.* 48.

§ *Vide*, for example, Aristophanes, *Ecc.* 903, and *Lysistrata*,

155. *Eclogue*, *viii.* 37—41. Theocritus, *Idyll.* xi. 25—27.

¶ *Eclogue*, *iii.* 64—65.

perhaps, the Apple specifically. In a broad and comprehensive sense, such as was never accorded to *mala*, it was extended to fruit of all kinds, even Nuts; so that one's idea of Pomona, the kindly goddess of the orchard, who takes her name from *pomum*, must not be too rigorously confined to care of the Apple alone. Ovid gives the name of *poma* to the berries of the Arbutus, which in southern countries are good to eat; also to Mulberries.* The limited sense of genuine Apple appears to be conveyed in the *jecticia poma* of the same author,† and in the *mitia poma* of *Ecclesiastes*, i. 81—the epithet in each case conveying the idea of mellowness, such as is usually predicated of the Apple alone, and the context implying that they were eaten just as gathered, which Quinces, at all events, would not be.

Something round enough to be rolled across the greensward is clearly intended in the famous story of Hippomanes and Atalanta, where the maiden loses the race through stopping to gather up the too tempting *poma aurea*; but what these were, Quinces or "Golden Pippins," dyed gloriously in the sunshine, there is no one now to tell, and the imagination may translate in the way it likes best. So with the famous "golden Apples of the Hesperides," in the story of which is wrapped up an immense amount of beautiful meaning, the clue commencing in the above-named metaphor in Theocritus. When Hera became the wife of Zeus, the divinities presented her with appropriate bridal gifts, Gaia—the earth personified—providing a tree which bore "golden Apples." Hera was the only really married goddess of all who sat on "beautiful Olympus." Practically she was the great presiding goddess of universal Nature, and these "golden Apples" were essential to her completeness. The tree was placed in charge of three chaste young ladies—the Hesperides—and by them it was safely kept in a secluded spot far away in the west, safe from intrusion and curiosity. There is no occasion here to go into the significance minutely. Every particular has its meaning; in the whole range of fable and myth it is impossible perhaps to find anything more delicate or more in harmony with all the best principles of Nature and virtue. Constantly in the front as a poetical emblem, no wonder that in the hands of the painters of the Temptation of Eve, the Apple should be represented as the fruit of the "tree of knowledge."‡ All things pure and good of necessity in this world get perverted; hence it is no wonder either that the Apple is a metaphor for all sorts of seductive things. It is curious to observe how in the times we call our own, and with perfectly different associations, it reappears in the doubtful story of William Tell, and in the unauthenticated anecdote of Sir Isaac Newton.

With these various and curious facts before us, it is quite reasonable to anticipate that when in the Old Testament, which abounds in collective and poetical expressions, we come once again upon the Apple, we shall not be far wrong if we approach it in the expectation of a metaphor. Very beautiful are the utterances in which it occurs:—"As the Apple tree among the trees of the wood, so is my beloved among the sons. I sat down under his shadow with great delight, and his fruit was sweet to my taste." (Song of Solomon, ii. 3.) So in verse 5, "Comfort me with Apples;" so again in vii. 8, where the breath of the bride is compared to the scent of the fruit; and so, yet again, in viii. 5. In Joel (i. 12) the Apple is enumerated among the precious fruits of the country, and takes its place, with the others, as a symbol of something in the spiritual life of man that it

behoves him to cherish diligently and faithfully. "The Vine is dried up, and the Fig tree languisheth; the Pomegranate tree, the Palm tree also, and the Apple tree; even all the trees of the field are withered, because joy is withered away from the sons of men." And lastly, we have that beautiful verse in the Proverbs—"A word fitly spoken is like Apples of gold in pictures of silver," i.e., in baskets or dishes, such as it is customary to place upon table at times of repast. Scriptural words and phrases, when there is no clear and incontestable evidence as to their precise meaning, must be interpreted by the light of the sciences which are open to human research. There is no such evidence as to the signification of the words rendered "Apple" and Apple tree; we must fall back, therefore, as in similar cases, upon comparative language. What this will supply has been illustrated in the meaning of *μήλον* and *malum*; and it is at once remarkable

as for the genuine Apple, as said above, this was probably not even known to the ancient Hebrews. G.

(To be continued.)

RHEUM NOBILE.

We extract from Dr. Hooker's *Illustrations of Himalayan Plants* the following details concerning this truly noble plant, which is now more in the hands of many of our nurserymen, who will, we trust, be more successful than before in rearing the plant:—

"The present is certainly the most striking of the many fine alpine plants of Sikkim; and though in every botanical character, as also in the acid juice of the stem, a genuine Rhubarb, it differs so remarkably in habit and general appearance from any of its congeners, that at first sight it could not be recognised as one of them. I first saw it from a distance of fully a mile, dotting the black cliffs of the Lachen Valley at 14,000 feet elevation, in inaccessible situations, and was quite at a loss to conceive what it could be; nor was it till I had turned back the curious bracteal leaves and examined the flowers that I was persuaded of its being a true Rhubarb.

FIG. 91.—RHEUM NOBILE IN ITS NATIVE HABITAT (REDUCED SKETCH).

and interesting to find at the very 'outset' that the same kind of difficulties pertain to the translation of all three, and that they respectively throw light upon one another. The Hebrew term is *tappûach*, also written *tappûah*, *tappuah*, and *tappuah*. The Septuagint translates it by the identical word *μήλον*, and as long ago as the time of Charles II. we find the pious and learned Bishop Patrick, author of the celebrated *Commentaries*, stating his belief in its being a purely collective term. At the present day the Arabs apply it to the berries of the Mandrake, calling them *tappûach-al-Shaltan*, "Satan's Apples." Etymologically, *tappûach* denotes something of delightful odour—something that, as we say ourselves of various fruits, "breathes fragrance." Consequently it will apply well to many of those called *μήλον* and *malum*, and immediately to the Quince, which in colour also, as already seen, gives the idea of "Apples of gold." Though the Quince may have been included in the *tappûach*, there are many obvious reasons why it should not have been meant specifically, the impression of John Ray notwithstanding; and

"The individual plants of *Rheum nobile* are upwards of a yard high, and form conical towers of the most delicate straw-coloured, shining, semi-transparent, concave, imbricating bracts, the upper of which have pink edges; the large, bright, glossy, shining green radical leaves, with red petioles and nerves, forming a broad base to the whole. On turning up the bracts the beautiful membranous, fragile pink stipules are seen like red silver-paper, and within these again the short-branched panicles of insignificant green flowers. The root is very long, often many feet, and winds amongst the rocks; it is as thick as the arm, and bright yellow inside. After flowering the stem lengthens, the bracts separate one from another, become coarse red-brown, withered and torn; finally, as the fruit ripens they fall away, leaving a ragged-looking stem covered with panicles of deep brown pendulous fruits. In the winter, these naked black stems, projecting from the beetling cliffs, or towering above the snow, are in dismal keeping with the surrounding desolation of that season."

New Garden Plants.

MASDEVALLIA MUSCOSA.*

This is a very queer little thing, reminding one of a Moss Rose by its stiff-haired peduncle and ovary. It belongs to the genus of *Masdevallia Echinida*,

* *Masdevallia muscosa*, Rehb. f., sp. n.—Pedunculo hispido setoso subulifero; floribus heterochromis; ovario dense papilloso; sepalis basi coatis, sepalis superiori triangulari longe caudato, mento bene angulato; sepalis lateralius triangularis

* *Met.* iv. 89 and 165, x. 101. † *Ibid.*, ix. 92.

‡ That the Forbidden Fruit was an Apple is the topic of Sir Thomas Browne's curious chapters in the *Fugles Errors*, and which by the analyst of these matters should not be overlooked.

* *Hist. Plant.*, vol. ii., p. 1453.

Xiphers, erinacea, but it is quite distinct in its lip. The sepals are triangular, with long tails, yellowish, perhaps with reddish nerves. They are 1 inch long. The lip, with its deep violet bearded blade, is rather curious, as are the singular petals, terminating in linear subulate ends, which are crowned by a broader retuse point. I have made use of a name Mr. Wallis had once proposed for another species, gathered by him, but named before from other specimens. Our plant comes from New Grenada, and I have to thank Mr. Bull for good dried flowers. It was discovered by Mr. Shuttleworth. *H. G. Rehb. f.*

MASDEVALLIA GUSTAVI.*

This is one of those species with rather unequal sepals, rather small flowers, standing in a raceme, and trifid petals—such a plant as *M. polysticta*, *pachyura*, *tridens*, *amanda*, *melanopus*, *caloptera*—which I refer to the *Amanda* group. The flowers appear to be yellowish, with numerous port-wine-colour dots and yellow tails. They scarcely reach half an inch in length, and usually stand in their original position, having the lateral sepals rising upwards. The small leaf has a long, very thin petiole. It may be recommended to those who love the species just named. Our plant has a very celebrated discoverer, to whom it is dedicated—Mr. Gustav Wallis, who found *Maranta Lindenii*, *Dichorisandra musacea*, *Odontoglossum vexillarium*, and so many good things. Yet I cannot complain of Mr. Wallis' specimen being too rich, it consisting of two flowers only. Hence I was much pleased to get satisfactory materials from Mr. Bull, gathered by Mr. Shuttleworth. We may expect soon to see this little gem in our gardens. *H. G. Rehb. f.*

ODONTOGLOSSUM WEIRII, †

This comes near *Odontoglossum tetraplasium*, but is quite distinct, amongst other points by its much longer column. The panicle is widely diffuse; the flowers being as large as those of a very good *Odontoglossum praestans*. I have the impression that they were white and lilac, but this is merely a guess from the dry specimens. The blade of the lip is wavy, acute, densely covered with velvet. The calli of the two species are totally different.

The plant was discovered in New Grenada, by Mr. Weir. I gladly accede to the wish of Mr. Bateman, who most kindly favoured me with very good specimens, but it would have been named from my own sense of justice in honour of a collector, who even sacrificed his health for the cause he served so well. It is a pity the plant is not alive in Europe, at least within my knowledge, but as New Grenada is now-a-days perhaps too much frequented hunting-ground of eight collectors, we are not sure when it may appear; whenever it does so it will be a great satisfaction to me. *H. G. Rehb. f.*

HEDYCHYUM GARDNERIANUM.

At one of the recent meetings of the Royal Horticultural Society, Mr. Bennett, of Hatfield Gardens, exhibited a fruiting spike of *Hedychium Gardnerianum* which attracted general attention from its striking appearance as well as from the rarity with which it is seen in this country. A general view of it is given at fig. 92, on a reduced scale, but no woodcut can produce the effect of its brilliant colours. The fruits or seed-vessels are aggregated together into a close spike, each one springing from the axil of a bract, and ultimately splitting up into three leathery orange-yellow valves with the seed attached to the middle of each. Those seeds are of a rich shining crimson colour, and are surrounded by a mace surrounding the Nutmeg, of nearly equal brilliancy. Nature sometimes combines colours in what we should call a daring way. Few of us would venture to combine orange and crimson, or would expect that so splendid a result would ensue as in this case, but probably the green leaves and bracts toned down the crude colours and caused them to blend. Again, if we consider what is the probable use of this

roque caudatis; tepalis a basi lata linearibus apice dilatatis retibus sublobatis carinis; labello a basi cuneato dilatato ovato reticulato apiculato ciliolato; carina per basin; columna brevis in gibbera duo supra labelli unguem exserta; columna breviori rostellato erecto.

Alzatevillea Gustavi, sect. *Amanda*, *Rehb. f.*, sp. n.—Folio tenuissime ac longae petiolato, erecto, obtuse acute; racemo nunc folium excedente, plurifloro; bracteis cucullatis abbreviatis; ovaris crispo alatis; sepalis impari galenato cauda lanina non aquante; sepalis parvis multo angustioribus crenulatis; tepalis curvis a cuneata basi dilatatis serratis, apice retibus tridentatis univris; labello trifido, laciniis lateralibus medianis semiblobis obtuse acutis; laciniis media ligulata obtusa, carinis tervis in lacinia antica elevato inersatis; columna gracili apice acuta.

Odontoglossum Weirii, *Rehb. f.*, sp. n.—Panicula ampla diffusa multiflora; ramis primariis validis; bracteis oblongo-acutis; ovaria pedicellata aequantibus; sepalis cuneato-lanceolatis acutis; tepalis cuneato-oblongo-acutis; labello carinis basilaribus extorxe bilaminatis ligulatis, lobatis, anticis acutis; carinis parvis crassis geminis interpositis; callis lobatis crassis tribus brevibus filiformibus; columna breviter striata; laciniis labelli oblonga acute crispa velutina; columna clavata, labello dimidio superante.

FIG. 92.—HEDYCHYUM GARDNERIANUM (HALF NAT. SIZE).

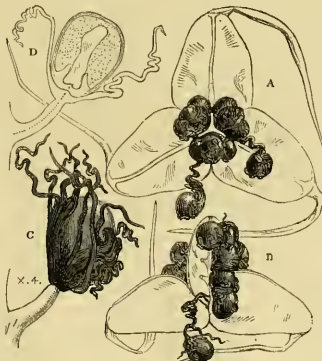

FIG. 93.—HEDYCHYUM GARDNERIANUM.

A, B, Top and side view of capsule, with remains of the tubular inner perianth; C, Seed clothed with its anilous, four times natural size; D, Section of ditto, showing embryo and vitellus.

brilliant colour, we can only infer that it is an attraction to birds who would eat and digest the outer softer portions and reject the true seed, and in this way effect the dispersion of the seed.

The structure of the seed with its vitellus partly surrounding the embryo is characteristic of the Scitamineae, and is found in but few other natural families.

So gorgeous is the fruiting spike that we trust gardeners will henceforth secure the ripening of the fruits by artificial fertilisation, which would not be difficult to accomplish.

FUNGUS-HUNTING AND FUNGUS STUDY:

THEIR CHARMS AND INFLUENCES.

SURELY my friend, Mr. Worthington Smith, must have been subject to a fit of depression by the long, foggy and dreary winter that has made so many persons victims to influenza and bronchitis, when he arrived, in the review of Mr. Cooke's recent work upon fungi, at the lamentable conclusion that after many years' experience the study of fungi "is in no way commensurate with the labour of the study." But every observant naturalist must be prepared to endorse the word that the Roman emperor, Severus, uttered on his dying couch, let him take whatever department of the domain of Nature he selects for examination—"Laboramus!" Close attention and labour—sometimes to little purpose—is the necessary concomitant of investigation in every department of natural history; and at times a little disappointment that mental exercise is ineffectual to overcome every difficulty, depresses the mind of the student; but he soon rises from momentary depression to renewed activity, and I do not believe that my studious and carefully-observant friend will, as he threatens, really abandon his pleasant researches on foot in woods and thickets, to mount his Kosinante and "go fox-hunting" instead. An ugly fall in attempting a leap would be more unpleasant than a difficult mental exercise, and the brush of "the varmint," if he got it, would not, I think, be a sufficient "reward" in his estimation.

We all know the difficulties attendant upon continuous researches in any department of natural history, especially in the minute tribes; but Mr. Smith's deprecatory tone would equally apply to the study of mosses, lichens, the numerous families of Algae, and the Infusoria. Time and trouble are inevitable for an investigator, but when we admit with the moralist that "Virtue is its own reward," the true lover of Nature will, or ought to be, equally satisfied with the pleasure and satisfaction that is the result of successful research; while the discovery of a new plant is as delightful to the prying botanist as the discovery of a new island or even desert rock is to the voyager. Mr. Smith justly complains that the "literature of fungi is very expensive," and it is likely to be more so if, as he suggests, fungology is in future to be "confined to the attention of the few." On the other hand I wish the study of fungology to be so extended that works on the subject may have a remunerative sale, and at a moderate price. Sowerby's *English Fungi*—so essential to the student of Agraria in particular, who may recognise a drawing or plate, though failing to master a technical description—is difficult to obtain, and its price is deterrent; but if there were lovers of Agraria and fungi in general sufficient to tempt the experiment, why could the public not enjoy another feast of "English Fungi," with additions and corrections, under the skillful editorship of Mr. Smith himself, with engravings made from his own beautiful and accurate drawings? Such a work a lover of funguses would devoutly wish for, but I quite admit that, if my friend's advice is taken and the public frightened from the examination of fungi, the work would not pay. Dr. Bull, of Hereford, has well shown that a general interest may be imparted to funguses, and "forays" in quest of them, and though his researches for sauces to flavour the edible ones have rather an Apician smell, suggestive of mere table luxuries, yet I would rather side with the sagacious physician by making trial of all the funguses fit to be eaten, and thus extend a wholesome vegetable diet, while, like him, I would make drawings of all that came under my notice. Thus poisonous species may be known and avoided. At the same time, while I would as far as possible extend a popular knowledge of fungology, I should neither desire nor expect that every gatherer of funguses would be as technically skillful in their knowledge and terminology as Mr. Smith, or the "king of the Mycenae," the unwearied investigator, Mr. Berkeley.

But looking only at the pleasure of the pursuit, I do not hesitate to declare that I would much rather, any autumnal day, go fungus-hunting with a few friends as enthusiasts as myself, than don the scarlet and appear at the cover-side to gallop over country

at the risk of my neck, and, as is often the case, lose the fox after all! The angler, who may stand bobbing his line by the brookside for hours together, may perhaps get his reward in a few fish, put into his basket, or he may not get a bite; and however delightful this may be to a contemplative man who may consult his Walton, and know how to treat a worm "as if he loved it," I greatly prefer an active search among woods and meadows for funguses, and eat the fish caught by other people when I get home. I may here quote what Dr. Badham has said as to the pleasure and excitement of fungus-hunting, at the same time that he makes an apology for the angler as not entirely making his play for the frying-pan, and showing that Dr. Johnson's definition of an angler was not quite correct. "In fishing it is not the fish we catch which alone repays us for our toil, it is the wandering as the rivulet wanders, at its own sweet will; the exercise, and the appetite consequent upon it; the prize in natural history; the reciting aloud, or reflecting as we walk, and, when it is pleasantly warm, the *mollis sub arboris sonus*, which console us for the lack of sport. On the other principle, however, no criticism may be recommended to the young naturalist, not only for the beauty of the objects which he is to come upon, but also because in that most beautiful of months (September), whether at home or abroad, it brings the wanderer out of the beaten paths to fall in with many striking vicissitudes which he would not otherwise have explored. The extremely limited time during which funguses are to be found, their fragility, their infinite diversity, their ephemeral existence—these, too, of the interest of an autumnal walk in quest of them."

To the colours and infinite diversity of the fungoid tribes may be added the scents with which several of them pervade the air—some exquisitely fragrant, others pungently fetid—and I have frequently found pleasure in tracking *Citotyce* in woody places, *Trametes suavelens*, and other scented species, which otherwise my eye would not have detected. After more than thirty years' attention to fungi, chiefly in the autumnal months, though I cannot now detect through damp weather the same impunity as formerly, yet my love of the pursuit is the same, and I have hundreds of drawings to show my friends, who are often astonished at the diversity of colour that the various species present to view, justifying Tennyson's remark of fungi—

"Which in autumn-tide do star
The black earth with brilliance rare."

Perhaps there is more difficulty in determining the species of fungi than with those of the flowering tribes, but every botanist is aware of difficulties even there, and the diversity of opinion is often very perplexing. In every department in the present day changes of nomenclature, and "involved and distracting terminology," is an evil that, as was once said in Parliament by an eminent statesman of the influence of the Crown, "has increased, is increasing, and ought to be diminished." But, unpleasant as it is, we must not be frightened at bad names; but direct things as well as names, adding to the unpronounceable number, unless to compliment some Russian or Polish friends!

Mr. Smith also complains of "pygmies innumerable," and no doubt it must be so if the microscope is used as it now is most extensively. But among the Cryptogamic tribes it is not an incitement to their study that there is almost a certainty of finding something new—an addition, it may be, to science? And though I would not myself care to go down to posterity on the back of some inconspicuous algal or microscopic fungus, still there is a charm in discovery; and, far from being afraid of "the vast number of minute species," I should feel inclined to say with respect to the "armies that come into the field," Be it so, if Nature wills it; for if my powers of observation fail, as they must, and I am obliged to pass from exhaustion of physical powers, as Linnaeus did, and it must be the case with the most enthusiastic, or other cause, the third of our sensation of pleasure, as they have left off, and "rising wonders sing," as the poet Thomson expresses it, for the benefit of future generations. At all events, let us not give way to a desponding spirit, or deter others from observation and research, even among the fungi, as if a "difficult mental exercise" was to be eschewed, and there was not a considerable amount of pleasure superadded as a balance to tortured thought and the valuable time employed.

Notices upon rocks get burnt up under the blaze of summer, and no doubt then exist knowledge of no use to themselves or the world; but they revive with the moisture of autumn, and display their fructification in the spring as beautiful as ever. So the naturalist is at times tired and perplexed, but his love of Nature and observation never quite deserts him, and he again returns to his work like a giant refreshed. I trust, therefore, that my thoughts of my friend Mr. Worthington Smith, will not be in a despairing mood born his books and drawings, or destroy his microscope, or, on mature reflection, wish fungus knowledge to be limited to a select few, although the

"reward" he sighs for, and which he as well as other diligent workers deserve, may be slow in coming, or, as too many many experienced does not come at all. *Edwin Lees, F.L.S., Green Hill Summit, Worcester, April 2.*

NEGLECTED PLANTS.

COUVE TRONCHUDA.—The Portugal Kale, or Couve Tronchuda, bears a sufficient family resemblance to the wild Cabbage which hangs on the opposite faces of the opposite cliffs at Dover and Cape Blazer, to be easily recognised as the plump descendant of a lean and scraggy ancestor. Like its parent, too, it does not heart, which is one of its chief peculiarities, and also, perhaps, the reason why it remains a little known rather than a neglected vegetable. For few of those who do know it neglect it, at least, for their own household supply. But being loose made, somewhat brittle when fresh cut, and, therefore, less easily packed in a small compass, it is not suitable for sending long distances to market, as Savoy, Broccoli, Cauliflowers, and the solid-hearted summer Cabbages, many of which latter are of such excellent quality as to leave little to be desired. What the eye does not see the heart does not long for; and as Couve Tronchuda seldom makes its appearance in public, the wish to have it is thereby mainly confined to the amateurs who already possess it in cultivation.

And it is worth the amateur's attention. Many people grow in their kitchen gardens only such things as they cannot readily procure in their immediate neighbourhood, or which they like to have absolutely fresh gathered, or to gather themselves, or to force—such as Seakale, Asparagus, Strawberries—obtaining the commoner and coarser vegetables from outdoor sources. For those, Couve Tronchuda is a plant to cultivate. It is a low-growing, open variety of Cabbage, manifesting a tendency to succulency in every part of its foliage, with fleshy, juicy leaf-stalks and leaf-ribs sustaining the green portion, which, gathered while tender and properly boiled, have a flavour something between Seakale and Broccoli, but coming in fit for table at seasons different to either of those useful vegetables. The colour of Couve Tronchuda is glaucous green, blanching, towards winter and in spring, to straw-yellow at the centres and on the young shoots. Not only does it make a good-looking and excellent dish when cooked, but while growing is a handsome, almost an ornamental, plant, very distinct, which is sure to attract the eye of any visitor to a kitchen garden who does not happen to have seen it before. For this reason, as well as for its culinary merits, it deserves the notice of those who exhibit collections of vegetables for prizes. Fairly judged, it ought to hold its own; and no competent judge would put an non-heating Cabbage into competition with an Enfield Market or a Wheeler's Cocos-nut, to the disadvantage of the former, if well-grown. Seed is to be had of the leading seedsman. Couve Tronchuda is included in some of the collections especially suited to the amateur's garden; in one seed catalogue it figures with the synonym of Braganza Cabbage; in short, those who like to try it easily can.

But to give it a fair trial it must be taken and used at the right season and in a proper state. Seakale has often been condemned in France, because people cooked it without blanching it, found it bitter and tough, and then wondered at the queer tastes those English had! In like manner, if Couve Tronchuda be sown too early and cut in the dog days after suffering a month's drought, the chances are that the leaf-stalks and ribs will prove as hard as the stems of run-up Asparagus in September—unless we could be sure of having, what few people want, a long wet, and sunless summer. On this account the middle of June is quite soon enough to sow it. The plants should be kept from the seed-bed in a light soil and watered during dry weather, will attain a useable size by the time when the nights have grown sensibly longer, the main crop of Celery is pushing on vigorously, and "dewy eve" falls every day earlier and earlier. The part to be eaten is the tender portion of the centre of the plant, which in the other Cabbages would form the heart. The stems, stripped of their leaves, may be left to form sprouts. Later plantings will come in during autumn and winter (if mild and open). Couve Tronchuda, rather a tender plant, would be called half-hardy, that is, not hardy at all when the winter is hard; but as it is never better than in spring, after a green Christmas, with January and February to match (the time when vegetables are becoming scarce), the gardener will do well to risk a late sowing in a warm border, covering with handlights and a sprinkling of straw, in case of frost. Loudon (*Encyclopædia of Gardening*) states that Couve Tronchuda, or large-ribbed Cabbage, was introduced in 1821; and the dwarf variety, known in Portugal by the name of Murciana, in 1822, which, possibly, may be the sort now chiefly cultivated in England. On

account of the tenderness of both, he advises the seeds to be sown in August and the plants kept in a frame till spring, and planted out at the same time as Cucumbers for an early summer crop; the succession to be kept up by spring and summer sowings. Couve Tronchuda is the Brassica var. costata of De Candolle. The *Bon Jardinier* just mentions it as *Chou à grosse côte*, of which there is a fringe-leaved variety, cultivated by the Paris gardeners under the name of *Chou fraise* (*fraise* is not only a Strawberry, but also a fall or Elizabethan ruff), an excellent winter vegetable, intermediate between the hearing Cabbages and the *Choux verts*, or non-hearing Kales. E. S. D.

HARDY VINEYARD AT CARDIFF CASTLE.

THERE are instances on record of the cellars of some of our British nobles being pretty well stocked with wine the produce of Grapes grown in the open air on favourable spots on their own domains, such, for instance, as at Arundel Castle. The Most Noble the Marquis of Bute is at present engaged in preparing a piece of ground on his Cardiff estates for the formation of a hardy vineyard on a somewhat extensive scale. The ground selected is about 7 miles from Cardiff, at a place called Castle Coch, an old ruin which his lordship is having partly restored. This castle is situated on a tract of limestone some 500 acres in extent. It is well wooded to the north, east, and west, but lies quite open to the south, overlooking the Bristol Channel. The field selected here for the vineyard is about 5 acres in extent, having a good fall to the south. It is of a light loamy soil, 2 feet deep, resting on the limestone rock, and requiring no artificial drainage. The only precaution necessary before planting is trenching and slightly manuring with stable-dung. The Marquis, in his earnestness to put the practicability of open-air culture of Grapes in favoured spots in this country to fair proof, sent his intelligent gardener, Mr. Pettigrew, on a tour of inspection among the most noted French vineyards last autumn, preparatory to his lordship's design being put into practice. Two thousand Vines will be planted this year, and the same quantity next year, and so on until the vineyard is stocked. They will be planted 3 feet apart each way, and it is proposed not to allow them to grow to a greater height than 3 feet. The varieties to be planted are Melier blanc and Fremet noir, in equal proportions, these being, from Mr. Pettigrew's observations on the Continent, the two most likely to succeed, they being very hardy and prolific. To further test the matter, 150 Chasselas de Fontainebleau are to be planted on the Castle walls. We earnestly hope the Marquis' experiment may turn out very successful. It may be added, the French system of culture will be adopted generally. *The Gardener.*

A REVIEW OF THE PROGRESS OF VEGETABLE PHYSIOLOGY IN 1874.

IT is a frequent difficulty with those who are engaged in any branch of science to hold themselves *au courant* with the multitude of publications regarding it in periodical and other literature. Hence, a summary of progress is often useful, and we propose here to avail ourselves of such a summary, made by M. Micheli, in the *Archives des Sciences*, in which the advance of knowledge of plant physiology in 1874 (on the Continent chiefly) is passed under review.

Without professing to deal exhaustively with the subject, the author's paper treats first of the action of external agents (heat, light, &c.) on plants, and the physico-mechanical phenomena in the latter; secondly, the chemical part of plant physiology; while a third section is devoted to chlorophyll.

GROWTH OF PLANTS.

A branch which grows is always turgescens. There is a certain tension between the cell-contents and their membrane; when this turgescence disappears growth ceases. Cellular membranes are extensible within a certain limit; beyond this their natural elasticity is the stronger; it stops the increase of volume of the cell and the entrance of new liquid particles into the interior. The object of growth is, then, to re-establish equilibrium between the tension exercised by the cell-contents and the elasticity of their membranes. Once this occurs the membrane is again extensible, and new liquid molecules can enter it. Such is, in substance, M. Sachs' theory of growth. The extensibility of cell-membranes plays an important part in it, and this has been specially studied by M. Hugo de Vries, who corroborates the theory just given. It has long been known that the elongation of cells is not uniform; at first slow, it is gradually attains to a maximum, then diminishes by degrees, till the organs have reached their definitive length. This is

probably due to variations in the extensibility of membranes, and M. de Vries examined this property in cells at different heights under the point of vegetation. He first studied the shortening which all branches undergo when they are cut, a result due to escape of a part of the liquid contained in the cell; the interior tension diminishes, the elasticity of the membrane prevails, lessening the organ. The phenomenon should be at its maximum where the dilatation of membranes is greatest; that is, in the section of the branch whose growth is most rapid. And exact measurement confirmed this. For example, if we divide a peduncle of the Poppy into successive segments 2 centimetres in length, then (reckoning from above downwards) it is the third that will present the maximum elongation in a given time, and the third also which will contract most in withering. This contraction is well marked; in two hours and a half it was as much as 3.8 m.m. in 2 c.m., or 19 per cent.

In his direct experiments, the author's results no less conformed to theory. He operated in three ways: elongating the branches mechanically (with the hand), or them, by placing them in A. A part of the elongation obtained was destroyed by elasticity, but a part persisted. In these three cases, the maximum of extensibility should not coincide with that of growth; it could not be supposed that cellular membranes, already subjected to very strong tension, would show marked elongation under mechanical action. It was more natural to expect that the maximum this time would be nearer the point of vegetation, in the region where the cells, yet passive (so to speak), have not yet reached the maximum elongation to accomplish. This was fully confirmed by experiment, and in the numerous branches M. de Vries examined the maximum artificial elongation was always in the first of the long segments of 2 c.m.

ROOT GROWTH.

The mode of growth of roots and the action of gravity on these organs have been the subject of interminable discussion among physiologists. M. Sachs has studied this subject *à sa manière*, and the results of his long and conscientious inquiry fall under the principal categories. The first, relating to mode of growth of roots, presents an interest specially theoretical. The elongation of roots, like that of stems, is not uniform for each cell; it is at first slow, increases gradually, reaches a maximum, then diminishes little by little, and finally ceases. The extremity of the root is hard and fragile. The parts which have attained their definite length are, on the other hand, flexible, and have but little elasticity. Hence, M. Sachs has been led to renounce the theory (of Hofmeister and others), that the end of the root penetrates into the ground like a soft and plastic substance, moved by gravity. He thinks, on the contrary, that it is driven forward between the particles of the soil, with a certain force, by the segments placed behind and whose elongation is very rapid.

The second category of results consists of geotropic curves of the roots, and is highly interesting as regards the relation of plants to the ground. These curves are always ruled by two general laws. 1. The part which elongates is subject to the action of gravity; and in a horizontal root the curve is, for each segment, greater the more rapid the period of elongation in which it occurs. 2. Different segments that have reached the same period of development are more curved the more open the angle their axis forms with the vertical.

But the intensity of the geotropic action varies much in the roots of different orders. It attains its maximum in the primordial roots; these, when they have deviated from the vertical, are brought back to it by successive curves, and often conclude by forming an acute angle with their first direction. The secondary roots, on the other hand, proceed from the axis at a certain angle (proper angle), which varies according to the height; almost a right angle towards the collar, it becomes more acute as we approach the point. The action of gravity on these organs is limited; it attains its maximum, as in the preceding case, when the axis of the root forms with the vertical a certain angle, but from this moment, instead of diminishing gradually it ceases abruptly, and consequently a secondary root is never brought back to the vertical position. Lastly, the roots of the third order have no apparent geotropism, they issue always at a right angle from the axis which bears them.

The biological bearing of these facts is easy to comprehend. If the roots of the second and the third order were geotropic in the same degree as the primary roots, they would all merely form a dense bundle. They would be mutually injurious, and would utilise only a small part of the nutritive elements distributed in the soil. But according to M. Sachs' observations, it is quite otherwise. The primordial root, endowed with strong geotropic properties, descends directly into the ground; the roots of the second order, separating from it, penetrate obliquely into even deeper layers, always removing further from the principal axis. Besides, owing to the variable value of the

proper angle, the roots withdraw the one from the other in proportion as they are elongated, the upper ones always running almost horizontally near the surface, the lower penetrating even deeper into the soil. Lastly, the layers of ground which escape these various actions are put under contribution by the roots of the third order, which radiate at a right angle round the secondary axis.

MOVEMENTS IN PLANTS.

The study of movements produced in irritable organs forms one of the most difficult chapters in vegetable physiology. Many observers are, however, agreed in attributing a prominent rôle in these phenomena to the displacement of a certain quantity of liquid, at least in leaves like those of the Sensitive Plant and Oxalis. This is the view taken by M. Pfeffer on the subject, in a memoir published in 1873. He has extended his study to the stamens of *Cynareæ* (*Cynara Scolymus* and *Centaurea Jacea*), which also have an irritability, easily observed; and with reference to these organs also, he concludes that the direct cause of the phenomenon is to be found in displacement of liquid, which passes from the interior of the cells into the intercellular passages, or into the vessels. He has observed the changes of volume in the staminal filaments under the influence of irrigation, and has found that a thickening of 2 to 3 per cent. is far from compensating the shortening, which may be as much as 10 to 12 per cent. By microscopic measurement of the cells themselves he has confirmed this observation, and proved that their cavity notably diminishes. He has further proved that the elasticity of the membranes has nothing to do with the irritability; that filaments subjected to the action of chloroform possessed the same elasticity, whether contracted or extended; and a stamen, in contracting, cannot raise the lightest weight.

M. Pfeffer thinks, therefore, that upon contraction of sensitive organs there is manifested an increase of the permeability of the cellular membrane, or the protoplasmic utricle. The tension which always exists in the turgescence tissues then causes a little of the liquid to escape, and pass into the intercellular passages or into the fibrovascular bundles; the turgescence exists no longer, the organ bends; later, when the irritation ceases, the inverse phenomenon occurs.

M. Pfeffer has completed his researches by studying, in a late memoir, the mode of transmission of irritability from one point to another in *Mimosa pudica*. As to the root of the case as fully elucidated, he accepts the old theory of Dutrochet, which represents that the irritation is transmitted by means of a displacement of liquid through the fibrovascular bundles. One cannot suppose that there is from point to point a series of irritable cells accompanying the bundles, for if, by means of an anæsthetic, we render insensible the median folioles of a leaf, the irritation applied to the terminal foliole is none the less transmitted to the base of the leaf, and thence to neighbouring leaves.

M. Heckel, in his researches on the same subject, has come to an entirely different point of view. In his opinion, the irritability of the stamens of *Mahonia*, *Berberis*, and *Sparmannia* is due to the particular properties of the epidermic cells, which contract under the influence of an excitant. In the *Synantheræ* M. Heckel thinks the irritability of the stamens is much more general than is usually supposed. He has observed it not only in the *Cynareæ* and *Cichoreæ*, but in many of the genera of *Corymbifereæ* such as *Impatiens*, *Aster*. As to the process of the phenomenon, his opinion is, that under influence of irritation the cells contract, and that thus the filament is shortened (theory of Cohn). According to his measurements (which contradict those of M. Pfeffer), the thickening of the filament compensates exactly the diminution in length. Thus he does not admit the possibility of a displacement of liquid, and absolutely rejects the view adopted by M. Pfeffer. Without wishing to pronounce here definitively as to the comparative merits of the two theories, it seems to us that some of the objections M. Heckel urges against a displacement of liquid are not well founded. He says, for example, that the filaments of *Cynareæ* do not contain lacune in which the liquid can be stored; now M. Pfeffer has precisely observed that in certain cases (*Berberis*) the absence of lacune was compensated by the presence of a spongy inter-cellular matter, which can absorb liquid. Further, M. Heckel has observed the irritability to persist in fragments of long isolated filaments of only 1 to 2 mm., and he concludes that here a displacement of water is impossible. It seems to us, on the contrary, that if we suppose an increase in permeability of the membrane, there is nothing to hinder the tension subsisting in an isolated cell from causing the escape of part of the contained liquid, which will then be simply deposited in the form of a drop on the exterior surface of the membrane.

At the same time, M. Heckel has observed the German physiologist leads us further into a knowledge of the phenomenon, since his explanation appeals only to a well-known property of membranes—permeability, the increase or diminution of which suffices to account

for the changes of volume of the cell. In the opposite theory, the contraction of the cell depends on a peculiar and, we believe, quite unknown property in membranes.

In another investigation as to the movements of the stigmatic lamellæ of *Bignoniaceæ*, *Scrophulariaceæ*, and *Sesameæ*, M. Heckel attributes to the spiral vessels or tracheæ a particular rôle in transmission of the movement from one lamella to another; in most cases, indeed, the more sensitive the stigmata the more tracheæ do their tissue contain (the *Mimulus*, however, is an exception; though very irritable its stigmata contain in each lamella only one trachean bundle). This idea was suggested to M. Heckel by a note of M. Ziegler, on movement of the hairs of *Drosera*, into each of which one trachea enters, which the author regards as the probable cause of transmission of the irritation. Here, again, this mode of view seems to us to assume a problematical property of tissues. It is not possible, in the present state our knowledge, to say anything of the mode of action of tracheæ transmitting an irritation directly. The theory of displacement of liquid, on the other hand, would find, we think, a very logical application in the stigmata in question, which are formed in great part of a turgescence parenchymatous tissue. Perhaps the tracheæ may intervene here as receptacle for the liquid expelled provisionally from the cells.

ACTION OF LIGHT, &c.

The action of exterior agents, such as light and heat, has also been the subject of some interesting observations. Thus, &c., M. Winter has remarked a case of positive heliotropism in a Mushroom. The plants of this family are generally supposed to escape more or less completely the action of light. The instance referred to was that of the *Peziza Fackeliana* of Bavy, which was cultivated in cases exposed to light on one side, and not only the styles, but the cupples themselves, turned energetically towards the light. The fructiferous cupple even appeared not to be capable of developing completely, except when it received in full the luminous rays.

M. Pedersen has studied the action exercised on vegetation by oscillations of temperature. The only researches we possessed on this subject were those of M. Köppen, who concluded that oscillations, regarded in themselves, had an unfavourable action. M. Pedersen does not accept this view. His experiments had reference to the growth of roots and seeds in germination. The plants were some of them subjected to sudden variations, plunged alternately, &c., in water at 16° and 20° C., others, again, were placed in water which was cooled gradually. Comparison was made in each case with a plant immersed in water at a constant mean temperature. The result was in all cases the same. The roots exposed to a variable temperature were elongated a little more quickly than the others. Thisis now very surprising if it be proved that, all other things being equal, a higher temperature favours the rapidity of growth. And this was demonstrated in an experiment by the author, in which the elongation in the same time was 100 at 10°, 179 at 15°, and 316 at 20° C. Given these figures, it is evident that a plant which has passed six hours in water at 10°, and six hours in water at 20°, must grow more than a plant kept twelve hours in water at 15° C. The author considers, therefore, that oscillations of temperature in themselves have no influence on growth.

M. Krasan has shown that Wheat grains can bear a very high temperature without losing their germinative power, if the precaution be taken to partially dry them before the experiment. Grains which had lost 10 per cent. of their weight were exposed during ten and twelve hours to temperatures of 60° to 70° C., and even on one occasion of 90° to 100° = 212° F. They all germinated ultimately, only a little later than the others, which is easily explained by the desiccation of the tissues. *A. B. M.*

(To be continued.)

Natural History.

TOADS, SNAKES, AND ADDERS.—The article by "R." at p. 410, brought to my remembrance some of the facts which I learned in this place when foreman some twenty years ago. At that time we had an excellent collection of Dahlias, and they were put to "test" on a bed of leaves in one of the early vineyards, where we were also very much troubled with earwigs, and woodlice eating them. I got a lot of toads and placed amongst them, and found they were quite at home in their new quarters, and soon rid us of our enemies. My toads and I got great friends, and they became so tame that they would eat from my hand, and I was also an eyewitness to one of them taking off his jacket and making it up in a pill and bolting it. One day, during the month of July in the same year, I was gathering Strawberries in the open garden, and came upon a very large snake, which I killed. Seeing a large lump about its middle I placed my foot on its tail and took a garden rake and

worked the lump upwards, and in much less time than it has taken me to write I had worked it out at the snake's mouth—a fine live toad. He winked and blinked a bit, and then hopped off, no doubt well pleased with his change. Snakes reproduce their species by laying eggs, usually in a heap of some material which will produce warmth; sometimes the carpenters used to find their eggs in a heap of sawdust, and put them in a box. These put in a warm place soon hatched and became lively little fellows. Snakes used to crawl up the Ivy of the Castle and get in at the bedroom windows, and the boys on the estate sometimes found them in birds' and squirrels' nests in the Spruce trees at a good height from the ground; and this brings me to a very different reptile to the preceding, viz., the adder, which we all know is dangerous, its bite causing great pain, and sometimes death. Before the Fir trees were cut down round the Castle and garden, adders were very plentiful, and sometimes people were bitten. The remedy used was immediately to cut a chicken in two, and put the half on to the wound; this brings the poison out to a certain extent, and the part almost immediately becomes black. [The adder, unlike the snake, gives birth to her young, and will lie and bask with them in the sunshine; on the approach of any danger she utters a "hiss," and the young ones one after another enter her mouth, when she decamps with them to a place of safety. I know that this fact is disputed by many eminent men, but from this very parish I could find as many persons as there are weeks in the year (and some of them persons of education and intelligence), who have been eye-witnesses to it. I daresay I shall bring down upon myself a certain amount of ridicule for believing this, but I must say that from the abundance of such evidence I believe it to be the fact; and were adders as plentiful now as then, I should have no difficulty in sending you up the parent and offspring as described. At that time they were far too numerous, and often took up queer positions, but the most remarkable was in one of the lodges; the bedroom was on the ground floor, and there the mother found one coiled up in a vessel after the children had gone to bed. *Y. Owl, Evesham Castle, Warwickshire, 1815.* It is singular that with so much positive assertion, there should be so little proof of the many similar statements that have been made. See *ants*, p. 115. EDS.]

RARE CONIFERS.

Not long since we drew attention to some valuable Conifers, of which specimens and seeds had been collected by M. Roehl, in New Mexico, and sent to Messrs. F. Sander & Co., seed merchants, St. Albans, who were good enough to submit the specimens to us. These have appeared to be of sufficient interest to merit being figured, and our readers will now have the opportunity of judging for themselves how far we were warranted in the conclusions at which we had arrived regarding them.

Picea concolor, var. *violacea*.—The first species that we examined was one bearing this name. The reader is referred to our remarks upon it in the number for January 23, p. 105, and we now ask him to compare what we then said with the figure now before him (fig. 94). We said that, notwithstanding that it had been admitted as a good species by Parlatore, it appeared to us to be only a variety of *Picea grandis*; and we grounded our opinion on having seen *grandis* growing in its native Rocky Mountains, with all the characters that are present here. The characters which were supposed to differentiate it from *P. grandis* were its white colour, the same on both sides of the leaf, and its somewhat falcate form, and some supposed difference in the bract of the scale. The former, we already explained, are common attributes of *P. grandis* in Utah, where the hoary hue of the vegetation of the plains extends also into the mountains; and as to the more erect attitude and slightly bent leaf, the variation is very slight, and occurs also in *P. grandis*. As to the cone, any one who has had cones of *P. grandis* through his hands will, on looking at this woodcut, recognise its cone. The bract, also, in no respect differs from the bract of that species. The reader knows that in this country *P. grandis* does not exhibit the white colour which it so often bears in various parts of the Rocky Mountains and the Sierra Nevada, and it will be very interesting to observe whether the seed of the variety now received from New Mexico maintains the white colour of its twigs and leaves, or reverts to the semi-transparent olive-green hue that always characterises it in Britain, and as often as the white hue in Utah. There the colour seemed to depend a good deal upon the nature of the place, whether near a stream or barren and exposed—the more barren the more white—although it would be to generalise on imperfect premises were we to lay this down as absolute. There was, in fact, very great differences in the habit of trees of *P. grandis* growing side by side, especially when young. One would bear its leaves scattered thin and sparingly and wide apart; another would have its fol-

FIG. 94.—PICEA CONCOLOR (ENGELMANN), VAR. VIOLOACEA (ROEHL).

FIG. 96.—BRACT OF P. BIFOLIA.

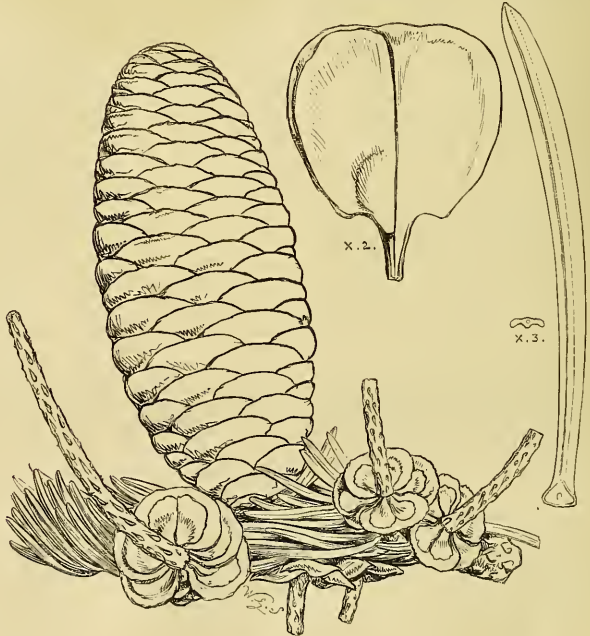

FIG. 97.—PICEA BIFOLIA.

age twice as thick; one would have long leaves, as in *Lasiocarpa* and *Lowiana*, another quite near it would have them only half the length. And even in colour a great difference was constantly to be seen; one would be of a darker green, another yellowish-olive, a third nearly white, and so on. For these reasons we have no doubt that the present species is a variety of *P. grandis*, but we shall hold ourselves open to correction when the young plants come up.

Abies (Picea) bifolia, Murr.—This, we believe, is the first time that seeds of this species have been introduced into Britain. We described it about ten or twelve years ago from specimens in the Kew Herbarium, brought home by Dr. H. K. Fox. It is not recognised as a good species by Parlatore, who makes it a synonym of *amabilis*; but we imagine that the accompanying cut (fig. 97) will satisfy Coniferists that in this he is in error. *Andrew Murray*.

BRITISH GARDENERS.—XV.

WILLIAM MILLER.

THE name of William Miller is well-known amongst gardeners. The fine samples of late Grapes Mr. Miller was in the habit of exhibiting a few years since from the new vinerias at Combe Abbey, and to which he modestly alludes in the accompanying very complete autobiographical notice which he has obligingly sent us, will not yet be forgotten by those who take interest in Grape growing.

"I was born at Knockdown, in the parish of Inverchoalin, Argyshire, on November 29, 1828. My father was then gardener to the late James Lamont, Esq., of Knockdown; at his death to his son Alexander, and latterly to his son James Lamont, Esq., the present proprietor. My father went to this place as gardener in 1827, and having served three generations, extending over a period of fifty-two years, he died on August 3, 1873, in his eighty-fifth year. My mother, who survived him only five months, died on January 13, 1874, in her eighty-fifth year. Mr. Lamont erected at his own cost a tombstone over her grave, with a suitable inscription, stating their age and the number of years they had served faithfully and honestly in the Lamont family. Such an instance of long service and good feeling between employer and employed should not be overlooked. My father was initiated into the profession of a gardener in the first place amongst the market gardeners of Glasgow; afterwards at Rosedoe, Dumbartonshire, the seat of Sir James Colquhoun; and at Kelvin Grove, now the fashionable West-end park of Glasgow, under the late Mr. Ninian Niven, afterwards of Kier Gardens, Perthshire.

I was educated at the parish school of Toward until I was fourteen years of age, when I was sent as dominie to teach two orphan grandchildren belonging to a wealthy sheep farmer in the neighbourhood. At the end of this service I was to enter a merchant's office in Glasgow, but this breaking down—for want of the necessary influence, I suppose—I was put to work under my father on the estate. My father at that time being general manager, I had great scope for observation, and in this way got early acquainted with the management of sheep and cattle, and fancied myself a very good shepherd.

"Plantations of Larch, Scotch Fir, Spruce, Oak, &c., were being plentifully made at that time on this and other estates on the West Coast for purposes of shelter, timber, &c.: I had a famous opportunity of taking part in these operations. The late Mr. Lamont was a man of great taste, and would insist upon having the outline of plantations, drives and fences eye-sweet. In the working out of these curves I have followed my father many a day with an armful of pegs. Here I learned the form the Hogarth line of beauty, which I never forgot. When still a lad, Mr. Lamont was not slow to acknowledge my aptitude to form a good curve. At that age I could measure a piece of land with any one. When a piece of land was set out for planting I was frequently sent by my father to get it surveyed, and to work out the number of plants required of the different kinds with which to plant it. There were no rabbits there in those days, and young plantations soon got up, and the landings were made available for estate purposes. Thinning plantations in Scotland was always carefully and neatly attended to; so also the pruning of young trees, and old ones, too, when they had been neglected in their earlier period of growth. Every cut must indicate a thorough mastership in the handling of the tool used.

"My elder brother, now at Clumber, who was at this time acting as foreman to my father in the gardens, left, and I was duly appointed to this charge. With the exception of a short time in spring, when a batch of men would be sent in to dig, and put in the general summer crops, I was mostly alone. Here I got initiated into the pruning and training of fruit trees, which has continued a favourite subject with me ever since; also the sowing of seeds by hand, the depth of drills, width apart, &c., for different seeds. This is a branch of gardening now almost over-

looked by the coming race. The only glass at this place at that time was some Melon and Cucumber frames.

Mr. Lamont gave me to read *Harrison on Fruit Trees*, also *Loudon's Encyclopædia*, which latter work so fired me with the love of gardening that I was not long before I began to feel that if I meant to be a good gardener I must get myself out into the world a bit to obtain further knowledge of the higher branches of the profession. After duly apprising my father and Mr. Lamont of my intentions, and obtaining their leave to go, I went after a place, and succeeded in getting one. From this time began the troubles and difficulties of my life, and which have been such as gardeners generally are the peculiar sport of.

"My first place from home was at Eskrine House, on the Clyde, the seat of Lord Blantyre. The veteran gardener at that time was Mr. George Shiels, a very superior man generally. He had the best walled garden at that time in the West of Scotland; and his fruit trees were in the best form of training and bearing that I have seen in any garden. Excellent Peaches were ripened on the open walls. Immediately on entry I got as a favour the management of the forcing houses, they chiefly consisted of Vine and Peach-houses, Cherries, Figs, and Vines were grown successfully on hot walls. The bothy here was a tolerably good one for those days. We each had a bed, although in the same apartment. In the evenings we read greedily, each paying for a pound of candles in turn. Our wages were not much, so they

were easily taken care of. Here I commenced horticultural drawing, which I have pursued ever since with more or less success, having always made and worked to my own plans. In consequence of having the care of the fires, which were all smoke flues, I never went to bed very early; and this prolonged my hours of study for some time after the others had gone to bed—with one exception only, and this was our out-door foreman, who fancied that he had discovered the 'real clue' to find out perpetual motion. Often this poor fellow, when he came in from work, and had taken his tea, would quietly go to bed and sleep for a few hours; and when we had retired, and all was quiet he would get up, and in the lonely midnight hours pursue his study of perpetual motion.

"At Eskrine I only remained one year. On leaving I did not meet with a place to my mind, so I again put myself to school—this time entering myself for the winter at the Andersonian University of Glasgow. I entered as many classes as I thought I could manage. During my short stay here I improved my education much. For the further prosecution of my studies there I fell short of the one thing needful, so in spring a situation as journeyman gardener was obtained for me at Dysart House, under Mr. Laing, now the worthy nurseryman at Stanstead Park, Forest Hill. Shortly after my arrival at this place a vacancy occurred in the outdoor foremanship, to which I was appointed by Mr. Laing. I carried through this department for about a year satisfactorily, I believe, to Mr. Laing, and to my own great delight. One of the chief features of this place, which was a pleasant one, and neatly kept, was its Rhododendrons. My last year at Dysart was filled in as foreman of the houses. I was there at the time when Mr. Laing succeeded in

flowering for the first time in this country Rhododendron Dalhousie.

"From this place I was sent by Mr. Laing to Mr. Fleming, then gardener to the Duke of Sutherland at Trentham. Here I encountered a wonderful change in the style of gardening, as compared with what I had been accustomed to in Scotland, to which style and practice I need not further allude here. Suffice it to say that during my two years' stay at Trentham I saw much practice which I booked and carried away, and I saw much also which I did not book but left behind. I was healthy and strong while there, for which there was much cause. 'Till at Trentham I was sent three times to London with Mr. Fleming's collections of fruit—once to the Crystal Palace, when Mr. Fleming beat the late Mr. M'Ewen, of Arundel; once to Chiswick, when Mr. M'Ewen beat Mr. Fleming; and once again to the Regent's Park. During these visits to London I had drank deeply of gardening; and as it is said of those who once drink of the waters of the Nile, that they will live to do so again, I was much to be envied that I might live some day to come back to London, and table my own fruit.

"At the end of two years of Trentham practice, I was sent to Gowran Castle, Ireland, as head gardener to the late Viscount Clifden, where I remained four years. During my stay here my time was occupied in improving the grounds, which I took great interest in. At Gowran I had most to do with the Hon. Leopold Agar Ellis, brother to Lord Clifden, who took great interest in the improvement of the place. Figs and Pears ripened to great perfection on the open walls. I did a good deal in Pear grafting. I lectured once grafting a Pear fruit bud; the bud expanded, set, and grew into a good-sized fruit.

"Some time in the year 1858 Mr. Fleming was promoted to the resident agency on the Trentham estate. Evidently he had formed a good opinion of me; for he sent for me from Ireland, with a view to my filling his shoes in the celebrated gardens of Trentham. I was for this purpose brought before the late Duchess of Sutherland. Whether it was from my Irish brogue, which I had caught strongly, or perhaps from my awkwardness, I cannot tell, but her Grace disapproved of me, so I went back to Ireland a disappointed man. The more fortunate, or perhaps unfortunate, man to receive the appointment was Mr. Wren, then gardener to the Duke of Leinster, at Carton. He held the situation a few months and then went off to New Zealand, where I am informed he is doing well, and where also most likely I should have gone had I been appointed to Trentham at that time.

"In the autumn of 1859 Mr. Fleming offered me, and I accepted, the halfship on the Home Farm at Trentham. I left Ireland and my friends there with a very sad heart, and have often repented most bitterly that ever I left the service of such a kind and indulgent family. I should perhaps mention here that the mother of Lord Clifden was Lady Dover, sister to the Duchess of Sutherland, and therefore, although at Trentham, I was still connected with the family. I accepted this situation with the hope that it might ultimately turn out to my advantage, but I was not long there before I found that my occupation was likely to prove a very unpleasant and a very uncomfortable one, and so it proved as time wore on. For the first time in my life I began to feel that in these situations a man's duties are not the most difficult things he has to contend with; but temper, whispers, and jealousies often beat the most assiduous and devoted of men; and these were the hidden rocks which compelled me to weigh anchor from Trentham. However, during my time as bailiff at Trentham I brought in a large, good deal of valuable experience, which has since often stood me in good stead.

"I left Trentham in the spring of 1861, and obtained a recommendation to work with a spade in the new gardens then forming for the Royal Horticulture Society at South Kensington. I worked with great pleasure in these gardens for about three months, when, through the kindness of Mr. Eyles, and my earlier friends, the Hon. Leopold Agar Ellis, then M.P. for Co. Kilkenny, and Mr. Fleming, I obtained my present situation at Combe Abbey, near Coventry. One day, when working in the Society's new gardens, an incident occurred which, perhaps, you will allow me to relate. It was at dinner-time, and I was in conversation with a young man named Macintosh, who formerly also lived at Dysart with my old master, Mr. Laing. He knew several of Mr. Laing's men whom I knew. Amongst them he told me there was one named Miller, who got on well; that from Dysart he went to Trentham, from Trentham to Ireland, and again back to Trentham, to some position on the estate. 'Ah!' added he, 'some men are fortunate; Miller is now a made man; asking me in the same breath, 'Did you know him?' I replied in the affirmative that I knew Miller well, and that all he had said respecting his movements was quite true. On this reply he looked me hard in the face, and asked if I was the man; and when I told him I was, he seemed for the moment dumb-

founded. Advertisers bring together strange bed-fellows, and such was the case with Macintosh and me.

"In the late Earl of Craven I had a most kind and liberal employer. He was a man of great taste, fond of horticulture and the improvement of his estate, and he knew trees well. My first duties here were to erect new forcing-houses, of which much has already been written in the pages of this paper, and other contemporaries. We then commenced the improvements in the pleasure grounds, which have been carrying on year by year ever since—transplanting many large trees, and introducing many young Conifers and other shrubs. At the request of the late Earl I formed some extensive green drives, and by clearing away trees and hedgerows added largely to the views and extent of the park.

"I have not been without my successes as a fruit grower, but of this the gardening public are the better judges. Suffice it to say, that during the years 1867, 1868, 1869, at the Royal Botanic Gardens, Regent's Park, I carried off successively the gold medals for collections of fruit. I have not exhibited lately.

"I have much to be grateful for in the confidence reposed in, and the kindness shown to me by the present Earl and Countess of Craven, and of which I have had many gratifying proofs. By their desire we are always adding to the beauty, improvement and embellishment of the gardens and grounds."

To this interesting sketch of Mr. Miller's horticultural career we may briefly add, that amongst his contributions to our pages, which excited some interest at the time of their publication, were his papers on the bottom heating of Vine borders, on Vine extension, and on the root fungus question. A paper on deep cultivation, which appeared in the first number of our present series, is eminently practical, and calculated to awaken thought.

UNDERLEY HALL:

THE SEAT OF THE EARL OF BECTIVE.

This fine place (see p. 469, fig. 99) is most beautifully situated in the far-famed valley of the Lune—a more lovely situation it would be difficult to find, even in these parts, where Nature has been so liberal in bestowing her favours—passing northward through Kirkby Lonsdale, one of those quaint old-fashioned North-country towns, where, from the rural attractions abounding in the neighbourhood, many visitors from the South during the summer season resort. A new ornamental lodge has been recently built, and many improvements made. The carriage drive winds its way through an extensive park, in which, at the time of my visit, was grazing a herd of some forty cattle, in all probability of greater value than any similar number of the bovine race ever seen together. I allude to the magnificent Shorthorns which Lord Bective possesses, and in which his lordship takes so much interest. Here, amongst an assemblage of splendid animals such as can only be fully appreciated by those who have an intimate knowledge of them, was the magnificent 10th Duchess of Geneva that, a year ago, was purchased in the United States for some seven thousand pounds. After a hurried glance at these beautiful animals, following the carriage-drive we arrive at the mansion, which is a combination of the Gothic and Elizabethan styles. At the southern, or principal entrance, is a double portico, supported by massive columns, imparting to the building a fine effect. Great additions have been and are being made, and these, when completed, will make this already noble mansion still more imposing. The roof is hidden by a perforated parapet, as will be seen from the view, fig. 99 given at p. 469, which represents the eastern front, with its massive tower, 100 feet in height. Looking round, one cannot help remarking that the place is well-named Underley, from the way in which it is sheltered north and west by the distant hills, partially yet sufficiently clothed with timber, and which break the winter winds that sweep down these northern valleys. The river—here a broad and goolly stream—bounds the grounds on this side some two yards distance. From the great depth of the banks, at this part almost perpendicular, the water, in its tortuous windings, is not visible until the visitor unexpectedly comes upon a point where the full beauty of the situation is displayed. There is here one of the most lovely bits of river scenery imaginable. No attempt appears to have been made to enhance the natural effect produced, neither would it be possible. Lingering for a time, and with reluctance leaving this charming spot, we follow the stream which here bends southerly, bounding the recently made portion of the grounds, which stretch a considerable distance in this direction. The high ground on the opposite side of the river retains its almost precipitous character—at this side the surface gets much lower, until it gradually becomes almost on a level with the water. This, as will be understood, adds much to the

effect produced by the bluff grey rocks opposite. Not far distant from the water's edge at this part is to be erected a summer-house on a large scale; it will be approached from the higher ground by several flights of rustic steps already made. The site is happily chosen, the whole surroundings here producing a feeling of natural repose in perfect harmony with the idea embodied in a retreat of this description. This part of the garden is exceedingly fine; the ground is well laid out, the combination being such as can never be produced except in the immediate proximity of a river of importance, so as to afford the indispensable element, water, in sufficient quantity and under conditions that harmonise with the particular style of gardening attempted. Near by is a slightly raised mound of considerable size, surmounted with wirework, which is to be covered with climbing Roses; the situation being sufficiently sheltered, they will no doubt do well. This is a consideration that should not be lost sight of in selecting a position for an arrangement of this description, as, if too much exposed, the shoots and leaves are literally ground away by chafing against the wire. Returning we proceed towards the eastern front of the mansion, which from this point is approached by a broad gravel walk, right and left of which lies a fine piece of lawn, on which have been planted some large clumps of flowering shrubs, such as Rhododendrons, Ghent Azaleas, &c. Here also is an arbour, the roof composed of a very large Weeping Ash, supported on a framework, the pillars of which are covered with Clematis, which, when in bloom, will be very effective.

The walk for some distance from the mansion is margined by a series of beds similar to the broad walk at Kew, filled and looking very gay with the usual summer bedders at the time of my visit. This leads to the south, or principal entrance front. The carriage way is of proportions in keeping with the building. From this we descend by an easy flight of steps to a terrace some two yards in width, the wall of which is surmounted at intervals by large vases, and from whence there is an extensive view over the park to the Lancashire hills. The kitchen gardens, with the various fruit and plant houses, are northwards, and at some distance from the mansion. We come first to the old walled kitchen garden, the south outside wall of which is planted one by one with Pears in good condition, the other portion with Peaches, over which is a broad glass coping. In this old garden is a range of large lean-to-houses, one of which is devoted to plants of a general decorative character. Adjoining is ainery, filled principally with Hamburgs and one or two Muscats, these producing useful fruit. Next is anotherinery, the greater portion planted with Black Hamburgs, with two or three West's St. Peter, all carrying a heavy crop, the bunches a fair size, and the berries a good quality. The Vines, which are not yet having been planted, I understand, about 1811, and so far as I can learn, they have regularly borne good crops. This range is heated by flues, and the borders in which the Vines are planted are all outside. The last house here is also a vinery, similar to the others, which are from 30 to 40 feet by 18. This is the latest house, and the inmates are all Hamburgs. The back wall is covered with Figs.

This garden, although old, was filled with a very fine crop of vegetables, remarkably clean, and in good condition. All the walks here are margined with an espalier fruit-trees, mostly Apples, with a few Pears. The walls are all of stone, and very substantially built, principally planted with Pears and Cherries. The varieties of Pear which answer best are Beuré Bosc, Louise Bonne of Jersey, and Marie Louise. Northwards from this, and adjoining it, is the new walled garden, similar in size to the old one, and in which the new ranges of houses, seventeen in number, are built. They are a good quality, and erected by Weeks, of Chelsea, some five years ago. In the centre of the principal range is a span-roofed plant-stove, 30 feet by 20, containing good plants of *Ixora coccinea*, *I. javanica*, *Anthuriums*, *Crotons*, *Eucharis amzonica*, *Bougainvilleas*, *Stephanotis*, some large healthy plants of *Dendrobium nobile*, *Draecenas*, *Diefenbachias* and *Palms*, conspicuous amongst which latter were fine plants of *Kentia Canterburyana* and *Chamaedorea* *Erri*.

To the left of this house is a vinery 36 feet by 18, planted with Muscat of Alexandria, Black Alicante, and Lady Downe's for the permanent Vines, and Hamburgs for removal as the others get up. There are 12 feet of border inside and as much out. The Vines have been planted two years, and are remarkably strong, as an evidence of which, although carrying not less than 20 lb. each of good Grapes, the young shoots from where they were cut back to when pruned are of an extraordinary thickness, not appearing in the least affected by the crop they were carrying.

Adjoining this vinery and in continuation of the range is an early Peach house, planted with Early Beatrice, Rivers' Early, Alexandra, Noblesse, and Dr. Hogg, Peaches; and Lord Napier Nectarine.

The next house at this end of the range, and similar to the last, is filled with Peaches and Nectarines; in it are Early Beatrice, Louise, and Rivers' Early,

Peaches; with Violette Hâtive and Lord Napier Nectarines. On the opposite side of the central plant stove, and corresponding with these comes a vinery 36 feet by 18, containing Muscat of Alexandria, Madresfield Court, Lady Downe's, Bowood Muscat, Black Alicante, and Gros Colman; the construction and size of border being similar in every way to the house at the other side.

This end of the range, like the opposite, consists of two Peach-houses, planted with Lord Beaconsfield, Prince of Wales, Early Alfred, and Grosse Mitonne Peaches; and Downtown, Erurge, and Stanwick Nectarines. In front of these fruit-houses (which flank the centre plant stove already described), but at some distance, are ranges somewhat similar, filled with succession Pines, Melons, and Cucumbers. These succession Pines are good, stout, short-leaved plants, calculated to produce first-class fruit when the time comes for fruiting. The Melons and Cucumbers were remarkably strong and fruitful, carrying large crops, clean and healthy. The varieties of Cucumber grown are Dixon's All-the-year-round, and Telegraph.

One of these houses is devoted to Heaths and other hard-wooded plants, amongst which were good specimens of *E. Aitoniana superba*, *E. tricolor impressa*, *E. ampullacea*, *E. Austiniiana*, *Hedera*, and similar things.

We now come to the houses filled with fruiting Pines, which Mr. Sandford, Lord Bective's able gardener, is so successful in growing, as those can testify who saw, at the great Manchester Fruit Show, in 1873, the feat he accomplished in producing a Queen of the extraordinary weight of 8 lb. 4 oz. I have heard doubts expressed as to the weight of this Pine being correct, yet for its accuracy I can vouch, having seen it weighed on the exhibition table at Manchester. It was not alone the exceptional weight of this fruit that made it so remarkable, but its beautiful proportions and perfect condition in every way, for which, in addition to the first prize it received, the position of special medal in the houses—three in number, each 27 feet by 16 feet, hip-roofed—that is, with a short span or back light. They face the south-east, are like all the others substantially built, very light, and have an abundance of heating power—the two latter essentials indispensable where high-class Pine growing is attempted. The sorts grown are principally Queens and Black Jamaica's. The plants are of the character invariably found to produce the finest fruit—not ever large, but exceedingly strong, short, and broad in the leaves. This condition of a sufficiency of light in all fruit and plant houses, not merely in their construction, but in the position in which they are placed, so as to be completely away from the influences of anything that obstructs or absorbs the light, is of the greatest importance, and very imperfectly considered by many previous to the erection of such houses, even at the present day, as is too often the case. The apparent reason for this is, that of which the results give only too much proof. If evidence were wanting of the effects of the greatest possible amount of light upon fruits and flowering plants grown under glass, it could not receive a better illustration than in the strong and vigorous condition of the different occupants of these new houses at Underley.

The new garden fronting this block of houses is, like the old one, thoroughly well cropped, and the different varieties of cultural vegetables well cared for, of which they give ample proof. Northwards from this, at some distance, Mr. Sandford has made another fruit and vegetable garden, some 3 acres in extent. The situation is high, and less likely to suffer from spring frosts. At the extreme end of this garden, on a considerable elevation above the river, the view northwards up the valley is uninterrupted, and unsurpassed by any in the district. In this direction a new carriage road has been made, and an approach from the village of Barbon, the river to be spanned by a noble bridge of three arches, now in course of completion, and which will be an additional ornament to the place.

The land in all this valley of the Lune is of the finest possible description—its extreme fertility is apparent everywhere; the shrubs and trees are enabled to push their roots deep down into some 6 or 8 feet of the finest alluvial soil. Situated, they never suffer from the parching effects of dry summers, or the equally injurious influence of too much water in the soil in wet seasons. Sufficiently sheltered by the distant hills, such trees as the common varieties of Spruce, where allowed enough room in their early stages, attain a size and elegance of growth, with their plum-like branches perfect down to the green turf on which they lie, as to be surpassed in beauty by any other variety of cone-bearing tree, not even the beautiful but unfortunately tender *Araticaria excelsa*.

The many improvements recently made here have been well carried out by Mr. Sandford, the evidences of whose abilities are apparent in each department of the garden, of which this short notice, taken from insufficient memoranda hurriedly made, will give some idea. *7. Bates.*

Apiary.

HOW I WINTER MY BEES.—“Wintering bees! Oh!” says one, “there is no particular art in that, the chief difficulty is in summering them—with the anxiety of attending to swarms, the dread lest we should lose the queen, thus breaking up the whole colony; but they will take care of themselves in the winter.” Now we happen to hold quite a different opinion to this; we are amongst those who believe there is considerable art in wintering bees well, so as to enable them to come forth to meet the following spring with healthy vigour. If asked which was the best time of the year to purchase stocks, we should unhesitatingly recommend the autumn, because then many cottagers are willing to sell their best stocks for the value of the honey; but a hive worth say 20s. in the autumn would be worth 30s. in the spring, after the risk of winter is passed over. Again, when the stocks are placed on their new stands in the autumn we suffer but little loss from the workers straying. Well, now comes the question, “How must we take care of our newly-acquired property?” We will give our experience in as few words as possible; then the results which follow our simple method.

DIFFERENT OPINIONS.—My near neighbour, who is a tailor, says, “The best plan to preserve your stocks through the winter is to keep them warm, and nothing is so good for this purpose as the clippings from the tailor’s board or shreds of cloth.” To another, another friend, who is interested in farming, declares “Nothing on earth can equal haybuds wound round the hives, for this keeps in all the heat generated by the bees.” Some bee-keepers remove their stocks to the garret, whilst others condemn the poor things to the cellar, and not a few think it an excellent thing to put them beneath the ground, somewhat like Potatoes are stored. For my own part I ignore all the above; in the first place, I cannot afford to purchase sufficient cloths to cover up my large apiary, and though I might be able to secure a quantity of hay, still I fancy it is slovenly, neither do I rejoice in having either a garret or cellar in my small house, so that I am unable to adopt these methods—suffice it to say the above, in my humble opinion, are all needless, if not superfluous; you need not remove them from the summer stands, if they are well sheltered from the weather. It used to puzzle many of my school companions to tell how a stock of bees managed to thrive for at least twenty years, behind the clock in the village church steeple, and to send out two swarms every year, yet they were never removed in the winter, but were kept free from both rain and wind in the chinks of the massive old masonry which was reared in the days of the Crusaders.

DAMP.—This is the greatest enemy to bees. In summer, when the temperature of the air is so much higher than in winter, all superfluous moisture in the hive is speedily carried off, but the case is altered in winter. The true reason why bee-keepers lose so many stocks in winter is generally through excessive damp in the hive. I will try to illustrate this by a familiar example, it is the common plan recommended too frequently by our most eminent apiarists, to close up every crevice about the hive just before winter; nay, so far is this carried now, that cow-dung and mortar are plastered around the base of common skeps to fasten them to the stands in the cold air. This severe frost comes, followed by a thaw; when this takes place the hive is actually filled with seething vapour or moisture; another frost quickly comes and freezes the pitiable bees in a solid mass, of course destroying the whole colony. This is not an imaginary picture—it is too common, but every sensible person can quickly perceive it could not have occurred had there been sufficient ventilation. Again, if they suffer no further loss the combs begin to decay through the excessive damp, not to mention the mould and mildew which will take possession of the lower part of the comb, defying any attempt on the part of the busy inmates to eradicate it.

Well, what are we to do? I fancy many cottage bee-keepers saying, “Why, give them plenty of fresh air, and keep your hives free from damp by ventilating them well.” Talking with a successful bee-master some years since upon this subject—I was but a young beginner then in bee-keeping and it was just at the time the Woodbury bar and frame hive was being introduced into our apiaries—he said, “I leave the entrance always open, as well as take the plug out on the crown-board, and thus allow a free passage for fresh air or keep up good ventilation; and,” in concluding his remarks—I am not likely soon to forget his words—“I never lose a stock during winter.” I have since followed his plan, most happily, but with this difference—I do not touch the wood, only at each corner of the top or crown-board (common wood matters answer for this purpose). Just to show the amount of moisture given out by a large stock in the winter, I placed over the feeding-hole in the crown-board, one of the large Lancashire tin-fenders, which I knew would condense the vapour as it issued from the hive or bees. I was astonished to find, the following February, not less than 9 oz. of water in the feeder—

surely this could not be confined in the hive without proving injurious. The reason why cottagers’ skeps commence the first winter they are used to decay is generally supposed, by rain or dew. The moisture is condensed on the top and sides of the hive, then runs down to the bottom-board, where it saturates the straw in the lower part. Most bee-keepers, when wooden hives were first introduced in Great Britain, the “Devonshire Bee-keeper” among the rest, great and learned though he was upon the subject, declared “They could manage bees well in them during the summer, but failed in the winter; that they found straw hives the best for wintering bees.” Why? Because the wood hives retained all the moisture, whilst the straw skeps took it away, as I have described above.

In concluding let me urge my readers to keep up a thorough ventilation all the winter. I do not doubt they will prove my words to be truthful, and in future they will succeed in wintering their stocks in a healthy state, all other things considered—that is, if they have a good supply of food, which no one will neglect, and are well protected from the weather; you need not fear anything from cold weather, it is not cold that kills our bees, or why does it not kill them in the tree-trunks in the Canadian forest?

Since I commenced writing this short paper I found the following note, from Mr. Pettigrew’s *Bee Book*. I cannot condemn wood hives, as he does—I make the quotation merely to show that I do not stand alone when speaking upon the need of a good ventilation; my remarks do not refer to wood hives exclusively, but I believe every hive, straw as well as wood, to be the better for fresh air:—“Hives made of wood at certain seasons condense the moisture arising from the bees, and this condensed moisture invariably rots the combs. The walls of a wooden hive are often like the walls of a very damp or newly plastered house. The outside combs, and sometimes the centre combs, too, perish before the wet walls of the wooden hives. They perish in this sense, that their nature or adhesive power goes like mortar in walls, and become as rotten as one will neglect, and all such combs are useless in hives, for they have to be taken down and fresh ones put in their places.” There is in this work of the bees a waste both of time and honey. R.

Notices of Books.

The second part of the *Revue de l’Horticulture Belge* opens with a coloured plate of two pretty varieties of *Ceanothus*. Among the articles are one by Count Goumer on window plants, in which he recommends as a stimulant manure the mixture prepared by Dr. Jaeuvel, and called the “Floral,” which is, he says, well suited to the peculiar needs of plants grown in apartments. M. Ballet, in giving a list of the best twenty-five Roses, places *Gloire de Dijon* and *Céline Forestier* before *Maréchal Niel* as more free-flowering. It may be interesting to our Kose growers to give the list complete, viz.: Aimé Vibert, Abel Grand, Baronne Adolphe de Rothschild, Baronne Prévost, Céline Forestier, Charles Margottin, Duchesse de Cambacérés, Duchesse de Sutherland, Elisabeth Vignerot, Général Jacqueminot, Gloire de Dijon, Gloire de Ducher, Hortense Mignard, John Hopper, Jules Margottin, Louise Odier, Madame Victor Verdier, Mademoiselle Thérèse Levet, Mélanie Willermoz, Pius IX., Prince of Wales, Souvenir de la Malmaison, Souvenir de la Reine d’Angleterre, Sombreuil, and Sydonie. We may say in passing that the second number is, in our judgment, superior in interest to the first, and with such an editorial staff as it boasts this progress should be constant.

Two numbers of the *Botanical Magazine*—those for March and April respectively—were before us, and contain a few words of comment. The March number opens with a double plate of the very lovely and very interesting *Gustavia gracillima*, a stove shrub or tree, native of New Grenada, with simple elongate serrate leaves, and large rose-coloured flowers like those of a *Camellia*, and of very singular conformation. The plant, we learn, flowered in Mr. Bull’s nursery last autumn, but we had not the good fortune to see it. Masdevallia Chimera, which forms

the subject of the next plate, has been so lately figured by us (1875, p. 41) that we need not further refer to it. *Colchicum* literature was also described in our columns by Mr. Baker, 1874, p. 33. It is a very interesting yellow-flowered species, native of Western India, and flowers of which were produced at Kew. *Theropogon pallidus* is an elegant Liliaceous plant, allied to *Ophiopogon*, with a raceme of nodding pinkish flower-bells, like those of *Scilla nutans*, but in form more like those of the *Lily of the Valley*, and with tufted foliage like that of a *Carex*. This also is a Himalayan plant, and was derived from the collection of Mr. Wilson Saunders. *Wahlenbergia tuberosa* is an extremely curious Campanula-like plant, native of Juan Fernandez, whence it was introduced through the mediation of Messrs. Veitch. It has a very singular branched tuberos root-stock aboveground, from which are sent up leafy stems 6 inches to 2 feet in height, with linear, toothed leaves, and bearing terminal clusters of erect, whitish, bell-shaped flowers, striped with pink. The April number does not contain quite such striking plants, but it is by no means devoid of interest. *Phyllocactus bifloris*, a native of Honduras, is chiefly remarkable for the small number of its flower-segments, which are of a reddish purple colour. *Pentstemon antirrhinoides* is a shrubby yellow-flowered Californian species sent to Kew by Mr. Niven, of the Hull Botanic Garden. *Pyrus prunifolia* is figured because no good figure exists of so beautiful and well-known a tree, and it certainly amply deserves its portrait. *Masdevallia Peristeria* was described in our columns by Professor Reichenbach in 1873, p. 500. It is in the flower of M. Chimera, but not so bizarre in its appearance. *Fourcroya undulata*, an elegant species which flowered at Kew last autumn, is very similar to *F. Selloi*, but is smaller in all its parts. *Cyrtopora sanguinea* is a curious tuberous leafless Orchid, from the Sikkim Himalayas, and which varies very much in colour in different specimens.

The plates in the last number of the *Illustration Horticolæ* are *Diefenbachia antioquiensis*, a variety or species from New Grenada, with oblong acuminate leaves of a dark green, mottled with pale yellow. *Azalea Madame Jean Wolfolk* is a very double variety, with the white flowers tipped and streaked with red. *Thrinax barbadensis* is a fine Fan Palm, with spiny petioles marbled over with silvery blotches. It is said to be very rare in collections. *Zamia Lindenii* is a very handsome Cycad from Ecuador. It and *Z. Roezlii* are said to be the finest Cycads of recent introduction. *Masdevallia amabilis*, var. *lineata*, is a fine crimson-flowered species with the yellow flower-tube marked externally with reddish lines. *Arucaria Balmans* is a splendid species, native of New Caledonia, where it attains a height of 130 to 160 feet. It has the habit of *A. excelsa*, with rich purple-brown coloured branches. It was shown in Florence under the name of *A. neo-caledonica*. The plate represents the tree, but the analytical details mentioned in the text are omitted; perhaps they will find a place in the next number.

The coloured figures in the January and February numbers of *Regel’s Gartenflora* are *Oxalis Ortgiesii*, *Sedum spurium*, var. *splendens*; *Rheum palmatum*, var. *tangutica*; *Campanula tridentata*, var. *Saxifraga*, a pretty bell-flower, with linear or lanceolate leaves; *Pentstemon albar*, var. *penelope*, a handsome suffruticose plant with large blue flowers; and *Enceltharpus Verschaellii*.

Messrs. Cassell & Co. are issuing a *Child’s Bible* in large type, and with plenty of pictures. The text is divided into paragraphs, which is very convenient in one sense, but as no reference even is given as to the verses, the poor child requested to find a text or verify a reference would find himself somewhat at a loss.

The *Journal of Botany* for January of the present year contains an interesting list of the plants growing wild in Kew Gardens and the adjacent pleasure ground, compiled by Mr. Nicholson. The list contains nearly 400 species and varieties, very few among which, considering the circumstances, have been naturalised exotics. The same thing has been noticed in the case of other botanic gardens. It is desirable on many accounts that the census should be revised every few years, and compared with that of preceding years. How curious it is to read that *Geranium Robertianum* is the rarest species within the prescribed limits. It is curious also to note that the American water weed, *Elodea canadensis*, once so troublesome in the pond before the Palm-house, has all but disappeared, though abundant elsewhere in ponds and ditches, no one knowing the why or wherefore.

APRIL.

A PRIL! sweet month of sunshine and of flowers, P ray be thou not too tearful, lest the flowers, R rejoice first at promise of the Spring, I n disappointment droop! that gloominess bring; I n Nature smile with thee, and thy curls sing. *M. A. Bateson Colburn’s “New Monthly Magazine.”*

HORTICULTURAL EXHIBITIONS, 1875.

APRIL.

- 21.—Royal Horticultural Society, South Kensington. Meeting of Fruit, Floral, and Scientific Committees.
- 22.—Royal Horticultural Society of Ireland. Spring Exhibition. Sec., A. Balfe, 25, Westland Row, Dublin.
- 27.—Manchester Botanical and Horticultural Society. Exhibition of Auriculas, &c., in the Town Hall. Manager, Bruce Findlay.
- 28.—Royal Botanic Society, Regent's Park. Spring Show. Sec., W. Sowerby.

MAY.

- 1 to 10, inclusive.—Royal Botanic Society, Regent's Park. Mr. William Paul's Special Show of Roses, Pelargoniums, &c.
- 11 to 24.—Royal Botanic Society, Regent's Park. Special Exhibition of Clematis, by Mr. G. Jackman.
- 7 and 8.—Exhibition of Plants and Flowers in the Kibble Conservatory and Royal Botanic Garden, Glasgow. Manager, Robert Iulien.
- 12.—Royal Horticultural Society, South Kensington. Meeting of Fruit, Floral, and Scientific Committees. Pot Rose Show.
- 14 to 21.—Manchester Botanical and Horticultural Society's Annual National Exhibition, at the Garden, Old Trafford. Manager, Bruce Findlay.

THE

Gardeners' Chronicle.

SATURDAY, APRIL 10, 1875.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, April 12	Sale of Bulbs of <i>Lilium auratum</i> and <i>Coniferous Tree Seeds</i> collected by M. Roezi, at Stevens' Rooms.
TUESDAY, April 13	Sale of <i>Lilium auratum</i> , <i>Azaleas</i> , &c., at Frohner & Morris' Auction Rooms, 98, Gracechurch Street, E.C.
WEDNESDAY, April 14	Sale of a Collection of British Birds' Eggs, also a Collection of British Birds, at Stevens' Rooms.
THURSDAY, April 15	Sale of Imported Orchids, at Stevens' Rooms.
	Meeting of the Linnean Society, at 8 P.M.
	Sale of a Collection of Established Orchids, by Order of the Council of the Royal Horticultural Society, at Stevens' Rooms.

UNDER the title NATIONAL HEALTH AND WEALTH the Rev. HENRY MOULE issues a new edition of his pamphlet on his favourite theme of dry earth closets, and the safe, inoffensive, and profitable disposal of liquid refuse. The title is an attractive one, whatever may be thought of the subject discussed under it, or the special views of the author. The health of the nation is also the basis of its wealth. In proportion as the first suffers the second declines. It must also be admitted that, notwithstanding all the sanitary legislation of late years, the means of cleanliness are still practically beyond the reach of large masses of the population alike in town and country, and that where such have been provided their efficacy is often imperilled through carelessness or ignorance; hence the need of still agitating such matters and urging the importance of what has been called a sewage policy. Each habitable house ought not only to be furnished with sufficient area for the number of inmates, pure air, abundance of light, but also with a liberal supply of clean water, and simple means of getting rid of all pollutions whether liquid or solid. So much may be taken for granted; cleanliness is the parent of health, and it is well impossible to be clean under the present arrangements in and around dwelling houses. Too many human beings are crowded into small rooms; the water supply is generally deficient, often the water is bad, and there are no facile means in use for neutralising nuisances or getting rid of them. On the contrary, nuisances are piled up within and around dwelling houses; the products of respiration and perspiration are too often shut up in unaired beds and unventilated rooms, so that the dead portions of yesterday's body poisons the living body of to-day or to-morrow. As to outside, here is what the author says (p. 35)—and a very slight acquaintance with the sanitary state of small villages is sufficient to prove the substantial truth of the sad pictures he presents:—“In some of the small villages of from 100 to 600 inhabitants, situated in marshes, fens, moors, or water meadows of Wilts and Dorset, epidemics prevail quite as frequently as in overcrowded towns, and in some of them the average rate of

mortality has been found to be as high as thirty-four per thousand. Why, in some of them the water is within 4 or 6 feet of the surface of the soil on which the cottage stands, and as if this damp bottom was not sufficient in itself to weaken or destroy the miserable inmates,” Mr. MOULE adds, “into that water the cottage well is sunk, and from it the family drink; and yet within a few yards of the cottage the privy vault is sunk, perhaps into the same bed of water, or so near it that poisoning is inevitable.”

On the next page the author quotes a more common state of things—populations of from 200 to 600 clustering around the squire or the parson, picturesquely scattered along the banks of a running stream from which the population drink. Ascend it a little way, and you find privies erected over it, or the refuse of farms and of mansions flowing into it. And so through several pages. In fact, throughout the rural districts the privy, the cesspool, and the drinking wells are in such close proximity to each other that the marvel is, not that so much sickness or debility prevails, but that any of the population are in health. Mr. MOULE proposes the abolition of surface wells, privy pits, and cesspools near dwellings by Act of Parliament. impose fines upon all such nuisances and slow means of killing the population, and this would stimulate other modes of abating the nuisances, and converting such into positive benefits and means of wealth—by the dry earth system, to wit.

Doubtless much diversity of opinion continues to prevail regarding the manurial worth or commercial value of the dry earth itself. According to the experience of Mr. FENN, one of the earliest advocates of the dry earth system, the manurial value is great. That it is a good manure, specially rich in phosphates, and admirably adapted for the production of vegetables, root crops, and such fruits as Grapes, is certain, but we confess that its manurial value is of quite secondary importance to its perfect efficiency as a deodoriser of closet and other offensive matter. Its potency in this respect can readily be tested by any one, and is, in fact, established beyond dispute. The author attributes much importance to using the same earth again and again. We see little need of this, and some risk from it. Earth is easily dried, and when once passed through the closet ought to be forthwith employed in stimulating growth and conversion into food. In absorbing all the unpleasant odours of excrements, and resolving these apparently into itself, the earth becomes enriched, and in fact converted into a fertiliser, and it is much better to use it at once than run any risk of unpleasantness by adding to the strength of dry earth manure.

The author's mode of procedure for cottages is so simple, and likely to prove so useful, that we venture to transfer it to our columns:—

“In the floor of a small projection from the upper storey there should be inserted a 12-inch earthenware pipe, glazed within, rising 18 inches above the floor and terminating at 9 or 12 inches above the vault, which in wet soils should be cemented and made water-proof. It should be furnished with a seat and used as a closet with or without machinery for admitting and discharging the earth. This pipe would also prove useful for emptying commodes, &c., in case of sickness. All upward draught must be prevented by keeping earth round the bottom of the pipe. All the attention needed would be to remove the contents from under the pipe once a fortnight or three weeks. Outside the houses another pipe should be erected over the same vault in a small projection like a pouch, for the male members of the family, and in this also a store of dry earth might be placed. The trouble of applying the earth, if done from the outside, is very small, and is really of no account compared with the value of the manure.

“The provision of the earth is very simple. In dry weather let the cottager rake off about half an inch or an inch of the surface of his garden, and spread it in a layer over his paths. In two days he will be able to sift it, and it will be fit for use. When the earth is applied from the outside the sifting can be dispensed with. All that is needed is that the earth be dry.”

The reverend author, however, has made another of another source of serious and mischievous nuisance, perhaps even more dangerous than any other—the vegetable and animal refuse, that is generally stored within a few yards of the cottage and suspiciously close to drinking wells. These, such as Cabbage-stalks, &c., when soaked with house-slops become deadly polluters of the atmosphere. The remedy for this is unique: every cottage should have 20 perches of land. Let one of these perches be wired in for the enclosure of twenty or twenty-five Cochins or Brahma fowls. Let these have all the vegetable and animal refuse to eat up bodily, and so make an end of it. Dig this ground over once a fortnight, and the manure and the refuse will keep the fowls with but little expense for Barley, and the two tons of manure made by the fowls—for twenty hens will eat as much, and consequently, we presume, make as much manure as a pig—and the eggs, will add, says the author, from £5, £7, to over £10 a year to the cottager's income. Doubtless, too, this new mode of folding by fowls for a year would form a capital preparation for Onions or Asparagus.

But then another great source of nuisance has to be dealt with—the house slops. As Mr. MOULE condemns the water system of sewerage we were somewhat curious to discover what was to be done with liquid manures. Well, two remedies are offered—the usual one of irrigation, and the new one of cremation. The latter might answer with fires on purpose; but the idea of placing the most villainous liquid pollutions in pans under our grates to aid combustion by their vapour, and to have them thus purified and destroyed, is too horrible to think of. What would become of the liquid cremations when the wind with its mischievous caprice sends a back current of smoke and half-consumed liquid pollutions back into one's sitting rooms? No, cremation won't do. It is wasteful as dangerous, especially while hungry soils, yielding only half a crop for lack of food, would form as thorough a cure for liquid manure as dry earth does for solid. The author also states that dry earth added to house sewage at the rate of half a hundred-weight to six hogsheads, will stay putrefaction for forty-eight hours. As a rule, too, putrefaction will hardly commence till after twelve hours.

There is an epitome of the water-sewage system for the rural districts, which hardly varies in principle from that adopted on small farms. On p. 26 the author deducts 4 perches from the 20 he advocates for each house, for the cottager's outhouse fowl-pen, which leaves 16 perches, or 483 square yards of cultivable land. Taking a household at ten persons, and the liquid refuse at 3 gallons a-head, gives 30 gallons a-day, or 22 gallons per square yard. The object to be aimed at is the distribution of this liquid refuse over the ground in such a way as to soil all the manured portions until they are appropriated by plants, and that no manure shall penetrate the subsoil so as to poison wells, &c. The author supposes the land to be laid out for the first time, say in October, and treated thus: Strips a spade wide, and 3 feet from centre to centre, are dug all over the 16 perches. As the digging proceeds Cabbages are planted in these foot-wide strips from 12 to 18 inches asunder, with 30 inches or so of undisturbed ground between, the 30 gallons of sewage to be applied each day to 120 feet in length of those Cabbage grounds. This would dispose of the refuse for twelve days to 960 Cabbage plants. The interspaces between the Cabbages are then to be dug or forked up each 12 yards, to receive 30 gallons of the refuse daily. The whole space would thus be manured within a month. The application might be several times repeated, and thus the liquid be disposed of for four months. In February the intermediate spaces to be cropped with Parsnips,

Broad Beans, Onions, &c. During these operations the Cabbages to have three more waterings, as in October the earth and the growing crops quickly absorb all offensive matters, which are further neutralised by a shovel of dry earth or fine dry coal ashes to 30 gallons of sink water, which the author affirms will prevent the putrefaction of sink water for thirty-six or forty-eight hours.

As to the value of the crops, the author estimates the crop of Cabbages at £4, a crop of Cauliflower and of Lettuces at £3 more. Assuming that the intermediate spaces are used for two rows of Beans, or three of Onions, Carrots, Parsnips, to be followed by a crop of Savoys, the full value of the produce of 16 poles or perches of land he puts down at £15. It will be observed, however, that this is close cropping indeed, and allows no room for the Cabbages to come to maturity. The author, how-

near to the pollutions in the rural districts, and is the only means by which they can be rendered innocuous and finally converted into produce. It is a grievous loss of productive force as well as a serious injury to health to waste or accumulate these, and finally to have to deal with and dispose of them by filtration, irrigation, or cremation. Doubtless, too, the dry earth closet, which is practicable for towns, would greatly simplify the problem of dealing with liquid manures by lessening their volume and impurity.

Without professing to endorse all the views of the author, who at times has thrown the reins of his judgment on the neck of his hobby, and in consequence may have ridden it too hard or too far, yet we would advise all to read his *National Health and Wealth*, and as far as practicable preserve the one and augment the other, by the adoption of his dry earth and irrigation in detail

change of the original arrangements would do an injury to the Royal Horticultural Society, without yielding any corresponding benefit to the Pelargonium Society. The show will therefore be held this year at South Kensington, as announced in the circulars already issued. The committee hope, moreover, to be able to make arrangements to hold the Pelargonium show next year at Chiswick, at a date which as nearly as possible may coincide with the height of the blooming season of the bedding varieties, which would scarcely have been the case this year, the date being fixed for July 21.

— We are informed that Mr. Alderman and Sheriff ELLIS, the senior Sheriff of London and Middlesex, has consented to become the Chairman of the executive committee of the POTATO EXHIBITION; and Mr. JAMES ABBISS, J.P., formerly an Alderman of the City, is the Vice-Chairman. The committee have put themselves into communication with Mr. W. A. LINDSAY, the secretary of the Royal Horticultural Society, with a view to the exhibition being held at South Kensington, probably in connection with the Fungus Show, early in October, and some liberal proposals have been put forward by Sir

FIG. 99.—UNDERLEY HALL, KIRKBY LONSDALE, THE SEAT OF EARL BECTIVE. (SEE P. 466.)

ever, affirms that from 20 perches of ground—a Vine against a wall and 100 Currant bushes—he raised, by this system of sewage resolution into food, produce to the value of £20 to £25 per annum. On a larger scale, or for the disposal of the liquid refuse of villages, &c., the author recommends grass plots and root crops, indeed sewage farms in miniature. And yet, singularly enough, throughout the pamphlet there are strong condemnations of the worthlessness and incompetency of the water system to deal with the problem, or remedy for the evils of our present sanitary state. On the contrary we gladly welcome both the dry earth and the water system—any and every means, in fact, that will rid us of the evil that sits as a nightmare on the health of the nation and thus saps the foundation of our wealth.

Assuredly to us this water preventive is better than cure. We quite agree with the author that the evil should be grappled with at its source and mastered in detail. The earth is

systems; and especially to endeavour to resolve all pollutions into produce by the express and simultaneous cropping of the ground, already, and in so many instances, so successfully practised by horticulturists. All vegetables luxuriate in liquid sewage; Roses and Mignonette become finer and sweeter on such savoury drinks, while there is hardly a fruit, from a Strawberry to a Pine-apple, that may not be enlarged in size and improved in quality by a judicious use of liquid refuse.

— SOME time since a suggestion was made that the PELARGONIUM SOCIETY should hold its show in the great conservatory at Chiswick instead of at South Kensington, and the proposal seemed so apposite that many of the members felt inclined to adopt it. On more mature consideration, however, it was found that difficulties stood in the way. The competition for Messrs. VEITCH'S fruit prize was fixed for the same day, and as the two items—fruit and Pelargoniums—made up last year one of the best South Kensington shows of the season, and as Messrs. VEITCH objected to the competition for their prizes taking place at Chiswick, the committee felt that any

EDWARD LEE, on behalf of the Alexandra Palace Company, with a view to the show taking place at Muswell Hill. The arrangements are being pushed on as fast as possible, so as to allow of the schedule being published without further delay. In addition to the special prizes already announced, Messrs. JAMES CARTER & Co., High Holborn, offer a silver cup, value five guineas, for six English and six American varieties of Potatoes, and 2d and 3d prizes of three guineas and two guineas respectively.

— We are requested to state that the PELARGONIUM TRIAL AT CHISWICK will be carried out as usual, and that the officers of the Royal Horticultural Society, with the laudable wish of keeping up to the utmost the *status* of the Chiswick garden in the present precarious state of the Society's affairs, desire this season to make a special effort in this direction. They therefore trust that the raisers of seedlings, as well as the introducers of foreign novelties, will, as usual, send for this purpose plants of such new varieties as they may be able to spare; and if they will at the same time specify whether or not they would desire any of them to be grown in pots, the superintendent, Mr. BARON, will be ready to give effect to their wishes. The superintendent is prepared to receive and take charge of the plants at once, and requests that those

who intend to send will do so as early as possible, addressed to him, at the Royal Horticultural Gardens, Chiswick.

— Through the kindness of our colleague, Dr. REBEL, we recently gave a conspectus of the *CYCADS* in cultivation. In looking over the collection at Kew the other day we observed several *Ceratozamias* in cone, among them two very fine specimens—a male and a female—*C. mexicana*. These plants are exceedingly healthy and vigorous, the female plant having leaves nearly or quite to leaf in length, and those of the male are about 8 feet. The longest leaflets measure nearly 18 inches. The male cone is from 18 to 24 inches long, and the female from 8 to 10. *C. Karwinskiana* and *C. Kusteriana* are also in cone in the same establishment. Not one of the species of this genus appears to have been figured in any English work. BRONGNIART, the founder of the genus, figures the first named species in *Annales des Sciences Naturelles*, but he had only imperfect materials at that time. The collection of living *Cycads* at Kew, if not so rich in species as some Continental ones, includes many very fine large specimens. The larger plants are in the Palm-house, where, also, will be found the species of *Ceratozamia* in question.

— *SAXIFRAGA STRACHEYI*, a beautiful and interesting plant, is blooming on the rockwork at Kew. The flowers on opening appear pure white, the pink colour which soon obtains over the entire flower being then restricted to the ovary. It is a near relative of *S. ligulata*, and of which it is perhaps a variety, though sufficiently distinct to be desirable in the same collection. It was raised from seeds sent to the Royal Gardens by General Strachey, F.R.S., in 1851, and has been cultivated on the rockwork for many years. A figure is published in the *Botanical Magazine* of 1872. It is native of the Western Himalaya and Tibet.

— THE WESTON-SUPER-MARE AND EAST SOMERSET HORTICULTURAL SOCIETY will hold its annual exhibition on Wednesday, August 4.

— The Paris Academy of Sciences awarded the following Prizes last year for BOTANICAL WORK:—The Barber Prize (in part) to M. J. Chatin, for studies of the Valerianæ; the Desmazieres (1872) to M. M. Cornu, for a monograph of the Saprolegnias; and 1000 francs to M. Boret for his labours among lichens; 1000 francs to M. Lefranc, for his paper on *Attractylis gummifer*; the Desmazieres (1873) to M. Girodot, on the Lemnaceæ (Algae); and 1000 francs to Messrs. Van Tieghem and Lemonnier, on the Mucorinæ; the Bordin (1873) to M. J. Vesuvius for the anatomy and physiology of Dictyotales; and the Geiger (4000 francs) to good works on fossil botany, approved by M. Brongniart. In like manner this year, several prizes are offered for botanical papers on various given subjects.

— We learn that the question as to whether THE INTERNATIONAL HORTICULTURAL EXHIBITION should be held next year at Brussels or at Amsterdam, has been settled in favour of the former city. Affairs, then, stand thus, Brussels, 1876; Amsterdam, 1877; London (?), 1878. Meanwhile we may deprecate the application of the word "international" to mere local display, however extensive.

— We have received from Mr. TYERMAN a bouquet of spring flowers, most beautiful, most interesting. We will try and enumerate some of them—Several varieties of the gorgeous *Anemone hortensis*, of various shades of crimson; the blue *Anemone apennina*, the yellow *A. ranunculoides*, the purple *Anemone pulsatilla*. Mr. TYERMAN also sends us numerous varieties of the common *Primula*, such as the blue-flowered *Polystrata*, a fine seedling gold-faced *Polyanthus*, various *Hose-in-hose* and "Jack" varieties; the common *Oxlip*, *P. vulgaris* var. *umbellata*, and a glorious form of it under the name of *Primula Golden Plover*; a similar form, but smaller, called *Golden Prince*; the *Bardfield Oxlip*, and a number of curiously deformed varieties, which, as Mr. TYERMAN says, lose little of their beauty, all deformed though they be. Before dismissing his flowers we may ask whether any amateur gardeners have practised the plan stated to be followed in Belgium of cutting away the corolla of *Primroses* in an early stage with the result of causing the colour to be developed in the calyx? (See MASTERS' *Vegetable Teratology*, p. 284.)

— DRIMYS WINTERI, a plant of considerable interest, is flowering in the economic-house at Kew. The genus belongs to the Magnoliaceæ, and stands next to *Illicium*, which is also in the same house, and represented in flower by *I. floridanum*, the "Poison Bay" of Alabama. The use of Winter's Bark was brought into notice by Captain WINTER, who found it very efficacious as an antiseptic, it having been administered to some of his crew with great success for scurvy. It is a stimulating aromatic tonic, and much resembles in appearance and properties the bark of *Canella alba*, with which indeed it was once

confounded; and has also been superseded by that medicine, as well as by others. It has an extensive range of habitat, extending from Terra del Fuego, along the west side of South America, to New Grenada and Mexico. It was first discovered on the Straits of Magellan, whence the bark was brought by Captain WINTER, when in company with Sir FRANCIS DRAKE, in 1578. On the Continent it is cultivated as *D. chilensis*, though that may be a slightly different form, as the leaves appear less glaucous. It attains a height of 50 feet, and, judging from cultivated specimens, must form a handsome tree. The leaves are oblong, coriaceous, green above, with a glaucous under-surface, and the pale yellowish white flowers are produced in simple or compound umbels towards the ends of the branches. *D. axillaris*, a distinct species, is a native of New Zealand; and another, *D. piperata*, is found in the mountains of Borneo.

— The following subjects are announced for discussion on the evenings of the dates named, at the SOCIETY OF ARTS:—

April 14.—"The Best Method of Making Field Experiments Practically Useful to Agriculturists." By Professor JOHN WRIGHTSON.

April 20.—"The India Museum Question." By Dr. FORBES WATSON.

April 23.—"The Preparation and Uses of Rhea Fibre." By Dr. J. FORBES WATSON.

April 28.—"The Protection of Buildings from Lightning." By R. J. MANN, Esq., M.D., President of the Meteorological Society.

April 30.—"The Growth of the Factory System in India, with special reference to the Production of Textile Fabrics, and the Relative Advantages of the British and Indian Manufacturer." By ELIJA HELM, Esq., of Manchester.

The chair will be taken at 8 P.M.

— We are informed that thirty-nine candidates have been elected Fellows of the Royal Horticultural Society since January 1 last.

— THE EXHIBITION OF THE NATIONAL AURICULA SOCIETY, to take place in the Town Hall, Manchester, on April 27, promises to be an extremely good one this year; one leading cultivator of this flower writes to say that it will be the best yet held for fifty years past. The purpose of being forth to make a "National Auricula grower calls "great Primula festival," by inviting examples of the newer types of the Primrose, Fancy Polyanthus, &c. Many species might be included, if it is not too late in the season to catch some of them in flower.

— Amongst the many alterations Mr. BENNETT, of Hatfield, has been engaged in during the past winter, is the removal of some large mounds of unsightly shrubs that marred the beauty of the pleasure grounds, and the FORMATION OF A VERY EXTENSIVE ROOFTERY for the culture of hardy Ferns, alpine plants, &c. This roostery is formed at the south side of the pond, on a portion of the ground fully described in a notice in the *Gardeners' Chronicle* Supplement, May 9, 1874.

— Mr. E. WILLMETT, late foreman at Wycombe Abbey Gardens, has taken to the management of the gardens at Berkeley Castle, Gloucestershire.

— We are glad to welcome the April number of the *Villa Gardener*, introduced, as it is, by a modest preface from the pen of the new Editor, Mr. D. T. FISKE, to whom as to his journal we heartily wish all success and prosperity. We know that in his hands journalism will not be degraded by illicit parasitism, nor will the public be defrauded by the dishing up of old matter or old illustrations as new. When we learn that he intends, be-like, to sip sweets from other journals, we know that he will respect the rights of the public and the interests of his compeers, and "maintain honourable friendship on the basis of mutual acknowledgment."

— We have had submitted for our inspection some dried flowers, the colours of which are very well preserved, and which, therefore, serve well as ornamental objects. In the instance before us a very pretty flower, surrounding a portrait, was made of flowers of the Virginia Stock and portions of Fern fronds. The preparation by means of which these results are obtained may be had of E. ROBERTS, Frankfort Terrace, Harrow Road, Paddington, N.

— Now that we are all on the look-out for signs of the coming spring, and all the more keenly so after the irritating weather we have had to endure, it may be well to mention that the Meteorological Society has issued a series of instructions for the observation of PHENOLOGICAL PHENOMENA. By this awkward expression is intended the first observation of the first appearance in spring of wild flowers, birds, insects, &c. This list has been drawn up by a conference of delegates from the Royal Agricultural, Botanic, Dublin, Horticultural, Marlborough College, Natural History and Meteorological Societies. Some years since the British Association published a similar list, and the records of Mr. M'NAB and Mr. PRESTON are

well known to readers of the *Gardeners' Chronicle*. We may remark that the nightingale was heard by us on April 4 in the neighbourhood of London. Blank forms for recording these phenological phenomena can be had from the secretary of the Meteorological Society, 30, Great George Street, S.W.

— In the *Montieur Horticole Belge* the following SIX YEARS are recommended for those who wish to finish their plants from July to May:—1. *Beurré Giffard*, ripe at the end of July and beginning of August; 2. *Williams' Bon Chrétien*, end of August or beginning of September; 3. *Louise Bonne d'Avanches*, end of September; 4. *Beurré Durocand*, October and November (M. GILLESKING states that the flowers of this variety withstand spring frosts better than any other); 5. *Beurré Diel*, November and December; 6. *Bergamotte Espéren*, January to April.

— We are requested to publish the following extract of a letter received by Messrs. THOMAS COOK & SON, from the British Executive of the INTERNATIONAL EXHIBITION AT PHILADELPHIA in 1876, under which they are appointed General Passenger Agents to the British Section.

The International Exhibition of 1876, at Philadelphia. Offices of the British Executive, 5, Craig's Court, Charing Cross, S.W., March 4, 1875.

"Gentlemen.—His Grace the Duke of RICHMOND, K.G., Lord President of the Council, bearing in mind the able manner in which you conducted the transit arrangements to and from Vienna, in view to the satisfaction of the Royal Commission, of which His Grace was a member, and to the advantage of the British exhibitors and visitors to Vienna, has instructed me to offer you the appointment of "General Passenger Agents to the British Section of the International Exhibition at Philadelphia in 1876." * * *

"His Grace, aware how well the arrangements you effected at Vienna worked for the interests of all concerned, desires that similar, and if possible greater, facilities may be afforded in Philadelphia, viz. a. that your special representatives on this, as on all occasions alluded to, should be under the immediate orders of the British Executive. * * * I have the honour to be, gentlemen, your obedient servant,

P. CUNLIFFE OWEN, Executive Commissioner. "THOS. COOK & SON."

Under this appointment Messrs. THOS. COOK & SON have to make on behalf of the British Executive the whole of the arrangement with the Atlantic steamers and railway companies for the conveyance of the exhibitors, their assistants, and workpeople, and also for the conveyance of the goods to be exhibited; and the exhibitors may rest assured that every effort will be made to obtain as liberal arrangements for crossing the Atlantic as were made for the English exhibitors at the Vienna Exhibition of 1873.

— The next meeting of the INSTITUTION OF SURVEYORS will be held on Monday evening, April 12, when the adjourned discussion on the Home Secretary's "Bill for Facilitating the Improvement of the Dwellings of the Working Classes in Large Towns" will be resumed. The chair to be taken at 8 o'clock.

— M. MAY, in the *Revue Horticole*, recommends for market purposes grafted plants of *Cranonitidis*, which form plants of great beauty. Young plants, with stems as thick as a goosequill, are taken early in autumn as stocks, and these are grafted the following summer en demi forte (clef-grafting).

— The germination of *ARUM ITALICUM* shows that it is the dilated end of the tigellum which forms the corm of this plant. When the seed begins to germinate the radicle first protrudes, then the long tubular sheath of the cotyledon, at the base of which is the plumule and tigellum, the latter dilating into a corm, from which adventitious roots spring. The cotyledon itself remains within the seed, and is of globular form.

— At the Council meeting of the ROYAL AGRICULTURAL SOCIETY OF ENGLAND on Wednesday, Mr. WHITEHEAD (Chairman of the Botanical Committee) reported that Mr. H. W. BATES, F.L.S., had consented to write a paper for the *Journal* upon the "Natural History of the Colorado Potato Beetle," and that the committee recommended to the Journal Committee that a coloured plate in illustration of Mr. BATES' paper should be given in the *Journal*.

— WAS *SPINEA PALMATA*, of THUNBERG (figured in the *Botanical Magazine*, tab. 5726, as a recent introduction), known in this country as a garden plant previous to its introduction, a few years since, by Mr. FORTUNE? LOUDON, in his *Encyclopaedia*, and in his *Hortus Britannicus*, gives "*Spirea palmata*, Thunb., China, 1823." It is clear, then, that something under the name of *palmata* was grown in this country at that time. The question is whether that was the true *S. palmata* or not. We incline to think not, although some of our old cultivators are of a different opinion. We think not, because the plant is Japanese, not Chinese; and because we think it most probable that the *palmata* of former days was not the true Japanese plant intended by THUNBERG

but a red-flowered variety of *S. digitata*. It may here be stated that three plants have been called *Spiraea palmata*. 1. The Japanese plant just mentioned, and to which alone the name should be applied. 2. *Spiraea palmata*, of LINNÆUS, a North American plant with rose-coloured flowers, and which is properly the *S. lobata* of MURRAY and of JACQUIN. 3. *Spiraea palmata*, of WILLD., figured in his *Flora Rossica*, t. 27, and which is properly the *S. digitata* of WILLEBRONN, *Sp. Pl.*, p. 161. This is a plant of Eastern Siberia, and very likely of China, and was introduced in 1823.

In a recent number of the *Revue Horticole* figures are given of an *ATLANTIS EXCELSA* which produced flowers only four months old, and when the seed-leaves were still attached to the plant. The flowers were male. It is possible that the similar case figured by ourselves was also a seedling, but we had no opportunity of ascertaining whether this was so or not. M. CARRIÈRE also figures a *Weigela* which flowered when little more than an inch in height. More than 200 seedlings showed the same precocity. *Chamaenas oleifolius* and *Pavia hybrida* have been observed by M. CARRIÈRE to present the like phenomenon.

— We learn that the HORTICULTURAL CLUB has been re-organised, and will in future be known as the LINDLEY CLUB. The subscription is 10s. a year, and the meetings are to be held in January, March, June, and November. The meetings in March and November will be initiated by a "conference for the consideration of any questions of importance directly related to, or incidental to, horticulture." The members are to dine together at each meeting of the Club, and the first time a newly-elected member dines with the Club he is entitled to a seat at the right hand of the Chairman! Such are some of the main features of the proposal. A special general meeting will be held on Wednesday, April 21, to pass the revised rules and regulations. Mr. RICHARD DEAN, Ealing, is the Secretary.

— M. GILLEKINS, in the *Moniteur Horticole Belge*, recommends the following SIX PEARS FOR WALLS with a southern and eastern aspect:—1, Doyenné d'Étiève, ripe from January—June; 2, Beurré d'Harlemont, ripe in December—January (this, with the preceding, are special recommendations for market purposes); 3, Passe Colmar, December—January; 4, Beurré Rance, January and February; 5, Joséphine de Malines, Feb.—March; 6, Passe Crassane, January.

Home Correspondence.

The Daffodil and its Double Varieties. I do not regret having called attention to the popular belief, confirmed, as I then thought, by my own experience, that Narcissus Pseudo-Narcissus becomes double under cultivation, because the fact will now be either refuted or established. Thirty-five years ago I cleared a corner of my father's garden, and filled it exclusively with wild flowers. Amongst others I planted two or three clumps of *N. Pseudo-Narcissus*, brought from a meadow near the Trent, where *N. major* was never seen. Two or three years after the other wild flowers were as I planted them, but double Daffodils were flowering on or near the spot where I had planted the single. I mentioned this to a gardener, who told me other people had found the same; and since that time I have never doubted until now that the double garden Daffodil and the single wild Daffodil were the same species. I own myself convinced by the opinion of such good florists as Mr. Harpur-Crewe and Mr. Barr, who tell us that *N. major*, the double garden Daffodil, and *N. Pseudo-Narcissus*, the single wild Daffodil, are quite distinct, and must have been misled by the "fallacy of imperfect observation," the probable fact being that *N. Pseudo-Narcissus* died, and that a few roots of that ubiquitous and persistent bulb, the garden Daffodil, had been left in the soil when cleared. I venture to suggest that "R." and Mr. Maw should repeat the experiment of planting *N. Pseudo-Narcissus* in their garden, selecting a spot from which *N. major* is entirely absent. I am doing so here, giving the bulbs the benefit of every variety of soil, and I will let you know the result. *C. W. Dox, Edg. Hill, Malpas, Cheshire.* [The only satisfactory way of settling the point. We may add that what has been sent to us as the double wild Daffodil have been various forms of *N. major*. Eds.]

—I must confess myself fairly puzzled since reading Mr. Crewe's letter, also that I was totally unaware that the common garden Daffodil is the double form of the wild plant, but of Narcissus major. My garden, an old one, swarms with the common double Daffy, which increases largely, and I fear I must have jumped too hastily at conclusions, and accepted without due investigation the common complaint of my neighbours that the wild Daffys all turn double when planted in the garden. Possibly the real fact is that they cease to bloom, and

as the common garden plant increases, one has assumed that such increase is—one's wild plant become double. Certainly I can find no flowers which differ from the common one, or I would send one to Mr. Crewe. However, Mr. Maw will probably be able to speak with more certainty if he transplanted his wild bulbs to a meadow, and knows exactly the spot where's planted them. As I mentioned in a former letter, I have two clumps which still remain single, but the rest have either ceased to bloom or have become double. *R., April 5.*

—The Daffodil is not common as a wild flower near here. I know it only in two places—one an old moated island in this parish, where it is probably introduced; another in Cranham, near Stroud, where it is plentiful. From this latter place I have for many years been in the habit of bringing a few roots for my garden, and I have never seen the slightest tendency to double, though I have planted for 60 years. I ever seen a wild Daffodil double, except at Malvern, in a cove, where I once found some specimens with stamens becoming petaloid. My own experience, therefore, quite coincides with that of Mr. Harpur-Crewe in your last issue. But only yesterday I came across an instance that shows how far any one person's experience is from exhausting the possibilities in even a limited set of circumstances. A friend who superintends the botanic garden being formed at the Cheltenham College was introduced by a former pupil to the Cranham habitat, and on March 28 with me he brought away some bulbs. These he planted in the College garden, and yearly has he watched for the flowers, which, however, came not. Leaves were there, but no flower. This year for the first time they have flowered, and he tells me that they are unmistakable double Daffodils of the garden. I send you specimens both of the double and the unsophisticated wild Daffodil, that you may see whether he is mistaken. He is quite botanist enough to be accurate in his species, and I have no doubt as to his fact, unless indeed some youngsters have been shifting his bulbs, as I have heard that at the botanic garden at Cambridge all the labels were once shifted. *R. C. Barnard, Bartlow, Leckhampton Hill, Cheltenham.* [The specimen sent is certainly not the double wild Daffodil but a form of *N. major*. Eds.]

—In reference to the wild Daffodil (p. 408), I am still sceptical about them coming double in cultivation, having this year seen the bulbs collected in Lincolnshire, Hertfordshire, and Kent, and I do not find amongst the thousands now in bloom any deviation from the single form; I find the roots are larger, and the flowers perhaps a little finer. When working up the Daffodils, the double form of the wild variety I had great difficulty in meeting with, and had almost come to the conclusion it did not exist. No one could give me any clue to it, and those who thought they knew it, having sent me the large double Daffodil, Telemionus plenty, and I might name a number of authorities with whom I came in contact, who maintained that this large double Daffodil was the double form of the wild single Daffodil of our fields. This I saw could not be possible, and the first point I succeeded in clearing was obtaining the single form of the large double Daffodil, and certainly this is the noblest of the sulphur-coloured section of the Pseudo-Narcissus. Through studying Parkinson, I found the locality where the double form of the wild Daffodil was supposed to have first appeared, and a good deal of correspondence I succeeded in procuring a few bulbs, and this season I have an advice that a few more are on the way. My correspondent remarks: "There is only one large clump, and a few odd bits, but all close to the same spot." Would "R." oblige me with a specimen of his double Pseudo-Narcissus? If it is the small one, it is so beautiful, and more refined in form than the large variety, and I am sure that they would be as an acquisition by all who are fond of spring flowers, and being so easily attained,—"R." is right in his conclusion. Would any of your correspondents name localities where this little beauty (the double Pseudo-Narcissus) is found wild? *P. Barr.*

—As you have of late been writing on the Daffodil, I enclose specimens of Narcissus major, which is commonly called "the Daffodil" near Tenby. I do not think it is generally known that this species is abundant within a radius of some miles round Tenby. South Wales. Some years since I happened to be in that neighbourhood just as the plants were going out of flower, and was much struck by the metamorphosis of Narcissus Pseudo-Narcissus there. I brought some bulbs away, and was much pleased to find in the following spring that they were Narcissus major, a native of Spain, and a very great addition to my spring garden. They grow very luxuriantly on the road from Tenby to Penally, in several places, and also beyond Penally on the Pembroke road, and (as I was informed by the Rev. Archdeacon Clark) in several other distant localities, from which he kindly sent me specimens. As I was collecting bulbs from the first place, and wondering in my mind how a Spanish plant got there, I caught sight of a very fine ruined tower chimney, peculiar to the neighbourhood of Tenby, and which are said to have been built by

the Flemings, of whom a large colony lived formerly in and round Tenby, driven from their homes by the persecution of their Spanish masters on account of their religion. This seemed at once to account for these beds of Narcissus major. Flanders had so much intercourse with Spain, that nothing would be more natural than for this showy Narcis to be a favourite with the Flemings; and it is equally natural that they would bring some of these easily carried bulbs with their families to South Wales when they migrated. Probably I am telling an old story, well known to many, but I do so because I have never met with any who did so, and because all whom I met at Tenby thought that their plant was the Narcissus Pseudo-Narcissus, which I did not see there. The Narcissus major is a great addition to the spring flower garden, its golden flowers coming out very early and with great luxuriance. Every one admires my Tenby clumps. It also lasts a long while: it has now been in beauty all this month, and will go on some weeks yet. I cannot understand the various opinions about Narcissus Pseudo-Narcissus becoming so frequently double: it has been a favourite in my garden for forty years, and I never saw the slightest tendency to its becoming so. We have acres of it in great beauty in many localities in this island, but the late Dr. Bromfield, who knew almost each individual plant in this island, says of this Narcissus, "One solitary clump in St. Urban's Copse, among thousands of the single kind, unquestionably wild, and perfectly similar to the double garden Daffodil." "Also a very double but certainly wild specimen on a bank at Yaverland." One would not have supposed that this pale flower would have produced a double one of the bright golden tint of our garden Daffodil. I have always supposed that the Narcissus major was the original of the garden Daffodil, and I see Dr. Bromfield says further on "I cannot distinguish the wild double variety from the common great yellow Daffodil of the garden, though that is supposed to be a different species—the *N. major* of *Botanical Magazine*, and a native of Spain." My Narcissus major bulbs have a tendency to become double, and are of a very beautiful golden yellow, as one would suppose from the single one. I have never seen a locality for the common Daffodil that did not make one doubt its being brought there, and the same with Narcissus biflorus and poeticus. They all seem to grow round old abbeys, or where cottages have been. In this island our largest bed is St. Urban's Copse (now written in all our maps "Centurion's Copse), where a church or chapel once stood, of which St. Urban was the head. All our other stations of it are suspicious, as I have observed, in all other parts of England where any of the three species of Narcissus grow. *W. D. F., Isle of Wight.*

The Great Double Daffodil of our Gardens. —I see Mr. Harpur-Crewe states that *N. major* is the single form of this. I differ from him, inasmuch as *N. major* flowers later and is a deeper yellow. I send you herewith the true single form, Telemionus of Haworth; by comparing it with the double which I send you, you will see that they correspond. *N. major* is only just opening, while Telemionus is nearly over, having been some weeks in flower. The double daffodil is one of the earliest, and vies with my magnificent Obvallaris maximus—the latter is golden-yellow, the former sulphur-yellow. The Daffodils of the Ajax section which are now in bloom with me are as follows—minimus, nanus, minor, Obvallaris maximus, Telemionus, T. plenus, Pseudo-Narcissus and its varieties (plenus, grande-plenus, lobularis, lobularis plenus, nobilis, rugilobus), cernuus plenus, c. plenus bincinus, *N. major*, *N. maximus*. *P. Barr, April 5.*

Sweet Nancy (Query 44, p. 443) is the common name in Cheshire for the double variety of Narcissus Poeticus or *N. biflorus*, or both, which is one of the most popular garden flowers in some portions of that county. The name is also used in Norfolk and the plant is known as "White Nancy" in Cheshire and Shropshire. The popular names of *N. biflorus* are not many, but of a somewhat unusual kind. Turner, in his rare and little-known *Libellus*, gives a long account of his meeting a little girl while "rusticating" in Norfolk who had a handful of white flowers ("dextera manu alborum forum manipulum gestans") which he considered to be Narcissi; but on inquiring of those "qui proximos pagos et castella habitarent," they all told him that the name was "Lansthi," nor could he learn from them any other name for the plant. In the same author's *Names of Plants*, he speaks of a white-flowered Narcissus which "groweth plentifully in my Lord's garden in Syon, and it is called of divers, Whyte Lans thi;" and a similar reference occurs in his *Herbal*. The origin of so unusual a name does not appear to be known; but it is worthy of note that other names of the white Narcissus seem to point to some ecclesiastical association of the plant. Thus, in the West-shire, *N. biflorus* is called "White Sunday;" and Halliwell gives "gray-days" as a name for the Daffodil in the same country. We have been unable to connect this name with any of the other designations of *N. Pseudo-Narcissus*; and as the botanical

identifications in Halliwell's *Glossary* are often vague or even inaccurate, it is at any rate possible that it is really applied to *N. biflorus* or *N. poeticus*. "Gracy-days" or (as Wright gives it) "gracy-day" is no doubt a corruption of *Gracia Dei*, a title given to various plants either from their medicinal or ornamental properties. In an old English MS. of the fourteenth century, which is preserved in the royal library at Stockholm, the name is applied to a plant which, with the *Dafoiid*, *Squill*, *Garlic*, and *Leek*, was reckoned among the five kinds bearing the last title. All that is said about it is, "Gracia Dei yt growth in Mede," but its conjunction with the *Dafoiid*, *Leek*, &c., shows that some monocotyledon of similar habit was intended. The name, "Primrose Peclresse," by which Lyte, Gerarde, and the other herbalists knew *N. biflorus*, is still in use in Warwickshire, and, in the corrupted form of "Primrose Farings," in Devonshire. Dr. Prior has not been as felicitous as usual in giving the derivation of this name. In his first edition he considers it as a corruption of *Primula paralyseos*, originating in a confusion between the *Narcissus*, which was supposed to cause palsy, and the *Cowslip*, which cured it; while in his later issue he thinks it "apparently transferred to it from a lady," although the quotation he gives at second-hand in support of this theory does not go far to countenance it. There can be no doubt, however, that Parkinson gives the true explanation when he says that its flowers are "of a pale, whitish, cream colour, tending somewhat neare unto the colour of a pale Primrose (which hath caused our country gentlewomen, I thinke, to entitle it Primrose Peclresse." Johnson, in his edition of Gerarde, writes it "Primrose Pearles," which Culpeper renders "Primrose Pearls." *B. M.*

Apricot Blossom and Apricot Prospects.—Never but once have I seen such a mass of Apricot blossom as we have had here this spring, and rarely, if ever before, has such a favourable season been experienced to aid in the fertilisation of the same. For whilst the walls have been sheets of white there has not been one solitary frost, during all the time they have been in bloom, that could injure them. At this moment an immense crop has "set," so numerous, in fact, that if one fruit in every score matures and ripens, there will be ample and to spare. I meditate resorting to the expedient of cutting back all the older worst placed "spurs" that exist on old trees here, and which anxiety for a crop forbade cutting back as severely as we could have desired at pruning time. The old adage runs something thus:—

"And during March you fruit trees lop,
Thus easily you guarantee a crop."

By taking advantage of this fact, this backward April, may we not ease, and it may be resuscitate somewhat, such Apricot patriarchs as look to us for succour and support? *William Earley, April 7.*

Cutting Fir.—My experience of cutting Fir is quite different from that of the writer of "Forestry" in your paper of March 27. If cut in May when full of turpentine, and allowed to lie on something to keep them off the ground for a season, the ends of the poles are sealed with turpentine and the bark adheres much longer than it does on winter-felled poles. Pinaster summer-felled will keep its bark on for years, whereas a winter-felled pole will some seasons have its bark rotten in one year. The summer-felled poles, if used full of sap directly it is cut, will decay in the ground rapidly. When passing through the Black Forest from Freiberg to Schaffhausen, June, 1868, I saw large Silver Fir being felled and barked. Since that I have always cut poles in May or June, and am convinced it is much better for the poles cut and for those left standing than the usual mode. It allows the trees room to grow when they can best take advantage of the breathing-room, the trees throw out corresponding roots, and are better able to withstand the exposure to gales the following winter. I also learnt on the Continent never to thin the whole of a plantation at the same time. I have seen several plantations in England checked in growth for years by the cruel woodman's practice of cutting every Bramble and stripping off every dead branch that they can conveniently cut all through a plantation, at the same time that they take down almost every other young tree and chill the whole plantation to the very pith at the coldest and most stormy time of the year. I was brought up in this school, and nearly thirty years ago was trusted by my father to thin a plantation of 6 acres by myself, since which time I have planted and attended several acres of my own, from 1856, and cut almost every pole myself. *H. R.*

Large Aucubas.—The description at p. 400 of the *Aucuba japonica* in the Royal Botanic Garden, Regent's Park, so singularly coincides in every respect with one I have in the garden here, that I should not trouble you on the subject were it not for the idea that a confirmation of the *modus operandi* of obtaining berries may induce all ordinary gardeners to do the same, and thus secure to themselves a most lovely plant when covered with its coral berries. The

Aucuba I have is about thirty years old. These plants do very well here, and I have others of large size; and having raised several male plants now coming into bloom, I hope another year to have many in full berry, which by the kind assistance of bees, flies, or the wind wafting the pollen, is so easily accomplished. *Stinsford, Dorchester, Dorset.*

Early Blooming Dahlias.—The critique at p. 399 on the assumed merits of German Dahlias should have special interest for Dahlia growers in the neighbourhood of Southampton, who propose to compete for the prizes offered in the schedule of the Horticultural Society of that town for "Dahlias in pots," the competition to take place on July 31 next. It is a fact that most of our own kinds do not come into good bloom until August, and I fear that exhibitors will find it exceedingly difficult to get their plants into decent bloom by so early a date, whilst any attempt to force them into flower under glass will only develop length at the expense of beauty. Without doubt the best varieties for pot culture are the Pompons, as these produce the greatest quantity of

the plant out of the pot, and I find it is rooting well into the fresh soil, but every one of the roots, even the smallest fibre down to the extreme tip of the young growth of the roots, to be the same as the piece I now enclose—exactly as before. *George Walker, Marks Hall, Essex.*

Pampas Grass.—"A Very Old Subscriber" asks at p. 444 about clearing old growths from a large plant of Pampas-grass. I have just been trying to meet the same difficulty by having all the dead shoots and stems cleared with a sharp knife, cutting them neatly away as far down as could be reached. The plant was an unusually large one, and the centre so choked with the dead mass that water lodged, and there seemed a fear of decay; also the great mass falling together like a mere heap of dried grass was an objectionable feature in the group of which it was the centre, so that something had to be done; but either taking or leaving seemed doubtful, and it was only on the assurance of the gardener that he knew the treatment answered that I ventured on it with such a large specimen. The plant at present looks

FIG. 100.—INVERTED GROWTH OF TURNIP.

flowers on the least surface, but most of these are too tall for pot-work, and any attempts at dwarfing them would probably make them worse rather than better. What was wanted for such a purpose is a race of plants that shall not exceed 2 feet in height, and which shall commence blooming at midsummer. With such a useful strain it would then be possible to convert the Dahlia into a capital exhibition plant for late summer and autumn shows. *A. D.*

Diseased Palm Roots.—Seeing the figures at p. 409, of the Palm roots I sent to you some time ago, I beg to offer a few words about the plant, thinking perhaps they may throw some little light on the cause of the peculiar formation on the roots. The plant was a small one, bought in about three years ago, and was in a very unhealthy state; every leaf that came up was covered with spider, and not one unfolded properly. It was reported several times, thinking the soil was not suitable, but all to no purpose, until last autumn it began to grow and make some nice leaves, but there was no unusual appearance on the roots up to this time. In the spring I turned it out to give it a larger pot, when I found every root of the plant looking exactly as shown in your figure; the plant was well rooted, and all being alike, it was a most peculiar sight. To-day I turned

very well, as also a somewhat smaller one, which was similarly treated, and having stood the winter well without any protection, as there were no very tender growths to be exposed. *O.*

Protecting Materials.—I find nothing so cheap, nothing so light and useful, as the common Bracken. Here we protect our Fig trees by tying it to the branches, our Broccoli simply covering them entirely up, and this season I shall protect Rose trees and dwarf Cherries; in fact, it is so easily applied that it requires no shifting, it being light and airy, so that if we have no spring frosts it does no harm, and should you have frost it certainly does good. The best plan to keep on the foliage is to cut in early autumn, tie in bundles, and keep it dry. *R. Gilbert.*

Reports of Societies.

Royal Horticultural: April 7.—W. Burnley Hume, Esq., in the chair. The Rev. M. J. Berkeley, addressing some eighteen or twenty persons present, remarked that only two subjects came under the notice of the Fruit Committee—a dish of Apples, the name of which was not known, and a pan of Watercress grown in a cold house. The latter had been sent to show that it might be usefully grown

under such circumstances through the winter months. At many places Mr. Berkeley remarked, it was a common practice to grow Watercresses under a north wall, but there was the great disadvantage in this system that the plants were liable to become infested with fly if not well watered. On the contrary, it was much better to eat plants grown in this manner than those grown in water, because it was known that the eggs of a very minute insect were deposited on aquatic plants, which produced the "rot" in sheep. The Fern shown as *Pteris Williamsii* proved to be an old plant—*Gymnogramma japonica*; and of two remarkably fine specimen Orchids—*Dendrobium nobile* and *D. densiflorum*—it was remarked that though the inflorescence of the latter was most handsome, it was comparatively fugitive, and the former was the most useful, as its flowers lasted so much longer. It was interesting to know, in connection with the exhibition of such a fine specimen of *D. densiflorum*, that the species was first sent to this country through the Society by Wallich. *Euryclades Cunninghamii* belonged to a genus of *Amaryllidaceae*, founded originally by Salisbury, and was closely allied to *Pantracium albinoense*, from which

chair. Mr. Berkeley stated that the so-called *Bambusa gracilis*, shown at the last meeting, was *Arundinaria falcata*.

Diseased Portugal Laurel.—The following letter from Miss Ormerod was read, and the specimens relating to it were laid on the table. It was considered by the committee that the dry raised bank on which the shrubs were planted was sufficient to account for the disease:—

"I enclose some specimens of the diseased Portugal Laurel roots, with another bit to show the condition when healthy.

"When I first saw the shrubs in July last year the leaves had turned to a dead whitish green, and as time went on they drew together at the edges, became patched with brown, and the shrubs have since died. Those affected were part of a dividing hedge in my garden about 90 feet long, and about three of them have died together at one end, and as many more together in another part of the line—those by them not showing any signs of unhealthiness. The trees were about 10 feet high, the bank on which the row stands artificially raised about 3 feet above the level of the garden, and if not watered must be exceedingly dry in summer; and in another place in Spring Grove, where

seen; but the trees of other kinds have mostly died off, or are rapidly succumbing to a disease which I shall attempt to describe and illustrate; and I may observe that, as far as I have been able to observe, those trees which are most sheltered are as much diseased as those exposed to the full sea breezes. The disease shows signs of later to be fatal to the tree, for I have not seen one tree attacked of which there seems any chance of recovering, seeing how many have died, and how very sickly they appear. The trees now in this diseased state are from 12 to 18 feet high, and with stems varying from 5 to 7 inches in diameter. The disease is most apparent in large, rough, open wounds about the commencement of the lower branches, and on the stem; but upon closer examination symptoms of the disease will be found all over the tree, even to the tops of the branches. The disease seems to show itself at first by a longitudinal fissure in the bark, which fissure is nearly straight and but of little depth, having its lips slightly elevated and reflexed. At first it will be perceived that the fissure does not penetrate the whole depth of the bark, but, gradually deepening and extending in length, the wood becomes exposed. This process of the fissure of growing deeper and increasing in length continues until the wood is quite exposed, and in a branch of two years growth the disease assumes the appearance of a long open wound, exposing much of the wood which the growth of the bark partially covers up. Tracing the progress of the disease further, side fissures will be seen producing the same results; and these fissures, running one into the other, break up the bark until occasionally the disease extends all round the branch. It may be perceived that the disease attacked a branch where it had two years growth, and that the other fissures commenced the year following. When a branch gets diseased, the portion above the wound dies. The disease is often slow in progress, particularly when on the main stem, when large open wounds appear, of some character as those on the branches, exposing much of the wood, but having the surrounding bark, although diseased and cracked, in a healthier state. My drawings represent the main stem of a young tree with a wound of this character, but still there would appear every probability of the tree lasting a few years longer in the living state. The figures have been carefully made, and are all to the natural size, except those which are coloured. Specimens of the leaves of this Poplar accompany this, that the species may be determined. The Poplar, which was planted at the same time and is found to do well, is, I have no doubt, the *Populus nigra*, L. The diseased *Populus* appears very like the *Populus candicans*, or false Balsam Poplar. The soil in which both kinds of Poplar were planted is a rich strong loam. The cause of the disease I dare not venture to give an opinion about; and I have gone into the foregoing details with a hope that we may be able to enlighten me on the subject. *W. Wilson Saunders.*

Dr. Masters stated that he had frequently seen a similar disease in the Lombardy Poplar, particularly when growing in water-logged soil. Mr. A. Murray referred to the similar disease met with in the Ash.

Colorado Beetle.—Mr. McLachlan referred to the letter of an Englishman in America, published in our last issue, and going to show that the tubers were eaten by the beetles, and that their importation might really be effected by means of seed Potatoes. Some of the committee still expressed doubt as to whether the beetle really fed on the tuber. Mr. McLachlan referred to a note in the report of Lieutenant Carpenter, of the American Geological Survey, in which it was stated positively that the insect was distributed by means of seed Potatoes, and that its absence in Utah and other parts of California was to be attributed to the fact that it has not yet been necessary to import seed Potatoes.

Tiliairea pedata.—Dr. Moore, Glasnevin, sent leaves of this plant partially affected with albinism, and which condition Dr. Moore thought was occasioned, in this instance, by the attacks of a fungus. Mr. Berkeley doubted the accuracy of these conclusions, but promised to report on another occasion.

Inverted Leaves of Fern.—Mr. Hemsley sent a Turnip with a cavity in the interior of the root nearly filled by leaves growing from the crown downwards and inwards as in the figure, reproduced from an earlier volume (see fig. 100).

Circulation in Myxozoyetes.—Professor Dyer showed under the microscope a portion of an *Ethallium*, consisting of protoplasm, only without any investing cell walls, and in which currents, sweeping granules with them in their course, were plainly visible. The plasmodium, or thallus, throws out processes in various directions, which sometimes make and unmake, forming a network. The meeting then adjourned.

FLORAL COMMITTEE.—R. B. Postans, Esq., in the chair. First-class Certificates were awarded at this meeting to Messrs. James Veitch & Sons for *Drosera spatulata*, an extremely interesting little species with obovate leaves; for *Croton Disraelii*, a most singular form received from A. H. C. Macaeffe, Esq., of Sydney, with for the most three-lobed leaves, bright green in colour, spotted with golden yellow, and having a golden band along the midrib—the greatest novelty the genus has produced; and for *Hyacinth Etna*, the petals of which are broad, smooth, and flat, and of a bright salmon-rose shaded with reddish crimson, the flowers inclining to become double. To Mr. William Bull for *Crimm brachynema*, an Indian species with

FIG. 101.—*MARTINEZIA EROSA.*

it differed in having only two ovules in each cell. *Exacum zeylanicum* was pretty, but seldom seen, owing to its being peculiarly difficult to propagate. The seeds were excessively small, and the practice was to sow them on the top of the earth, then gently press them down, and trust to chance for their germinating. Messrs. Veitch's small group of *Droseras* then came under notice; and, with regard to *Drosophyllum lusitanicum*, Mr. Berkeley remarked that he thought it might some day be found in the West of Ireland. The discussion on the wild Daffodil going on in our columns was alluded to, the speaker taking the side of Mr. Harpur-Crewe, Mr. Barr, and others, and showing flowers of the true double common Daffodil—*Narcissus Pseudo-Narcissus flore-pleno*, which was accurately figured in Parkinson's *Paradisus* under the name of *N. Pseudo-Narcissus anglicus flore-pleno*. A specimen was also shown of a singular double form of *N. Pseudo-Narcissus*, known to Herbert as *Ajax Eystettensis*, and to Parkinson as *N. p. s. gallicus minor flore-pleno*. Both of these flowers were exhibited by Mr. Burbiage. On examination at Kew, Mr. Berkeley found that the plant shown by Mr. Stevens, gr. to the Duke of Sutherland, at Trentham, at the last meeting, under the name of *Bambusa gracilis*, was *Arundinaria falcata*.

the Portugal Laurels fail similarly, the ground is (naturally or artificially) above the surrounding level. I cannot find in my own garden that the roots have reached any injurious subsoil, nor are there the slightest indications of insect injury.

"When freshly cut the smaller diseased roots look wet, of a greyish colour, with brown spots scattered in the discoloured wood—to the unassisted eye looking very much like the mottlings of a diseased Potato. They dry very rapidly, but perhaps some of the small stumps of the largest section (if freshly cut) would still show this appearance.

"This disease gives a good deal of trouble here, and besides the interest of the subject in itself it would be of great service to know how to check it.

Diseased Poplars.—The following letter, addressed to Professor Dyer, was read from Mr. Wilson Saunders, and illustrative drawings were exhibited:—

"Some few years since a number of young Poplar trees of two different kinds were planted on the sides of the roads in East Worthing, with the object of forming rows of shade-giving trees, which would grow quickly. The roads mentioned are broad, and run either directly towards the sea or parallel to the seashore. Hence some are much exposed to the draft of the sea breeze, while others are comparatively sheltered. The whole of the roads are within a quarter of a mile of the sea shore. Of the trees so planted one Lime has done well, and there are several vigorous young trees here and there to be

drooping white, sweet-scented flowers, produced on a scape about 3 feet high. The plant, originally described by Herbert in 1824, was introduced to the Royal Gardens, Kew, from Cayenne, by Mr. Woodrow, Superintendent of the Botanic Gardens, Footscray, and figured in the *Botanical Magazine* (1871), tab. 5937. For *Dracena insignis*, a dwarf, compact, very habitated plant with leaves of a rich metallic purple colour; and for *Dracena candida*, a plant of identically similar habit to the above, but with the older leaves margined with creamy white, and the young ones almost entirely of the latter colour. Both of these plants must be welcomed by those in quest of suitable subjects for table decorations, on account of their excellent habit. To Mr. B. S. Williams for *Geonoma gracilis*, an elegant stove Palm, which has been thought to be the same as *Cocos Weddelliana*, but is quite distinct from that fine species (an illustration will be found in the left-hand corner of our Almanac for the present year); and for *Martiniezia ceras*, a striking South American Palm, the characters of which are well shown in the accompanying illustration (fig. 70), reproduced from a photograph by Messrs. James Veitch & Sons, for a pale-fruited variety of *Anthurium violaceum*, an old stove plant, better known under the former name of *Pothos violacea*; and for *Drosophyllum lutanicum*, an interesting Sundew, which is found in Spain, Portugal, and Mauritania, which produces yellow flowers on a stem about a foot high. The plant is figured in the *Botanical Magazine* (1869), tab. 5796. Cultural Commendations were awarded to Mr. J. Staples gr. to Mrs. C. Candy, Chipstead Place, Sevenoaks, for a specimen of *Dendrobium densiflorum*, with twenty-eight fine spikes of flowers, all in a perfectly fine condition; and to Mr. F. Moore, gr. to W. C. Pickersill, Esq., Blendon Hall, Bexley, for a specimen about 3 feet through, and remarkably well flowered, of *Dendrobium nobile*. Messrs. Veitch also showed a striking and beautiful Aroid under the provisional name of *Spathiphyllum Wallisii*, upon which the committee deferred their award till the plant was botanically examined, to see to what genus it really belonged. We propose shortly to give an illustration of this striking plant. The same firm also sent a flowering plant of *Exacum zeylanicum*, with pale blue flowers, and belonging to the Gentianaceae; *Croton tortile*, somewhat in the way of *C. spirale*, but a much stronger grower, with the deep bronze leaves spotted with crimson red, and banded with the same colour along the midribs; *Croton Lord Gains*, in the way of *C. Disraeli*, but not so good; and *C. appendiculatum*, a very curious green-leaved sort, the midrib of which is continued like a thread, bearing a leafy appendage at the end. From Mr. J. Perkins, gr. to Lord Henniker, Thornham Hall, Suffolk, came a box of nice cut blooms of the Maréchal Niel Rose, which gained the thanks of the committee; and Lord Radnor, Covent was paid to Mr. Eckford, gr. to a similar compliment for a fine lot of some finely-coloured gold-laced Polyanthuses. From Mr. R. Dean, Ealing, came a large and most interesting collection of Primroses, Polyanthuses, Violes, Myosotis, &c., and which included about three dozen pots of *Myosotis dissitiflora*, which were literally a sheet of bloom, and strikingly beautiful. Amongst the Primroses, which Mr. Dean is doing his utmost to improve and bring into popularity, we noticed *Crimson Queen*, very large, and of a rich glowing crimson colour; Splendour of colour; *Violeace*, deep violet; *Crimson Banner*, Fairy Queen, white; Queen of Violets, rich deep violet; *Sulphurata*, sulphur-yellow; *Rosy Morn*, deep rose; and *Charmer*, a good shade of pink. In the Polyanthus section were *Regalia*, rich maroon-crimson, each segment marked with a wedge-shaped white spot; *Black Knight*, pure maroon; *Victory*, sulphur-yellow; *Magnific*, pure crimson; *Bedder*, and *De la Roche*, a fine white variety of excellent form. Bedding *Viola White Swan*, a large smooth white flower; and a new quilled white Daisy named *White Globe*, large and very fine, were conspicuous in the same collection, to which a vote of thanks was accorded. In addition to the plants previously mentioned, Mr. B. S. Williams showed *Varsciewiczella discolor*, and *Erycades nunglinghamii* and from Mr. Dean came a fine white variety of *Oxoteglossum Koehlii*. Messrs. Paul & Son, Chesham, sent a box of cut blooms of *Roses*, and flowering specimens of the new *Hippolyte Jamin* and other *Roses*; and G. F. Wilson, Esq., contributed flowering plants of the pretty little *Primulas pulcherrima*, viscoso, and denticulata.

The Royal Horticultural and Agricultural Society of Antwerp: April 4. — This important show, which was opened on April 4, and lasted till the 7th, was one of the most interesting of the kind ever seen in the neighbourhood of Antwerp, Ghent, and Brussels, nearly all classes of plants were very well represented. Azaleas and

Camellias constituted perhaps the principal features of the show, the former being especially magnificent and numerous. On entering the Salle de la Grande Harmonie, where the show was held, one looked down on three splendid groups of these plants, each consisting of thirty large plants trained with broad umbrella-shaped heads, and one mass of flowers. This mode of training, which is preferred in Belgium to the pyramid or balloon shape, is certainly more effective when viewed from above, and requires much less tying and training than the shapes preferred in England. Mr. Ghellincx de Walle, of Ghent, gained the 1st prize of a gold medal or 400 francs in this class; and M. Jean Vervain the 2d. The following varieties were among the most beautiful — Baron de Pret, Charles Enke, Comtesse de Flandre, Modèle, Comtesse Eugénie, Roi Leopold, Madame Dominique Vervain, Cedo Nulli.

Of Camellias the most remarkable were some plants about 20 feet high sent by Mr. Edmond Le Greille, of Antwerp, which, though rather narrow for their height, were full of bloom and very healthy. They gained a prize of a gold medal, or 300 francs.

Of Rhododendrons there were a few fine specimens, of which nothing was superior in beauty to that fine hybrid, Comtesse of Haddington.

M. Louis Van Houtte, of Ghent, carried off the prize for hardy Azaleas, though his plants were not very remarkable either for their form or colour.

Orchids were not largely shown, but in the collection of M. Louis Le Greille, of Antwerp, were some of the grand plants of *Cypripedium Dominatum*, *Crossii*, and *purpureum*; and in that of M. Beaucarne a fine plant of *Dendrobium densiflorum*, with seven flower-spikes.

Among the curiosities of the show was a collection of terrestrial Orchids, shown by M. Louis Van Houtte, which, considering that they had been forced into flower two months before their natural season, were very of good condition. It included plants of the North American *Cypripedium spectabile*, acule, pubescens, and parviflorum; *Orchis spectabilis*, a plant hardly ever seen in cultivation; *Arethusa bulbosa*, one of those delicate little inhabitants of the sphagnum bogs of Canada; and *Ophrys lutea* and *apifera* in a less flourishing state.

Amaryllis were well represented by several collections. M. Van Houtte winning the 1st prize with a very fine batch of thirty unnamed seedlings, and M. H. Van der Linden, of Antwerp, the 2d. Though these plants were not perhaps quite equal in variety to some of those lately raised in England, the variety of colour was very striking, a pure white one and some very pretty pinks being among the best. They are mostly, I believe, hybrids of *A. vittata*, and have a good deal of hardness in their constitution.

Messrs. Krelage, of Haarlem, were an easy 1st in the classes for *Hyacinths* and *Tulips*, though their plants, perhaps owing to the long journey they had to undergo, were not quite equal to those shown by Messrs. Veitch and Douglas at South Kensington lately. The Belgians exhibited little or nothing in these classes, three of which had no entry, and the Tulips, with the exception of Messrs. Krelage's lot, were very poor. Neither *Cyclamen* nor *Roses* were so good as I have seen them. *Primulas* were entirely absent, and *Heaths* by no means up to the English standard.

When we come to the foreign plants, however, the most critical judge could not have passed by the splendid plants sent by Madame La Grèlle d'Haïn and others without admiration. This lady, whose beautiful gardens at Antwerp are celebrated on the Continent, sent a collection of plants which gained her the gold medal offered by the Federation of the Belgian Horticultural Societies, as well as the prize for the exhibitor who contributed most largely to the embellishment of the exhibition. It included magnificent *Arenas*, *Aroids*, *Plantains*, and foliage plants of all kinds, among the most remarkable of which were the following:—*Ceratostema mexicana*, *Pitcairnia Martiana*, *Latania borbonica*, *Arenga saccharifera*, all very large and perfect specimens.

To mention all that were included in the numerous classes of the exhibition would take up more space than you can spare, but I may say that *Agaves*, *Aralias*, *Yuccas*, *Phormiums*, *Araucarias*, *Caladiums*, *Crotons*, *Orchidaceous plants*, *Aroids*, *Acacias*, *Violas*, *Hollies*, and variegated plants of all kinds, were much more numerous and better represented than in English exhibitions generally. The *Hollies* of M. C. van Geert were particularly noteworthy. Among the most beautiful plants in the show were some seedling *Bertolonias*, sent by M. Van Houtte, of Ghent, which received the special notice of the judges. *Bertolonia Van Houtte*, *Mirandiei*, and *Marchandi*, the best of them, will no doubt soon become known in England, and must be admired by all. Many rare hard-wooded plants were shown by the Baron de Caters and others, including *Isaëkas*, *Grethias*, *Proteas*, and *Frostemons*, in perfect health; also fine specimens in flower of *Metrosideros semperflora*, *Oreopanax dactylophylla*, *Theophrasta macrophylla* vera, *Kennedyja nigricans*, *Cianthus Dampieri*, and many others. The *Cacti* of Mr. Story, of Lacken, near Brussels, were models of good

cultivation, and included many rare and pretty things. The *Echeverrias* of M. Louis De Smet, of Ghent, were also very beautiful; among them *E. agavoides rubella*, *E. casia*, *E. Desmetiana*, and *E. pulverulenta argentea*, surpassed anything of the kind I have seen before.

A few Lilies were shown by M. Van Houtte in very fair order for the time of year—*L. croceum*, with about fifty flowers on four stems from one bulb; *L. Brownii*, with ten flowers; and *L. canadense* being the best.

The only English exhibitor was Mr. Williams, of Holloway, who sent over a very nice lot of new and rare plants, which received a medal from the judges.

It is a pity some of the other English nurserymen did not contribute to the show, as the journey from London is so short and easy that it would have been a good opportunity of showing the Belgians what we have in the way of *Cyclamen* or *Orchids*. The show of fruit, consisting of Apples and Pears, was good for the season. As regards the bouquets the less said the better; the want of taste shown in their construction being, with few exceptions, lamentable. On the whole the exhibition was well worth the journey to see it, and I hope it may prove as great a success financially, as it was in a horticultural sense. The banquet, presided over by Baron de Caters, was—as Belgian *Fêtes* usually are—as cordial as splendour. (From a Correspondent.)

The Villa Garden.

PATHS AND EDGINGS.—An old gardener once remarked: Above all things in a garden, let there be the appearance of order. And he was right; for while a slovenly garden will spoil the otherwise excellent effect of good features, an orderly garden will cast a lustre on mediocre aspects. A well-managed garden will have a neat appearance in the opening days of April, and this neat appearance can be maintained by keeping walks, borders, grass edgings, Box edgings to paths, and lawns neat and tidy. Nature may almost be said to give us a dry March for this purpose; and if the weather be cold and harsh, yet so long as it is dry the dying process can be pushed on to a proper conclusion. If walks have been turned (and this is sometimes of great importance, for walks will become moss-covered when overhung with trees), and rolled, they will be smooth and clean, and will remain so for some time to come, if the roller be passed over them after a softening shower. If weeds put in an appearance they should be pulled out by hand after a rainfall, or when the ground is soft they readily come away from the yielding soil—small fibrous roots and all. A good rolling soon makes all smooth and orderly again.

Grass edgings should be made even by placing a garden line along them and cutting away the margin, which always grows out in course of time, and becomes ragged and uneven. All the pieces cut away with the edging iron should be gathered up and wheeled away into the compost yard, there to lie and rot and eventually become of great value for potting purposes. Box edgings should be clipped this month, and gardeners recommend it to be done at the time of showery weather, the reason being that they sooner start into growth again, and lose that stunted and rough appearance they are apt to present when the trimming is done in periods of dry weather. If some of the clippings be picked out on a shady border, and pressed firmly into the soil, they will root and form nice plants by the autumn, and they come in very useful to supply vacancies in the edgings to paths.

CELERY.—It has been observed that if a garden be so circumscribed in respect of space that a kitchen or vegetable plot is an impossibility, yet some space will surely be given to Celery. This favourite salad well deserves such a special recognition. Many a Villa Garden grows excellent Celery, and the gardener places it on his table with conscious pride; that his home-grown, crisp, sweet-tasting stalks are incomparably better than the best that can be had in the market. This is the time of year for sowing seed to produce the plants to go out into the Celery trenches by-and-by. The seed being very small it should be thinly sown on some finely sifted soil, on a bed having a little bottom-heat if possible, or, if this is not available, under a handlight, in a cold frame, or in a shallow box that can be afterwards placed in the greenhouse or any suitable place in order that it may have all the encouragement possible.

In order to be successful with Celery it must be planted out in the trenches early—say at the end of June, or the beginning of July, so as to have the benefit of the showers that fall during what market gardeners term the "dripping season," that is, the showery days of July—when July happens to yield them.

When the plants in the seed-bed or box are large

enough to be transplanted, they should be planted out where they can have every encouragement to grow into size. Gardeners who have the necessary accommodation plant out in highly manured soil in a cold frame, and under such circumstances the plants form masses of fibrous roots, which, when placed in the trenches in showery weather, soon lay hold on the soil and become established. Celery should be kept growing quickly and vigorously, and then it is certain to do well.

CUCUMBERS.—Not long since we gave directions as to the making up of a Cucumber frame for an early crop of this favourite fruit. Many who are in the alphabet of gardening prefer to wait until April before they commence the culture of Cucumbers. The days are then lengthening and becoming warmer, and these favourable circumstances greatly assist a deficiency of manure for giving artificial heat. The bed should be prepared without delay, and a commencement should be made by marking out where the frame is to stand, but keeping the dung a foot wider all round than the size of the frame. In forming the foundation of the bed with manure, which should be fresh in order to generate the necessary warmth, it should be well shaken out by means of a fork, at the same time beating it down as layer after layer is laid on. The ranked dung should be laid at the bottom, and the driest on the top; and if too dry, throw some water over it to moisten it. The bed should be so built up as to allow for subsiding, and when this has taken place it should be 4 feet behind and 3 feet in front. When the bed is completed, and well beaten down, place a layer of soil 3 or 4 inches in depth over it, and place the frame on it. In the centre of each light a mound of nice turfy loam should be placed; and in this, when it is nicely warmed through, the plants should be placed, one or two to a light. Air must be given night and day for a time if a rank heat becomes generated, or the plants will be shrivelled up. The plants should be pinched back to the fruit-bearing wood, at the same time thinning out the shoots, so that they should not become matted. The roots run near the surface of the soil, and when the plants make vigorous growth they will soon show themselves through the mounds, which should receive a fresh covering of soil to afford them nutriment. As the plants grow and the weather becomes hot, water must be given, but it should always be warm.

Such a bed as this is very useful in many ways. In it can be raised half-hardy annuals and tender plants required for summer bedding, and also for borders, such as *Asters*, *Stocks*, *Petunias*, *Phlox Drummondii*, *Zinnias*, *Geraniums*, *Cockscombs*, &c. All these can be sown thinly in 48 or 32-sized pots that are well-drained and filled up with a light, free, sandy soil. A line of these can be stood round the sides of the frame, where they will not impede the growth of the plants; and in this manner many things can be grown that could not else be at the disposal of the Villa gardener for the decoration of his garden.

The Weather.

STATE OF THE WEATHER AT BLACKHEATH, LONDON, FOR THE WEEK ENDING WEDNESDAY, APRIL 7, 1874.

MONTH AND DAY.	BARMETER.		TEMPERATURE OF THE AIR.				Hygrometrical Deductions from Glaisher's Tables 5th Edition.	WIND.	RAINFALL.
	Mean Reading.	State of Sky.	Lowest.	Range.	Mean for Day.	Mean for Month.

- April 1.—Overcast, dull, and mild, though fine at intervals throughout the day.
- 2.—Overcast, dull, and foggy in early morning. Fine, and bright afterwards.
- 3.—Fine, partially cloudy, mild, and brisk wind throughout.
- 4.—Fine, partially cloudy, and mild. Heavy rain fell in early morning.
- 5.—Overcast, with rain fell at 7 A.M. Fine, and bright afterwards. A gale of wind.
- 6.—Fine, and partially cloudy throughout. Occasional showers of rain and hail from noon to 2 P.M.
- 7.—Fine, mild, and cloudy throughout. Rain fell in early morning, and again at night.

— In the neighbourhood of London the reading of the barometer at the level of the sea increased

from 30.03 inches at the beginning of the week to 30.37 inches by the evening of March 31, and then turned to decrease, and by the end of the week the reading was 29.74 inches. The mean reading for the week was 29.37 inches, being 1.14 inch above that of the preceding week. The mean daily readings were all above their averages, those for March 31 and April 1 being respectively 0.60 inch in excess.

The highest temperatures of the air at 4 feet above the ground ranged between 47° on March 28, and 55° on the 31st, the mean value for the week being 52°. The lowest temperatures of the air varied from 37° on March 28, to 44° on the 31st; the mean for the week was 41°. The mean daily range of temperature in the week was 13°; the greatest range being 12° on April 3, and the least 9°, on the 1st. The mean daily temperatures of the air, and the departures from their respective averages, were as follows:—March 28, 41° S., -1° 2'; 29th, 44° 3', +3'; 30th, 47°, +3'; 31st, 48° 4', +4'; April 1, 46° 9', +2° 7'; 2d, 47° 4', +2° 9'; 3d, 40° 4', +1° 6'. The mean temperature for the week was 46°, being 2° above the average, as deduced from observations extending over a period of sixty years.

The highest readings of a thermometer with blackened bulb in vacuo, placed on grass in sun's rays, were 98° and 104° respectively on March 28 and April 2, but on March 31 it did not rise higher than 62°. The lowest readings of a thermometer on grass, with its bulb fully exposed to the sky, were 33° and 34½° on March 28 and 29, but on April 1 the lowest reading of this thermometer was 41°, the mean for the week of these low readings was 37°. The direction of the wind was generally from the N.W., and its strength gentle.

The weather during the week was dull, mild, and the sky generally overcast, with slight fog on March 31 and April 2.

No rain fell during the week. In England, the extreme high day temperatures ranged between 61° at Sunderland and 51° at Liverpool, the general average over the whole country being 56°. The extreme low day temperatures ranged from 30° at Liverpool to 31° at Bristol, the general average being 35°. The mean of the extreme range of temperatures in the week from all stations was 21°, varying from 27½° at Bristol to 11½° at Liverpool. The mean high day temperatures ranged from 57½° at Sunderland to 49° at Liverpool, with a general average of 52½°. The mean low night temperatures varied from 42½° at Bradford to 37½° at Bristol, with an average value of 45°. The mean daily range of temperature in the week was 12°, the greatest range being at Bristol, 17°, and the least at Liverpool, 7°. The mean temperature of the air for the week was 45°, being 1½° lower than the value for the corresponding week in 1874. The extremes were 47° at Sunderland and 43° at Eccles. Rain fell on one or two days in the week at most stations. The amounts collected were very small, varying from four-tenths of an inch at Manchester to one-hundredth of an inch at Wolverhampton and Leeds. At Blackheath, Birmingham, Newcastle-on-Tyne, and Sunderland no rain fell. The average fall over the country was seven-hundredths of an inch.

The weather during the week was fine, but somewhat dull, and the sky generally cloudy.

In Scotland, the highest temperatures ranged from 58° at Aberdeen to 53° at Glasgow; the lowest temperatures varied between 39½° at Paisley and 32½° at Greenock, their respective averages being 50° and 35½°. The range of temperature in the week was 21°. The mean temperature of the air for the week was 46½°, being 3° above the value for the corresponding week in 1874. The highest occurred at Dundee and Aberdeen, both 47°, and the lowest at Greenock and Glasgow, 45½° respectively. Rain was measured to the amount of 1 inch five-tenths at Greenock, but at Aberdeen and Perth one-tenth of an inch only was recorded. At Dundee no rain fell. The average fall over the country was four-tenths of an inch nearly.

At Dublin, the highest temperature was 55°, the lowest 36°, the mean 47½°, no rain fell.

JAMES GLAISHER.

Garden Operations.

(FOR THE ENSUING FORTNIGHT.)

[The subjoined directions are intended to supply general information, and must, of course, be adapted to the peculiar circumstances of each locality. Other departments of the garden will be treated on from week to week in succession, according to the requirements of the season. Special directions for the management of "The Villa Garden" will be found in the preceding columns.]

PLANT HOUSES.

PLANT STOVES.—The number of spring and summer flowering plants that require immediate care at the present time are apt to absorb the attention so much as to leave the autumn and winter insufficiently provided for. There are several winter-flowering subjects that want pro-

pagating. Old plants of *Poinsettia pulcherrima* that have been kept dry, to rest them after flowering, should now receive water, and be placed in a growing temperature, previous to which it is necessary to shorten back, if not already done, even such as are only intended to furnish cuttings. There are two methods of growing this fine autumn and winter plant. One is with single growths, in small pots, from spring-struck cuttings, which is the most useful for general purposes; but if for variety or conservatory decoration some of larger size are required, then a portion of the old plants should be cut back to within 6 inches of the pot, and placed in a moderate heat—the temperature should not be high, 60° at night will be enough; they should also be placed where they will get plenty of light, the object with these being to keep the shoots short and stocky, and not at all drawn. As soon as they have broken they should be turned out of their pots, the balls reduced considerably, and repotted with good loam, either in the pots they have before occupied or others larger in proportion to the size of the plants.

Winter-flowering *Begonia* should at once be propagated by cuttings. The old *B. fuchsoides* is very useful either as a decorative subject in the shape of moderate sized plants in 7 or 8-inch pots, or in furnishing drooping flowers for cutting, to be used in large vases—its habit and intense colour rendering it better adapted for this purpose than most of the more recent introductions, but to get it to bloom freely it must be well ripened by growing it through the season where it will receive a full share of light, with sufficient air and a moist atmosphere, not too moist; cuttings put now in small pots will root quickly, after which move them into 5-inch pots, in loam and a little sand. *B. insignis* may be treated similarly, giving it a little more pot-room. Where a plant of larger growth is required *B. manicata* is useful, requiring similar treatment in propagation and soil, but it needs more root-room; this variety should not have less than a 12-inch pot to flower in.

The above *Begonia*s are much the best grown from young plants. The bright-red-flowered *Scrotophila Chrysantha* is very useful in the autumn. Young plants struck now and grown on in loam with a fifth of leaf-soil and a good sprinkling of sand, will make nice sized plants, potting them on without allowing their roots to get pot-bound until in their flowering-pots (8 or 10 inch), stopping them two or three times during the season, so as to induce a bushy habit of growth.

Plumbago rosea.—Take the cuttings off as soon as they get 6 or 8 inches long, with a heel, or they do not strike so freely as some things; give them singly in small pots, and root them in a moderate heat. This is the most useful when grown in loam and a little leaf-soil, as the flowers produced in it are stouter than when grown in peat, to still further assist which it should not be grown too hot or moist, and have plenty of light with no more shade than is required to keep its leaves from burning. *Luculia gratissima*, now propagated and kept growing on freely through the season, will make very small flowering plants by winter, and will be nice scabellæ for standing about in the conservatory. *Centradenia floribunda* and *C. rosea* are both nice small-sized winter blooming plants, flowering profusely from the base of almost every leaf; cuttings struck now in sand and grown on in heat through the summer will make plants in 6 or 8 inch pots—they will do in either peat or loam.

For suspended baskets the *Echynanthus*—*Lobbianus* and *grandiflorus*, are well adapted, and may be had in nice sized plants in a single season by inserting now a dozen cuttings round the side of a 6 inch pot, drained and half filled with sandy loam and peat in equal parts, the remainder filled up with sand. When the pots are well-filled with roots shift the whole into others 9 inches in diameter; these can then be plunged in wider wooden baskets filled up with moss: so treated they have a nice appearance even when not in flower. The points of their shoots later in the season are very effective, clothed with bunches of brilliant singular-shaped tubular flowers. *Troscaria asiatica* may be grown in a basket placed for the stove or intermediate house; it comes best from cuttings, struck half-a-dozen in a pot, and grown on in loam—the plants kept stopped for a time until large enough, then allowed to flower, after which destroy them, retaining young newly-struck plants for the ensuing year.

Where elegant, sweet-scented flowers are esteemed for bouquets, a good stock of *Pancretium fragrans* should be grown. It is an easily managed plant, that can be grown without difficulty in the stove, on the shelves, or in a fine-house, or in a cold frame, or in any situation where there is a tolerable heat. A succession of its highly fragrant flowers can be secured by the use of several plants introduced into stronger heat from a comparative state of rest. *Franciscas* that have flowered early will now have become growth; a few cuttings should be put in of *F. confertiflora*, the almost continuous flowering *F. Hopeana*, and *F. Lindeni*—the latter a beautiful sort, not so well known as it once was to be. Young shoots, 6 inches in length, taken

off with a heel, will strike readily in a brisk heat in sand, after which pot them on in good peat, to which add one-seventh of sand, as they all like plenty of water whilst growing, and at no time must they be allowed to become dry, or their leaves will suffer. *T. Baines.*

CATTLEYS.—Now that the sun has more power, the East Indian plants will require syringing overhead on fine days, even in dull weather (now the plants have fairly started into growth), and the surface of the pots should have a damping with a syringe or a fine-rose water-can. Most of these plants require a greater amount of atmospheric moisture than heavy root waterings. Plants growing on blocks must be syringed two or three times a-day, but where Sphagnum is used on the blocks they will require less attention in this matter. Shading will be required for most of these plants, using canvas sufficiently thick to exclude the fierce rays of the sun: the blinds must be rolled up immediately all fear of the sun scorching the plants is past. *Dendrobium* will now require more water at the roots, although water must be administered with care, especially to the delicate rooted kinds; above all, they should not be over-potted, in fact they all appear to succeed better when potted in the "root-room," with one or two exceptions they require the heat and moisture of the East India house. *D. Cambidgianum*, *D. Parishii*, *D. primuminum*, *D. Wardianum*, *D. Devonianum*, and many other varieties do best grown in baskets suspended from the roof; such strong growing kinds as *D. densiflorum* and *D. Farmeri* are best grown in pots. The most fibrous peat, sphagnum, and charcoal is the best mixture to grow them in. *D. formosum* should have pieces of charred wood placed perpendicularly in the pot, for the roots to cling to, with a very small quantity of sphagnum and peat intermixed between the pieces of wood. Continue to report and top-dress any plants making new growth. *Cattleya labiata* and *Laelia elegans* require good fibrous peat and good drainage; they should be placed at the warmest part of the Cattleya-house. Growing Cattleys like plenty of moisture about them, hence it is a good plan to separate them from those not in a growing state. The new variety *C. rigida*, like *Orontia*, appears to succeed best in a day temperature of 60° to 70°, at no time should these plants be subjected to a lower temperature than 55°. They root well in fibrous peat and charcoal, so that what water is given it should be enabled to pass freely off. *Angulos* and *Lycastes* should now be repotted; they require a greater depth of material to root into than Cattleys; they nevertheless require a thorough drainage. For potting use a mixture of equal parts of peat and sphagnum with pieces of charcoal the size of nuts mixed with it; some species require a good supply of water at their roots. *Burlingtonias* are seldom seen now in good specimens, though the flowers of most of them are beautiful, and the plants are of easy cultivation. Rather a deep basket, with pieces of charred wood and sphagnum placed rather loosely in the basket, appears to suit them very well. They require plenty of heat and moisture to grow in, especially *B. candida*. This variety should be hung up to the glass in the East India house. As soon as *Odontoglossum citrosium* opens its flowers, the plants should be moved into a dry house, otherwise the flowers will become spotted. *G. Baker, Clapham Common.*

FLOWER GARDEN, &c.

PARTERRE AND MIXED GARDEN.—LAWNS, grass verges, &c., will now require constant attention. Immediately after heavy rains they will be found in a soft spongy state, and advantage should be taken of this condition to get them beaten down and well rolled previous to cutting the edges, which should be done with great care and regularity. This operation is simple enough to perform if the lines are straight, but requires some little skill if the edgings are curved, or at all intricate. For beds on grass, it may be necessary to re-strike them out from given points instead of trusting the eye and depending on guide-sticks, and in the end it is a saving of time. Choice evergreens may now be transplanted with the greatest safety. Choose dull damp weather for the operation, and in filling in give a good soaking of water, after which cover with dry soil, and mulch over to prevent evaporation. With the genial showers and soft balmy air to be expected during April they will become quickly established, far outstripping any that were transplanted in the autumn, and may have survived the winter.

Where it is desirable to increase any of the above, recourse should be had to layering, and if done now the layers will form nice plants for removal at this time next season. To accelerate the formation of roots, the branches should receive a slight twist previous to layering. Well stir the soil, and bury the branches so operated on to the depth of 5 or 6 inches. Coniferæ and other ornamental trees should now be looked over to see if any have branched off into rival leaders contending for ascendancy. If so, the strongest and best should be selected, and all others

cut out, or be made subservient to this, or the beauty and symmetry of the plant will soon be destroyed. Any lateral branches in like manner that are taking the lead, or are making disproportionate growths, should be shortened back. By a little timely assistance in this way the growth will be equalised, and afterwards maintained with great regularity. Severe pruning and undue formality should be strictly avoided, as the natural forms of trees are far more pleasing than if pruned and trained into shapes not habitual to them.

Herbaceous plants are among the first that come in to cheer us with their blooms, and have a charm and interest possessed by few other plants. It may be necessary to divide and re-arrange many of these, which should now be done. Before replanting, some mild rotten manure or fresh soil should be worked in, as the plants, if strong-growing, will most likely have exhausted that within reach. The double *Scythrum* are a most useful class of plants, having showy flowers but little inferior in form and colour to first-class Asters; but flowering in May, when showy flowers are scarce, they are even more valuable. *Pentstemon*s have been much improved of late. These, too, make a fine display, and are most valuable for cut flowers. *Astrimerias* should not be lost sight of, as they are very showy and lasting. These should be placed where they are intended to bloom, as they are difficult to transplant. Continue to plant *Glaucolus* at intervals, to give a succession of bloom, and allow the bulbs with a little sharp sand, and do not allow them to come in contact with manurial matter, as it will be sure to generate decay. No time should be lost in planting-out *Hollyhocks*, or the spikes will be short and poor. Well enrich the ground previous to planting, and look sharp after the disease that proved so fatal to many last year. Any showing symptoms of being affected should at once be destroyed. Roses that were left unpruned to afford a succession of bloom should now receive that attention, or the plants will suffer a severe check if allowed to get in a more forward state. Seeds of most kinds of annuals and perennials may now be sown. The hardier kinds may be sown outdoors, but all will be found to vegetate better if they can be afforded the protection of glass. Our practice here is to scatter a little light vegetable soil on a hard bottom and sow the seeds in rows, covering with fine soil. They are then protected with any old spare sash lights, and kept close till they vegetate. Treated in this way they involve little labour, and may be lifted and planted where desired without a check. Sow *Sweet Peas* and *Mignonette* where they are wanted to bloom, and make choice of plants having scented flowers or foliage to plant or sow near the margins of walks or entrances to dressed grounds, to exhale their pleasing fragrance. Such plants as the following, and of hardly edging plants, should now be sown, to save time at a more busy season.—*Polemonium*, *Echeveria* variety *glauca*, *Sempervivum*, *Sedum Golden Thyme*, *Stellaria*, *Cerastium*, &c. The bedding season is fast approaching, and little time remains for propagating. If the stock is still deficient their increase must now be pushed on vigorously. Such things as *Alternantheras*, *Irisine*, *Colous*, &c., may be propagated for some time longer. *J. Sheppard, Woolverstone Park.*

FRUIT HOUSES.

MELONS.—The first batch are just setting a fair crop of fruit on the first laterals. During the period of setting a much drier condition of both the roots and atmosphere is necessary; indeed, the plants should only receive as much water as will prevent flagging, and the temperature, both night and day, should be increased by 3° or 4°. Fertilise the female blossoms every day at the same time up to the growing points at two or three joints above the fruit. Directly the fruits begin to swell off give them a good soaking, and about the next day earth up the roots with good rich compost, ramming it down fairly tight. If it is perceived that one or two of the fruits on individual plants lead the rest, they should be removed forthwith—unless, indeed, very early Melons are desired regardless of a full crop. In regard to later plants, continue the general treatment as used in previous years, using more moisture as the days lengthen and the power of the sun increases. Apply the syringe moderately, about 3 P.M., on bright warm afternoons. Apply good thick linings to pits and frames where the bottom-heat is found to be on the wane, and afterwards be careful to allow the escape of rank heat and steam, and especially when the sun shines. Be careful also not to overcrowd the foliage; every alternate lateral may, at least, be removed with the thumb and finger directly they are perceived, and the remainder should be trained at right and left angles from the primitive stem. The points of these laterals should be nipped out at the fourth or fifth joint, and if any fruits show on the first laterals they should be removed if a crop is desired. The original stem should be stopped after it has advanced two-thirds of its distance. Employ a good thick night

covering, and beware of slugs. Sow for succession. *Thos. Simpson, Chelmsford.*

PINES.—Suckers or drooped plants which were started in March will soon require shifting into larger pots. Our usual practice is to shift from the sucker pots into the fruiting ones. We have proved this mode, which does not involve so much time, to be attended with better results than that of making more shifts, excepting it be in the case of very small plants, when it is not to be recommended. If advertised in the Calendar for the week ending February 27, pots of from 5 to 8 inches in diameter were used for the plants in question, these sizes will afford a suitable shift into the fruiting ones of 9, 11, and 12 inches in diameter, as may be necessary, having due regard to the size and variety of plants requiring them. The pots should be clean inside, and drained with clean crocks about an inch deep, of moderate size, which, when placed, should have a fish or two of ashes over them. At the time of potting, which should take place as soon as the sucker-pots are fairly well filled with roots, take advantage of the occasion when the plants are removed to replenish the bed, if it be needful, in the case of those which are composed of fermenting materials. Much experience is requisite to avoid having an unnecessary degree of heat in the bed, which oftentimes proves to be detrimental, and prostrates the plugging of the plants at a time when it is much to be desired for the purpose of assisting the roots to take hold of the fresh soil. If 80° should be the minimum of a tan-bed, merely turning it about a foot deep will suffice; if a lower degree exists, add a foot of fresh tan, and well mix it with the old to the same depth as before named. Where leaves are employed they will require to be turned over deeper. A temperature of 95° at the base of the pots is the best standard for newly potted Pine plants in all stages of growth. This, if the same plants are plunged should not be allowed to exceed 90° beyond this point there is great danger of injury to plants with roots in an active condition at the sides of the pots, as will now be the case with fruiting plants. Keep the air about such plants well charged with moisture during the time the house is closed; use no more fire-heat than is absolutely necessary to maintain the requisite degree of heat, namely, 70° at night and 75° on mild nights. Slightly ventilate the house at 10° and 11° in the latter half, close with sun-heat at about 85°, and syringe the plants, excepting those which are in bloom at that time. Skilful watering is most essential to insure success, and can only be effected in this manner, by examining the state of the soil in which the plants are growing. This should be done about once every week at this season. *G. T. Miles, Wycombe Abbey Gardens.*

VINES.—The season and manner of planting has very much to do with the after success of all kinds of trees and shrubs, and it is considered the best season for the planting of Vines. I will explain the best way of doing the same. It is presumed that the Vines to be planted are in 8 or 10-inch pots, and propagated from eyes of last year; the canes having been cut back in December last, and, having been kept in a cool house, or pit, the buds will now have started, and in some cases, perhaps, be several inches long; but, notwithstanding, they should be entirely shaken out of the pots, every particle of soil removed, preserving all the roots, and cutting the roots, and shortening back the long hard woody ones. The soil of the border having been made to the desired height, place the Vines in position, spreading out the roots perfectly flat, and cover them with soil to a depth of 4 or 6 inches, working it well about the roots with the fingers; afterwards give them a good watering with warm water, and mulch with a little soil or dung. Do not attempt to force growth immediately after planting, but let them, as it were, take their own time. A good start is ever to be desired, high temperature, before new roots are being made, prevents this. They should be sprinkled or syringed two or three times a-day, according to the weather, guarding, on the one hand, against a stagnant, overmoist atmosphere, and on the other an arid or parching one. Young Vines that were planted last spring will now be breaking naturally, and as soon as the buds are well pushed—say, half an inch long, will be benefited by a little fire-heat, especially on cold nights. Rub all buds off but one at each "break" as soon as it can be seen which is the best, and crop but lightly. Of course any super-numeraries may be fruited heavily. See that the borders have plenty of water; half the failures in Vine growing arise from a too scanty supply of this. That terrible pest "shanking" is, I believe, generally caused by drought. In succession houses let the bunches and berries be thinned lettimes, for it is remembered that just so long as these superfluous bunches and berries remain on the Vine they are drawing on the supplies that would otherwise go to the improvement of the permanent crop. Where Grapes are fully ripe a reduction in temperature may take place with advantage; but it will still be advisable to keep up a little air moisture for the benefit of the foliage, and to keep in check red-spider, which

By Her Majesty's Letters Patent

RENDEL'S PATENT SYSTEM of GLAZING.

RENDEL'S PATENT SYSTEM of GLAZING is the most economical ever introduced; being about one-third cheaper than the old putty system.

RENDEL'S PATENT SYSTEM of GLAZING. The Woodwork is completely covered by the Metal and the Glass, so that it is not exposed to the external action of the atmosphere.

RENDEL'S PATENT SYSTEM of GLAZING. All the Paint-work is completely covered by the Metal and the Glass, so that it is not exposed to the external action of the atmosphere.

RENDEL'S PATENT SYSTEM of GLAZING. If a Pane of Glass is broken it can be instantly replaced, by any workman or labourer, without the aid of the Glazier.

RENDEL'S PATENT SYSTEM of GLAZING. It is portable in the truest sense of the word. The Carriage of a Span-Roofed House, 40 feet long, for a distance of 250 Miles, is not more than £5.

RENDEL'S PATENT SYSTEM of CIRCULAR GLAZING. Bent Glass is very expensive, and a broken Pane will cost ten times as much as an ordinary one. On this System Bent Glass is entirely dispensed with, so that the saving on Circular and Curvilinear Roofs on this System is enormous.

RENDEL'S PATENT SYSTEM of GLAZING. All Houses erected on this System are Tenant's fixtures, and can be easily taken down and fixed again.

RENDEL'S PATENT SYSTEM of GLAZING. A Span-Roof Orchard House, 30 feet long, and 12 feet wide, can be supplied for £52 10s.

RENDEL'S PATENT SYSTEM of GLAZING. A Span-Roof Orchard House, 40 feet long and 15 feet wide, can be supplied for £75.

RENDEL'S PATENT SYSTEM of GLAZING. A Lean-to Greenhouse, 30 feet long and 10 feet wide, can be supplied for £33 10s.

RENDEL'S PATENT SYSTEM of GLAZING.

To Horticulturists the specimens of Rendel's Patent System of Glazing and the Portable Glass Protectors for walls proved attractive.

Their distinctive features are that all the work is done without putty.

It is asserted that 1500 square feet of glass can be put in the building in one hour by one man, and any damaged glass can be replaced without difficulty in the aid of a glazier.

All the wood and paint are covered by the glass, and the system was well and satisfactorily tested by the heavy shower on Wednesday, there not being the slightest leakage of water to the interior. The Times, June 27, 1874.

RENDEL'S PATENT SYSTEM of GLAZING.

Rendel's Patent System of Glazing has been used for some time past in Horticultural Works with complete success.

It is proposed to think its use may be, and will be, much extended.

In this system the Glass is placed in horizontal metal grooves, and fixed on wooden rafters, without putty.

The woodwork is completely covered by the metal and the glass, so that it is not exposed to the action of the atmosphere.

The glass moves freely in the metal grooves, and can be easily removed, so that if a pane of glass is broken it can easily be replaced without the aid of a glazier.

Moreover, the system is said to be very economical.

The Winter Garden and Aquarium to be formed in Westminster are to be erected in this way; and so will be many other buildings before long. The Builder, Jan. 30, 1875.

RENDEL'S PATENT SYSTEM of GLAZING.

IMPORTANT TESTIMONIAL From Mr. J. P. McCulloch, the Head Gardener to Sir Alexander Acland Hood, Bart., St. Andrews, near Bridgewater.

"I am glad to say that the Houses here stand and all through the late severe days, and have far exceeded my most sanguine expectations. The Wall Protectors, too (the combination system, as recommended by Mr. Ingram, of Belvoir Castle), have answered most excellently, and I secured a first-rate crop of Apricots, being the best and only crop since I have been here (about sixteen years ago). In the newly-converted Orchard House (on your system) all the old Trees have broken afresh, and I hope for a good crop next season. Sir Alexander Hood has several times expressed his satisfaction at the efficiency of the Houses, and I have heard him recommend the system to several Gentlemen."

RENDEL'S PATENT SYSTEM of GLAZING. The highest references can be given, and first-class Testimonials can be had on application.

RENDEL'S PATENT SYSTEM of GLAZING has been adopted by Noblemen and Gentlemen in every County in England and Wales, in Scotland, Ireland, the United States, and the Colonies.

RENDEL'S PATENT SYSTEM of GLAZING. Illustrated Catalogues and Books of Designs can be obtained, containing eighty-first-rate Illustrations, on application to the Patentee, Mr. W. EDGUMBE RENDEL, WESTMINSTER CHAMBERS, VICTORIA STREET, WESTMINSTER.

SOUTH AFRICAN FLOWER and FERN PRESERVER, in all colours, 12, the bottle. Sold by E. ROBERTS, Frankfort Terrace, Harrow Road, N.

PIPING BULLFINCHES, from £1 to £5 each; PIPING CANARIES, in addition to their natural notes pipe twice; GERMAN CANARIES, 7s. 6d., 10s. 6d., 15s., and 21s.; NORWICH CO., Cocks and Hens, and every description of foreign Aviary Birds; SEED for feeding the above, 6d. per quart; GOLD and SILVER FISH, and every requisite for the Aquarium. Many thousand FERNS and PALMS, from 6d. to Five Guineas each. All kinds of CLIMBERS, EVERGREENS, and FANCY TREES in pots. GREEN'S Belford Conservatories, Covent Garden Market, N.E.—Up the steps.

Labels-Labels. PARCHEMENT or CLOTH LABELS, TREE or PLANT LABELS. Punched Parchment, 4 inches long, 31. 6d. per 1000, or 30s. per 10,000; if cycled, 40s. above, 9d. per quart. GOLD and SILVER FISH, and every requisite for the Aquarium. Many thousand FERNS and PALMS, from 6d. to Five Guineas each. All kinds of CLIMBERS, EVERGREENS, and FANCY TREES in pots. GREEN'S Belford Conservatories, Covent Garden Market, N.E.—Up the steps.

PRUSSIAN WOOD GARDEN STICKS and TALLIES, commended by the Royal Horticultural Society. The above can be had, of all sizes, wholesale, of CHARLES J. BLACKHILL and CO., Cox's Quay, Lower Thames Street, London, E.C. Retail of the principal Seedsmen. Prices on application.

Indestructible Terra-Cotta Plant Markers. MAW and CO'S PATENT.—Prices, Printed Patterns, and Specimens, sent post free on application; also Patterns of Ornamental Tile Pavements for Conservatories, Entrance Halls, &c. MAW and CO., Beetham Works, Proseley.

Under the Patronage of the Queen.

J. SMITH'S IMPROVED METALLIC LABELS.

The above Labels—which have just been adopted for the Royal Gardens at Windsor—are made of a White Metal, with RAISED BLACK-PAPER LETTERS, and are of various shapes and sizes. Samples and Price List free. Sole Manufacturer: J. SMITH, the Royal Label Factory, Stratford-on-Avon.

The Royal Pottery, Weston-super-Mare.

UNDER ROYAL PATRONAGE.

JOHN MATTHEWS (late C. PHILLIPS), Manufacturer of TERRA COTTA VASES, FOUNTAINS, ITALIAN BASKETS, RUSTIC FLORAL ARBORETTES, STATUARY, GARDEN POTS from 2 to 30 inches in diameter, of superior quality, withstand frost, and do not become green; EDGING TILES, &c. See specimens in the Royal Horticultural Gardens. Price List free. Books of Drawings, 7s. each. JOHN MATTHEWS, Royal Pottery, Weston-super-Mare.

Conservatories for the Many. VINE'S REGISTERED PORTABLE CONSERVATORY.

The advantages of this Conservatory consist in its Strength, Durability, and Cheapness.

It forms its own packing case, can be delivered free to any Railway Station in London, and can be put up by any carpenter in half an hour.

It is made in three sizes, glazed, floored, and shelved, all complete. 8 feet by 4 feet 6 inches, height 8 feet ... £12. 10 feet by 5 feet 6 inches, height 8 feet ... 15. 12 feet by 6 feet 6 inches, height 8 feet ... 18.

Estimates given for Larger Structures. J. H. VINE, Horticultural Builder, 119A, Aldersgate Street, London, E.C. A Specimen may be seen at the Manufactory.

Heat your Horticultural Buildings Free of Cost for FUEL by using THE ORIGINAL COLLES' LIMEKILN BOILER and HEATING APPARATUS.

No expense for Fuel, and in some places a clear profit made on the Linc while heating Vines, &c., to any extent. Send for particulars, information, plans, and estimates of the System, which is much superior to any other.

Mr. ALEXANDER COLLES, Millmont, Kilkenny, Ireland, where this System has been many years at work, and can be seen at all times; or to MAGRIE AND SON, Heating Engineers, 10, Dawson Street, Dublin.

Rosher's Garden Edging Tiles.

THE above and many other PATTERNS are made in materials of great durability. The planer sorts are especially suited for KITCHEN GARDENS, as they harbour no Slugs or Insects, take up little room, and, once put down incur as further labour or expense, as do "grown" Edging, consequently being much cheaper.

GARDEN VASES, FOUNTAINS, &c., in Artificial Stone, very durable and of superior finish, and in great variety of design. F. ROSHER and CO., Manufacturers, Upper Ground Street, Blackfriars, S.E.; King's Road, Chelsea, S.W.; Kingsland Road, E.

Agents for LOOKER'S PATENT "ACME FRAMES," PLANT COVERS and PROPAGATING BOXES; also for FOXLEY'S PATENT BEADED GARDEN WALL BLOCKS.

Illustrated Price Lists free by post. The Trade supplied.

ORNAMENTAL PAVING TILES, for Conservatories, Halls, Corridors, Balconies, &c., from 3s. per square yard upwards. Pattern Sheets, of plain or more elaborate designs, with prices, sent for selection.

WHITE, GLAZED TILES, for Lining Walls of Dairies, Larders, Kitchen Ranges, Baths, &c. Grooved and other Stable Paving of great durability, Wall Copings, Drain Pipes and Tiles of all kinds, Roofing Tiles, of great variety, Slates, Cement, &c. F. ROSHER and CO., Brick and Tile Merchants. See addresses above.

SILVER SAND, fine or coarse grain as desired. Prices by Post per Ton or Truck Load, on Wharf in London, or delivered direct from Pits to any Railway Station. Samples of Sand free by post.

FLINTS and BRICK BURKS for Rockeries or Ferneries. KENT PEATS or LOAM supplied at lowest rates in any quantities.

F. ROSHER and CO.—Addresses see above. N.B.—Orders promptly executed by Rail or to Wharves. A liberal Discount to the Trade.

DEANE AND CO., 46, KING WILLIAM STREET, LONDON BRIDGE, E.C.

VIENNA PRIZE WIRE NETTING.

Awarded At
The Medal Vienna,
For Merit 1873.

**CAUTION TO BUYERS
OF WIRE NETTING.**

The great reputation and success of Messrs. J. B. BROWN AND CO.'S VIENNA PRIZE WIRE NETTING seem to have induced certain Dealers in Wire Netting to advertise an inferior article at reduced prices, specifying the mesh, gauge, &c., as if such were the same in quality and value as the Prize Wire Netting of which Messrs. J. B. BROWN & Co. are the SOLE MANUFACTURERS.

Messrs. BROWN & Co. would suggest that, before ordering quantities, one roll of their Wire Netting should be ordered and one roll of that advertised at reduced prices. The size and shape of the mesh may then be examined, the thickness or strength of wire, the weight of the rolls and the exact measurements, the general finish of the manufacture, and the quality of the galvanising.

This examination will prove the respective qualities of the Netting.
50, Cannon Street, London, E.C.—March 12.

TANNED GARDEN NETTING, 1d. per
Square Yard, for Protecting Seed-beds, Peas, Fruit, Strawberries, &c., from Birds, Frost, Blight, &c., and as a Fence for Fowls, in 1, 2, 3, and 4 yards widths. Beehives.—Two Silver Medals awarded to GEO. NEIGHBOUR AND SONS at the Paris Exhibition of 1867. The only English Exhibitors who obtained a Silver Medal for Beehives.

NEIGHBOUR'S IMPROVED COTTAGE
BEEHIVE, as originally introduced by GEORGE NEIGHBOUR & SONS, working three bell-glasses, is neatly and strongly made of straw; it has three windows in the lower Hive. This Hive will be found to possess many practical advantages, and is more easy of management than any other Beehive that has been introduced.

Price, complete £1 15 0
Stand for ditto 0 10 6
The LIGURIAN or ITALIAN AIP BEE being much in repute, Geo. N. & Sons supply a Swarm of Bees with genuine Italian Queen, in the Improved Cottage Hive, at £4. Hive included.
An Italian Aip Queen, with full directions for uniting to Black Stock, 15s. each.

ENGLISH BEES.—Stocks and Swarms may be obtained as heretofore.
THE APIARY. By A. NEIGHBOUR. 5s., postage 4d.
A newly arranged Catalogue of other improved Hives, with Drawings and Prices, sent on receipt of two stamps.
Agents for Straw, Woodbury, and other Hives and Supers, made by James Lee, at his prices.

RICHARDSONS' PATENT PORTABLE HORTICULTURAL BUILDINGS have the most perfect system of ventilation combined with complete protection from the weather. They are forwarded, ready glazed and painted, carriage paid and safe, to any part of the United Kingdom.
Apply for particulars, enclosing stamp, to W. RICHARDSON AND CO., Horticultural Builders and Hot-water Engineers, DARLINGTON.

FOWLER'S PATENT STEAM PLOUGH and CULTIVATOR may be SEEN at WORK in every Agricultural County in England.
For particulars apply to JOHN FOWLER AND CO., 71, Cornhill, London, E.C.; and Steam Plough Works, Leeds.

GEORGE'S PATENT CALORIGEN,
FOR
Warming and Ventilating Small Conservatories.

COAL CALORIGEN, £6 6s.
Height, 36 inches; diameter, 21 inches.
GAS CALORIGEN, £3 3s.
Height, 28 inches; diameter, 14 inches.
The only Gas Stove in which the product of combustion is entirely excluded from the Conservatory, while a constant stream of warmed, not burnt, fresh air is introduced. The "Coal Stove" consumes the smallest amount of Fuel—of per diem being the average cost. It will be found very valuable in the Nursery or Sick Room, Damp Buildings, Conservatories, Offices, &c. Exhibited at the Exhibition of 1873 (Department of Scientific Inventions).

Illustrated Prospectuses and Testimonials on application.
J. F. FARWIG AND CO., 36, Queen Street, Cheapside, E.C. This Stove introduces a strong current of warmed (not burnt) fresh air.

JONES'S PATENT "DOUBLE L" SADDLE BOILER.

These Boilers possess all the advantages of the old Saddle Boiler, with the following improvements—viz: the water space at back and over top of saddle increases the heating surface to such an extent that a "PATENT DOUBLE L SADDLE BOILER" will do about twice the amount of work with the same quantity of fuel; the cost of setting is also considerably reduced, and likewise the space occupied; at the same time these Boilers are simple in construction, and being made of wrought iron, are not liable to crack. They are made of the following sizes:—

Sizes.		To heat of 4-in. Pipe.		Price.	
High.	Wide.	Feet.	£ s. d.		
20 in.	18 in.	300	7	0	0
"	"	400	8	0	0
"	18 "	30 "	5	0	0
24 "	24 "	24 "	7	0	12
"	24 "	30 "	8	5	14
24 "	24 "	36 "	1	0	16
24 "	24 "	48 "	1	4	20
28 "	28 "	60 "	1	8	25

Larger sizes if required.
From Mr. CHARLES YOUNG, Nurseries, Balham Hill, S.W., May 29, 1873.
"Having given your Patent "Double L" Boilers a fair trial at my Nurseries, I beg to say that they are most satisfactory. I consider them the best in use, and without doubt the most economical of all boilers; they will burn the refuse of other tubular boilers I have in work."

PRICE LISTS OF HOT-WATER PIPES and CONNECTIONS, with Boilers, of all sizes and shapes; or ESTIMATES for HOT-WATER APPARATUS, erected complete, will be sent on application.

J. JONES AND SONS, Iron Merchants, 6, Bauskide, South-work, London, S.E.
When ordering Boilers please refer to the above advertisement.

STEVENS' TRENTHAM GREENHOUSE BOILER,
After long experience, has proved the most Simple, Economical, Effective, and Lasting Boiler extant; recently much improved. For Illustrations, with full particulars, apply to the Sole Makers, P. AND J. SILVESTER, Castle Hill Foundry, Engineering and Boiler Works, Newcastle, Staffordshire.

Important to Market Gardeners and Others.
THE PATENT HAND GARDEN PLOUGH.

This effective little implement meets a long-felt want. It consists of one light but strong steel shovel, for marking out rows to plant, or for loosening up the ground after the plants are up. Also a small Steel Plough, to be used for hilling up the rows when desired; and a Cutter for exterminating weeds, and Rake for pulverising the ground. These pieces are made separate, and attached or detached in a moment by means of a simple fastening. Its construction enables the user to push it readily and easily through the ground, stirring the earth, if required, to a depth of six inches. It is exceedingly light, strong, and tasy, and fully adapted to the purposes designed. A large number have been sold, and are giving unqualified satisfaction.

Price, complete, with Shovel, Plough, Weed-Cutter, and Rakes, £2 2s.

FOLLOWS & BATE, Makers, Dutton Street Works, MANCHESTER.

„ with 21-oz. Glass, 24 feet by 14 feet, by 7 feet at eaves, £94.

A Certain Crop of Fruit, in spite of Frost, is secured by PARHAM'S

PATENT GLASS COPING For Sheltering Fruit Trees.

The Patentee has sent out many miles of it during the past three seasons, and additional orders have each year been received from those who have tried it.

Price—Per foot run, with 21-oz. glass. With the iron framework painted, 2 feet, 2s. 6d.; 3 feet wide, 3s. 9d. With the iron framework galvanised, 2 feet, 3s. 3d.; 3 feet wide, 4s. 9d.

From Mr. F. SAUNDERS, Gardener to Sir Wm. Miles, Bart., Leigh Court, Bristol, October 23, 1874.

“Sir,—I have much pleasure in saying the Wall Coping you erected here in April, 1874, has given the greatest satisfaction. Many of the Peach trees, at that time apparently worthless, are now in full vigour, and have borne extraordinary crops this season, the fruit being unusually fine, and of excellent flavour. I have recommended it to several gentlemen, who, I believe, will give it a trial.”

Sold by LONGMAN and CO., Paternoster Row, E.C.; and by Mr. KIPPIST, at the Apartments of the Society, Burlington House, Piccadilly, W.; of whom may be had all, or any of the preceding Volumes. The Fellows of the Society are requested to apply to Mr. KIPPIST, for their copies, between the hours of 12 and 4 o'clock.

Second and Cheaper Edition. This day is published, with Engravings, 3s. 6d. HANDY BOOK OF BEES.—A Practical Treatise on their Profitable Management. By A. PETERGEE.

A practical treatise on the profitable conduct of apiculture, by an author thoroughly familiar with the theme. He writes largely for working men, emphatically urging on them the advantages, both in pocket and in habits, which the keeping of bees will confer; and the unpretentious, clear style, and extensive treatment of the subject, make the little volume a safe guide to a very interesting and self-rewarding recreation. "Daily Telegraph." We recommend his book to all who wish to spread a knowledge of this useful art amongst their neighbours and friends. "Land and Water." WILLIAM BLACKWOOD AND SONS, Edinburgh and London.

THE NEW METHOD OF GROWING FRUIT and FLOWERS. By the Rev. J. FONTAINE, Southsea, Hants, being a practical combination of Viney, Orchard House, and Conservatory, as now worked in a new house erected for the purpose at Chiswick. Fourth Edition, illustrated. Free by post for seven stamps to the Journal of Horticulture Office, 171, Fleet Street, E.C.; or to the Author. Second Edition, Price 3s., Post Free 4s.

THE AGRICULTURAL GAZETTE ALMANAC, 1875.

The best Illustrated Agricultural Almanac.

OPINIONS OF THE PRESS.

"It is an excellent and useful work for farmers and all interested in rural pursuits. Beyond the matter usual in such compilations are many good serviceable hints on fattening cattle, growing of root crops, &c. The illustrations are admirably executed, many being engraved from photographs."—Weekly Dispatch, Jan. 31, 1875. "The 'Agricultural Gazette Almanac,' which deals with matters of interest to farmers, has reached a second edition."—Lloyd's, Jan. 17, 1875. "It is a very cheap treasurery of information of interest and utility to farmers, and contains numerous illustrations."—The Field, Jan. 16, 1875. "In addition to the usual matter to be found in an almanac, we have here useful information to the farmer, as to stock raising, with illustrations of prize animals."—GloUCEstershire Chronicle. "This is a cheap and useful almanac and diary, well illustrated. Its contents will be found interesting to the agriculturist, and adapted for daily use."—Farmers' Terms, &c. "The Calendar contains all the fixtures for cattle shows, races, &c., space for diary and memoranda by the side, and various useful information of an agricultural character."—Oxford Times. "The 'Agricultural Gazette Almanac' is a cheap quarto almanac, comprising information on agricultural topics and a series of portraits of the Prince of Wales, Dr. Voelcker, and Viscount Bridport, and engravings of different prize cattle, reproduced from the 'Agricultural Gazette.'"—Isthmian Press. "To farmers, cattle dealers, and others interested in agriculture, this work will be found invaluable. It contains a deal of information relative to cattle, crops, land, and miscellaneous matters, and is profusely illustrated with engravings chiefly taken from photographs."—Devonshire Chronicle. "This almanac, which appears to be carefully compiled, and the contents judiciously selected, may be commended to the notice of agriculturists generally. It is issued at a low figure, and contains a large variety of information. There are numerous illustrations, and the likeness of the Prince of Wales, which forms the frontispiece, is especially deserving of mention."—GloUCEstershire Chronicle. "To all persons interested in agriculture in this neighbourhood 'The Agricultural Gazette Almanac' for 1875, price 3d., will be worth obtaining. It contains a fund of information, as well as a variety of advertisements on topics especially connected with the portion of the community which it is intended to serve."—Hullfax Guardian. "Although this almanac comes rather late it is none the less welcome; as containing a mass of information, both interesting and valuable to any person connected with agriculture, it is to be commended. In addition to the usual calendar it contains a diary, supplies us with authentic portraits and verbal descriptions of prize cattle, sheep, and pigs, a list of the members of both Houses of Parliament, another of the Chambers of Agriculture, another of County Agricultural Societies, besides hints as to practical farming. Such a combination of information must recommend itself to every agriculturist."—Western Daily Mercury. "Though it is rather late to be noticing an almanac for 1875, we make an exception in favour of the one before us, which owing to its great merits and low price, ought to be purchased by every agriculturist in the kingdom. The illustrations of prize cattle, implements, &c., are a valuable feature in the Almanac."—Preston Reporter.

W. RICHARDS, 7, Catherine Street, Strand, W.C.

KINAHAN'S LL WHISKY. This celebrated and most delicious old mellow spirit is the very CREAM of IRISH WHISKIES, in quality unrivalled, perfectly pure, and more wholesome than the finest Cognac Brandy. Note the Red Seal, Pink Label, and Cork brandied "Kinahan's LL" Whisky. Wholesale Depot, 20, Great Titchfield Street, Oxford Street, W.

Grateful-Comforting EPPS'S COCOA BREAKFAST.

By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of the purest Cocoa Beans, we have provided our breakfast-tables with a delicately flavoured beverage, which may save us many heavy doctors' bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up until strong enough to resist every tendency to disease. Hundreds of subtle maladies are floating around us, ready to attack and often to overpower the weakest of us. We may escape many a fatal shaft by keeping ourselves well fortified with pure blood and a properly nourished frame." See article in the *Civil Service Gazette*.

Made simply by boiling water or milk. Sold in packets (in tins for abroad) labelled—**JAMES EPPS and CO., HOMOGENEOUS CHEMISTS, 48, The Strand, London, and 120, Piccadilly, W. Works—Euston Road, and Camden Town, London, N.W. Makers of Epps's Glycerine Jujubes for Throat Irritation.**

In consequence of Spurious Imitations of LEA and PERRIN'S SAUCE, which are calculated to deceive the Public, LEA and PERRINS have adopted a new and improved method of bearing their Signature, thus—

which will be placed upon every bottle of **WOLFE'S SAUCE.** After this date, and without notice none genuine. Sold Wholesale by the Proprietors, Worcester. Sole Wholesale in London, by **Export Grocers, Mr. Egan; Retail, by Dealers in Sauces throughout the World.**—Nov., 1874

THE "ARCHIMEDEAN" AMERICAN LAWN MOWER

HAS BEEN AWARDED
GRAND DIPLOMA of HONOURABLE MENTION, Vienna, 1873.
SILVER MEDAL, Vienna, 1870. SILVER MEDAL, Hamburgh, 1869.

NOTE.—The "Archimedean" was specially selected from the Mowers exhibited at Vienna for constant use in the Exhibition Grounds, and gave great satisfaction; and we have pleasure in calling attention to the following Testimonial, received from the Inspector of the Royal Gardens, Schönbrunn, Vienna:—

"Your 'Archimedean' Lawn Mowers have been used for some time past at the Imperial Gardens, and I have great pleasure in stating that they have given perfect satisfaction. Their quick and good work prove them to be the best and most efficient machines of the kind."

PATRONIZED BY

HER GRACIOUS MAJESTY THE QUEEN,
HER IMPERIAL MAJESTY THE EMPRESS OF GERMANY,
THE LATE EMPEROR OF THE FRENCH,

HIS ROYAL HIGHNESS THE PRINCE OF WALES,
HIS IMPERIAL MAJESTY THE EMPEROR OF AUSTRIA,
THE VICEROY OF EGYPT,

And many of the Nobility and Gentry of Great Britain.

CHIEF ADVANTAGES.

They are extremely LIGHT IN DRAUGHT,
SIMPLE IN CONSTRUCTION, WELL
MADE, and NOT LIKELY TO GET
OUT OF ORDER.

They cut LONG or SHORT, WET or DRY
Grass, and do not clog.

They have no ROLLERS in FRONT of the
Cutters, and therefore cut the Grass as it
GROWS, and do not miss the BENTS.

They work well on SLOPES, STEEP EM-
BANKMENTS, UNDER SHRUBS, and
close up to Trees, &c.

They can be USED either WITH OR WITH-
OUT GRASS BOX, as may be desired.

TESTIMONIALS.

From A. F. BARRON, Esq., *Royal Horticultural Society, Chiswick Gardens, W.*

"GENTLEMEN,—We have now had your 'Archimedean' Lawn Mower in use for several months, and without hesitation I can truly say it is the *best* and most *efficient* implement of the kind we have ever used."

From the late Mr. GEORGE WYNESS, *Royal Gardens, Buckingham Palace.*

"GENTLEMEN,—I beg to say that we have had your Patent 'Archimedean' Lawn Mower at work in Her Majesty's gardens at Buckingham Palace for some time past, and I have much pleasure in testifying that it has given every satisfaction, as it does its work well and quickly."

From the Rev. J. H. WHITE, *Hemingford Grey, St. Ives, Hunts.*

"I am much pleased with the working of your 'Archimedean' Mowing Machine. I think it superior to others which I have used in previous years."

OPINIONS OF THE PRESS.

"The quickest, most simple, and most efficient Mower ever used."—*Gardeners' Chronicle.*

"Far superior to any of ours."—*The Field.*
"Remarkably easy to work."—*Gardeners' Mag.*

"We feel bound to recommend it to our readers as one of the best Mowers we have as yet made acquaintance with."—*Floral World.*

EVERY MOWER IS WARRANTED TO GIVE AMPLE SATISFACTION,
And if not approved of may be returned within a Month, and the amount paid be refunded.

GIANT ASPARAGUS PLANTS, the best that money can procure, all certain to grow, 22. 6d. per doz. This delicious vegetable does not require half the expense usually incurred in planting it. See RICHARD SMITH'S SEED LIST for 1875.

Double Petunia. "MRS. WILSON."—The above is a fine Double Crimson variety, striped and edged with white, very fine and distinct. It received three First-class Certificates last year. Good Plants, now ready, 3s. 6d. each, post free 3s. 9d. THOMAS AND SON, The Nurseries, Kingston, Surrey.

ZONAL PELARGONIUMS.—A fine, well-grown stock of extra strong autumn-stuck plants, in 4-inch pots, of the choice new varieties of last year, at 40s. per 100; also an immense quantity of the best Bedding Pelargoniums—Tender, of Gold, Silver, and Zonal. LIST of sorts and prices on application.

Mr. Postan's New Zonal and Fancy Variegated PELARGONIUMS for 1875. CHARLES BURLEY begs to announce that he has been entrusted with the distribution of the above magnificent NEW PELARGONIUMS, to be sent out, for the first time, the beginning of May next. PRICE LIST and full descriptions on application. Paradise Nursery, Brentwood.

CRANSTON'S CRIMSON BEDDER: strong plants, in 5-inch pots, 50s. per dozen. TEA-SCENTED, CHINA, NOISETTE, and HYBRID-PETAL ROSES, in 4 and 5-inch pots, 5s. to 12s. per dozen.

Now is the best time for bedding-out the Tea-scented and China Roses, and Hybrid Perpetuals, on their own roots. Address, CRANSTON AND MAYOS, King's Acre Nurseries, Hereford.

Silver-margined leaved Geranium, Laura. FRANCIS R. KINGHORN has much pleasure in offering this superior variety, being a strong grower, with very large trusses of pale scarlet flowers, freely produced in the centres of the beds and back to the borders. Received the highest commendation (a First-class Certificate) from the Floral Committee at Chiswick in 1873, which was again repeated at Plants in each, seven for 30s. Sheen Nurseries, Richmond, Surrey.

New White Lobelia. "DUCHESS OF EDINBURGH."—This variety possesses an excellent compact habit, and is a good free grower. The flowers, which are produced in great abundance, retain their purity of colour the entire season. Received a First-class Certificate at the Royal Horticultural Society, Kensington, 1874.

CHARLES TURNER, The Royal Nurseries, Slough.

New and Choice Ferns. W. AND J. BIRKENHEAD, having a Collection of many thousands of the most beautiful and choice BRITISH and EXOTIC FERNS, and giving their cultivation special attention, are prepared to supply large or small quantities at most reasonable prices.

CATALOGUES on application. Special quotations for large quantities. Fern Nursery, Sale, near Manchester.

Larger Collections, 15s., 21s., 42s., and 63s.

CARTER'S (The Queen's Seedsmen), 237 and 238, HIGH HOLBORN, LONDON, W.C.

CARTER'S

NEW NASTURTIUM RUBY KING (With dark-coloured foliage), per packet, 1s. 6d.

A seedling variety of that type of Dwarf Nasturtium originated by us—viz., the dark-folaged or King of Tom Thumb section—the popularity of which is now universal, from the fact of their bright colours contrasted with dark foliage, compact habit, and duration of bloom, rendering them quite equal in effect to bedding Geraniums. The colour of the new variety now offered is quite unique and distinct—pure pink shaded with carmine—and forms an effective contrast with the varieties already in cultivation.

Spring Planting. FOREST TREES, ORNAMENTAL TREES, and SHRUBS, a large stock at moderate prices. CATALOGUES free on application. THE LAWSON SEED AND NURSERY COMPANY (Limited), 106, Southwark Street, London, S.E., and at Edinburgh.

To Gardeners. Gardeners are most respectfully invited to visit THE PINE-APPLE NURSERY, MAIDA VALE, LONDON, W., Where it is anticipated they will be highly gratified. JOHN BESTER, Manager.

The Only Really and Thoroughly Distinct LOBELIA of the SEASON, BLUE STONE — hitherto a hidden gem.

Strange that this, by far the best of all the Lobelias, should have been kept back from the public by a "rotchet," and it is only within the last few days that the seed has been placed in my hands. The darkest blue, no eye, strong compact panicle habit; foliage, strange to say, is a most peculiar purplish green, and its whole character far exceeds any other Lobelia. Five hundred seeds, post free, 1s. 1d.; plants sent post free 1s. each, 12 for 7s. Vide p. 94 *Gardeners' Magazine*, February 20. "Challenging the whole of the horticultural community to produce a better."

H. CANNELL, F.R.H.S., begs to announce that his FLORAL GUIDE for 1875 is now ready, and will be sent, post-free (cost price), for ten stamps. It is beautifully illustrated with 200 splendidly executed engravings. It also contains particulars, and correct descriptions of all the novelties, and the best new and old varieties of soft-wooded plants in cultivation, and it is highly important to amateurs and gardeners that they should peruse it continually, for it contains invaluable and practical information on Florists' Flowers and Bedding Plants and their Seeds; and the cheap, ready, and correct manner in which they are supplied and forwarded to any part of the world cannot fail to be a great advantage and highly appreciated by all who are really fond of the choicest flowers.

NEW FUCHSIA, "MRS. H. CANNELL." — This magnificent variety last year bore out even more than the high character previously given it, and is by far the best double white corolla variety; foliage and flower even an advance on the good old dark Avalanche. Fine half-specimen plants, 2 feet high, in 6-inch pots, 7s. 6d. each; small ditto, 5s.; nice plants in thumbs, 1s. 6d. each; small rooted little plants, or two cuttings, 1s., post free. New Florist Flowers and Florist Flower Seed Merchant, Woolwich, S.E.

JAMES VEITCH & SONS' FRUIT PRIZES FOR 1875.

MESSRS. JAMES VEITCH AND SONS have the pleasure to announce that they have again arranged with the Council of the Royal Horticultural Society to offer the following Fruit Prizes, to be competed for at the Gardens at Kensington, on the 21st July next:—

The following List of Prizes has been decided upon!—

	1st Prize	2d Prize.	3d Prize.
1. For the best COLLECTION of FRUIT in ten distinct kinds... ..	£15	£10	£7
In this class only one variety of Pine, Melon, Peach, Nectarine, or Strawberry will be admitted; but Black and White Grapes, Black and White Cherries, and Black and Yellow Plums, will be considered distinct.			
2. For the best COLLECTION of FRUIT, in six distinct kinds... ..	£9	£6	£4
The same exhibitor cannot compete in Classes No. 1. and 2.			
3. For the best Three Bunches of MUSCAT of ALEXANDRIA GRAPES	£6	£4	£2
4. For the best Three Bunches of BLACK HAMBURGH GRAPES	£6	£4	£2
5. For the best Three Bunches of GRAPES, any kinds, excluding Muscat of Alexandria and Black Hamburgh	£6	£4	£2
6. For the best Three PINE APPLES	£6	£4	£2
7. For the best Six FRUIT of PEACH, one kind	£3	£2	£1
8. For the best Six FRUIT of NECTARINE, one kind	£3	£2	£1

The competition for these Prizes is limited to the *bona fide* Gardeners of Great Britain. All entries to be made as usual, at the Royal Horticultural Gardens, South Kensington. In all cases the decision of the Judges to be final. These Prizes are quite distinct from the "Veitch Memorial" Prizes.

ROYAL EXOTIC NURSERY, KING'S ROAD, CHELSEA, S.W.

NEW PLANTS

FOR 1875.

B. S. WILLIAMS

WILL HAVE

THE FOLLOWING NEW PLANTS

READY FOR DISTRIBUTION THE FIRST WEEK IN MAY:—

ACALYPHA MARGINATA.

This species is a welcome addition to the myriads of foliage plants introduced of late years. The size of the leaves are incidental with those of *A. tricolor*, but the markings are totally distinct. The centre of the leaf is brown, around which is formed a distinct margin of rosy carmine about a quarter of an inch wide, rendering it a most beautiful object. The leaf is entirely covered by quantities of little hairs, which add much to its beauty. This plant is well figured in Plate 156, in the *Floral Magazine* for March, 1875. Price 21s.

AGERATUM, COUNTESS OF STAIR.

This variety is without doubt a decided advance upon any other *Ageratum* yet offered. There is not a shoot but throws up a head of dense blossoms, beginning a few inches from the ground, and is held erect when its entire height of 6 or 8 inches is attained, when the whole top of the plant is one mass of fragrant lavender-blue blossoms. It was raised by Mr. Fowler, of Castle Kennedy, where it has been bedded out for 5 or 6 years with great success, withstanding, as it does, the heavy rains better than most bedding plants. Being of such compact habit and free flowering qualities, it cannot fail to recommend itself for flower-garden purposes. Price 3s. 6d. each, 30s. per dozen. Special quotation per 100.

ALSOPHILA AUSTRALIS WILLIAMSII (Moore).

THE WEeping TREE FERN.—This is an extremely handsome variety of *A. australis*, but is very distinct from that species, owing to its pendent habit. It was figured and described for the first time in the *Gardeners' Chronicle*, by Mr. Moore, as being a most charming variety. It will be found to succeed well in a greenhouse, as it is quite as hardy as the species. This variety shows its pendent character in the seedling state, a quality of which no other Tree Fern of the same habit can boast. Nice young plants, 21s.

ANTHERICUM VARIEGATUM.

A most striking novelty, introduced from the Cape of Good Hope in 1873. It is quite hardy, and will therefore be found quite invaluable as a decorative plant, being suitable either for the greenhouse, stove, or dinner table. It has been prepared by many to *Pandanus Veitchii*, which it resembles in its general bearing, the variegation and habit being precisely the same. The foliage is of bright grassy green, beautifully striped and margined with creamy white. It was awarded a First-class Certificate from the Royal Horticultural Society, under the name of *Anthericum Williamsii*. Price 21s.

ANTHURIUM PATINII.

This is a very free flowering species, producing an abundance of white flowers, with spathes $3\frac{1}{2}$ inches long by $1\frac{1}{2}$ inch broad, produced on very slender stems. The leaves are ovate-lanceolate, slightly tapering towards the point, the edges being beautifully undulated. It was discovered by my collector (Mr. Patin), in honour of whom it is named. Price 21s.

ANTHURIUM SCHERZERIANUM WILLIAMSII.

This is undoubtedly the greatest novelty of the season, and will prove as great a favourite with the plant-growing public as *A. Scherzerianum* itself, and to which it will form a splendid companion plant. In habit and growth it is in all respects like the normal state, but its spathe and spadix differ entirely: in the variety now offered the spathe is pure ivory-white, and the spadix a pale lemon colour. The distribution of this plant will be duly advertised. Price 10s. each.

CYRTODEIRA COCCINEA.

A very pretty basket plant, producing bright scarlet flowers; leaves dark metallic green, from 3 to 4 inches long, and $2\frac{1}{2}$ to 3 inches broad. This is a very free flowering species, literally covering the basket in which it is grown with flowers. Price 10s. 6d.

CYCLAMEN PERSICUM GIGANTEUM.

The *Cyclamen* is now established and pronounced to be the finest winter-flowering plant we have, so that any improvement that can be made must be of the greatest value. The variety now offered, *giganteum*, will be the commencement of an almost new or greatly improved type, having very broad beautifully mottled coriaceous leaves and stout flower-stalks, throwing the flowers well above the foliage, each flower from 2 to $2\frac{1}{2}$ inches in depth, with broad petals of great substance, pure white, with a fine bold violet-purple eye. Price 5s.

DICTYOGRAMMA JAPONICA VARIEGATA (Moore).

An interesting greenhouse Fern, introduced from Japan. The fronds of the young plants are from 1 foot to $1\frac{1}{2}$ foot high, furnished with one or two pairs of linear-lanceolate serrulate pinnae, and a somewhat longer terminal one, somewhat as in *Pteris cretica*, with which, however, this has no affinity. As the plants get older and more vigorous these pinnae divide, so that the fronds become bipinnate, the pinnules being of similar form to the pinnae, but rather smaller, and the pinnae and pinnules being always few in number. The venation is reticulated in the costal half of the pinnae or pinnules, while the veinlets of the outer half running out to the margin, are straight and parallel. The sori are naked, produced in transverse lines corresponding with the lines of the venation. The peculiarity of this variety consists in the parenchyma of the frond showing paler or yellowish-green blotches along each side of the midrib, which gives to the surface of the frond a variegation very distinct. Price 10s. 6d.

FUCHSIAS.

JOHN GIBSON.—Very bright scarlet tube and sepals, the latter well reflexed, corolla lavender-purple, beautiful shape. Price 7s. 6d.

KING ALFONSO.—Tube and sepals rich crimson, the latter very broad and of great substance, corolla deep violet, a most extraordinary flower. Price 7s. 6d.

LADY WATERLOO.—Tube and sepals white, beautifully striped and flaked with scarlet, nicely reflexed, corolla rich magenta, a most profuse bloomer. Price 7s. 6d.

MRS. MUR.—Tube and sepals bright carmine-scarlet, well reflexed, corolla pure white, and single, perfect shape. Price 7s. 6d.

SURPRISE.—This will make a splendid market plant, being of clean habit and free bloomer, tube and sepals pure white, with a rich crimson corolla. Price 7s. 6d.

PLATYCIERIUM WALLICHII.

A very distinct stove Fern, described by Mr. Moore, the eminent authority on Ferns, in the *Gardeners' Chronicle* as being an extremely elegant plant, the fertile fronds measuring from 1 foot to 2 feet in length, the plant producing two fronds each season, one falling towards the right, the other towards the left. The sterile fronds are erect, with copious dichotomous segments, whilst the fertile ones, which are drooping, are divided into much more elongated segments. Strong plants, 10s.

POLYSTIUM LEPIDOCALDON (Hooker).

This plant at first sight has the aspect of a *Cyrtium*; it is quite evergreen; the fronds measure a foot or more in length, narrow but broadest at the base, and either acuminate at the apex or prolonged and proliferous. This will probably prove a hardy plant, as it grows very freely in a cold greenhouse. It will be found invaluable as a basket Fern on account of its pendent habit. Price 21s. Ready in autumn.

SCOLOPENDRIUM.

VULGARE CRISTATUM VIVIPARUM (Moore).—A close growing, compact variety, only attaining about 6 to 8 inches in height, having thick-set, much-tufted viviparous fronds, a most desirable addition. Received a First-class Certificate, South Kensington, June, 1874. Price 10s. 6d.

The NEW PLANT CATALOGUE, containing Descriptions and Illustrations of the above New Plants, will be ready the first week in May, and will be sent, Gratis and Post Free, to all applicants.

VICTORIA AND PARADISE NURSERIES, UPPER HOLLOWAY, LONDON, N.

NEW PLANTS.

MR. WILLIAM BULL

Intimates that the following New Plants will be sent out for the first time in the beginning of May :—

RHEUM NOBILE.

This plant is beautifully illustrated in plate six, of *Illustrations of Himalayan Plants* from Mr. Cathcart's drawings. It is thus described by Dr. Hooker &c.—"The individual plants of Rheum nobile are upwards of a yard high, and form conical towers of the most delicate straw-coloured, shining, semi-transparent, concave, imbricating bracts, the upper of which have pink edges; the large, bright, glossy, shining, green, radical leaves, with red petioles and nerves, forming a base to the whole. On turning up the bracts the beautiful membranous fragile pink stipules are seen, like red silver-paper, and within these again the short branched panicles of insignificant green flowers." "The plant occurs in Sikkim, at an elevation of from 7,000 to 15,000 feet." "I first saw it," remarks Dr. Hooker, in the work above alluded to, "at a distance of fully a mile, dotting the black cliffs of the Lachen valley at 14,000 feet elevation, in inaccessible situations, and was quite at a loss to conceive what it could be, nor was it till I had turned back the curious bract-leaves and examined the flowers, that I was persuaded of its being *Rheum nobile*."

RHEUM OFFICINALE.

Very much interest attaches to this plant, as being the ascertained source whence is derived at least a portion of the true Turkey Rhubarb. This has long been a vexed question, since many attempts have been made to discover the true source of the drug have been made, and have generally ended in increasing, rather than clearing up the mystery of its origin. *R. officinale*, which inhabits and is cultivated in the interior of China, is a very distinct and well-marked plant, of a somewhat character. It is a perennial herb, producing orbicular-ovate or cordate shallowly three-lobed to seven-lobed leaves, and flowering-stems a foot to two feet high, branched at the top, and quite at a loss to conceive what it could be, nor was it till I had turned back the curious bract-leaves and examined the flowers, that I was persuaded of its being *Rheum nobile*."

RHEUM PALMATUM TANGUTICUM.

A stately robust-habited perennial, which agrees with *R. officinale* (the reputed source of the true source of the drug) have been made, and have generally ended in increasing, rather than clearing up the mystery of its origin. *R. officinale*, which inhabits and is cultivated in the interior of China, is a very distinct and well-marked plant, of a somewhat character. It is a perennial herb, producing orbicular-ovate or cordate shallowly three-lobed to seven-lobed leaves, and flowering-stems a foot to two feet high, branched at the top, and quite at a loss to conceive what it could be, nor was it till I had turned back the curious bract-leaves and examined the flowers, that I was persuaded of its being *Rheum nobile*."

SATURDAY, APRIL 17, 1875.

THE APPLE OF LITERATURE.

(Concluded from p. 485.)

THE primitive history of the Apple is at present quite undetermined. An immense amount of labour has been bestowed upon the subject by Prof. Koch, who between 1836 and 1844 spent much time in investigations in Armenia and the adjacent countries, purposely with a view to ascertain something precise. The very trustworthy result of his enquiries and profound study of the subject is that the Apple never grew wild anywhere in the southern Caucasus; and to this it may be added that Boissier, in the *Flora Orientalis*, entirely omits the Holy Land as a native locality of the Apple, though he allows it to some of the adjacent countries. Of course it may have been cultivated in Palestine as an exotic, but in any case the Palestine climate is altogether unfavourable to its prosperity, and to its becoming a tree such as the one mentioned by the prophet. Like the Currant and the Gooseberry, and for similar reasons, the Apple does not thrive in southern latitudes, unless in very elevated districts. In certain parts of the Lebanon, and near Damascus, for example, it is said to be tolerably good. Thither, in all likelihood, it would be originally introduced by the monks of western Europe. Certain inexact travellers of recent date, determined to stand by the literal expressions of the A. V., whatever they may really denote, have asserted that the Apple, and the Apple only, is intended by *tapphach*, and they tell us how conspicuously beautiful it is in the Holy Land; but it is perfectly plain that they have been misled by the spectacle of the Quinces, which are there very attractive.*

Two fruits have been suggested as perhaps specially intended by *tapphach*, the Citron and the Apricot. Considering the many and various good qualities of each, and how differently they strike different observers, while at the same time not any single kind of fruit thoroughly answers to all the requirements implied in the biblical allusions to the *tapphach*, one cannot but feel satisfied that the term is collective; and that it fails to apply specifically simply because it was never designed to do so, carrying rather the idea of the aggregate qualities of everything upon which it was at any time bestowed. The ancient poets ascribe to their heroes the virtues and noble qualities of all the brave men by whom they were surrounded, including qualities now and then not quite compatible one with another; and something like this appears to have been done in the summing up in *tapphach* of qualities which to all appearance no single plant possesses, or at all events not in uniform perfection.

The argument for the Citron is recognised by Dr. Royle, to whose opinion it is objected that the tree is too small, and that, like the Quince, the fruit is harsh instead of "delicious." But Risso, in the *Histoire Naturelle des Oranges*, describes the Citron as magnificent when full grown, and calls it the most beautiful of its genus. The foliage is Laurel-like, glossy, of a deep rich green, and remains upon the tree all the year round. The flowers resemble those of the Orange, but are flushed on the exterior with rosy purple; the fruit seems an immense Lemon, sometimes attaining a length of 9 inches, and weighing 20 lb. The ancients believed that

in the odour there were properties almost miraculously restorative. The faith exists to this day, for with the modern oriental ladies the Citron is the favourite though rather bulky *vinaigrette*. "Comfort me with *tapphach*" thus appears to point very definitely to the Citron; and even if the original of this expression be more accurately translatable, as stated by Mr. Drake, "Strew me a couch of *tapphach* leaves,"* the Citron still meets the requirement, for every leaf is charged with little cysts of essential oil, the fragrance when the leaf is bruised exhaling like that of the Myrtle. The sweet sense of refreshing verdure presented by the ordinary Orange tree is well-known, as well as the exotic richness of the enveloping atmosphere when the tree is most copiously in bloom, not to mention the oriental splendour of the golden fruits that hang "like lamps in a night of green." These qualities pertain equally to the Citron, so that one may verily "sit under his shadow with great delight"; and even if the individual tree be small, no violence is done to the meaning of the words, since "under his shadow" implies, necessarily, no more than "beneath the branches." It is not to be overlooked, either, in regard to the general fitness of the Citron for poetical imagery, such as that of the Old Testament, that the processes of flowering and fruiting are like a waterfall, nearly constant; and we know already how Scripture loves to introduce the evergreen in preference to the deciduous. This is the intrinsic reason why to-day the bridal wreath is made of Orange or Citron blossom, the two trees being alike in the phenomena of their life. Wearing a chaplet of Orange, the ideas are simultaneously presented of sweetness of deportment and complexion, of perennial or evergreen happiness, and of a home or fireside circle, all in good time, such as flower-buds, incipient fruit, and ripening fruit, coterminous, and side by side, represent in the most perfect and beautiful manner. That the fruit of the Citron cannot be strictly called "delicious" is quite true, since the rind is thick and spongy and the juice acid, though less so than that of the Lemon. Here, accordingly, we are thrown back upon the probability of *tapphach* including the good qualities of several different things, not one of which answers in every particular. Before it can be eaten, the Citron requires to be dealt with after the manner of other hard and poignant fruits, and to be sweetened with honey or sugar. How agreeable the taste then becomes every one knows. Perhaps, after all, we are not called upon to demand from the Hebrew expression any more than the deliciousness which accrues upon proper preparation. Even Melons and Strawberries are scarcely delicious without sugar. The characters in question were well hit off by the Mantuan :—

* Media fert trias succos, tardumque saporem Felices mali, †

—*tristis*, or "sad," denoting the flavour of the fresh rind, while the "delayed taste" nearly implies its long continuance upon the palate. The fecundity of the Citron, spoken of by the two Greek writers upon plants, and likewise by Pliny, is another excellent feature of this famous tree. The Romans used the fruit for perfuming their wardrobes.

These various persuasive claims on the part of the Citron to be, as Dr. Royle and others think, the *tapphach* absolutely and exclusively, or, at all events, to be one of the trees intended by that appellation, are interfered with rather seriously by the doubt on fair grounds whether the Citron was cultivated in the Holy Land so early as the time of Solomon, the almost universally admitted composer of the Canticles, and whose reign commenced B.C. 1015. It may be considered certain that it was not indigenous to Palestine. Don says

* Smith's Dictionary of the Bible, i. 86. † George, ii. 126.

* See, for instance, the *Land and the Book*, by Dr. Thomson, p. 545.

The following New Plants are now being sent out :—

ANTHURIUM COLUMBIANUM.

A charming and elegant stove plant, introduced through my collector, Mr. Shuttleworth, from the United States of Colombia. It has a creeping rhizome, from which spring up ovate-lanceolate attenuately-acuminate leaves, 6 to 8 inches long, on slender petioles. The dense smaller leaves, some what longer than the leaves, are often, if not constantly, knee-jointed just below the spathe, which is ovate-acuminate, about 3/4 inches in length, an inch wide, and pure white, being straight, slender, cylindrical, and shorter than the spathe. Mr. Shuttleworth, in his letters, graphically describes the difficulties under which this remarkable plant was obtained, the climbing of a steep rock, owing to the rarified atmosphere, being almost beyond his physical powers. 1/2 guinea.

ASTROCARYUM ARGENTUM.

A fine silver-leaved Palm, introduced from the United States of Colombia. The stalks and the under-surface of the leaves are covered with a fine white scurf, which gives them a silvery appearance. The leaves are arching, and in young plants, a foot high, are wedge-shaped and bilobed, distinctly plicate, and of a light green colour on the upper surface, which contrasts strongly with the whitened under-surface. The petioles, or leaf-stalks, are furnished with numerous spreading dark-coloured spines, about an inch in length, a few being continued up to the base of the costa. It is a distinct and effective plant, and very ornamental. One of the best of the so-called Silver Palms. 2 guineas.

ASTROCARYUM FILARE.

This very distinct and elegant Palm, which is comparatively of small and slender growth, is also an introduction from the States of Colombia. The leaves appear to grow quite erect, and are narrow and cuspidate with two divergent lobes, so that they resemble an arrow-head pointed downwards. The petioles are thickly covered with white scurf, which is continued up the costa for some distance, both on the upper and under surface. There are numerous scattered brown spines on these petioles, and also on the back of the costa, as well as along the principal veins on the upper surface, which is green. The slender habit and erect foliage are quite peculiar. 1/2 guinea.

FOR NAMES, DESCRIPTIONS, AND PRICES OF—

New Double-flowered Ivy-leaved Pelargonium,
"Pelargonium Lateripes König Albert,"
New Nosegay Pelargoniums,
New Bronze and Gold Pelargoniums,
New Ivy-leaved Pelargoniums,

Write page 459 of last week's *Gardener's Chronicle*.

FOR NAMES, DESCRIPTIONS, AND PRICES OF—

New Fuchsias,
New Chrysanthemums,
New Zonal Pelargoniums with Variegated Flowers,
New Zonal Pelargoniums,

Write page 459 of the *Gardener's Chronicle* for April 3, 1875.

Establishment for New and Rare Plants,
KING'S ROAD, CHELSEA, LONDON, S.W.

the original locality was North Africa, but here he is unquestionably wrong. Apparently, like most of the other species of Citrus, the Citron belonged in the beginning to the cooler parts of India, and especially to the woods upon the lower ranges of the hills of Nepal. It becomes needful, accordingly, to assume a very early transmission of the tree westwards. Considering what splendid commercial enterprises were carried out by Solomon, and how many articles of oriental origin found their way to the Holy Land through the medium of the ancient merchants, there is nothing actually incredible in regard to such transmission. There is no occasion to suppose that it was immediate; and while we remain so imperfectly informed as we are with regard to the early migrations of mankind, and of the Aryan races in particular, it seems best to wait awhile. Mr. Carruthers, however, does not hesitate to express his belief that the Jews became first acquainted with the Citron during the Captivity in Babylon, taking it home with them when they were released (B.C. 536). "At all events," he says, "it may be considered certain that the Citron was not introduced into Palestine during the patriarchal era."* This, if proved, would of course be fatal also to the *tapphach* of Joel, who speaks of it so familiarly as one of the "trees of the field," his prophecies having been delivered about 700 or 780 B.C.

The last-named author (Mr. Carruthers) accords with Mr. Tristram in considering the veritable *tapphach* to be the Apricot. Here, without question, the fruit is "delicious" just as it comes from the tree, exquisite of smell, and well adapted to be laid in "pictures of silver," "shining," as Mr. Ruskin says, "in sweet brightness of golden velvet." But placed by the Citron, the tree subsides to the level of the Quince, being deciduous, while in dimensions it cannot be greatly different, though no doubt Mr. Tristram makes a perfectly truthful statement when he says, "many times have we pitched our tents in its shade, and spread our carpets secure from the rays of the sun." "At the present day," he continues, "with the single exception of the Fig, the Apricot is perhaps the most abundant fruit of the country."† It is scarcely necessary to remark that the abundance of any particular fruit or plant in Palestine to-day, cannot be taken as evidence in regard to the state of affairs so long ago as 2900 years. Of the place then held by the Apricot in Palestine we have not an atom of evidence. Nor, for that matter, have we the slightest evidence as to the frequency, or the reverse, of the Citron and the Quince. The native region of the Apricot is said to extend from Armenia, eastwards, to the Himalayas, and as far as China and Japan. Pallas describes it as indigenous to the whole of the Caucasus. Regnier ascribes it to the oases of Egypt.‡ It had reached Italy by the time of Dioscorides, but is very rarely mentioned in the writings of the Romans. Possibly, in the Scriptural *tapphach* may also have been included the Peach. In any case the name must have covered fruit trees that were plentiful and conspicuous, since several towns or cities of ancient Palestine were called "Beth-tapphach." The memory of one of these is preserved in the modern Tefhah, a village upon the hills north-west of Hebron. It is scarcely necessary to add that the idea of the Orange being included in the "mala" of the ancients is quite erroneous. This fruit did not reach Europe or Palestine either, till several centuries after the commencement of the Christian era. If anything is to be made out in regard to *tapphach* from the existing abundance of any particular fruit in Palestine, the Orange itself might ask to be recognised, for in the vicinity of Joppa alone there

are now 420 Orange gardens, which produce annually the estimated number of 33,300,000 Oranges. *Leo Grindon, Manchester.*

P.S.—In the first portion of this article, p. 459, col. 3, "Paris received from Venus" should be "Venus received from Paris"; and on p. 469, col. 2, *Shallan* should be "Shuacan."

New Garden Plants.

DENDROBIUM MARMORATUM, n. sp.‡

This is a Dendrobe like in the way of *D. transparens*. The stems, however, are much stouter, and the sheaths are very nicely mottled with grey bars on a whitish ground—hence the name. The flowers appear in pairs on the sides; they are white. Both sepals and petals are purplish at their ends, and the lip has the whole anterior portions of the disk purplish, while there are also some such purplish signs at the very base. Its chief peculiarity consists in its having whole the border ciliate and a hairy disk in front of the base. I cannot speak fully about the merit of the plant, for it unfolded its flowers in the case when travelling, which must have been most uncomfortable for such a creature. I would, however, guess that it may prove just such a gem as *D. amenum*, perhaps it has even its smell. It is easily distinguished from both named species by its very short, blunt chin, and by its ciliate lip. It may even get to be a beauty, such as we do not know now. I have to thank for it Mr. Low, who obtained it from Burmah through his collector, Mr. William Boxall. *H. G. Rehb. f.*

ODONTOGLOSSUM COMPACTUM, n. sp.†

This must indeed be a noble species, though not of the highest noblesse. It is far larger in all its parts than *Odontoglossum aureo-purpureum*, a New Grenadan plant which is much inferior in its more distant, smaller flowers, which stand too wide apart to produce such an effect as those of *O. ramosissimum*. What Dr. Lindley said about the nobility of the plant only applies to the Peruvian species. Since I described *O. aureo-purpureum* from New Grenadan specimens, those have to keep the name given by me. An excellent distinction is afforded by the lip, which is scarcely trilobed, while the New Grenadan plant has it trifid. The rather large flowers (not much inferior to those of a middle-sized *O. maculosum*) must be of a very bright yellow (as those of a good *Oncidium macranthum*, the so-called hastiferum of Belgian nurserymen), and there are purplish spots on the broad lip. I judge the colours to be very bright since they last so well on the dried specimens. I have at hand specimens gathered by Messrs. W. Lobb, Pearce, and Davis, all obtained through the kindness of Messrs. Veitch. It will, no doubt, appear soon in the establishment of those gentlemen, where is a fresh importation of plants gathered by the last named very promising collector. *H. G. Rehb. f.*

NEODRYAS DENSIFLORA, n. sp.‡

This is an unexpected novelty. It has the habit of some *Oncidium* with very shining pseudobulbs. The leaves are cuneate, oblong acute, nearly a span long. The inflorescences are quite covered with dense purplish flowers, standing on short lateral branches, as in a *Polystachya*. They are smaller than those of *Oncidium ornithorhynchum*, but larger than those of the hitherto known *Neodyrias*. The plant would perhaps be liked by those who loved the now nearly forgotten *Rodriguezia secunda*, one of those plants one understood to grow well twenty years ago. (If I am not a mistaken, a lot of this, the *Rodriguezia*, was lately imported by M. Roelz.) It is one of Mr. Davis' previous discoveries, and will, no doubt, flower soon in the Royal Exotic Nursery of Messrs. Veitch. *H. G. Rehb. f.*

‡ *Dendrobium macranthum*, Rehb. f., n. sp.—*Eudendrobium* aff. *D. transparent*. Caulis microglossis validioribus, squallibus (non nodosis), merito valde abbreviatis retosis; labello a basi cuneato oblongo ciliato, basin versus dense ac breve velut; columna brevissima, apice tridentata, antro in basi cum angulo superiori merito decurante breviter truncata.

THE YUCCA, ETC.

DR. PARRY'S last instalment of his "Botanical Observations in Southern Utah," now publishing in the *American Naturalist*, contains some interesting notes, such as the following upon the Yucca of the deserts of that region:—

"This is universally known among the Mormon settlers under the name of 'the Joshua.' The mail rider over these desert tracts had furnished us weekly reports of its progress in flowering, so that we were constantly on the look-out for a first view of what had never yet been examined by a scientific botanist. At first a few scattering clumps of the peculiar stiff spiny leaves that characterise this genus of plant attracted attention, then some gaunt forms raised on withered trunks revealed the identical species. On hastening forward to a more vigorous growth, where the masses of compact flowers were visible at a distance crowning the top of the upper branches or main axis, we soon had one of the lower flowering stems ruthlessly torn down for a closer inspection. The first feeling was one of disappointment. The flowers crowded in a close pyramidal head, failing to exhibit the ordinary graceful forms pertaining to the Liliaceae. The perianth was of a dull greenish-white colour, its divisions long-linear, thickened and confusedly massed together, while the odour given out was decidedly repulsive. The present species of Yucca attractions only to various beetles and insect larvae. An examination of the inflorescence shows a regularity such as the botanist would expect; the upper leaves of the flowering branch gradually becoming bract-like subtend in their axis small jointed pedicels, with the lower flowers spirally arranged in threes. These, in continuing their spiral arrangement on the main axis, form the condensed mass of flowers which, opening from below upwards, prolong the flowering process for several weeks. Only a few of the flower-stems perfect fruit, and the flowers which open during the present season all prove abortive, possibly owing to the absence of some insect-agency for effecting fertilisation. In the desert districts lower down, where this species especially flourishes, the flowering heads are said to weigh frequently over 50 lb."

Another interesting observation by Dr. Parry, in the same paper, is the following, on the dissemination of the seeds of *Gilia setosissima*:—

"Wishing to collect somewhat largely of the seeds of this neat little annual, I watched more closely than usual the maturing of the capsules. In most of the other species of this prevalent genus there is a succession of flowers and maturing capsules, which latter opening at the summit discharge their seeds while the plant is still producing flowers, thus rendering it difficult to secure a large quantity of seed without including capsules not sufficiently mature. But in the case of *Gilia setosissima* all the capsules remain tightly closed till the whole plant becomes dry and brittle. In then gathering seed by picking each plant separately, I noticed the seed projected with some force against my hand. On closer examination I found that these capsules open from below upwards, and that the tension accumulated by the shrinking of the tissues in the process of drying gives an elastic spring to the three separating valves when freed from their attachment. The seeds are those of a nut that throws the contained seed from 2 to 6 feet. After making this discovery, it was interesting to watch the process by loosening the attachment of the valves with the point of a knife, and see how far they would shoot. The majority of the seeds were dispersed within a radius of a foot, while the plumper capsules the shots took effect to a distance of 6 feet or more. The three separated valves of the capsules, on account of their light, chafy texture, were not thrown as far as the seeds. A similar character, though less marked, was also exhibited in certain species of cress-pole *Phlox*, though in this latter case the explosions observed occurred some time after the capsules were detached from the calyx. The conclusion arrived at is, that the character of explosive capsules in this particular family is peculiar to those that open at the base instead of the summit."

THE YAM FEAST OF NEW CALEDONIA.

AMONG the various days set apart by the New Caledonians for special solemnities, the feast of the gathering of Yams is one of the most important. It takes place, according to M. Vieillard's account of which this notice is an abstract, at different but predetermined periods in different tribes, and is attended by persons from 15 to 20 miles round. For some days previous a smaller *fête* is celebrated by the women themselves, and on this occasion they are allowed to take a certain number of Yams from the field, and to indulge in dancing, of which they are passionately fond.

Some time before the day appointed the chief of the principal tribes sends invitations to those of the smaller neighbouring tribes with whom he is on friendly terms. Each village is obliged to supply a contingent of Yams and other provisions proportionate to its rank and importance; and from this obligation the chief himself is not exempt. On the day of the feast the inhabitants of the villages, headed by the chiefs, make their way to the place appointed, the women bearing the provisions. The chief, surrounded by the elders of the tribes, then makes his way to the

WINTER CUCUMBER.

We copy from the columns of the *Revue Horticole* the subjoined illustration (fig. 102) representing a Cucumber called the Alsace or Winter Cucumber. It is so called because it is eaten in Strasburg and its neighbourhood in the winter time, just as an ordinary Cucumber would be in summer time. Its form and dimensions are much more like those of a Gourd than that of a Cucumber. Moreover, its flesh is less watery than that of a Cucumber, and when it is eaten raw its flavour is more that of an Artichoke with a dash of Filbert in it. It is cooked in various manners, and served up with gravy it is excellent. It appears to be a recent introduction into Alsace, where it is still cultivated in but a few gardens.

FIG. 102.—THE ALSACE CUCUMBER.

It was introduced to Paris by M. Weber, an army surgeon, and appears to have been quite unknown to Parisian gardeners. M. Carrière gives it an excellent character as a winter vegetable. It may be preserved till spring in a dry place, and slices may be cut from it as they are wanted. It may be eaten in thin slices like Cucumbers, and when cooked it has the consistency of a Turnip, but is infinitely more delicate. The fruit is about 18—20 inches long, with a smooth rind, at first green, but afterwards becoming marbled with yellow. The flesh is yellowish white, firm, not watery, and with a delicate flavour. The seeds are small, elliptic, and of a dirty white colour. The cultivation is the same as for ridge Cucumbers or Vegetable Marrows.

A REVIEW OF THE PROGRESS OF VEGETABLE PHYSIOLOGY IN 1874.

(Continued from p. 463.)

RESPIRATION OF PLANTS.

MM. DEHÉRAN and Moisson have studied the respiration of plants kept in constant darkness. Their results were briefly these: 1. The quantities of carbonic acid emitted by leaves in darkness are comparable to those produced by some of the lower animals (frogs, cockchafers, silkworms, &c.). They vary considerably in different species, and are generally greater in the case of caducous than in that of persistent leaves. 2. As M. Garreau observed, the quantity of carbonic acid emitted by the leaves increases with the temperature to which they are subjected; but the maximum appears not to exceed 40 to 45 per cent. 3. The quantity of oxygen

absorbed exceeds that of carbonic acid produced; the difference is most marked at low temperatures, which seem to favour formation of products incompletely oxidised in the plants, such as vegetable acids. 4. Leaves placed in an atmosphere without oxygen continue to give out carbonic acid several days at the expense of their own tissues; this emission only ceases, apparently, when all the cells are dead. The resistance to asphyxia from absence of oxygen varies much in different species. 5. It is probably that the slow combustion which takes place in the leaves produces the heat necessary to the formation of the immediate principles that are elaborated in them. It is observed that emission of carbonic acid is favoured by obscure heat, which thus exerts a decisive influence on the rapidity of growth of plants; so that horticulturists have long found it useful to dispense with a part of the luminous heat which the sun gives, by keeping plants in glasshouses, where, on the other hand, the obscure heat is concentrated.

CHEMISTRY OF GERMINATION.

M. Dehérain has also (with M. Landrin) made researches on germination. He has brought to light a fact previously unnoticed, viz., that when the testa of the seed has been moistened with water it admits a certain quantity of gases (oxygen and nitrogen), which are condensed in the tissues; and this is accompanied by a rise of temperature, which favours the action of the atmospheric oxygen, and perhaps determines it. From the time this action becomes sensible, the chemical transformation commences, and life awakes. In experiments made in a limited atmosphere, and not of too long duration, there was always more oxygen absorbed than carbonic acid produced. A part of the former remained fixed in the tissues, and served, perhaps, to oxidise the azotised matter, in order to transform it into asparagin. But in the long run the carbonic acid much exceeded the oxygen absorbed, the oxidation of immediate principles continuing even in an atmosphere deprived of this gas. Hydrogen is liberated only in an atmosphere deprived of oxygen. Lastly, the nitrogen, which always appears during germination, seems to be merely that which was at first condensed in the tissues. Experiments made on germination in different media proved with certainty the condensation of gas in the tissues. There was always diminution of volume of gas. The authors also confirmed M. de Saussure's observation of a deterioration of carbonic acid on plant life. In a mixture of hydrogen, or nitrogen and oxygen, a few traces of the last gas sufficed to produce germination, whereas germination did not occur in a mixture of one-third carbonic acid with two-thirds oxygen.

M. Boehm has studied the development of starch in the cotyledons of etiolated plants (Cress, Radish, and Flax). According to the researches of MM. Faminzin and Krauss, the starch appeared to originate in decomposition, under the influence of light, of the carbonic acid of the air. M. Boehm thinks otherwise; he considers it is partly, at least, the product of transformation of substance that already existed in the plant. He experimented by making the etiolated plants vegetate in an atmosphere without carbonic acid, or exposing them to light which, though sufficient to colour chlorophyll, did not cause decomposition of carbonic acid. In every case he found starch in the tissues, and he inferred that it arose from transformation of nutritive principles originally accumulated in the seed. These principles, in the plants experimented with, occur in the form of a fatty oil, which, before serving for the production of cells, has to undergo change. It is the substance thus produced (hydrate of carbon) which, being in excess in the tissues, comes to assume, under influence of light, the form of fecula.

This theory of M. Boehm's is opposed to certain well-ascertained facts. Young plants completely etiolated cease to develop when they have exhausted the provision of nutritive principles contained in the seed. Why should it be so, if a part of these principles remained in the tissues in the form of hydrate of carbon? It cannot be the deleterious influence of darkness; for the absence of light is favourable to the production of new cells. Further, M. Boehm does not take account of the experiments of M. Krauss, in which the plant exposed to light increased in weight whenever the starch commenced to appear in the grains of chlorophyll. That was a case, not of the transformation of a pre-existent substance, but of bringing in of new elements. We ask, lastly, what advantage could the plant derive from the phenomenon? The starch is not directly utilisable, before serving in the production of new cells it must take another form similar to that which, according to M. Boehm, it had in the tissues before the period of etiolation. Of what good this double transformation?

True, some of M. Boehm's experiments are not explicable on the theory of direct assimilation; but we think these are particular cases, perhaps of plants which had not been kept in the dark sufficiently long, and which consequently do not invalidate the general theory.

sacred tree, where are then brought to him Yams, Sugar-canes, and Taro (the tubers of *Caladium esculentum*), as well as the results of the fishing expedition which always takes place the evening before the feast. A fire being lighted, the fruits are cooked, and a portion of them is placed by the chief in an appointed place, with a solemn invocation to "the spirit" requesting his protection, and a plentiful supply of Yam and fish.

The inhabitants of the different villages being assembled, the examination of the provisions is proceeded with. To this end one of the inferior chiefs, assisted by one of the elders of the tribe, takes his seat upon an eminence from which he can survey the whole assembly, and gives the order for the untying of the packages. Those of the principal chief are first opened. A native takes a Yam and presents it to the presiding chief, who, after stating that it is from the Great Chief, holds it up so that all may see it, and says in a monotonous voice, "One?" to which the assistant elder answers in the same tone, "Yes." The Yam being placed on the ground, the same native takes another, and the same formalities are gone through, and so on until ten have been offered, when the ceremony is recommenced.

This monotonous performance continues for a considerable time, as all the provisions have to be inspected in a similar manner. At its conclusion the Yams are arranged in an octagonal column 6 or 7 yards high, the base of which is formed of Sugar-canes and Cocoa-nuts; the whole is supported by long poles laid together with the tough, plant stems of climbing plants.

In many tribes the arrangement is different, and as many lots of Yams, Taro, Sugar-canes, Cocoa-nuts, &c., are made as there are chiefs present. If strange chiefs are in attendance their part is the first selected, and is the finest; then comes that of the principal chief, then that of the second, and so on, ending with those of the chiefs of each village. These lots arranged, the principal chief makes a speech and then distributes them. Each petty chief then proceeds to a second distribution among his subjects, reserving a good share for himself; a lot is reserved for the women, but, contrary to our notions of politeness, it is always the poorest and most meagre. The heads of families then distribute their shares among those under them, and, the business of the day being thus concluded, the assembled company devote themselves to dancing and other amusements.

Five species of Yam occur in New Caledonia, two (*Dioscorea bulbifera* and *D. pentaphylla*) being indigenous, and three (*D. alata*, *D. note*, and *D. aculeata*) only being found in cultivation. It is the first of this last-named group which is of the greatest economical importance, and which forms the principal feature of the festival which has been already described. Its cultivation is carried on in the following manner.

In the month of July in the north, but somewhat later in the south of the island, each person burns the herbs which cover the field which he intends to plant. Some days afterwards he calls together his friends to assist him; men and women then repair to the field; the men clear the ground with the aid of long-pointed stakes, while the women and children break the clods and pick out the roots. As the Yam requires a loose and deep soil, and the imperfect construction of the tools does not permit the earth to be stirred to a sufficient depth, soil is brought from the neighbouring fields and placed on the top, so that a sufficient depth of earth may be obtained. After about fifteen or twenty days, a second work takes place, which has for its object the levelling and dividing of the earth, after which the planting is proceeded with. The tubercles are cut into pieces and planted in rows, or in lots of five, with the space of about a yard between each; the planter makes with his hand a little ditch in which the pieces of tubercles are placed horizontally, and are then covered with the earth, which is heaped up over them so as to form a little mound.

On the fifteenth or twentieth day the Yams begin to shoot; and in proportion as the stems appear, they are provided with supports of reeds, &c. When the plants have attained the height of about 40 or 50 centimetres, they are weeded, and the reeds are replaced by other props. From this time until the tubers are ripe the natives are continually occupied in weeding and training the plants. At the end of seven or eight months the tubers are ripe, and the feast already described is then celebrated. The Yams are allowed to remain in the ground until the leaves are entirely withered; they are then taken up and stored either upon a kind of hurdle, or in little cases constructed expressly for this purpose.

All the species of Yam are eaten either cooked in water or broiled upon coals. The natives prepare also from slices of Yam and grated Cocoa-nut a sufficiently good soup, which they call *Loto*.

The number of varieties of *D. alata* which are cultivated is very great, and each has its distinctive name. When the best species fail the tubers of the indigenous *D. bulbifera* are collected by the women and eaten, after being soaked in water in order to remove an acid principle which they contain. *E. M.*

ABSORPTION OF AMMONIA.

M. Schloesing has proved experimentally the possibility of a plant absorbing directly the gaseous ammonia expanded in the atmosphere. Two Tobacco plants were grown in identical conditions; the limited atmosphere of one contained ammonia, the other did not. The former yielded on analysis much more nitrogen than the second, and had absorbed about three-quarters of the ammonia presented to it.

The presence of a considerable proportion of nitrate of potash in certain plants is a fact already known. M. Bontin has proved it in the case of certain species of *Amaranthis*, indigenous and exotic. *A. ruber* (originally from India), dried and analysed, contained 16 per cent. of its weight of nitrate of potash, or 22 grammes of nitrogen and 72 of potash per kilogramme of the dry plant. The author speaks of the advantages agriculture might derive from using these plants as manure. It would be interesting to study the origin of this salt and of its accumulation in the tissues.

CHEMICAL CONSTITUENTS OF PLANTS.

M. Borscow has studied some substances distributed in certain plants, with regard to their micro-chemical reactions, and their mode of distribution in the tissues. It is a very interesting kind of investigation, and one of the best means for finding the key to the rôle of these substances in the vegetable economy. M. Borscow's observations have thus far related to the following substances:—*Asarum*, a principle like camphor, found in the parenchyma of the roots of *Asarum europæum*; chrysophanic acid, in the tissues of a Lichen (*Physcia parietina*), which has also been met with in the root of *Rhubarb* and certain *Rumex*; franguline, resembling chrysophanic acid in several points, and found in the bark of *Buckthorn* (*Rhamnus Frangula*); syringine, bitter crystallisable principle from the branches of *Lilac*, and which may be a product of transformation of cellulose; veratrine, an alkaloid in the root of *Veratrum album*.

M. Pfeffer has found in small Oranges, which had remained a certain time in contact with crystals of a substance which he has called hesperidin. It is a non-zotised substance, the chemical composition of which is not exactly known, and which is dissolved in the tissues; it is precipitated in crystalline form, like the inuline of the tubercles of *Dahlia*. Hesperidin is most abundant in the fruits, but is met with also in the branches up to the point of vegetation, and in the leaves. Its presence may be detected in the pistil; it increases until the small Orange is about 20 millimetres in diameter, and then appears to remain stationary. Citrons do not contain it. The physiological rôle of the substance is still unknown. The author thinks it is related to tannin.

In a very important work published in 1872 on proteic substances and their rôle in plants, M. Pfeffer showed the particular functions of asparagin. This body may be considered as a transitory form assumed by the zotised matter in the seeds of leguminous plants where it is stored, and the point of vegetation where, in the form of albumen, it serves for the production of new cells. Subsequent researches have enabled the author to give a more exact account of these successive transformations.

Asparagin contains less carbon and hydrogen, and more oxygen than albumen (the proteic matter of the seeds), and than the albumen of tissues. It is, then, a product of oxydation (respiration), and to take a place in the young cells it must anew assimilate molecules of carbon and hydrogen. This reaction does not take place in the dark, nor in an atmosphere deprived of carbonic acid. Here, again, we are in presence of a phenomenon connected with the general action of light on plants and the decomposition of carbonic acid. According to M. Gorup Besanetz, asparagin is not able in playing the part indicated. Another zotised substance, leucin, which chemists have long referred to organic albuminoid substances, is found frequently in Beans and Vetches in fermentation, along with asparagin. The author does not say anything of the rôle of this new substance, nor of the circumstances accompanying its apparition.

FORMATION OF WOOD.

Precise researches on the lignification of tissues were rendered difficult by the absence of a delicate reagent fitted to reveal the presence of lignin. M. Bürgerstein has used, for this end, sulphate of aniline, the special properties of which, for colouring wood, were shown by M. Kunz and H. von Arnim. Armed with this new means of investigation, M. Bürgerstein has methodically examined the various categories of vegetable tissues; and he notes, as completely exempt from lignification, only the tissues of *Algae*, of *Champignons*, of certain *Lichens*; and, in vascular plants, only the collenchyma, the cambium, and the punctated vessels. All the other elements are more or less lignified. In stems, it is the fibro-vascular bundles that are first lignified, then follow the cortical cells, and, much later, the medullary cells.

VEGETABLE POISONS.

Passing now to consider substances which act unfavourably to the life of cells, we may first notice the

researches of M. Conventz on the physiological action of camphor and similar substances. Some experimenters, and most recently M. Vogel, have affirmed that camphor has a stimulating action on vegetation: M. Conventz has made, under the direction of Prof. Goppert, at Breslau, some experiments which point to an opposite conclusion. He employed filaments of *Spirogyra*; and, to avoid all chance of error, he began by studying the action excited on these organisms by solutions of neutral salts (nitrate of potash, carbonate of ammonia, &c.). The protoplasma of filaments immersed in these liquids contracted into masses of irregular form, and the algal evidently suffered. If the action were not continued too long, however, the *Spirogyra*, transferred to distilled water, even recovered its previous vigour. Evidently, the neutral salts only injured the organism by drawing to themselves a part of the water of the protoplasm. It was quite otherwise when filaments of *Spirogyra* were immersed in solutions of camphor, of strychnine, of prussic acid, and some other substances which act as exsiccants in the animal kingdom. Here not only did the protoplasm contract, but it underwent other alterations, and, in particular, it became brown. The plant was quickly transferred to distilled water, but it soon died. All the substances acted like veritable poisons on the vegetable tissues.

Studying the injurious influence on vegetation exercised by sulphurous acid, even in small quantity, in the atmosphere, M. Schröder has observed that it acts principally on transpiration, the intensity of which it tends to diminish. One may often remark, in leaves that have been acted upon by it, a somewhat transparent area about the median nerve, while further off the tissues are darker and more opaque. This is due to the fact that the water, no longer circulating in the normal manner, accumulates in a part of the leaf, and does not spread throughout it. The hurtful effect of vapours of sulphuric acid is most marked at times when the transpiration is strongest, and particularly during the day. These facts may have a certain importance for wooded countries where charcoal is manufactured, and where the smoke, always containing sulphurous acid, injures the trees.

GUMMING OF FRUIT TREES.

M. Prillieux has made a complete study of the production of gum in fruit trees. In his opinion it is a true disease, having its seat most often in the cambium, and to which he has given the name "gommosc." It commences in the centre of a cell or lacuna, by transformation of the granula of fecula; the alteration presently spreads, radiating around the central point, and the gum fills, successively, lacunæ, cells, and vessels. But the most remarkable feature of the malady consists in the production, round the point of attack, of numerous adventive cells filled with fecula, which are immediately transformed into gum. There is a derivation of the nutritive principles, which are brought to the affected part and contribute to augment the quantity of fecula. The first cause of the phenomenon is difficult to indicate, but the result recalls, in some measure, the development of galls. The best remedy seems to be in incisions on the bark, an operation causing an energetic production of cells at the periphery, and which consequently diverts the nutritive principles from the diseased part. *A. B. M.*

(To be continued.)

PRINCE OF WALES PLUM;

WITH AN INQUIRY AS TO CERTAIN CAUSES THAT ARE TENDING TOWARDS ITS DESTRUCTION.

The general excellence of this very popular Plum is now so well known as to require but little notice. The object of these remarks is rather to call attention to some of its peculiarities, or, it may be, constitutional defects, with a view therefrom—amongst the multitude of observers—of ascertaining the true cause or causes of these, and possibly the means for their prevention.

The Prince of Wales Plum is a seedling raised, we believe, by the late Mr. Chapman, a large grower for market at Isleworth. It has now been a good many years in cultivation, and is very generally known as Chapman's Plum. It belongs, in the first place, to the Orleans class of Plums, but the fruits are far larger and of much better quality than those of that variety. It ripens early, and is a great and almost certain cropper: there is, in fact, no more certain cropping Plum than the Prince of Wales. This is in part attributable to the leaves, which, according to the observations of Mr. Dancer (who is a great cultivator and special observer of the peculiarities of this Plum), expand somewhat earlier than those of most other Plums, and, being large as well, they serve in some measure to protect the young fruits from late frosts.

Thus its fine appearance, earliness, and general good qualities soon established its reputation in Covent Garden, and its free, abundant, and constant fruiting properties won its way with the great growers for

market. Its reputation is as a London market Plum, and it is one of the very few varieties that are cultivated in quantity by the London market gardeners. Since its introduction by Mr. Chapman, and within a few years ago, it has become one of the best reputation, or has been much more extensively planted—our great fruit cultivators, such as Mr. Wilmot, of Isleworth, Mr. Edwards, and Mr. Dancer, growing the trees by the thousand, and supplying the markets with the fruit by the wagon-load.

This fine Plum then, as it would appear, has nearly all the virtues or good qualities that pertain to Plums, and so far so good. But there is as usual some alloy. The Prince of Wales Plum trees have always been strangely subject to die off, but of late years so much so that its cultivation may have to be abandoned altogether. The manner in which the trees of the Prince of Wales die out, or are killed, is very extraordinary, and as yet quite inexplicable. We do not mean to infer that it is by any means an uncommon occurrence for a Plum tree, or the branch of a Plum tree, to die, but this is chiefly from the effects of gumming, or from some other easily traced cause, as to this all varieties are alike. In regard to the Prince of Wales Plum, there is no trace of any outward or even inward injury that can be detected; the shoot or branch simply dies down so far, below which it is as healthy as may be. It is no single tree or branch that is affected; the destruction is wholesale, and truly appalling. How or when they are affected or injured is not accurately known; that is one of the points upon which information is required. There is nothing special in the manner of the trees at pruning time; they all seem in their usual health and vigour; the blossom appears, the fruit is set and swelling off, the trees are clothed with leaves and the young shoots are growing, and everything is looking fair and promising, when suddenly a great portion of the leaves seem to droop and flag, and in the course of a week or so they are mostly withered up, and present the appearance of having been scorched. Some portions are killed, or, at least, are very much injured, and even ripen an early crop of fruit, and then die.

In some plantations not a tree but is more or less touched—here it may be only a small twig or branch, there one half or one side of the tree, while the next is wholly destroyed. It is seldom, however, that the trees are entirely killed—the stock or stem is not so often injured, and this, on the tree being headed down, again pushes forth shoots and grows up as vigorously as before. This peculiar fatality, as we may term it, has long been observed by those most interested, who have cultivated it extensively, but no real facts as to the probable cause or remedy have yet been brought forward. In some seasons the trees escape quite uninjured in any way, whilst in the following (as was the case in the last two years) the most disastrous results occur. It is safe to affirm that last season (1874) quite one-third of the whole of the Prince of Wales Plum trees in Mr. Dancer's grounds were destroyed. Mr. Wilmot and Mr. Edwards, in several instances, the seeds of trees or portions thereof, and wherever inquiry has been made the same result occurred. Is not this then of sufficient importance to excite the interest of our scientific horticulturists, and to merit attention and investigation? Here is one of our favourite popular Plums in a fair way of being exterminated through possibly some constitutional defect, or with a constitution such as renders it peculiarly liable to certain exigencies. This case is far more tangible, and more to be feared in its consequences, than the wearing-out theory of the Ribston and Golden Pippin Apples.

Despite the closest inquiries and the most careful observations for years past, opinions are greatly at variance as to the real cause of the injury. Some attribute it to one thing, and some to another. A very popular belief for a long time was that it was owing to the unsuitable stock on which it was worked. This was Mr. Chapman's belief. He strongly recommended growing them on their own roots as being a certain success. But in the autumn of the last season came, and all suffered alike, and so the "own root" system was found wanting. It is still, however, believed by many that the stock has something to do with it, and it might be so; but a stock could only influence it in this way, either by checking its somewhat gross growth, or inducing it to start later, after the dangers of frosts are over. Seeing, however, that the stock is the least injured of any part, it is not at all, and that the branches on all kinds of stocks that we have examined are about equally affected, it must naturally be concluded that it is pretty well innocent. Again, it is by some attributed to dryness at the roots, since it is a gross growing variety with large leaves, requiring much moisture, but this theory is open to the same objection as the former. I have seen them affected alike in dry and wet situations and seasons. A better grounded theory is that it is due to the agency of frost, but even here opinions are not reconciled. We are all conversant with the destructive work of frost in winter amongst young Apricot and Peach trees, &c., in nursery quarters, and so many believe that this injury is effected in the same manner, and it may be so, yet it seems extremely doubtful. In

the first place, trees injured by frost in winter seldom get into growth in spring, but at once die. In this particular case, however, the trees put forth blossom, and begin to grow and bear fruit in an apparently uninjured manner, boding nothing of the ruin coming. Mr. Dancer is of opinion, from repeated observations, that all the mischief is done after the trees commence to grow, and in spring in the months of April and May. The months of May, 1873 and 1874, were remarkable for extreme cold and the great number of severe frosts, which certainly destroyed the crop of Plums. Both those years were also remarkable for the great destruction of those Plum trees, so that this leads us almost inevitably to the conclusion that this peculiar destruction amongst the Prince of Wales Plum trees, which we have attempted to describe, is due to the direct agency of late spring frosts. This is Mr. Dancer's opinion, formed, as it is seen, after many years of the closest observation, during which the number of trees he has lost of this Plum may be counted by thousands. In order, however, to test the matter thoroughly, might we ask growers of this fine Plum to take particular notice this spring of the frosts, and what effect (if any) is produced on these Plum trees? I call attention to the subject now, in order that observations may be taken at the proper time, otherwise no will be able to ascertain after the injury has been effected, and it is impossible to trace the causes that may have led to it.

Bearing on the importance of this may be mentioned a remarkable lawsuit tried before Mr. Justice Mellor at the Assizes a few years ago, respecting the death of a great number of these Plum trees, in the manner above stated, at Isleworth. A brickfield was established near to these Plum orchards, and that season the deaths and destruction among the trees was more than usually severe, so the proprietor of the brickfield was sued for the loss, it being alleged that it was due to the influence of the smoke, and damages were actually recovered in that case. We know now that all this was due to natural causes, over which we have none of us any control.

A. F. Barron.

ELEMENTARY LESSONS IN BOTANICAL GEOGRAPHY.

VII.—ON THE WAY IN WHICH HEAT INFLUENCES THE DISTRIBUTION OF PLANTS.

(Continued from p. 432.)

THE influence of temperature upon the distribution of any plant depends largely upon its season of vegetative activity. Annuals, which run their course from the seed stage to leafing and flowering, and back to the seed stage, in a period varying in length from two to six months, can only be affected by the temperature of that portion of the year during which they are growing. Biennials have to last through the winter, and often concentrate their energies for a large proportion of their existence in storing up materials in their rootstocks, and spring up into flower and seed in a short time when warm weather comes, and the expense of tissue previously elaborated. Trees and shrubs have usually a well-marked time of flowering and fruiting, once a year, and it is the same with a great many perennial and annual herbs, but the season with different species is very different. Helleborus niger, and the Snowdrop and spring Crocuses, push out their flowers and leaves as soon as the snow melts. Hawthorn and Blackthorn, and our common fruit trees, push out their flowers in April and May, before the leaves are developed or perfected. The flowering of Ragwort and St. John's Wort takes place long after the leaves appear, and marks that the summer season is past, and the days are beginning to grow shorter. Colchicum autumnale produces its flowers regularly in August, but its leaves do not until the following spring; whilst Asters and Chrysanthemum flower regularly at Michaelmas; and Holly and Ivy, and Aucuba, and Cherry-Laurel, are in full leaf all winter; and Lamium album, Poa annua and Capsella bursa-pastoris, may be seen during any month of the twelve in simultaneous leaf and flower. So that the time of the year at which different plants are at all sensitive, especially sensitive to temperature, varies extremely.

It is evident that, in the first place, plants need very different degrees of temperature to start them into life. The seeds of many of the Microtherms, and even of plants of our middle latitudes, will germinate at a temperature of little over 32°. Of cold temperate species, for which the experiment has been carefully tried, Sinapis alba, has been found to germinate at 35°; Lepidium sativum and Limnium tetragonum at 35° to 36°; Nicotiana glauca, Iberis amara, Trifolium repens, and Solanum cocineum at 41° to 42°; and Wheat, Barleys, and Oats, at 44° to 45°. With heat added over and above these degrees, the time from the sowing of the seed to its germination is found to be materially shortened. Sinapis alba, which took seven-

teen days to germinate at 32°, was found by M. Alphonse De Candolle to take sixteen days at 35° to 36°, nine days at 37° to 38°, four days at 42°, three and a-half days at 48°, one and three-quarter days at 51° to 52°. Passing to Mesotherm types, the temperature needed for germination becomes gradually higher. For Maize it is stated to be 48°, and for the Macrotherms at least 50° to 60°, but it may take place at a much higher temperature. Sesamum orientale has been found to germinate in nine days at 51° to 52°, in three days at 62° to 63°, in thirty to thirty-six hours at 68° to 69°, in twenty-one to twenty-two hours at 75° to 76°, in twenty-five hours at 82°, and some even in ten and a-half hours at a heat of 104° to 105°.

The start once made, it is evident that plants need a certain amount of heat to enable them to flower and fruit, but that, with some species at any rate, it is immaterial whether the heat comes gradually or rapidly; and that if the latter, the times of flowering and seeding are accelerated. Nothing shows us better how flexible in this respect a plant may be than the familiar facts about the sowing and harvesting of the common cereal grains. In the north of India Wheat is a common winter crop, to be followed in summer by Maize or Indigo, and is sown, and the harvest gathered, within three months. In Britain the barley ripens at the end of March, and the Wheat by the end of April, November being the month of ploughing and sowing. In Malta and Sicily they sow at the end of November, and harvest through May. In the countries round the north side of the Mediterranean basin they sow early in November, and harvest in June. In Central Europe they sow in October, and harvest in July. On the Yorkshire wolds, and in the alpine valleys of Switzerland, they have to sow in September, and cannot harvest till the following August; so that the time that elapses between sowing and ripening may be said to vary between the different parts of the tract in which the common cereal grains are cultivated for the use of man, on a grand scale, from 90 to 320 days. If too much heat be applied the embryo refuses to germinate, or if it has germinated already, the leaves, or flowers, or fruit, according to the stage which the plant has reached when the hurtful heat is applied to it, are not developed.

Then, again, it is equally evident that a gradual or sudden access of cold below a certain point in point which varies with different species—coming when the plant is in a state of vegetative activity, injures or kills it. It may be simply a cold north-east wind in spring, blighting the blossoms of the Appricots, and Apples, and Pears, and whilst destroying the seed for the year, doing no permanent harm to the tree; or it may be a mild frost, at the beginning of winter, cutting off entirely our garden Dahlias, Pelargoniums, and Mesembryanthemums; or a hard frost in the middle of winter, killing the Eucalypti, Arancarias, Hollies, and Aucubas.

It follows, from these familiar facts, that some plants are checked from spreading from warmer latitudes towards the poles by the want of plenty of heat in summer to carry them from the seed stage, round the circle of life, to the seed stage again; and that others, for which the heat of summer is sufficient, are cut off by sudden fits of cold, that catch them at a time of vegetative activity. If it is of no use, it seems to be almost surprising that this last matter in close detail as a question of figures and thermometric degrees, because the different habits of growth of plants, and the different degrees of the wateriness of their sap, dependent upon the hygrometric conditions of the surrounding atmosphere and soil influence it greatly, and their vegetative action passes through so many intermediate stages between the fulness of life in spring and their nearest approach to a dormant condition. But we may safely distinguish broadly between the two great classes of plants which I have indicated, and which I will call the *heat-lovers* and *cold-fearers*. Annuals are usually heat-lovers; trees and bushes, especially evergreens, are usually cold-fearers; and it follows, from what has been explained already about the characters of the two kinds of climate, that the cold-fearers can work up further from the equator in insular, and the heat-lovers in continental climates.

We can perhaps understand best this matter of polar limits, and illustrate the difference between the two great classes of plants just indicated, by a rapid glance at the general character of the vegetation of Britain as compared with that of the continent. The range of the plants of Britain, both within the island and outside it, has been studied out and recorded in full detail by my friend and master in geographical botany, Mr. Hewett C. Watson, whose book entitled *Cybele Britannica* contains a record and classification of the enormous mass of facts bearing upon this subject, which he has accumulated.

Britain extends over nearly 10° of latitude, and its hills reach a height of 4200 feet. As the high hills are in the northern parts of the island, there is a difference between the climate of its extreme points equal to that caused at sea-level by 22° of latitude. Mr. Watson separates the surface into six zones of

heat, the boundary between the third and fourth being the line of the practicable cultivation of grain and Potatoes, which we have already regarded as being equal to the arctic circle at sea-level. Very little of the actual surface of Britain falls on the cold side of this line, because it is only mountain peaks and ridges that overtop it. Taking these zones in ascending order, the number of plants known in each is as follows, the total number found in Britain as a whole being 1425:—Infragrarian zone, 1225 species; Midagrarian, 1070 species; Supragrarian, 760 species; Infrarctic, 293 species; Midarctic, 244 species; and Superarctic, 111 species.

Arranging the species under "types of distribution" according as they are spread through the whole or part of the island, 532 species are found to be spread at sea-level generally from north to south, 606 to run out so that they do not reach the northern latitudes or climb the hills, and 238 species to have a decidedly northern or montane partiality, the remaining 49 being too local to class fairly as either northern or southern. Out of these 1425 British plants, no less than 460 have a sufficiently wide range of climatic adaptability to be inhabitants also of Lapland, but a large proportion of the 606 species, which are more or less southern in their range within the limits of Britain, are cold-fearers, which are stopped by the cold winters from advancing beyond the middle or into the middle of the European continent. The following are a few of these, with mention of how many of the six climatic zones they reach into: in Britain, and an outline of their line of polar limit upon the continent—

Ilex Aquifolium—our common Holly—grows in the three warmest of the heat zones in Britain, its polar limit upon the continent stretching from South Norway to Mecklenburg, Pomerania, Austria, and Thrace.

Erica cinerea—the commonest of our five British Heaths—reaches into four zones in Britain, stretching across the continent from Norway and Belgium to Transylvania, and occurs only in a single station (in the neighbourhood of Bonn) in Germany.

Ulex europæus—our common Furze—three zones in Britain, runs across the continent from Denmark, Mecklenburg, and Switzerland and Italy.

Ulex nanus—the dwarf annual Furze—two zones in our London heaths; three zones in Britain. Does not extend on the continent beyond Flanders, France, Spain, and Portugal.

Achillea millefolium holosericea—two zones in Britain; in Denmark and Belgium to Dalmatia.

Iris fetidissima—one zone in Britain; France to Hungary, Tyrol and Constantinople.

Erica ciliaris—one zone in Britain; West and Central France, Asturias, Galicia, and Portugal.

France, Spain, Portugal, Italy, Dalmatia, Greece.

Adiantum Capillus-Veneris—the common Maidenhair Fern—one zone in Britain; Belgium, Switzerland, Tyrol, Dalmatia, Turkey, Greece.

Prickmannia palustris—one zone in Britain; on the continent does not extend beyond Spain.

Hymenophyllum Wilsoni—five zones in Britain; Norway, Luxembourg, West France, Tyrol.

The four following are plants of Ireland, which are not known to be wild anywhere in Britain proper:—

Arbutus Uvedalei—the Strawberry tree, so plentiful about the lakes of Killarney, and so well known in gardens—France, Tyrol, Dalmatia, Turkey, Greece.

Erica mediterranea—Gironde, Aragon, Galicia, Portugal.

Daboecia polifolia—the St. Daboc's Heath of Connemara—West France, Spain, Portugal.

Neotinea intacta—a little inconspicuous Orchis lately found in Galway—South France, Spain, Italy, Dalmatia, Greece.

It would be easy to multiply illustrations, but these are enough. We may fairly say that upwards of 300 of the plants of Britain, or more than 20 per cent., belong upon the continent specially to the south-west and west. It will be observed that these lines of polar limit run not due east and west, but from north-west to south-east, in accordance with the temperature of the winters; and it is quite clear that, taking the British flora as a whole, its most distinctive feature is that it contains a large infusion of cold-fearing plants, which, through our mild winters, can ascend in Britain to an exceptionally high latitude.

The same point is well illustrated by the flora of New Zealand. We find that as a rule the cold-fearing Mesotherms, types of the torrid zone, reach high latitudes in the southern part of the northern hemisphere, because, from the distribution of sea and land, the southern climates are more insular in character. The three islands of New Zealand cover the same latitude as Spain and France, and in their indigenous flora are represented the following tropical types, viz. 1. Palms, one species (*Areca spatulata*); Pandanus, one species; *Adiantum*, six; *Cyathaceæ*, six species; *Hymenophyllaceæ*, twenty-two species; epiphytic Orchids, five genera, five species; and Peppers, one *Cassia*, two *Lanana*s, five *Myrsinaceæ*, one *Cyperus*, four *Dracæna*s, and two panicoid grasses.

The way in which a characteristically cold-fearing, damp-loving, tropical group runs out from the tropic

zone into the insular climates, and avoids the continental climates, is well shown by the Tree Ferns. The only instances in which any Tree Fern grows outside the two tropics are the following:—There is one species of *Cyathea* in Japan, an *Azophila* in the Bonin Isles, a *Cibotium* in South China, and in the East Himalayas one *Cyathea*, two *Hemitelia*s, seven *Azophilas*, and the same *Cibotium*. In the southern hemisphere there are two Tree Ferns at the Cape, at least ten in extratropical Australia, eight in New Zealand, two in Lord Howe's Island, one in Raoul Island, two in Chili, and two in Juan Fernandez.

Essentially similar results are given by the study of the distribution of the two other most decidedly tropical Fern groups, Marattiaceæ and Hymenophyllaceæ. Of the latter, out of about 160 known species, there are two in Britain, sixteen in the East Himalayas, two in the Southern United States, ten in South Africa, twenty-six in New Zealand and Australia taken together, and twenty-one in Chili.

On the other hand we find that in the continental climates many heat-loving tropical annuals flourish, and their ripen in latitudes far higher than might be expected when the average annual temperature alone is considered, and in places where the winter sinks very low indeed. Our British January only sinks down to an average of 32° at the very north of the island; but in Canada, where the January average is 15°—20°, they grow good Peaches and Grapes in the open air, and cultivate Maize and Tobacco in the fields. For instance, where the January average is 26°, Grapes and Oranges ripen in the open air; they cultivate on a grand scale such Mesotherm types as *Gossypium herbaceum*, *Dolichos Lablab*, *Soja hispida*, *Capsicum annum*, *Dioscorea sativa*, *Sesamum orientale*, and Maize; and in the wild flora there are such plants as *Nelumbium*, *Gynandropsis*, *Pistacia*, *Grewia*, three species of *Indigofera*, two *Acacias*, *Begonia*, *Commelina*, two *Cyrtandraceæ*, *Phyllanthus*, and two *Andropogons*.

Other things being equal, it follows from the fact that the cycle of its life is run through in a portion of the year, that an annual can adapt itself to varying climates better than a perennial, and a herbaceous perennial better than a shrub or tree. Of plants characteristic of cool temperate latitudes, Wheat, Barley, and sometimes Oats are grown through the plains of India down to the tropic, because they can be sown and reaped during the coldest quarter of the year, and with them are introduced a crowd of the common annual weeds of the same latitudes, such as *Capsella*, *Chickweed*, *Euphorbia Helioscopia*, *Anagallis arvensis*, and *Veronica agrestis*, which also run through the cycle of their lives in the winter quarter. "But in Sikkim (to quote the introduction to Hooker and Thomson's *Flora Indica*, p. 194) no European fruit of any kind, save the Strawberry, comes to perfection; even the Peach, the only commonly cultivated tree, does not ripen; and the Apricot, the most abundant West Himalayan fruit, is unknown. In Central Nepaul, further west, Apples, Figs, Peaches, Quinces, and Apricots, all ripen, but hardly arrive at perfection. Towards the interior of Kumaon, at which the capital, Almora, is 5500 feet above sea-level, Apricots and all the above fruits become abundant, with the Pear and Cherry; and from Kumaon westward vineyards and large orchards form a conspicuous feature in the interior of all the valleys." F. G. B.

WHEAT AND RYE HYBRIDS.

BY A. STEPHEN WILSON.*

THE following experiments were begun in July, 1873, for the purpose of testing whether hybrids could be produced between two of the grasses, Wheat (*Triticum sativum*, L.), Spelt (*Triticum Spelta*), Rye (*Secale cereale*, Will.), Barley (*Hordeum distichum*, L.), and Oats (*Avena sativa*, L.), all of several varieties; or between these and Darnel (*Lolium temutatum*, L.), Wheat grass (*Triticum repens*, L.), Wild Oat (*Avena sativa*, L.), and Fly Oat (*Avena sterilis*, L.).

The number of florets treated was between 400 and 500. And when an experimenter goes through a good deal of labour perhaps he may be pardoned for expecting positive results. Undoubtedly the proper scientific spirit to cultivate is, not to anticipate results at all. The results of the present experiments were mostly negative; but whether they were negative from unknown facts hostile to hybridisation in the florets treated, or from failure, through ignorance, to impress the proper conditions into the experiments, cannot be here determined.

Only a general description of the methods employed need be given. When a floret of Wheat, Rye, or any of the others, was observed to be opening, the pollen was shaken into a test tube. In other cases, when it was known that the opening was about to take place, the ear was drawn through the hand and several sets of anthers brought out at the same time, thus securing a good supply of pollen. The ears of

other plants were then watched for opening florets. In most cases the anthers of these florets were removed with a pincers before discharge had taken place, and pollen from the test-tube dusted upon the stigmas with a camel-hair pencil. In many cases opening was induced at various stages before the natural date of opening. In some cases the anthers were not removed, but only the cross pollen applied. The endeavour was made to have a certain number of experiments under all the conditions which it was thought likely would favour fertilisation. It may be mentioned that all the plants were growing in ordinary circumstances in the open air. The earlier stages, when the anthers and pollen are greenish white, were avoided, florets being mostly selected in ears which had begun to flower, and in which the anthers were bright yellow or purple.

All the spikes and florets treated were marked by numbered tickets attached to them, and the conditions registered under which the experiment was made—such as what pollen was applied, whether the floret opened naturally, or was opened otherwise.

When the ears were ripe they were cut and collected for examination. Many had produced seeds, and many were barren, and many had fallen into the hands of the sparrows and were eaten up.

All that remained were put aside. Only two or three presented any abnormal appearances; they were swelled out into an unusual shape. The others were no way distinguishable from ordinary kernels of the respective grasses.

Of course, it was impossible to tell whether these seeds were hybrids or not. An experiment which should detail that a cross had been effected between two Wheats, because something had been produced not quite corresponding to either parent, might still be fallacious. We do not know that the removal of the anthers immediately after self-fertilisation would be without effect.

All the seeds of the various kinds were placed on damp cloth between inverted plates, in the spring of 1874, to discover which were alive and which were dead. A great many never vegetated; so that, when I came to plant my treasured hybrids, not many flower pots were sufficient for that purpose.

But the Oat seeds grew up Oats, and the Wheat seeds grew up Wheat, and the Barley seeds grew up Barley, and the Rye grew up Rye, all with the exception of the two plants, six stems of which are submitted to the Society. These are from Wheat vules and Rye pollen, and the whole aspect of the culm and ear is intermediate between Rye and Wheat. The elongation of the outer pales into awns midway in length between the blunt termination in Wheat and the longer needle of Rye, is the most noticeable feature. The thinness of the culm is characteristic of Rye, and so is the slight villosity below the ear, not so observable now as when green. The glumes, also, are intermediate in size between those of Wheat and Rye.

All the florets on these spikes fully opened, as if intending fertilisation, and on some of the ears they did not close again. But what seem to be the most important facts regarding these hybrids are, that the anthers did not open nor discharge any pollen; that the pollen was imperfectly developed and contained very little fovilla; and that the imperfect grains remain in the test-tube. There are, therefore, a sufficient reason why these hybrids are absolutely barren; not a single kernel having been produced. The anthers did not get blanched as empty anthers do, and instead of falling away as is usual they still remain attached, so that the imperfect pollen may be examined by breaking up an anther in a drop of water. The anthers are of the Wheat size. In the ordinary fertilisation of a grass, the pollen grains continue to grow until they rupture the anther; in these hybrids this full growth of the pollen grains has been arrested.

It would be going further than caution warrants to affirm positively that the plants under notice are hybrids beyond all doubt. Whole spikes of the cereal grasses are sometimes barren, or at least remain unfertilised; and other circumstances than the transfer of the reproductive elements may have brought about the peculiar structure and the sterility of the supposed hybrids before us. But as the experimenter has considered the reason for allowing the plants to be actually hybrids; and as the immediate cause of their sterility is a true and sufficient cause, and not some fancied purpose of Nature; he presumes to submit his observations for what they are worth to those who may purpose going further into the subject.

METROXYLON FILARE.

IN his paper on Palms, published a few years since in our columns, the late Dr. Seemann refers to this plant and an allied species, *M. clatum*, as being the only representatives of the genus. These two plants form the section *Pigafetta* of Martius, who included in the same genus another section, *Sagus*, represented by some half dozen species, which form the genus *Sagus* of other authors. *Sagus* differs from *Metroxylon* in

producing a terminal spadix and dying after flowering, while *Metroxylon* is polycarpous, with lateral spadices which are produced annually. The trunks do not contain any sago, in which also they differ from *Sagus*, which is sago-yielding.

Our sketch of *Metroxylon filare* (fig. 103, opposite) is taken from a plant in the collection of Mr. Bull, of Chelsea. It is described as having a tall stem, pinnate erecto-patulous leaves, the petioles of which bear numerous slender spines, each of which the pinnae are aristate and three-veined. The spadix is decomposely paniculate, and bears small oval berries. Both species are natives of the islands of Ceram and Celebes. The present, it will be seen, is a very elegant plant, the pinnate leaves having a gracefully spreading character.

ON FLOWERS OF TREES.

THE importance of studying "deciduous trees in winter," so as to learn the distinctive "disposition of the branches and arrangement of the sprays," was well explained by Mr. McNab in his paper on this subject, read before the Botanical Society of Edinburgh.

I should like to press the subject one step further, and suggest that the early flowering trees should have the first consideration in planting, particularly in town squares, villa gardens, and other small places, where each individual tree must be thoroughly known and valued for its distinctive character and qualities.

It is delightful to watch the thickening of the branches in early spring, and that is more marked in the case of the flowering trees of the leaf buds. For example, a group of either Scotch Elm with its round buds and bunches of inflorescence, or Alder with its long purple catkins, in a park, gives a decided colour and thickening to the landscape very early in spring. But the various Willows are the first flowering trees. *Salix violacea*, *purpurascens*, *cerulea* (under all these names it is sold), is the earliest of all, and has a beautiful large, soft green catkin, which, however, seldom grows to the end of the twig in Scotland, and the well-known *S. caprea* and *S. glauca*, which flower thickly to the very tips of the branches. The male flowers of caprea are particularly striking when not fully out and the one side of the catkin only is ticked with the bright red anthers, soon bursting into full yellow flower. *S. caprea* is somewhat later, but is very attractive, while the white catkin is still half enclosed in its round, shining brown husk; and plants of about 5 or 6 feet high are in February very useful, thickly studied with flowers, and of a compact, thick growth, for the shrubbery. *S. viminalis* and its varieties, with long and remarkably soft white catkins, is another early Willow. *S. rubra*, with prettily marked purple catkins, very like *S. Helix* (true), comes about the same date. *S. nervosa*, sent to me in February by Mr. Scaling, is another, with rods a perfect mass of grey catkins. *S. tomentosa* is interesting from the brown leathery clothing of the ends of the branches and the rather coarse grey catkins. *S. Kerkii*, *Lambertiana*, or *purpurea*, is another purple-catkin Willow, the flowers of which are long and narrow. *S. aurita* is quite distinct, and were it not for the round white catkins budding out, one would fancy it a Beech, from the hard, wiry, brown twigs. I find all these Willows with early catkins do well in water. The male caprea flowers are very interesting, and by removing the husks at different stages a great variety of shades of soft green and rose are brought out, which we do not find when the twigs are left alone on the tree. I should much like to know what mode of pruning (if any) would secure yearly a fine crop of catkins. Hot summers we cannot command, and I do not know if Willows are as dependent as other flowering trees on well-ripened wood. They have been very late this severe winter, both here and in England, but the catkins do not seem to suffer materially from such a season, as Mr. Scaling to Mr. Seemann in the question of pruning, he answers—"The lower branches of Willows do not flower so profusely as the upper; when the lower branches are cut close back, leaving the upper ones untouched, the flowers are finer and fuller"; he "is not prepared to say how far a tree would be permanently injured for flowering by a judicious pruning back at any given time; certainly it would not flower to any extent the season was protracted."

The trees are most vigorous the third and fourth year after being cut in for nursery purposes (in which no heed is taken of the flowers), is a fact; and that where an undergrowth of colour (red, yellow, or purple) is wanted, a yearly cutting down ensures the greatest quantity of brightest young wood (as with Dogwood and Buckthorn) is another fact; but for catkins would it be wise to have three specimens of each early-flowering Willow to make a fine crop of inflorescence every year, pruning in its yearly rotation one of the three? One specimen of one species is, of course, no rule; but we find that a stock of caprea (8 feet high), the grafts of *S. argentea*, *lanata*, *chrysanthes* on which had died, flowers yearly, thicker than a neighbouring tree growing naturally.

*Read at the April meeting of the Edinburgh Botanical Society.

FIG. 103.—METROXYLON FILARE.

It would be well if all gardens were provided with a few stocks (caprea, male and female, nurserymen consider the best) for grafting, budding, or inarching such Willows as succeed best that way; one year is safe for budding, two years for the other methods. We lost our argentea by having it taken too soon from the parent tree. It is an interesting Willow, from its very silvery catkins, which grow at the tips of the branches. The Kilnarnock Weeping Willow is at present a very interesting object, well covered with white catkins.

To plant trees that flower before they come into leaf is, I am certain, an object well worthy of consideration for landscape effects, and trees for garden boundaries; the cut twigs of such for indoor decoration are very interesting.

I find the Willow catkins that come out with or just after the leaf do not last in water; possibly no tree flower does at that time, as the young leaves are sure to flug; but the Lime, from being later to flower, does stand.

In several of the squares in Edinburgh the flowers of the Aspen are very thick when seen against the sky; when faded and strewn on the pavement they

are wondrously like the cast-off skins of caterpillars. But I was struck by the effectual blind group of three trees formed (Aspen, a Scotch Elm in flower, and a Laburnum still loaded with its bunches of seed-pods), quite concealing an ugly row of houses opposite the street.

The prominent female flowers of the *Populus balsamifera* (Balsam) are now also very striking, yellow ticked with red, contrasting well with the soft, fluffy, grey and red catkins of the Aspens (two varieties). A group of either tree in March is valuable. Another curious Poplar catkin is *P. polonica* (a Continental Aspen), with green and black ticked flowers, all curved in and hanging on one side of the twig; but this Poplar does not grow to the size of a forest tree.

There is a very common idea that the *P. tremula* (Aspen) is the only Poplar that quivers; the *P. alba* (Abele, Dutch Beech, Downy Poplar), that has a white leaf and peculiarly marked trunk, and the *P. balsamifera* (Balsam), the only sweet-scented ones. All have more or less slender footstalks, compressed vertically, which causes the quivering motion, and there are at least nine or ten white-leaved Poplars.

To judge alone by the white bark with its triangular-toothed scoriings of the upper part of the trunk, it would be difficult to decide if the tree were an Aspen or an Abele. Both the *P. monilifera* (Black Italian Poplar) and the *P. canadensis* (Ontario Poplar) are sweet-scented; this last is also white-leaved.

I do not know if it is the climate, or that greater attention is paid abroad to propagating from the very whitest variety, but certainly the Abeles one sees in ornamental avenues on the Continent are far more striking than ours when the breeze turns over the leaves. An avenue of Planes (*occidentalis*) and Abeles, even although pollarded, as they so frequently are abroad for shade walks, looked very well; and in another town Mountain Ash in full fruit was added to these two trees. The Alder in March is no longer purple as is the Birch, but is yellow in the landscape like the Hazel, with its long unfertile catkins ticked with purple, and the little puce-coloured fertile ones, like miniature cones, are hardly noticed, and require to be sought for, as do the crimson female flowers of the Nut; they are set at the end of the twig in groups of three or four—in vain have I searched for a set of five. With the exception of the

Larch and Ash, the flowers of the other forest trees are too late to do us any winter effect. Few ever think of looking for the queer flower-spine of the Walnut or those of the Spanish Chestnut, although the fruits of both are very welcome and sought for; indeed I have been told, as a fact, that Horse Chestnuts and Limes are the only forest trees that have flowers! My informant having seen the former in Bushey Park, and having often been overpowered with the fragrant perfume of the Lindens.

Mr. McNab's opening remark, that there are "people who are actually incapable of discriminating between the various kinds of forest trees when bare of leaves," may be extended to a complete inattention to and ignorance of their flowers.

As the power of observation (far less the habit) cannot be acquired in one season, and therefore deciduous trees will not be distinguished after one winter's walk, I would recommend that the page containing Mr. McNab's distinct description of the various trees be carried for reference in it or pocket until thoroughly mastered; there is such complete confusion among the names of Willows, each nursery having its own, that possibly the best plan for those who would wish a collection of these Willows with early and interesting catkins is merely to give such an order to their nurseryman, or, better still, to go round and mark at the various tree-nurseries those they fancy. I find myself frequently answered with "We have never paid attention to the names of Willows and Poplars—they are not grown on that account." Now I think that they should be, for their catkins alone, as well as for their very many other valuable properties, all planters being alive to Willows and Poplars bringing the quickest return of any timber tree, and for many years that will increase, unless our railway carriages, like our ships, are turned into iron ones; also for their great diversity of growth (the large *Salix Russelliana* at Stone is 80 feet high, and *S. herbacea*, crawling on the ground, is our smallest forest tree, and is 4 inches in height); and for their power of growing in all situations, swamps and mountains, the Willow being the last woody plant we met when climbing a mountain. Of all varieties of habit, erect, weeping, always graceful, and of distinct colours in bark and leaf at all seasons, yet nevertheless the flowers of Willows have been comparatively overlooked in ornamental planting.

Were the popular belief proved that "the more prominent kinds [of Willows] have hybridised and yielded intermediate varieties without number," causing this genus of plants to be more confused than any other (*vide Arboriculture*, Grigor, 1868), a skillful hybridist might possibly utilise this confusion, and we might have additions to and improvements in our stock of early flowering trees, on whose flowering we could with certainty count, and in a season when they would be most seen and valued. Then, indeed, would the Willow be in all senses a pliable tree. Mr. Sealing writes, in his *Series of Papers on the Salix*, or *Willow*, part ii., p. 5, "referring to a register kept in the Basford Nursery, in 1871, of nearly 300 varieties of Willows, 92 were in flower and 115 in leaf on March 25." That our native species are not exhausted is proved by the discovery of *S. Sadlerii*, last autumn. It was observed by Mr. Robertson, for the first time, in Mr. Robertson's nursery here, the flower-buds of *S. vitacea*, which were then of a bright rose colour; but Mr. R. told me that this depends on the season, and it is not invariably to be counted on. *F. J. Hope, Warride Lodge, Edinburgh, March.*

Foreign Correspondence.

BRAZIL.—Some observations made by Mr. Drummond, Her Majesty's representative at Rio, upon the properties of the good and wholesome, especially when taken with milk, animals readily fatten upon it. The leaves of the young tree, when 2 feet long by about the same breadth, are cut down and dried in the shade; they then discharge from the surface pale grey-yellow dusty scales, which, melted over the fire, become a brown wax. The wax occurs mixed with heterogeneous substances, bark and fibre, and it loses considerably by sifting. The material is tasteless, and soft to the

touch; the smell has been compared with that of newly made hay. Its chief fault is its brittleness. This, however, is remedied by mixing with three parts of vegetable one part of animal wax, or one-eighth to one-tenth of tallow. The value of the annual production of the wax is stated to amount to above £50,000.

The Arceira.—This is called the monarch of the forest. The timber is of excessive hardness, resists weather admirably, and takes a fine polish. The leaves are used as epispastics, the decoction serves to alleviate rheumatic pains, and the gum, rubbed on ropes, preserves them from decay. The natives avoid this tree, as tumours are produced by sleeping under it; and the highly sensitive who pass underneath it suffer from swellings in the face. The Indians use the green juice of the young branches for eye diseases. A curious tree of the Bombacaceæ was met with in 1863; by Mr. Wallis, whilst exploring the upper Rio Branco, and its gigantic proportions quite astonished him. It measured at the top 173 feet diameter, which gives it a circumference of 520 feet; under this immense ceiling of foliage 100,000 people might find cover. The Baobab is a tree also belonging to the species "Sumameira." Its diameter at the top is 108 feet, and 324 feet in circumference. It is popularly asserted that this tree is found of the age of several thousand years.

Natural History.

CHLOROPS.—The Chlorops lineata, a small two-winged fly, about three-eighths of an inch across in the spread of the wings, and distinguishable at a general glance by the quadrate, somewhat barrel-shaped thorax, longitudinally striped with yellow, the round head, with large eyes, and the triangular mark at the summit behind, is one of a genus represented in England by several species, whose presence is yearly more or less made known amongst the corn crops by the ears still remaining in their sheathing leaves, whilst those around are developed and ripened, and which occasionally, when more than usually numerous, appears in sufficient quantities to be the cause of serious damage.

These insects attack Wheat, Barley, and Rye, but in the course of a few years' observations made in the west of Gloucestershire, the Barley alone appeared selected, and here they were constant visitors. If specimens of injured growths were required, a glance round a field of growing Barley, or, later in the season, a handful or two pulled from a stack, usually furnished them at once; and in 1870 the *C. lineata* swarmed to such an extent in a Barley stack shortly after it had been put together, as to fall off in hundreds, or rather in showers, on gently opening and shaking the stack, so gently.

The summer attack of the Chlorops appears to begin by laying an egg on the still young plant near the base of the developing ear, sometimes a little way up it. "About fifteen days after these issues from the egg an oblong larva, yellow, and without legs," which attaches itself to the stem and gnaws an irregular furrow down one side as far as the first joint; and, ascending again for its change, may be found in the course of a few days, as a blackened channel, usually beneath the leaves, in which it still remains wrapped about the middle of August. The pupæ which I have seen have been of a kind of hard point-like appearance exteriorly, and corresponding in colour with the deepening orange tints of the ripening straw.

The affected ear may be distinguished at a glance by being still enclosed in the leaves or only partially freed, whilst those round are perfected; and on opening the leaf the injured growths in stem will be found deeply scored with a blackened channel, usually running in an irregular line from beneath the base of the ear to the first joint beneath, but with some degree of variety in the appearance of the injury. In a few heads taken for examination one showed the growth so stunted that the length between the ear and first joint was only about 1½ inch, and the stem was flattened and twisted; in another the insect gnawings stopped abruptly a short distance beneath the ear, and then made a completely fresh start downwards again from one side of the end of the first track; and in a third the course of the Chlorops larva to start with appeared to have been taken through the four lowest grains of the ear, which were stunted, injured, and blackened.

A somewhat similar appearance is noted by Curtis on two Wheat ears affected by *C. tenipus*, and these views are especially pointed out, that the larval attack is commenced in the stem, whilst grain is still so young and tender as to be susceptible of check from the slight gnawings, and that the stem and ear, continuing to grow whilst the injuries continue, give, when complete, rather the diseased growth of the lengthening stem from the gnawings, than the gnawings themselves.

The descriptions given by M. Herpin in journals to

Wheat near Chalons-sur-Marne by Chlorops, supposed to be *lineata*, correspond almost exactly with those to the English Barley in the locality where the *lineata* was found close by in great quantities, excepting that in the case of the English Barley there was usually no great difference in the height of the infested or healthy stems, whilst in the French Wheat at Chalons the stalks are mentioned as being scarcely half the height of the healthy growths. The loss from these insects was estimated in 1840 as one-seventieth part of the Wheat crop, and in another place Dr. Dazomet mentions their numbers as being so considerable, that it was impossible "to set a step" without meeting with injured ears, and that the insect was a formidable scourge to agriculture. Amongst other species of Chlorops noted are the *C. Herpinii* (mentioned as only attacking Barley similarly to the *C. tenipus* and *C. lineata* by scooping a longitudinal furrow down the stem); the *C. (?) hypostigma*, found in immense quantities on some ceilings and windows in the autumn of 1834, and 1844, and especially the *C. tenipus*, or ribbon-furrow-corn-fly. This fly is about 3½ lines in expanse of wings, light yellow in colour, the thorax squarish in shape, the same width as the head, with three black stripes down the back, and a narrow black line on each side; head with a black triangular marking at the summit behind, abdomen greenish black, and is especially distinguishable by the ochraceous band across the black feet, from which it takes its name.

The recorded injuries from this species appear to be exactly similar, as regards the growing Wheat stem, to those already described, consisting of a channel scored between the ear and first joint, and the larva similarly undergoing its change beneath the still sheathing leaves; so that, as far as I am aware, from the comparison of the injuries I have met with, and those so clearly described (with accompanying figures) by Curtis in his *Farm Insects*, and in one of the early volumes of the *Gardener's Chronicle* (unless there is a difference in the pupa case of the *tenipus* being darker than that of the *lineata*), the presence of the perfect insect appears necessary for identification of the specific cause of the injury.

These injuries are at times both severe and also spread over a large extent of country, but the cause of attack and the remedies seem uncertain or wholly unknown. Some years appear more favourable to the development of the insect than others; as in 1841 Wheat in Surrey and Barley in Lincolnshire are mentioned as being injured, and in 1846 the barley at places in Norfolk, Essex, Middlesex, and Lincolnshire is noted as being injured to the extent of half the crop or more.

In Gloucestershire the Barley attacked was on stiff clay; but the exposures of the fields were most various, from almost complete shelter from every direction, to lying open to east wind sweeping uninterruptedly down many miles of the Severn; and the presence of the insects in great numbers in one spot in 1846 did not appear to recur in any other year in a greater number in the following season. Still, as the diminution of the numbers of the Chlorops must necessarily be beneficial, the only remedy which seems available, that of drawing the affected plants, is very desirable.

The plants are perfectly distinguishable, and with a little care could be hand-pulled without injury to the standing corn; and the affected ears being entirely or in great part sterile, would occasion no loss by their removal—only the clearing away of the already spoiled crop; and if the time was judiciously chosen, before the development of the pupæ into the perfect flies, the germs of much future mischief might get rid of. *O.*

Florists' Flowers.

A FEW of the newer ROSES exhibited by Messrs. Paul & Son at the meeting of the Royal Botanic Society on the 31st ult., deserve something more than the passing notice they are apt to receive in a necessarily abbreviated report. The Roses (including some fine varieties from Mr. W. Paul) were fresh and beautiful, plants and cut blooms alike.

The much-talked-of H.P. Captain Christy is a lovely light-coloured Millé. Eugénie Verdier, exquisite in the bud, and of a charming shade of colour; it may be set down as a ladies' Rose, so delicate in its light rosy flesh tint. The white H.P. Madame Christy was a true white Rose as seen on this occasion, the flowers large and globular, and in every respect first-rate; vigorous in growth and free of bloom, it promises to make an excellent exhibition and forcing variety, as it has no less proved itself a fine Rose for outdoors in the late summer. H.P. Marie Finger has the peculiar shape and build of Millé. Eugénie Verdier, also, but is of a darker hue, being of a shaded salmon-rose colour. It, too, promises to become a great favourite. If brilliancy of hue can be a recommendation to a Rose, then H.P. Thomas Mills, one of Messrs. Paul & Son's own seedlings, has it in a remarkable degree; as seen on this occasion it was of

a brilliant red hue. As a forced Rose it appeared to be thin in point of substance, but this may not be so apparent when grown in the open air. H. P. Star of Waltham, one of Mr. William Paul's seedlings, was very fine, quite maintaining the character it possessed when it received a First-class Certificate at the Royal Botanic Society two years ago. The splendid bull and substance which then characterised it, is undoubtedly a permanent quality. It is of a very bright deep crimson colour, and it promises to make a splendid exhibition Rose. Princess Beatrice, another of Mr. W. Paul's seedlings, was very fine also. The following newer H. P. Roses are well worth looking after by cultivators:—Duchess of Edinburgh, Etienne Dupuy, and Madame Louis Leveque. Noisette Caroline Kuster was finely shown by Messrs. Paul & Son. It is of a bright orange-yellow colour, and will be an excellent companion to Céline Forestier. Tea Marie Van Houtte is a charming Rose, very free of bloom, but it is said the beautiful flowers soon fall away and decay. A very promising seedling was shown by Messrs. Paul & Son, which may be set down as a shaded Charles Lefebvre. It promises to make a good outdoor Rose. R. D.

THE VINE.

[THE paper from which the following has been abstracted, was read by Mr. Hunter, of Lambton Castle Gardens, before the Gardeners' Institute at Darlington, on March 25, and affords evidence that Mr. Hunter can preach as well as practise. It will be read with great interest by those who are curious to learn the secret of the monster bunches exhibited by Mr. Hunter. That secret, in a word, seems to be judicious feeding.]

"I have come before you to fulfil the promise I made to you when you asked me to read a paper on the treatment of the Vine in cement borders. The large Hamburg bunch, being the one then in question, is included in the treatment of this house, to which only I will refer. I had the house put up in the early spring of 1869; it occupied the old foundations so far as regards depth, but was in every way made nearly double, by putting two into one. It may be interesting to some of you to know that this house stands on piles; and while I was making alterations I found after boring that we stood 31 feet 9 inches from anything solid to work on; however, after getting a cement and brick bottom to my satisfaction, some 4 feet in depth, I resolved to have the borders made without further delay. Drainage on such a bottom as this must be efficient and thoroughly well carried out. In this case our front drain is built with brick, and pipes put inside, so that the top of the drain is 12 inches below the cement bottom border; at every 6 feet a line of 6-inch pipes crosses from front to back, and at every 4 feet from end to end of the house, the pipes thus forming a number of oblong squares, 6 feet by 4 feet. These were filled up with brickbats to a foot in depth, and then with small stones and coarse gravel, after which it was turfed over, with the grassy side of the sod downward. Soil suitable to make the border was the next important item. The park, or a portion of it, having been drained previous to my coming to the gardens, I used turf which had been laid aside for gaining purpose, and it was worked forward with it. To every six cartloads of soil I added one of lime *débris*, one of charcoal, one of burnt clay, 3 cwt. of broken bones, and a good dressing of clean cow manure, when the whole was turned over twice in the border, and then the soil was worked forward. Some of them were from one-year-old canes, and the others from eyes struck the same spring, the latter having a decided advantage at the end of the first year's growth, which advantage is maintained still. I found wirework a most destructive enemy the first year. To check these, the surface of the cement border, with the back of a spade, coated over with rape dust, laid over with thin boards, and covered up with two inches of old mushroom manure; this was turned over every alternate morning, then the wireworms were picked off the boards by hundreds. After this treatment the Vines carried their foliage well into December, when they were cut back to 6 feet from the bottom. I very soon after felt disposed to see what wireworms were left in the border, and also with a view of further assisting the Vines, I had an opening taken out at the back of the house, and worked forward on them carefully with steel forks; every portion of the border was hand-picked and turned back until within 3 feet of the Vines; by this time we had a fine lot of roots laid bare. The soil was worked forward again, with the addition of 2 cwt. of guano to the soil, and the roots being carefully laid in again. This has been done this every year, with one exception, since planting—I doubt not with advantage to the Vines. At one place where I was, under a noted Vine grower, I assisted in making over 2000 yards in length of new cement borders, at various widths, and to my surprise on removing the old Vines, which were considered A 1 in their day, I found each had but a root or two to support them; they had taken up their abode in some quarter never made for them, as they passed out and put their roots, and left a fibrous root in it. Imagine a gardener trying to assist the Vines by repeatedly watering and top-dressing such borders!

"I shall close my remarks by giving the outlines of treatment the Vines had in the latter part of the year, and of February the house was kept close, previous to start-

ing on March 1, when syringing, morning and evening, was well done, according to the weather. Fire-heat was applied at 6 A.M., and taken off at noon. No fire-heat was given at night unless compelled by frost. During the month the outside and inside borders were watered with 1800 gallons of tepid water, running out at the rate of 7 gallons per minute through a line rose. By the 15th no syringing was allowed overhead. April—for this month fire-heat was turned off sooner in the day, weather permitting, but was applied immediately after shutting up. On the 6th, so rapid was their progress, that the shoots were picked two leaves beyond the fruit and tied down. On the 13th the evaporating troughs were allowed to become dry, and fire-heat was used freely, front air was put on at 8 P.M., and increased at 10 P.M. On the 20th the Vines were in full flower, the treatment was altered, and the troughs becoming dry, on the 27th all the flowers had set, the evaporating troughs were refilled, and front air admitted more freely. We commenced thinning on May 1; airing as last month. On the 13th we watered the inside border with 3500 gallons of guano-water, at a temperature of 75°. After the 13th the temperature of this house was not allowed below 65°, when front air at nights was admitted much more freely. On June the 15th the outside border was served with guano-water as inside, running at the rate of 6 gallons per minute, which lasted 7 hours; the quantity being 4250 gallons. Again, on the 20th, this house received 5040 gallons, and on July the 20th, 1680 gallons. All this was put on at a uniform tepid temperature. The regular requirements, such as stopping, tying, and thinning, were of course duly attended to. The record of the temperature was taken four times daily, I also experimented with the border of this house in the growing season of the Vines, the results of which I hope at another time to be able to bring before you, should they prove as suitable and satisfactory as they did last year.

"Some say wet localities have their advantages; here we have a dry one; in the Grape growing season at Lambton Castle our rainfall did not exceed 10 inches. Some say soil; if so, why did not our predecessors, who used the same, do the same as us? In the way of experimenting last year, I had a small lot of Vines planted in soil of natural soil, except a small quantity which was used to surround the newly-planted Vines. The Vines have made roots from 8 to 10 feet in length, and turned out pretty good yearlings. This I only mention to show that Vines can be grown, whatever the staying powers may be, without turf or garden soil."

Notices of Books.

Les Bois Indigènes et Etrangers. Par Adolphe Dupont et Bouquet de la Grye. Paris: Rothschild.

This is a book devoted to the explanation of the proper cultivation of forests, but written more from the point of view of the statist and mechanist than of the physiologist and the woodman. In all that relates to woodcraft, and the formation and management of plantations, the present work seems deficient; on the other hand, there are many other subjects, relating to what we may term the mechanical part of forestry lore, which are treated with fulness and ability.

One subject which has excited some attention in our columns lately—the eccentricity of growth—is referred simply to the fact that the tree in which it is manifest has grown on the steep slope of a hill; but it is clear that this is not the only cause for this phenomenon. With reference to the effect of forests on climate and public health, the authors judiciously state that observations are neither sufficiently numerous nor sufficiently precise to enable us to arrive at a correct conclusion. Speaking also of the desirability of afforesting or disafforesting according to circumstances, the authors state that where the soil is of excellent quality it is better to grub up the woods and cultivate cereals, except in exceptional cases, where some timber of special value is required; on the other hand, sterile unfruitful lands, which require an expenditure for labour out of proportion to the return from them, should be planted. Mountain slopes, whether their soil be rich or poor, should always be planted. The return for capital expended, however, is too slow for the French proprietor to look on planting with favourable eyes. In mountainous countries, where the arable land (the capital in the soil) is washed away yearly by the rains, the cultivator prefers to lose this capital rather than save it by making a present sacrifice in the way of planting; on the other hand, he is always ready to clear and grub up. He does not consider whether the soil itself is fertile or not, he only sees riches occasioned by the accumulation of humus occasioned by the growth of the wood—riches which he can specify and easily realise. When he has cleared the land and exhausted the supply of humus, the soil, reduced to its mineral ingredients, is pretty sure to be very poor, and the land is then left uncultivated, sterile, and unproductive. The individual may have enriched himself, but

at the expense of posterity and of his country. Public interest, then, demands the conservation of forests in all mountainous districts, and in many cases the replanting or reconstitution of those which have been destroyed; it requires also the plantation of plain too sterile for arable cultivation to be profitable, and in any case it is essential that the nation should preserve those rare plantations whence military and civil engineers may derive timber of large size and of superior quality to that which can be produced by private estates.

Forty Years of American Life. By T. L. Nichols, M.D. Longmans. 1874.

The fact that this is a second edition relieves us of the necessity of saying much as to the merits and demerits of a book so extensively known already. It may be, however, that some of our readers may not have fallen in with it before, and they certainly cannot have met with it previously in so convenient a shape. To all such we say, get the book and peruse it from chapter 1 to the *admissiones*. It is a veritable cyclopædia of information concerning America and Americans, concerning which and whom we English ought to know so much, and as a rule know so very little. Save to specialists anything beyond the main facts of American history is unknown to the great majority of Englishmen. How prejudicial and unwise this ignorance is may be gleaned from the book before us. The author is a warm partisan, but he is straightforward and honest, so that his partialities need, by no means blind the intelligent reader, or prevent him from forming his own unbiased conclusions. A more instructive and interesting volume it has not been our luck to meet with for a long time.

La Terre Végétale, &c. Par Stanislas Meunier, Paris: Rothschild. (Williams & Norgate.)

An interesting little book on agricultural geology, the most valuable part of which, perhaps, is the map of France, by M. Delesse, which accompanies it. This map is founded on a much more complete one, whose construction is explained as follows—"First of all a collection of soils from all the different districts of France was made. Two samples were taken in every canton at a depth of 15 centimetres, and forwarded to Paris, with a descriptive label indicating the precise position from whence it was obtained. In this way more than 6000 samples were obtained. In sorting them the first step taken was to separate those that contained lime from those in which that element was not present. In this way, even in the limestone districts, it was found that many samples were destitute of lime. Peaty and sandy soils were then sorted out, and their localities marked on the map, to which were added also lines indicating the levels of the soil, the distribution of rain and temperature, as well as the direction and force of the wind. It would be impossible in a small book like that before us, to reproduce such a map as that just alluded to, even on a very reduced scale. What is given is a small map indicating the districts allotted to the cultivation of cereals, Vines, forests, as well as pasture lands and sandy wastes. By differences in shading the average annual revenue per bectare is given. We are much struck on looking at the map at the large extent of country over which the Vine is grown, and the relatively small patches in any particular district, even in the Burgundy and Bordeaux countries occupied by Vines. Again, we are surprised to find the Vine cultivated in sufficient quantities to be worth mapping so far north as Beauvais and Laon. The text of the volume before us is devoted to the description of the several varieties of soil and their mode of formation, and to the improvements which may be effected, where necessary, by drainage and the application of various artificial and natural manures.

—A new monthly journal, devoted to the interests of millers, and appropriately called *The Miller*, has just been established.

—The numbers of the *Belgique Horticole* for January, February, and March contain, *prima*, a biographical sketch, with portrait, of Ogier de Busbecq, the first to introduce the Tulip, the Lilac, the Horse Chestnut, and other plants into Europe. The coloured plates are devoted to Billigeria amona, Adiantum lunatum, and Rose Saint George—the latter a reproduction of the plate given recently in the *Florist*.

—A new and thoroughly revised edition of *Faxton's Calendar of Garden Operations* has just been published, and may be had from our publisher. We need add nothing in the way of commendation of this little book as a guide for cottagers and amateurs generally, as the fact that the present issue commences the two hundred and twenty-first thousand is a sufficient evidence of the utility of the book. We may add that the portions relating to the vegetable garden have been specially revised by Mr. Cox, of Madresfield. All the other portions have been modernised and revised.

HORTICULTURAL EXHIBITIONS, 1875.

APRIL.

- 21.—Royal Horticultural Society, South Kensington. Meeting of Fruit, Floral, and Scientific Committees.
- 22.—Royal Horticultural Society of Ireland. Spring Exhibition. Sec., A. Balfie, 25, Westland Row, Dublin.
- 27.—Manchester Botanical and Horticultural Society. Exhibition of Auriculas, &c., in the Town Hall. Manager, Bruce Findlay.

THE

Gardeners' Chronicle.

SATURDAY, APRIL 17, 1875.

AFFORTUNES FOR THE ENSUING WEEK.

- TUESDAY, April 20 | Sale of Poultry and Pigeons, at Stevens' Rooms.
- Wednesday, April 21 | Royal Horticultural Society's Early Rhododendron Show.
- Wednesday, April 21 | Royal Horticultural Society's Meeting of Fruit and Floral Committees, at 11 A.M.; General Scientific Committee, at 1 P.M.; General Meeting, at 4 P.M.
- Thursday, April 22 | Sale of Imported and Established Orchids, at Stevens' Rooms.
- Thursday, April 22 | Royal Horticultural Society of Ireland's Spring Exhibition.
- Friday, April 23 | Sale of Palms, Cactilias, Orchids, Agaves, &c., at Stevens' Rooms.
- Friday, April 23 | Sale of Exotic and British Lepidoptera, at Stevens' Rooms.

THE interest which has been excited about the DAFODIL and its double varieties must have been a source of gratification to those who love our old border flowers, and who regret that modern taste, if taste it can be called—fashion we would rather say—has well-nigh banished from our gardens some of the fairest and sweetest flowers that formerly adorned them. When we remember what associations gather round the Narcissus, what pretty legends, classical as well as national, are attached to them, it is indeed a matter for congratulation that our columns should bear witness to the revived taste for these beautiful and interesting flowers. The interest attaching to them is indeed manifold—they are beautiful in themselves, they are harbingers of spring and deck the glorious summer-tide with beauty; they are associated with much that is charming and delicious in our literature and poetry, they suggest endless questions to the botanist and to those who love to study and dwell upon the marvels of Creation.

Amid the many points that have been raised in our columns lately as to the Daffodil, no one of the controversialists seems to have remembered that the Daffodil so called now-a-days, is not the Daffodil of our forefathers.

Again, the double Daffodil of many modern writers is not the double Daffodil which Mr. HARPUR-CREWE and Mr. BARR mean; and this confusion applies not only to one particular variety but to many others, "one calling that by one name which another calleth by another, that very few can tell what they mean." This was so in PARKINSON'S time—that it is so now, even after the labours of Mr. BAKER and the history which he gave of all the species in the *Gardeners' Chronicle* in 1869, is evident from recent correspondence. What we now call the Daffodil is the bastard Daffodil—pseudo—

Narcissus for PARKINSON. The name itself bears witness of the fact. It is a sorry discovery to make that all the legend, the poetry attaching to the wild English plant applies to a pseudo—a bastard Daffodil! It is matter of thankfulness from this point of view, however, that the words pseudo, or bastard, have in this case no such signification as they have generally: the Daffodil of our woods is no impostor, it is no cross between different species. Call it Pseudo-Narcissus if you will, it is for all that a true Narcissus! But some may say this is mere quibbling: let us to the point. Our correspondent "C. W. D." first set the ball rolling by stating that the wild Daffodil of the woods, if transplanted to the garden, would become double after two or three years' cultivation; and conversely, that the double Daffodil of the gardens, if transplanted to a meadow, would speedily become single unless the soil were very rich and strong. This statement was not allowed to pass unquestioned for long. Counter-assertions were made. Our correspondents took sides; many forwarded us specimens in confirmation of their assertion. These specimens we are bound to say were for the most part not the double wild Daffodil, but belonged to the form—we dare not call it species—which

FIG. 104.—THE TRUE DOUBLE DAFODIL.

we know in gardens as *N. major*, and which is more or less naturalised in certain parts of the country. In order to put this matter at least at rest, we begged Mr. BARR to allow us to figure one of his specimens of the true double Daffodil as now understood. This he kindly permitted us to do, and at fig. 104 it is faithfully represented (as to the flower) by the skillful pencil of Mr. W. G. SMITH. Mr. BARR has told us already (see p. 471) of the difficulty he had in getting the true double Daffodil, and we ourselves began to look upon it as great a myth as the redoubtable Mrs. HARRIS herself. However, amid many so-called wild double Daffodils which we received, and which were all forms of *N. major*—the South European representative of our British Daffodil—we have received by the courtesy of our correspondents some few indubitable double Daffodils. Captain KING, for instance, sends us the true double Daffodil from his garden, which said garden was a Turnip field a dozen years ago. Into that garden, as we understand it, single-flowered wild Daffodils were transplanted from a meadow two or three years since. So far this appears to corroborate "C. W. D.'s" assertion. A second letter from Captain KING, however, states "that he has just visited the copse from which they [the double Daffodils] were brought by my gardener two or three years ago, and find them to be nearly all double within the tub."

As the writer well says, these specimens "prove nothing as to the transformation from single to double" but they do prove—that is, if the habitat be quite unexceptionable—that wild double Daffodils are still to be found, and this from some points of view is an interesting fact to have elicited. Meanwhile, we hope we are not too heretical in stating our opinion that the single Daffodil, the Daffodil of WORDSWORTH and JEAN INGELOW—we were going to write of HERRICK, but the dictum of PARKINSON above quoted restrained us—is far prettier. Our botanical and cultural instincts, however, forbid us to rest satisfied with a flower merely because it is pretty; we want to know in what its beauty—and, shall we say, its ugliness?—consists; how we may perpetuate and increase the beauty and the interest, and so give to others a share of the pleasure we ourselves enjoy.

As to the question of the specific identity of *Narcissus Pseudo-Narcissus* and *Narcissus major*, we own that, speaking from a botanist's point of view, we can find nothing but very arbitrary lines to be drawn between them. What is the botanist's point of view in this matter? We may be asked. In other words, What is a species? No one knows. What we mean at the time of this our writing is simply this, that *N. Pseudo-Narcissus* and *N. major* are so very much alike, except in point of size, that the great probability is they had a common origin. Who is to prove that? Direct proof we have none. We never saw a bulb or a seed of *N. Pseudo-Narcissus* produce *N. major*, or *vice versa*; but, on the other hand, we have seen many specimens (and some are on our table before us as we write) which we can with difficulty refer to either—which are, in fact, intermediate between the two, and therefore, according to our notions, afford evidence of the specific identity of the two. Some of the flowers reputed to have been introduced as bulbs from the woods a few years ago into gardens, are decidedly nearer like *Narcissus major* of gardens than they are like the common Daffodil. So with some of the double forms before us. The double form of the true *Pseudo-Narcissus* cultivated in gardens is larger and fuller than that of the woods, and passes by gradual transitions of size, form, and colour, into *N. major* fore-plant.

The true double *N. Pseudo-Narcissus* above figured (fig. 104) is, as we take it, the same as that shown in HALES' *Complete Body of Gardening* as the "Silver and Gold Daffodil," while the "double Lemon Daffodil" of the same author appears to be a form of *N. major*, though in the work above cited it is distinctly stated to have been produced from the common English Daffodil.

We postpone till another time some remarks on the structural changes, which are very varied, in different "double" *Narcissi*, and for a collection of blooms of which we owe our thanks to Mr. BARR; but as a contribution to the enquiry how far this "doubling," various as it is, is affected by cultivation, we append the following extracts from the work we have just quoted, and referring to the "double Lemon Daffodil":—

"Originally it is only a little waved about the edge; the first effects of culture make the undulations so many indentings; from this state it becomes fringed and ragged in a wild variety of forms; and, as the extreme force of culture in the present instance, it is cut deeply into a multitude of segments, resembling so many petals. These mix themselves with the proper petals, from which they are distinguished only by being a little narrower, and form together with them a vast and very elegant flower.

"But though it is not easy to raise it from the common *Narcissus* seed, yet the gardener who follows our general instructions of sowing the seeds of a good plant in that species, and resowing the seeds of the best flowers raised from those, will not fail, amidst the varieties he shall produce from those several proceedings, to see some of the true double *Lemon Narcissus*. These will be of various degrees in colour, and even the meanest fall of beauty."

FIG. 105.—AGAVE DENSIFLORA, ETC., IN THE GARDEN OF M. THURET.

We may to this add what PHILIP MILLER says of the way in which Narcissus incomparabilis becomes double under cultivation :—

"This sort sports and varies more than any of the other; the following variations I have traced in the same roots. The roots of these the first year produced very double flowers of the sort which is commonly called the Incomparable Daffodil. The six outer segments of the petals were longer than either of the others, and white; the middle was very full of shorter petals, some of which were white, others yellow, and collected into a globular figure. Some of these roots the following year produced flowers less double than before, with white petals in them, but the larger petals were of a sulphur colour, and the others yellow; from this they afterwards degenerated to half double flowers, and at last to single flowers, with a cup half the length of the petal, in which they have continued to flower many years; so that we may conclude that those varieties were first obtained from the seeds of this single flower. (Miller's *Gardeners' Dictionary*, 8th edition.)

"We give a prominent position to the accompanying remarks on INTERNATIONAL FLOWER SHOWS, inasmuch as they contain suggestions which are deserving of full consideration by those who have to do with the management of these great exhibitions :—

"I notice your remark that you hope the word 'International' will be omitted in future announcements of shows, however large, which are really only local shows. I trust your wishes may be realised; and, having taken part in most of the really International shows on the Continent, perhaps I may be allowed to remark that they appear to have wanted, in order to make them more complete, the distribution of two or three more medals. I take it—

1. That these International Shows require to be made imposing, as well as to show good cultivation.
2. That one main object is to exhibit not only what the nurserymen of the country in which the show is held can produce, but also what the nurserymen of foreign countries can do.

3. That, as there are many amateurs who could produce plants of every class of excellent size and good cultivation to add much to the beauty and interest of the show, the managers should do all they can to induce amateurs, both native and foreign, to send their productions.

4. When we consider the great labour, and also the great expense of getting up and conducting these shows of a few extra pounds can be of no consequence, if the success is thereby made more certain and complete.

Usually there is one—sometimes there are two—grand medals of honour given to the exhibitor who has conducted most to the beauty and *claret* of the show. Instead of two, I would suggest that four should be distributed, namely, one to native nurserymen, one to foreign nurserymen, one to native amateurs, and one to foreign amateurs. Managers, in order to determine the award of these medals should be clearly laid down in the programme. It seems to me that a vast many more persons would pay to see foreign productions, than to see plants which they may have seen many times before at their ordinary shows.

"In the forthcoming Brussels show, imagine the excitement there would be in that city if it were known that Lord LONDESBOURGH, Mr. BOCKETT, Mr. DAY, Mr. WRIGLEY, and some of the Manchester Orchid growers would exhibit Orchids; or if Mr. WILKINS, Mr. HUTCHINGS, Mr. FRANKS, and others of our good plant growers were to show their specimen plants. It might be that the additional Médaille d'Honneur given by the King or Queen or Municipality, for having contributed most to the success of the show, would tempt them to exhibit, when merely the ordinary prize, however good, would not. Robert Warner, 8, Crescent, Cripplegate."

— THIS week we give another illustration (fig. 105) from the rich garden of M. THURET, of Antibes. Like the others it is engraved from an exquisite photograph taken by M. BORNET. The Agave in the centre of the picture is *A. densiflora*, of HOOKER; the Aloe to the left is *A. coccinea*; the *Dasylium* to the right of the reader is *D. confertiflorum*; the *Aspidistra* is *Opuntias*, *Euphorbias*, *Mammillarias*, &c. is shown, while a fine Olive forms the background. With noble objects the Agaves make what they can give in this way our illustration sufficiently shows.

— A rumour having obtained credence that the Council of the ROYAL HORTICULTURAL SOCIETY do not intend paying the prizes of 1874, we are requested by the Secretary to say that such a rumour is unfounded in fact, and that the prizes of 1874 will be paid as soon as the funds of the Society will admit of it.

— THE tributes to the memory of the late DANIEL HANBURY are sure to be neither few nor formal. Among others who have received the following from N. NAUDIN, of Collioure in the department of the Eastern Pyrenæes :—

"I cannot express how shocked I was at the sad announcement in the *Gardeners' Chronicle* of the unexpected and premature death of my excellent friend, DANIEL HANBURY. What a cruel loss for science, for his family, and his friends. Allow me to express in the

Gardeners' Chronicle the sorrow I feel at the loss of one with whom I have so intimately associated for more than fifteen years. I have had abundant evidence of the value of his friendship, of his generosity and kindheartedness. It was partly by his aid and encouragement that I was enabled to establish here an experimental garden, to which I have devoted my time and my energy for the last six years. It is to him, also, that I owe very many of the most interesting plants which I cultivate. This modest establishment was, in his eyes, the auxiliary and complement of his brother's establishment at La Mortola near Mentone.

"Scarcely a month ago he sent me seeds of *Furca allacea* for trial. I was about to write to him to tell him of their progress when I saw the announcement of his death. How many associations those plants recall. I have them continually under observation, and constantly have them awakened better regrets. These who have been intimate with DANIEL HANBURY will understand and share this feeling. Would that this slight expression of sympathy could soften the grief of his family, C. Naudin."

— Friday and Saturday, July 23, 24, and 25, are the dates fixed for holding the first exhibition of the HELENSBURGH and WEST OF SCOTLAND ROSARIANS' SOCIETY.

— From Oxford we learn that "A general course of BIOLOGICAL INSTRUCTION, devised so as to give a survey of the leading features of plants and animals, will be given during the summer term conjointly by Professor LAWSON and Mr. RAY LANKESTER, in the herbarium at the Botanic Gardens. The course will be carried on daily, commencing on April 19, and will consist of thirty-six lectures, each followed by practical study of the subject treated of in the lecture. The lecture hour will be from 10 to 11 A.M.; the laboratory work from 11 A.M. to 12.30 P.M., and from 1.30 to 4 P.M. The following is an outline of the subject-matter of the lectures, and an enumeration of the types, whose structure and (where possible) life-history the student will be enabled to examine in actual specimens provided for the purpose :—

EXAMPLES:

PLANTS.—Class I. Algae. 1, *Palmella*; 2, *Protococcus*; 3, *Volvox*; 4, *Notoc*; 5, *Oscillatoria*; 6, *Bacterium*; 7, *Closterium*; 8, *Bacillaria*; 9, *Zygnema*; 10, *Laurencia*; 11, *Fucus*; 12, *Ceramium*.—Class II. Fungi. 13, *Torula*; 14, *Penicillium*; 15, *Edwardsia* (plasmidium); 16, *Aschophora*; 17, *Peziza*; 18, *Agaricus*.—Class III. Muscæ. 19, *Marchantia*; 20, *Funaria*.—Class IV. Filices. 21, *Pteris*; 22, *Selaginella*; 23, *Coniopsis*.—Class V. Gymnosperms. 24, *Pinus*.—Class VI. Angiosperms. 25, *Pisum*; 26, *Scilla*; 27, *Arum*; 28, *Chamærops*; 29, *Orchis*; 30, *Euphorbia*; 31, *Primula*; 32, *Toraxacum*; 33, *Hieracium*; 34, *Rosa*; 35, *Dianthus*; 36, *Ranunculus*.—ANIMALS.—Sub-kingdom I. Protozoa. 1, *Gregarina*; 2, *Actinophry*; 3, *Spiræocystis*; 4, *Corticella*.—Sub-kingdom II. Coelenterata. 5, *Hydra*; 6, *Coriophora*; 7, *Spongilla*; 8, *Actinia*.—Sub-kingdom III. Vermes. 9, *Planaria*; 10, *Tenia*; 11, *Rotifer*; 12, *Lumbricus*; 13, *Ascaris*.—Sub-kingdom IV. Echinodermata. 14, *Crotalaria* (shell).—Sub-kingdom V. Mollusca. 16, *Plumatella*; 17, *Limacina*; 18, *Anodon*; 19, *Sepia*.—Sub-kingdom VI. Arthropoda. 20, *Asteius*; 21, *Apus*; 22, *Blatta*; 23, *Scorpio*; 24, *Limalia*.—Sub-kingdom VII. 25, *Stages of the Embryon*; 26, *Ascaris*; 27, *Ascidium Tadpole*; 28, *Lamprey*; 29, *Dogfish*.

This course is intended not only to provide for the student, who may take honours in biology in the natural science school, the general survey of the structure of both plants and animals which is necessary preliminary to a more detailed study of anatomy and physiology, but is also open to other students who are not preparing for examination in the subject. It may be indicated that such a course as the present, with a sufficient supply of specimens, can only be carried out once a year—namely, in the summer; and it is therefore suggested to those who may desire to attend, the subject (such as that connected with the various preliminary examinations) may be advantageously postponed until the Michaelmas term, i.e. it is such as to interfere with attendance at the proposed course."

— Some few years since a hybrid between *Libonia floribunda* and a pericarpic *Gliesbreghtii* was exhibited at South Kensington and elsewhere as *x LIBONIA PENHOSIANA*. The plant was interesting, not only for its beauty, but from the fact that it was a hybrid between two genera, *Libonia* and *Sericographis*, and served to show how arbitrary are our so-called genera. Lately M. LINDEN obtained the same hybrid, and, unaware of its previous production, sent it out as a new plant; and in the schedule for the former show it is classed for "new and rare plants, whether in bloom or not (open)," with prizes to the amount of £7, £5, and £3, respectively; and in my con-

— The schedule of prizes has just been issued for the summer exhibition of plants and flowers at the Crystal Palace on Saturday, May 29, and for the Great Rose Show to be held at the same place on Saturday, June 19. A new feature in the schedule for the former show is a class for "new and rare plants, whether in bloom or not (open)," with prizes to the amount of £7, £5, and £3, respectively; and in my con-

nection therewith we are requested to supply an accidental omission in the schedule, by stating that the prizes are offered for the best collections.

— A large Rose Show is announced to be held at the ALEXANDRA PALACE on June 24 and 25, and the managers contemplate holding Fruit Shows in September and December.

— The collection of specimen stone and greenhouse plants formed by the late J. PHILPOT, Esq., of Stamford Hill, came under the hammer at Stevens' Rooms on Friday the 9th inst. Almost all the species realised we may mention *Anthurium Schzerianum*, 120s. to 140s.; *Azalea Duchesse Adelaide de Nassau*, 100s.; *A. Magnificum*, 130s.; *A. Lecontei*, 100s.; *A. Brilliant*, 110s.; *A. Perriana*, 110s.; *Erica Cavendishiana*, 140s.; a larger plant, 200s.; *E. coccinea minor*, 160s.; *E. ferruginea major*, 130s.; *E. Parmenariensis rosea*, 100s.; and *Hederaa tulipifera*, 120s. A covered van, 14 feet by 6 feet 6 inches, 630s. Total amount realised, £568 5s. 6d.

— It is impossible to travel through the large fruit gardens that abound in West Middlesex without being struck with the magnificent PROMISE OF BLOOM DISPLAYED ON ALL KINDS OF FRUIT TREES. Remembering how, in former years Jack Frost has rudely dashed the fall crop upon our lips just as we felt assured of a rich and an abundant produce, so now it would be premature to rejoice although the prospect is so tempting. Last spring we had a magnificent bloom, and had a good crop followed, a comparatively thin bloom must have resulted this year. The early destruction of bloom, however, left the trees at liberty to mature another crop of fruit; and these stood the trees all over, so that we may well look shortly for orchards not less beautiful than they were last spring. Fortunately we have better reason to be hopeful than we had then, as the present is a notoriously backward season—that is, relatively and backwardness in relation to fruits is a pretty certain forerunner of fruitfulness. We have had no occasion to record any prematurely warm forcing days, indeed a general absence of sunshine has made the present spring so far remarkable, and yet vegetation is everywhere looking vigorous, healthy, and promising. In these days, however, populations so much that is of importance to them have been suffering of good crops of fruit that it is no longer one of persons or of localities but of national interest.

— The following prices were realised at a SALE of unusually choice EAST INDIAN ORCHIDS at Stevens' Rooms on April 8.—*Dendrobium Falconeri*, single specimens, 95s. to 100s.; four plants, 90s. to 95s.; six plants, 120s. to 130s. *Dendrobium crassinode*, single plants, 65s. to 105s.; two plants, 84s. to 90s. *Dendrobium Wardianum*, a grand mass, containing upwards of seventy bulbs and numerous young growths, went to Lord LONDESBOURGH for 100 guineas; ten other specimens sold at from 180s. to 200s.; pairs realised from 100s. to 130s.; and in fours from 120s. to 170s.; *Dendrobium vastissimum*, single specimen, 84s.; *Saccolabium truncatum*, single specimen, 84s.; *Phalenopsis amabilis*, var. 80s. Total number of lots offered, 447; total amount realised, between £1400 and £1500.

— There is now in fine flower, in the conservatory at Hatfield House, a magnificent plant of the rather scarce *BRUGMANSIA LUTEA*. The plant is in the finest possible health, and the bright yellow flowers contrast well with the dark green foliage. The plant is worthy of more extensive cultivation where room is plentiful.

— THE KINGSTON AND SURBITON ROYAL HORTICULTURAL SOCIETY will hold its eleventh great show on Tuesday and Wednesday, June 22 and 23, at Norbiton.

— We extract the following from the *St. Louis Daily Globe*. It will be seen that Mr. RILEY's remarks are of a nature to allay the fears of those who dread the importation of the COLORADO BEETLE, and of those who would impose restrictions on the introduction of American tubers to this country :—

"At the meeting of the Academy of Science, last Monday evening, Professor RILEY delivered the following remarks in view of the alarm manifested by certain European Governments about the importation of our Colorado Potato bug—Belgium, France, Switzerland, and Germany having issued edicts of prohibition, and Italy, the Netherlands, and Great Britain having the matter under consideration.

"I must repeat the opinion I have expressed in my all which has very generally coincided in by all who have any familiarity with the insect's economy—that if it ever gets to Europe it will most likely be carried there in the perfect beetle state on some vessel plying between the two continents. While the beetle, especially in the non-growing season, will live for months without food, the larve would perish in a few days without fresh Potato-tops, and would, I believe, starve to death in the midst of a barrel of Potatoes, even if it could get there without being crushed; for, while it is so voraciously devours the leaves, it will not touch the

tubers. The eggs, which are quite soft, and easily crushed, could, of course, only be carried over on the haulm or on the living plant; and, while there is a bare possibility of the insect's transmission in this way, there is little probability of it, since the plants are not objects of commercial exchange, and the haulm, on account of its liability to rot, is not, as far as I can learn, used in packing. Besides, Potatoes are mostly exported during that part of the year when there are neither eggs, larvae, nor Potato vines in existence in the United States. There is only one other possible way of transmission, and that is in sufficiently large lumps of earth, either as larva, pupa, or beetle. Now, if the American dealers be required to curiously sift, after the haulm or soil, and to ship none but clean Potatoes, as free as possible from earth, the insect's transmission among the tubers will be impossible; and when such precautions are so easily taken there can be no advantage in the absolute prohibition of the traffic in American Potatoes. The course recently adopted by the German Government, in accordance with the suggestion made in my last report, is much more rational, and will prove a much better safeguard; it is to furnish vessels plying between the two countries with cards giving illustrations of the insect in all its stages, and to request that passengers and crew destroy any stray specimens that may be found. Let England and Ireland, together with the other European Governments, co-operate with Germany in this plan, and have such a card printed in the newspapers of both the countries, and the meeting-rooms of agricultural societies, and a possible evil will be much more likely avoided."

— POLYGONATUM MULTIFLORUM (Solomon's Seal), is now fine in pots in the flowering house at Chiswick. Mr. BARON finds it best to plant the roots out in a highly manured, rather light soil, after they have done flowering, and allow them to remain there for a couple of years. Treated in this way the roots flower freely when forced in pots, showing very fine graceful spikes of pendent flowers.

— A paper on the best mode of making FIELD EXPERIMENTS useful to agriculturists was read by Professor WRIGHTSON before the Society of Arts on Wednesday evening. He recommended that county agricultural societies should organise field experiments in every district. The plan recommended has been, for a number of years, tried on the Coltswood Hills by members of the Cirencester Chamber of Agriculture, under the direction of Professor WRIGHTSON. The paper, together with a full report of the results of last year's experiments in the Cirencester district, is given to-day in the *Agricultural Gazette*.

— CARDAMINE TRIFOLIA, a plant that cannot be too well known, is flowering on the rockwork at Kew. It is a charming species, of most robust constitution, thriving on dry sandy soil, where few moisture-affecting plants will live. The flowers are of the purest white, and the leaves dark green, forming a neat dwarf tuft, pleasant to look on at all seasons. It was apparently a favourite of the main botanist JOHN PARKINSON, who, after describing the plant, says that "It was sent me by my special good friend JOHN TRADESCANTE, who brought it among other dainty plants from beyond the seas, and imported thereof a root to me." It is a native of Switzerland.

— We owe to the courtesy of Mr. McLACHLAN the following extract from the *Reports of the Zoological Collections of Lieut. W. L. Carpenter, made in Colorado during the Summer of 1873*, concerning *Doryphora decemlineata*, the COLORADO BEETLE.

"This insect is still marching eastward, not a single specimen having been seen west of the dividing ridge. It is probable that should the Potato be cultivated on the western watershed, it would be free from the ravages of this destructive insect for a number of years, but that it would not be so in the case of the potato in that region through the agency of the seed. This I believe to be the manner of their introduction to distant localities, as they are sluggish travellers, and quite incapable of spreading so rapidly by their own instinct. This belief is rather sustained by the fact that the potato from the Salt Lake basin, occasioned by the cheapness of vegetables in the Mormon settlements excluding the importation of Potatoes from Colorado. Not found at a greater altitude than 8000 feet."

— DORONICUM CAUCASICUM, one of the most brilliant of the early spring flowering hardy perennials, can now be seen in fine condition in the herbaceous border at Chiswick. An established clump of it is literally covered with showy yellow Daisy-like flowers. What an effective ribbon it would make in the spring garden!

— THE NOTTINGHAM AND MIDLAND COUNTIES GRAND ROSE SHOW AND HORTICULTURAL EXHIBITION will be held at the Nottingham Arboretum on Friday and Saturday, July 9 and 10.

— IMPURITY IN THE TULIP! Such is the expression frequently made use of by Tulip fanciers, and a tyro in matters relating to this gorgeous flower might be led to think that it is capable of experiencing impure emotions, and giving play to desires of an immodest character. No such moral taint belongs to this flower; it simply applies to the ground colour of

the bloom becoming shaded and stained, and the markings splashed and broadened out of the exquisite proportions which go to the summing up of the possession of high-class quality. A flower that a novice in Tulip lore might regard as paramourly beautiful, is likely to be contemptuously ignored by a Tulip fancier as absolutely impure. There are some flowers that appear to be hopelessly impure. Fifteen and twenty years ago such varieties as Black Prince, Licantique, Sable Rex, Unique, Vesta, &c., were interdicted by some cultivators because of their tendency to come impure. Purity, form, and marking, are three main points in the Tulip that are strongly insisted on; and purity has the first place, because such an indispensable condition of quality. Because purity ranks so high, impurity is regarded as a most glaring defect; it practically disqualifies a Tulip from competing.

— We have lately received through Dr. M. C. COOKE a specimen of *Agaricus ascoporus* (PECK), sent by that gentleman from New York. The species clearly belongs to the subgenus *Flammula*, and we therefore felt greatly interested in examining the gills for the supposed asci. We readily discovered the bodies in question, but we could by no means satisfy ourselves that they were really asci containing sporidia. We therefore forwarded the only specimen to Mr. BROOME, who has sent a sketch of what he himself saw, confirming our own observations, and which is here reproduced (fig. 106). The singular matter is, that besides these bodies there are forked ascidia, which are, however, far less numerous than the bodies in question. These, according to Mr. BROOME's and our own observations, are shortly pelliculate, somewhat top-shaped bodies, with a reticulate surface, the reticulations increasing in number with the process of growth. We do not at all consider them as asci, but as analogous to the hispid bodies which occur on the gills of some species of *Marasmius*, and possibly of the same nature with the echinate bodies which are so obvious on the pileus of *Marasmius Hudsoni*. It is true that such asci have been observed on the gills of *Agaricus melleus*, but this was probably due to the presence of some species of *Hymenozyma*, and the

FIG. 106.—HYMENIUM OF AGARICUS ASCOPORUS (PECK).

observation has not been confirmed. Indeed, late examinations of the spores of some *Coprinus* under germination seem to show that impregnation takes place at a very early period, and that the result is a sporiferous fungus, as in *Ascobelus* or *Peziza* we have from the same process a sporidiferous fungus. The spores of *Agaricus ascoporus* were like those of allied *Flammula*, and were .0004 inch in length. Our figure represents a portion of a gill, showing the tips of the sporophores, a cystidium, and three of the supposed asci in different stages of growth. The dried gills did not show the spicules when moistened. Mr. F. B.

— COSTUS AFER is blooming in the Economic-hall at Kew. It is very little known as a subject of cultivation, and the only original information as to its economic use appears to be that given in the *Botanical Magazine* of 1857, in which volume the plant is well figured. Living specimens were communicated to the Royal Gardens through the Hon. FOS STRANGWAYS, accompanied by the information that "this plant comes from the Isles de Los about 60 miles north of Sierra Leone, west coast of Africa. It is valued by the natives as a specific against nausea, from whatever cause arising, and the part used is the stem after stripping off the leaves and peeling." The leaves also are said probably to contain the active principle, though they are further said to be harmless, and are eaten in a green state, the taste being near that of *Oxalis Acetosella*. It grows very freely in Africa, and may be obtained in any quantity if found of medicinal value. "As far as I have had the opportunity of trying it, it has been uniformly successful in relieving nausea." The roots of *Costus partake* somewhat of the qualities of Ginger, and have had considerable reputation as tonics, but are now out of use. Dr. LINDLEY says that the Brazilian species are subacid and mucilaginous, are used in some disorders, and by the natives are held in great repute. "We are not aware that the property attributed to the present species is at all known to the faculty." Since this was written no investigation seems to have taken place, or further information arisen; and it yet remains to be decided whether the species possesses any virtue of value or not. The stems are simple, about 4 feet high, with elliptical acuminate leaves, glabrous (as is also the

entire plant), and bearing at the summit a dense ovate spike, the bracts broad and imbricating; flowers white, with a slight tinge of yellow. From beneath the spike often proceeds a young shoot; which, when the stem falls or bends to the ground, takes root, and becomes an individual. The roots of *C. speciosa* are used by the natives of the East Indies as an ingredient in a kind of preserve.

Home Correspondence.

Mr. Lee's Violets.—I send you flowers of some of my seedlings. You will see that they vary very much, and upon the plants the heads of blossom present very distinct appearances. Some are much smaller than those sent; some have very upright growth, others will not bear their own weight; some have very glossy leaves, others are downy; and some have very large leaves, 5 inches across, while others are very small, only between 2 and 3 inches. Many have the habit of *Devoniensis*, others more the habit of *The Czar*. What I hope to get is one having a compact, upright growth, and a dark-green leaf, a profuse bloomer, with a round even flower, and the floral scent as *Victoria Regina*. Although the *Florist's Companion* did not think me sufficiently entitled to merit a certificate, yet the demand for its flowers for bouquets is something astonishing. *George Lee, Market Gardener, Clevedon, April 7*. [Some of the flowers sent are remarkable for size, and there is also to be found amongst them not only advance as to form, but considerable variation as to colouring. We hope Mr. Lee may soon realise his anticipations. Eds.]

Tea Rose, Duchess of Edinburgh.—This beautiful Rose quite deserves all the praise that has been lavished on it—it is brilliant colour and perfect shape will soon make it a popular favourite. I got a small plant from Messrs. Veitch, Chelsea, last February, and although it was very weak I at once put it in heat, for my employer, who is an ardent lover of the Queen of Flowers, wished to see it in bloom. It soon began to make a fresh growth, every shoot of which showed a bud. I have sent you a bloom which I think speaks very highly for it, considering the treatment it has undergone. *E. Woods, Tranby Hall, Hull*.

Violet (Neapolitan) Culture in Pots.—In the first or second week in May we shake out some of those grown in pots and select all the young plants, which we plant in rows, singly, 18 inches apart, and at the same distance in the rows, after which they receive a good watering, which must be repeated when necessary. After they have started well into growth, and begin to throw out their runners, five of the strongest, and those having the most solid crowns, are selected and stopped at the points, and kept stopped a fortnight, the object in view being to concentrate the sap into those left, and which eventually are to form the principal blooming crowns. In the first or second week in September we lift the plants, and pot into three sized pots, viz., 24's, 32's, and 48's. We grow 200 plants in pots, namely, 100 in 24's, fifty in 32's, and fifty in 48's; those grown in the 32 and 48-sized pots come in very useful for decorative purposes. We pot them in an admixture of good friable loam, decomposed cow-dung, and leaf-mould, with sufficient sand to keep the whole porous. The pots are well crocked—a thing always to be observed in potting; we have several sieves with meshes of different sizes, through which we pass the crocks, viz., 1½ inch, 1 inch, ¾ inch, and ¼ inch mesh. The largest "rudder" is placed on the floor close to the crock heap, and the others (according to size) are placed on top of it; the top and largest sieve is filled with the crocks, and then receives a shake or two, and the contents are thrown into a large tub, and so on, each sieve receives a shake or two until all are empty, and the contents of each one is kept separately, and placed in the pots in the order named. In potting, the young crowns are placed regularly round the edge of the pots, and the soil pressed firmly together and watered. This done, they are transferred to the frames allotted to them, and plunged in either sawdust or leaf-soil; the former appears very well for the winter months, being a lighter and dryer substance, which consequently retains less moisture at a time when it is our object to keep the temperature of the frame moderately dry; but the latter (leaf-mould) answers better during the spring months, when the roots become more active, and consequently require more food and moisture, which they derive by pushing out of the pots into the leaf-soil. We shade them for a few days when the sun is bright, until they have taken hold of the soil, after which we subject them to the full rays of the sun, when soon after they throw up their ever-welcome and charming flowers, which seldom fail to call forth expressions of admiration from all who see them. We apply liquid manure occasionally, but not before the pots have become pretty well filled with roots. The lights are pulled off every fine day in the winter, to

get the foliage dry, and shut up again before the sun goes off the frame. Chislehurst and neighbourhood is the place, and perhaps the only place, where Violets are cultivated to any extent under glass, and with such satisfactory results. It was whilst I was in the gardens of Earl Sydney, Fingal, Chislehurst, that I first saw the Violet cultivated under glass, both planted out in frames and in pots, and with such satisfactory results that I resolved, when opportunity offered—that is, when I got a head gardener's place—to devote some of my attention to the cultivation of the Violet under glass, as well as out-of-doors, and with the result both my employers and myself are satisfied. There is a difference of opinion with regard to the cultivation of the Violet under glass. Some say they do better planted out in a frame about 6 inches from the glass; others maintain that they do better in pots, treated as above stated; while Mr. Thomas March, Lord Sydney's efficient gardener, who grows the Violet superbly, like most other things he takes in hand, is of the latter opinion. For the last two months we have been picking from two to three dozen bunches per week, and for the last three weeks we could have had as many bunches per day. We place the leaves around the flowers, instead of the Violet leaves—the former acting as a kind of tonic to the flowers, many of which are nearly as large as a two-shilling piece. By this post I send you a small boxful for inspection. *H. W. Ward, Longford Castle, Salisbury.* [A very good sample. Eds.]

Fruit Prospects and Protection.—The cold, sunless weather that has prevailed during the last three months will in all probability save the fruit crop, as it has fortunately retarded the time of flowering at least three weeks. In April, so far, has been most unfavourable, and had the trees bloomed at their usual time the present inclement weather must have proved fatal to them, at least in the case of Peaches and Nectarines. Apricots appear to endure a great amount of cold, provided the blooms can be kept dry. It will be remembered that during March of last year, when most of us despaired of saving even a single fruit on account of the severity of the weather, the flowers set in the freest manner, and the crop in places was unusually heavy. This may have been doubt owing to the cold being continuous, as it is the sudden transition from one extreme to the other that proves so fatal to tender blossoms. The sap is put in rapid motion by a sudden rise in the temperature, to be succeeded by stagnation caused by an equally sudden fall, chilling and paralysing the energies of the plant. Any expedient that will stop such extreme variations of temperature, by preventing the sun from shining too freely on the walls after cold chilly nights, is of the greatest assistance in keeping the trees in health, and securing a crop of fruit. On cold clear nights radiation goes on very rapidly unless interrupted in some way, and the thinnest material possible will make several degrees difference in the temperature of the front of a fruit wall. Old fishnets are perhaps equal to anything that can be obtained for the purpose, and can be had at a cheap rate. If possible, the trees should have a temporary coping, such as a board 8 or 10 inches wide, and from this the nets can be suspended and strained along the front of the trees. By having three thicknesses the meshes cross each other and effectually prevent rain or snow from reaching the wall; thin temporary coverings, such as old nets, branches of Fir or evergreen Oak, are often far more effectual than others of a more costly nature, such as rollers and blinds, that are let up and down and subject the trees to more sudden variations of temperature. The former sift the air and intercept the direct rays of the sun, thus keeping a more equable degree of heat. I have sometimes thought that the dark colour of the net has something to do with the protection it affords, as it is a well-known fact that heat is absorbed by black or dark colours, while those of an opposite shade reflect it. If this is the case, it may be worth while to use black nets instead of those of a brown hue; and the colour of hexagon net, muslin, and other materials for protecting the blossoms of tender fruit may with advantage be changed too. Be this as it may, it is evident that protecting materials of some kind will yet come into requisition this season, for while I write the wind is howling from the north in a manner that portends mischief. Such primitive coverings as Fir branches, evergreen Oak, &c., often save a crop. These should be inverted, so as to throw off any rain that may fall on them, as, placed in the contrary way, they would conduct it on to the trees, and wet it often more fatal than frost. Should we get anything like favourable weather shortly, the present season will be one of the most fruitful on record, as all kinds of trees are thickly studded with bloom-buds. The dry summer of last year checked that exuberant tendency to produce wood, and it is always fostered and encouraged by a season of the opposite character, and the result has been an unusual development of flower-buds. Apricots have been laden with bloom, and appear to be setting well. The trees were quite a sight, and I do not remember to have before seen them with anything

like the quantity of flower they have had this season. Peaches and Nectarines give equal promise of an abundant crop, as their blossoms are just opening, and look strong and vigorous. Pears on the Quince are very full of bloom-buds, but less so on the Pear, except the Passe Colmar, which is laden. Cherries of all kinds are thickly set, and the buds are fast swelling. Apples are more promising than I ever remember to have seen before in this district. The present season is therefore one of great promise as regards fruit, especially the harder portion of it, as they will be unusually late before getting into bloom. *J. Sheppard, Woolverstone.*

Tulipa sylvestris.—Some years ago I brought over from Nyon, in the Canton de Vaud, a quantity of this plant. It has flourished in my garden ever since, spreading rapidly. Last year several blossomed, having two blooms on the same flower-stalk; and this year three bulbs have thrown up stems, bearing three buds each. This, coupled with the fact that a specimen *Triteleia uniflora* growing close by has adopted the same plan of proceeding, and produced two flowers on a single stalk, seems worth recording. *Bernard Piffard.* (Both specimens are instances of fasciation, the result, probably, of an over-vigorous condition. Eds.)

Five-rayed Stars.—I should be very glad if you would tell me and my companions how to strike out a five-rayed star. We have tried and tried again to accomplish it successfully, but in vain, and shall be very thankful for a few hints. *A Youngster.* [We reproduce from a former volume a diagram (fig. 107) which, with a few words of explanation, will put our correspondent in the right way to work. Describe two circles, the inner one with a radius of 5 inches, the outer one with a radius of 20 inches, or in the same proportions. Divide

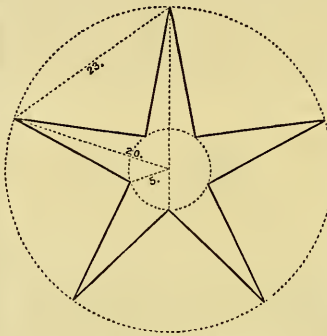

FIG. 107.—DIAGRAM OF A FIVE-RAYED STAR.

the outer circle into five parts by five points, 2/3 inches from each other. Then mark the inner circle off in the same way, but place the points just halfway between those on the outer circle, and by ruling lines from the points on the outer circle to those on the other, a five-rayed star is obtained. The points on the inner circle of a five-rayed star may be easily determined by ruling lines from the points on the outer circle, through the centre and beyond it, until the inner circle is reached. Eds.]

Acubas.—Some years ago a very fine Acuba, 10 feet high, was budded in three or four places with the male plant, and it has been covered with berries every spring since. The male grows much stronger budded than on its own root. *F. H. N., Tenterden.*

"National Health and Wealth."—I have read your review of my *National Health and Wealth*, Part I, and for the greater part of it return you my sincere thanks. There are, however, two or three points in this review with respect to which I feel confident you will allow me space for a few remarks. 1. If such of your readers as shall act on your recommendation to read this little book will first look at the title of my other work, which is given on the cover, and then read in chapter 1 that which I call my apology, they will surely judge me undeserving the taunt of "riding a hobby;" and of having made dry earth closets my favourite theme. 2. For dealing with "liquid manures" I cannot be said to have proposed two remedies. Chapters 3 and 4 of my pamphlet go to establish the fact that, wherever there is a sufficient extent of ground the operation of removing the liquid refuse may, and ought to be at once changed into that of an inoffensive and profitable manuring of the soil. Cremation is mentioned only in the two appendices to the work—in the former in connection with the abolition of ash-pits in

London and other large towns, and in the latter as a safe inoffensive mode of destroying infectious matter. That which I have set forth on these points is indeed novel and very startling, I admit; but I am not about to rest it—I am too old for such work. Let others, with the object of improvement in view, dive into the court and yards of St. Giles' and Mary-lebone, and judge whether anything can be "more horrible to think of" than the watercloset accommodation there for the working classes. 3. If your readers will look with some degree of attention at pp. 8 and 39 of my pamphlet they will see that there is no real inconsistency between my recommendation for the disposal of the liquid refuse of villages, and my "strong condemnation throughout of the pamphlet of the worthless and incompetent of the water system to deal with the problem or remedy for the evils of our present sanitary state." For, first, the two manures entirely differ. The one is free from the solid and most offensive matter, and is applied before putrefaction. The other is heavily charged with that matter, and can scarcely ever be applied otherwise than in a state of putrefaction. The one is undiluted with flushing water, the other diluted five times its bulk. The one would be applied as much as possible in detail, the other in a very large mass or masses. 4. As to "the abolition of privy vaults and cesspools near dwellings, by Act of Parliament" (I have not spoken of surface wells), the substance of my remarks is as follows:—If a safe and profitable substitute for the privy vaults, the cesspools, &c., can be provided, then the abolition of these evils may reasonably and justly be the subject of an Act of Parliament. If no such substitute be provided their attempted abolition would be absurd. The earth system can provide such a substitute, the water system cannot; and no other device has ever been mentioned. Your concluding hint on this subject, "by the dry-earth system to wit," is perfectly just. *Henry Moulle, Fordington Vicarage, Dorset.*

Making Asparagus Beds with Seaweed.—In April, 1874, I made two plantations of Asparagus, one bed being composed of equal parts of seaweed and long dung, and the other of good rotten dung and the same quantity of seaweed. The first bed, on no drainage was required. The plants, which were very small, were taken from the seed-bed, and duly planted out. The one made with seaweed held out against the parching drought of last summer without showing the least signs of distress—without the help of the water-pot; and the "grass" on this bed is 8 inches above ground, so strong that I am almost tempted to cut; whereas the bed made of dung was watered frequently, and at present shows no signs of growth, although the crowns are good. I am about to plant another bed this season, and shall make it entirely of seaweed and sea sand, as I consider the success was owing to the diffusion of the moisture in the seaweed contained. *G. Taylor, Gr. to G. C. Bentinck, Esq., M.P., Branksan, Poole.*

Masdevallia Trochilus.—This interesting Masdevallia having been discovered by me, it may be interesting if I communicate some observations respecting it. In the year 1868 I first met with this plant growing in the frosty heights of the Sorsan district in New Grenada. The whole of the plants I then remitted to Europe died, and I afterwards sent others, in the year 1872, to M. Linden, of Brussels. Masdevallia Trochilus suffers greatly from tropical heat, and from excess of heat generally. Only a dozen out of 200 plants arrived alive in Europe the first time—I brought them under my personal care. The name Colibri, which is given to this plant in its native country, is simply an allusion to the fantastic and bird-like appearance of the flower—though this allusion is rather far-fetched, as there are so many of the allusions in use by the South Americans, especially the Indians. The long-tailed petals seem to be comparable to the long-drawn, prominent feathers of a bird's tail and to the beak of a bird—hence the reason for the vernacular name! I heard it surmised that the name Colibri alluded to a sheen such as exists on the colours of the flower. This is erroneous, as the colours have no metallic glitter whatever. The colours must rather be designated as dingy and monotonous. Nevertheless this Masdevallia is a very interesting one in more than one sense. It seems, indeed, that Nature, in compensation for the poor colours of its flowers, has bestowed on this plant a most exceptional and picturesque shape. From my sketches and notes (taken from flower-stemmed specimens), now before me, I reproduce here the following items. The flowers, as to colour, are less showy than interesting by their original shape. The contour is strangely and sharply cut out, especially as to the upper petal; it is elegantly bent, first backward and then gradually forward. The general size of the flower (properly speaking) does not surpass that of a Walnut. The winged sepals have a length of about 4 to 5 inches each. There is a peculiarity of the plant well worth mentioning, and that is its power of producing out of the same spathe several subsequent flowers. I observed many plants in my stores that

produced flowers out of the old stalks, and which I had considered as being dead. It is possible, therefore, that this *Masdevallia* in its native place has two flowering seasons each year. The strong and compactly formed root-balls get sometimes to a considerable weight and size. The plant, being once established, must possess an extraordinary vital power. The flower-stalks are exceedingly strong, and have in section a well-marked triangular outline; the leaves are of a bright green colour, short and strong, and of an unusual thickness—the term coriaceous will not suffice for them. *Masdevallia Trochilus* has the happy faculty also of growing and in any conditions. It grows quite as well in a loose compost as on the bark of trees, or on decomposed pieces of trunk, and even in a common heavy soil. The amateur Orchid grower will also appreciate its habit of growing in highly elevated regions, as cold as any *Masdevallia* can exist in, not even exceeding *M. elephantopus*. *Gustavus Wallis*.

Hardy Varieties of Broccoli.—The severe winter has tested the hardiness of the different varieties of Broccoli in a manner scarcely to be desired, and it may not be without profit to compare notes respecting them, especially as the time for sowing has arrived, as it will afford an opportunity of selecting such as appear tolerably frost-proof for growing for next season's supply. We have here the following varieties growing side by side under the same conditions as to soil, shelter, cultivation, &c.—Backhouse's Early Winter, Snow's do., Vetch's Spring, and the Great Wiltow, Knight's Protecting, Dilcock's Bride, and Cattell's Eclipse. Most of these appeared to have passed safely through the severe weather, owing to the protection afforded by the snow; but since then two-thirds of all except the two latter have succumbed. Cattell's Eclipse appears thoroughly hardy, for out of 500 plants only one is at all impaired, and that does not appear to have resulted from frost. Dilcock's Bride seems equally hardy, as the whole of these (over 300) are standing nearly unscathed. Eclipse is one of the latest and most serviceable Broccoli grown, as it comes in after most of the other sorts are over, affording a supply of close compact heads till the early Cauliflowers come in. Dilcock's Bride is a very desirable variety, having pure white heads, which attain a large size and are well protected. The two appear, from all I have seen of them, and the satisfactory way they have resisted frost during the past winter, to be the best late spring varieties we have in cultivation. Adams' Early White, at least a select variety we have of it here, is a first-class mid-season kind, as it is very hardy, having withstood the weather much better than any referred to above; and it is now turning in fine heads of the purest white, equal in this respect to a Cauliflower. Such as Snow's, Osborn's, and Backhouse's are indispensable for an early winter supply, and Adams' Early White appears the best to succeed them. Broccoli planted in ground that has been recently dug and manured are not capable of standing nearly the degrees of cold as others grown on hard poor land. The thing is to get a hard woody stem to resist the effects of frost, and this may be partly attained by planting in hard undug land that was fairly cultivated for the previous crop. The stems of such as are planted in loose heavily-manured ground are sure to be soft and sappy, and in this state the sap vessels are easily ruptured. Of course the heads of such as grow in hard ground will not be quite so large as on others more freely cultivated, but it is better to secure small heads than to risk an entire crop for the chance of obtaining large ones. Cattell's Eclipse and Dilcock's Bride have naturally hard woody stems, hence the reason of their having passed through such a winter in so satisfactory a manner. *J. Sheppard, Worcester.*

Obituary.

FROM our Irish contemporary, the *Gardener's Record*, we obtain the intelligence of the death of **THOMAS BEWLEY**, Esq., who had sad event took place on the evening of the 5th inst., at his residence, Rockville, Blackrock, near Dublin. Mr. Bewley's name has been long known in connection with horticultural affairs, of which it may safely be said that he has been, in that division of the United Kingdom, the leading spirit. In him horticulture has lost one of its most liberal, genuine, and staunch supporters. As a cultivator of Orchids, Ferns, and other plants he was remarkably successful; and, indeed, the collection now existing at Rockville is, perhaps, second to none in Ireland. Mr. Bewley was one of the leading merchants of Dublin, and took a very active part in commercial matters, being at the same time among the foremost of its citizens in promoting by voice and purse whatever might tend to advance the prosperity of the country. In private life he was greatly esteemed among a wide circle of friends, for his kindness, benevolence, and generosity. His volume for 1864 contains at p. 580, 669, 675, and 698, a full account of Mr. Bewley's garden, and his grand collection of

plants, which is there spoken of as "the finest collection of exotics to be found in any private garden in the United Kingdom."

The Villa Garden.

SEED SOWING.—How imperfectly this is done by inexperienced gardeners can very frequently be observed by any one residing in a suburban district, who takes an interest in what his neighbours attempt in their gardens. Two main faults are committed by persons who take an immense deal of trouble about their gardens, and yet do not succeed as they could desire, because they do the right thing in the wrong fashion. They sow seeds in unsuitable places, and they sow them in an imperfect manner, which prevents them germinating so freely and vigorously as they would if better managed. Looking over into a neighbour's garden some days ago, we were much interested in his mode of sowing peas; it was an excellent illustration of the principle just laid down, of doing the right thing in the wrong fashion. Between the Box edging and a line of Gooseberry trees on one side of his garden path there was a space, some 18 inches in width, that would have done well for rearing some Parsley, Mustard and Cress, Broad-leaved Cress, Radishes, and other useful things of dwarf growth; but of all the unsuitable places in his garden he selected this, seemingly the most unsuitable, to sow some tall Peas; and the way he went to work furnished an excellent example of "how not to do it." In the first place, he merely pricked the surface of the soil with a fork, for the purpose of loosening it, so as to enable him to draw a drill, instead of boldly digging it deeply—for it had lain by all the winter without moving, and had become close and stiff—and then breaking it finely so as to be suitable for the seed. His next proceeding was even more alarming, for by dint of a good deal of chopping with a hoe he drew a drill, pulling the soil into the gravel path and tearing up or breaking off the Box edging in the act of doing so. This done, the Peas were sown, far too thickly; and the layer of Peas was something like 3 or 4 inches in width. To make matters worse, rain fell during the act of sowing; the work had to be suspended, and when the rain had passed away the state of the path can be better imagined than described. Alas! that so many good intentions, and so much patient labour, should have been so unprofitably invested. Even had the spot been suitable for Peas, the mode of sowing was radically wrong.

PEAS.—If the garden be small let dwarf Peas, such as Maclean's Advancer, Wonderful, and Premier, be selected—varieties that require only short sticks to support them. An open spot must be provided, and the ground deeply dug, and some manure mixed in with the soil if it be poor, for it is a waste of labour to sow Peas in poor soil. The drills should then be drawn, using a line across the ground to have them straight, and they should be at regular distances from each other, say from 2 to 2½ feet apart in the row for such sorts as those just mentioned. Such Peas are of a branching habit: the main stalk throws out branches, and therefore the seed should be sown thinly to allow of a free branching growth. Peas sown in this way cannot fail to bring good and acceptable crops. Supposing that the early crops of Peas are above the ground, some such varieties as these we have suggested should be sown for successional crops, if the size of the garden will admit of it.

FRENCH AND RUNNER BEANS.—As a general rule, amateur gardeners, and especially those who are not much versed in the art of gardening, attempt too much to restrict rather than to extend the dimensions of their vegetable beds, and the result sometimes is a mere taste of all and a good crop of nothing. It is said a man should cut his coat according to his cloth, but it seems to be a sounder principle to improve on that by saying, cut out your coat according to the size of the body it is intended to cover. In like manner we would say to amateur gardeners, adapt your vegetable crops to the size of your garden. If it is limited in space—and the tendency of these modern times is to restrict rather than to extend the dimensions of Villa Gardens—grow a few good leading vegetables, such as Peas, French Beans, Asparagus, Cauliflower, Potatoes, Salads and Onions. The common green crops, useful as they are as winter vegetables, might reasonably be excluded, to give room for better things. Thus space should be reserved for a few Dwarf French Beans, which may soon be sown. The Nurg Dwarf and the Early Dun are good free bearing varieties; and the best proof of their excellence is that they are so much grown in kitchen gardens, and the first-named is an esteemed market variety. Dwarf French Beans might be sown

sufficiently wide apart to allow of the Celery trenches coming between the rows. And what is a more profitable and acceptable vegetable than the Scarlet or any other Runner Bean? A line of beans running up stakes, or tall pea-sticks, combines the useful with the ornamental; for not only is a fence of Scarlet Runner Beans a cheerful aspect from the floral point of view, but it may also serve as a temporary screen to shut out an unsightly object. Let the Scarlet Runners have some of the best ground the garden affords; let the plants grow to a height of from 2 to 2½ feet, then pinch out each leader about 6 or 8 inches from the top, and place the sticks against them. Then draw up the soil on either side so as to form a slight trench, and if dry weather sets in water can be poured into the roots without danger of its running away.

Some economical gardeners, desirous of saving a little seed, leave their first crop of Beans for this purpose. This is scarcely a sound principle in gardening, because the energies of the plants are directed in part towards the ripening of seed-pods, instead of being wholly devoted to the production of pods for table purposes. Some pods are pretty certain to be overlooked during the successive gatherings, and these will supply ample seed in the long run.

HARDY ANNUALS.—Some of the dwarf and more showy hardy annuals should now be sown in cases where it is desirable to use them for decorative purposes. Now-a-days seedsmen employ packets in which to retail them, and these packets are printed with minute directions for sowing, &c. A few simple hints may, however, be supplied, which are likely to prove useful to elementary gardeners; and first, here is a selection of pretty annuals that may be employed for the summer display:—*Acroclium roseum*, rose; *Sweet Alyssum*, white; *Campanula Loreyi*, blue, and the white form also; *Candytuft*, crimson and white; *Collinsia bicolor*; *Convolvulus minor*, blue; *Indian Pink*, *Eschscholzia crocea*, yellow; *Gilia laciniata*, dark blue; double *Jacobaea*, *Leptosium roseus*, *Lupinus nanus*, *Mignonette*, dwarf *Nasturtium*; *Nemophila insignis*, blue; and *N. maculata*, spotted; *Portulacas*, double and single; *Santivallia procumbens*, double; *Saponaria calabrica*, *Silene penula*, and red and white *Virginia Stock*. All the foregoing can be sown in the open ground, but let the soil in which they are sown be good and friable; let it be well stirred, and broken to pieces before sowing. Use some fine rich soil to sow the seeds on and cover them with; sow thinly; sow just below the surface, for they all strike root downwards; sow the dwarfest towards the front of the border, and the tallest at the back. Lastly, have the courage by-and-by, when the plants are above the ground, to thin them out, so that a few may go on vigorously, and not all be pany for want of room in which to grow. Add to all this the virtue of cleanliness, which will induce the gardener to keep his patches of annuals free from seeds, and the soil occasionally stirred about them, as well as kept moist in dry weather. Do all this, and an exceedingly precious reward of floral beauty will crown the labours of the attentive and interested gardener.

The Weather.

STATE OF THE WEATHER AT BLACKHEATH, LONDON, FOR THE WEEK ENDING WEDNESDAY, APRIL 14, 1875.

MONTH AND DAY.	BAROMETER.		TEMPERATURE OF THE AIR.				Hygrometric Deductions from Glaisher's Tables 5th Edition.	WIND.	RAINFALL.		
	Mean Reading for Day.	Barometric Depression from 18 in. Bar.	Highest.	Lowest.	Range.	Mean for Day.					
April 8	30.45	-0.20	56.5	36.1	19.6	44.0	0	ESE: NNE: N	0.51		
9	29.74	+0.01	45.4	38.5	6.0	40.3	5.3	39.4	N.E.	0.35

April 8—Fine, cloudy, and mild; rain fell in early morning. Overcast at 5 P.M., and heavy rain fell till midnight.
 9—Overcast, very dull, and thin rain fell throughout.
 10—Overcast, dull, and mild; rain fell in morning and evening.
 11—Overcast, dull, and mild; fine at intervals.
 12—Overcast, dull; fog in early morning. Brisk wind.
 13—Overcast and dull till noon; fine, and nearly cloudless afterwards.
 14—Fine, bright, and nearly cloudless throughout. Dense fog in early morning.

— In the neighbourhood of London the reading of the barometer at the level of the sea decreased from 29.74 inches at the beginning of the week to 29.33 inches by the morning of the 4th, increased to 29.40 inches by about mid-day on the 6th, then turned to decrease to 29.38 inches by the morning of the 7th, again increased to 30.14 inches by the morning of the 10th, decreased to 30.11 inches by the afternoon of the same day, and was 30.13 inches at the end of the week. The mean reading for the week was 29.66 inches, being 0.71 inch below that of the preceding week, and 0.28 inch below the average.

The highest temperatures of the air (at 4 feet above the ground) ranged from 45° on the 9th to 50° on the 4th, the mean value for the week being 52°. The lowest temperatures of the air varied between 43° both on the 4th and 5th, and 37° on the 8th; the mean value was 40°. The mean daily range of temperature was 12°, varying from 10° on the 8th to 6° on the 10th. The mean daily temperatures of the air and the departures from their respective averages were as follows:—4th, 49°; 7, 47°; 5th, 48°, +2°; 8, 46°, -2°; 9, 47°, +1°; 6th, 44°, -2°; 10th, 49°, +7°; 11th, 43°, -5°; 12th, 47°, +1°. The mean temperature of the week was 45°, being 0.4 below the average, as deduced from observations extending over a period of sixty years.

The highest readings of a thermometer with blackened bulb in vacuo, placed on grass in sun's rays, were 118° and 120° on the 4th and 8th, but on the 10th 52° was the highest reading. The lowest readings of a thermometer on grass, with its bulb fully exposed to the sky, were 36° on the 3rd, 33° on the 6th and 8th, but on the 4th the lowest reading was 42°. The mean for the seven low readings was 38°. The direction of the wind was S.W. and N.E., and its strength brisk.

The weather during the first five days of the week was fine, partially cloudy, and mild, but on the last two it was dull, somewhat cold, and the sky overcast.

Rain fell on every day in the week: the amount collected was 1.22 inch.

In England, the extreme high day temperatures ranged from 64° at Sunderland to 51° at Liverpool and Newcastle-on-Tyne, the general average over the country being 55°. The extreme low night temperatures varied from 39° at Sunderland to 32° at Bristol, the general average being 35°. The mean of the extreme ranges of temperature in the week was 20°, the greatest range being at Sunderland, 29°, and the least at Bradford and Truro, 14°. The mean high day temperatures ranged between 53° at Sunderland and 47° at Newcastle-on-Tyne, with a general average of 50°. The mean low night temperatures varied from 42° at Truro to 37° at Newcastle-on-Tyne, with an average value of 39°. The mean daily range of temperature in the week from all stations from 10° to 13°, varying from 14° at Sunderland to 7° at Truro. The mean temperature of the air for the week was 45°, being 1° lower than the value for the corresponding week in 1874; the highest was at Blackheath, 45°, and the lowest at Newcastle-on-Tyne, 40°.

Rain fell on every day in the week at Blackheath, Bristol, and Leicester, and on five or six days at most other stations; the amounts varied from 1½ inch at Bristol to a quarter of an inch at Liverpool, the general average fall over the country being three-quarters of an inch.

The weather during the week was fine, dull, showery, and the sky generally cloudy.

In Scotland, the highest temperatures ranged from 57° at Greenock and Paisley to 51° at Leith, the general average value being 54°. The lowest temperatures varied between 37° at Leith and 29° at Perth, with a general average of 35°. The mean range of temperature in the week was 21°. The mean temperature of the air for the week was 43½°, being 3° lower than the value for the corresponding week in 1874. The highest occurred at Leith, 44½°, and the lowest at Glasgow, Aberdeen, and Perth, 43½°, respectively.

Rain fell to the amount of 1 inch at Aberdeen, but at Leith a quarter of an inch only was measured. The average fall over the country was rather more than half an inch.

At Dublin, the highest temperature was 54½°, the lowest 31½°, the mean 44°, and the rainfall 0.11 inch.

JAMES GLAISHER.

Variorum.

THE BAMBOO.—Among the minor products of the Indian forests the production and utility of the Bamboo, as referred to in the report of Mr. Baden Powell, the Inspector-General of Forests, are such that their use supercedes in many instances the necessity for wood. In the northern districts they are not common. Thus, in the Punjab, only a few are found in the lower hills, as Kangra, Hushyapore, and Umballa, and a few near Kaulwulpiee and the Salt Range. Some are small and solid and are prized

for spear handles, staffs, &c.; others are larger and hollow. In the higher hills a small graceful species, said to be *Arundinaria falcata*, found above 8000 feet, is used only for the stems of pipes. In the North-western Provinces Bamboos are found throughout the forests of Dehra Doon, Kumaon, Gurkwal, and Goruckpore, and form a considerable item of revenue. In Bengal they are everywhere abundant. In Sikkim they are almost as much used as in Burmah; buckets, water-troughs, and every kind of utensil being made from them. The very large *Bambusa gigantea* is not found, and, indeed, it is said that no true *Bambusa* is found in Sikkim; all are referred to *Dendrocalamus*, *Schizostachyum*, &c. The peasantry almost everywhere are dependent on these useful articles for building. In many districts two-thirds of the houses are mere huts, consisting of a Bamboo framework, thatched with grass, and filled up at the sides with mats made of split Bamboos or of grass screens. In Madras immense quantities are floated down the various rivers on the western coast. The Bamboo is one of the riches of these provinces. The stems are used for the stems of pipes, and 6 inches diameter near the root. They are readily purchased standing, at 5r., and small ones at 3r. per mille. Millions are annually cut in the forests and taken away by water in rafts. From their great buoyancy they are used for floating heavier woods, and piles of them are lashed to the sides of "pattimars" going to Bombay. The larger ones are selected as outriggers for ferry-boats, or studding-sail booms for small craft.

In addition to the vast export by sea, it is estimated that two lakhs are taken eastward from the Supatalook. The Malabar Bamboo is smaller than the Burmah species. The export by land is stated to have affected these jungles near the railway line so as to threaten exhaustion. But of all provinces producing Bamboos Burmah is unrivalled. As there is no fee charged for the cutting, use, or export of the stems, it is impossible to give even an idea of the quantities cut and exported. The Durian and Karens have names for twenty-eight varieties, from the Bamboos *gigantea*, whose huge hollow stem is often from 10 to 16 inches in girth and upwards, to the useless creeping Bamboo that is found in shady dells along streams. The Burmese turn the Bamboo to every purpose; they weave slips of it into boxes, mats, and baskets, floor their room with flattened pieces, and weave fine slips into boxes, which are then lacquered, and but for their beautiful elasticity would never be supposed to be made of Bamboo network as a basis. The common kinds are used by all classes to hold betel and tobacco. The Karens readily light a fire with two pieces of dry Bamboo. They place the half Bamboo on the ground, cut a notch in it, put a little bit of tinder under the hole of the notch, and then inserting a small bar of Bamboo crosswise saw it backwards and forwards with great rapidity till the heat produced ignites the tinder below.

THE HELENSBURGH HORTICULTURAL ASSOCIATION.—The annual meeting of this Association was held on March 26, at Greenock, in the evening. From the report submitted by Mr. Galloway, the secretary, it appears that the Association has just completed its third session, and that the work of the past year has been of a highly satisfactory character. Instructional papers on various botanical and horticultural subjects have been read every fortnight during the year, which have led to lively discussions at each meeting. The attendance of members has been fairly satisfactory, and the number on the roll has now reached seventy. The medals and other prizes competed for last session were the means of evoking the enthusiasm of the members, and we are glad to learn that several prizes are to be competed for at the end of the present session. The following office-bearers were unanimously elected for the year, viz.:—President, ex-Provost Breingan; vice-presidents, Walter Ure Waddell, Esq., ex-Baillie Stuart, and James Niven, Esq.; secretary, Mr. George Galloway; treasurer, Mr. James Telford; and auditors. After the business was concluded, the members spent the evening in a social manner, the President occupying the chair, and Mr. WADDELL, Vice-President, acting as croupier.

THE OREGON MYRTLE TREE.—Dr. F. S. Matson, of Coos County, Oregon, sends us the following account of the Myrtle tree of that region:—The Myrtle is one of the most beautiful of trees. It grows from 20 to 50 feet high, and from 6 to 20 inches in diameter. Many specimens are larger. It is of very full foliage, with a leaf about 3 inches long by half as broad, of an ovoid-lanceolate form, not serrated, and of a deep shining green. It is an evergreen, and after the habit of its class sheds its leaves in summer. Before they fall, these old leaves turn a bright golden yellow, glistening in the sunlight and flecking the green foliage of the tree with golden splashes. The leaves are delightfully fragrant, and a ride through a grove of Myrtles reminds one of the storied "odours of Araby," or the flower-perfumed "vale of Cashmere." The wood is hard, heavy, fine-grained, and susceptible of receiving a high polish, and when thus finished, and varnished, is of a

dark variegated colour. It is useful for all the purposes for which Walnut, Mahogany, and other like woods are used, and is scarcely surpassed even by Rosewood. The tree is very tenacious of life, sprouts freely from the stump after the tree is felled, is a vigorous upright grower, and may be trained or cut into almost any desired shape. It blossoms in early spring, and the finest honey in the world is gathered by bees which work in the Myrtle groves. It grows in abundance on the river bottoms in this county and one or two counties south of here, but only on the western slope of the coast mountains, and along the streams. It is being cut for lumber and for fuel, and burned in heaps to clear the land for cultivation. Many trees are left standing for ornamental purposes, for which they are unsurpassed by any evergreen known. The fruit is also ornamental, being a round nut inclosed in a smooth green hull, which hangs pendant-like on the branches, something after the manner of *Fuchsia* blossoms. These nuts are somewhat bitter, and are therefore not eaten by people, but are valuable food for pigs, which in these river bottoms keep fine and fat all year. Large numbers of young trees are to be found in the woods here, grown from nuts which have lain over winter. This tree must certainly become a leading evergreen for ornamentation, as it is unsurpassed by any known tree for all the qualities which make an evergreen desirable; and I have no doubt that a very fine fragrant oil may be distilled from the leaves, useful as a perfume, and perhaps for medicinal purposes. Having no facilities at hand to try the purpose, I have not experimented in this direction, but propose to do so at no distant day. Dr. Matson, in the *Boston "Journal of Chemistry,"*

CARBONIFEROUS FRUITS.—Dr. Dana, in the new edition of his *Manual of Geology*, states that the well-known genus of fossil fruits in the coal measures called *Cardiocarpus* was probably related to the modern *Conifers* of the *Welwitschia* type. This is shown by the similarity of the fruit, and also by the close relation of the leaves, that is to say, if those called *Cardites* belong, as is generally supposed, to *Cardiocarpus*. The *Welwitschia* is a botanic form of *Conifer*, producing no leaves except the cotyledonous; but while probably unlike *Cardites* in its embryonic features, it shows what leaves and fruit are consistent with the type of *Conifers*. *Hardwick's Science Gossip*.

THE WOOD INDUSTRY OF SWITZERLAND.—The wood-carving industry of the Bernese Oberland, which does not date further back than 1815, now furnishes remunerative employment for upwards of 2000 workmen, and within the last few years the sales have risen from some £40,000 to nearly double that amount. These are not, absolutely speaking, large sums, but still they have sufficed to spread ease over districts the inhabitants of which, before the introduction of this industry, were pinched by want, and that, too, by supplying work of such a nature that it does not interfere with many other avocations. The cowherd and shepherd tending their flocks in the alpine pastures, the charcoal-burner watching his fires, and the peasant families sitting around the stove during the long winter evenings can, at the expense of a little physical exertion, add greatly to their store of comforts by means of some little skill in carving. A very large proportion of the cheaper articles are actually produced in this manner. The wages for regular workmen in this branch of industry range from one franc (10s.) to six francs (5s.), and even reach eight francs (6s. 8d.) per diem. Almost every variety of timber may be utilised: Fir, Lime, Walnut, Oak, Pear, and Apple trees have all their special applications, and of late years the most renowned makers have taken to carve "Palissandre," or Rosewood, Mahogany, Cedar, &c. Side by side with the wood-carving industry, but greatly surpassing it in pecuniary results, is the manufacture of parquets, which is of still more recent introduction. This trade is carried on in eighteen out of the twenty-two cantons of Switzerland, and is now in the most flourishing condition. As nearly as can be ascertained, the annual production of the twenty odd establishments which carry it on reaches the value of 8,000,000 francs (£320,000). It may fairly be said that hardly a Swiss house, with any pretension to comfort, is now built without a parquet in at least one of its rooms. In respect to neatness, solidity, durability, elegance, and cheapness, the use of machinery here certainly enables the makers to achieve wonders.

The prices throughout the country are nearly all the same; they vary from fifty centimes (a little less than 5d.) per square foot for the cheapest description of parquet, to several francs, according to the richness of the designs and the fineness of the wood. The usual price for the kinds most in demand is, at present, from one franc to two francs per square foot. The ordinary parquet is made of deal, but the oaken floorings are more prized for their solidity. There are varieties of the former, however, made of the wood of *Fir* trees grown in the Alps, at a certain elevation, in which the snowy whiteness and the fineness of the grain is such as to render them suitable for the most elegant apartments. The favourite woods are Walnut, Pear,

Plum, Cherry, Maple, Lime, and Fir, and fine foreign woods are gradually being introduced. The diversity in the patterns is something really astonishing when the low rates obtaining are taken into consideration. Every species of mathematical figure is made use of, together with designs in various colours; and the white, yellow, brown, and black lines are combined in every possible manner, forming lozenges, squares, rectangles, triangles, &c. The venes of floors, and in every direction as the massive parquets varying from 1 inch to 1½ inch in thickness. So far but little use has been made of curved lines in adding to the beauty of the patterns, which is to be attributed to the higher prices which the greatly enhanced difficulties of execution would render necessary. The home demand for parquets in Switzerland has been so far proportionally greater than that for any other country. The facility of getting materials on the spot, the abundance of water-power, and the great increase of new buildings for the well-to-do classes, furnish a ready explanation of this fact. Hitherto the exportation, owing chiefly to the heavy expense for carriage, has not been very large; it attains perhaps to about 20 per cent. of the amount manufactured. *The Timber Trade's Journal.*

CALIFORNIA REDWOODS.—Great forests of the Pacific coast: at many points, especially within easy sailing distance of San Francisco, the available timber has been destroyed. There is, however, an immense belt extending from the Russian River northward. Mills are located at every available point, and at the present moment in Humboldt Bay, the great lumber port of the Redwood belt, even the little creeks and sloughs running into the bay have been cut; thus logging becomes every year more expensive and difficult. The supply is, however, so extensive, and the opportunities for opening new districts so great when the demand for lumber will justify increased expense, that it is not probable that our supply will diminish for many years. There are immense forests of Redwood on both the Eel and Mad Rivers, in this section, yet untouched. There is an immense belt also back of Trinidad. Thence northward the Redwood becomes scattered until we reach the vicinity of Crescent City. Back of this place, and covering the whole of the Crescent Bay and Del Norte Bay on the north and east, and the south, is an exceedingly heavy body of this timber. It extends up the flanks of the lower Siskiyou Mountain, which here juts down to the sea, and ceases at an elevation of about 1200 feet above tide. Many of the trees have a diameter at their base of 13 feet and 14 feet, and the average run of saw logs would be from 6 feet to 8 feet. *North Western Lumberman.*

Garden Operations.

(FOR THE ENSUING FORNIGHT.)

[The subjoined directions are intended to supply general information, and must, of course, be adapted to the peculiar circumstances of each locality. Other departments of the garden will be treated on other days to week in succession, according to the requirements of the season. Special directions for the management of "The Villa Garden" will be found in the preceding columns.]

PLANT HOUSES.

GREENHOUSE HARD-WOODED PLANTS.—As the weather gets warmer young growing stock should have the house closed in the afternoons whilst there is yet a considerable amount of sun-heat, and at the same time syringing the plants overhead, and keeping the stage on which they stand damp. As has before been urged, the stage on which growing stock are placed should be covered with some material that will hold moisture, such as a mixture of sand and ashes. It should be borne in mind that young plants grown in pots in a necessarily small body of soil, and stood upon dry shelves, are surrounded by an atmosphere that, although well suited to them during the damp, dull, winter weather, is unnatural, and much too dry in the growing season when the sun is powerful. This is best corrected by the pots being stood as above described upon a material that will hold moisture from one day to another, regularly giving it a good wetting as it becomes dried. Where the atmosphere is too dry for the formation of healthy growth, what is made is necessarily small and puny, especially the leaves, and without these are developed to their natural size the health and constitution of the plants are far below what they ought to be. As a means of still further securing this necessary condition of the atmosphere continuously, day and night, through the season of active growth, keep the soil under the stages quite moist. The above is an important matter connected with the growth of hard-wooded plants, and one often insufficiently considered. Go carefully over the stock to see that they are free from aphides and red-spider, the eggs of which, if remaining from last summer, will now come to life with the increase of solar heat; moderate fumigation for the

aphides and a liberal use of the syringe for the spider are the best means to apply to these plants. *Solanum Capsicastrum* and *Pseudo-Capsicum* cuttings, advised to be put in some time ago, should now be well-rooted, and at once moved into 48-sized pots, and kept growing freely in a genial temperature for a few weeks, after which gradually harden off and plant them out-of-doors; these next winter will succeed the old plants, which for profusion of berries and general effect as well as coming in early are the best: they should now be cut in nearly as close as three or four years' old *Pelargonium*, at once turned out of the pots, two thirds of the soil removed, and plants of 18 inches apart each way on a warm open border. These plants will stand a good deal of frost, and there is nothing that may be expected to come after this time that will hurt them. The plants so treated and got out thus early get a start, are early in flower and berry, a good portion of the latter being coloured in the autumn by the time of taking them up and potting. It is a considerable advantage with these plants to use a syringe when flowering subjects coloured early in the autumn. Many grow them in pots through the summer, but this is a mistake. So treated the leaves are always deficient in quantity, vigour, and the deep green colour, without which their appearance is much inferior. *S. Capsicastrum* makes naturally a beautiful little pyramid. *S. Pseudo-Capsicum* is equally useful grown in the shape of a small bush or trained with a clear single stem 18 inches or 2 feet in height, and then encouraged to form a head. These standards require frequent syringing.

SOFT-WOODED GREENHOUSE PLANTS.—*Hydrangea* cuttings should now be struck for flowering next spring; suckers that spring from the bottoms of plants that are being forced into flower now taken off and inserted in small pots in a little heat will quickly root, after which they may be moved into 4-inch pots, grown on, and as soon as these are filled with roots remove them into others 6 or 8 inches in diameter—larger than these they should not be grown in, as with good management they will flower well in, as with poor management they will flower in the south of the kingdom that has heads of flowers double the size of the old sort; it is equally as free in blooming, and in every way a most desirable plant. Remove *Campanula pyramidalis*, both the blue and white varieties, into their flowering pots, putting the weaker plants into 8-inch, and giving the strongest 10 or 12-inch. Use for them good loam, with one-sixth leaf soil and a little sand. These are fine things for conservatory decoration, coming in when flowering subjects are not plentiful. Suckers now taken off from the base of the blooming plants will come in for next year, potting them simply in 48's, and placing them in a little warmth to induce them to root, after which they may be moved on, and kept growing in a pit or frame during summer. Seeds of these may also now be sown in a shallow pan in a little heat, and they will attend through the summer, and they will flower next season. *Salvia gmeliniflora* and *splendens* should now be struck. Select cuttings of moderate strength, and put them in half loam and sand; place them in a moderate heat, keep moist and shaded during bright weather. As soon as they are well-rooted, place singly in 48-sized pots, and keep them in a little heat until fairly established, when they may be removed to a cold pit, and grown on, giving them more pot-room as they require it.

CONSERVATORY.—Remove Camellias that have done flowering to their growing quarters. Their place should now be filled by *Asaleas*, *Acacias*, *Daphne indica*, *Anaryllis*, *Cinerarias*, *Primulas*, *Mignonette*, with *Holcias*, *Dentzia gracilis*, *double Primus*, *Roses*, and similar forced plants. *T. Baines.*

FRUIT HOUSES.

FIGS.—The earliest forced Figs in pots will on some small varieties, such as the Early Violet and Early Prolific, soon show signs of ripening their fruit, when watering must be gradually reduced. Still continue to supply those swelling their fruit with a little manure-water twice a week, and syringe the trees at closing-up time. At this period the house can be kept well ventilated in favourable weather, which will cause healthy foliage and improve the quality of the fruit at the ripening time. In the later planted out trees continue to pinch out the points of the young growths, and likewise to thin all the over-crowded shoots. No kind of fruit tree is more benefited by the direct and full rays of the sun than the Fig, any kind of shading, therefore, by too much of their own foliage or that of other plants is injurious. The suckers may now be mulched with rotten manure, which the watering will carry down to the roots, thus imparting vigour to the trees. The night temperature may now be increased to range from 60° to 65°, and in the daytime from 75° to 80° by sun-heat. Early Figs.—If the shifting of the cuttings intended for growing in pots is not already done, it should be attended to as soon as possible, so as to give them a chance of forming nice small bushes before the autumn. A shift from the cutting pot into a 5-inch pot will be

sufficient, then, as they get larger, which they will do rapidly, they may get another shift into a 12-inch pot for fruiting in. Use plenty of drainage, for the frequent waterings they get to percolate freely through it; and if soil can be got of a turfy loamy nature with a little old lime or brick-rubbish, burnt ashes, and rotten manure mixed in, it will form a compost that will suit pot Figs in all their different stages of growth. *William Tillyer.*

MUSHROOM-BEDS.—Materials should now be collected for the making of Mushroom-beds in more open and airy or exposed situations, and in view of procuring a supply of wholesome Mushrooms at such times as those which are grown within-doors become maggoty, as they invariably do about the month of May. Far less time or trouble will be requisite to collect and prepare the materials at this particular time than at others, owing to the fact that the dung may be dried so quickly by simple exposure to the outer air and drying winds. It will be necessary to have rather less of "straw litter" in admixture, as though this addition may have, and indeed has, its advantages during the more adverse winter months, it would at this time cause the materials to become too light, and to dry so quickly as not to leave sufficient latent moisture to ensure the necessary degree of success. Procure, therefore, crude fresh horse-droppings as early as possible, and add to them, where obtainable, about one-fifth part of cow-dung and sheep-droppings respectively, taking care to dry the latter somewhat, separately, before mixing all together. Older beds, which are in bearing, will now need sprinkling daily overhead with tepid water; and, what is equally important, should any show symptoms of exhaustion they may be aided by a good watering with liquid manure. Following this, in about four or five days, give also a surface watering with water containing a few ounces of salt to each gallon, and with the same heated to about 100° Fahr. By such means insect pests will be destroyed, without injury to the buds. *William Early.*

KITCHEN GARDEN.

The condition of the walks and edgings which surround them, even in the best cultivated and most systematically managed gardens, seems a matter which either materially adds to or detracts from their general appearance. Among the multitude of things requiring attention at this period are those, which, if neglected now, and the seed of those weeds which may exist are allowed to become scattered, will add to this source of trouble and annoyance. Salt, in whatever manner it may be applied, is undoubtedly the cheapest and best means to be employed in extirpating weeds and purifying the walks. The application of this would prove fatal where live edgings exist as outlines, particularly in the case of Box, which is the plant most commonly used for the purpose, and which is peculiarly susceptible of injury from its effect, unless preventive measures are taken to arrest its penetration to the roots. So much time was formerly occupied in these gardens under such circumstances in hand-weeding the walks, that it became both vexatious and intolerable. We have, therefore, adopted the following means in the kitchen garden, which, so far as appearance is concerned, rather adds to the effect than otherwise: By placing a belt of finely sifted ashes, about 6 inches wide and 2 inches thick, next the Box on either side of the walks, these can then be moderately salted without in any way interfering with the well-being of the edging plants, and the walks are rendered clean at about a tithe of the cost in labour.

Certain kinds of hardy herbs are constantly in request in most establishments. These are such as hard and soft Thyme, pot and sweet Marjoram, Winter Savory, Sage, Tarragon, and Chervil. Plantations of those of kinds which are largely used should be made annually at about this time, in a moderate way, place, change of soil in the soil, in most other cases being highly beneficial. Divide the roots of soft Thyme, the Marjorams and Tarragon, and plant in rows about 18 inches apart. Sow seeds of hard Thyme and Winter Savory at once, either in pans or outside, and that of Chervil about three times during the season outdoors. Cuttings of Sage should likewise be put in this month. The seeds of other kinds of herbs which are not so generally cultivated should be sown now, and those which are increased by cuttings or a division of the roots should also be made if a further supply be necessary.

The plots of ground where *Potato* crops are intended to be planted should all be in readiness for that operation, which should be proceeded with at once, and be terminated as expeditiously as possible. The distances between the rows and individual plants should be regulated by the condition of the soil; feet apart in the rows, and 1 foot between the sets, will be a suitable distance apart in highly enriched soil. As soon as the early planted ones make an appearance, protection should be afforded either with litter, or by carefully drawing the soil round them, to prevent frost destroying the tops—an injury which, if

repeated, is irreparable. As the rows of recently-sown seeds, such as *Onions*, *Carrots*, &c., become visible, take advantage of the first favourable opportunity to use the hoe lightly between them, and attention to this matter will save much after trouble by destroying multitudes of weeds which are scarcely visible. See to the state of crops in seed beds. Where slugs abound sprinkle the plants through a fine-sieved watering-pot in the evening, and dust the plants over with slaked lime. To check the advancement of fly, dust in the same way with wood-ashes, or lightly with soot. Towards the end of the month make another sowing of Broccoli and similar plants if they will be required. When *Peas* are required in quantity, with quality combined, in August, sow now such sorts as *Vetch's Perfection*, *Wonderful*, and *James Prolific*; and another planting of *Broad and Loosepod Beans* should also be made. That invaluable winter sort, *Stanstead Winter Cabbage Lettuce*, is now furnishing new heads. Look over the *Cos* varieties, and tie up the earliest of these to succeed the others, keeping up successional supplies by using small quantities of seed occasionally. *Crystal and Brighton Cos* are both excellent summer kinds. Prepare the ground for *Beet*, which should be sown towards the end of the month; the true variety of *Hampshire* *Pinable* is one of the best, if not the best, for general use. Different methods of storing this root are practised; we have found no plan to equal that of putting it in a shaded corner, adding a little litter on the top of it, and covering it up with soil: by these means an early sowing is quite unnecessary, as the roots will keep in excellent condition until the ordinary crop is fit for use. If a warm south border is at liberty it will afford a suitable place for a sowing of water *Broccoli*, which should now be made. *Canadian Wonder* is certainly an admirable sort, and should be grown everywhere. Continue to apply former directions in regard to ventilating pits and frames; pot off and prick out seedling plants, as may be required in this department. As early *Tomatoes* advance in growth, abundantly supply them with water having a dash of some stimulating agent in it. *G. T. Miles, Wycombe Abbey.*

Enquiries.

He that questioneth much shall learn much.—BACON.
[MANY enquiries which reach us would be more suitably answered by those of our correspondents whose experience or requirements are, or have been, similar to those of the questioner. These we propose, in future, to gather together for facility of reference; and as far as possible make us wondrous kind, so we would have faith hope that this enquiry column may serve as a bond of sympathy and good-will between our correspondents and readers, and be the means of eliciting much valuable information. Eds.]

46. ROSE TREE BORER.—*G. L. A.* asks if any one can tell him how to get rid of the incrusts of an insect which bores into the stocks of his standard Rose trees, and apparently does much mischief. He also would like to know what the insect is, and whence it comes.

Answers to Correspondents.

BEES: *J. H. N.* writes: "On March 20 a drone was caught at the entrance of a strong hive, and on the 12th another was brought out dead."
BOOKS: *Enquirer, Garden Plants, &c.*, 5s., published at 174, Fleet Street, E.
BOUSSINGAULTIA, &c.: *W. W. C.* Boussingaultia basilloides is not the same as *Basella tuberosa*. The last-named plant is the same as *Uliculus tuberosus*, that was tried some years ago as a substitute for Potatoes. The answer to your query of reference; and as far as possible make us wondrous kind, so we would have faith hope that this enquiry column may serve as a bond of sympathy and good-will between our correspondents and readers, and be the means of eliciting much valuable information. Eds.]
CAMELLIA LEAVES: *R. M.* The injury is doubtless caused by some insect; possibly by the leaf-center beetle. *CAMELLIAS*: as *S. S. Roscoe*. Camellias live to a great age, if kept healthy—we really cannot say to what age or size they will attain. A tree 120 feet high and 60 feet in circumference might go on increasing, if still in health and vigour; but such a tree must already be a grand specimen, and can scarcely be expected to increase very rapidly. Perhaps some of our readers may be able to supply records of still larger ones.
CROPPY GROWING POTATOES: *A. S. B.* Chicory is largely grown in Belgium and Holland, and imported into this country, even though a duty of £30 per ton was levied on the dried root. We think it probable that you might succeed, if you possess the means and knowledge necessary to produce flowers for market. The crop should be sown in drill-rows in April like field-Carrots, and thinned, &c., accordingly. As it is sold dry, we cannot inform you as to its market value in London. *W. E.*
CINERARIAS: *J. G. P.* A good showy variety for home growth, but not so good as many of the many flowers obtained from good strains—James', for example. *F. & S.* Varied and rich in colouring, and generally showing high quality as to form; some are perhaps rather wanting in size. They are a fine strain for decorative use, but scarcely the best named for sale. Indeed many strains of this flower now come so good, and the differences are so slight, that the naming of them has in great measure been given up.
FUNGUS: *An Old Subscriber, Dublin.* The name of

your fungus is *Reticularia umbrina*. The architecture of a door is certainly a most unusual habitat for such a plant.
GARDEN ENGINEERS: *G. T.* 25, Regent Circus, Piccadilly.
NAMES OF PLANTS: *Amateur*, 1, Helichrysum; 2 and 3, Gnaphalium, but in their dried state we cannot say which.—*T. H. S.* We cannot name your plant from the leaf only.—*W. S.* We do not undertake to name florists' flowers. There is too much of a family likeness amongst them.
POLYANTHUS: *J. G. P.* Exceeding rich as a border flower, large, deep maroon, with short whitish bars along the margin and broad deep yellow eye; not a florist's variety, but well worth cultivating as a border flower.
SHADING: *C. H. S.* and *R. S.* A mixture of whitening and new milk, made to the consistency of paint, will answer well.
TANK: *J. H.* If tolerably well diluted with rain-water, the contents of your tank will not be at all injurious to the roots of fruit trees and garden products.
VALLISNERIA: *Subscriber.* *Vallisneria spiralis* is a perennial of the easiest culture. Plant it in a shallow pan or leamy soil, and sink the bottom of a pan or glass dish of water, 1 to 3 feet deep. It will grow very freely in a hothouse temperature; less rapidly, but in quite a healthy manner, in that of a greenhouse or sitting-room. A very suitable place for it would be a glass tank or aquarium, placed in front of a window.
WIREWORMS: *Lady Amateur.* The only remedy you can apply is to catch them. Spread Rape dust or cotton-cake dust on the surface of the soil, and if Cabbage leaves on this, covering over with litter or straw, and sowing the seeds the second day. If you do not succeed in this way, carefully turn over the soil affected and pick out the wireworms.
* * * Correspondents are specially requested to address, post-paid, all communications intended for publication to the "Editors," and not to any member of the staff personally. The Editors would also be obliged by such communications being posted as early in the week as possible. Letters relating to Advertisements, or to the supply of the Paper, should be addressed to the Publisher, and not to the Editors.

Markets.

COVENT GARDEN, April 15.
A moderate supply, sufficient for the general requirements of trade, business not having improved to any extent. Large quantities of excellent Broccoli are still consigned from various places in the West, as well as the Channel Islands, filling up a large gap that would otherwise be felt in respect of French Asparagus has much improved both in quality and quantity. *Theis Taylor, Wholesale Apple Market.*

There is no alteration in the prices of cut flowers or plants in pots.

SEEDS.

LONDON: April 14.—As the season advances the seed trade naturally assumes a retail character. A fair business, however, is still going in Red Clover and other farm seeds. Stocks being now reduced to narrow limits, prices of all descriptions keep exceedingly firm. A good quantity of Trefoil seed has been changing hands at full rates. Alskate and White Clovers are steady. For Eye-grasses and Italian there is an improved request. An active inquiry at enhanced currencies has been shown for Sainfoin seed. The brisk demand for spring Tares noted last week still continues; of the larger varieties the market is now almost bare. Increased attention is directed towards sowing Malt and Rape seed; 2,000 samples of either kind are scarce. In bird-seeds the business passing has been too small to materially affect quotations; more money is, however, asked for Hemp seed. Linseed is without change. Blue Peas are dearer. *John Shaw & Sons, Seed Merchants, 37, Mark Lane, E.C.*

CORN.

At Mark Lane on Monday trade was quiet. The show of English Wheat was small, but that of foreign grain, and millers were not generally disposed to operate in either, unless at some reduction from previous rates. Grinding Barley of choice quality was about 6d. per qr. higher in price, but there was little notice taken of malted and other sorts. Malt was somewhat cheaper. In Oats it was difficult to maintain the rise of 1s. per qr. realised on the preceding market day. Maize was firm, and slightly dearer on the week. Beans and Peas were purchased at about late rates. In flour there was little business, and prices remained unaltered. Business was quiet on Wednesday. Prices for Wheat underwent no material decline. Grinding Barley was fully as dear, but other qualities were cheaper, if anything. Malt remained dull. Oats were comparatively plentiful, and consequently somewhat easier in value; but there was no change in Malting, and the market was quiet. Average prices of corn for the week ending April 10:—Wheat, 43s. 1d.; Barley, 40s. 8d.; Oats, 29s. 6d. For the corresponding week last year:—Wheat, 59s. 5d.; Barley, 48s. 8d.; Oats, 28s. 3d.

CATTLE.

At the Metropolitan Market on Monday the number of beasts was not quite so large as on the previous Monday. The average quality was middling, consequently choice descriptions were not quoted lower. For sheep the demand was good, and some choice half-breds and Downs were sold dearer. The Lamb trade was about the same as last Monday. Choicest calves were rather dearer. Quotations:—Beasts, 3s. 6d. to 4s. 8d., and 5s. 6d. to 5s. 10d.; calves, 5s. 6d. to 4s.; sheep, 4s. 6d. to 5s. 6d., and 5s. 4d. to 4s. 6d.; lambs, 7s. 4d. to 8s. 4d., pigs, 4s. 4d. to 5s. 4d.—Trade in beasts was not brisk at Thursday's market, but Monday's prices were pretty generally realised. Sheep were readily disposed of at fully late rates. A large number of middling calves met with a heavy trade, and the market was continued dear. Lambs did not sell freely, and for milch cows trade was very dull.

HAY.

At the Whitechapel market good hay has been particularly scarce, and in consequence higher in price; but other kinds of fodder, though not plentiful, were not dearer than on Saturday. Prime Clover realised from 10s. to 12s.; inferior ditto, 8s. to 9s.; prime meadow hay, 9s. to 12s.; inferior ditto, 5s. to 7s.; and straw, 3s. to 4s. per load. Cumberley Market quotations:—Superior clover hay, 12s. to 13s.; inferior, 10s. to 11s.; superior Clover, 12s. to 13s.; inferior, 10s. to 11s.; and straw, 4s. to 4s. per load.

POTATOS.

The report from King's Cross is to the effect that trade is quiet at the following prices:—York and Lincoln Flukes, 120s. to 150s.; do. Victorias, 120s. to 140s.; do. Regents, 110s. to 140s.; do. Rocks, 70s. to 100s.; East Lothian Regent, 120s. to 130s.; Perth, Fife, and North County Regent, 80s. to 90s.; do. Rocks, 60s. to 65s.; Essex, Kent, and Cambridge Rocks, 60s. to 60s.; do. Regents, 100s. to 130s.; French, 50s. to 60s.; do. seedlings, 62s. 6d. to 70s.; Belgium, Kidneys, 65s. to 60s.—Dorchester and Spitalfields Markets report that the supplies on sale are moderate, and trade steady at the following prices:—Regents, 80s. to 120s.; Victorias, 100s. to 140s.; Flukes, 110s. to 150s.; Rocks, 65s. to 70s. per ton.

COALS.

The market on Monday was steady, and no alteration occurred in prices. The quotations were as follows:—Walls Ends—Hetton, 26s.; Hetton Lyons, 23s. 9d.; Whitburn, 25s. 9d.; Lamberton, 26s. 6d.; South Hetton, 26s.; Caradon, 25s. 6d.; East Hartlepool, 25s. 9d.; Original Hartlepool, 26s.—The demand on Wednesday was a dull one, but no change occurred in prices. The following prices were quoted:—East Wylam, 20s. 6d.; Holywell Main, 20s. 6d.; West Hartley, 20s. 9d.

H. CANNELL begs to draw the attention of the Public to the **COLEUS "CHAMELEON,"** which is unquestionably by the most attractive and the greatest acquisition in Coleus ever sent out; even the most accurate description conveys but a very inadequate idea of its beauty. The entire Horticultural Press speak of it in the most eulogistic terms. The following is the report of the Editors of the *Gardeners' Chronicle* (May 16, 1874):—

"We have received from Mr. Cannell specimens of a new type of Coleus, of great beauty, and very distinct from those already in cultivation. Sometimes the leaf is mainly of an intense velvety maroon, flushed with bright rose, giving a kind of shot-crism hue, the edge being just tinged with green. In other cases half the leaf is of this character, while the other half is mostly of a deep rosey crimson with golden beaded edge, and sometimes the rose-tinge and the maroon-crimson are variously stratified and blended. The flush of rosey crimson appearing in the maroon gives a remarkably velvety richness, which must be seen to be appreciated. With this superb and varied colouring the plant must be exceedingly effective."

This variety has received First-class Certificates wherever shown. Post free, 2s. 6d. each.
New Florist Flowers and Florist Flower Seed Merchant, Woolwich, S.E.

CHEAP BEDDING PLANTS.

Messrs. CRANSTON & MAYOS

Have this season to offer an immense Stock of Bedding and Spring-flowering Plants—all established in single pots, and thoroughly hardened—comprising—

The Plants offered are quite unsurpassed in the Trade, and are remarkably strong, vigorous and healthy, many of the kinds measuring from 24 to 36 inches in height.

NEW ROSES OF 1874,
Splendid Plants, from 18s. to 21s. per dozen.

Descriptive Catalogues sent free on application.

Address: WILLIAM WOOD & SON,
NURSERIES, MARESFIELD, UCKFIELD, SUSSEX.

New Fuchsia procumbens.

T. JACKSON AND SON have much pleasure in introducing this exceedingly interesting Novelty, which they have purchased from the Gardener of T. C. H. Smith, Esq., of Torquay, and seeds of which are procured from New Zealand. It is of a shrubby trailing habit, producing freely at the axils short erect flowers with orange-yellow tube and violet-black sepals. Strong Plants 5s. each, free by post 5s. 6d.; extra strong 6s. 6d. each.
Nurseries, Kingston, Surrey.

NEW CLEMATIS, to be sent out by JOHN STANDISH and CO. on May 10:—

ASCOTENSIS.—The flowers are considerably larger than the common variety, and are well adapted for cutting each colour, a fine azure-blue; it throws a profusion of flowers the whole summer long, and is of a very vigorous habit. 10s. 6d. each.

MRS. QUILTER.—A magnificent white flower, containing eight petals; it is the largest, smoothest, and purest of all the whites, and a very free bloomer, with strong habit. 10s. 6d. each.

The above are decided acquisitions, and should be in every collection. Orders are now being booked for them.

Royal Nurseries, Ascot, Berks.

Verbenas for Sale.

S. BIDE can now supply for cash, Verbenas, spring-struck, strong, and free from disease of any kind, including Purple King, Scarlet, White, Pink, and many other varieties (of which a list may be had on application), at 8s. per 100, package free. **PEARCOCK EYES**, show and fancy, of the best varieties, 40s. per 100. **GERANIUMS**, plain-leaved and zonal, strong autumn-struck plants, 10s. per 100; Mrs. Pollock, single pots, 20s. per 100. **Cyclid Folia Gem.** in single pots, 20s. per 100. **COLEUS VERSCHAFFELTII**, 12s. per 100. **IRENE LINDENI**, 10s. per 100; **IRENE HERSTI**, 10s. per 100. **CEUTAURIA CANDIDISSIMA**, struck last autumn, and well established, in large 6s. pots, 20s. per 100. **AUREA FLORIBUNDA** and other **CALCEOLARIAS**, 8s. per 100. **HELIOTROPES**, light and dark, 8s. per 100.

S. B. would particularly wish to draw the attention of his numerous customers to his fine stock of **VERBENAS** for this season, which are the admiration of all who see them; and would request that all orders should be sent to him as early as convenient, as he was unable to supply many who applied late last season—general satisfaction being expressed by all those who favoured him with their orders.

S. BIDE, Alma Nursery, Farnham, Surrey.

TREE SEEDS.—Just arrived from India a fine sample of CEDRUS DEODARA, new fresh seed. Price 2s. per lb.

Also the following Californian TREE SEEDS, lately received from San Francisco in excellent condition:—

To Planters and the Trade.

MESSRS. MASTERS AND KINMONT beg to call the attention of Planters and the Trade to their stock of the following trees, which can be furnished at low prices:—

- LIMES, 7 to 9 feet, clean grown.
 - THORNES, of sorts, Standard and Pyramid, including Paul's new Double Scarlet.
 - ASH, Weeping, 6 to 10 feet stems, good heads. [rock.]
 - WILLOWS, Weeping American, American, and Killarney, of sorts, grafted, 5 to 7 feet, including Huntingdon, fastigiated, and cork-barked.
 - BIRCH, 8 to 10 feet.
 - PHILADELPHUS, of sorts.
 - VIBURNUM, of sorts.
 - ILAC, of sorts.
 - OAK, Scarlet, 6 to 8 feet.
 - YUCCA RECURVA, very fine.
 - ROSES, Standard and Half-Standard.
 - Dwarf, of standard.
 - CURRENTS, Black.
 - GOOSEBERRIES, of sorts.
 - APPLES, CANADIAN, of sorts, 2 to 5 feet.
 - ACUBA JAPONICA, 1 to 2 feet.
 - CUPRESSUS SEMPERVIRENS, 2½ to 4 feet.
- Exotic and Vauxhall Nurseries, Canterbury.

Grass Seeds.

BOLTON and CO.'S stock of **NEW GRASS SEEDS** for PERMANENT PASTURE is now complete. It comprises all the best varieties of Fescue, Poa, Meadow Foxtail, Cocksfoot, &c., and the mixtures are arranged to suit the different kinds of soil.

Prices can be given either by measure or by the acre, but in sending orders it is desirable as far as possible to mention the nature of the soil on which they are to be sown.

BOLTON and CO., Seed Merchants, Wood Green, London, N.

NEW PELARGONIUM—"DUCHESS OF EDINBURGH"

This splendid new Pelargonium received First-class Certificates at the Royal Horticultural Society, May 13, and at the Royal Botanic Society, May 20, 1874. It is of dwarf compact habit, and a most profuse bloomer; we have at the present time (April 20) in 6-pots, with forty trusses of bloom averaging from six to fifteen flowers in each truss. The flowers, which are crinkled-edged and of good form, are delicate white blotched with purple. It is without doubt the best decorative variety ever offered. See the Opinions of the Press in the *Gardeners' Chronicle*, the *Garden*, and the *Gardeners' Magazine* of May 16, 1874.

To be sent out May 1. Price One Guinea each. A remittance or reference to accompany all orders from unknown correspondents.

G. BRAD, Nurseryman, Winchmore Hill, Middlesex.

Mangel Wurzel Seed.

BOLTON AND CO. beg to call attention to their fine stock of MANGEL WURZEL. They particularly recommend their—
CHAMPION YELLOW GLOBE.
GORDON'S DORSETSHIRE YELLOW GLOBE.
BERKSHIRE PRIZE YELLOW GLOBE.
MAMMOTH LONG LEG.
TWO FLOVED RED GLOBE.
GOLDEN-FLESHED TANKARD.
All at moderate prices, to be had on application.
BOLTON AND CO., Seed Merchants, Wood Green, London, N.

RICHARD WALKER can supply, for cash—
Red Dutch Pickling CABBAGE Plants, 7s. per 100.
SEAKALE, for forcing, 20s. per 100; do., planting out, 3s. 6d. per 100.
SAGE, and THYME Roots, 6s. per 100.
Best SHOW POLYANTHUS, 8s. per 100.
Mixed laced PINKS, splendid plants, 20s. per 100.
Real Red-skin Flourish POTATOS (they produced 20 tons to the acre last year, 1 believe, and are free from disease), 8s. per cwt.; Myatt's Prolific Kidney, 6s. per cwt.; Jackson Whites, imported from America in 1873, 12s. per cwt.; they are the best Potatoes I have ever grown, and are fit for any gentleman's table, and free from disease. I have grown all sorts of Potatoes, but none like the Jackson Whites.
Market Gardens, Biggleswade, Beds.

Fuchsia procumbens (true).
FRANCIS R. KINGHORN is now sending out the above plants, which obtained Botanical Certificate, and was named and figured in the Botanical Magazine of December last, where Dr. Hooker states that Mr. Blackett's plant is not the same as above, but after my very published list of plants, circulars, and advertisements, I find, at the eleventh hour, a neighbouring firm announcing Mr. Blackett's plant as Fuchsia procumbens, thereby endeavouring to force the attention of those who have already favoured me with their orders, which I hope to merit a continuance of.
Strong established plants at 6s. 6d. each, with a liberal reduction where six or twelve are ordered. Extra plants added to compensate for carriage. All orders delivered free in London.
I can now state with confidence that this plant has proved hardly ever on record to have failed at any expense.
I am convinced the Public and Trade generally will believe that I have the certified stock, and all orders entrusted to me shall have my prompt and careful attention, for the benefit of those who have already favoured me with their orders, which I hope to merit a continuance of.
Strong established plants at 6s. 6d. each, with a liberal reduction where six or twelve are ordered. Extra plants added to compensate for carriage. All orders delivered free in London.
I can now state with confidence that this plant has proved hardly ever on record to have failed at any expense.
Sheen Nursery, Richmond, Surrey.

1875.

READ & CO., THE ORIGINAL PATENTERS and INVENTORS of GARDEN WATERING MACHINES, Garden Engines, Pumps, and Syringes.

"Few things are of more importance in Gardening than good Syringes and Engines. We have seen and had experience of many, but we presume it would be difficult to find more efficient instruments than those made by Messrs. Read, of Regent Circus."—Gardener's Chronicle.

Illustrated Catalogue free on application.

35, REGENT CIRCUS, PICCADILLY, LONDON, W.

RANSOMES' AUTOMATON LAWN MOWERS.

TEN THOUSAND IN USE, GIVING FULL SATISFACTION.—
 These Machines leave no Ribs in the Grass, and are unsurpassed for keeping a Lawn or Croquet Ground in first-rate order. They are now fitted with adjustable handles, to suit the height of the person using the Machine. Either "corrugated" or "plain" front rollers can be supplied at pleasure. A pair of short side rollers is sent with every Machine, to replace the usual front rollers when cutting long grass. The grass can be either collected in the box—the neatest plan—or delivered at the back of the Machine and left on the lawn, to prevent the grass burning in dry seasons. These Machines are fitted with the best wheel gearing, the best steel-edged knives, and hardened steel points and bearings.

Sizes from 8 to 20 inches. Prices from 55s.

Carriage paid to the principal Railway Stations in England. Warranted to give satisfaction, and a month's trial allowed. Orders executed on receipt.

Write for Illustrated Price List to

RANSOMES, SIMS AND HEAD, IPSWICH.

THE "INVINCIBLE" LAWN MOWER (S. EDWARDS' PATENT).

WINNER OF THE GOLD MEDAL AT THE NATIONAL LAWN MOWER CONTEST, BIRMINGHAM, July 8, 1874.

WINNER OF SEVEN First Prize Medals, FROM Sept. 17, 1873, TO Sept. 24, 1874.

The Wood Rollers can be used either at the Front or at the Back of the Cutters. It will do all that any other Lawn Mower can do, of whatsoever make or description.

Prices of Horse, Pony, and Donkey Machines on application. Carriage Paid to all the principal Railway Stations in the United Kingdom.

The "SIENS MESSOR" Machines have a world-wide reputation for their superiority and excellence, and the improvements which have been made in them from time to time still keep this Machine the best and most approved one in the Market. They will cut either short or long grass, hedges, &c., and wet as well as dry, advantages which no other Lawn Mowers possess. They are the only Lawn Mowers in constant and daily use in the Royal Gardens, and in most of the principal Gardens and Parks throughout the Kingdom.

A stock of 500 Mowers is kept at our London Establishment, including all sizes, from which purchasers can make their selection and have prompt delivery.

GREEN'S PATENT "ROYAL" LAWN MOWER is a far superior Machine of its kind to any Lawn Mower extant, and it will cut either short or long grass, hedges, &c., and wet as well as dry.

6 inches	8 inches	10 inches	12 inches	14 inches	16 inches
25s.	35s.	50s.	65s.	80s.	100s.

Delivered carriage free at all the principal Railway Stations and Shipping Ports in England, Ireland, and Scotland. Every Machine is warranted to give entire satisfaction, and if not approved of, may be returned at once unconditionally, without any expense to the purchaser.

Our reason for bringing out the "Royal" Mower is to meet a want which has been repeatedly expressed by the purchasing public, to have a good, useful, and efficient Machine, cheap. N.B.—Those who have Lawn Mowers to repair will do well to send them either to our Leeds or London Establishments, where they will have prompt attention, as an efficient staff of workmen is kept at both places.

GREEN'S PATENT ROLLERS FOR LAWNS, DRIVES, BOWLING GREENS, CRICKET FIELDS, and GRAVEL PATHS.
 Suitable for Hand or Horse Power.

The above can be had from all respectable Ironmongers and Seedsmen in the United Kingdom; or from the Manufacturers, **THOMAS GREEN & SON, SMITHFIELD IRONWORKS, LEEDS;** And 54 and 55, BLACKFRIARS ROAD, LONDON, S.E.

Carriage paid to all the principal Railway Stations in the United Kingdom. Descriptive Illustrated Price List Free on application.

BOULTON & PAUL (LATE W. S. BOULTON & CO.), NORWICH, HORTICULTURAL BUILDERS AND HOT-WATER APPARATUS MAKERS.

Improved Steam-power Machinery for working wood enables us to supply first-class Horticultural Buildings of every description at very low prices. Only the best materials used. Houses designed to suit any situation. Estimates given Free. Gentlemen are respectfully invited to have price from us before ordering elsewhere. Ladies or Gentlemen requiring advice as to the Situation, Style, Dimensions, &c., of proposed Horticultural Buildings, waited upon in any part of England, Ireland, or Scotland.

Our NEW ILLUSTRATED CATALOGUE OF HORTICULTURAL BUILDINGS, containing upwards of 60 Engravings of Conservatories, Greenhouses, Peach Houses, Forcing Houses, &c., Free by Post for 12 stamps.

BOULTON & PAUL'S PATENT UNIVERSAL PLANT PRESERVERS—GREAT IMPROVEMENTS for 1875.

The Judges at the Royal Horticultural Society's Great Meeting lately held at Birmingham, pronounced these to be by far the best and most useful articles of the kind they ever saw, and awarded them the ONLY PRIZE.

Now Ready, our NEW LIST of PATENTS, containing full description and a number of Woodcuts clearly showing the uses to which these handy articles may be applied. Free by Post. PATENT UNIVERSAL PORTABLE PLANT PRESERVERS and GROUND VINERIES.—Instead of having to remove or slide loose glass every time it is necessary to attend to the plants, we attach the glazed lights (21-oz.) with hinges to the frame of each light, thereby doing away with continual breakage of glass and loss of time. Two men can instantly remove a complete length, 12 feet by 3 feet wide; thus proving them to be really portable.

PATENT UNIVERSAL PLANT PRESERVERS, Large Sizes to Build on Brick Walls, for use as Span-roof Pits, suitable for Forcing, Propagating, Growing Cucumbers, Melons, and a variety of other things too numerous to mention. *Far superior to anything of the kind yet offered.*

OPINIONS OF THE PRESS.

GARDENERS' CHRONICLE, February 6, 1873.

The uses to which such frames can be put are fully recognised by practical gardeners, and if any notice can be taken of the great demand arising for such contrivances amongst amateurs, it would appear that they too are not ignorant of their great value.

FLORAL WORLD.

The Ground Vinery which has the greatest advantages is unquestionably that manufactured by W. S. Boulton & Co.

MELON OR CUCUMBER FRAMES.

All sizes (glazed with 21-oz.) ready for immediate delivery. Height at back, 24 inches; at front, 13 inches; sides, 14 inch thick; lights, 2 inches thick. All made of very best red deal. Painted three coats. Every pane of glass is nailed as well as putted in. Each light is provided with an iron strengthening rod and handle.

Glazed with 21-ounce.

GARDENERS' MAGAZINE, May 25, 1872.

Considering their substantial character, portability, and the many ways in which they may be employed, we anticipate a very large demand when they become generally known.

THE GARDEN.

Every convenience is provided to save time in cases of removal, planting, watering, and giving air. The glass is firmly fixed and putted—an essential point. They are complete and ready for use the moment they are received, &c.

Important to Market Gardeners and Others. THE PATENT HAND GARDEN PLOUGH.

This effective little implement meets a long-felt want. It consists of one light but strong steel shovel, for marking out rows to plant, or for loosening up the ground after the plants are up. Also a small Steel Plough, to be used for billing up the rows when desired; and a Cutter for exterminating weeds, and Rake for pulverising the ground. These pieces are made separate, and attached or detached in a moment by means of a simple fastening. Its construction enables the user to push it readily and easily through the ground, stirring the earth, if required, to a depth of six inches. It is exceedingly light, strong, and tasty, and fully adapted to the purposes designed. A large number have been sold, and are giving unqualified satisfaction.

Price, complete, with Shovel, Plough, Weed-Cutter, and Rakes, £2 2s.

RALPH WALLER AND CO.,
 45, Dale Street, Manchester, MANUFACTURERS of all kinds of GARDEN NETTING, &c.
 The serious injury done every spring to Fruit Crops by frost has proved to every Gardener the absolute necessity of providing some Protection to the Trees early in the year. If the blossom in its earliest development be but slightly weakened by frost, the vitality of the fruit-germ is destroyed, and the fruit lost. In this climate, on the average of a century, there is not more than one year in nineteen when the protection is unnecessary. Many fabrics have been tried for this purpose of protection, with more or less success; and we may now say, without fear of contradiction, that we have succeeded in manufacturing the only fabric which is altogether unobjectionable for this purpose. Without unduly nursing, it effectually protects the young germ, and does not impede the action of light and due circulation of air. Some other fabrics do this, and thus weaken the vitality of the tree altogether. Almost every large grower in the three Kingdoms can testify to these facts.

HOthouse SHADING of various thicknesses, superior to any other yet discovered for lightness, strength and durability, standing, as it does, all weathers.

Testimonial from ROBERT WARNER, Esq.
 "I have had the netting No. 6 on my Orchid-house for eighteen months, and I find it now in very good order, and likely to last as many more months, and I intend to use it on all my houses in future, being well satisfied both as to its lasting qualities and also as to the shade it gives, which is sufficient to prevent burning, and yet not thick enough to keep out the light, as the ordinary strong shading stuffs do; indeed, it is suitable for shading any kind of plants."—*Broomfield, Feb. 13, 1871.*

TIFFANY of various kinds always on hand. NETTING and SHADING, in pieces 30 yards long, 1 1/2 yard wide. TIFFANY, in pieces 20 yards long, 38 inches wide. For prices, &c., apply to the above address—
 45, Dale Street, Manchester.

VIENNA PRIZE WIRE NETTING.

Awarded
 The Medal
 For Merit

At
 Vienna,
 1873.

CAUTION TO BUYERS OF WIRE NETTING.

The great reputation and success of Messrs. J. B. BROWN and CO.'S VIENNA PRIZE WIRE NETTING seem to have induced certain Dealers in Wire Netting to advertise an inferior article at reduced prices, specifying the mesh, gauge, &c., as if such were the same in quality and value as the Prize Wire Netting of which Messrs. J. B. BROWN & Co. are THE SOLE MANUFACTURERS.

Messrs. BROWN & Co. would suggest that, before ordering quantities, one roll of their Wire Netting should be ordered and one roll of that advertised at reduced prices. The size and shape of the mesh may then be examined, the thickness or strength of wire, the weight of the rolls and the exact measurements, the general finish of the manufacture, and the quality of the galvanising.

This examination will prove the respective qualities of the Netting.
 90, Cannon Street, London, E.C.—March 12.

PARTNERSHIP.—Owing to the decease of the Proprietor of an Old Established Nursery Business, the Executors are desirous of meeting with a person possessing moderate capital, who would be disposed to take the whole or a portion of the business.—Address, EXECUTOR, care of Messrs. Protheroe & Morris, 93, Gracechurch Street, E.C.

Gardener and Wife. WANTED, as HEAD GARDENER, a steady, middle-aged, married Man, without encumbrance, to reside in the house at Twickenham, his Wife as COOK. Both must be experienced and of unexceptionable character for honesty, sobriety, diligence, and good temper. They would not be required immediately, but any time this month. Apply, by letter, stating the respective wages required, to H. G. BOHN, Esq., 28, Henrietta Street, Covent Garden, W.C.

WANTED IMMEDIATELY, a young Man as PROPAGATOR; one who has a fair knowledge of Plants, and can produce satisfactory references as to character and ability.—Apply in own handwriting, stating experience, age, and wages required, to FRANCIS R. KINGHORN, Sileen Nursery, Richmond, Surrey.

WANTED, a sober WORKING NURSERY FOREMAN and PROPAGATOR, also a practical Man in the Laying-out of Grounds. Good wages given.—J. R. GARDINER, Clarendon, W.C. WANTED, a good GENERAL PROPAGATOR, who is well up in Soft-wooded Stuff, and can Bud Roses.—Apply, with references, wages, age, &c., to JOHN HUNTER, Eastgate Nursery, Peterborough.

To Gardeners.

WANTED, as FOREMAN, a married Man, to look after a Conservatory, Plant Stove, and Fern House. He must be a good hand at Tins and Leadwork, with some knowledge of lower Gardening. Wages £1 per week, with cottage. Wife to attend to Lodge Gate.—B. J. Dean, Salisbury.

WANTED, TWO or THREE good NURSEY MEN—such as can use the knife well, and make themselves useful in Permanent situations. State wages and references to R. AND F. ALLUM, Nursermen, &c., Tamworth.

WANTED, BOUQUETISTS and FLORISTS FURNISHERS, for Plymouth.—Those thoroughly experienced can apply to J. H. FOYNER, 23, Villiers Street, Strand, W.C.

WANTED, a MAN to take charge of Houses in which Pains, Ferris, Ambler, &c. are grown—with a Nursery training preferred.—DRUMMOND KROTHERS, Larkfield Nursery, Edinburgh.

WANTED, several young MEN, accustomed to Nursery-work—they must be good at Tyng and Potting; and also one that understands the Grafting and Budding of Roses.—J. H. DONKEL, Kilburn Nursery, N.W.

WANTED, as HEAD SHOPMAN, a Man of some experience in retailing to one of our large Nurseries. Applications by letter, stating age, experience and salary. BARR AND SUGDEN, 12, King Street, Covent Garden, W.C.

Warehouseman.

WANTED, a SECONd WAREHOUSE-MAN, an active, industrious Man, who is thoroughly master of the work, in a Seed Warehouse to Superintend Pickers, Struggle Pea Crop, &c. Wages, 30s. per week.—HEWLETT, CLARKE AND SONS, 39, King Street, Covent Garden, London, W.C.

WANTED, TWO or THREE MEN, accustomed to Packing Hampers of Plants, or General Nursery-work.—J. R. PEARSON, Chilwell Nurseries, Nottingham.

WANTED, TWO YOUNG MEN for the Glass Department of a large Nursery, where Stove and Greenhouse Plants are largely grown. They must have some knowledge of the business. State wages and references.—B. W. ITHAM, The Nurseries, Reddish, near Stockport.

WANTED, a married MAN, to live in Lodge—Wife to attend Gate, the Man to work in the Gardens. Must be strong and active.—T. HUTLER, Umberslade Park, Hockley Heath, Birmingham.

WANT PLACES.

To Gardeners in Want of Situations,

WHOSE CHARACTERS WILL BEAR STRICT INVESTIGATION. THE PINE-APPLE NURSERY COMPANY devote special attention to this important matter—proper Men to suitable situations. For a GARDENER in a SITUATION, please send particulars to Mr. JOHN BESTER, the Pine-Apple Nursery Company, Maida Vale, London, W.

B. S. WILLIAMS, having at the present time several very excellent GARDENERS upon his Register, is desirous of placing them in Situations where great Experience and trade are required. B. S. W. would at the same time be glad to intimate that when a Gardener is applied for that the filling of the situation should be left with him, as that would prevent unnecessary correspondence and delay.—Victoria and Paradise Nurseries, Upper Holloway, London, n.

Head Gardeners.

JOHN LAING can at present recommend with every confidence several energetic and practical Men, of tested ability as first-rate carter, Ladies and Gentlemen in WANT of GARDENERS and BAILIFFS or GARDENERS for First-rate Establishments or Single-hand situations, can be suited, and have full particulars by applying at Stansfield Park and Rutland Park Nurseries, Forest Hill, London, S.E.

Gardeners and Under Gardeners.

M. CUTBUSH AND SON beg to state that they have at all times on their Books MEN of various QUALIFICATIONS, whose characters will bear the strictest inquiry. Any Gentleman making application would save time by clearly stating the duties to be undertaken, wages offered, &c., so that suitable Men may be selected.—Hedgecroft Nurseries, London, N.

IMPROVER, or UNDER GARDENER, in a Gentleman's Garden.—Age 18. Four years' experience. Suburbs of London preferred. Good character.—D. W., B., Alpha Street, Slough, Bucks.

IMPROVER, in a good Establishment, or JOURNEYMAN where four or five are kept.—Address, with full particulars, A. A., 2, Dulmanston, Terrace, King's Road, Chelsea, S.W.

IMPROVER, in a large Establishment.—I would prefer Kitchen Gardener and Framing Ground Department. Four years' good character from present situation in House and General Work.—W. S., Weacombe, Bicknoller, Taunton.

ROSE GROWER, in a small Nursery.—Age 21. Five years' experience, both in and out-door.—H. N., Mr. Carr's Nursery, Greenstead Road, Colchester.

TO NURSERYMEN.—A Youth (age 17) is desirous of entering a large Nursery Garden in the locality of London, where he could learn the profession thoroughly in all its branches.—Address, with every particular, H. M., Post Office, Richmond, Surrey.

TRAVELLER and CORRESPONDENT.—Mr. THOMAS DUNSTON, The Heathside Nurseries, Bagshot, Surrey, can thoroughly recommend a highly respectable and energetic young Man as TRAVELLER and CORRESPONDENT in the Nursery or Seed Trade. One who understands his business, and is well known in England and Scotland.—T. T. will be pleased to answer any communications in reference.

TRAVELLER, or CLERK or TRAVELLER.—A young Man; thoroughly up in the trade. Highest references.—A. B., 8, Albion Place, Lower Broughton, Manchester.

LABOURERS.—Constant work Wanted as Labourer in a Gentleman's Garden, by a single Man; also for Two Ladies, and another of 12 years of age.—Address full particulars to A. B., Post Office, Ashford, Kent.

KINAHAN'S V.V. WHISKY. This celebrated and most delicious old mellow spirit is the very CREAM of IRISH WHISKIES. It is of a quality unrivalled, perfectly pure, and more wholesome than the finest Cognac Brandy. Note the Red Seal, Pink Label, and Cork branded "Kinahan's V.V. Whisky. Wholesale Depot, 20, Great Titchfield Street, Oxford Street, W.

Grateful—Comforting.

E P P S B I F K A S T

"By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected Cocoa, Mr. Epps has provided our breakfast-tables with a delicately flavoured beverage, which may save us many heavy doctors' bills. It is by the judicious use of those articles of diet that a constitution may be gradually built up until strong enough to resist every tendency to disease. Hundreds of subtle maladies are floating around us, ready to attack wherever there is a weak point. We may escape many a fatal shaft by keeping ourselves well fortified with pure blood and a properly nourished frame." See article in the Civil Service Gazette.

Made simply with boiling water or milk. Sold in packets (in tins for abroad) labelled.—JAMES EPPS AND CO., HOMOEOPATHIC CHEMISTS, 48, Threadneedle Street, and 179, Piccadilly, W. Works 1—Euston Road, and Camden Town, London, N.W. Makers of Epps's Glycerine Jujubes for Throat Irritation.

DINNEFORD'S FLUID MAGNESIA.

The best remedy for Acidity of the Stomach, Heartburn, Headache, Gout, and Indigestion; and the best mild Aperient for Delicate Constitutions, especially adapted for Ladies, Children and Infants. DINNEFORD AND CO., 172, New Bond Street, London, W., and of all Chemists throughout the World.

SPRING.—At this Season PARR'S LIFE PILLS are the best clear from the body all hurtful impurities, and promote a regular and healthy action of the Liver and Bowels. Sold by all Chemists.

THE "ARCHIMEDEAN" AMERICAN LAWN MOWER

HAS BEEN AWARDED

GRAND DIPLOMA of HONOURABLE MENTION, Vienna, 1873.
SILVER MEDAL, Vienna, 1870. SILVER MEDAL, Hamburgh, 1869.

NOTE.—The "Archimedean" was specially selected from the Mowers exhibited at Vienna for constant use in the Exhibition Grounds, and gave great satisfaction; and we have pleasure in calling attention to the following Testimonial, received from the Inspector of the Royal Gardens, Schönbrunn, Vienna:—

"Your 'Archimedean' Lawn Mowers have been used for some time past at the Imperial Gardens, and I have great pleasure in stating that they have given perfect satisfaction. Their quick and good work prove them to be the best and most efficient machines of the kind."

PATRONIZED BY

HER GRACIOUS MAJESTY THE QUEEN,
HER IMPERIAL MAJESTY THE EMPRESS OF GERMANY,
THE LATE EMPEROR OF THE FRENCH,

HIS ROYAL HIGHNESS THE PRINCE OF WALES,
HIS IMPERIAL MAJESTY THE EMPEROR OF AUSTRIA,
THE VICEROY OF EGYPT,

And many of the Nobility and Gentry of Great Britain.

CHIEF ADVANTAGES.

They are extremely LIGHT IN DRAUGHT,
SIMPLE IN CONSTRUCTION, WELL
MADE, and NOT LIKELY TO GET
OUT OF ORDER.

They cut LONG or SHORT, WET or DRY
Grass, and do not clog.

They have no ROLLERS IN FRONT of the
Cutters, and therefore cut the Grass as it
GROWS, and do not miss the BENTS.

They work well on SLOPES, STEEP EM-
BANKMENTS, UNDER SHRUBS, and
close up to Trees, &c.

They can be USED either WITH OR WITH-
OUT GRASS BOX, as may be desired.

TESTIMONIALS.

From A. F. BARRON, Esq., Royal Horticultural
Society, Chiswick Gardens, W.

"GENTLEMEN,—We have now had your 'Archimedean' Lawn Mower in use for several months, and without hesitation I can truly say it is the *best and most efficient* implement of the kind we have ever used."

From the late Mr. GEORGE WYNESS, Royal Gardens,
Buckingham Palace.

"GENTLEMEN,—I beg to say that we have had your Patent 'Archimedean' Lawn Mower at work in Her Majesty's gardens at Buckingham Palace for some time past, and I have much pleasure in testifying that it has given every satisfaction, as it does its work well and quickly."

From the Rev. J. H. WHITE, Hemingford Grey,
St. Ives, Hunts.

"I am much pleased with the working of your 'Archimedean' Mowing Machine. I think it superior to others which I have used in previous years."

OPINIONS OF THE PRESS.

"The quickest, most simple, and most efficient Mower ever used."—*Gardener's Chronicle*.

"Far superior to any of ours."—*The Field*.

"Remarkably easy to work."—*Gardener's Mag.*

"We feel bound to recommend it to our readers as one of the best Mowers we have as yet made acquaintance with."—*Floral World*.

EVERY MOWER IS WARRANTED TO GIVE AMPLE SATISFACTION,

And if not approved of may be returned within a Month, and the amount paid be refunded.

To Gardeners.
 Gardeners are most respectfully Invited
 to Visit
THE PINE-APPLE NURSERY,
 MAIDA VALE, LONDON, W.,
 Where it is anticipated they will be
 highly gratified.
JOHN BESTER, Manager.

Carters

NEW NASTURTIUM RUBY KING
 (With dark-coloured foliage), per packet, 1s. 6d.
 A seedling variety of that type of Dwarf Nasturtium origi-
 nated by us—viz., the dark-tinged or King of Tom Thumb
 section—the popularity of which is now universal, from the fact
 of their bright colours contrasted with dark foliage, compact
 habit, and duration of bloom, rendering them quite equal in
 effect to bedding Geraniums. The colour of the new variety
 now offered is quite unique and distinct—pure pink shaded with
 carmine—and forms an effective contrast with the varieties
 already in cultivation.

Carters

THE QUEEN'S SEEDSMEN,
 237 and 238, HIGH HOLBORN, LONDON, W.C.

DRACÆNAS—PRIZE-WINNERS.

MR. WILLIAM BULL

Offers a dozen Specimen Plants, probably the most handsome in Europe, in twelve varieties embracing the newest and most distinct kinds in cultivation. Apart from the value of these Dracænas for winning prizes wherever and whenever exhibited, the Plants are pictures in themselves for ornamental and decorative purposes.

AN INSPECTION IS INVITED.

ESTABLISHMENT FOR NEW AND RARE PLANTS, KING'S ROAD, CHELSEA LONDON, S.W.

TO THE TRADE.

TO OBTAIN THE

Best Garden Lawns and Croquet Grounds

sow

SUTTONS' LAWN GRASS MIXTURE,

Which forms a close velvety turf in a very short time. For making New Lawns or Croquet Grounds 3 bushels or 60 pounds is required per acre, or 1 gallon to every 6 rods (or perches) of ground.

For improving these already in turf, 20 pounds should be sown per acre.

March, April, and May are the best months for sowing.

Price 1s per lb.; 20s per bushel.

From Mr. J. MERRICK, Gardener to S. Forster, Esq., Le Court.

“The Seed you sent me last year turned out uncommonly well. Several gentlemen who came to Le Court could scarcely credit, from the appearance of the lawn, that it was only sown in May. In August it was as fine and thick as I have seen some lawns that had been laid down for three years.”

Instructions on the Formation and Improvement of Garden Lawns and Croquet Grounds Gratis and Post Free.

American Plants without Peat.

W. M. MAULE and SONS beg to offer the choicest Hardy English and Continental RHODODENDRONS, with Belgie and other AZALEAS, at 20s. per dozen, £10 per 100.

The Plants are grown in a stiff Loamy Soil, on an exposed and elevated situation, and will thrive in any soil free from Lime, Iron, or Chalk. Large Bushes of the Ponticum and Catawbiense varieties, 4 to 5 feet high and as much through, 60s. per dozen. Arrivals in May is the best time for planting.

The Nurseries, Bristol.

Hollies.

ANTHONY WATERER respectfully invites the attention of Holly buyers to the very fine Stock to be seen growing at Knap Hill. It comprises upwards of Thirty Thousand Plants, from 7 to 10 and 12 feet high, of the finer Gold, Silver, and Green-leaved kinds, affording a choice in size and variety such as can be met with in no other Nursery in Europe. Every Plant has been recently removed, and will be guaranteed.

The Stock of Common Green Hollies alone occupies 5 acres of land, and Purchasers will find them in large numbers of all heights up to 15 feet.
Knap Hill Nursery, Woking, Surrey.

Varietied Bedding Geraniums.

ALFRED FRYER offers the following GERANIUMS at per dozen for each—Golden Tricolors: Mrs. Dummett, 3s. 6d.; Louisa Smith, 3s. 6d.; Mrs. Pollock, 3s. 6d.; Sir Robert Napier, 3s. 6d.; Sophia Dumasque, 3s. Silver Tricolors: Miss Burdett Coutts, 3s. 6d.; Mrs. John Clutton, 3s. Golden Bronze: Annie, 3s. 6d.; Bronze Beauty, 3s. 6d.; Kentish Hero, 2s. 6d.; Roi de Siam, 3s. 6d.; Walkham Bronze, 2s. 6d. Baskets and packing, 6d per dozen, or 3s. 6d. per 100 extra.

PRICED LISTS post free.

ALFRED FRYER, The Nurseries, Chatteris, Cambridgeshire.

Carnations, Picotees, and Pinks.

ISAAC BRUNNING and CO. beg to announce that they have this Season a very fine and extensive Collection of the above to offer, strong plants of which are now ready for sending out. LIST of Varieties and Prices, together with Illustrated SEED CATALOGUE, on application.

Our ONE GUINEA COLLECTION of CARNATIONS, &c., contains six pairs of choice Show Carnations, six pairs of choice Show Picotees, twelve pairs of Show Pinks, and twelve choice mixed Carnations and Picotees for borders. Carriage and packing free on receipt of Post Office Order. Half of the above quantities, 11s.

Belgrave, Queenstown, County Cork, Ireland.

"Mr. W. E. Gumbleton has this day received the Carnation and Picotee Plants, with which he is much pleased, and would like another dozen of either the same or other varieties."
ISAAC BRUNNING and CO., Great Yarmouth Nurseries.

New Double Zonal Pelargonium for 1875.
First-class Certificate Royal Horticultural Society.

Emily Laxton.

MESSRS. W. AND J. BROWN have again been entrusted by Mr. Laxton with the distribution of the following set of New Double ZONAL PELARGONIUMS raised by him, viz.:

EMILY LAXTON.—First-class Certificate Royal Horticultural Society. The largest flowered and most remarkable Scarlet Pelargonium, either double or single, hitherto sent out. Individual flowers upwards of 2 inches in diameter; full, but not crowded; sprays enormous. Free-flowering, and suitable for winter work. Figured in the *Floral Magazine* for October last. Strong plants, 15s. each.

GUIDING STAR.—The most shrubby and dwarf Double Pelargonium yet raised. Foliage pale green, and partaking somewhat of the character and habit of the Show Pelargonium. Flower very pretty purplish pink, and double: quite unique and distinct. Strong plants, 10s. 6d. each.

ILLUMINATOR.—A striking and distinct purplish carmine-colored variety of the Emily Laxton type, but darker in colour; semi-double, but full; petals large and stout. Strong plants, 7s. 6d. each. The set for £4 10s.

Prizes will be offered for the above in 1876. To be sent out in May next. Coloured Plates of Emily Laxton post-free for 1s. 6d. Electrocs of Single Bloom 2s. 6d. each.

NEW STRAWBERRIES.

MESSRS. W. & J. BROWN are also now sending out Mr. Laxton's fine firm-fleshed New Strawberries—TRAVELLER and EXQUISITE, the flavour of both these is distinct and unequalled. Traveller has received a First-class Certificate from the Royal Horticultural Society, and is undoubtedly the most suitable Strawberry for transmission yet raised. Strong plants of last season—Traveller, £1 per 25, £3 per 100. Exquisite, 12s. 6d. per 25, £2 per 100. Early struck runners of each, in 60-sized pots, 7s. per 25 extra. Prizes for fruits of these will be offered in 1876. Trade terms on application to W. AND J. BROWN, Nurserymen and Florists, Stamford.

Silver-margined leaved Geranium Laura. FRANCIS R. KINGHORN has much pleasure in offering this superior variety, being a strong grower, with very large trusses of pale scarlet flowers, freely produced. Suitable for centres of beds and back rows in borders. Received the highest commendation (a First-class Certificate) from the Floral Committee at Chiswick in 1873, which was again confirmed in 1874. Plants 5s. each, seven for 35s. Sheen Nursery, Richmond, Surrey.

Vines.—To the Trade.

S. BIDE can still supply good strong PLANTING VINES, in Pots, of the undermentioned varieties, at 20s. per dozen (a special price for a large quantity will be given on application)—Tynningham Muscat, Madresfield Court, Black Hamburg, Mrs. Pince's Black Muscat, Lady Downe's Seedling, Burchard's Prince, Seaciff Black, Frankenthal Hamburg, Ferdinand de Lesseps, Black Morocco, Primrose's Frontignan, Black Barbarossa, Sweetwater, Trowers Muscat, Bowood Muscat, Muscat of Alexandria, White Nice, Duchess of Plorench, Kasin de Calabre.

S. BIDE, Alma Nursery, Farnham, Surrey.

LOBELIA "LADY MACDONALD."—Pure white, deeply edged with ultramarine-blue, in the way of "Paxtonii," with flowers four times the size; unrivaled as a bedding or pot plant; one of the greatest novelties introduced for years. This beautiful variety was twice submitted for the opinion of the judges at two of the Exhibitions of the Royal Caledonian Horticultural Society, Edinburgh, last summer, and on both occasions was unanimously awarded a First-class Certificate.

Plants first week in May, 2s. 6d. each.
DOWNE and LAIRD, 17, South Frederick Street, Edinburgh.

NEW PELARGONIUM—"DUCHESS OF EDINBURGH."—This splendid new Pelargonium received First-class Certificate at the Royal Horticultural Society, May 13, and at the Royal Botanic Society, May 20, 1874. It is of dwarf compact habit, and a most profuse bloomer: we have it at the present time (April 12) in 48-pots, with forty trusses of bloom averaging from six to fifteen flowers in each truss. The flowers, which are crinkled-edged and of good form, are delicate white blotched with purple. It is without doubt the best decorative variety ever offered. See the Opinions of the Press in the *Gardeners' Chronicle*, the *Garden*, and the *Gardeners' Magazine* of May 16, 1874.

To be sent out May 1. Price One Guinea each.

A remittance or reference to accompany all orders from unknown correspondents.

G. BRAID, Nurseryman, Winchmore Hill, Middlesex.

NEW CLEMATIS, to be sent out by JOHN

STANDISH and CO. on May 10—
ASCOTIENSIS.—The flowers are considerably larger than Jackmann, and are well shaped, containing six petals each, colour, a fine azure-blue; it throws a profusion of flowers the whole summer long, and is of a very vigorous habit, 10s. 6d. each.

MRS. QUILTER.—A magnificent white flower, containing eight petals; it is the largest, smoothest, and purest of all the whites, and a very fine bloomer, with strong habit, 10s. 6d. each.

The above are desired acquisitions, and should be in every collection. Orders are now being booked for them.
Royal Nurseries, Ascot, Berks.

WOODLANDS NURSERY, MARESFIELD, NEAR UCKFIELD, SUSSEX.

WILLIAM WOOD & SON

Have now the honour of offering a Magnificent Stock of ROSES in POTS, consisting of CHINA, TEA, NOISSETTE, CLIMBING and other Kinds.

The Plants offered are exceedingly robust and healthy.

From 9s., 12s., to 18s. per dozen, and Established in 6-inch Pots at 24s. to 30s. per dozen.

CATALOGUES READY. TRADE PRICE ON APPLICATION.

NEW PLANTS.

MR. WILLIAM BULL

Intimates that the following New Plants will be sent out for the first time in the beginning of May :—

ACALYPHA MARGINATA.

This remarkably fine and elegant stove plant, which is a native of the Fiji Islands, is very distinct, not only in the form of its leaves but also in their markings, from the *A. Wilkesiana* (tricolor), previously introduced. It is of a rather stoutish and vigorous habit, having the erect stems furnished with stalked leaves, which are about 2 inches long and 3 inches wide, ovate-acuminate in outline, somewhat narrowed towards the base, and acuminate at the apex, while the margins are beset with very distinct and somewhat distant saw-like teeth, into each of which run out one or two branches from the marginal vein. The leaves are green with a variable border of rose-colour, extending about one-eighth of an inch in breadth. In a letter which accompanied plants sent to me in 1873, it is referred to as "a very beautiful shrub, never seen in its most vigorous growth in its native country." The leaves have a downy overlapping each other, and completely hide the stems." The flowers are small and inconspicuous, in tall-like spikes. 1 guinea.

CURMERIA ROZELII.

This fine bold-habited rhizomatous perennial was introduced from the United States of Colombia, where it was found by Mr. Rozei; it was described and figured in the *Gardener's Chronicle* of December 27, 1874 (p. 524), by Dr. Masters, as a new and interesting Aroid. The colour of the foliage is a deep green, blotched freely on the outer half of each side with bright yellow-green spots and patches very irregular in size and form; the under surface is of a paler green. The flower spathe are ovate acute, somewhat convolute, hooded at the apex, of a brownish olive hue externally, and cream-coloured within, the spadix scarcely equalling the spathe. 1 guinea.

MARANTA LEOPARDINA.

A deciduous perennial stove plant, growing from 1½ to 2 feet high, with slender erect terete petioles arching at the base, and bearing at the top a spreading limb which is oblong acuminate in outline, abruptly rounded at the base, and with one side considerably larger than the other. The colour is green with a golden rib, but all those near the end of the branch bright yellow in the basal half, the upper half being green or green with golden ribs. At the upper ends of the branches they appear to be almost entirely golden. The upper leaves are shorter than the lower, somewhat wavy-edged, and occasionally about once the length of the petioles, and the bark of the young wood yellow. The peculiar style of colouring, which might almost be called golden-crowned, and the dwarf close habit of the plant give it a very distinct appearance. 1 guinea.

The following New Plants are now being sent out :—

CROTON CHRYSOPHYLLUM.

A very dwarf bushy-habited stove plant, densely branched, and with comparatively small-crowded leaves, which are linear-oblong, ovate, half an inch broad, the lower ones green with a golden rib, but all those near the end of the branch bright yellow in the basal half, the upper half being green or green with golden ribs. At the upper ends of the branches they appear to be almost entirely golden. The upper leaves are shorter than the lower, somewhat wavy-edged, and occasionally about once the length of the petioles, and the bark of the young wood yellow. The peculiar style of colouring, which might almost be called golden-crowned, and the dwarf close habit of the plant give it a very distinct appearance. 1 guinea.

CYCAS NORMANBYANA.

A handsome addition to this ornamental class of greenhouse plants. The leaves have a dorsally compressed petiole, with both faces angular, and the base clothed with furfuraceous down. The lamina is oblong ovate, with a prominent ridge continued up the face of the furfuraceous rachis, the segments numerous, continuous, linear, about 6 inches long, and ½ inch wide, very sharp pointed, almost spiny, slightly narrowed and decurrent at the base, the mid-rib strongly developed both on the glabrous upper and furfuraceous under surface. Mr. W. B. has received a large importation of this new Cycad from New South Wales. The name has been given to it by the celebrated botanist, Dr. Mueller. 1 guinea.

DEMONOROPS ORNATUS.

A charming stove Palm introduced from Java, and having, like most of the other species, finely cut pinnate leaves. At present it is only a young plant, but, however, it is sufficient to show that it will prove to be a plant of very ornamental character. 1 guinea.

FOR NAMES, DESCRIPTIONS, AND PRICES OF—

SATURDAY, APRIL 24, 1875.

LORDS AND LADIES.

IF we examine the flowering plants which form the most conspicuous portion of our British flora, we shall be struck with the comparative want of variety in type which they present. This is the more striking if our view should be a very superficial one; indeed, it is in external features that the general resemblance is noticeable, although, of course, in some cases these are united with other points of greater scientific importance. Excluding such well-marked and natural groups as the Umbellifera, Compositae, and Leguminosae, we shall find a certain type of flower echoed as it were in very different orders; thus, the round five-petalled flowers of the Buttercup are repeated in the larger Cranebills, and again in the Potentillas and Strawberry. Yet further evidence of this general resemblance is offered, on the principle that "the exception proves the rule" by the way in which the attention is arrested by any plant which is strikingly different from the surrounding species, and of this no better instance would be found than is offered by the common *Arum maculatum*, one of the many names of which heads the present paper.

The *Arum* is now beginning to occupy an important position among spring-flowering plants, and is expanding its handsome arrow-headed and usually spotted leaves on many a hedge-bank, while in the centre shoots up at the present unexpanded green spathe. This plant is so different in general appearance from any other British species, and is, moreover, so well known, that any description of it would be unnecessary. Indeed, it is not surprising to learn that it is an outlying species; that is to say, a species which occurs in regions remote from the rest of its congeners, most of the Aroideae being tropical, abounding especially in the large forests of South America.

"Lords and Ladies," one of the most widely known names of the plant, is a favourite flower of the children, who find amusement in opening the spathe, and examining the colour of the spadix. Should this be of a dark hue it is called a "lord;" if light, it is a "lady." Dr. Prior says that this name is "of recent introduction, to replace certain older, and generally very indecent ones." From the wide diffusion of the name the accuracy of this opinion may be doubted, although it does not appear in any of the old Herbals. For the observations as to the objectionable nature of some of the older names of the *Arum* there is, unfortunately, only too much justification. Our ancestors called a spade a spade; and many of their designations for the *Arum* correspond closely with the "grosser name" which "liberal shepherds" used to give to the "long purples" of Shakspeare (*Orchis mascula*), and which we believe is still in use in some parts of Warwickshire. Dr. Prior's comments on Wake Robin and Cuckoo-fruit—two of the most romantic-sounding names of the *Arum*—supply all necessary information, and show plainly enough that the poetical explanations of these designations, which are often given by popular writers, must be unhesitatingly rejected.

But the *Arum* has as many names in English alone as would suffice for several Spanish grandees—far too many, indeed, for bare enumeration here, although one or two deserve special notice. Such, for instance, is that of "Bobbins," or "Bobbins-Joan," by which

it is known in the lace-making districts of Buckingham and Northamptonshire, in allusion to the resemblance of the spadix to the bobbins employed in lace-work. "Parson-in-the-pulpit" and "Jack-in-the-box" explain themselves: while the relative idea of male and female which is exemplified in "Lords and Ladies" is carried out in "Bulls and Cows" and "Stallions and Mares," two of its Yorkshire names. When the spadices are very dull and sober-looking they are called "Quakers," in some parts of Lancashire. This connection of the dark and light colours with the male and female sex respectively is very general; and is exemplified in many of the paintings of the Holy Family and other sacred subjects, where the Virgin Mary is usually represented in a robe of a blue colour, while a red or dark green one is given to Joseph and other saints.

The *Arum* has quite as large a number of names in other languages, many of which correspond closely with our own. Thus in some parts of France it is known as *Vicaire*, or *Curé* while it is called in its spadix *Butant de Clode*, or *Chandelle*; *Chou poivre*, or *Pepper Cabbage*, is another of its common French names. In the neighbourhood of Frankfurt it is called *Aaron's-wort*, and its relative abundance or scarcity is regarded as an indication of the fruitfulness or sterility of the ensuing season.

In Hertfordshire, the handsome spotted foliage is called "Our Lord's Leaves," and is associated with a tradition that the plant grew at the foot of the Cross, and was stained with the drops of the Saviour's blood which fell upon it. A similar tradition is connected with other spotted-leaved plants, as with the Purple Orchis (*O. mascula*), which is called in Cheshire "Gethsemane;" and the idea is not peculiar to England, as it is applied in Belgium to a spotted leaved plant, called in Flemish *Roodselken*, because it stood under the Cross; this grows in Flax fields, but we have been unable to identify it from the meagre description given. With regard to the *Arum*, the superstition is probably widely spread in England, although we have no other names which are connected with it. It was familiar to Mrs. HEMANS, who, speaking of the spots on the leaves, says :—

"These deep untroughed marks
The villager will tell thee (and with voice
Lowered in his true heart's reverent earnestness)
Are the flowers' portion from the atoning blood
On Calvary shed. Beneath the Cross it grew;
And in the vase-like hollow of its leaf,
Catching from that dread shower of agony
A few mysterious drops, transmitted thus
Unto the groves and hills their healing stains.
A heritage for storm or vernal winds
Never to wait away."

Those who are interested in tracing out the employment of plants in the sculptures of the middle ages should not omit to consult a little brochure, by Dr. Woillez, entitled *Iconographie des Plantes Aroides*. He enumerates and figures a large number of examples of sculpture, in which he considers *Arum maculatum* to have been employed, and enters at some length into the symbolical sense which they were intended to convey. We are inclined to think that in some, at any rate, of the instances which he cites, no aroidaceous plant is intended; but the paper is evidently the result of careful study and investigation, and demands attention. He also regards some aroidaceous plant as having originated the fleur-de-lis of France—that much debated emblem, which has already been traced by different authors to crosses, bees, toads, halbert-heads, and yellow Iris!

Regarded simply from a utilitarian point of view, the *Arum* has considerable claims to our consideration. The thick fleshy farinaceous roots yield a pure white starch, which was at one time in great repute, and which explains the name *Starch-wort* which was applied to the plant by Gerarde and other herbalists. For

many years, and, indeed, until a comparatively recent period, a preparation similar to arrowroot was sold in shops under the name of "Portland Sago," or "British Arrowroot." This was chiefly manufactured in Portland Island, where the Arum was very abundant; the root was crushed in a mortar, and then stirred in water, which was afterwards strained off. The remainder was then again washed and dried, the yield being about four pounds of flour to a peck of corms. The repeated washing was necessary in order to dispel the acidity of the root, which is very considerable, and not removed by several hours' boiling. Some advocate the drying and subsequent grating of the root, the water in which it is subsequently soaked being strained off, as in the previous method. According to Pallas, the flour from the Arum roots enters largely into the food of the Lapps and Finns. At one period the collecting of Arum roots for the London dealers was the regular occupation

New Garden Plants.

*IRIS (POGONIRIS) RUBRO-MARGINATA, Baker, n. sp.**

This is a well-marked new species of the fugacious-flowered vernal Irises, cultivated in the collection of Herr Leichtlin, from the neighbourhood of Scutari, where it was gathered by M. Barbey, of Geneva, the son-in-law of the distinguished botanist, Boissier. The specimen from which these notes were made was sent by him to me by post in the first week of April of the present year. In its long tube, and the shape of its two rows of perianthial segments, it is most like *Iris pumila*, but in other respects (the size of its flowers, and the fact that there is a pair of them, one following the other in expansion) it agrees with *pseudo-pumila* and *nudicaulis*. The flower, though large, is not at all handsome, and in all these the flower is too fugacious for them to be general favourites, when there are so many other species in which it is fairly persistent. The most striking note about it, from the horticultural point of view, is the red edge of its leaves and spathe-valves.

Whole plant, when flowering, not more than 4 inches above the surface of the soil, quite glabrous. Leaves ensiform-falcate, not at all glaucous, green,

viously had an opportunity of seeing them. In colour they vary from purple to greenish white; many of the latter flowers are sprinkled with pink dots (fig. 108), which give a very striking appearance to the flowers. Some of the sepals are fringed, while in other flowers the tubular petals (formerly called nectaries), instead of being in a single row, are in two or three series. The flowers then show a tendency to become double, and we may predicate, from the results before us, the introduction of a new and distinct race, valuable for their beauty and botanical interest.

*ODONTOGLOSSUM PRÆNITES, n. sp.**

This is a most interesting addition to our knowledge of *Odontoglossa*. The flowers are smaller than those of *O. triumphans*; the petals very wavy, both sepals and petals beautifully shining, of a bright yellow colour, with much more sulphur and less orange than the above-named species, and with a few large maroon spots. The claw of the lip is white, its anterior part bright yellow, with a cinnamon blotched spot in the centre. Accustomed as we are to see natural males, I had to see whether I could find any traces of such descent; I presumed *O. triumphans* and *tripudians* might be the parents, but nothing would have then ex-

FIG. 108.—HYBRID HELLEBORE.

of some of the Portland islanders. As recently as 1797 the Society of Arts granted a gold medal to the preparer of a sample of starch from the tubers of the Arum. The powdered root also formed an important ingredient in the French cosmetic called *Cypress powder*, which was said to be both harmless and efficacious; and Ray mentions the use of a lotion for similar purposes prepared from the roots. In severe winters the handsome scarlet berries are eaten by birds; and White, of Selborne, says that thrushes will even dig up and eat the roots.

The Arum is almost exclusively a European plant, being widely distributed throughout the Continent, and extending into Algeria. The structure of its flower is at first puzzling, but a little investigation renders it easily intelligible. A considerable development of heat in the spadix at the time of expansion is one of the more remarkable phenomena presented by the Arum; in our British species it does not exceed from seven to nine degrees that of the surrounding atmosphere, but in some foreign members of the order the development of heat is much greater. *B. M.*

with a distinct red edge, 2–3 inches long at the flowering time, $\frac{1}{2}$ inch broad. Flowers two to a root, one expanding after the other. Stem absolutely none, the ovary being placed direct on the crown of the root-stock. Spathe-valves lanceolate-navicular, reaching quite to the top of the tube, 2½–3 inches long, 1–1½ inch broad, green and almost herbaceous in texture, acutely keeled, and both keel and edges with a distinct red-purple line, like the leaves. Ovary oblong, green, $\frac{1}{4}$ inch deep; tube 2 inches long, green, tinged with lurid purple in the upper half; limb 2–2½ inches deep, a uniform lurid purple; segments of both rows oblong-spathulate, the falls with a reflexed limb as long as the claw, which is $\frac{3}{4}$ inch broad, eroso-dentate at the tip, and bearded down the lower half of the face with a row of purple hairs; the standards erect, an inch broad at the middle; stigmas an inch long, the same colour as the perianth, the recurved points deltoid, small, and little-toothed. *J. G. B.*

NEW HYBRID HELLEBORES.

M. Heinemann, of Erfurt, has sent us a box of flowers of crossed seedling varieties of Hellebore raised by him. These were first mentioned in our columns in 1874, vol. 1, by Professor Koch, but we have not pre-

* *Iris (Pogoniris) rubro-marginata*, Baker, n. sp.—Vernalis, aculis, foliis parvis ensiformibus, viridibus rubro-marginatis; floribus geminis perfecte sessilibus; spathe valvis magnis lanceolato-navicularibus rubro-marginatis et carinatis tubo

plained the novel shape of the lip, recalling the old *Miltonia cuneata*. Hence I must give up any suspicion about the loyal descent of the plant. It may prove as good a species as *O. nevadense*. The shining clear colours are very meritorious. This plant was collected in New Granada by Mr. Gustav Wallis for Messrs. Veitch, who kindly sent it for inspection. A young bulb has two peduncles, just as *O. luteo-purpureum* has. *H. G. Rehb. f.*

ANTHURUM PATINI, sp. nov.†

A handsome *Anthurium*, with dark green lanceolate leaves and erect flower-stalks, bearing spreading

aequilongis; ovario oblongo sessili; tubo bipollicari, limb. segmentis luride violaceis omnibus oblongo-spathulatis exterioribus facie barbatis, interioribus erectis reliquis latis.

* *Odontoglossum prænitens*, Rehb. f., n. sp.—Pseudobulbis oblongo-triangulis acutibus, medio tandem tricostatis; folio terminali ac foliis fulviteribus ligulatis acutis; racemo pluri-floro; sepalis tepalisque oblongis acutis; labello basi utriusque angulato vix linearis, subito in laminam hastato-rotundatam denticulatam crispam dilatato; carinis geminis apice acutis basi confluentibus a basi in discum; callis acutis geminis extorsis utriusque; columna trigona medio angulato, alis rhomboidis.—New Granada.

† *Anthurium Patini*, Mast., sp. nov.—Caulibus caespitosis, assurgentibus; foliis vaginatis lanceolatis basi apice que acutatis, 7-nerviis; pedunculis folia æquantibus vel superantibus; spathe aperta pauce oblonga longissime acuminata albidâ nervo medio viridi percursa; spadice erecta cylindrata utra spathe persistentem breviter stipitata eoque breviori; floribus 6-meris.—*Anthurium Patini*, hort. Williams; Columbia ubi legit Patin.

oblong acuminate white spathes, traversed by a green midrib. The spadix is shorter than the spathe, and densely covered with green-tipped flowers.

The contrast of the dark foliage and green striped spathe is very striking, and the greenish spadix is also noteworthy. Remembering what a poor thing *A. Scherzerianum* was on its first introduction we venture to anticipate that this plant (fig. 100), striking as it already is, will become more so as the plant gets more cultivated. It is, we believe, a native of Columbia, whence it was introduced to Mr. Williams' nursery by M. Patin.

The stems are tufted, about 2 feet in height. The leaves are provided with stalks about 6 inches in length, the lower portion being sheathing and mem-

cells dehiscing longitudinally, pollen elliptic; ovary truncate, oblong 3-sided, with a sessile cushion-like stigma, 4-celled, with 1 (or 2?) erect anatroous funiculate ovules, arising from the base of each. The 6-parted flowers are unusual. The walls of the ovary are remarkable for the numbers of very large branching cells which they contain, similar to what are found elsewhere among Aroids, but so far as we have observed not to the same extent. *M. T. M.*

THE LANCASHIRE OPERATIVE BOTANISTS.

IN the columns of the *Gardeners' Chronicle* on two or three occasions some particulars have been pub-

man whose acquaintance, thirty-five years ago, it was a pride and delight to possess. The Whitefield Society is possessed of a good library and herbarium. In addition to the fifty well-established societies, there are many smaller associations, less methodically constituted, but the members of which are as active as their brethren, and find, in their simple field botany, recreation at once permanent and substantial. As far as can be distinctly ascertained, it is now rather more than ninety years, say close upon a century, since the original society, the Adam of all the existing ones, was set on foot. It was established at Eccles shortly after the publication of that famous old book, Dr. Withering's *Arrangement of British Plants*, now nearly forgotten, but in its time inestimable, and

FIG. 100.—ANTHURIUM PATINI.

branous at the edges, the upper portion is compressed sulcate, provided at the top with a short thickened geniculus. The blade of the leaf measures about 6 by 1½ inches, is sub-membranous, glaucescent, lanceolate acute at both ends, midrib prominent beneath secondary lateral nerves distant, tertiary nerves smaller, closer, all arching from the midrib to the margin. Peduncle as long or longer than the leaf, erect, slender, sub-compressed, spathe 2¼ by ¾ inches and upwards, flat spreading, persistent, sub-coriaceous, oblong, acute at the base, acuminate at the apex, and traversed by a green midrib; spadix shortly stipitate within the spathe, 1¼ inch long, cylindrical obtuse, as thick as a swan-quill, densely covered with hermaphrodite, 6-merous flowers; perianth segments oblong truncate, hooded at the top, whitish beneath, green above; stamens opposite the perianth segments, filaments flat whitish, anthers whitish, with two parallel

lines respecting the Lancashire botanists in humble life, and their long-standing and earnest love of plants. Much remains to be stated, alike as to their beneficial influence upon horticulture and upon the temper of the particular communities in which the various societies have their centres. The devotedness of these men is not only interesting in itself, it has been remarkably efficacious as an example to others. Incredible as it may appear, there are at this moment in the Manchester district no fewer than fifty independent societies definitely organised and holding regular meetings. Among the chief of them are the societies at Ashton-under-Lyne (sixty members), Tyldesley (forty members), Miles Platting, Padiham (sixty members), and Whitefield, near Prestwich, the meetings of which last are held at Besses o' th' Barn, once the abode of the celebrated handloom weaver, John Horsfield, for many years the leading botanist of the county, and a

which incited thousands to the study of our native flora. As with many other societies, in course of time the old Eccles Club was succeeded by a progeny of younger ones, several of which may be considered the immediate parents of the confederacies now existing. Botany since 1780 has moved forwards in South Lancashire like the concentric ripples on a sheet of smooth water. In those beautiful undulations we have the truest picture this world affords of growth from small beginnings.

Curious is it to note at the same time how the manufacture of Cotton, and the botanical and horticultural tastes of this neighbourhood have advanced *pari passu*, since it was only in 1770 that American Cotton was first brought to England, and only in 1789 that a steam cotton-spinning engine was first erected in Manchester. The expansion of the love of plants in and about Manchester, as most people in-

terested in horticulture are aware, has not been confined to the artisans; it has shown itself, with corresponding conspicuousness, among the wealthier, though not more zealous classes. The *modus operandi* of the societies is simple enough. They explore every nook and corner of the adjacent country, hunting up its productions, determining the species with minute accuracy, and learning the names, but not attempting much in the way of physiology, except when incidental. As a rule they appear indifferent to the lower Cryptogamia. But in mosses and Jungermannias the knowledge of many of the members is often astonishing. For ready reference in the matter of plant names there was printed at Ashton-under-Lyne, many years ago, "A Little Guide to Botany," price one penny. In addition to Withering, the patriarch of the societies made considerable use of old Galpine, the volume being more portable, and of another once celebrated English Flora, the guide compiled by Dr. Hull, himself a Manchester botanist. Being constituted of harmless, peaceful, and consistent men, bent only on plant-finding, the societies very generally have the privilege granted them by the large landowners of traversing moors and other portions of property previously for game, and to which no one could obtain access. Hence, whenever a gentleman desires to visit some particular spot forbidden to all, with the object of seeing some rarity or curiosity in its natural habitat, he is glad to seek the kindly aid of some member of the local society, whose passport will go anywhere, and neutralise the most terrible of keepers, though these, upon the whole, are friends rather than foes. The excursions, of course, are controlled by circumstances, and are generally of short duration, of only three or four. In addition, from time immemorial, there have been regular monthly indoor meetings, held upon Sunday afternoons, or more generally, perhaps, on Sunday evenings.

No doubt it would be more in harmony with the established theory of the Sabbath, if the meetings took place on week days. But with 999 out of every 1000 working-men, to insist upon this would be to put a stop to the meetings altogether. Beginning work at 5 or 6 A.M., exhausted when they finish, and probably sored from head to foot, they are in no very fit state for either reading or intellectual exertion on week-days. Sunday is the only time when these worthy men can assemble, either with comfort to themselves or with nervous energy enough to do one another good; and it is no little credit to them, as well as a compliment to botany, that they decline to approach the Lady Flora except in their Sunday clothes. Silly and degrading and vicious entertainments, and the public-house, do not require that a man shall be either clean or intellectually receptive and communicative; noble and commendable pursuits require that body and mind alike shall be unfatigued. Besides, only the very prejudiced would make objections to the reverent study of God's works on the Sabbath. Were the Sunday meetings to be forbidden by law there cannot be a doubt that botany would disappear from among the Lancashire operatives, their wholesome and kindly industry would die clean out, and the country would certainly be the poorer for it. They are no worse than reading a Monday morning's newspaper, the editors and compositors of which have had to stay away from church in order to get it ready. Being held on different and specific Sundays the meetings allow of much pleasant reciprocal visiting, and brotherly fellowship is constantly encouraged. The aggregate number of meetings in the course of the year, including the annual meetings, amount to little short of 700, the total quantity of work done must therefore be immense. Every one who attends a meeting brings what he considers curious or novel. At a fixed hour it is the duty of the president to name the plants exhibited, and the remainder of the time is spent in conversation. Many of the members of the different societies have little gardens, crowded with rare plants, chiefly British. From some of these it is that there are sent for sale in the Manchester flower-root market, such uncommon plants as *Veronica filiformis*, *Lychnis alba*, *Antennaria dioica*, *Megum Athamanticum*, my first acquaintance with all of which, and with many more of the kind, was first made at the stalls of these rustic cultivators, or at all events at those set out by their fathers. Rare herbaceous exotics are also extensively cultivated. In the Manchester root-market years ago I saw for the first time and purchased *Conoclinium*, *Ranunculus pyrenicus*, *Ranunculus anemoneifolius*, *Hordeum jubatum*, and a score of others of kindred description. The gardens are owned chiefly by men who earn their livelihood in or in connection with cotton mills. It must not be supposed, however, that there are operatives of no other class in the societies. Collieries, foundries, and other scenes of hard and subduing toil furnish their contingents; one of the most distinguished of the present generation of botanists is happily employed at a dye-works, another of rare promise is a journeyman painter, and a third—an honoured old leader, formerly engaged in a mill—is now the village postman. Many of the societies are united in a kind

of loose federation—once a year endeavour is made to have a grand gathering of representatives of the whole. Subordinate annual meetings are likewise held of the local federations, and one of these it was, held in Ancoats, a suburb of Manchester, on the 11th inst., which suggested the writing of the present sketch. The report on this occasion, duly read by the secretary, consisted simply of a record of quiet, painstaking, and industrious effort; of rising at daybreak so as to secure a ramble without trenching on the time for earning wages, and of the successful "finds" of the season. The cash account lay in a nutshell. Honest, straightforward, faithful in every particular, the unanimity and whole-heartedness displayed from beginning to end were most delightful. Would that the same could be said of every other annual meeting! *G. Manchester, April 16.*

A REVIEW OF THE PROGRESS OF VEGETABLE PHYSIOLOGY IN 1874.

(Continued from p. 454.)

THE COLOURING MATTERS OF PLANTS.

The last important work on the constitution of chlorophyll was published by M. Krauss in 1872: he inferred the existence of two colouring principles—xanthophyll and cyanophyll, which, by their mixture, produce the green colour we are familiar with. This hypothesis was partly based on the fact that superposition of the spectra of these two substances reproduces the spectra of chlorophyll with its characteristic absorption-bands.

M. Pringsheim has been studying the subject, and has arrived at somewhat different results. He affirms that the colouring principle of chlorophyll is single, cannot in any case be divided into two, and only undergoes certain transformations, according to the conditions of illumination. This theory is mainly based on the fact, that in the different solutions, yellow, blue, or green—the author always found all the bands of absorption that are characteristic of the chlorophyllian spectrum. It is only necessary to employ liquid layers of sufficient thickness and concentration.

Examining, e.g., the alcoholic extract of etiolated plants (which, according to M. Krauss, contains only xanthophyll), M. Pringsheim has found in it, quite distinctly, the seven spectral bands. Only while a layer 0.4 m.m. thick of the green solution (normal chlorophyll, mean concentration) was sufficient to yield them, the band III. (the least visible of all) appeared in the yellow solution only with 370 m.m. thickness of liquid. The same with fluorescence, which M. Krauss denies to his xanthophyll, but which M. Pringsheim has observed quite clearly. If we retain the theory of co-existence of two colouring principles, it will be necessary, in order to explain these observations, to suppose that a certain proportion of cyanophyll had already been developed in the darkness, and that the action of the light was limited to modifying the proportions of the mixture. But none of the means indicated for producing dissociation of the chlorophyll had the least effect on the yellow solution; moreover a slight difference in the position of the first bands would oblige one to conclude that the cyanophyll of the etiolated plants is not the same as that of normal plants. In view of these contradictions M. Pringsheim considers the other hypothesis much more probable. He thinks, then, that the colouring principle of etiolated plants is only a modification of normal chlorophyll, to which he proposes to give the name *etioline*.

In his attempts to separate the green solution into a blue and a yellow (e.g., by means of benzine), M. Pringsheim says he has found it impossible to prepare a yellow solution, which, examined in suitable conditions, did not present all the absorption-bands, and therefore no longer contained chlorophyll. It was the same with a blue solution. Further, cyanophyll is a substance really existing in the green matter of leaves, how is it that a green, very dilute, alcoholic solution (or employed in thin layers) does not give all the absorption-bands, but only those which are specially attributed to xanthophyll?

The differences between the blue and yellow solutions may be explained by the degree of affinity of each solvent for the colouring matter, by the degree of purity of the solvent itself, &c. In every case each of the two solutions contains true chlorophyll, and not merely one of its elements.

The colouring principle of yellow plants (anthoxanthine) is closely allied to etioline; solutions employed in layers sufficiently thick give the absorption-bands. It is not a principle uniform in all flowers, but rather a series of substances, the first of which is closely related to chlorophyll, whereas the last is considerably removed from it: still the band I. is always found most characteristic of it. The autumnal yellow colour of leaves is also derived from chlorophyll, as its spectrum proves, which is, however, distinguished by a marked weakening of certain rays (xanthophyll).

M. Pringsheim, then, considers chlorophyll as a unique colouring principle, beside which there are three other principles of similar constitution, etioline, xanthophyll, and anthoxanthine: the first precedes the appearance of chlorophyll, the second succeeds it; they are perhaps also found sometimes mixed together, and then the green solutions may indeed contain a yellow principle, but this is not a constituent part of chlorophyll.

M. Wiesner had already taken a step in the same direction as M. Pringsheim, in suggesting the idea that the cyanophyll of M. Krauss is no other than chlorophyll, of which it has all the important characters. The same author showed that benzine is not the only neutral substance which may be employed for these observations, but that others, such as sulphuretted carbon, chloroform, and castor oil give quite similar results.

M. Wiesner has also studied the action of light in conservation and destruction of the colouring principle. He has brought forward two interesting considerations. 1. Etiolated plants become green more quickly when they are exposed to the more refrangible rays of the spectrum than when they only receive the bright rays. This may be explained by supposing that the plant is always the scene of a double action; production of green matter and its destruction, which advances equally with the phenomena of assimilation. It is the yellow and adjoining rays that preside over the latter operation. The green colour which we see in plants is only the difference between these two opposite actions, and when the blue rays, which have hardly any action on carbonaceous acid alone, the coloration of the tissues progresses more quickly. 2. The destruction of the colouring principle of chlorophyll is always connected with the presence of oxygen, and is only effected by the laminous rays which act at the same time in the decomposition of CO₂. It is natural, then, to think that a part of the oxygen which the assimilation of carbon has set at liberty serves for oxidation of the grain of chlorophyll itself. The phenomena, which are later to be mentioned, are very common, and it is not correct to conclude directly from the quantity of oxygen eliminated to the nature of the organic substance produced.

M. Chauvart has for some time been engaged in researches as to the modifications of the spectrum of chlorophyll under certain agents, such as alkalis, sulphurised substances, &c. These modifications are all reduced to the appearance of new lines or the decomposition of characteristic lines, and though very interesting as regards chemical analysis of solutions of doubtful origin, they have no very direct bearing on vegetable physiology, properly so called.

M. Filhol some time ago indicated a method for obtaining in the alcoholic solution of chlorophyll a precipitate by means of hydrochloric acid. This precipitate collected on a filter is almost black, while the liquid is yellowish brown. Renewing these observations, the author has remarked that the precipitate is a gelatinous plant, consisting of pulverulent amorphous precipitate, while that of monocotyledons gives one that is crystalline. The crystals take the form of small needles gathered into tufts. Their solution varies in colour; it is brown-yellow in ether or benzine, yellow and fluorescent in sulphuretted carbon, and violet in chloroform. The absorption-bands are similar to those of chlorophyll. This fact is entirely new; hitherto observations have concurred in showing the perfect identity of chlorophyll in all plants, and the subject deserves to be thoroughly investigated.

We have still to notice some interesting observations on chlorophyll considered in living plants. M. Krauss has studied the winter coloration of evergreen plants; he has not arrived at any general conclusions, but enumerates the following cases.—1. In the Gramineæ the state of things appears to be the same in winter as in summer. 2. In herbaceous plants (*Bellis perennis*, *Stellaria media*, &c.) the grains of chlorophyll of palisaded cells accumulate irregularly in the middle of the cell; the others do not change their places. 3. In plants in which the cell contains in winter small masses of tannin, the grains of chlorophyll accumulate irregularly along the walls; in the palisaded cells they occupy the inferior half of the cavity (leaves of *Mahonia*, *Ledum*, bark of branches of Oak, young Elm, Lime tree, &c.) 4. In branches, the cortical part of which does not contain chlorophyll, the chlorophyll grouped round the nucleus (*Ribes*, *Lonicera*, *Sambucus*). 5. Lastly, in certain isolated cases, the grains are scattered in the cells without apparent order (branches of Ash, leaves of *Lavender*). These modifications are directly due to the influence of the cold; all the movements of the grains of chlorophyll were effected in four days—from November 7 to 11, 1873—at the time that the frost appeared.

M. Bataillon has studied the estival discoloration of certain plants. The Conifers especially are remarkable in this respect. In many of them, and under the influence of a too ardent sun, the branches grow yellow, and the cells of the leaves come to contain only yellow grains of chlorophyll surrounded by colourless protoplasm. This effect is quite local, and

while the upper face of a branch bears yellow leaves, the lower, withdrawn from the sun, will remain quite green. Sheltered some days by a screen, the leaves will resume, if the temperature be sufficiently high, their normal colour. The yellow colour may persist during the whole summer, and then during winter the temperature is too low for greening to be possible; it does not appear till spring. The same leaf may be discoloured several times without suffering. It is especially exotic Conifers that have presented this phenomenon (*Chamaecyparis obtusa* is the subject most favourable for the observation); but the author also observed it in several indigenous species (*Juniperus communis*, *Picea excelsa*). It is to be remarked that the branches which have reached autumn without having recovered their green colour are much more apt to suffer from frost in winter.

Lastly, M. Prillieux has studied the movements of chlorophyll in *Sinigella* exposed to the sun. *Sinigella*, in particular, presents, in the cells of the superficial layer of its leaves, an amorphous chlorophyll which uniformly covers the upper wall. Under influence of the solar rays a white spot presently appears in the centre of the cell; the protoplasmic mass is set in motion, goes along the walls, and finally is applied to the lateral wall, leaving the upper face completely free. The general colour of the leaf then diminishes in intensity.

In *Eloëa canadensis* the grains of chlorophyll accumulate similarly at one point of the wall, under influence of the solar rays. M. Prillieux does not think that their transport can be attributed to protoplasmic currents that one observes in the cells; these he considers accidental, and due to the disturbance produced in section of the leaf.

PLANT GOSSIP.

CULTIVATORS of *CELOSIA PYRAMIDALIS* and its varieties are frequently found complaining that the young hearts are apt to throw a small comb, and this leads them to infer that the strain is bad, and they throw the plants away believing them to be unworthy further trouble. But it must not be supposed that because the plants develop the small and insignificant comb in the young state, they are not worthy a farther attempt; and if for the future the growers would content themselves with pinching out the small combs, and encourage the plants to make a vigorous growth, they will be surprised at the result and at the quality of the strain. It is a fine decorative plant for late summer, and the wonder is it is not more generally cultivated. If the seed be sown in April on a gentle bottom-heat, and treated as one would the Balsam, the result will be satisfactory. One great point in the cultural process is to occasionally stop the other shoots by pinching them back, so as to produce bushy plants of vigorous growth. The *Celosia* is a Cockscomb that has shot up and producing heads of elegantly feathered plumes, and of these the yellow carmine, crimson, and silver are very attractive.

In order to appreciate the decorative beauty of the new race of FANCY POLYANTHUSES, they should be seen growing at Castle Ashby, Northampton, the seat of the Marquis of Northampton, in many semi-wild spots and woodland ways. Mr. Beech, the gardener at Castle Ashby, makes spring gardening a prominent feature during the spring months, and the gardens have a high reputation for this feature of modern gardening. But, in addition to the ordinary flower-beds, there are many nooks and corners profusely aglow with floral life in March and April, in which the free-blooming Polyanthuses play the most important part, and the changing common Primroses bearing them company. They are planted out in big clumps and patches in cool and inviting spots, and, flourishing in a congenial soil, they grow vigorously, and send up very strong flower-stems, surmounted with umbels or trusses of immense high-coloured flowers. Numbers of these flowers are in constant requisition for decorating the dining-room at Castle Ashby, and, in addition to their affording bright and agreeable colour, they emit a most agreeable and sweet perfume.

A GOLDEN-LEAVED form of VALERIANA, probably a sport from *N. officinalis*, is now a very showy and striking object in one of the hardy perennial borders at Chiswick. It is also very telling at South Kensington, where Mr. Barron employs it along the Rhododendron beds in the Royal Horticultural Gardens. It is a plant worthy the attention of spring gardeners, as its foliage assumes its best tint in early spring, and retains it up to May, when it turns green. It is a good subject for the mixed border, because the golden foliage blends well with the spring flowers; and it blossoms in June and July, thus affording a second period of decorative service.

A fine example of the CHUSAN PALM (*Chamaerops Fortunei*) can be seen growing in the open

ground at Gunnersbury Park, Acton, the residence of Baron L. de Rothschild. It is thought to be one of the finest specimens to be found planted in the open air in this country, as the dimensions of the plant are remarkable. It occupies a somewhat moist position on the south-west side of the mansion, and below the level of the ornamental water. It is protected during the winter by a tent of mats, and now it is uncovered it presents no trace of injury from the severity of the past winter.

On the rockwork at Kew several plants of *PRIMULA CORTUSIOIDES* are producing a lively effect. The rose-coloured flowers are very pretty, and quite distinct from the reputed varieties, which, though much larger, should not be permitted to drive the species from alpine collections. *P. nivea*, sometimes known as *P. nivalis*, is also in flower, and is one of the most beautiful and easily cultivated of all. *P. carniolica* is now very attractive. It is interesting to see, after the past winter, that the delicate and rare *Omphalodes Lucilike* is alive, and commencing to grow.

The charming Violet, which has on two or three occasions come before the Floral Committee of the Royal Horticultural Society as an improved form of *Deviensis*, and which was shown by Mr. C. Turner under the name of Lady Hume Campbell, is so nearly, at least, identical with one known as Marie Louise, that it cannot be recognised as a distinct variety. Several who are growing the latter unhesitatingly pronounce it to be the same. It is a beautiful variety for flowering at this season of the year; the blossoms are large, very double, lavender-blue in colour, with a white centre, and are produced with great freedom. It is a continuous flowerer, and has a close and compact tufted habit of growth.

PRUNUS TRILoba makes a great display every year on one of the walls at Kew, and this season is, perhaps, more beautiful than ever. The tree on every twig is studded thickly with fine double flowers like little Roses, and being in different stages of variety of colour is presented—the younger buds are dark pink, and the older buds almost white. It is best to manage the tree by allowing some of the shoots to retain the natural position of their growth, and to defer the final pruning to a week hence; there is then the greatest possible display of bloom. It is one of the best of its allies to force for the conservatory.

The great freedom with which *PRIMULA INTERMEDIATA* flowers at this season of the year commends it to the attention of all lovers of hardy Primulaceæ. We have seen a plant scarcely more than 3 inches across, growing in a 48 pot, bearing eight trusses of its deep-lead-rose-purplish flowers, two or three of the trusses carrying as many as sixteen individual pips. It may be said to immediately succeed *P. nivea*, and, like that species, if kept in the shade, the flowers will last for a considerable time. It is a plant that should be allowed to well establish itself when grown in pots, top-dressing it from year to year, until the plants require more roomy quarters in which to develop itself.

A fine plant of *FUCHSIA DOMINIANA* can be seen in one of the greenhouses at Chiswick House, originally planted out for the purpose of training it over the interior surface of the roof. Mr. Edmonds states, however, that the training process appeared to be so distasteful to the plant that it did not flower. It was then allowed to grow at will, spreading out its branches freely and in any direction to which it pleased. The effect was remarkable; it blooms with great freedom on the untrained shoots, and it may be said to be never without flowers, though they are only sparingly produced at this season of the year, as might be expected.

Glancing over the herbaceous collection at Kew we observe the following that deserve mention:—*SANGUINARIA CANADENSIS*, the Blood-root, is in great beauty, from the profusion of its large, pure white Anemone-like flowers, and is indispensable to the spring collection. *MUSCARI BOTRYOIDES PALMIDUM* exhibits a pale porcelain-blue, forming a fine contrast with the darker blue and pure white forms. Among the *ERYTHRONIS* are *E. americanum*, with flowers of golden-yellow, and *E. giganteum*, with creamy-white. The leaves of the former somewhat resemble those of *E. dens-canis*, for which it is a good companion plant.

A good useful single yellow HYACINTH, named ALPHONSE KARR, pure in colour, and forming a good spike, is much grown by Mr. A. F. Barron at Chiswick, for decorative purposes. Good as it appears to be, it does not seem to have found its way into the bulb catalogues of this country. It is cultivated by Messrs. E. H. Krelage & Sons.

CARNIVOROUS AND SENSITIVE PLANTS.

In the hard frost which we experienced in the past winter there was something to be learnt of the behaviour of certain plants under its influence. In the hoar-frost, the exposed edges of the evergreen leaves had an elegant fringe of lace added, not niggardly, but profusely, as if the new year had made himself a nuptial robe worthy of the occasion. Every twig and thorn had holiday attire, and the long bare shoots of the autumnal Roses seemed to fringe their shrouds with silver, grand even in decay. But it is not to the beauties of the plants thus clad that I would now beg leave to direct attention, but to the movements of the Rhododendron leaves, suiting their position to the action of the weather. When the hard frost comes on, instead of the leaves stiffening where they stand, they do just the reverse, and every one with supple joint drops some 50° or 60°, thereby exposing the smallest surface to the storm, just as a skilful general would command a drop, that the enemy's fire might go harmlessly overhead. But this is not all, for as soon as the thermometer shows a rise in the temperature, the Rhododendron leaves take notice of the fact, and raise themselves up to meet the thaw, just as they had drooped to receive the frost, and at the while the earth was a lump of ice where the roots of the plants were locked up. We wonder to see the Mimosa drop its pinne first, and then its footstalk, and raise them again at its leisure; but we do not give the Rhododendron its due, for who would call such a shrub sensitive? Yet here is the evidence of its rising and falling, and that by a power and an influence exerted contrary to the natural law, which renders the foliage exposed to frost rigid. If we take a Cabrage leaf, and bend it in frosty weather, it will break short; but who would have imagined, *a priori*, that the leathery leaf of such a shrub as the Rhododendron would have behaved in this way by having its petiole hinged so as to rise or fall full 50° to meet the emergency? Many alpine plants seem to be improved by a mantle of snow, and as soon as the snow has disappeared the green cushion shows its lovely contrast to all the death and ruin around; and many succulent plants, such as the Houseleeks, that one would expect to find in ruins after a visitation of frost and snow, seem to be preserved equally contrary to the natural law which should have ruptured every watery leaf that was above-ground, just as we see to our cost that tender shrubs are ruptured and killed.

I see that we are promised a monograph on the insectivorous plants—*Sundew*, *Venus' Fly-trap*, *Fingulica*. It may be as well to prepare the reader for this coming storm—this trial by jury, where certain plants, hitherto of fair reputation, have to be acquitted or condemned for carnivorous propensities. Now, without forestalling my superiors in their argument, let me hint that I have known all these plants for at least thirty years, and their natural irritabilities and power to draw themselves up when tickled, and I have grown *Sundews* under glass in the sphagnum on which *Orchids* were planted, and I have sent by post many *Droseras* from the peat bogs around Manchester, where I have seen thousands of all ages, in flower and in leaf, evidently in the best of health; and having plenty of peat soil, water, and sphagnum, they grew, flowered, and seeded, leaving nothing to be desired.

But, some one will say, did you never see any of these plants more robust than their fellows, with their arms full of the wings and legs of departed flies? Gentle reader, 'Carrión' and 'coarse fare' did not please them at all as well, and I should just as soon have looked for a condor eating flesh of Carrión or Moss as the elegant *Sundew*. There is a class of plants that have not till lately been blamed for feeding on insects, but which are beyond all doubt treacherous daughters, and these are the *Sarracenia* and all the *Pitcher-plants*: only look into their pitchers and you will find them fair enough without, but dark and dismal within, and many a score of ants, some in their agony and others dead and far gone in decay. When I first saw the substance of the Sundew being carnivorous mooted, I considered it a sensational ruse, and made light of it, supposing the author to be rather pressed for point to his pamphlet, but able hands seem to have taken up the cause, and would fain convince us that in the fair face of *Flora* there is a pit for dead flies, and, in short, that such fly-traps are guilty of premeditated cruelty: for what else could they mean by opening their jaws to catch the unwary insect, and weary it at their leisure?

Far be it from me to hinder the birth of new ideas, especially those which are said to throw light upon the relations of the animal and vegetable kingdom, for it is a law with very few, if any exceptions, that the animal kingdom has always been the aggressor on the vegetable—not, as is now sought to be set

up, by confusing irritabilities with accident, that a plant which is perfectly passive has become all at once an active butcher. Now, if science is to be exact, and this is never more necessary than in botany, we ought to have no romantic ideas introduced like those we have gathered at the wane of the moon, or the marvels done by the forked roots of the Mandrake. Many plants are of no known service to either man or beast, and many that I could name seem only created to confound our ideas and foregone conclusions, for many plants are playful, as it were, and others are grotesque. Thus we can see no reason for the heads and tails of many Orchids, the monkey's face in the Cocoa-nut, and the two sham outlets beside the real one for the milk to flow out of. [If our correspondent had studied the ovary or unripe seed-vessel, he would have seen the meaning of this. Eds.] The agency of insects in the fertilisation of flowers, upon which so much stress has been laid, is only one more example of the fitness of the machinery by which the work of the world is done. Where a mere shake in the wind will fertilise, as in grasses, nothing else is possible; but where a spring process is required, from the male to the female flower, then there is a winged messenger provided to carry the dispatches, and a sop in the shape of honey to pay him for his pains. But although this is a general law, it is by no means universal, for some like the Fig have a mode of impregnation after its own kind; while some have the male and female organs on different plants, as if they had made an unhappily marriage, and gone through the Divorce Court. No one disputes these ideas, because they are borne out by facts and every-day observation; but who can say with truth that a Drosera could pick a bone like a yard dog and digest the carrion; Dionaea may still be Venus's fly-trap without being her charnel-house; and as for Pinguicula doing that kind of business, judging from its locality, it would seldom have the chance, and would always lack the ability. When the leaves of some succulents are put in a saucer of sand to strike as cuttings, some small pebbles are sometimes put to rest them in their places, and they will curl up towards the pebbles, but no one supposes that they mean any harm to the stone that holds them down. *Alex. Forsyth.*

BRITISH GARDENERS.—XVI.

JOHN WEBSTER.

OUR gallery of portraits of British Gardeners is this week enriched by that of Mr. John Webster, the talented gardener to the Duke of Richmond at Gordon Castle in the North of Scotland. Mr. Webster, in his autobiographic notes, informs us that he was born on December 8, 1814, at Blancerie, a small and beautiful estate on the banks of the Whiteadder, one of the lower tributaries to the Tweed in Berwickshire, where his father was then gardener to General Balfour, the proprietor. "In the autumn of 1817," he continues, "my father went to Manchester, about 3 miles distant, as gardener and general manager on the estate, in the service of General Maitland, father of the present Earl of Lauderdale. I received my education at Dundee, and having early formed a taste for gardening, was placed shortly after I was thirteen years of age to do light work in the gardens for three or four months during summer, when I again returned to school. I continued to do this until I was sixteen, when I went into the gardens for regular employment, and with the object of making horticulture my profession. As a proof that gardening was pretty well up at Manchester at that date, I may mention that several prizes for Grapes, &c., were gained at the shows of the Caledonian Horticultural Society in Edinburgh, the awards consisting of tea-pot, cream-jug, and silver spoons, with inscriptions upon each, and which are still heirlooms in the family. I left home about the age of eighteen, and went to Dalmeny Castle in Ayrshire, as journeyman under Mr. David Dick, and remained there until November, 1833, when I went to Whittinghame, in East Lothian, under Mr. William Rintoul. The place was then in high keeping, and had a good range of vineries, Peach-houses, Pine-stoves, Pine-pits, &c. I derived considerable advantage during my services here from my having to assist in the laying-out of a new flower garden, of which I had the principal superintendance. It was three years at this place, the last one as foreman, and then took my departure in November, 1836, going to Claremont, in Surrey, as foreman in the houses of the fruit department under Mr. C. McIntosh, author of the *Practical Gardener*, who was then in the service of King of the Belgians. From Claremont all the Grapes and Pine-apples had to be sent during the summer and autumn months for the supply of the Royal table at Laken.

"In the month of February, 1838, I went to Earham, Sussex, as gardener to the Hon. Mrs. Huskisson, widow of William Huskisson, Esq., M.P. for Liverpool, who was killed at the opening of the Manchester and Liverpool Railway. My employer

was a great admirer of Orchids, and during my long stay there, which was upwards of twelve years, I had an opportunity of getting together a choice collection. It was here successful in getting that shy-flowering Orchid, *Renanthera coccinea*, to produce fine large flower-spikes for a number of years in succession. On November 5, 1844, I was awarded a Silver Banksian Medal for one sent to the Horticultural Society's meeting in Regent Street; while on November 3, 1846, I had again a similar award for another spike, which was one of five borne on the plant at the same time. I am also in possession of a Gold Banksian, received for six Orchids shown at Chiswick on June 19, 1847, having been placed first out of seven competitors. These were the only occasions on which I competed in London.

"I then engaged with the late Duke of Richmond to take charge of the gardens and forests at Gordon Castle; and I also undertook to lay out for the Duchess a new flower garden in the Italian style, which had at that time been commenced. I came here on November 30, 1850. While carrying out the work of the flower-garden in an altered design, and completing it in its present form, which was the work of a number of years, I had the assistance of the late Sir Joshua Jebb, C.E., and also the guidance of the good taste of the Duchess, in deciding upon plans for the balustrades, fences, fountain, and ornamental work. The balustrading springs from each end of the Castle, which is 540 feet in length, and encloses a space 300 feet in breadth. The ornaments

John Webster

on the principal piers are large classic dogs, and on others are deer in a standing position, while on all the intervening piers are placed vases of different sizes and forms. The central beds are raised and panelled with Portland cement, while to the right and left of these are two fountains, with walks 15 feet wide running towards each at four different points. The central walk, 22 feet wide, runs through the garden to a distance of 1150 feet, and is furnished at each side with a broad margin of grass, on which are placed alternately large Portugal Laurels in tubs, and large tazza vases on pedestals. This walk, which is nearly on a level, is terminated by a flight of stone steps of the same breadth, and margined by a stone balustrade fence, the design being different to that of the one that surrounds the flower-garden, which, although distant, may be said to be within it."

CARPET BEDDING.

WHERE hardy plants are used this is perhaps the easiest, certainly the cheapest, and possibly the laziest style of gardening. I would wish to raise a warning voice to amateurs on the subject, having felt the demoralising effect of the last superlative in myself, and therefore I can speak from experience.

I will not own how many seasons the following arrangement of a border and beds has stood. As all looked as well as possible, uninjured by any weather or season, we were thankful to let them stand, having in our small way always more trials, experiments, and work on hand in the garden than we can get through;

and to have a border that required no digging, no manure, no time or labour, and yet to be filled with increasing and flourishing plants, is a temptation difficult to resist.

The border is 86 feet long and 5 feet 8 inches broad, exposed to the full sun, which is reflected off a low wall at the back, and trees beyond the wall, which intercept rain, dew, and frost, and whose roots below the wall eat up all nourishment in the soil. In short, a very hot, dry and exhausted border, and suitable therefore for succulents, hoary and variegated plants. The whole is a carpet of *Sedum acre aureum*, margined at the back with a row of *Sempervivum tectorum*, and in front with *S. calcarum*, a narrow band of *Sedum lydium* forming a green line between the grey Houseleeks and the *Sedum acre* when it has got its yellow growth on. A line of purple Crocuses within the bottom verge completes the border in front, and behind the native Houseleeks is a row of Rosemary, which when first planted admitted of a variegated *Pelargonium* between each plant in summer, or a white variegated Kale in winter. Now, in spite of constant cutting for the inmates of the Royal Infirmary and the Blind Asylum, the Rosemary this winter will be heading, but it is simply an aromatic spike edge. In the carpet of gold *Sedum* are cut out sixteen circles of grey *Sedum* or Saxifrage, alternating with small Houseleeks, as *Sempervivum montanum*, &c., the object being that these rings show out of the carpet by colour or form, either when it is green or yellow. The circles are filled in summer with bright-leaved *Pelargoniums* which cannot have too much sun, and in winter with purple and lilac variegated Kale. In the flat piece of groundwork between each circle is a single good-sized plant of variegated tree Ivy, *Cineraria acanthifolia*, *Yucca*, or *Aloë*.

In summer a tuft of blue *Lobelia* was dotted at the four corners of the flat piece of gold *Sedum*, which in winter is replaced by *Carex japonica variegata*, *Snowflakes*, and *Scilla bifolia*. The *Leucopium* are in flower while the *Sedum* is still green, and the blue *Scillas* tell when it turns gold. This arrangement certainly requires the minimum of time, trouble, and expense, for the good effect it has. Some fresh soil or course is required before planting the summer plants, and the *Sedums* are cut into shape in spring where they have encroached on rings or margins. When the plants on the wall—*Roses*, *Chrysanthemums*, *Clematis*, *Smilax*, *Jasminum nudiflorum*, *Ampelopsis Veitchii*—require pruning, training, or to be gathered, careful, steady footsteps do the *Sedums* no harm, rather otherwise, and weeds can hardly make their way through the consolidated groundwork.

The soil is so utterly dry and ash-like that *Verbena* and *Pelargoniums* have stood the whole winter, and I have an idea that we might venture to leave out many a plant (or even plunge them for the winter in such a border) that would suffer or be killed in properly dug and worked ground, and this I fancy is the great advantage of the carpet-bedding, and one that admits of progress and experiment; at the same time the mere saving of trouble is such a temptation, and indeed so much of a necessity in many cases, that a warning voice must be raised, or it is possible that this fashion may end in a standstill—worse, as far as progress is concerned, than even the summer bedding when carried to excess led to.

The centre beds consist of a *Yucca* or variegated *Aloë*, centre plant, the *Aloë* replaced in winter by a *Phylirea* or *Box*; groundwork of the common grey *Sedum* dotted with *Carex japonica variegata*, a ring of variegated Ivy, and edged with Crocuses. A few scarlet Tulips on the grey groundwork finishes off for spring. The groundwork of the opposite bed is the *Sedum* spectabile, edged also with Ivy and Crocuses; and another pair of "lazybeds" are composed of a tender *Cupressus* (?) replaced in winter by a hardy evergreen and the *Ajuga* groundwork, dotted with *Euonymus japonica aurea*, and edged with *Euonymus radicans variegata* and Crocuses: when the dark blue flowers of *Ajuga* were in bloom these were charming little beds. The gold *Euonymus* has stood since the winters of 1871, 1872, and 1873; it suffered in 1870, and my belief is that the drying effect of the groundwork has both kept up bright variegation (only one plant of fifteen having sported a branch black to green), and so checked gross growth that in spite of the late and wet season the plants were in a condition to resist the 13th of frost we had here last winter. We find a *Sedum* groundwork (a solid soil) saves as fully 6° of frost in the soil. We are near the sea, which often means no frost at all, and we can carry on our winter bedding work in such beds when we are stopped on uncovered ones. The roots and neck of the dotted plants are very considerably protected, and I think something useful and improving might be gained by experimenting on this system.

One other disadvantage of a *Sedum* groundwork, and I have done. A neighbouring walk (not much used) was so hopelessly dotted with the gold-tipped

Sedum that any hoeing or hand-picking merely broke and spread it, and we had to skin the whole walk, and have a complete new coating of fresh yellow ballast and thorough and repeated rollings. We flatter ourselves we are safe until next year. Such an accident can be avoided by using this inveterate Stonecrop on beds on grass, not on a border with gravel-walk.

It is our intention to lift and rearrange our little succulent border next spring, and collect there all our treasures in that department. The manure required to keep that border cool, and to feed plants of decent growth, would have gone far to supply us with Cauliflowers.

It is a wise plan to turn one's disadvantages into advantages, and there is no end of study, variety,

A beautiful perennial species of *Convolvulus* or *Ipomoea*, common in the gardens of Algiers, climbs up the two nearest Palms in the sketch, and its profusion of large blue flowers renders them very gay.

The effect of this unique and magnificent grove is very striking to European eyes, especially when viewed with the blue Mediterranean air at the northern end, and never fails to astonish and delight the visitor.

The grove is crossed at right angles by an avenue of Bamboos of similar length, equally fine, and forming, from their dense umbrageous canopy of foliage, a striking contrast to the graceful feathery character of the Palm grove. Many of the canes, which grow in clumps, are very large, measuring 6 inches in diameter 4 feet from the ground, and are not less than 30 feet long. *W. L. B.*

The crops sown during the first rainy season are harvested in the succeeding dry season, when the ground is at once ready to receive a second crop. The splendid climate and fertile soil of Haiti produce a luxuriant and gorgeous vegetation, which is famed even in the West Indies for the beauty and variety of its forms. The vast primeval forests which clothe the mountains and valleys contain some of the noblest products of the vegetable world, and the countless gay flowers and blooming shrubs which stud the savannas attract no less by their extreme beauty than by the fragrant odours with which they fill the air. So little of the surface of the island is actually cultivated that it may be divided into two parts, forest and savanna. The lofty mountain ranges, which traverse the island from east to west, and the broad

FIG. 111.—PALM GROVE IN THE JARDIN D'ESSAI, ALGIERS.

beauty, and interest, in a succulent border, easy to grow, difficult to know, and quite distinct from mere lazy carpet bedding. *F. F. Hope, Wardie Lodge.*

A PALM GROVE.

The Palm grove which my sketch (fig. 111) illustrates, forms the central avenue of the Jardin d'Essai, or Botanic Garden, of Algiers. It is 1500 feet in length and about 30 feet wide. The Palms (*Phoenix dactylifera*) are fifty in number on each side, and are about 30 feet high; many of them are fine specimens, but some appear to have suffered a good deal from winter storms. Between every two there is a *Dracena Draco* and a *Livistonia borbonica* alternately; the former are very fine, the trunks being nearly a foot in diameter before branching, and some of the *Livistonia*s are also fine plants.

Foreign Correspondence.

NOTES ON HAITI.—The island of Haiti occupies an area of about eighteen millions of acres, and contains one million of inhabitants, or scarcely one-twentieth part of the population it could actually support. The surface of this island is irregular and mountainous, and beautifully diversified by hill and valley, forest and savanna, lake and waterfall. Along the coverts and in the valleys the surface soil is a deep black alluvium, with a subsoil of hard red clay or chalk. Upon the hills and mountain slopes a reddish clay prevails. The climate is damp and intensely warm in the lowlands, but in the highlands it is mild, equable, and more healthy than in any other country within the same degrees of latitude. The year consists of the two usual seasons of the tropics, viz., the rainy and the dry, both of which occur twice in the year, so that vegetation never ceases.

valleys, which intersect it in all directions, are clothed with dense forests full of magnificent timber and ornamental trees, whose value is scarcely known, much less utilised. The savannas resemble in many respects the prairies of North America, but, being studded with clumps of trees, and broken by low green hills, are less tame and monotonous, and have more the appearance of an English park. There are few native grasses, and the savannas are chiefly covered with Guinea-grass (*Panicum maximum*) and Bahama-grass (*Cynodon Dactylon*). The former, which was introduced by the French colonists in 1744, makes excellent fodder, and is generally cut three or four times in the year. The Bahama-grass forms a close, smooth turf, quite as beautiful as that of our famed northern pastures. The loveliest part of the savanna is unquestionably that which borders upon the forest. Here the foreground consists of an open grassy space carpeted with gorgeous flowers, and dotted with clumps of flowering shrubs, such as

Oleanders, Myrtles, Magnolias, and Laurels. Palms, isolated or in groups, meet the eye on every side; here is the beautiful form of the Royal Palm (*Oreodoxa regia*), with its ever-rusting leaves; there is a beautiful group of Dwarf Palms (*Bactris minor*), and here is the *Coccoloba* (*Coccoloba nucifera*), with its slender trunk and handsome crown. Here and there lofty *Ceibas* (*Bombax Ceiba*) lift their lofty crowns high over the surrounding trees. Silver Tree Ferns alternate with elegant Bamboos (*Bambusa vulgaris* and *Guadua latifolia*). On every side are fruit trees, too various to enumerate, and either covered with gay blossoms or laden with luscious fruits. In the background towers, dark and gloomy, the primeval forest with its massive trunks, dense foliage, and deep solitudes. Gorgeous insects and birds of bright plumage enliven this charming scenery. Swarms of parrots shriek and flutter in the outskirts of the forest; beautiful doves coo on lofty tree-tops; wood-peckers, in search of grubs, hammer loudly upon the trunks; and from the depths of the forest comes the shrill cry of the mocking-bird. Gaily-coloured colibris swarm around the blossoms, and magnificent butterflies sport in the balmy air.

Few of these savannas are of great extent. One of the most beautiful, and at the same time best cultivated, is the *Vega real*, which is situated in the north of the island. It is a rich alluvial plain, about five miles long by one broad. The view from all parts of this plain is extremely beautiful. It is bounded upon the north and south by lofty mountain ranges, which rise in wooded terraces to a height of 5000 or 6000 feet. The higher regions of these mountains are clothed with magnificent forests of evergreen Oaks and Pines (*Pinus occidentalis* and *P. religiosa*). The value of these forests for ship-building is manifestly immense, but, owing to the want of roads, and the indolence and ignorance of the people, many years will doubtless elapse before they are utilised. Great Britain possesses only three species of Oak, but in Haiti there are fourteen species, all of which differ considerably from our British Oaks in the form of their foliage and fruits. The value of the Oaks, Firs, and Pines at present growing in Haiti is estimated at £800,000,000 sterling. Upon the south-west of the *Vega real* is visible the lofty peak of Loma Tina, which, with its forest-clad sides and snow-capped summit, forms an imposing and striking object in the landscape. This peak, which is the highest in the island, is 10,250 feet above the level of the sea. Oaks are found upon its sides only to an elevation of 7800 feet, but Pines (*Pinus religiosa*) extend as high as 9500 feet. Some of the most important trees upon the lower terraces and plateaus are—*Cypress* (*Taxodium distichum*), *Ironwood* (*Xanthoxylon Pterota*), *Logwood* (*Hæmatoxylon campechianum*), *Fustic* (*Maclura tinctoria*), *Mahogany* (*Swietenia Mahagoni*), *Craicou* officinale, *Homalium racemosum*, and *Dipholis nigra*. The natives, however, are so far from endeavouring to utilise these valuable treasures that the boards employed in house-building, even in the interior of the island, are imported from the United States. In 1863 only \$53,347 tons of wood, chiefly Mahogany and Logwood, were exported, and in 1873 the exportation did not reach one half of this amount.

Haitians bestow little care upon the culture of fruit trees, and are content merely to plant a few of different kinds in the immediate vicinity of their dwellings. Prominent amongst the cultivated trees is the Banana (*Musa*), the fruits of which form the principal sustenance of the poorer inhabitants. This useful plant, of which there are two species and numerous varieties, was introduced into Haiti, in 1516, from the Canary Islands. Almost every part of the Banana is nutritious. The young, juicy, well-flavoured, and aromatic; the young shoots and marrow are also eaten, and the wood, fibres, leaves, and roots are employed for various purposes. The Banana lives and bears fruit for fifteen or twenty years. One acre planted with Bananas yields as much food as 44 acres planted with Potatoes. The Breadfruit tree (*Artocarpus incisa*) ranks next to the Banana. This handsome and valuable tree was brought from Tahiti, in 1793, to the island of St. Vincent, whence it has spread over all the West Indian Islands. It is a tree of very rapid growth, and in seven years frequently attains a height of 40 feet. It is at maturity when sixty years old, and has then a massive, erect trunk, from 70 to 80 feet high, and from 3 to 4 feet in diameter. The branches are long and slender, and form an imposing and picturesque crown. The leaves are large, smooth, and dark green. The male and female flowers grow in this upon the same tree; the former depend on long hairy peduncles from the angles made by the leaves with the twigs, whilst the latter grow at the extremities of the twigs. The fruits ripen from November to July; they are of a greenish yellow colour, and weigh 4 lb. or 5 lb. The Mamey (*Mameia americana*) is indigenous to Haiti. The trunk of this tree is 60 or 70 feet high, and the crown closely resembles that of the common British Oak (*Quercus Robur*). The wood is close-grained and durable. The fruits, which are about the size of a

swan's egg, are sometimes angular and sometimes oval in shape. The flesh is yellowish, and very luscious. The Melon tree (*Carica Papaya*) is also indigenous. It has an erect, branchless trunk, about 20 feet high. The crown is composed of a large number of hand-shaped leaves of a greenish yellow colour, and furnished with very long petioles. The blossoms are yellow, and grow upon the trunk immediately beneath the leaves. When ripe the fruits are yellow, and contain a large number of black seeds. The leaves of this tree are used as a substitute for soap, and it is said that tough meat, if hung amongst them, soon becomes tender. The Guava tree (*Psidium pomiferum*) is a native of the island. It is a comparatively small tree; the trunk is low and crooked, the branches few and slender, and the bark smooth; the leaves are ovate in form; the fruits are round, and resemble an Apple in shape. Another species (*Psidium pyriferum*) bears a Pear-shaped fruit, about the size of a hen's egg. The Coco Plum (*Chrysobalanus Icaeo*) is a small, handsome shrub, 5 or 6 feet high. Its fruits are acid, but very juicy, and are eaten with sugar. Amongst the other fruit trees may be mentioned the Sugar-apple (*Anona squamosa*), a small tree, with handsome fan-shaped leaves, and greenish compound fruits; the Sour-leaved, or *Anona muricata*, whose acid fruits frequently weigh 3 lb. each, and are covered with weak prickles; and the Sweet Sapote (*Achras mamosa*), Lemon, Orange, and Coffee trees are generally planted for fences.

The population of Haiti is composed of 600,000 negroes, 390,000 mulattoes, and 10,000 whites. Both physically and intellectually the negroes of Haiti are superior to the negro races of the other islands, and they are a great improvement in every respect upon their African ancestors. Almost the whole population is engaged in agriculture, but each family produces little more than what satisfies its own demands. There is a lamentable want of co-operation and division of labour; and it is to these causes, as well as the partition of the island into two independent States with republican forms of government, rather than to the indolence or ignorance of the people, that the present wretched condition of the country is to be attributed. Ruins are one of the most characteristic features of the island. Everywhere throughout the green savannas and quiet valleys of the island the traveller perceives ruined villages and crumbling mansions, surrounded by deserted fields, and overgrown with wild and tangled vegetation. The magnificent mansions which were once scattered over the island are now piles of crumbling ruins; the gorgeous saloons, in which beautiful creoles and gay planters lounged, are become the lairs of wild beasts; the plants once waving with golden Sugar-canes, or fragrant with the rich perfume of Coffee plantations, are now covered with a dense growth of trees and shrubs, with here and there the miserable wooden or mud hut of the native; and the deep silence, which broods over the ruined factories once echoing with the busy tread of hundreds of slaves, is broken only by the scream of the Haitian bat, or the harsh shriek of some bird of prey. *J. D. W.*

Forestry.

It not unfrequently happens that what we ourselves know and are familiar with, we conclude, or rest satisfied, that others know equally as well as ourselves. I was forcibly reminded of this the other day, on having some queries put respecting the propagation and culture of the Larch in its early stages of growth, and which have led to the production of this article at the present time.

First, respecting the seed of the Larch, I would say, always endeavour to procure the heaviest and soundest; and it matters little whether it is home-grown or foreign, so far as respects the future ultimate growth of the trees in the forest, or even in the nursery, beyond a few years. That is, plants grown from foreign seed, and those from seed collected at home, become so like each other after a few years that no person could distinguish them. After twice transplanting the difference is generally quite extinguished, nor is it ever again practically traceable in the history of the trees.

The seed imported from the Tyrol is generally larger and plumper than that of home growth, and consequently produces plants both in themselves stronger and earlier in the season than home-grown seed.

The greatest disadvantages that I know of arising from the use of foreign seed are the earliness of the growth of the plants in spring, and their protracted growth in autumn, thus exposing them at both seasons to frosts from which plants from home-grown seed are exempt.

The price of seeds, both of home and foreign growth, vary greatly according to scarcity or abundance, being sometimes as low as 6d. and sometimes as high as 3s. per lb.; 2s. may, however, be regarded as a common price. Foreign seed is in general

cheaper than home-grown, owing to the expense of labour and the difficulty in procuring the latter, which want of space forbids my describing.

2. The preparation of the soil and its quality are matters little less important than those respecting the seed. It is very difficult to describe soils so as to be properly understood, and so this description must be plain. The soil for seedling Larch should rather be over- poor than over-rich, light rather than heavy, and the situation should be well exposed, rather than sheltered.

Stimulating manures should be avoided, and to do this it is best to sow upon ground that had been manured the previous year, and cropped with Peas, Tares, Cabages, or Turnips. Very rich black loam can only be rendered fit for seedling Larch by first putting it under grass for two or three years, and digging it down in the autumn previous to sowing, observing to turn over the ground sufficiently deep to cover the grass, which is done by digging it two spades deep. If, however, the ground cannot be prepared as above, but must be dug and manured the same season as above, then old mould or very old rotten manure should be used. When the soil is at all stiff, it should be well exposed to the frost, so that it may pulverise under the rake, and form a very fine mould.

3. Sowing in the North of Scotland should be done about the last week of April or first week of May, and in the South about ten days earlier, observing, however, that the state and condition of the soil is of greater importance than a few days difference in the time of sowing.

The seed-beds may be of any convenient length, a feet wide, with an alley 1 foot wide between. The seed after being steeped in water, in bags or tubs, twenty-four hours, is taken out and spread upon a floor 4 inches deep, and regularly turned every day for eight or ten days, sprinkling it with water and keeping it covered with sheets to keep it moist, when it may be sown; but in order to prevent small birds from picking up the plants when they appear above ground, the best method now of it is to dust over the seeds, while they are wet, with red lead in the powdery state.

As the formation of seed-beds is so well understood, I need not describe the operation, beyond stating that the seed should be very lightly covered with about half-an-inch of fine earth.

If the weather is moist and warm the plants will appear above ground in from fifteen to twenty days, and if the seed is what is considered good, about 40 to 50 per cent. of the seeds will produce plants, and the crop will stand at about 2000 plants per lineal yard of bed. Though many more plants are frequently grown, it is not advisable to do so, as to give abundance of room in the seed-bed is the first proper step to take in the culture of the Larch. If the plants grow well they should be from 4 to 8 or 10 inches high the first season, and should either be well thinned out, or entirely lifted from the bed, and run out into nursery lines in the form of what is termed bedding. If left in the seed-bed they should be well stirred up with a fine-tined steel fork, so as partially to check the top and encourage root growth, the object more fully attained by lifting and bedding.

The following are the prices at which the plants are sold this season in the North of Scotland, seedlings being very scarce:—One-year seedlings, 2s. to 2s. 6d. per 1000; two-year seedlings, 6s. to 7s. per 1000; bedded plants, 8s. 6d. to 10s. per 1000; one-year seedlings one year transplanted, 10s. 6d. to 12s. 6d. per 1000; two-year seedlings one year transplanted, 15s. to 20s. per 1000. *C. Y. Michie, Cullen, April 12.*

Apiary.

WORK TO BE ATTENDED TO IN APRIL.—Hitherto we have been very idle, and allowed our favourites to have their own way, thinking there was plenty of time before the working or busy season commenced, but now it is high time, if we have not yet done so, to awake out of sleep; for, if we are unwilling to give them a little attention, it is scarcely safe to set about their work as they like, we may before long repent of this apathy, and incur losses that cannot afterwards be repaired.

1. Do not forget to encourage your weak stocks by rather liberal feeding every warm evening. You will soon learn when they have sufficient food, for when honey can be gathered your sugar will be left untouched. By neglecting a little attention in this month I have, when I first commenced bee-keeping, lost many large stocks. They appeared to be very healthy and lively up to April, when all at once they died—yes, died of actual starvation. Nothing causes the kind bee-keeper so much sadness in his bee pursuits as this, because the thought will constantly arise in his mind, "Well, I might have saved the poor things, only I was careless."

Recollect, this is the most dangerous month in the year. Be as active as your bees. A little attention and care bestowed upon them now, will be amply repaid by your industrious subjects.

Floor, or bottom boards, should be scrupulously

cleaned; if it is not attended to now, on some sunny afternoon, it is probable you will never do it. Cut away all the little bits of comb which the bees last season fastened to the floor-board; they are only in the way, and will cause the inmates much annoyance and inconvenience in the busy season now rapidly approaching. I give all the straw skeps in my apiary either a new board, or, at all events, one which was well washed in the summer and laid by until the next spring to sweeten, so that it is equal to a new one. If you have no new ones at hand, be sure you scrape the old ones with an old knife, and make them as clean as your own dinner-table. Do not for one moment think it is useless your doing so, a waste of time, labour, &c. Try the difference—clean one hive-board well, and leave the other you to fight its own way uncared for—then another year you will remember our homely advice.

Water.—Observe your bees flying and humming lazily about the water-butts, pump-trough, and the like pools of water about your premises; and they will alight watch them eagerly drinking, then flying off to their homes with joy. Bees are all water drinkers, so every teatotaler should be a bee-keeper. Perhaps in April and May, water is more needed than in any other month during the whole year. A friend has a square tin vessel, about 3 inches deep, placed opposite the stands, in which, when nearly filled with water, he places a quantity of moss; the bees seem to appreciate this contrivance, for they have no fear of death by drowning when running over the mossy ponds. I am sorry to find that even thousands of my neighbours' bees are now (April 2) to be seen drowned in a water or rain tub, reared against his house. The water is rather low in the tub from the late drought, the bees have, therefore, been unable to make their escape, in fact they are veritable death traps. However, my bees seldom leave the garden if water is placed conveniently for them. It is surprising how soon they all learn where to go for the supply of water, for their young brood and cell-building.

Another matter should be attended to this month, although it does not exactly come within the bee-master's scope, yet if he studies the welfare of his stocks he will keep a sharp look out for *Queen Wasps*, which now begin to put in an appearance. The vicar of our parish, an enthusiastic apiarian, every spring encourages the boys belonging to his large day school to destroy these insects, and gives a penny for each wasp brought to his residence. This has been found to work well, for we have now but few wasps' nests in the district. Remember each queen wasp commences and sustains a new colony; they are more independent and vigorous than the queen of the hive, so every queen destroyed in April, in reality destroys a whole nest, or what would be a nest later in the season. It is not uncommon for one queen to rear a nest of 50,000. These thieves are so much a few pence of your best honey, not to mention the immense number of working bees which they murder in the fields. Let war to the bitter end be at once and for ever declared against these villainous-looking insects. Look out for

Robbers and Thieves.—We read the light-fingered gentry about our houses and homes, but hive-robbers are far worse to deal with. We have just mentioned a thief who is dressed in yellow livery. We are, however, informed in the good book that a man's foes are they of his own household. In respect to bee-hives this is a fact, for the little busy bee's foes, which it evidently breeds most of all, are bees from a neighbouring hive, often on the same stand, where several hives are placed close together. Every warm afternoon, if you can spare a few minutes, walk gently round your stocks, and note the entrance of each hive; you will easily detect friend from foe. The thief is buzzing about; when it alights at the mouth of the hive it first peeps in to see if the coast is clear, then, with a cautious and unobtrusive gliding, he darts into the hive, but often, or we might say always, if the stock is strong, as quickly darts out again, pursued by several bees. If robbing is actively going on, the sooner the hive is removed to a new stand the better. Sometimes it is well to remove them to a new locality, unknown to the robbers; it is only by this means that the stock can be saved. If it has only just commenced, enable the bees to defend their hives with a few pence of your best honey, or, at most, two bees can pass and re-pass each other at one time. I have always found the last remedy the best; and in several instances I have known those stocks which have been sadly weakened by robbers increase and become most valuable, simply by narrowing the entrance and liberal feeding. R.

Natural History.

ASPIDIOTUS CONCHIFORMIS (MUSSEL SCALE)
APPLE.—Before the advancing growth on the Apple tree makes it almost an impossible matter to attend to the state of a little without much injury to the young shoots, a bark without much to be well bestowed on clearing away the mussel scale where it exists in any great quantities.

These scale insects, scientifically known as *Aspidiotus conchiformis*, are distinguishable by their resemblance to a mussel shell in miniature, sometimes curved to one side, sometimes to the other, at the smaller extremity, and sometimes straight. The length is about the sixteenth of an inch, the texture hard and shiny. The scale is transversely wrinkled, attenuated at the head end, and rounded at the other extremity, and adheres with great firmness by means of the white filmy substance beneath it, which leaves a very permanent mark on the bark when the scale has been removed. The colour is deep rich brown, but much paler, and of an orange tint at the head end.

Beneath the shell, and free from it, is the female and her eggs, and at present the scale will be found filled for the chief part with eggs—thirty or upwards in number—white, and of various irregular forms of oval, the extreme irregularity in the shape observable just at present being presumably merely the alteration sometimes noticeable when the insect egg is on the point of hatching.

From the minute size of the scales, and their correspondence in colour with the bark on which they are fixed, they attract little observation, and are apt to be passed over till they have increased into a settlement not easily got rid of. They appear to exercise some kind of choice in the selection of the spot on which to change from the more active condition of their early existence to the immovable state in which the females pass the latter part of their lives, preferring seemingly the dampest side of the tree, and the smoothest part of the bark, and also some special varieties of apple.

In my own garden, where, under previous ownership, the trees seem to have been little attended to, these scales have established themselves in myriads, and show at present in numbers far beyond anything I have ever met with elsewhere, appearing mostly on the Wellington and a kind of small Ribston Apple, and in the greatest quantities on the north side of the

FIG. 112.—ASPIDIOTUS CONCHIFORMIS.

trunks and the under side of the branches, as if shrinking from direct exposure to sun-heat.

The position of the scales is not as generally (or often) the case with other cocci, with their heads pointing in one direction; the mussel scales point vertically or horizontally or in any direction indifferently, and on one of the trees are so numerous as literally almost to cover the trunk (excepting a strip up the sunny side) from a little way above the ground to the fork of the branches, about 5 feet above, the lower part of the branches being thickly infested also.

A little later in the season (probably in the course of May) the eggs contained beneath the little mussels that form the scale-like covering of the female *Aspidiotus* will hatch into temporarily active little cocci, which, whilst their legs and the power of using them remain, will spread over the more juicy branches, and provide themselves with a living by means of their rostrum, at the expense of the tree.

Just now is a good time for attack, before the young insects have begun to spread. The means especially recommended are, scraping off the bark and burning it with the infesting insects, or crushing the scales with a wooden knife on the tree, and rubbing the surface with gas-tar; but as far as my own experience goes, the most effective plan seems to be to wait till a wet day, and then with a large, fairly sharp pruning knife, held upright, to scrape the bark just firmly enough to bring away the scales, which come off easily under these circumstances. The curved shape and smooth edge of the knife gather the creatures off thoroughly and rapidly, where a rougher treatment might fail or do more injury to the bark, and the wet soft moss, scales, and dirt generally make a kind of plaster together on the knife which can be easily scraped off and destroyed, whilst the same operation in dry weather would probably let many of the scales fall to where the eggs might hatch in safety.

When the young cocci are in the act of hatching (which may be made out by examining the infested parts with a common magnifying glass) a band of any kind of soft woollen rag well soaked in Gishurst Compound, or any other fluid prejudicial to insect life, and tied round the boughs above the scale-infested part, would probably check the advance of

the young insects towards the more tender parts of the tree; but where the *Aspidiotus* is found in great numbers it is desirable to get rid of it as soon as possible, as, though of little consequence when in moderate numbers, were allowed to gain possession it often causes much injury. O.

Notices of Books.

Fungi Britannici excisicanti. Editio secunda curâ M. C. Cooke. Fasciculus I. London: Williams & Norgate, 1875.

This is a great improvement on the former series, the specimens form being much more convenient, and the descriptions more nearly distinct. There is, however, a feature in the publication which makes it peculiarly valuable. Dr. Cooke, who is certainly indefatigable, has, in a large proportion of the specimens, figured the spores under the camera lucida, and has appended figures to the specimens. This is indeed not an entire novelty, for in the *Plantæ Cryptogamæ du Nord* Desmazieres adopted this very useful plan, but not to the extent in which it is carried out here by the author. We have seen that Dr. Cooke had added in every case the microscopic measurement, and we should then have little left to desire. Four specimens appear on each page, in such a manner, however, that they can be readily divided if it should be thought advisable to intercolate them in the general herbarium. We wish Dr. Cooke every success in his laborious undertaking.

Obituary.

We sincerely sympathise with our Belgian friends in the severe loss they, and horticulture generally, have sustained in the sudden death of M. EDMOND DE GHELINCQ DE WALLE. This gentleman was known to a large number of our own horticulturists as the able, courteous, and hospitable President, since 1870, of the Royal Horticultural and Agricultural Society of Ghent, in which capacity he presided with much tact and with splendid hospitality at the last quinquennial exhibition in that city. We owe to M. Oswald de Kerchove de Denterghem the following particulars concerning his distinguished townsman.

"Death has robbed us of a friend who took the highest rank as an amateur, and who was justly esteemed throughout Belgium. He died on the day following one of his greatest successes, when he had maintained the ancient reputation of Ghent at the neighbouring city of Antwerp, and obtained fresh honours in the contest. As a member of the jury he had fulfilled his duties with the delicate tact and kindness of heart characteristic of him. On his return from this exhibition symptoms of his fatal disorder first made their appearance. The news of the dangerous condition of the President spread with rapidity, and excited consternation in the minds of his friends and of all those concerned in the advancement of horticulture. In his vast conservatories at Wondelghem he had accumulated a collection of Palms, Ferns, Dracenas, Selaginellas, and Aroids, which were well known to amateurs. His fine *Azaleas* gained him the prize wherever they were exhibited. His *Cycads* were notorious, and many were the foreign visitors who begged permission to see the splendid specimen of *Encephalartos Cafier*, which, as many of your readers will remember, formed one of the main objects at the last quinquennial in 1873. It is needless to add that this permission was always freely granted, and the cordial reception accorded by M. Ghelincq de Walle to strangers showed that the traditions of Flemish hospitality were in him associated with the high breeding and refined feeling of the nobleman. The important services which M. de Ghelincq de Walle rendered to horticulture were acknowledged in 1873, when the King conferred on him the Cross of Chevalier of the Order of Leopold. By the votes of his fellow-citizens he was elected as their representative in the provincial Council of East Flanders, and the Government nominated him as Chairman of the Committee of Visitors (*Conseil de Surveillance*) of the school of horticulture connected with the University of Ghent. As President of the Royal Agricultural and Botanical Society of Ghent, and of the "Cercle d'Arboriculture," he had won the good opinion of all the members of those bodies. Impartial and just, active and devoted, retiring and well informed, M. Ghelincq de Walle exercised his delicate duties with a tact and a courtesy which will remain in the memory of all with whom he was associated. Indeed, his goodness of heart was only equalled by the modesty with which he disclaimed the favourable verdicts which were his due. His name will remain for ever associated with horticulture and the city of Ghent, less perhaps for the love he had for plants than for the *États* in which he presided over the quinquennial exhibitions which took place under his auspices; and his memory, justly honoured, will survive those of his venerated predecessors still held in honour by the Society."

HORTICULTURAL EXHIBITIONS, 1875.

MAY.

- 1 to 10, inclusive.—Royal Botanic Society, Regent's Park.
Mr. William Paul's Special Show of Roses, Pelargoniums, &c.
- 11 to 24.—Royal Botanic Society, Regent's Park. Special Exhibition of Clematis, by Mr. G. Jackson.
- 7 and 8.—Exhibition of Plants and Flowers in the Kibble Conservatory and Royal Botanic Garden, Glasgow. Manager, Robert Bulchin.
- 12.—Royal Horticultural Society, South Kensington. Meeting of Fruit, Floral, and Scientific Committees. Pot Rose Show.
- 14 to 21.—Manchester Botanical and Horticultural Society's Annual National Exhibition, at the Garden, Old Trafford. Manager, Bruce Findlay.
- 17 and 18.—Halifax Floral and Horticultural Society's Annual Exhibition. Sec., Leonard Kershaw, 20, Gladstone Road, West Hill Park.
- 20.—Royal Horticultural Society of Ireland. Early Summer Exhibition. Sec., A. Balfie, 25, Westland Row, Dublin.

THE

Gardeners' Chronicle.

SATURDAY, APRIL 24, 1875.

APPOINTMENTS FOR THE ENSUING WEEK.

- MONDAY, April 26
Sale of Bruce's Nursery, Kingston, Surrey, at the Mart, Tottenham, Yard 2 & C, by Protheroe & Morris.
Agricultural Show at the Town Hall, Manchester.
- TUESDAY, April 27
Sale of Plants, &c., at Theobald's Park, Walkham Cross, Herts, by Protheroe & Morris.
Sale of a Collection of Minerals, at Stevens' Rooms.
- WEDNESDAY, April 28
Exhibition of Spring Flowers at the Royal Botanic Society's Gardens, Regent's Park.
Sale of East Indian Orchids, at Stevens' Rooms.
Sale of Imported Orchids from Messrs. Veitch & Sons, at Stevens' Rooms.
- THURSDAY, April 29
Sale of Stone and Greenhouse Plants at Tanners' End, Edmonton, by Jackson & Son, of Hertford.
Opening of the Alexandra Palace.
Special Exhibition of Clematis at Regent's Park (until 1st).
- SATURDAY, May 1
Mr. W. Paul's Special Show of Roses, Pelargoniums, &c., at Regent's Park (until 10th).

LIKE many other expressions in general use the term "double flowers" covers several totally distinct conditions. We will not affirm that under the title "double" things as different as chalk and cheese are included, but we may fairly say that double flowers are far more different in their essential nature one from another than are the several varieties of cheese.

We do not propose at this time to descant upon this subject at length. The reader desirous of ascertaining what are the principal varieties among so-called double flowers will find them enumerated in a paper in the Proceedings of the London Botanical Congress, 1866. At this time we may confine ourselves to DOUBLE NARCISSI, pleading as our apology for so doing the interest which is felt in these beautiful flowers. It needs but a glance to see that these double Narcissi include very different changes in different cases. Some are comparatively simple, others very complex in organisation. In the single flowered varieties we have a perianth of six pieces, separate above but inseparable below, where they form a tube investing and inseparable from the so-called "inferior ovary" or immature seed-vessel. From the throat of the perianth springs the crown, or corona, or cup, or trumpet, or nectary—for it has been called by all these names, and by some others which we need not stay to cite. Probably we shall not be misunderstood if we use the term "corona," which is perhaps a little more definite than some others, and which, at any rate, does not convey any misleading idea as to its nature.

Within the corona, and springing from the flower-tube, are the six stamens, while quite in the centre is the style, proceeding as a single thread from the top of the ovary. Such is in general terms the structure of a single Narcissus flower. The most interesting peculiarity about it is the "corona," and this is. If the ordinary observer saw a wing proceeding from the shoulders of a man, he would be somewhat surprised; and if he were a man of intelligence

and of a scientific turn of mind he would not rest satisfied till he had made out what that wing was and why it was there. So in the case of the Narcissus. The flower is "complete" in a botanical sense without the "corona." This latter is neither fish, flesh, fowl, nor good red herring—that is, it is neither sepal, petal, stamen, nor pistil; and it is the business of the botanist to settle what it is. It would take us too far out of our track to enter here into this discussion. It may suffice to say that while some—most, now-a-days—consider it a mere excrescence or outgrowth from the perianth-structure, others look upon it as a series of disguised or abortive stamens. Double Narcissi, as we shall explain presently, throw some light on this question, though the evidence derived from this source must not be taken by itself, but requires to be checked by evidence derived from other quarters.

All this by way of preface to double Narcissi, but really it is a question whether the preface here is not the most important part of the whole; and at any rate, it is certain no one can understand a double Narcissus unless he is first of all conversant with the structure of the single one.

The double Narcissi are, as we have said, very varied in their construction, but their varieties admit of being classed under two primary categories—increase in the number of parts, and change in the nature of those parts, or, in other words, substitution of one part for another.

The increase in the number of parts takes place in different manners; the mutation or substitution of parts is equally varied. These changes occur together or separately, in slight or in excessive degree.

To illustrate these changes we must advert to some of the double Daffodils. First of all let us take the one concerning which there has been so much written lately—the double Daffodil, the double form of the wild Daffodil of our copses, the one we figured last week at p. 500, the "Narcissus pseudo-Narcissus Anglicus flore-pleno," of PARKINSON, in whose *Paradisi in sole Terrestris* it is well, though somewhat conventionally, figured, and where also it is called Gerrard's Double Daffodil. In this we have first of all a condition analogous to the "hose-in-hose" condition in the Primrose, *i.e.*, the perianth with its corona is repeated twice or oftener; then within that the stamens are more or less changed into perianth segments, and probably increased in number.

Mr. SHIRLEY HIBBERD sends us a form almost exactly like this, but more than twice the size, and which we take to be the N. Pseudo-Narcissus hispanicus flore-pleno, or PARKINSON'S Daffodil, which he says is "of mine own raising." We cannot distinguish with certainty the double forms of N. Telamonius and N. major. We are not now, however, concerned with the question what this is—that is, to what species or variety we are to refer it; enough for us that it is structurally the same as the true double English Daffodil of GERRARD and PARKINSON. Mr. BARR sends us flowers of N. cerneus and moschatius, which are changed in the same general way. It will be remarked that, in these hose-and-hose Daffodils the flower-tube and the corona are not more divided than in the single flowers, or but slightly so.

The ordinary double Daffodil of cottage gardens, and which is now so largely grown between the Gooseberry bushes under the Apple trees in the London market gardens, presents but a slight structural, though to all appearance a great difference from that just described. PARKINSON called this, or a very nearly allied form, Master Wilmer's Great Double Daffodil. Who was Master WILMER? But all this is beside the question: *revenons à nos Narcissus*. This great double Daffodil differs structurally from the smaller one first men-

tioned, in the circumstance that the flower-tube is much shorter, that is, the perianth segments are separated one from the other to a much greater extent than usual; the corona, which in the former case was trumpet-shaped, and only divided at the edge, is here apparently split into distinct segments, or rather, the segments were never united as they are usually; moreover, the stamens and the style are increased in number, and variously changed, some being quite petaloid, others half petal half stamen, and so on. Among the specimens obligingly communicated by Mr. BARR the following belong to this type, that is, so far as their doubleness is concerned—"the large double Daffodil, N. Pseudo-Narcissus lobularis plenus, and N. odorus plenus." We may remark that the lemon-and-gold Daffodil belongs to this section, and we may further add that the perianth segments are often of a green colour while the coronal segments are yellow.

A still more exaggerated form of double Daffodil is that resulting from proliferation or branching of the axis or stem of the flower; so that in place of one centre, three to six or more "centres" or rosettes—each representing one flower—are found within one common envelope. The parts of these supplementary flowers are multiplied and changed as in the former cases. An illustration of this latter change is afforded by Mr. BARR'S "Narcissus Pseudo-Narcissus grande plenus." We may as well say, *en passant*, that we believe this "prince of Daffodils" to be "Narcissus Pseudo-Narcissus aureus Anglicus maximus sive Roscus Tradescanti" of PARKINSON. Good reader, we appeal to you, *en parenthèse*, do you not think LINNÆUS did good service when he made the rule that plants should have but two names—one the family or surname, the other the specific name? And do you not agree with us that it is a mistake to go back to pre-Linnæan prolixity of appellation, as some are inclined to do?

In some other forms the perianth segments and the corona remain unchanged, but the inner parts of the flower—the stamens in particular—are increased in number, and more or less replaced by petals.

In all the preceding forms we have seen that the corona, whether changed or unchanged, plays an important part in the flower, often by its deeper colour serving to give a quasi-striped or parti-coloured appearance to the flower.

We have now to speak of a form of doubling in which the corona is entirely absent, and where the perianth segments are multiplied by equation or outgrowth one from another, so as to produce a star-shaped flower, with the segments laid over one another in strictly regular order. In these flowers the segments do not alternate one with another, as is the usual rule in most flowers, one segment coming between two others, but the segments are placed "opposite" one another, one immediately in front of another, like a pile of books, or like the leaves of a book. In this form, which is of high botanical interest, the corona is absent, or, if present, of the same colour as the perianth segments. To this form belongs the "N. capax" of Mr. BARR, the *Ajax* *eyestentis* of HERBERT, figured long before under a long name by PARKINSON.

The double forms of *Narcissus incomparabilis*, *poeticus*, *odorus*, *Jonquilla*, *montanus*, all come under one or other of the preceding heads. It would be tedious to pursue the matter further; suffice it to say that the forms were recognised by the older botanists. PARKINSON, in particular, figures several of them, and he was quite aware of the difference between a *flos duplex* or multiplex, *i.e.*, a hose-in-hose condition, and the *flos plenus* arising from the multiplication and transformation of the stamens.

We may fittingly add a postscript to this article by announcing the publication of a

volume on the flower of the day—*The Narcissus*,* by Mr. F. W. BURBIDGE, copiously illustrated, and of which it will be our duty and our pleasure to make further mention hereafter.

It is a rather disheartening thing to see so many lamentable examples of the inability, first, to observe properly, and, next, to weigh evidence, or reason correctly on what has been observed. We had occasion to allude to this lately (see p. 112), and we should not have referred to it again were it not for a discussion which took place at a recent meeting of the Society of Arts, as reported in the *Agricultural Gazette*. The subject of discussion was the utility and proper method of conducting experiments for agricultural purposes; the speaker was Professor WRIGHTSON, the Chairman Mr.

crop of Wheat. In other cases, Barley and Rye had been the result. It was only Oats, however, which thus varied—other grain always reproducing itself."

We have quoted this verbatim lest we should be accused of ridiculing a very estimable man. Seriously he might as well ask us to believe that, by keeping an ass shaved all the winter, and keeping it in the stable, it would in the spring develop into a horse. The one thing is not more preposterous than the other.

However perverted these statements may be—however erroneous the interpretation put upon them—yet they generally originate from some fact or condition not obvious in the sequel, though possibly they would be so in the beginning. The business of an intelligent man, if he have it in his power to do so, is, not to take

mittee were naturally desirous that their exhibition should take place at South Kensington about the time of the Fungus Show. Certain proposals were made to the Council by the committee, but they did not meet with the response reasonably looked for, and the promoters had to abandon their intention of going to the Royal Horticultural Gardens. Negotiations were opened with the executive committee by Sir EDWARD LEE on behalf of the Alexandra Palace Company, and these were so comprehensive in scope and liberal in character that the committee closed with them, and the exhibition has been fixed as above stated. The sum of £30 has been placed at the disposal of the committee by the Alexandra Palace Company, as special prizes; and it has been arranged that this sum shall be given in the leading class of twenty-four varieties of Potatos in prizes respectively of £8, £6, £4, and £2, the balance to be added to the 1st prize in the form of a handsome silver cup. The show will extend over two days, and the committee have announced their intention of paying the prize money before the close of the exhibition. On the evening

FIG. 113.—VIEW IN NAGASAKI, JAPAN.

CLARE SEWELL READ, M.P. We may find occasion in another issue to make some comments on Professor WRIGHTSON'S paper. Our object now is to express our astonishment that the Chairman, unless by way of badinage, could ever have uttered such nonsense as is attributed to him. "Speaking to an audience, the majority of whom," said the Chairman, "probably were more gardeners than farmers, he would suggest that there were experiments which could be conducted on even a very small piece of ground; one in particular of a very interesting nature was the following:—If Oats were sown, and kept constantly cut as they grew, it would be found next year that they produced, not Oats, but something else. He knew an instance where this had been tried in a garden, the Oats being kept cropped with a pair of shears, and covered from the first with a little straw in the winter, and the next spring they produced a

these marvellous stories and old wives' fables for gospel, but to test them for himself—to ascertain what is the real basis of the story; or, if he cannot do so himself, at least to withhold his assent till some one with the requisite knowledge and care has done so. We are quite certain that neither Messrs. LAWES and GILBERT, nor Professor WRIGHTSON, nor any of the many observers at the German Agricultural Stations, ever witnessed anything so marvellous as that of which Mr. READ "knew an instance." When a person in Mr. READ'S position makes such astonishing statements, we cease to wonder at the belief and faith of the electors for Stoke and their fellow-thinkers.

— It has now been definitely arranged that the INTERNATIONAL POTATO SHOW will take place at the Alexandra Palace, Muswell Hill, on Wednesday, September 29, and Thursday, September 30. Regarding the Royal Horticultural Society as the headquarters of practical horticulture in London, the com-

mittee, judges, exhibitors, and others, will dine together at the Alexandra Palace, under the presidency of Mr. Alderman and Sheriff ELLIS; and at noon on the second day a conference of Potato cultivators and others will be held, which, if well carried out, is likely to prove of an instructive and interesting character. It is hoped that collections of Potatos for comparison, if not for actual competition, will be forthcoming from Ireland, Scotland, the United States of America, France, Germany, and Belgium, as the committee are exerting themselves to give this exhibition a truly international character. The exhibition will take place in the commodious concert-room, which can be shut off from the remainder of the building, and securely locked by night. The comfort and convenience of exhibitors will be studied as much as possible, both by the committee and the managers of the Alexandra Palace Company. Schedules of prizes are now ready, and can be had of the Hon. Sec., Mr. PETER MCKINLAY, 23, Upper Thames Street, London, E.C.

— Amongst recent additions to the Kew Museums may be mentioned a fine collection of the CONES or FRUIT HEADS OF PANDANUS from Mauritius and Seychelles, gathered and sent home by

Mr. HORNE. These fruits will prove a very valuable aid in working up the Pandanaceae for the *Flora of Mauritius*, upon which Mr. J. G. BAKER is now engaged. A large series was sent to Kew by Sir HENRY BARKLY some five years since, but the fruits having apparently been too ripe at the time of gathering, and not having been sufficiently secured before placing in fluid, they fell to pieces before reaching their destination. Mr. HORNE seems to have obtained his specimens at the right age, and though they were well secured, each one being sewn up separately in canvas before being consigned to its barrel of rum, the separate drupes hold firm together into a solid compact head. Out of about two dozen of these cones, one alone upon being unpacked showed any tendency to collapse, and this was the largest of the whole series—an immense fellow from the Seychelles—measuring more than 10 inches through, and weighing 30 lbs. It was, however, speedily enveloped in a net and preserved in its original form. It will probably prove to be a new species.

— Mr. MEECH sends us the following appeal on behalf of the ROYAL AGRICULTURAL BENEVOLENT INSTITUTION:—

"Believing, as I think we must all believe, that the art of producing human food is the first, the most important, and the most extensively necessary of all the arts, I am surprised and grieved that for those farmers engaged in that most important business (and their number in Great Britain 560,000, and in Ireland 600,000), there was no charitable institution for the relief of those among them on whom the name of pauper had not so lately been there, as a labour of love, but, as may be supposed, at considerable personal anxiety and cost, succeeded in 1860 in originating the Royal Agricultural Benevolent Institution, for the relief of decayed farmers, their widows, and orphans. It has pleased God so far to support my efforts with success, assisted, as I have been, by our Council, officers, and honorary secretaries; and we have now several hundred recipients, receiving about £8000 annually. But, large as this sum may appear, it is totally inadequate to supply the rapidly increasing demands for its aid. Nor can we wonder at this, when we consider that the farmed area of the United Kingdom, according to the Board of Trade statistical returns, covers 47,000,000 of acres, farmed, as I have said, by more than a million occupiers, possessing a tenant's capital of £300,000,000 sterling. There can be no doubt that the good farmer has often and long since desired to promote such an institution, but it was impossible to succeed with the enormous rates of postage formerly existing, when that which now costs only a penny then, in many cases, cost from 5s. to 8s. Thanks to Sir ROWLAND KILNICKER, that impediment to the current of charity has been removed, and I look forward to the time when our present income shall have been many times multiplied. I well know how wide and how bountiful are not only the wealth, but the hospitality and charity of that noble city in which I have passed nearly half a century of my now fast declining years. His Royal Highness the Prince of WALES has kindly consented to preside on Saturday, June 5, at our Fifteenth Anniversary Dinner, and I need hardly say how happy I shall be to meet and meet at that dinner a number of your readers have contributed to its much required funds. *John Joseph Mechi.*"

— Mr. PEACOCK'S collection of CACTI and AGAVES is the subject of an interesting article, from the pen of Mr. FRANK BUCKLAND, in *Land and Water* of the 17th inst. This is what Mr. BUCKLAND has to say of the Agaves:—

"Agaves are generally called American Aloes. They consist of strong-bladed leaves, the tips of which are surmounted with sharp bayonet-like thorns. The sides of the leaves are also armed, and, strange to say, many of them—a fact hitherto unknown to Mr. PEACOCK—have these sides armed with the sharp edges of sharks' teeth. Thus in the Agave Peacockii, the spines are almost an exact model of the teeth of the 'oak kettle,' a large cod-eating shark, found off the coast of Iceland. In Agave Regeli macrodonata the spines are in the shape of the teeth of the Bonnet shark (see specimens in my fish museum, South Kensington). For some reason or other Nature seems suddenly to have changed her plan, for in Agave schidigeri, the 'needle-and-thread plant,' the spines exist no longer, but, on the contrary, are converted into a silky web of threads, a good name I should propose for the plant would be 'Eve's Huswife.' I wish also to mention Agave Gilbeyi, named after the well-known wine merchant. This specimen is the only plant of the species in England. There is also a Brazilian Agave, the armed distal end of the plant, which is throwing up a spike like a long and as thick as a man's wrist, the spike being surmounted with a broom exactly resembling the feather that used to be worn in the bearskin caps of my old regiment, the 2d Life Guards, at about the time of Waterloo. This is the only plant of the kind that has ever flowered in this country."

— The *Kölnische Zeitung* of March 25 reports that a new glass has been invented by Herren LUBSCH and FREDERER, of Count SOLLA'S glass-works, Andresshütte, near Bunzlau. This new glass

is called METAL GLASS, and is so hard that if a pane of it is laid on the ground, and a leaden ball of 40 grammes weight is allowed to fall upon it from a height of 12 feet, it is not the least injured. Nor is it the least affected when dipped whilst red-hot into cold water. It is, therefore, practically unbreakable, and will be very useful for glazing greenhouses, &c., as well as for lamp chimneys and other articles of domestic use.

— We received lately a large quantity of TULIP BULBS in a STRANGE STATE OF DISEASE. Some were a mass of corruption, never from the first having been able to germinate; others were in every intermediate state, from the first growth to the expansion of the flower; but all in a very weak and wretched condition. Every bulb was carefully dissected, on the possibility of finding the larva of some Diptera like that which attacks bulbs of Narcissus; and there was nothing of the kind, while, on the contrary, in every case there was the peculiar brown tissue, in patches of greater or less extent, which is indicative of the disease which MONTAGNE called *Taon*, a translation of whose memoir appeared in the *Journal of the Royal Horticultural Society*. *Coronae*, *Crocus*, and *Gladioli* are very subject to the disease, and the intensity is just proportionate to the position which it occupies. If it is situated near the disc from which the roots are given off, the whole mass is sure to perish sooner or later, and the vegetation cannot proceed to perfection. Where the disease was extensive at first the bulbs decayed, but according to its virulence very various degrees of perfection were obtained. Unfortunately no remedy is known, and the existence of disease is seldom ascertained before its effects are too prominent to remain unnoticed. *M. Y. B.*

— PATENT PAPERED WOOD HANGINGS, as they are called in the advertisements, have long been known in America, where they were first introduced, and from whence they have appeared in England, though their use with us at present is, we believe, rare. Since their first introduction in America, some years back, many improvements have been made in them. At first the shavings, for such they are, were thick compared with what we now find them. They were, as now, removed from the trunk, by a kind of gigantic planing machine, in lengths of several feet; these sheets, however, it was found, were very liable to crack in the grain of the wood, and so it became necessary to cover the sheets on one side or line them with thin but strong paper. By adopting this means of strengthening the sheets the shavings themselves have been reduced very much in thickness, indeed, to quote a brief description of these wood hangings, sent out by a firm in Boston, which deals largely in them, we may have in these wood-shavings "Nature's own production in her most attractive form: a pearl birch's-eye Maple, one two-hundredth of an inch thick."

Applied to plastered walls in the same manner as ordinary paper-hangings, and finished off in oil, wax, or varnish, they not only have an elegant appearance, but are also very durable, as heat and dampness do not have any effect upon them, the colours of the wood being perceptibly improved by age, and moreover the walls can be washed as often as required. The cost is said to be no more than that for good graining, which, however well done, can never equal the real wood. These veneers are also applicable for the larger articles of furniture, such as pianos, organs, &c. Woods of all kinds are treated in this way, amongst them being Walnut in all its varieties, such as plain, curly, blistered, striped, French, &c.; white, brown, Hungarian, and Circassian Ash; bird's-eye, blistered, and curly Maple; red, white, and curly Oak; yellow and silver Birch, plain and figured Cherry, Pine of various kinds, besides Rosewood, Mahogany, Satinwood, Red Cedar, &c. To fix these wood-hangings to a wall is as necessary as to hang paper, the wood and paper sides, allowing the wood sufficient time to swell out evenly and smooth before fixing to the wall, which is done with flour-paste, as in ordinary paper-hangings.

— THE ANNUAL EXHIBITION OF THE CENTRAL HORTICULTURAL SOCIETY OF FRANCE will be held this year in the Orangery at the Tuilleries Palace, from May 29 to June 6. All letters should be addressed to the President of the Society, Rue de Grenelle, Saint Germain, 84, Paris.

— A very old subscriber has kindly shown us an interesting chart of the weather of December, 1829, and January and February, 1830, as noted at Tours. On December 28, 1829, the thermometer was as low as -15° C., = 5° F., and on February 3 it was as low as 6° F. We presume the record is of extreme not mean temperature.

— FROM COLOGNE we learn that great preparations are making in the Flora Garden for the forthcoming INTERNATIONAL EXHIBITION of 1876. In addition to plants there will be exhibitions of implements, buildings, vegetable products,

fossil plants, objects of art. Altogether there are 923 classes, arranged in eight divisions.

The next meeting of the Institution of Surveyors will be held on Monday evening, April 26, when a paper will be read by Mr. W. L. HURDISON, entitled *LARGE ESTATES and LARGE FARMS in PEASANT PROPERTIES*. The chair to be taken at 8 o'clock.

VIEW IN NAGASAKI, JAPAN.

OF late years there has been an immense progress in general acquaintance on the part of foreigners with all regions of the country of Japan; and, although the original rule is still in operation by which no foreigners, with the exception of ministers and their suite, are permitted to travel in any part of Japan outside of the treaty limits, yet, owing to a variety of circumstances, foreigners of one or other nationality have, in fact, visited nearly every province of the Mikado's dominions. Amongst others, Sir Rutherford Alcock, Sir Henry Farnes, Mr. De Long, and Dr. Willis, are among the modern explorers of an empire which so recent an author as Dean Swift compared with the visionary regions of Lilliput and Brobdingnag. But of all the travellers who have visited Japan none have contributed more to the advantage of the European horticulturist than the late Dr. Siebold and the well-known Robert Fortune, who published a charming narrative in 1863, and who first transferred from the Japanese islands so numerous examples of those trees and shrubs which produce such charming sylvan effects in the distant Oriental landscape.

Thanks to the Wardian cases, our parks and gardens have been enriched with many beautiful exotics, which, but for this admirable invention, would never have been seen beyond those countries in which they are indigenous. Amongst Conifers we may mention the beautiful Parasol Fir (*Sciadopitys verticillata*), *Thuopsis dolabrata*, *Retinospora obtusa*, and *R. pisifera*, *Nageia ovata*, and several new Pines, Cypresses, and varieties of almost all these species having variegated leaves. Amongst shrubs are the charming *Eurya*, with its broad Camellia-looking leaves, variegated *Daphnes*, *Privets*, *Yews*, *Hollies*, *Box*, and *Ferns*, sweet-scented *Skimmia*, *Weigelas*, and *Chrysanthemums*, &c.; nor should we omit the *Aucubas* and the *Osmanthus aquifolius*, and many others, all either "pleasant to the eye" or "good for food."

The engraving on the previous page (fig. 113) represents a portion of one of the numerous temples which are scattered on the hillsides in and about Nagasaki, which are much in the same condition in which Kempter found them 200 years ago. Fortune describes his pleasure at finding the names of *Kämpfer* and *Thunberg* carved on a large rough rock in the island of Desima.

Nagasaki is a town containing about 70,000 inhabitants, and situate at the head of a long picturesque harbour surrounded with wooded hills. One marked feature of the people of Nagasaki (indeed throughout Japan) is their enthusiastic love of flowers and trees and ornamental shrubs, and they zealously follow out their favourite pursuits of gardening and floriculture to the extent of their means. The Buddhist temples, of which the engraving is a specimen, are placed in the best situations on the terraced hill-sides behind the town; the view over the town, the bay, and the distant hills is most charming, and well repays the visitor for the toil of the ascent. Camphor trees of great size are common about these temples; some of them are of great age; the *Pinus chinensis* or *P. Massoniana* are also common, and attain a good size. Higher up are clematises with combinations of past generations. Observe the supports under the limbs of the Pine tree on the terrace, which tree has been deliberately planted in front of the centre of the steps beyond with a view to its picturesque effect.

An English surveyor, Mr. Macvean, is now employed in making an accurate survey of the Japanese dominions with a qualified staff of assistants, and Capt. Douglas, R.N., has established a hydrographical department under the Japanese Government.

Western civilization is making rapid strides throughout Japan, and it is now almost as usual to meet in Yedo a Japanese noble wearing the two swords as it is to meet a gentleman in London attired in the Highland costume. Mr. R. G. Watson, late Chargé d'Affaires, read a most interesting paper on the progress of Japan not long since at the Royal Geographical Society in London, and in the *Illustrated London News* lately there was a capital sketch representing the European costume as adopted by the Japanese dandy. Our illustration is from a drawing by Capt. S. F. Oliver, of the Royal Artillery.

Home Correspondence.

The Broomesbarrow Yew.—This magnificent tree, which grows on the site of the old British camp that crowns Coneygre Hill, in the parish of Broomesbarrow, Gloucestershire, and which has suffered terribly by the growth and encroachment of surrounding trees, has now had the treatment of being cleared away from around its trunk, and them cleared about five years ago by order of Osman Ricardo, Esq., the owner of the property upon which it grows, not only enables the spectator to survey the magnificent proportions of the tree, but will enable itself to recover its pristine health and vigour. A full history with particulars of the Broomesbarrow Yew will be given in the *Rector of Pendock's* (the Rev. W. Symonds') forthcoming volume, *Records of the Stones of the Valley*, which will contain geological, topographical, historical, and natural history notices of the Worcestershire and adjoining districts of the Severn valley. The approximate girth of the Broomesbarrow Yew is 25 feet, and it is to be hoped proprietors of similar sylvan veterans, whether Yews or other trees, will follow Mr. Ricardo's example, by taking steps for the preservation of natural objects of so great historical and scientific interest. *J. D. H.*

The True Double Daffodil.—The identification of this plant is a matter of some importance, because a quite distinct and much more showy form is usually regarded as the true double Daffodil. I enclose a flower taken from a plant growing wild in a meadow adjoining my garden. You will see that it is the same as you have figured at p. 50 [No.], but if you will bestow a little extra care upon it, you will perhaps throw a doubt on the accuracy of Mr. Worthington Smith's drawing. To find fault with one so much accustomed to the observation of the niceties of plant structure, is, of course, not agreeable, but it will not harm his reputation much if I point out the deficiencies of his figure. Emerson says that an artist cannot draw a tree until he becomes a tree, and Mr. Smith may justly plead that he has not yet become a perfect Daffodil. The doubling process is obviously accomplished in different degrees in these flowers. In the *Fuchsia* the petals are multiplied, and petaloid stamens appear to augment the massiveness of the flower. The doubling of the Composites is pretty well understood, for the nature of the process is plainly illustrated by the comparison of a single with a double flower. Now I wish to point out that the doubling of a Narciss is not by the multiplication or interchange of the several parts of a flower, but by the endeavour of the plant to develop a number of flowers within one spathe; and if an artist has not noticed this, he is not likely to make an accurate drawing of a double flower. In the sample sent with this the tube or crown contains a complete flower, and you may discern the outer segments as distinct from the tube or crown though these several parts are compressed within the tube to a mere bunch of wrinkled and casual observation, quite indistinguishable from those. As the words "true and simple" afford but little help in discussing matters of this kind, I propose to discuss the true double Daffodil as the double Daffodil of the fields. The distinctive character of this form is that the tube or crown is intact, the doubling taking place within it. But a better known plant is the double Daffodil of the gardens; there are, indeed, many such, but the prevailing kind is well known, and as it is now in perfection, it may be examined to advantage. Here instead of a distinct tube containing a second perfect flower, we have a large, closely-packed rosette, and this rosette consists, precisely as in the former case, of a number of flowers within one spathe, but the tube is gone; each of the several centres has a tube and perianth of its own, and the brevity and compressing make a confused mass of a number of parts that have a certain symmetry of arrangement, and strictly agree in plan with a single flower of the Narcissus major. I have seen many flowers drawn by artists, and experience, and have frequently observed that primary elements of structure were neglected by them for the sake of general effect. As they had not become Daffodils, they could not draw Daffodils; and the common bunchy rosette flower is undoubtedly a difficult thing to make out, apart altogether from the reproduction of its form in black and white. Having a collection of about 20 kinds of Narciss, that have, for the most part, been established some years, I have a simple opportunity of observing them critically, and I never fail to make out the structure of the rosette or bunchy kinds, which, as remarked above, consists in the production of a number of short, imperfectly developed flowers within one spathe. It is a matter of interest that the stems on which these multiple flowers are borne show no signs of fasciation. It is not the least interesting that these flowers do not produce seed. And it would be very interesting were they some day to begin to produce bulbs, as I feel con-

dent they will—a stride forward I fear I shall not live to see. But I have seen the promise, and perhaps the beginning of this, in the form of minute scales at the base of the multitude of pieces of which a rosette of Narciss consists; and were their flower stems leafy as those of Lilies are, and an approximation made thereby to articulations, I feel confident that they would produce bulbs, as many of the Lilies do, not within the spathe, but on the stem. But should they ever attain to the capability of reproduction in the way of the Garlic or Tree Onion, we must expect the bulbs to be formed within the spathe, so as to take the place of seed. That this will happen I have no doubt whatever. *Skirrey Hilbert, Stoke Newington.* [The specimen sent was not, in our opinion, of the true wild double Daffodil, but a false one of which it is not N. major fore-peno, but very close to it. Eds.]
—I fear that the habit of my double Daffodils is by no means "unexceptionable." They grow at the end of a copse close to the garden of an old building, which for two centuries was the manor house of the Bettesworths, and there is no doubt that it either was, or stands upon the site of, an ecclesiastical edifice prior to the Reformation; the garden has, therefore, existed from a time immemorial. For years past I have known of a patch of the same kind which grew at some distance from any house; but now that the others have come to light, it seems probable that they may have been carried there with manure. *H. K.*

Double Daffodils.—I enclose two double Daffodils, the larger from a field, the site of an old garden, near Cambolow Green, in this county, where it grows in the greatest profusion. This does not seem to be exactly the same as the ordinary form of N. major—at least, as it occurs in the same neighbourhood in gardens, or as an escape. The smaller flower was taken from a cottage garden at Hitchin. Both were strikingly beautiful when fresh. *R. A. Pryor, April 21.* [The larger flower we believe to be the *cultivated* form of the double wild Daffodil, which runs so close to the double form of N. major that it is an arbitrary line can be drawn between them. N. major we believe to be to the same species as our wild English Daffodil, but larger and more luxuriant, owing to the more propitious climate of the South of Europe, where it is a native. The small flowers sent by you are those of N. incomparabilis fore-peno. Eds.]

Nemophila insignis and Cats.—I should feel much obliged if any fellow-sufferer could tell me a good working method of preserving *Nemophila insignis* from cats. Till this spring I have never noticed that they had any peculiar taste for this plant, but being partial to it myself, I have sown a good many patches, and every one of these is successively rolled flat, so effectually that, at first, I thought that for some reason or other the gardener had beaten the plants down into the ground with his spade. The performance seems to be simply rolling, presumably to enjoy the smell of the bruised plants, and no other of the annuals are meddled with, and the aggressor is certainly a cat, as it has left plenty of tabby hair on the scene of action. No common preservative measures are of any avail: the stout garden pegs seem only (like the nails in the telegraph posts to the buffaloes) to add to the pleasures of the operation; and a moderate supply of prickly shoots, stuck in above the young plants, hardly answer better. If any of your correspondents could tell me of some powder which I could scatter to keep these most objectionable garden-rollers away, I should feel greatly obliged. *A Suburban Resident.* [Try pepper, or Pooley's tobacco powder. Eds.]

Natural Phenomenon.—A somewhat unusual phenomenon was observed here on the morning of the 13th inst. The previous night had been clear, and in the early morning there was a sharp white frost; later on the mist arose and the frost went off; shortly after 6 A.M. the sun gradually broke through the mist, and immediately he began to give evidence of the sun's presence by emitting vapour in all directions: gradually this increased in volume, and in a short time as far as the eye could see, over pasture, arable, and market garden, nothing was to be seen within a few feet of the earth but a complete shroud of white vapour. This, however, soon passed away, and the earth regained its ordinary appearance, and we have not seen the exact resemblance of this phenomenon since the break-up of the memorable severe weather in the winter of 1860-61. I well remember that the change took place during a Saturday night in January, and on the Sunday morning the temperature had risen so high that on going into the open air from that of the cold house it seemed like entering another climate—the snow was rapidly disappearing and all Nature was involved in a steamy vapour. I have noticed but few thaws since so rapid as that one. *Alex. Deane, Bedford.*

Double Cinerarias.—Having read glowing reports of a new double *Cineraria*, which had been introduced by a German house, I obtained seed which produced me eighty plants; these, however, I may

mention, were of inferior habit, but I looked forward to being compensated for this in a brilliant show of fine double flowers; the result is as follows—out of eighty plants there was only one that produced blooms having any claim to be called double; the remainder are in flower, and I forward you a few average specimens of the blooms, which I think you will admit are perfect rubbish. [Yves. Eds.]
I should be glad to know if any of your correspondents have been more successful than myself. *William Cletcher, Aldon, Farnes Abbey.*
[We have not heard of any one having been more successful than yourself. We do not know that it is necessary to defend the "glowing reports," but we may say that the plants shown at South Kensington, and last year at Florence, by the German house in question, were perfectly double, and the strain worth having, with a view to improving. We can only speak of what we see. Messrs. E. G. Henderson & Son exhibited some of these double *Cinerarias* at South Kensington on Wednesday last, and some few of these were as double as those originally sent from Erfurt. Eds.]

Araucaria imbricata.—We have some fine specimens of *Araucaria* growing here, two of which look bad health and bleed in different places up the stem, and some of the under branches are turning brown. The soil is a good deep loam free of lime or chalk; the trees have not been wounded, and should like to know what is the cause. *The Gardener, Greenfield.* [When the *Araucaria imbricata* bleeds much, and especially when it forms small masses of a white resinous substance on its main stem, it indicates something seriously wrong; the cause is not always easy to discover, often very difficult. Low temperatures, such as we have had during the past winter, often cause this, and it is to be observed most frequently on those trees which grow in low situations. Uncongeniality of soil has often to do with it, as also a damp retentive subsoil. I have often seen *Araucarias* planted in made earth, standing on a wet subsoil, so soon as the roots fairly penetrated the subsoil. I have also observed it on a plant which was growing in a poor thin soil on a gravelly subsoil abounding with oxide of iron. Unless the bleeding has been caused by the severity of the winter, carefully examine the roots, tracing them into the soil and subsoil; if the conditions are not favourable they too will show an unhealthy appearance. If soil renew with light rather than heavy loam to the roots now, or large, lifting only about one-third of the roots now, or moderate sized plants one-half, and the remainder in one or two more years, putting in at least 3 feet deep of fresh soil. If the subsoil is wet drain thoroughly, as the *Araucaria*, although at certain seasons it rejoices in a great deal of moisture, cannot endure stagnant water. *A. Fowler.*]

The Prince of Wales Plum.—I have read with intense interest Mr. Barron's article on the death of the Prince of Wales Plum trees. My old Orleans Plum tree, and other trees of the same race, has just died. It appeared to be well when I pruned it, but as soon as the east wind and hot sun set in it died. I have had it for many years. It died, no doubt, from the effect of the severe winter frosts. The other four trees next it, on a west wall, ascanted by the north, appear to be well. They are Diamond, Dove Bank, Belle de Septembre, and Mitchelson. They all cropped last season wonderfully—quite a sight—inasmuch that I took people who came to see the Roses, and Peaches and Melocotons—my two hobbies—to see them. Mr. Barron and Mr. Dancer combinedly, I think, touch the causes of the death of the trees. Mr. Barron says it may be from "constitutional defect, or with a constitution such as renders it peculiarly liable to certain exigencies." No doubt the great annual crops tend to weaken the trees. Mr. Dancer attributes it to the spring frosts, which I know are very severe in the flat country near London. I read in my Harrow Days to stop at Honslow, where I arrived at half-past 4 A.M. and I recollect the fog from the hoar frost. The death takes place by injury to the skin or rind, which in some trees is tenderer than in others; and probably the cells and sap-vessels suffer also. When the sun comes out powerfully like the skin and sap-vessels dry up, and the tree goes out like the snuff of a candle. This last winter was extra severe, but I have observed always that the Orleans had more dead wood than the other trees. I recommend it to Mr. Dancer, if he has not got it; it is of good constitution, and crops well annually. The four trees were Mr. Rivers' selection. Mitchelson is an admirable cropper, but a smaller Plum. Mr. Francis Rivers, some time back, spoke in his letter to me highly of Prince Englebert, which I have not got. The Cherry trees (pyramids on the stem, but not the old) were wonderful promise, but I do not think the Plum crop will be great. At one time I thought some of the other named Plum trees would die, but at present they look well. Frosts, either in winter or spring, are the main causes of the disaster, together with the

weakening of the constitution of the trees by inordinate annual cropping. The skin or rind is important. The leaves are the first lung, and the skin or rind is the second lung, and both have stomata. It is plain, therefore, if the stomata in the rind—through which the tree breathes till the second lung (or leaf) is developed—are injured, the leaf or first lung (first, not in time), must in due time suffer; and by these two injuries the tree must die. The tree may live on for some little time, but ultimately dies from an inadequate supply of sap. I have only five other Plum trees, all the gift of Mr. Rivers. They are pyramids, 6 feet in advance of my south Peach wall. Their names are—Rivers' No. 4 Seedling, Reine Claude Rouge, delicious; Royale de Brabant, a Violette de Galopin, most delicious; and the Late Black Orleans, a most valuable October Plum, either for dessert or culinary purposes. I specially recommend this last Plum to Mr. Dancer. Of all the Plum trees, culinary or dessert, here, the Late Black Orleans has stood the winter best, and looks best now. *W. F. Radclyffe, Okeford-Fitzpaine, April 17.*

The destruction of the leaves and young shoots of the staple market Plum, Prince of Wales, mentioned at p. 404, seems to me to be due to the night frosts of May, rather than to any of the other causes assigned. That the older wood should equally suffer argues a tender habit, which does not appear to have been noticed. If no retarding stock or more sheltered position be possible for the Plum orchards (and these would detract from the precocity of the produce) recourse must be had to some kind of protecting material. The large scale needed makes this very difficult to effect, and I am disposed to suggest, as I have seen in newspapers, with light plant rods passed into at intervals, and twine, as needed also, and that only the upper portions of the trees should be covered with these, as sky radiation would thus be arrested. Nets or tiffany would be dear, and as difficult to apply, besides being far more so to extricate, while newspapers would perfectly defend the leaves and fruit for the short time needed, and be cheap to buy and easy to place. A trial of these "paper protectors" for early potatoes has perfectly succeeded in the Channel Islands during the severe winter, and their use is likely to be general; why, then, should not a portion of the trees be equally and similarly defended? If even a few trees here and there were so treated, some insight into the real nature of the injury would be gained should these be safe and their neighbours ruined. *T. C. Brabant.* [Has the protection of the main stems and branches by hay-bands, or any similar covering, been tried? Eds.]

Terrestrial Orchids and their Odours.—Some time since *Orchis mascula* was somewhat strongly recommended for pot and bed culture, and for room decoration; but many of the readers of the *Gardeners' Chronicle* must, at the time, have been taken to task for a perceptible objection generally taken to this plant, on account of its potent scent of the cat; this scent is intermittent, generally given out at dusk, and often so powerful as to be quite insufferable in a living-room. It does not appear to be generally known that *Orchis tephrosanthos* and *O. pallens* are both possessed of a similar odour, and one more powerful of the quintessence of the tom-cat than *O. mascula* itself. For six days I have had flowering plants of the two former on my writing-table, and during the first five of these days the plants were quite passive, but on the evening of the sixth day they were both suddenly taken with ecstatic fits, and discharged such a volley of otto of tom-cat that the room became simply unbearable, and the plants had to be removed. This odour, it will be observed, also resembles the habit of the cat in being more active at dusk. The cultivation of *O. coriophora* is proscribed, owing to its smell of bugs. I have seen *O. pallens* grown in pots, but its foliage of the he-goat is so horrible that it is insufferable in a living-room; Dr. Hooker tersely says of it (*Student's Flora*, p. 354), "scent detestable, hircine." The same odour pertains to *Odontoglossum Lindleyanum*, but in a less degree. *W. G. S.*

Leek Bulbs.—A year ago I made a note on Leek bulbs. Now is the time for those who want a supply to take measures to secure them. Leeks that remain in the ground are now of little use, and will soon throw up flower-spikes, and run to seed if allowed. The rule is to pull them up and destroy them, as from this time worthless, unless seed is required, in which case, of course, it is a very simple matter to sow them to produce seed, as they will do in great plenty. It is, however, a fact of some importance that these worthless plants that are usually destroyed will, if allowed, produce a crop of elegant and delicious underground bulbs, and those who wish to obtain such bulbs have but to do as will be advised to ensure complete gratification. In the first place, clean the ground and hoe the surface to admit the showers to the roots, and cut the tops of the flags, but not severely. In the second place, at short time the pointed scapes or flower-heads will appear. Pinch them out the instant they can be got at, for not one must be allowed to rise. This pinching out will have to be

done again and again, for scapes will show themselves to the last. When the flags begin to wither lift the roots, and you will find that the old bulb (or Leek proper) has perished, and in its place are two or three silvery bulbs of the size and shape of the largest Tulips, attached to the shrivelled stem. These underground bulbs may be kept some time, and may be useful in the place of Onions. But the way to understand their real value is to stew them in gravy, and eat them hot with butter and pepper. *S. H., in Gardeners' Magazine.*

Aerides cylindricum.—With the accompanying illustration (fig. 115) of a two-flowered spike of the singular *Aerides cylindricum*, which flowered lately in Lord Londesborough's rich collection, at Norbiton, we give the following remarks on the plant, from the pen of Mr. Denning:—"This plant would not, at first sight, be taken for an *Aerides*, but would appear to belong to that section of *Orechids* which includes the great *Vanda* teres; indeed the plant in question, in both growth and form of flower, bears great resemblance to the above-named species. The flowers of *A. cylindricum* are pure white, and last a long time in full beauty, but, unfortunately, owing to its slow growth and apparent scarceness, we are not likely to soon see a large mass of it in bloom. From the comparatively large size of the individual flower, and its very striking form, with its purity of colour, it is a plant that would become a general favourite if it could be procured in any abundance. This plant requires to be grown in the East Indian-house, and prefers a long slender block, on which to attach its roots; the block should be bare, as the roots perish quickly if covered with any moss or other substance. Unless the atmosphere is very moist the syringe should be plied daily."

A Spring Barrow.—From the *Bulletin d'Arboriculture* we extract a notice of a newly invented spring barrow (fig. 114), which seems likely to be useful in

FIG. 114.—A NEW SPRING BARROW.

saving fatigue. The application of springs to the barrow is described as an important invention both for the gardener, the objects that he moves, and for the barrow itself. The common barrow has not only a more or less injurious effect on the spinal column, but the continual shocks to the arms, shoulders, and head considerably increase the fatigue of the workman. The spring barrow saves much of this inconvenience, and enables objects to be transported with comparative ease over roughly paved streets, at the same time that the barrow itself is more durable than the ordinary vehicles. The barrow is made in five sizes, and has been patented. The cost is from £1 to £1 5s. It may be obtained of H. Renette, of Louvain.

Reports of Societies.

Royal Horticultural: April 21.—W. Burnley Hume, Esq., in the chair. In the absence through illness of the Rev. M. J. Berkeley [Of whom we are glad to have subsequently heard better reports, Eds.], Professor Dyer announced the awards made by the committee, and briefly commented upon several subjects alluded to in our reports below.

SCIENTIFIC COMMITTEE.—Andrew Murray, Esq., in the chair.

Colorado Beetle.—Mr. Smea again raised the question of the Colorado Potato beetle, and elicited from the Chairman a renewal of his assertion that he had seen thousands upon thousands of the beetle, full grown insect and larva, on the haulm of the Potato and of the Tomato in Canada West (London, Ontario). The question was raised owing to statements that had been made that the insect would not live in the climate of Canada.

Peziza lanuginosa.—Mr. Edmonds, the Gardener, Chiswick House, sent a basket of *Peziza lanuginosa* from this locality, one of the very few where this handsome fungus is known to grow. The peculiar bird's-nest-like appearance of the fungus attracted great attention.

Great of Entophalartos Attacked by an Insect.—This was referred to M. Murray, who will report further on another occasion.

Female Flowers of Yew Destroyed by an Acarus.—Prof. Dyer showed specimens of the female flower

entirely destroyed by a mite. Dr. Masters suggested that it might have been destroyed by the same insect that produces the peculiar tufted growth on the ends of the shoots of the Yew.

Primrose, Oxlip, &c.—The Hon. and Rev. J. T. Boscaew showed flowers of many-coloured varieties of Primrose, together with the Oxlip, &c., gathered in plantations and woods in Cornwall, which raised an interesting discussion among the members as to the varieties of Primrose, Oxlip, &c. Dr. Hogg was of opinion that there were at least three so-called Oxlips—one a hybrid between the Primrose and Cowslip, one the umbellate Primrose, and one the Barfield Oxlip.

Diseased Peach Shoots.—Dr. Masters showed shoots of Peach trees received from a gardener who, to remove scale from them, had thickly painted them with colza oil, and allowed it to remain while the shoots were exposed to the sun under glass. The result was that the plant was suffocated, and the shoots died.

Elm Bushes.—Dr. Masters brought specimens of Elm bushes and elicited a discussion on the cause of the peculiar downward curvature of the young shoots in this tree, as also in the Hazel and Lime. Dr. Masters stated that while the outermost scales were arranged on the $\frac{3}{4}$, or distichous plan, the lowermost leaves had but a single stipule, while the succeeding ones had two oblique stipules, one of which in the very early stage was much larger than the other. It was suggested that possibly the change in leaf-arrangement, and the organic obliquity of growth, might account for the downward tendency. The similar downward tendency of coniferous leaders and other plants was alluded to by various members, and the suggestion broached that it might be a provision for throwing off rain-drops, or melting hoar-frost, so as to prevent injury to the young bud.

Early St. John's Cabbage.—Mr. W. W. Saunders communicated the following note on this Cabbage:—

"Among the seeds distributed by the Royal Horticultural Society in the spring of last year was a Cabbage called Early St. John's. I sowed the seed the latter end of April; it vegetated freely, and when the young plants were sufficiently strong they were placed at one end of an open plot in the garden, where by the end of August, notwithstanding the dry summer, the plants formed heads very regularly, and a series of white, solid Cabbages, not very large (the largest not exceeding 6 lbs. in diameter) was the result. A more uniform bed of Cabbages it would be difficult to conceive, and the regularity with which the plants all came to perfection at the same time was much admired by those interested in such matters. The Cabbage proved excellent when cooked. There is nothing, perhaps, very unusual in this little history so far, but a change soon took place, and in this manner. When the bed of Cabbages was about at its best, a long, warm, very dry period was succeeded by much rain and a very growing state of the atmosphere. This sudden impetus soon to vegetation by this state of things, soon caused the solid heads of the Cabbage to burst, and in a few days a series of smaller, well-shaped, rounded, compact heads were formed from the central axis of growth, closely touching each other, and backed up by the leaves of the original head, and the heads grew and full of sap. The number of these smaller heads varied from three to six in each Cabbage, and proved equally excellent when cooked as the original heads. In the drawings, carefully made from nature, one shows a head of the Early St. John's Cabbage bursting into smaller heads, a cluster of smaller heads originating from a very well-formed head before it burst open during the damp weather. There were six well-formed, small, rounded heads, but only five are shown, the other being hidden by the head. These details of the history of a Cabbage may be of some interest, as showing the effect of atmospheric changes on plants. I am aware that Cabbages often burst in wet weather and spoil, but here the bursting was rather to the advantage of the grower, I think, than otherwise, and the regularity of the process was remarkable. *W. W. S.*"

Grafted Potatoes.—Prof. Dyer read a communication transmitted by Mr. Darwin, being an abstract from the *Sitzungsberichte der Gesellschaft für Natur- und Geschichte in Berlin* for Nov. 18, 1874, in which an account was given by Magnus of the production of graft hybrids in the Potato by Reuter, the chief gardener at Potsdam, in 1874. He used the white long Mexican and the dark grey black kidney, both of which sorts had been introduced from America by the Novara Expedition. A wedge-shaped piece of the former, bearing an eye, was grafted upon the latter. The graft hybrid exhibited an intermediate character in form between the parents. They were broader and thicker than the long thin Mexican, longer than the black kidney. One of the Potatoes also exhibited a blending of the colours. The two ends were red, and the middle zone a greyish yellow. The dark grey colour of the black kidney is produced by the intense red sap in a layer of cells covered by the corky rind. In a subsequent communication Magnus mentioned that the hybrid which had been made by Dr. Max Heimann, and communicated to the botanical section of the *Schlesischen Gesellschaft in der Sitzungsbericht* for Nov. 19, 1872. Magnus described similar results obtained by Dr.

Neubert, of Stuttgart, by herbaceous grafts of the stems.

In the discussion which followed doubts were expressed as to the possibility of Potato grafting, whereupon Dr. Masters stated that in his opinion it was not creditable to the Society that so simple a matter as this should not be set at rest by being subjected to the test of experiment under proper supervision at Chiswick, and suggested that the committee should make a representation to this effect to the Council, which was adopted.

Seedling Hellebore.—Dr. Masters called attention to some varieties of seedling Hellebores, received from M. Heinemann, of Erfurt, and first brought to his notice by Professor Karl Koch. These are elsewhere alluded to.

Seville Long-pod Bean.—In allusion to this Bean, which was stated by some not to produce seed freely at Chiswick, Dr. Hogg reported that a whole quarter had been sown at Chiswick with seed gathered in the previous season in that garden.—The meeting then adjourned.

EARLY RHODODENDRON SHOW.—We quote the official title for our heading to this paragraph, though almost anything else would be quite as appropriate. We are sorry to have to say it, but the fact cannot be

of *Masdevallia Lindenii*, with fifteen flowers; *Odontoglossum luteo-purpureum*, with two spikes, and twenty-five flowers in the aggregate; *Dendrobium nobile*, 2 feet through, well-flowered and very fresh; *Odontoglossum Phalenopsis*—a well-marked variety, with four flowers; *Cypripedium villosum*, with about sixteen flowers; and *Camarotis purpurea*, a pretty diminutive Orchid, seldom seen at exhibitions. The present specimen had a dozen spikes of its pretty little lilac, rose-tipped, wax-like flowers. A group of nine *Cinerarias*, the only one shown, calls for no special comment; but the hardy spring flowers shown by Mr. Parker, of Tooting, and Mr. R. Dean, of Ealing, were particularly attractive. The former was 1st with beautiful examples, amongst others, of *Doronicum austriacum*, yellow; *Triteleia uniflora*, white, and its lilac flowered variety; *Scilla italica*, lilac, a fine mass; *Primula clatior*, Early Admirable, deep purple velvet, yellow centre; *Cardamine trifoliata*, white, and very dwarf; *Iberis linifolia*, white; *Muscari racemosa pallens*, violet-blue; *Ranunculus amplexicaulis*, white; *Orobanchaceae*, rose lilac; *Dicentra spectabilis*. In the collection from Mr. Dean, the most conspicuous were *Myosotis dissitiflora*, a bedding *Viola Royal Blue* and *White Swan*, both fine in form and very free; *Primula cortusoides amena*, and its variety *grandiflora*; *Aubretia purpurea*, well

foliage, but that is not an object of much consideration where flowers for cutting only are wanted.

The large contribution to the show from the Society's garden at Chiswick consisted of Azaleas, Palms, Ferns, Accacias, a few Orchids, Clematis, Cytisus, Richardias, alpine Auriculas, Narcissus, Salomon's Seal, and *Spiraea japonica*, and it was fortunate that so many plants in flower were at hand for the purpose.

There were only two competitors in the class for Black Grapes, and the 1st prize went to Mr. Bones, gr. to D. McIntosh, Esq., Havering Park, Romford, who showed nice bunches of new Black Hamburgs, good in berry, and well coloured for the season. Mr. J. Ridout, gr. to W. S. Brown, Esq., Woodhatch Lodge, Reigate, took the 2nd prize with Alicante, fine in bunch, berry, and colour, and admirably preserved. Of two brace of Cucumbers, the best was of Tender and True, shown by Mr. J. Lane, gr. to Major-General Fytche, Pyrgo Park, near Romford. The nicest brace of Marquis of Lorne we have seen were staged by Mr. W. Rapley, gr. to K. Hudson, Esq., Clapham Common.

FLORAL COMMITTEE.—R. B. Postans, Esq., in the chair. First-class Certificates were voted to Messrs. Veitch & Sons for *Dicentra hybrida*, a broad-leaved

FIG. 115.—*AERIDES CYLINDRICUM*.

disguised, that this was, as regards extent, the poorest show that has been known for some considerable time, and had not Mr. Barron promptly come to the rescue with a large collection of excellent decorative stuff from Chiswick, the result would have been even more deplorable. The schedule consisted of twenty-three classes, and the sum total of the money prizes offered was £75 7s., or, deducting 50 per cent., £37 13s. 6d. The subjects of seven classes only were represented, and ten was the total number of exhibitors. The prizes awarded amounted to £3 7s. 6d.; and, allowing £5 odd for the miscellaneous class, shows a clear saving of about £60; but at what a sacrifice!

Messrs. Lane & Son's twelve forced Rhododendrons—the only group exhibited—were admirable in every respect. The plants were well-furnished with foliage, from 3 to 4 feet through, and splendidly bloomed. Amongst the varieties represented were Blandyanum, bright rose; Limbatum, white, edged with crimson; Nero, dark crimson, maroon spots; Queen of the West, shaded rose, chocolate spots; Auguste Van Geert, dark purple, nicely spotted; Etendard de Flandre, white, edged with rose; Towardianum, rose, with carmine spots; fastuosum flore-pleno, double, pale lavender, and chocolate spots; Minnie, white, with brown spots; Impératrice, rose, with chocolate spots; and Sir Isaac Newton, rose carmine, with dark spots. The 1st prize was awarded. The six Orchids shown by Mr. B. S. Williams, which were awarded the 1st prize, consisted

flowered; *Lithospermum prostratum*, a lovely blue; the new white quilled Daisy, White Globe; crimson-flowered *Bellis acaulis*, *Polyanthus Black Knight*, very dark crimson, &c.

In the miscellaneous class the pride of place must be given to three boxes, each containing thirty-six magnificent blooms of the *Maréchal Niel* Rose, shown by Mr. J. Walker, nurseryman, of Thame, Oxon. In a small group of plants from Mr. B. S. Williams we noticed a good specimen of the South African *Toxicophleba spectabilis*, showing numerous clusters of its white flowers in the axils of its leaves; a small specimen of *Dendrobium pulchellum* nicely flowered; a plant with one fine flower of the white variety of *Odontoglossum Roedlii*; the pretty *Warszewiczella discolor*; and of Palms nice young specimens of *Plectocoma Andersoni*, *Cocos Weddelliana*, *Calamus montana*, *Areca Verschaffeltii*, &c. Messrs. E. G. Henderson & Son showed a selection of plants of their strain of double *Cinerarias*, many of them poor, as might be expected for the first break, but affording good evidence that double *Cinerarias* are not a myth, but a thing of substantial reality, and which must become popular where cut flowers are always in demand. Experience this season of German seeds of double *Cinerarias* leads one to doubt the advisability of trusting to that method of raising a stock, and common prudence recommends one to get hold of the plants and propagate them by division. None of the double varieties we have seen have been remarkable for the abundance of their

type, the older leaves of which are of a dull green, margined with crimson of various degrees of intensity, and younger or crown leaves, greenish white on the upper side, and pale rose beneath; to Mr. H. Bennett, Stapleford, *Salisbury*, for Hybrid Perpetual Rose Captain Christy, a large full flower, with pale pink outer petals and flesh-pink centre—in the way of Duchess of Edinburgh, but lacking the fine perfume of that flower; and to Mr. R. Dean, Ealing, for his new double quilled white Daisy, White Globe, which produces large and perfectly quilled flowers—a welcome companion to the double quilled red form. The thanks of the committee were awarded to Mr. R. P. Barr, Tooting, for a large and fine collection of cut blooms of Narcissi; and to Mr. Stevens, gr. to the Duke of Sutherland, Trentham, for a large specimen with about three dozen spikes of flowers of the variety of *Ceoloyne cristata* known as *Lemoniana*, which has longer and narrower bulbs, longer leaves, and comes into flower from three weeks to a month later than the typical form. From Messrs. Veitch & Sons also came a small group of Orchids and other plants, including *Masdevallia Veitchii*, *Phalenopsis grandiflora* with seven very fine flowers; several varieties of *Odontoglossum Alexandre*, *Dendrobium Bensonae*, *Phalenopsis Lüddemanniana* and its variety, ochracea, in which the petals and sepals are shaded with soft yellow ochre; *Odontoglossum prænites* (see p. 524), with medium sized flowers, of a greenish yellow ground colour, heavily spotted and barred with chocolate; and *Saccolabium ampullaceum*, with eight spikes, a very

pretty specimen, &c. Mr. Kinghorn, Sheen Nursery, Richmond, again sent a flowering specimen of the interesting *Fuchsia procumbens*; and Mr. B. S. Williams showed *Francisca magnifica*, with large lavender-blue flowers. From Mr. H. Bennett, Stamford, came a large lot of very fine blooms of his new pink *H. Rose Duchess of Edinburgh*; and Mr. Bull had flowering specimens of *Tillandsia muscica*, and *Angulosa Turneri*. From Mr. T. W. Bond, gr. to G. A. Smith, Esq., The Beeches, Weybridge, came nice specimens of *Brassia maculata*, and *Oncidium altissimum*; and from Mr. William Paul two new *H.P.* Roses named Villaret de Joyeuse and Amelia Hoste.

FRUIT COMMITTEE.—H. Webb, Esq., in the chair. A Cultural Commendation was awarded to Mr. J. W. Bond, gr. to G. A. Smith, Esq., for two plants, fifteen months old, of Foster's Seedling Grape, carrying about 4 lb. each of ripe fruit; and the thanks of the committee were voted to W. Terry, Esq., Peterborough House, Fulham, for eleven fine pods of *Vanilla aromatica*, ripened in his garden; to Mr. Sydney Ford, gr. Leonardlee, Horsham, for a small collection of well preserved Apples and Pears, including, of the former, Dumelow's Seedling, Royal Russet, Norfolk Paradise, Spanish Pippin [?], and Alfriston; and to Mr. John Munro, Potter's Bar, for Keens' Seedling Strawberries, Cucumbers, and early Grapes.

Amsterdam Horticultural Exhibition.—This exhibition is held annually in a fine building called the Grand Palace of Industry, and is well adapted for the purpose, being of large size and well lighted. Adjoining are two or three smaller halls, which are very useful for arranging collections of various kinds which would not make so good an appearance in the large building. The exhibition was opened by the Queen of the Netherlands, who was conducted round by the committee, amongst whom were some of the principal gentlemen of the country who take delight in horticulture.—Mr. J. A. Willink, Mr. C. A. Dudok de Wit, and several others. The *tout ensemble* had a very pretty effect, as the arrangements of the different collection of plants were good; they were arranged in the form of beds on which was placed soil for the pots to stand on, and a deep edging of turf round them, giving the plants the appearance of growing in a garden. This was all completed after the judging was over, by the Messrs. Groenewegen and Mr. J. C. Krok, with a staff of men under their supervision. I must give these gentlemen great credit for the taste displayed; I never saw a show better arranged, or the plants made more of than they were here, especially as the season was cold and late, and consequently the plants could not expand their beauties to the full extent. The *Azaleas*, *Roses*, and hard-wooded plants were well backed with foliage plants; the building is large and the effect produced, viewed from the galleries, by the blending of the various flowering plants with the Tree Ferns, Palms, &c., was grand. The sides and centre of the Palace were well arranged: in the latter was a large bed, in which was a collection of ten Tree Ferns from Mr. C. A. Dudok de Wit, consisting of *Dicksonia antarctica*, *C. florosa*, *A. alpicola australis*, some good heads of *Cibotium princeps*, with their graceful fronds; those of the rare *Angiopteris Willinkii*, and *Alsophila contantiana*.

In front of these were some fine collections of *Azaleas*, greenhouse plants, *Roses*, &c. In the four corners were some fine standard Bay trees. In the next bed was a collection of *Rhododendrons* in full bloom, exhibited by Mr. Groot, of Utrecht. These always make a good display. In the two following beds were fine collections of Palms, Cycads, &c. I also noticed some fine plants of *Chamærops*, *Areca*, *Scaevola*, and other fine Palms. Then came a collection of *Camellias* and standard *Roses*: arranged in beds, these produced a good effect. The *Cinerarias* formed a nice feature arranged in clumps at the sides of the building. There were some very fine *Acacias*, such as *A. Drummondii*, a large specimen; also *A. ovalis*, *A. palmata*, with its showy flowers. *A. grandis*, &c. At each end of the building were grand clumps of *Dracænas*, Palms, *Rhododendrons*, *Azaleas*, *Euphrasia*, *Camellias*, and that charming old plant we seldom see—*Metrosideros*—commonly called the Bottle-brush plant, with its showy scarlet flowers. At the sides were fine collections of *Agaves*, *Conifers*, *Orange trees*, and a host of other showy plants, all owing to make a good display. Mr. Krelage of Haarlem, exhibited a fine collection of *Phormiums*, which were very attractive. Leaving the grand hall a large room was entered, in which were arranged many fine collections of plants that require a warmer temperature. Some of the pots were hidden with moss, and the tables were covered with green moss: the effect produced by this was very pleasing, and showed great taste, for which thanks are due to Messrs. Groenewegen and Krok. One may learn a great deal as regards arrangement and taste in decoration by visiting these shows. The first object that attracted my notice was a well arranged basket of *Lycopodium*,

from Mr. J. A. Willink. In it the different species were so well grown, and such taste displayed in putting them together, that no one could pass them unobserved. Near this, from the same exhibitor, was a kind of cushion formed of *Lycopodium*, in which were placed different kinds of cut *Ochlid* blooms, amongst which were *Cypripedium villosum*, many flowers of the beautiful *Cattleya Skinneri*, with its dark mauve flowers; near these the fine *Dendrobium fimbriatum*, then rows of the flowers of *Vanda suavis*. At the outside edge of this floral cushion were flowers of *Angulosa Clovesiana* and *Lycaste Skinneri*; near this was a good specimen of *Anthurium Scherzerianum*, also belonging to Mr. Willink, with about twenty of its bright orange-scarlet flowers of a large size. There was also another grand plant of the same shown by Mr. J. J. Kluppel, with about the same number of blossoms. The collections of *Dracæna* were very good, especially those exhibited by Mr. C. A. Dudok de Wit. *Dracæna magnifica* was a grand showy plant. *D. Baptistii* a fine variety, and *D. striata*, which is one of the best coloured kinds; *D. amabilis* formed a good contrast, with its light foliage. The next best collection of *Dracæna* was from J. Van Leuwen, of Leyden. The *D. amabilis* was very fine, also *limbatum*, *Gulfoylei*, and *D. striata* were of a good colour. The *Echeverrias* were shown well by Mr. J. C. Krok: amongst them were fine specimens of *E. metallica*, *E. pulverulenta*, with its white powdery leaves; *E. globosa*, *E. de Smetiana*, a new and distinct kind; and *E. agavioides*, a splendid plant. Besides this collection there was also another very good one shown. The collection of *Lycopodiums* made a good feature. Mr. J. Van Leuwen, of Leyden, exhibited a grand collection of twenty-five variegated plants in fine condition, consisting of *Ficus Parcelsii*, the new *Aphelandra fascinator*, with finely variegated foliage; also well coloured *Pandanus Veitchii*, &c. Messrs. Groenewegen also exhibited a good case of variegated plants, consisting of *Crotons*, *Pandanus*, *Cyanophyllum*, *Tillandsias*, &c. Twelve *Crotons* were also shown in a glass case by Mr. C. A. Dudok de Wit; they were fine healthy well coloured plants, consisting of *C. majesticum*, *C. spirale*, *C. volutum*: these three are new and very distinct; also *C. Youngii* and multicaule were well grown. Messrs. Groenewegen also exhibited *Crotons*, but the plants were small; a collection of tropical plants of great interest, and many other good collections of plants. I also noticed some fine *Pelargoniums*, and a stand of ten *Liliums*, very good for so early in the season. *Spiræas* also formed a part; *Todax superba*, and many other plants, which gave great credit to their owners. I hope in a year or two hence to see a grand international show in Amsterdam; the present committee have all the tact and energy required for carrying such an exhibition into good effect. Many of your readers can bear witness to this from their success on a former occasion. (From a Correspondent.)

turned to increase, and by noon on the 15th the reading was 30.42 inches, it then decreased to 30.16 inches by the end of the week. The mean reading for the week was 30.27 inches, being 0.61 inch higher than that of the preceding week. The highest temperature of the air at 4 feet above the ground ranged from 46° on the 12th to 62° on the 17th, the mean for the week being 53°. The lowest temperatures of the air varied between 42° on the 11th and 34½° on the 14th, with a mean for the week of 37°. The mean daily range of temperature in the week was 16½°, varying from 8° on the 12th to 27½° on the 17th. The mean daily temperature of the air, and the departures therefrom by its respective hours were as follows:—2: 61, 44, 42, 3, 2, 43, 12, 40, 5, 5, 4; 13th, 43, 4, 2, 6, 11, 44, 42, 3, 2, 43, 15th, 42, 0, 3, 5, 16th, 44, 5, 2, 1; 17th, 47, 5, 4, 1. The mean temperature of the week was 43°, or 3° below the average, as deduced from observations extending over a period of sixty years.

The highest readings of a thermometer with blackened bulb in *vacuo*, placed on grass in sun's rays, were 118½° on the 14th and 117½° on the 17th, but on the 12th it did not rise higher than 53½°. The lowest readings of a thermometer placed in grass with its bulb fully exposed to the sky, were 30° and 32° on the 14th and 17th, but on the 11th 40½° was the lowest reading. The mean for the several low readings was 33½°.

The direction of the wind was E.N.E., and its strength gentle. The weather during the week was fine, mild, and clear; dense fog prevailed in the early morning of the 14th.

No rain fell during the week. In England the extreme high temperatures observed by day ranged from 66½° at Leicester to 52° at Newcastle-on-Tyne, with a general average all over the country of 61°. The extreme low temperatures observed by night varied between 35° at Newcastle-on-Tyne and 26° at Hull, with a general average of 30½°. The mean of the extreme ranges of temperature in the week was 39½°, the greatest range being at Leicester and Eccles, both 37½°, and the least at Newcastle-on-Tyne, 17°. The mean high day temperatures varied from 58° at Eccles to 48½° at Newcastle-on-Tyne, the general average being 54°. The mean low night temperatures ranged between 39½° at Liverpool and 33° at Hull, with an average value of 36½°. The mean daily range of temperature in the week was 17½°, varying from 2½° at Eccles to 11½° at Newcastle-on-Tyne. The mean temperature for the week was 43½°, being 1½° lower than the value for the corresponding week in 1874; the highest were at Liverpool and Manchester, both 45½°, and the lowest at Newcastle-on-Tyne, 40½°.

The weather during the week was fine, cloudy, the days mild, but the nights cold; scarcely any rain fell over the country; at Bristol 0.01 inch was measured, at Newcastle-on-Tyne 0.02 inch, and at Truro 0.02 inch were recorded; no rain fell at any other station. In Scotland the highest temperatures ranged from 66° at Dundee to 62½° at Glasgow; the lowest temperatures varied between 36½° at Greenock and 31° at Perth; their respective averages being 64½° and 33½°. The mean range of temperature in the week was 31°. The mean temperature of the air for the week was 47½°, being 4° higher than that of England, and 3° higher than the value for the corresponding week in 1874; the highest occurred at Greenock, 49½°, and the lowest at Leith, 46°. No rain fell over the country with the exception of 0.01 inch at Aberdeen. At Dublin, the highest temperature was 67½°, the lowest 24½°, the mean 44½°; no rain fell.

JAMES GLAISHER.

The Weather.

- April 15.—Fine, bright, partially cloudy, and mild throughout.
- 16.—Fine, mild, bright, and light clouds prevailed throughout.
- 17.—Fine, mild, and nearly cloudless throughout. Slight fog in early morning.
- 18.—A fine, mild, cloudless day.
- 19.—Very fine, clear, and mild throughout the day.
- 20.—Fine, bright, mild, and cloudless throughout. Fog in early morning.
- 21.—Increase, dull and gloomy, though fine at intervals. Heavy rain after 7 P.M.

— In the suburbs of London the reading of the barometer at the level of the sea decreased from 30.15 inches at the beginning of the week to 30.13 inches by about mid-day on the 11th; it then

Garden Operations.

(FOR THE ENSUING FORTNIGHT.)

PLANT HOUSES.

PLANT STOVE.—In addition to the greenhouse subjects that have been previously advised for table, hall, and room decoration, the following stove plants should now be propagated, and grown on in such quantities as are required. In the case of these, especially if used for table decoration, it is necessary to propagate every year, as, when the plants get too large, they are objectionable. *Dracænas* are particularly adapted for this purpose, especially some of comparatively recent introduction, that possess narrower leaves than the older varieties, and are consequently more light and airy in their appearance. Amongst them are *D. nigro-rubra*, *D. albicans*, *D. angusta*, *D. Guilfoylei*, and the old *D. terminalis*. Any plants of these that have got too tall, or leafless and naked in the stem, may have the tops taken off, and these will quickly root in a brisk heat, if placed singly in 48-sized pots forming in a short time nice plants. The harder parts of the old stems may be cut into lengths an inch long, denuded of any leaves they possess, and inserted thickly in pots, and kept close and warm. When rooted pot singly, and encourage them to make all the

growth possible through the season by keeping them in a warm stove and syringing daily. As soon as the soil has become firm, turn the pots, so that the whole of the soil from them, remove the bottom portion of the main root, which, if turned the opposite end up to that in which it has grown naturally, and potted, will soon make a plant. Place the stools in pots no larger than just sufficient to admit the roots.

Crotons.—Cuttings of these, in a much larger state than would succeed with most plants, will strike freely without losing their leaves if kept close and hot until they have a good amount of roots. Shoots 6 or 10 inches long of the varieties *angustifolia*, *varicatum*, *pictum*, *undulatum*, and the newer kinds, such as *Woismanni*, *majestatum*, and *spirale* (the latter three sorts from their elegant habit are well adapted for the purposes under consideration), when rooted and encouraged to push growth, in a few months make beautiful small decorative plants. The elegant Fern-like *Cubania filicifolia* is one of the most beautiful table subjects. A strong plant that has become bare of leaves at the bottom of its requires heading down, will break up at the bottom of shoots; when these are 4 or 5 inches long, if taken off with a heel they will strike in a moderately close place in a brisk heat, after which gradually inure them to bear more air; but with these care must be taken that the leaves which the young plants already possess do not get injured, as the loss would spoil their appearance. The tops of *Aralia reticulata* and *Ptelea* (the last decorative variety good), if taken off to inches in length will root, if they are placed in a brisk heat and moist atmosphere. When struck inure them gradually to more air. The stems of the plants lower down, so far as they are not too hard, will make cuttings, a couple of eyes to each; the harder bottoms of the stems will break, which shoots take off with a heel, placing them singly in small pots, in sand. When all the cuttings that can be got are taken off, the stools may be turned into pots; some of the roots if made into cuttings an inch long, inserted in sand, and kept warm, will make plants. These partially disrooted plants should then have most of the old soil removed, and be replaced in smaller pots. *Terminalia elegans* is a good companion for *Aralia* *Velehii*, with narrow lanceolate leaves, beautifully marked. It requires similar treatment in every way to the *Aralias* above named. *Asparagus decumbens* is a good plant for this kind of decoration, with finely divided leaves. As that most elegant of Palms, *Coccoloba Weddelliana*, gets more plentiful, it cannot fail to be in general request for table and room embellishment. There are few plants equal to Palms, when small, for table decoration, and it is surprising how some of naturally large growth can, by suitable treatment, be kept for a very considerable time in a small state, and yet quite fresh and healthy in appearance. The following may be kept in 7- or 8-inch pots, and may be made large, by keeping them during the summer, when not doing duty in the dwelling, in a temperature not higher than an ordinary greenhouse, and in the winter at about 45°; but as they are moisture-loving plants, the soil must never be allowed to get dry:—*Lantana rubra*, *Hyophorbe glauca*, *Kenia australis*, *K. Caeterborviana*, *K. sapida*, *Livistonia australis*, *Areca Verschaffeltii*, *Demonrops Bissis*, *Yucca elegans*, *Yucca rubra*, *T. distachya*, *Chamaerops excelsa*, and *C. lunulata*. As these get too large for table decoration they come in for halls and similar places.

Camellias.—Few growers of these plants like potting them in the spring, on account of their not liking their roots disturbed, even in the least, at a time when growth is about to commence. When in good healthy condition the roots of *Camellias* always begin to grow before the buds swell—a natural process being usually made to have a certain amount of the supply of nutriment required in the formation of their large quick-growing leaves. Any disturbance of the roots in the spring generally interferes with the setting of their flower-buds, except in the case of plants in a more than ordinarily vigorous state; consequently it is better with those of considerable size to defer their potting until the flower-buds are just formed, but with small growing stock that can be doing for want of root-room, and which would cramp if not moved until the end of the growing season, it is better to pot them now, not disturbing the roots any more than just removing the crooks from the bottom. Good fibrous loam imparts a greater disposition to flower, but they grow much faster in peat, and always have deeper green colour in the leaves; pot quite firm, and give plenty of moisture over-head as well as at the roots whilst the growth is being made. *T. Baines*.

FLOWER GARDEN, &c.

PARTERRE AND MIXED GARDEN.—The planting of all kinds of evergreens should be put off until so late as to bring this work to completion before the young shoots advance sufficiently to suffer injury. The late severe winter will have proved fatal to many evergreens that were transplanted in the autumn, and has

shown the necessity of deferring such work till this season of the year, when root-action is encouraged by the daily increasing warmth and genial showers, which to newly planted shrubs are very beneficial. Unless large plants are required for immediate effect or other special purpose, it will be found more satisfactory to plant such as are of medium size, as they are sure to succeed. If large plants are to be operated on, the holes for their reception should be dug of sufficient size and depth to take the respective plants previous to their removal, so that they are not kept out of the ground longer than is absolutely necessary for their transit from place to place. After planting, see that all are securely staked, to prevent them from blowing to and fro, or the roots will be strained. Give a good heavy mulching of half rotten litter, and the plants will require but little after-attention. The hardy fernery is perhaps the most interesting department of a garden during the months of May and June, as at this season the young fronds vie with each other in the display of their lovely rich tints of delicate green. No place of any pretensions can be considered complete without an appendage of this kind, as here may be associated a very interesting class of plants, that cannot be cultivated so well, or look so much at home in any other portion of the grounds. Such things as *Daphne Cneorum*, *Aubrietia*, the lovely *Lithospermum prostratum*, *Omphalodes verna*, hardy *Geraniums* and *Anemones*, and a whole host of beautiful and interesting subjects, may here find a suitable home; while the margins of walks should be crammed with the different wild flowers, such as *Orchis*, *Bluebells*, *Primroses*, *Anemones*, and such like shade-loving plants.

The old fronds of *Ferns* should now be cleared away, as the young growth will soon be protruding, and, as they spring up quickly, they may suffer injury. The plants will be greatly benefited by a top-dressing of fresh peat and loam, or, failing the former, some thoroughly decomposed manure. *Andropogon* and *Cytisium falcatum* make grand plants in the hardy fernery, and only require a slight protection during the winter. The latter stands out as distinct among hardy Ferns as the Holly among evergreens, and those who are not cultivating these striking species should add them to their collection. *Struthiopteris germanica* and *Oncoclea sensibilis* are equally desirable, and should be in every fernery.

Verbeecoe Plants may still be divided, and any half hardy varieties wintered under protection should now be planted out. *Lobelia* of the fulgens type, are a very interesting class of plants that have long been esteemed for their brilliant flowers. To grow these to perfection they should be potted on till the middle of May, and be then planted out where they can obtain plenty of moisture at the root.

Most of the annuals are too woody and ephemeral in their character to render them useful at all desirable in the modern flower garden, but there are some that are very showy and durable, which should have a place somewhere in the grounds. The double *Zinnias*, *Asters*, *Stocks*, and *Phlox Drummondii*, stand foremost among these, and are almost indispensable. *Zinnias*, on account of their somewhat tender nature, should be sown in gentle heat, and kept under glass till the middle of May, or later, according to the state of the weather. The following may be named as showy varieties, deserving cultivation:—*Dianthus Heddewigii*, and its many varieties, both double and single, are very beautiful and lasting. *Godolin Whiteleyi*, with its vivid-coloured, crimson-spotted flowers, is very striking and showy. The *Helichrysums*, *Nemophilas*, *Collinsias*, *Clarkias*, *Marigolds*, and *Rhodanthes* should all be grown; and for hot, sunny places *Portulacas*, both single and double, are just the thing. The whole of the above, except *Portulaca*, should now be sown thinly, under the protection of hand-lights or old frames, in fine light, leaf-soil and loam. *J. Sheppard, Woolverstone Park.*

FRUIT HOUSES.

PINES.—Promptitude in ventilating Pine-houses, particularly those in which high temperatures are maintained, at this season is indispensably necessary; the cold nature of the nights renders a liberal supply of fire-heat absolutely necessary in certain houses, as in the case where fruit is progressing towards maturity. Although the circulation through the hot-water pipes may be stopped, still there is a considerable radiation of heat going on from them which, with sudden outbursts of powerful sunshine (such, for instance, as we have experienced during the present week), would render matters in this department very precarious, if ventilation were at all neglected. In those houses where large planes of glass are employed, and the panes are in close contiguity to them, a slight shading should be applied on the most circuitous during the hottest part of the day; but in such as are glazed in the old-fashioned way, with small squares of glass, it will scarcely be required in the ordinary way, as the laps provide a circulation sufficient to prevent the sun's rays from scorching the plants. For summer use the

old-fashioned sashes are admirably adapted to swell Pine-apples off well, but the reverse is the case during winter. Attend to ordinary requirements in regard to management as before indicated in the Calendar. Scarcely too much moisture can be employed about the houses in which fruit is swelling off. As the fruits get ripe, if they be in pots, remove both plant and fruit to a cooler place. They will keep sound for a longer period at this season than at any other, which is an advantage when other kinds of fruit are scarce. As the suckers of fruiting plants become large enough to handle, screw out the hearts of those which will not be required for stock; one sucker, or two at most, is ample to retain, unless the stock is to be largely increased. *G. T. Miles, Wycombe Abbey Gardens.*

VINES.—A very desirable change in the weather took place on the 14th, since which date there has been sunshine in abundance; consequently Vines have made rapid progress, and for a time it will be difficult to keep pace with thinning, pinching, tying, and regulating the shoots; but as it is important that all such work should be done at the proper time, a push should be made to accomplish it. Thinning ought always to be done in the evening or early morning, both for the greater comfort of the operator, and as a safeguard against rust, which is sure to take place if the berries are pinched or rubbed with a sweating hand. Take off or handle on the points of lateral growth regularly. It is bad management to let them get so long that they have to be cut off wholesale, which gives a severe check to the Vines. Where Grapes are ripe, and the foliage is good, the lateral growths should also be kept pinched quite close, and the house kept at an equable a temperature as possible, with just sufficient moisture to keep the foliage healthy. If spider makes its appearance, sponge both the under and upper sides of the leaves with clear water, but do not water more than half so effectively. Inside borders of Vines that are swelling their fruit or near the colouring process should be examined, and if at all dry give a thorough drenching of manure-water, and as this watering will be a final one till after the Grapes are cut, give a surface mulching of either soil or dung to prevent evaporation. Air should be freely given in suitable weather; a "crack" left on all night is a beneficial aid in the laying on of beautiful bloom and colour, the two great characteristics of high finish. Late Vines are now breaking freely, and should be encouraged in every possible way to make rapid growth. Our seasons are so short for the thorough maturation of late kinds of Grapes. In insufficiently heated or unheated houses—and in such structures they should never be planted—*Barbarossa*, *Gros Colman*, *West's St. Peter*, *Trebiano*, and *Lady Downe's* all require plenty of fire-heat in September and October to fully ripen them. No matter how expeditious they may be in keeping their fruit, they will not keep if unripe; ripeness alone ensures success. We have a quantity of *Lady Downe's* that were ripe in September, and out from the Vines on January 12, and at the present date (April 19) they are as plump as on the day they were cut—a circumstance attributable to perfect maturation. Young Vines intended for next year's planting or fruiting in pots should be shifted on as soon as their roots have well filled the small pots they are now in. As a rule, 10-inch pots are quite large enough, but for those intended for planting out and fruiting, as generally the latter are placed on a bed of mould, into which the roots find their way out of the bottom of the pot, and are allowed to ramble at will. They should be carefully tended in the matter of watering and syringing. *W. Wildsmith, Heckfield.*

MELONS.—The last few sunny days have wrought wonders in the progress of Melons, and the first batch are now nicely swelling off. Every ray of sun that shines must for the present be secured to them. While the water is so quiet, and the ground both the roots and atmosphere during the setting period, do not omit to add a modicum of flowers of sulphur amongst the foliage and on the side walls, as an antidote to red-spider. Water liberally at the root in hot weather plants not yet in flower, as well as those which have set their fruit, and provide plenty of atmospheric moisture. In regard to plants growing in pots or boxes, it is not improbable they may require to be watered twice as any other weather. Attend regularly to the setting of the female blossoms, and cease to use the knife during the setting period; afterwards use both the knife and the finger and thumb freely, to remove all superfluous growths. Fairly strong plants should carry at least six fruits each; remember that large size is not a desideratum. Use but a small amount of stimulants to plants before they have set their fruit; afterwards feed them liberally till almost ripe. Maintain a night temperature of 72° day and 60° during the day. The cultivator must exercise both skill and industry to provide a continuous supply, and to make the best use of the structures at his command. We have many times grown very good summer crops in houses wherein were forced the earliest pot Vines; Strawberry houses and general purposes forcing houses may be

Mangel Wurzel Seed.
BOLTON AND CO. beg to call attention to their fine stock of **MANGEL WURZEL**. They particularly recommend their—
CHAMPION YELLOW GLOBE.
CORNER'S DEVONSHIRE YELLOW GLOBE.
BERKSHIRE PRIZE YELLOW GLOBE.
MAMMOTH LONG RED.
IMPROVED RED GLOBE.
GOLDEN-FLESHED TANKARD.
 All of moderate prices, to be had on application.
BOLTON AND CO., Seed Merchants, Wood Green, London, N.

To Propagators and Plant Growers.
 The most useful material for the attainment of successful and rapid culture is
COCOA-NUT FIBRE REFUSE.—
 Price 12 per bushel, or 6d. per bushel for quantities of 20 bushels and over.
DAGNALL and TILBURY, Steam Cocoa-nut Fibre Works, Farn Lane, Waltham Green, S.W.

Fibrous Peat for Orchids, &c.
BROWN FIBROUS PEAT, best quality for Orchids, Stove Plants, &c.
BLACK FIBROUS PEAT, for Rhododendrons, Azaleas, Heath, New Holland Plants.
BROWN and BLACK PEAT, for general purposes.
 Delivered on rail at Blackwater (South-Eastern Railway), or Farnborough (South-Western Railway), by the truck load. Sample sacks, 12s. 6d. each.
WALKER and CO., Farnborough Station, Hants.

PEAT.—A few hundred tons of a SUPERIOR quality delivered at the Blackwater or Farnborough Stations for 17s. a ton. Apply to
W. TARKY, the "Golden Farmer," Bagshot, Surrey.

THE LONDON MANURE COMPANY
 (ESTABLISHED 1840)
 Have now ready for delivery, in fine dry condition—
CORN MANURE, for spring sowing.
PURE DISSOLVED BONES.
FURSER'S BONE MANURE.
FURSER'S BONE TURNIP MANURE.
SUPERPHOSPHATE.
NITROPHOSPHATE.
NITRATE OF SODA, SULPHATE OF AMMONIA,
 Genuine **PERUVIAN GUANO,** &c.

 116, Fenchurch Street.

ODAMS' MANURES,
 FOR ALL CROPS,
 Manufactured by the **NITRO-PHOSPHATE** and **ODAMS' CHEMICAL MANURE COMPANY (LIMITED),** consisting of Tenant-Farmers occupying upwards of 150,000 Acres of Land.
Chairman—**ROBERT LEEDS,** Castle Acre, Norfolk.
Managing Director—**JAMES ODAMS.**
Sub-Manager and Secretary—**C. T. MACADAM.**
CHIEF OFFICE—100, Fenchurch Street, London, E.C.
WESTERN COUNTIES BRANCH—Queen Street, Exeter.
 Particulars will be forwarded on application to the Secretary, or may be had of the Local Agents.

MILLER AND JOHNSON
 (ESTABLISHED 1859)
 Manufacture the highest quality of
ARTIFICIAL MANURES
 For ROOT, CORN, and GRASS CROPS.
 36, Mark Lane, London, E.C.

GISHURST COMPOUND.—Used by many of the leading Gardeners since 1859, against Red Spider, Mildew, Thrips, Greenfly, and other Blight, in solutions of from 1 to 2 ounces to the gallon of soft water, and of from 4 to 16 ounces as a winter dressing for Vines and Fruit Trees. Has outlived many preparations intended to supersede it.
 Sold Retail by Seedsmen, in boxes, 12s., 3s., and 10s. 6d. Wholesale by **PRICE'S PATENT CANDLE COMPANY (Limited).**

SIMPSON'S RED SPIDER, THIRPS, &c., ANTI-TOE. Testimonials of the highest order for its efficacy. Sold in quart, condensed, 6s. Supplied to Seedsmen and Chemists.
 Prepared by **JOHN KILNER,** Wortley, near Sheffield.

MILDEW.—Ewing's Infallible Cure. ("The finest of all antidotes." Wm. EARLEY.) Retail of most Seedsmen, at 12. 6d. per bottle—12s. 10d. per bottle, if packed for travelling, of the Manufacturers,
EWING and CO., Norwich.

MARENDAZ and FISHER, RUSSIA MAT
 Merchants, Importers of RAFFIA FIBRE, &c., Manufacturers of IWINE, TIFFANY, NETTING, &c., 9, James Street, Covent Garden, W.C.

RUSSIA MATS.—A large stock of **ARCHANGEL and PETERSBURG,** for Covering and Packing—Second sized **PETERSBURG, 100s.; PETERSBURG, 60s. and 80s.;** superior close Mat, 45s., 50s., and 55s.; **PACKING MATS,** 20s., 30s., and 25s. per 100; and every other description of **MATS** at equally low prices, at **J. BLACKBURN and SONS,** Russia Mat and Sack Warehouse, 4 and 5, Wormwood Street, E.C.

RUSSIA MATS, for Covering Garden Frames—**ANDERSON'S TAGANROG MATS** are the cheapest and most durable. Price List, which gives the size of every class of Mat, forwarded post free on application.
JAS. T. ANDERSON, 7, Commercial Street, Shoreditch, London, E.C.

BROWN'S FLORAL SHADING.—A Protection for the Bloom of Wall Trees from Frost, and for Shading Plants under Glass from the Sun. Sold by Nurserymen and Seedsmen. Prices and samples on application to **CHARLES BROWN,** Greenhays, Manchester.

SHAW'S TIFFANY AND ELASTIC NETTING for Shading and Protecting. Sold by all respectable Seedsmen. For Circulars and Prices apply to **JOHN SHAW and CO.,** Tiffany Manufacturers, 20, Oxford Street, Manchester.

TANNED GARDEN NETTING, 1d. per Square Yard, for Protecting Seed-beds, Peas, Fruits, Strawberries, &c., from Birds, Frost, Blight, &c., and as a Fence for Fowls, in 1, 2, 3, and 4-yards widths, Hexagon, Tiffany, and other Netting. Galvanised Wire Netting, Pea Hurd, and Seed Protector, &c.
C. WRIGHT, 29, Lime Street, E.C., late 376, Strand, W.C.

NETTING for FRUIT TREES
SEED BEDS, RIPE STRAWBERRIES, &c.
TANNED NETTING for protecting the above from Frost, Blight, Birds, &c., 2 yards wide, 3d. per yard, or 100 yards, 20s. 4 yards wide, 6d. per yard, or 50 yards, 20s.
NEW TANNED NETTING, suited for any of the above purposes, or as a Fence for Fowls, 2 yards wide, 6d. per yard; 4 yards wide, 12 per yard; 6-inch mesh, 4 yards wide, 12. 6d. per yard.
TIFFANY, 6s. 6d. and 7s. 6d. per piece of 20 yards.
EATON and DELLE, 6 & 7, Crooked Lane, London Bridge.

HARRY BUNYARD
 supplies—
NETTING for FRUIT TREES, &c., 2 yards wide, 2d. 4 yards, 4d. per yard—in pieces 50 yards each.
SHADING CANVAS, 1 yard wide, 3d. and 6d.; 2 yards, 7d. per yard—only in pieces 140 yards each. Smaller quantities at an advance.
TENTS, Garden and Cricketing. CRICKETING NETS. MARQUEES and FLAGS on Sale or Hire.

Preparation by Post Office Orders payable at Tooley Street, S.E., from unknown Customers, ensures goods, carriage paid, on amounts of 4s. and over.
HARRY BUNYARD, Manufacturer, 63 and 64, Tooley Street, S.E.; and 11, Bernonsey Street, London, S.E.

E. T. ARCHER'S "FRIGI DOMO,"
 Patrons by Her Majesty the Queen for Windsor Castle and Frogmore Gardens, the late Sir J. Paxton, and the late Professor Lindley, &c., &c.
MADE OF PREPARED HAIR and WOOL.
 A perfect non-conductor of heat or cold, keeping a fixed temperature where it is applied. A good covering for Pits and Forcing Houses.

PROTECTION from COLD WINDS and MORNING FROSTS.
"FRIGI DOMO" CANVAS—
 2 yards wide 12. 10d. per yard run.
 3 yards wide 15. 0d. per yard.
 4 yards wide 18. 0d. per yard.
ELISHA T. ARCHER, only Maker of "Frigi Domo," Stanstead and Brockley Roads, Forest Hill, London, S.E.; and of all Florists and Seedsmen. All goods carriage paid to London.
NOTICE.—REMOVED from 3, CANNON STREET, CITY

Frigi Domo.
TO BE GENUINE every length will be marked "E. T. ARCHER'S FRIGI DOMO," with the Trade Mark. An infringement will meet with legal proceedings.
FOWLER'S PATENT STEAM PLOUGH and CULTIVATOR may be SEEN at WORK in every Agricultural County in England.
 For particulars apply to **JOHN FOWLER and CO** 71, Cornhill, London, E.C.; and Steam Plough Works, Leeds.

HEATING AND LIGHTING BUILDINGS

ALMOST ENTIRELY FREE OF COST OF FUEL,
The perfect Success of every Apparatus erected guaranteed.
 THE SYSTEM IS SUITABLE FOR HEATING GREENHOUSES, MANSIONS PUBLIC BUILDINGS, FACTORIES, &c.

THE COMPANY HAVE PURCHASED MEREDITH'S VINEYARD,
 At Garston, near Liverpool, which will be at once Heated on their System.

THEY ARE PREPARED TO SUPPLY POT VINES FOR PLANTING, FROM THE WELL-KNOWN STOCK at Garston. THEY CAN ALSO SUPPLY BEDDING AND OTHER PLANTS IN GREAT VARIETY.

ILLUSTRATED CATALOGUES, With Full Particulars, will be sent on application, and Plans and Estimates prepared.

THE COWAN PATENTS COMPANY, LIMITED,
 21, WHITEHALL PLACE, LONDON, S.W.

PRUSSIAN WOOD GARDEN STICKS and TALLIES, commended by the Royal Horticultural Society. The above can be had, of all sizes, wholesale, of **CHARLES J. BLACKITH AND CO.**, Cox's Quay, Lower Thames Street, London, E.C. Retail of the principal Seedsmen. Prices on application.

Indestructible Terra-Cotta Plant Markers. **MAW AND CO.'S PATENT**—Prices, **M** Printed Patterns, and Specimens, sent free on application; also Patterns of Ornamental Tile Pavements for Conservatories, Entrance Halls, &c.

MAW AND CO., Benchall Works, Brimsley.

J. SMITH'S IMPROVED METALLIC LABELS.

The above Labels—which have just been adopted for the Royal Gardens at Windsor—are made of a White Metal, with RAISED BLACK-FACED LETTERS, and are of various shapes and sizes. Samples and Price List free.

To Gardeners and Nurserymen.
THE CELEBRATED CAERGWRL SILVER SAND, admitted to be the best in this country for Potting and Propagating Plants. Large stocks of the various qualities always kept ready for despatch in any quantity. Samples free by post.

From **ROBERT F. KER & SON**, Liverpool.—“We have for many years used Caergwrl Silver Sand, and have found it well adapted to the growth of both hard and softwooded plants—both stone and greenhouse.”

Sole Agent: **ALEXANDER DEAN**, 8, Dutton Street, Liverpool.

Rosher's Garden Edging Tiles.
The above and many other PATTERNS are made in materials of great durability. The plainest sorts are especially suited for KITCHEN GARDENS, as they harbour no Slugs or Insects, take up little room, and, once put down, incur no further labour or expense, as do grown Edgings, consequently being much cheaper.

ORNAMENTAL PAVING TILES, for Conservatories, Halls, Corridors, Balconies, &c., from 32. per square yard upwards. Pattern Sheets, of plain or more elaborate designs, with prices, sent for selection.

SILVER SAND, fine or coarse grain as desired. Prices by Post per Ton or Truck Load, on Wharf in London, or delivered direct from Pits to any Railway Station. Samples of Sand free by post.

FLINTS and BRICK BURRS for Rockeries or Ferneries. **KENT PEATS or LOAM** supplied at lowest rates in any quantities.

THE ROYAL POTTERY, WESTON-SUPER-MARE.
UNDER ROYAL PATRONAGE.
JOHN MATTHEWS (late C. PHILLIPS), Manufacturer of TERRA COTTA VASES, FOUNTAINS, ITALIAN BASKETS, RUSTIC FLORAL ARBORETTES, STATUARY, GARDEN POTS (from 2 to 30 inches in diameter), of superior quality, withstand frost, and do not become green; EDGING TILES, &c. See specimens in the Royal Horticultural Gardens. Price List free. Books of Drawings, 7d. each.

WEST BROTHERS, MANUFACTURERS OF GARDEN EDGING TILES, in various patterns, in Blue Terra Metallic, Terra Cotta, and Glazed Stone-ware. Warranted impishable.

White and other Fancy GLAZED TILES for Walls, Hearths, &c.; Ornamental PAVING TILES for Halls, Conservatories, &c., &c.; also Manufacturers of FIRE CLAY LUMPS and TILES for Furnaces, Fires, Boiler Settings, &c., to any pattern. Drawings and Prices to the Trade on application. Delph Works, Church Road, Battersea, S.W.

VIENNA PRIZE WIRE NETTING.

CAUTION TO BUYERS OF WIRE NETTING.

The great reputation and success of Messrs. J. B. BROWN AND CO.'S VIENNA PRIZE WIRE NETTING seem to have induced certain Dealers in Wire Netting to advertise an inferior article at reduced prices, specifying the mesh, gauge, &c., as if such were the same in quality and value as the Prize Wire Netting of which Messrs. J. B. BROWN & Co. are the SOLE MANUFACTURERS.

Messrs. BROWN & Co. would suggest that, before ordering quantities, one roll of their Wire Netting should be ordered and one roll of that advertised at reduced prices. The size and shape of the mesh may then be examined, the thickness or strength of wire, the weight of the rolls and the exact measurements, the general finish of the manufacture, and the quality of the galvanising.

This examination will prove the respective qualities of the Netting.
90, Cannon Street, London, E.C.—March 22.

THOMAS' PEA and SEED GUARDS. Reduced Prices for the remainder of the Season.

SUPERIOR QUALITY. GALVANISED AFTER MADE. With one Longitudinal and Two Cross Stays.

No. 80. 3 feet long, 6 inches wide, 6 inches high. Price 9s. per dozen. Two end-pieces included with each dozen. Having a large Stock of the above, Orders can be executed on receipt.

Illustrated and Priced Catalogues of Horticultural Wire-work on application.
J. J. THOMAS & CO., PADDINGTON WIREWORKS, 285 and 269, EDGWARE ROAD, LONDON, W. P.O. Orders to be made payable at 310, Edgware Road.

BELGIAN GLASS for GREENHOUSES, &c., Can be obtained in all sizes and qualities, of **BETHAM & SON,** 9, LOWER THAMES STREET, LONDON, E.C.

B. & S. have always a large Stock in London of 20-in. by 12-in., 20-in. by 14-in., 20-in. by 16-in., 11 1/2 in. by 21-in. 1875.

READ & CO., THE ORIGINAL PATENTEES AND INVENTORS OF **GARDEN WATERING MACHINES,** Garden Engines, Pumps, and Syringes.

“Few things are of more importance in Gardening than good Syringes and Engines. We have seen and had experience of many, but we presume it would be difficult to find more efficient instruments than those made by Messrs. READ, of Regent Circus.”—Gardener's Chronicle.

RANSOMES' AUTOMATON LAWN MOWERS.

TEN THOUSAND IN USE, GIVING FULL SATISFACTION.—
 These Machines leave no Ribs in the Grass, and are unsurpassed for keeping a Lawn or Croquet Ground in first-rate order. They are now fitted with adjustable handles, to suit the height of the person using the Machine. Either "corrugated" or "plain" front rollers can be supplied at pleasure. A pair of short side rollers is sent with every Machine, to replace the usual front rollers when cutting long grass. The grass can be either collected in the box—the neatest plan—or delivered at the back of the Machine and left on the lawn, to prevent the grass burning in dry seasons. These Machines are fitted with the best wheel gearing, the best steel-edged knives, and hardened steel points and bearings.

Sizes from 8 to 20 inches. Prices from 55s.

Carriage paid to the principal Railway Stations in England. Warranted to give satisfaction, and a month's trial allowed. Orders executed on receipt.

RANSOMES, SIMS AND HEAD, IPSWICH.

Beehives.—Two Silver Medals awarded to GEO. NEIGHBOUR AND SONS at the Paris Exhibition of 1869. The only English Exhibitors who obtained a Silver Medal for Beehives.

NEIGHBOUR'S IMPROVED COTTAGE BEEHIVE, as originally introduced by GEORGE NEIGHBOUR & SONS, working three bell-glasses, is neatly and strongly made of straw: it has three windows in the lower Hive. This Hive will be found to possess many practical advantages, and is more easy of management than any other Beehive that has been introduced.

Price, complete £1 15 0
 Stand for ditto 0 10 6
THE FIGURIAN or ITALIAN ALP BEE being much in repute, G. N. & SONS supply a Swarm of Bees with genuine Italian Queen, in the Improved Cottage Hive, at £4. Hive included.
 An Italian Alp Queen, with full directions for uniting to Black Stocks, 12s. each.
ENGLISH BEES.—Stocks and Swarms may be obtained as heretofore.
THE APIARY. By A. NEIGHBOUR. 5s., postage 4d.
 A newly arranged Catalogue of other improved Hives, with Drawings and Prices, sent on receipt of two stamps.
 Agents for Straw, Woodbury, and other Hives and Suppers, made by James Lee, at his prices.
GEO. NEIGHBOUR AND SONS, 127, High Holborn, W.C. or 149, Regent Street, London, W.

FOLLOWS & BATE, Makers, Dutton Street Works, MANCHESTER.

Important to Market Gardeners and Others. THE PATENT HAND GARDEN PLOUGH.

This effective little implement meets a long-felt want. It consists of one light but strong steel shovel, for marking out rows to plant, or for loosening up the ground after the plants are up. Also a small Steel Plough, to be used for hilling up the rows when desired; and a Cutter for exterminating weeds, and Rake for pulverising the ground. These pieces are made separate, and attached or detached in a moment by means of a simple fastening. Its construction enables the user to push it readily and easily through the ground, stirring the earth, if required, to a depth of six inches. It is exceedingly light, strong, and tasty, and fully adapted to the purposes designed. A large number have been sold, and are giving unqualified satisfaction.
 Price, complete, with Shovel, Plough, Weed-Cutter, and Rakes, £2 2s.

THE IMPROVED SELF-ACTING HYDRAULIC RAM.

This useful Self-acting Apparatus, which works day and night without needing attention, will raise water to any height or distance, without cost for labour or motive power, where a few feet fall can be obtained, and is suited for supplying Public or Private Establishments, Farm Buildings, Railway Stations, &c.

Prices of Horse, Pony, and Donkey Machines on application.
Carriage Paid to all the principal Railway Stations
in the United Kingdom.

The "SILENS MESSOR" Machines have a world-wide reputation for their superiority and excellence, and the improvements which have been made in them from time to time still keep this Machine the best and most approved one in the Market. They will cut either short or long grass, ferns, &c., and wet as well as dry, advantages which no other Lawn Mowers possess. They are the only Lawn Mowers in constant and daily use in the Royal Gardens, and in most of the principal Gardens and Parks throughout the Kingdom.

A stock of 500 Mowers is kept at our London Establishment, including all sizes, from which purchasers can make their selection and have prompt delivery.

GREEN'S PATENT "ROYAL" LAWN MOWER is a far superior Machine of its kind to any Lawn Mower extant, and it will cut either short or long grass, ferns, &c., and wet as well as dry.

Prices of the "Royal" Machines. To cut—

6 inches	8 inches	10 inches	12 inches	14 inches	16 inches
25s.	35s.	50s.	65s.	85s.	100s.

Delivered carriage free at all the principal Railway Stations and Shipping Ports in England, Ireland, and Scotland. Every Machine is warranted to give entire satisfaction, and if not approved of, may be returned at once unconditionally, without any expense to the purchaser.

Our reason for bringing out the "Royal" Mower is to meet a want which has been repeatedly expressed by the purchasing public, to have a good, useful, and efficient Machine, cheap.
N.B.—Those who have Lawn Mowers to repair will do well to send them either to our Leeds or London Establishments, where they will have prompt attention, as an efficient staff of workmen is kept at both places.

GREEN'S PATENT ROLLERS for LAWNS, DRIVES, BOWLING GREENS, CRICKET FIELDS, and GRAVEL PATHS.
Suitable for Hand or Horse Power.

The above can be had from all respectable Ironmongers and Seedsmen in the United Kingdom; or from the Manufacturers,

SOLE MAKERS:

JOHN CROWLEY & CO., Meadow Hall Ironworks, near SHEFFIELD.

MESSINGER & COMPANY,
CONTRACTORS, MIDLAND HORTICULTURAL BUILDING
AND HOT-WATER ENGINEERING WORKS, LOUGHBOROUGH,

beg to inform their numerous Patrons and the Public generally, that since the recent disastrous fire they have erected new, more extensive, and commodious works, fitted with the best steam-power machinery, for the construction of Horticultural Buildings in wood or iron, plain or ornamental, of any required dimensions. T. G. MESSINGER & CO. are now, therefore, in a position, from their great facilities and experience, to carry out with dispatch and in the best manner, at moderate cost, the orders with which they may be entrusted. Glasshouses erected on Messinger's Patent principles are, owing to mechanical arrangements, very strong, most durable, light, elegant; perfect efficiency for purpose intended is guaranteed, are economical in cost and maintenance. Hot-water engineering in all its branches. Messinger's Patent Hot-water Boilers, Flexible Jointed Hot-water Pipes and Valves, are now in use in many thousands of instances, with the greatest success. Particulars on application.
 Plans and Estimates forwarded. Ladies and Gentlemen waited upon. The Plans of Architects and others carried out.

AVELING & PORTER,

ROCHESTER, KENT; 72, CANNON STREET, LONDON, E.C.; and 9, AVENUE MONTAIGNE, PARIS

AVELING & PORTER'S ENGINES have gained the highest Prizes at every important International Exhibition. The Two Medals for Progress and Merit were awarded them at Vienna for their STEAM ROLLERS and ROAD LOCOMOTIVES; and at the last trials of the Royal Agricultural Society of England their AGRICULTURAL LOCOMOTIVES gained the First Prize after exhaustive trials, when one of their 20-horse power Engines, fitted with single slide and ordinary link-motion, indicated 35-horse power with a consumption of three and one-fifth pounds of coal per horse-power per hour.

JONES'S PATENT "DOUBLE L" SADDLE BOILER.

These Boilers possess all the advantages of the old Saddle Boiler, with the following improvements—viz: the water space at back and over top of saddle increases the heating surface to such an extent that a "PATENT DOUBLE L SADDLE BOILER" will do about twice the amount of work with the same quantity of fuel; the cost of setting is also considerably reduced, and likewise the space occupied; at the same time these Boilers are simple in construction, and being made of wrought iron, are not liable to crack. They are made of the following sizes:—

Sizes.			To heat of 4-in. Pipe.	Price.
High.	Wide.	Long.	Feet.	£ s. d.
20 in.	18 in.	18 in.	300	7 0 0
20 "	18 "	24 "	400	8 0 0
20 "	18 "	30 "	500	9 0 0
24 "	24 "	24 "	700	12 0 0
24 "	24 "	30 "	850	14 0 0
24 "	24 "	36 "	1,000	16 0 0
24 "	24 "	48 "	1,400	20 0 0
28 "	28 "	60 "	1,800	25 0 0

Larger sizes if required.

From MR. CHARLES YOUNG, Nurseries, Balkam Hill, S.W., May 29, 1873.

"Having given your Patent 'Double L' Boilers a fair trial at my Nurseries, I beg to say that they are most satisfactory. I consider them the best in use, and without doubt the most economical of all boilers; they will burn the refuse of other tubular boilers I have in work."

PRICE LISTS of HOT-WATER PIPES and CONNECTIONS, with Boilers, of all sizes and shapes; or ESTIMATES for HOT-WATER APPARATUS, erected complete, will be sent on application.

J. JONES AND SONS, Iron Merchants, 6, Bankside, Southwark, London, S.E.

When ordering Boilers please refer to the above advertisement.

STEVENS' TREATHAM GREENHOUSE BOILER,

After long experience, has proved the most Simple, Economical, Efficient, and Lasting Boiler extant; recently much improved. For Illustrations, with full particulars, apply to the Sole Makers, F. AND J. SILVESTER, Castle Hill Foundry, Engineering and Boiler Works, Newcastle, Staffordshire.

THE

AGRICULTURAL GAZETTE ALMANAC, 1875.

The best Illustrated Agricultural Almanac.

OPINIONS OF THE PRESS.

"It is an excellent and useful work for farmers and all interested in rural pursuits. Beyond the matter usual in such compilations are many good serviceable hints on fattening cattle, growing of root crops, &c. The illustrations are admirably executed, many being engraved from photographs."—Weekly Dispatch, Jan. 31, 1875.

"The 'Agricultural Gazette Almanac,' which deals with matters of interest to farmers, has reached a second edition."—Lloyd's, Jan. 17, 1875.

"It is a very cheap three-pennyworth of information of interest and utility to farmers, and contains numerous illustrations."—The Field, Jan. 15, 1875.

"In addition to the usual matter to be found in an almanac, we have here useful information to the farmer, as to stock and crops, with illustrations of prize animals."—Gloucestershire Chronicle.

"This is a cheap and useful almanac and diary well illustrated. Its contents will be found interesting to the agriculturist, and adapted for daily use."—Farmer's Herald.

WANTED, TWO or THREE good NURSERY HANDS—such as can use the knife well, and make beautiful Plants.—Permanent situation. State wages and reference to R. AND F. ALLUM, Nurserymen, &c., Tanworth.

Warehouseman.

WANTED, as SECOND WAREHOUSEMAN, an active, industrious Man, who is thoroughly master of the work, in a Seed Warehouse to Superintend Pickers, Struggle Pea Crop, &c. Wages, 30s. per week.—HENRY CLARKE AND SONS, 29, King Street, Covent Garden, London, W.C.

WANTED, as HEAD SHOPMAN, a Man of experience—reference given to one having a knowledge of Plants, and make himself useful, stating age, experience and salary. BARR AND SUGDEN, 12, King Street, Covent Garden, W.C.

WANTED, in an old-established Seed and Nursery Business, a competent SHOPMAN, SALESMAN, and CLERK; he would be required to Wait on Customers, keep the Books, and make himself useful; must be well up in the Seed Trade, and have a Knowledge of Plants and their Value.—The situation will be permanent and comfortable.—THOMAS BUNYARD AND SONS, Maidstone, Kent.

WANTED IMMEDIATELY, a steady young MAN for the Jobbing Trade in a small Nursery; one who would not object to make himself generally useful.—J. FUZZARD, 18, Maids Vale, W.

WANTED, an intelligent YOUTH, or a young MAN who has had one or two years' experience, to Assist in the House of FALCONING, 4, Elm Tree Road, St. John's Wood, London, N.W.

WANTED, a respectable young MAN, for the House; one from a Nursery preferred. Permanent situation.—JAMES WALTON, Horn Park Nursery, Lee Green, S.E.

WANTED, a strong Youth as an APPRENTICE to a Gentleman's Garden, where he can learn the profession in all its branches. A small Premium required.—J. S., The Gardens, Highnam Court, Gloucester.

WANTED, as SHOP PORTER, an active, industrious Man, who has had experience in a Seed Shop or Warehouse. Wages 30s. per week.—HY. CLARKE AND SONS, 29, King Street, Covent Garden, W.C.

WANTED, a MAN, to attend to Cows and other Farm-work. Three small rooms and firing will be provided. The Man and Wife can be accommodated, but no children.—Apply, by letter, giving full particulars of previous occupation, age, why leaving, and wages required, to G. B., Stone Hall, Oxford, Surrey.

WANT PLACES.

To Gardeners in Want of Situations, WHOSE CHARACTERS WILL BEAR STRICT INVESTIGATION. THE PINE-APPLE NURSERY COMPANY devote special attention to this important matter—proper Men to suitable Situations.—For a GARDENER, or for a SITUATION, please send full particulars to Mr. JOHN BESTER, the Pine-Apple Nursery Company, Maids Vale, London, W.

B. S. WILLIAMS, having at the present time several very excellent GARDENERS upon his Register, is desirous of placing them in Situations where great experience and trust are required. B. S. W. would at the same time beg to intimate that when a Gardener is applied for that the filling of the situation should be left with him, as that would prevent unnecessary correspondence and delay.—Victoria and Paradise Nurseries, Upper Holloway, London, N.

Head Gardeners.

JOHN LAING can present recommend with every confidence several practical and practical Men, of tested ability and first-rate character. Ladies and Gentlemen in WANT of GARDENERS and BAILIFFS, or GARDENERS for First-rate Establishments or Single-hand Situations, can be suited, and have full particulars by applying at Stanstead Park and Rutland Park Nurseries, Forest Hill, London, S.E.

Gardeners and Under Gardeners.

W. M. CUTBUSH AND SON beg to state that they have at all times on their Books MEN of VARIOUS QUALIFICATIONS, whose characters will bear the strictest inquiry. Any Gentleman making application would save time by clearly stating the duties to be undertaken, wages offered, &c., so that suitable Men may be selected.—Highgate Nurseries, London, N.

GARDENER (HEAD), where not less than four are kept.—Age 27; thoroughly experienced. Good references.—W. POPE, Holmhurst, Horsham, Sussex.

GARDENER (HEAD), where two or more are kept.—Age 20, married, two children; twelve years' experience in forcing all kinds of Fruit, Flowers, and Vegetables, also good Kitchen and Flower Gardener. Good reference to late employers.—Y. Z., Cooksbridge Nursery, near Lewes, Sussex.

GARDENER (HEAD), where two or more are kept.—Age 25; understands the Management of Stove and Greenhouse Plants, Vines, Melons, Cucumbers, and Kitchen and Flower Gardening. A good character can be had.—R. C. Mr. Lev's Royal Nursery, London Road, Croydon.

GARDENER (HEAD), to any one requiring a trustworthy competent Man, where several others are kept.—Age 40, married. Nine and a-half years' first-class character, and highest testimonials from former and present employers.—A. B., Broon Hall, Oswestry, Salop.

GARDENER (HEAD).—J. MASON, fifteen years Head Gardener to the late Jesse Watts Russell, Esq., Ban Hill, Staffordshire, is at liberty to engage with any Nobleman or Gentleman requiring a practical and persevering Man.—Ham, Ashbourne, Derbyshire.

GARDENER (HEAD), age 25.—A GENTLEMAN seeks a situation for a Man, as above, who understands Vines, Greenhouses, Stove Plants, &c. Ten years' experience. Excellent character. He only became anxious to marry.—T. K., Sim's Nursery, Foot's Cray, near Sidcup, Kent.

GARDENER (HEAD), married.—JOHN DERRICUT, over nine years Gardener in the late Robert Hammy, Esq., is now open to an engagement in a first-rate Establishment. References given only because absent, also to previous employers, if required.—The Gardens, Springfield, Ulverston, Lancashire.

GARDENER (HEAD), married.—where three or more are kept.—Age 25, married; thoroughly experienced in all branches of the profession. Five and a-half years' good character.—H. T., Northgate Nursery, Chichester, Sussex.

GARDENER (HEAD, WORKING).—Age 26, married, to family of Lands in Leamington and Stoke and Greenhouse Plants, also good Flower and Kitchen Gardener.—E. GEEVES, 3, Albert Road, Belvedere, S.E.

GARDENER (HEAD, WORKING).—Age 30, married, two children; thoroughly understands the profession in all its branches. Three years' good character. Y. Z., Mr. Eroomfield, Roehampton, Surrey.

GARDENER (HEAD, WORKING).—Age 33, married, one child; thoroughly understands all branches of the profession. Has first-class characters.—H. H., Post Office, Henley-on-Thames.

GARDENER (HEAD, WORKING).—Age 36, married; has a thorough practical knowledge of the profession. Will be shortly disengaged.—THE GARDENER, The Lodge, Sompting, Worthing, Sussex.

GARDENER (HEAD, WORKING).—Age 37, married; has a thorough practical knowledge of the profession in all its branches, and Land and Stock. Three years' good character. M. W., Mr. Wood, Heaver, near Edenridge, Kent.

GARDENER and BAILIFF.—Age 40, married; has had twenty-three years' experience in the cultivation of Pines, Vines, Peaches, Melons, Bushmosses, Stove and Greenhouse Plants, and Flower and Kitchen Gardening. Has also a thorough practical knowledge of Farming, the Management of Stock, and Buying and Selling. Wife can superintend Dairy, and thoroughly understands Poultry.—T. B., Messrs. Cripps & Son, Nurserymen, Tunbridge Wells, Kent.

GARDENER.—Age 36, married, three children; experienced in Kitchen and Flower Gardening; no objection to small quantity of Glass, or Pony and Trap. Good references.—G. S., Wandale Terrace, Merton, Surrey.

GARDENER (GOOD SINGLE-HANDED OR OTHERWISE).—Married, respectable; understands the profession, Management of Stock, Nursery Work, and Jobbing Out. Good reference.—FOSTER, Gardener, Essendon, Hatfield, Herts.

FOREMAN in a large Establishment, or HEAD GARDENER where three or more are kept.—Age 26, married. Nine years in first-class places. Highest references.—W. E., 26, Derby Street, Burton-on-Trent.

FOREMAN, in a good Establishment.—Age 26, Eight years' experience in good Establishments. Good references.—H. B., 20, Vorley Road, Upper Holloway, London, N.

FOREMAN, in a good Place, or SECOND HAND in the Houses in a large Establishment.—Age 22, Two years' good character.—E. W., The Gardens, near Audring Court, near Bridgewater.

GARDENER (SECOND), in a Gentleman's Garden.—Age 22; well up in Forcing, and Flower and Kitchen Gardening. Highest references can be given.—C. CROCKETT, Coppell Hill, Tottenham.

GARDENER (SECOND), in a Nobleman's or Gentleman's Garden.—Age 21. Highly respectable. Good character.—B. G., Mrs. Bluck, East Acton, London, W.

GARDENER (UNDER), or PLANTSMAN, in a first-class Garden.—Age 15; ten years' experience. Good testimonials or reference.—A. F., Post Office, West Dulwich, Surrey.

GARDENER (UNDER).—Age 20, active and obliging. Wages £1 weekly. Eighteen months' good character.—A. F., Mr. Green, bookseller, North Finchley.

GARDENER (UNDER).—Age 21; has had six years' experience under Glass. Two and a half years' good character.—R. M., 144, Southampton Street, Camberwell, S.E.

GARDENER (UNDER), a good Foreman.—Age 20; has a knowledge of Orchids, Fruit and Plant Growing. Good references. State particulars.—F. C., Wray Mill, Reigate.

GARDENER (UNDER), in the Houses.—Has had five years' experience in the profession. Accustomed to Greenhouse and Conservatory Work. Bothy preferred.—R. H., Post Office, Cuckfield, Sussex.

NURSERY FOREMAN.—Married; well up in Fruits, and competent to take entire Charge of them; can Execute Orders, and Writes a good Hand.—Can be recommended by THOMAS HUNYARD AND SONS, Maidstone Nurseries, to apply.

PROPAGATOR, Soft-wooded Grower for Exhibition or Market, or a first-class character.—C. C., Lordship Road, Stoke Newington, N.

IMPROVER, or UNDER GARDENER, in a Gentleman's Garden.—Age 18. Five years' experience. Suburbs of London preferred. Good character.—D. W., 8, Alpha Street, Slough, Bucks.

IMPROVER, under a Nobleman's or Gentleman's Gardener.—Age 20; has been brought up to Gardening. A Premium will be given.—H. S., Mr. Surman, Florist, High Street, Wisney, Oxon.

ROSE GROWER, in a small Nursery.—Age 21. Five years' experience, both in and out. No objection to work under an experienced Foreman.—H. N. Mr. B. R. Cant's Nursery, Greenstead Road, Colchester.

TO HORTICULTURISTS and FLORISTS.—The Friends of a respectable Youth wish to place him in the above Trade, to reside with the Principal. He is nearly 16 years old, willing and industrious.—B., 519, Connaught Road, London, E.

TRAVELLER and CORRESPONDENT.—Thoroughly acquainted with the Wholesale Seed Trade, and many years' experience on the Road, with good connection.—S., 44, Devonshire Road, Holloway, N.

TRAVELLER, or CLERK and TRAVELLER.—A young Man; thoroughly up in the trade. Highest references.—A. D., 8, Albion Place, Lower Broughton, Manchester.

SHOPMAN (JUNIOR).—Young. Has had considerable experience at Counter and Warehouse-work; also fair knowledge of Plants.—A. Z., 12, Elsworth Street, York Street, Chesham, Manchester.

SHOPMAN.—Age 28; has had fourteen years' experience in all branches of the Retail Trade. Four years' reference from last employers.—HORTUS, Post Office, High Street, St. John's Wood, N.W.

SALESMAN, or FURNISHER in the Market or out. Well known in the Trade. Thirty years' experience.—H. B., 8, Heron Road, Camberwell, S.E.

FOREMAN or SALESMAN to a Market Gardener.—C. B., Post Office, Ealing, Middlesex.

Epp's S. C. C. O. A. BREAKFAST. Grateful—Comforting.

"By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of this diet, a Constitution may be gradually built up until strong enough to resist every tendency to disease. Hundreds of subtle maladies are floating around us, ready to attack wherever there is a weak point. We may escape many a fatal shaft by keeping ourselves well fortified with pure Blood and a properly nourished frame." See article in the Civil Service Gazette.

Made simply with boiling water or milk. Sold in packets (in tins for export) labelled "JAMES EPPS AND CO., HOMOEPATHIC CHEMISTS, 48, The Quadrant, Street, and 29, Piccadilly, W. Works—Euston Road, and Camden Town, London, N.W. Makers of Epps's Glycerine Jujubes for Throat Irritation."

In consequence of Spurious Imitations of LEA AND PERRIN'S SAUCE, which are calculated to deceive the Public, LEA AND PERRIN have adopted a New Label, bearing their Signature, thus— which will be placed on every bottle of WORCESTERSHIRE SAUCE, after this date, and without which none is genuine.—Sole Wholesale by the Proprietors, Worcester; CROOK & BLACKMAN, London, and Export Olives generally; Retail, by Dealers in Sauces throughout the World. Nov., 1874.

DINNEFORD'S FLUID MAGNESIA. The best remedy for Acidity of the Stomach, Heartburn, Headache, Gout, and Indigestion; and the best mild Aperient for Spasmodic Constitutions, especially adapted for Ladies, Children and Infants. DINNEFORD AND CO., 172, New Bond Street, London, W.; and of all Chemists throughout the World.

CURES OF OLD STANDING ASTHMA, COLDS, &c., by DR. LOCK'S PULMONIC WAFERS.—From Mr. KINROSS, Chemist, Trinity Street, London. "In all affections of the Lungs, Asthma, and neglected Colds, they seem to act like a charm." In Asthma, Consumption, Bronchitis, Coughs, Colds, and Rheumatism, they are an instant relief. Sold in 1s. 1/2d., 2s. 9d., 4s. 6d., and 11s. per box by all Druggists.

THE "ARCHIMEDEAN" AMERICAN LAWN MOWER

HAS BEEN AWARDED

GRAND DIPLOMA of HONOURABLE MENTION, Vienna, 1873.
SILVER MEDAL, Vienna, 1870. SILVER MEDAL, Hamburg, 1869.

NOTE.—The "Archimedean" was specially selected from the Mowers exhibited at Vienna for constant use in the Exhibition Grounds, and gave great satisfaction; and we have pleasure in calling attention to the following Testimonial, received from the Inspector of the Royal Gardens, Schönbrunn, Vienna:—

"Your 'Archimedean' Lawn Mower have been used for some time past at the Imperial Gardens, and I have great pleasure in stating that they have given perfect satisfaction. Their quick and good work prove them to be the best and most efficient machines of the kind."

PATRONIZED BY

HER GRACIOUS MAJESTY THE QUEEN,
HER IMPERIAL MAJESTY THE EMPRESS OF GERMANY,
THE LATE EMPEROR OF THE FRENCH,

HIS ROYAL HIGHNESS THE PRINCE OF WALES,
HIS IMPERIAL MAJESTY THE EMPEROR OF AUSTRIA,
THE VICEROY OF EGYPT,

And many of the Nobility and Gentry of Great Britain.

CHIEF ADVANTAGES.

- They are extremely LIGHT IN DRAUGHT, SIMPLE IN CONSTRUCTION, WELL MADE, and NOT LIKELY TO GET OUT OF ORDER.
- They cut LONG or SHORT, WET or DRY Grass, and do not clog.
- They have no ROLLERS in FRONT of the Cutters, and therefore cut the Grass as it GROWS, and do not miss the BENTS.
- They work well on SLOPES, STEEP EMBANKMENTS, UNDER SHRUBS, and close up to Trees, &c.
- They can be USED either WITH OR WITHOUT GRASS BOX, as may be desired.

TESTIMONIALS.

From A. F. BARRON, Esq., Royal Horticultural Society, Chiswick Gardens, W.

"GENTLEMEN,—We have now had your 'Archimedean' Lawn Mower in use for several months, and without hesitation I can truly say it is the best and most efficient implement of the kind we have ever used."

From the late Mr. GEORGE WYNES, Royal Gardens, Buckingham Palace.

"GENTLEMEN,—I beg to say that we have had your Patent 'Archimedean' Lawn Mower at work in Her Majesty's gardens at Buckingham Palace for some time past, and I have much pleasure in testifying that it has given every satisfaction, as it does its work well and quickly."

From the Rev. J. H. WHITE, Hemingford Grey, St. Ives, Hants.

"I am much pleased with the working of your 'Archimedean' Mowing Machine. I think it superior to others which I have used in previous years."

OPINIONS OF THE PRESS.

"The quickest, most simple, and most efficient Mower ever used."—*Gardeners' Chronicle.*

"Far superior to any of ours."—*The Field.*
"Remarkably easy to work."—*Gardeners' Mag.*

"We feel bound to recommend it to our readers as one of the best Mowers we have as yet made acquaintance with."—*Floral World.*

EVERY MOWER IS WARRANTED TO GIVE AMPLE SATISFACTION,

And if not approved of may be returned within a Month, and the amount paid be refunded.

On view the day previous to and morning of Sale, and Catalogues to be had of the Auctioneer, HENRY HAYWARD, Auctioneers and Surveyors, 27, New Bridge, Dover, and 12, Queen Victoria St., London, E.C. THE NURSERY to BE LET, inquire of the Auctioneer.

Gairnforth House, Moorgate, Rotterdam. TWO DAYS SALE OF CHOICE PLANTS on THURSDAY, May 12 and 13, commencing each day at 11 A.M.

MR. ROWLAND WARD, of the Central Nurseries, Sheffield, is favoured with instructions from George B. Gairn, Esq., Rotterdam, to hold a SPECIAL COMPETITION will take place, as above, of very choice PALMS, CROTONS, TREE FERNS, Specimen ALLAMANDA, CLERODENDRUM, and other Plants, also PALMS, ALOES, FODIAS, PHORNIUMS; also a variety of choice ORNAMENTAL PLANTS. For days to view, prior to Sale, and Catalogues (if desired), to be had of Mr. H. ALLEN, Gardener, Gairnforth Lodge, Moorgate, Rotherham; and of the Auctioneer, Central Nurseries, Castle Hill, Sheffield.—April.

TO BE LET, a NURSERY, FLORIST, and SEED BUSINESS—about 10 acres of Garden in capital cultivation (entirely English, Scotch, and Sicily), and the Residence if required. Stock comprises Roses, Fruit Trees, Forest Stunt, Evergreens, Flowers and Plants of descriptions. A minute list of the contents of the Nursery will be sent. Apply to CHALLEN and SON, Stowington, Puffborough.

Victoria Estate, Kansas, U.S.—To Farmers and OTHERS. FINE STOCK FARMS of 640 Acres and upwards, to be SOLD, Freehold, from 125 to 205 per acre. In its natural condition unsuited for feeding Sheep and Cattle. For PAMPHLET containing full particulars respecting this Property, apply to CHARLES HOWLAND, Esq., U.S.A., 14, Fitzroy Square, London, W., Architect to the Estate.

To Nurserymen and Others. TO BE SOLD, by Private Contract, with immediate possession, on the South Coast and near to the fashionable and rapidly rising town of Worthing, the unexpired LEASE for fourteen years, from September 29, 1875, of the SALVINGTON NURSERIES, where a good trade has been carried on for many years, the whole containing 14 a. 3 r. 2 p., a great portion of which is cultivated as a Nursery and Market Garden. The Land is well sheltered by intersecting Hedges of Beech, Laurel, and Hornbeam. A good roomy House is attached, with Seed-shop, Barn, Stables, Cart-shed, and Pig-sties, three convenient Glass Structures, and Propagating House, all thoroughly heated by hot water, with Pits, Frames, and Hand-lights. Annual Produce, £25, together with a Stock-in-trade of Plants, Carts, and Engines, and about the £5000. Income about £600.

For further particulars, and for Cards to view, apply to Mr. RICHARD HOWLAND, Solicitor, Arundel; or Mr. GHEA, Esq., on the Premises.—April 28.

To Practical Men with a little Capital. TO BE DISPOSED OF, a FIELD of the excellent MARKET-GARDEN LAND, capably situated midway between the two important towns of Ramsgate and Margate, and about a quarter of an hour's drive from each. These two towns and adjacent coast contain a resident population of 40,000, increased during four months of the year to more than double, so that the Market for Garden Produce is very large, and a Man who understands his Business could not fail of success. About 1/4 acre of the Land has been planted with Asparagus and other vegetables, and the remaining 1/2 acre has been erected, but the house need not be taken unless wished. The price of the Freehold altogether is £1050, or without House and Ground, £600. Two-thirds of the purchase money of these sums may remain, if wished, at 4 1/2 per cent. Apply to Mr. R. ALLSOP, Manston, near Ramsgate.

GRANTHAM and SOUTH LINCOLNSHIRE HORTICULTURAL SOCIETY. President, the Right Hon. EARL BROWNLOW, Lord-Lieutenant of the County. The next EXHIBITION will be at Grantham, JULY 7 and 8. Schedules of Prizes (£200, 200 Silver Cup) are now ready, and may be had of Mr. LYNE, Bookseller, Grantham.

NOVELTIES

FOR 1875.

JAMES VEITCH & SONS

BEG TO ANNOUNCE THAT THEY ARE NOW PREPARED TO SEND OUT

THE UNDERMENTIONED SPLENDID NOVELTIES.

ADIANTUM SEEMANNI.

Though not a new name amongst our garden Ferns this is in reality a new garden Fern, and is described by Mr. Moore in the *Gardeners' Chronicle* of March 27, 1875 (p. 396), as "a noble species of the Maidenhair Fern, for which we are indebted to Messrs. Veitch & Sons, who gave us fronds from their specimen plant which are fully 2 feet long, with fertile pinnae, 3 inches long and 2 inches broad at the base, while some of the sterile pinnae are nearly 4 inches long and 2½ inches broad. They have a comparatively slender glossy black stripe, bare at the lower part, and bearing towards the top from four to eight of the magnificent pinnae already noted, which are attached by a slender petiole an inch long." It received a Certificate at the Royal Botanic Society's Fête in June, 1874, under the name of A. Zahnii, but the above has been proved to be identical with the Maidenhair described by Sir W. Hooker, so long since as 1851, as A. Seemannii, the plant previously sold under this name being A. Wilsoni.

Price 10s. 6d.

ADIANTUM SPECIOSUM.

A very elegant Fern, of semi-scandent habit, with large tripartite fronds, which frequently attain a length of 36 inches, with a width of 21 inches, the pinnales of which are ¾ to 1 inch across, the lobes cuneate, annunciated, serrifurrow at the apex. The whole of the pinnales are covered with dense short hairs, giving the foliage a woolly feeling when touched. This beautiful plant is very distinct from any Adiantum we have previously sent out, and has the peculiarity of being deciduous. It formed one of our collection of six new plants with which we won the First Prize at the Exhibition of the Royal Horticultural Society, June 4 and 5, 1873, and it has also received a First-class Certificate from the Royal Botanic Society.

Price 21s.

AMARYLLIS (HIPPEASTRUM) LEOPOLDI.

A magnificent species introduced by us from Peru, through our Collector, the late Mr. Pearce. It is more robust in its growth, and bears larger flowers than any other Amaryllis in cultivation. When sending it home Mr. Pearce described it as the finest of all the Amaryllis he had met with—a description which it has fully realised. The leaves are broadly strap-shaped, and the scape stout, supporting two flowers which each measure fully 7 inches in expansion, and consists of six broadly ovate perianth segments, the lower half of which is a clouded crimson colour, while the tips are of a creamy white. The base of the shallow tube is also greenish white, and from this a bifid white bar passes upwards into each of the segments, forming a ten-pointed star. This fine novelty was named, by permission, in honour of the King of the Belgians, on the occasion of his visiting a flower show at the Royal Horticultural Gardens, in 1869, on which occasion we exhibited the plant for the first time. It has received a First-class Certificate and a Special Certificate from the Royal Horticultural Society, also a Certificate of Merit from the Royal Botanic Society. An excellent representation of the plant will be found in the *Gardeners' Chronicle* for 1870, p. 733, and it is figured in the *Floral Magazine*, 1870, pp. 475, 476.

Price 42s., 63s. and 105s.

BEGONIA HYBRIDA "MODEL."

A seedling raised at this Nursery, the result of intercrossing B. Pearcei, B. Veitchii, and B. Sedeni. The plant is of neat and robust habit, and very free blooming, with medium-sized green foliage. The flowers are the finest formed yet obtained, in colour a delicate rosy blush.

Price 10s. 6d.

BEGONIA HYBRIDA "EXCELSIOR."

A cross between B. Chelsooi and B. cinnabarina. The plant is robust in habit, with medium-sized green foliage; the leaves are more acuminate than those of B. "Model." A very free blooming variety, with large flowers of the form of B. Chelsooi, with the colour of B. cinnabarina.

Price 10s. 6d.

CROTON COOPERI.

A fine and distinct variety of this popular class of stove plants. It has large oblong slightly wavy leaves, conspicuously veined and blotched with yellow, the markings as the leaves get older changing more or less to red, the stalks being also red. It is of free growth, and will prove an excellent decorative kind. It has been frequently exhibited, and received a Certificate of Merit at the Royal Botanic Society's Exhibition, June 24, 1874.

Price 21s.

DIEFFENBACHIA BRASILIENSIS.

A very handsome plant, with the well-known D. Bausei style of growth. Its leaves average 18 inches in length by 8 to 9 inches in width. The variegation is very striking, the ground colour of the leaf being deep green, and the whole surface beautifully marked and mottled with small blotches of greenish yellow and white. It was awarded a First-class Certificate by the Royal Horticultural Society, June 4, 1873, also a Certificate of Merit by the Royal Botanic Society, July 1872.

Price 21s. A few extra-sized plants, 105s.

DRACÆNA LEVANGERII.

An interesting variety, from the islands of the South Pacific Ocean. The plant is free growing, with the distinctive symmetry of the genus; the leaves are ovately lanceolate and acuminate, from 12 to 14 inches long, with a width of from 2 to 3 inches at the broadest part, very gracefully curved, the lower ones strongly marked, but not uniformly so, with deep rose, almost crimson, the colour becoming more distinct as the foliage increases in age, thus giving a pleasing variety in the same plant. It is an improvement on D. imperialis, and will prove a useful addition to our decorative plants.

Price 21s. A few extra-sized plants, 84s.

DRACÆNA BALMORIANA.

Another interesting and attractive variety, from the same region. The leaves of this variety differ both in size and form from D. Levangerii, being shorter and more broadly ovate, but not less gracefully curved. The foliage, as it increases in age, has a metallic lustre, some leaves being conspicuously marked with rich rose-coloured stripes of variable length and width, while others show but a slight crimson tinge on the metallic surface. The nerves of the leaves are beautifully distinct and regular. It is altogether a very distinct plant, and cannot fail to be received with favour.

Price 21s. A few extra-sized plants, 63s.

DRACÆNA HYBRIDA.

This is a very distinct seedling, raised at our Chelsea Nursery, and the first hybrid which has been offered to the public. It is a cross between D. magnifica and D. albicans. The plant is of medium growth, with leaves averaging from 10 to 12 inches in length by 3 inches in breadth. They are of a deep green colour, which, as the plant attains age, becomes entirely suffused with deep rose and creamy white, the older leaves being margined with bright rose. The variegation shows itself whilst the plant is quite young, and from its graceful habit and beautiful colouring it cannot fail to be exceedingly useful for all decorative purposes. It has been frequently exhibited, and received Certificates of Merit both in London and at Birmingham during the last year.

Price 63s.

MASDEVALLIA DAVISII.

A charming Orchid, from the Western Cordilleras of South America. We cannot give a better idea of it than by quoting Professor Reichenbach's description of it in the *Gardeners' Chronicle* for 1874, p. 710:—"This is a beautiful thing, much like M. Harryana and M. Veitchiana, but differing in its very narrow fleshy leaves, by a straight tube of the perigon, by the lateral sepals not being gradually tapered to the point, but oblong and with suddenly abrupt short tails, as well as by the outline of the upper sepals, the petals, and the lip. The tube appears to be whitish yellow, with a blackish violet eye-spot on each side. The other parts of the flower are yellowish, white outside, and of the deepest splendid orange inside, so that it gives a most welcome contrast placed in a group of the scarlet, vermilion, and white Masdevallias."

Price 21s. and upwards.

NEPENTHES ALBO-MARGINATA.

A dwarf-growing species, with peculiarly narrow leaves; pitchers, 2 to 2½ inches in depth, of elegant shape, greenish below, reddish-green above; around and below the rim is a membranous-looking marginal white ring, a distinctive characteristic of the species.

Price 42s.

NEPENTHES INTERMEDIA.

A very distinct hybrid, raised at this Nursery, and obtained by our foreman, Mr. Court, from N. Rafflesiana, and an unnamed species with small spotted pitchers. The plant is of robust and free growth. The pitchers, which are produced very abundantly, are somewhat similar in shape to those of N. Rafflesiana, but longer, and are densely spotted and flaked reddish brown. This novelty will prove an excellent companion to the well-known N. Rafflesiana and Dominiana. It received a First-class Certificate from the Floral Committee of the Royal Horticultural Society, January, 1875.

Price 42s. to 105s.

A NEW ILLUSTRATED DESCRIPTIVE CATALOGUE will shortly be ready, and will be forwarded free on application.

VICTORIA AND PARADISE NURSERIES,
Upper Holloway, London, N.

H. CANNELL begs to draw the attention of the Public to the **COLEUS "CHAMELEON,"** which is unquestionably by far the most attractive and the greatest acquisition in Coleus ever sent out; even the most accurate description conveys but a very inadequate idea of its beauty. The entire Horticultural Press speak of it in the most eulogistic terms.

The following is the report of the Editors of the *Gardeners' Chronicle* (May 16, 1874):

"We have received from Mr. Cannell specimens of a new type of Coleus, of great beauty, and very distinct from those already in cultivation. Sometimes the leaf is mainly of an intense velvety maroon, flushed with bright rose, giving a kind of shot-crimson hue, the edge being just banded with green. In other cases half the leaf is of this character, while the other half is mostly of a deep rose crimson with golden headed edge, and sometimes the rose-crimson and the maroon-crimson are variously streaked and blended. The flush of rose crimson appearing in the maroon gives a remarkably velvety richness, which must be seen to be appreciated. With this superb and varied colouring the plant must be exceedingly effective."

This variety has received First-class Certificates wherever shown. Post free, 2s. 6d. each.

KNAP HILL NURSERY, WOKING, SURREY.

Carters

NEW NASTURTIUM RUBY KING

(With dark-coloured foliage), per packet, 1s. 6d.

A seedling variety of that type of Dwarf Nasturtium originated by us—viz. the dark-folaged or King of Tom Thumb section—the popularity of which is now universal, from the fact of their bright colours contrasted with dark foliage, compact habit, and duration of bloom, rendering them quite equal in effect to bedding Geraniums. The colour of the new variety now offered is quite unique and distinct—pure pink shaded with carmine—and forms an effective contrast with the varieties already in cultivation.

Carters

THE QUEEN'S SEEDSMEN,
237 and 238, HIGH HOLBORN, LONDON, W.C.

New Dwarf Silver Variegated Geranium,

"LITTLE TROT."

WM. POTTEN is now sending out the above GERANIUM, which is the best and most distinct silver variegated variety yet offered. Its dwarf and free habit, and broad clear white margin, will make it invaluable as a bedder for edging or panel-work. Price 2s. 6d. each, 24s. per dozen. The usual Discount to the Trade.
A Post Office Order, payable at Sissinghurst, must accompany all orders from unknown Correspondents.

DRACÆNAS—PRIZE-WINNERS.

MR. WILLIAM BULL

Offers a dozen Specimen Plants, probably the most handsome in Europe, in twelve varieties, embracing the newest and most distinct kinds in cultivation. Apart from the value of these Dracænas for winning prizes wherever and whenever exhibited, the Plants are pictures in themselves for ornamental and decorative purposes.

AN INSPECTION IS INVITED.

ESTABLISHMENT FOR NEW AND RARE PLANTS, KING'S ROAD, CHELSEA, LONDON, S.W.

PALM SEEDS of splendid quality.

CORYPHA AUSTRALIS, 1000 grains, 36s., 10,000 grains,

LATANIA RUBRA, genuine, germinating, 100 grains, 36s.,
each, 10 fruits 12s.

ARECA CATECHU, 100 fruits, 30s.

DEMONCUS HORRIDUS, 1000 grains, 75s., 100 grains,

ASTROCARVUM TUCUMA, 100 fruits, 30s.

LIVISONIA RAMSEYI, a beautiful, newly-discovered

Palm. The same was discovered last fall by Mr. Ramsey,

of the Sidney Museum, and named after him by Baron von

Müller; it is smaller than Corypha australis, but just as

hardy, with larger fronds, and a rapid grower; certainly

more beautiful than the well-known Corypha. 10 grains, 4s.,

50 grains, 18s., 100 grains, 30s.

All doubtful Palm seed returned directly after receipt, postage

free, are retaken at the charged rates.

J. C. SCHMIDT, Erfurt, Prussia.

CHOICE ORCHIDS.

HUGH LOW & Co.

Have on hand a very large Stock of CHOICE ORCHIDS, which they are prepared to offer on the most reasonable terms. Amongst recent importations, may be named:—

DENDROBIUM CHRYSANTHUM,
" CRASSINODE,
" DALHOUSIANUM,
" DEVONIANUM—(this lovely species can
be offered by the root at a very low price).
" FARMERI,
" FALCONERI,

DENDROBIUM MARMORATUM,
" PARISHI,
" PIERARDI,
" PRIMULINUM,
" THRYSFLOSUM,
" TRANSPARENS,
" WARDIANUM,

VANDA CATHCARTI,
" CERULESCENS,
" CRISTATA,
" BENSONLE,
" BICOLOR,
SACCOLABIUMS in variety,
THUNIAS, two distinct species.

The Stock of Established Plants of PHALÆNOPSIS, consisting of AMABILIS varieties, SCHILLERIANA, LUDDMANNIANA, and GRANDIFLORA, is very large.

AMATEURS ARE RESPECTFULLY INVITED TO INSPECT THE PLANTS.

CLAPTON NURSERY, LONDON, E.

NEW CLEMATIS, to be sent out by JOHN STANDISH AND CO. on May 10—
 ASCOTIENSIS, fine flowers, considerably larger than Jackmanni, and are well shaped, containing six petals each, a fine azure-blue; it throws a profusion of flowers the whole summer long, and is of a very vigorous habit.
 MRS. QUILTER—A magnificent white flower, containing eight petals; it is the largest, smoothest, and purest of the whites, and a very fine bloomer, with strong habit.
 The above are decided acquisitions, and should be in every collection. Orders may be had by sending in looking for them. Royal Nurseries, Ascot, Berks.

NEW PELARGONIUM, "DUCHESS of EDINBURGH."—This splendid new Pelargonium received First-class Certificates at the Royal Horticultural Society, May 13, and at the Royal Botanic Society, May 20, 1874. It is a dwarf compact habit, and a most profuse bloomer; we have it at the present time (April 12) in 48-pots, with fine trusses of bloom averaging from six to fifteen flowers in each truss. The flowers, which are crinkled-edged and of good form, are of a white blotched with purple. It is without doubt the best decorative variety ever offered. See the Opinions of the Press in the *Gardener's Chronicle*, the *Garden*, and the *Gardener's Magazine* of May 16, 1874.
 To be sent out May 1. Price One Guinea each.
 A recommendation or reference to accompany all orders from unknown correspondents.
 G. BRAID, Nurseryman, Winchmore Hill, Middlesex.

 A LIST of other varieties, post free.
 Boston Park Road Nurseries, Brentford, Middlesex, W.

New Pink Geranium "Mrs. Halburton."
FRANCIS R. KINGHORN has much pleasure in again offering this favourite variety, sent out by him last season, and which gives such general satisfaction. On three occasions it has received the highest commendation from the Floral Committee at Chiswick, associated with all the best varieties grown there for 1874, and sent out in large pots for 35s., 100 for 38s. Extra-sized cut-down plants, 2s. each.
 Sheen Nursery, Richmond, Surrey.

GIANT ASPARAGUS PLANTS, the best that money can procure, all certain to grow, 2s. 6d. per dozen. This delicious vegetable does not require half the expense usually incurred in planting it. See RICHARD SMITH'S SEED LIST for 1875.
 Extra strong SEAKALE, 2s. per dozen.
 RICHARD SMITH, Nurseryman, Worcester.

Bedding Roses.
CRANSTON'S CRIMSON BEDDER: strong plants, in 5-inch pots, 30s. per dozen.
 TEA-SCENTED, CHINA, NOISETTE, and HYBRID-PERPETUAL ROSES, in 4 and 5-inch pots, 9s. to 15s. per dozen.
 Now is the best time for bedding-out the Tea-scented and China Roses, and Hybrid Perpetuals, on their own roots. Address—CRANSTON AND MAYOS, King's Arms Nurseries, Hereford.

LOBELIA "LADY MACDONALD."—Pure white, deeply edged with ultramarine-blue, in the way of "Fanny" with dark spots on the stem, suitable for bedding or pot plant; one of the greatest novelties introduced for years. This beautiful variety was twice submitted for the opinion of the judges at two of the Exhibitions of the Royal Caledonian Horticultural Society, Edinburgh, last summer, and on both occasions was unanimously awarded a First-class Certificate.
 Plants first week in May, 2s. 6d. each.
 DOWNE AND LAIRD, 17, South Frederick Street, Edinburgh.

Vines.—To the Trade.
S. BIDE can still supply good strong PLANTING VINES, in Pots, of the undermentioned varieties, at 20s. per dozen (a special price for a large quantity will be given for orders of 1000).—Pyramidal Muscat, Madresfield Court, Black Hamburg, Mrs. Prince's Black Muscat, Lady Downe's Seedling, Burchard's Prince, Sealife Black Muscat, Epaulham, Hamburg, Perle de Lesseps, Black Morocco, Primari's Frontignan, Black Barbrossa, Sweetwater, Troverum Muscat, Bowood Muscat, Muscat of Alexandria, White Nile, Duchesse de Buedelche, Raisin de Calabre.
 S. BIDE, Alma Nursery, Farnham, Surrey.

Carnations, Picotees, and Pinks.
ISAAC BRUNNING AND CO. beg to announce that they have this Season a very fine and extensive Collection of the above to offer, strong plants of which are now ready for sending to the Trade, in various quantities, together with Illustrated SEED CATALOGUE, on application.
 Our ONE GUINEA COLLECTION of CARNATIONS, of which we contain six varieties, viz. Show Carnations, six pairs of choice Show Fuchias, twelve pairs of Show Fines, twelve choice mixed Carnations and Picotees for borders.
 Carriage and package free on receipt of Post Office Order. Half of the above may be had on order.
 Belgrave, Queenstown, County Cork, Ireland.
 February 15, 1875.

Mr. W. E. Gumbleton has this day received the Carnation and Picotee Plants, with which he is much pleased, and would like another dozen of either the same or other varieties.
 ISAAC BRUNNING AND CO., Great Warmouth Nurseries.

 Terms cash, package included.
 Cemetery Nursery, Gravesend.

Verbenas for Sale.
S. BIDE can now supply, for cash, Verbenas, in spring-struck, strong, and free from disease of any kind, including Purple King, Sealife White, Pink, and many other varieties (of which a list may be had on application), at 8s. per 100, package free. PELARGONIUMS, show and fancy, of the best varieties, 9s. per 100, 2s. 6d. per dozen. PELARGONIUM, strong autumn-struck plants, 10s. per 100; Mrs. Pollock, in single pots, 20s. per 100; Crystal Palace Gem, in single pots, 2s. 6d. per 100, 12s. per 100; IRESINE HERBIFLORA, 10s. per 100. CENTAUREA CANDIDISSIMA, struck last autumn, and well established, in large pots, 40s. per 100. AUREA FLORIBUNDA and other CALCEOLARIAS, 8s. per 100. HELIOTROPIES, light and dark, 8s. per 100.
 B. would particularly wish to draw the attention of his numerous customers to his fine stock of VERBENAS for this season, which are the admiration of all who see them; and would request that he be sent to him as early as convenient, as he was unable to supply many who applied late last season—general satisfaction being expressed by all those who favoured him with their orders.
 S. BIDE, Alma Nursery, Farnham, Surrey.

NEW PLANTS.—The three best new plants recently sent out are:—
CROTON MAJESTICUM,
DIPLODENDRA BRICKLEYANA,
CROTON SPIRALE.
 Price Two and Three Guineas each.
 Mr. WILLIAM BULL'S Establishment for New and Rare Plants, King's Road, Chelsea, S.W.

Australian Seeds and Plants.
SEEDS OF TIMBER TREES, PALMS, SHRUBS, &c. Plants indigenous to Australia, New Zealand, and Fiji, including ARCAUCARIAS, TREE FERNS, variegated FLAX, &c. Orders may be left with our London Agents, Messrs. C. J. BLACKHILL AND CO., Cook's Quay, Lower Thames Street, London, E.C., for transmission.
SHEPHERD AND CO., Nurserymen and Seedsmen, Darling Nursery, Sydney, New South Wales. (Established 1827).

Silver-margined leaved Geranium, "Laura."
FRANCIS R. KING has much pleasure in offering this superior variety, being a strong grower, with very large trusses of pale scarlet flowers, freely produced. Suitable for centres of beds and back rows in borders. Received the highest commendation (a First-class Certificate) from the Floral Committee at Chiswick in 1873, which was again confirmed in 1874. Plants 5s. each, seven for 30s.
 Sheen Nursery, Richmond, Surrey.

Carpet Bedding, Carpet Bedding.
ALTERNANTHERAS, 30,000, all good, strong, bushy plants, pricked off in store pots, in four varieties, at 8s. per 100—ambalis, paronychioides, paronychioides major, magnifica tricolor.
GOLDEN TERN, per 100: ECHEVERIA CALIFORNICA, 6s. per 100. Package and packing free. Terms cash.
 C. ALLEN, Stone Hills Nursery, Heigham, Norwich.

Adiantum Farleyense.
MESSRS. JOHN STANDISH AND CO. have a number of magnificent specimens of the above splendid FERN, fit for immediate exhibition. They are in 16 and 28-inch pots, and of perfect form. Also a few well-grown specimens of ADIANTUM GIGANTICUM, fine plants, 18 inches through, in 8-inch pots.
 Further particulars and price on application.
 Royal Nurseries, Ascot, Berks.

W.M. POTEN has now to offer strong healthy plants, in single pots, of GERANIUMS, VERBENAS, Imperial Dwarf AGERIUM, VERBENA ALTERNANTHERAS, MESEMBRYANTHEMUM cord. var. Double and Single PETUNIAS, HELIOTROPES, LOBELIAS, COLEUS, ECHEVERIAS, &c. Price List on application.
 Camden Nursery, Sissinghurst, Staplehurst, Kent.

Hollies.
ANTHONY WATERER respectfully invites the attention of Holly buyers to the very fine stock to be seen growing at Knapp Hill. It comprises upwards of Thirty Thousand Plants, from 3 to 10 and 12 feet high, of the finer Gold, Silver, and Green-leaved kinds, affording a choice in size and variety such as can be met with in no other Nursery in Europe. Every Plant has been recently removed, and will be guaranteed.
 The Stock of Common Green Hollies alone occupies 5 acres of land, and Purchasers will find them in large numbers of all heights up to 25 feet.
 Knapp Hill Nursery, Woking, Surrey.

FRANCIS R. KING is now sending out the above novelty in Fuchsias, which obtained Botanical Certificate, and was named and figured in the Botanical Magazine of December last, where Dr. Hooker states that Mr. Blackett's plant is not the same as above, but after my freely publishing the stock by plates, circulars, and advertisements, I find, at the eleventh hour, a neighbouring firm announcing Mr. Blackett's plant as Fuchsia procumbens, thereby endeavouring to reap a benefit at my expense. I am convinced the Public and Trade generally will believe that I have the certified stock, as all orders entrusted to me shall have my prompt and careful attention—thinking those friends who have already favoured me with their orders, which I hope to merit a continuance of.
 Strong established plants at rot. 6d. each, with a liberal reduction where six or twelve are ordered. Extra plants added to compensate for carriage. All orders delivered free in London.
 "I can now state with confidence that this plant has proved hardy here on rockwork during the late severe winter."
 Sheen Nursery, Richmond, Surrey.

American Plants without Post.
W.M. MAULE AND SONS beg to offer the choicest Hardy English and Continental RHODODENDRONS, with Helig and other AZALEAS, at 30s. per dozen, £10 per 100.
 The Plants are grown in a stiff Loamy Soil, on an exposed and elevated situation, and will thrive in any soil free from Lime, Iron, or Chalk. Large Bunches of the Fonticium and Catawbiense varieties, 4 to 5 feet high and as much through, 60s. per dozen. April and May is the best time for planting.
 The Nurseries, Bristol.

New Alpine and Herbaceous Plants.
JAMES BACKHOUSE AND SON'S CATALOGUE of the above, for 1875, may now be had on application. It contains many new and rare species of great interest and beauty, in addition to the general collection of approved kinds, with Descriptions and Cultural Notes.
 Stove, Greenhouse, and Bedding Plants.

JAMES BACKHOUSE AND SON'S CATALOGUE of these for the present season is also ready, and will be sent, all applied for, free of charge. The Collections of Orchids, Palms, and Ferns will be found specially rich and worthy of notice.
 Nurseries, York.

ORCHIDS.—Being a large importer of Orchids direct from their native habitats, Mr. WILLIAM BULL can make special offer of the following, at the extremely low prices announced:—

TO OBTAIN THE

Best Garden Lawns and Croquet Grounds

SOB

SUTTONS' LAWN GRASS MIXTURE,

Which forms a close velvety turf in a very short time. For making New Lawns or Croquet Grounds 3 bushels or 60 pounds is required per acre, or 1 gallon to every 6 rods (or perches) of ground.

For improving those already in turf, 20 pounds should be sown per acre.

March, April, and May are the best months for sowing.

Price 1s. per lb.; 20s. per bushel.

From Mr. J. MERRICK, Gardener to S. Forster, Esq., Le Court.

"The Seed you sent me last year turned out uncommonly well. Several gentlemen who came to Le Court could scarcely credit, from the appearance of the lawn, the fact that it was laid down three years."

that it was only sown in May. In August it was as fine and thick as I have seen some lawns that had been laid down for three years."

Instructions on the Formation and Improvement of Garden Lawns and Croquet Grounds

Manufacturers of Hot-water Apparatus

FOR

Heating Hothouses, Churches, Mansions, Public Buildings, Harness Rooms, &c.

Our Works being situated within a few miles of Glasgow, we are enabled to forward Materials at the Lowest Rates, by Rail or Water, and to compete, on equal terms, for Contracts, in any part of Great Britain or Ireland.

Having extensive Sawing and Moulding Mills, employing skilled workmen in all branches of the trade, and giving our whole attention to this business, we can execute any orders entrusted to us with economy and despatch, combined with tasteful and substantial workmanship.

OUR WORK MAY BE SEEN AT:—

- Hatfield, Herts.
Haydon Hall, Pinner, Middlesex.
Ashfeld, Edgbaston, Oaklarks, Harborne.
Cardiff Castle, South Wales.
Togerdan, Aberystwith.
Thornton-le-Street, Thirsk, Yorkshire.
Sea-View, Sunderland.
Browtop, Keswick, Cumberland.
Newbottle, Dalkieith.
Castle Kennedy, Stranraer.
Auchmore, Perthshire.
Inverary Castle, Argyleshire.
Ravcliffe Lodge, Glasgow.
"Kibble Crystal Palace," Glasgow.
Duart Castle, Mull.
Powerscourt, Co. Wicklow.
Lismany, Cregelare, and Garbally, Co. Galway.
Asford, Cong, Co. Mayo.
Rathmore, Belfast;
And in most parts of Great Britain and Ireland.

Illustrated Circular Post Free.

As we are overwhelmed with Orders at certain seasons of the year, much disappointment would be prevented by our Friends giving us longer Notice of any Work they intend having done.

JAMES BOYD & SONS, HORTICULTURAL BUILDERS, PAISLEY, N.B.

NEW PLANTS.

MR. WILLIAM BULL

Intimates that the following New Plants are now being sent out:—

CINNAMOMUM SERICEUM.

A branching evergreen greenhouse plant, native of Japan, and having a well-marked individuality of character. The young branches are tetragonal, bearing opposite or sub-opposite obovate-cuneate leaves, which are three-nerved, smooth, and of a glaucous green on the upper surface, whitish and glaucous beneath, from 1½ inch to 2 inches long, and about an inch wide. It is an interesting plant, with something of the aspect of a *Ceanothus*, the leaves having a strong cinnamon flavour. 10s. 6d.

DALECHAMPIA ROEZLIANA ALBA.

A perfectly distinct form of the well-known *Dalechampia*, discovered by M. Koelz, and sent by him to Europe. Like the type, the plant has an upright stem, with little tendency to branching, and rather large obovate-spatulate nearly sessile leaves, which are marked with the markings of the type on their upper surfaces of the involucre are pure white instead of coloured. This will make a very interesting companion plant for the other varieties. 10s. 6d.

DRACENA GEMMA.

One of the smaller-growing forms of *Dracena*, elegant in character, and useful for decorative purposes. The leaves are stalked oblong-lanceolate, acute, recurved, entire, or finely undulated and twisted, the surface partly dark green and partly bronzy-tinted, with a distinct and often broadish edge of rusty crimson. The small size and dwarfish habit, together with the peculiar curvature of the leaves, give to it a very distinctive character. One guinea.

DRACENA RUBELLA.

A fine ornamental-leaved stove plant of the rusty series. It has erect-patent, oblong-lanceolate, sharply acuminate leaves, which are dark green in colour, edged with crimson, the laminae being green beneath, broadest towards the base of the leaf, where the bordering is a quarter of an inch wide, and of a fine rusty crimson line, the midrib and veins being flushed with the same colour. It appears remarkable amongst the red variegated series for its erect and finely pointed leaves. The petioles are 4 to 5 inches long, with a red convergent margin. It has been obtained from the Fiji Islands. One guinea.

GONIOPHLEBIUM GLAUOPHYLLUM.

A very distinct and interesting stove Fern, well suited for basket culture. It has widely creeping rhizomes, which are clothed with scales on the younger portions, and from which spring the simple coriaceous oblong-lanceolate fronds, which are from 6 to 10 inches long, with a stipe of from 2 to 6 inches more. The lower part of the frond is glaucous green on the upper surface, silvery glaucous beneath, and rather conspicuously veined. *Gonio-phlebium glauophyllum* is a West Indian and South American species, which has been imported by Mr. Bull from New Granada. An illustration of this plant was given in the *Gardener's Chronicle* for July 4, 1874. 10s. 6d.

LAPORTEA SCHOMBURGKII VERSICOLOR.

A very remarkable stove plant, obtained from the South Sea Islands, and sent to me from Australia by Dr. Schomburgk. It has thickish stems, which are quite fleshy in the young, and bear large alternate deep green leaves, irregularly mottled with greyish green, and variegated with patches of cream white, which colour is continued along the midrib and the principal side veins. The leaves are elliptic-obovate oblique from being larger on one side of the midrib than on the other, indistinctly three-nerved, slightly rounded at the base, acuminate at the apex, and irregular on the margin, the irregularities being occupied by sharp indentations of the white portions. Sometimes the creamy white marking covers the whole of the leaf surface on one side of the mid-vein. One guinea.

PANAX OBTUSUM.

A neat-habited stove plant, of dwarfish growth, with an erect stem, furnished towards the top with a crown of rather crowded bipinnate leaves, the leaflets of which are roundish oblique, dark green, and furnished at the base with irregular pallid spiny teeth, which are more or less incurved. The terminal leaflets, of which there are two, often take on a singularly one-sided development. It has been introduced from the East Indies. One guinea.

NEW PLANTS.

FOR NAMES, DESCRIPTIONS, AND PRICES OF—

- Acalypha marginata*, *Curmeria Roezlii*,
- Maranta leopardina*, *Croton chrysochlymum*,
- Cyssa Normandiana*, *Demonorop crinitus*.

10s. 6d. per list of last week's *Gardener's Chronicle*.

- Rheum noble*, *Rheum officinale*,
- Rheum palmatum tangulium*,
- Astrocaryum argenteum*, *Astrocaryum flare*,
- Anthurium candidum*, and *Anthurium*.

10s. 6d. per list of last week's *Gardener's Chronicle* for April 17, 1875.

- New Double-flowered Ivy-leaved Pelargonium,
- "Pelargonium Lateripes König Alberti,"
- New Nosegay Pelargonium,
- New Bronze and Gold Pelargonium,
- New Ivy-leaved Pelargonium,

10s. 6d. per list of last week's *Gardener's Chronicle* for April 10, 1875.

- New Fuchsias and Chrysanthemums,
- New Zonal Pelargoniums,
- New Zonal Pelargoniums with Variegated Flowers,

10s. 6d. per list of last week's *Gardener's Chronicle* for April 3, 1875.

MAY FLOWERS.

"March winds, April showers,
Bring forth May flowers"

SAYS the old rhyme, which has its exact equivalent in French, German, and Spanish; and, whether the March winds have anything to do with it or not, there can be no doubt that May is *par excellence* the month of flowers. In seasons like the present, indeed, the beginning of the month may be somewhat less flowery than usual; but when a week or two has elapsed the meadows will become "fields of the cloth of gold" in their thick embroidery of Buttercups; the woods will be carpeted with Bluebells; and the hedges white with Hawthorn, the special flower of the season, which in its very name of "May" is so intimately connected with the month. "Welcome as flowers in May" is one of our prettiest proverbial expressions; and many of our wild flowers bear in their popular titles a reference to the season. Thus the Lily of the Valley (*Convallaria maialis*) not only recalls the month by its Latin specific name, but was formerly called May Lily and May Blossom, just as the Germans now-a-days term it Maiblume. The Marsh Marigold (*Caltha palustris*) is in many places called May-blob or May-flower, which latter name is frequently applied also to the Lady's Smock (*Cardamine pratensis*). *Maianthemum* is a genus which owes its name to the month; the Germans call it *bifolium Maiblume*, as they do also the *Caltha* and the *Hepatica*.

In North America the *Podophyllum* is called May-apple, and the fruit of *Passiflora incarnata* May-hops; while in New England the beautiful little *Epigaea repens* is known as the May-flower. In these columns for May 13, 1871, p. 611, will be found an account of the enthusiasm with which this plant, which is the floral emblem of Nova Scotia, is sought for each year at the beginning of May; and we are reminded in reading it of the old days of England when "going a Maying" was the almost universal occupation of both great and small—when the Eton boys were wont to rise at four o'clock to gather May branches, and when kings and queens—notably Henry VIII. and Queen Catherine—sallied forth with their courtiers to take part in this diversion.

The Hawthorn or Whitethorn (*Crategus Oxyacantha*) has been known as the May-bush since the time of Gerard, and the traditions connecting it with May-day, which, before the adoption of the "new style" was twelve days later than it is at present—are numerous. In Suffolk farmhouses it was customary to give the servant who brought a flowering branch of Hawthorn on May morning, a bowl of cream for breakfast. Scott speaks of the hanging up of Whitethorn gathered on the 1st of May as a protection against witches, and Aubrey mentions a similar custom as occurring in Germany. In some parts of Switzerland it is considered unlucky to bring May-blossoms into the house, and the same superstition obtains in certain parts of England—notably in Essex, as the present writer can testify. Langham tells us in his *Garden of Health* that "the Whitethorne is never stricken with lightning;" and a similar belief is still general in Normandy. It is said by a French writer that tree-worship still retains its hold in a modified form in some parts of France, and that women may be seen praying before a Hawthorn tree.

The abundance of Hawthorn blossoms is said in England to presage a severe winter, just as the Scotch say—

"Mony haws
Mony snaws."

And the French in the Dordogne district—

"Quand le buisson blanc entre en fleurs
Crains toujours queique fraicheurs."

The popular history of the Hawthorn demands indeed a more lengthy notice than the present, but two or three other May-flowers yet remain to be noticed.

The Whitethorn shares its name of "May" with certain other trees. The Lilac is called in Cornwall May-flower, and in Devonshire, May; and the Sycamore-flowers (*Acer Pseudo-Platanus*) are so called in Cornwall—indeed, in that region the natives appear to apply the term in a very wide sense. The following extract from *Once a Week* for 1870 relates to the use of the Elm on May Day:—"At Looe, in south-east Cornwall, every devout worshipper of Flora goes early into the country on May-day morning, plucks a sprig from a 'narrow-leaf' Elm tree, having the leaves well open, and places it on some conspicuous part of his or her dress, that it may be obvious to the world. This is known as 'May,' and will be of great service to the wearer throughout the day. It is perfectly allowable to perform one's devotions by deputy: in other words, whilst it is indispensable that it be worn by every one, it is not necessary that the wearer should have gathered it. Any one may distribute it to whomsoever and to as many as he pleases. All that is insisted on is, that it was without doubt gathered on May-day, and that it is the narrow-leaf Elm. Should it be known to have been gathered the day before, it is indignantly torn from the wearer, and denounced as 'April-May,' whilst the 'broad-leaf' Elm is simply laughed at as 'horses'-May.' To wear April-May is a sham in the way of religion, and a crime; whilst the exhibition of horses'-May is a display of botanical ignorance and a useless blunder. Even the garlands carried through the streets must have on them a sprig of the narrow-leaf Elm." The object in wearing May is as a protection from the attacks of the town boys, who by long-established custom have obtained the right of "dipping" those who do not possess it. This "dipping" is performed with a "dipping-horn"—the point of a bullock's horn sawn off, with the end of a stout stick, about 4 feet long, inserted into the aperture: this was filled with water, and its contents discharged upon the unlucky being who had no "May."

The Auricula seems to have been a popular May-day flower. The refrain of an old Lancashire May song runs—

"And the Baziers are sweet in the morning of May."

Baziers is a corruption of Bear's Ears, the old name for the Auricula, which was similarly called in Latin *Auricula ursi*, and in French *Oreilles d'ours*.

May poles, May songs, and May queens are somewhat beyond our province, but we may just refer to a passage in Hillyard's *Practical Farming and Grazing* in which the phrase "gone a-Maying" is somewhat curiously applied. He says:—"The generality of the crops of Wheat look yellow in the month of May; this is called Maying. If a blade of Wheat be pulled up in April there will be found, at the root, a part of the seed-grain, from which the root is receiving some nourishment. If it is examined in May it will be found that the whole of the seed has been absorbed, and that the root has then the earth only for its nourishment; thus being deprived of its parent support the plant feels its loss for a time, and shows, by the plant looking yellow, that it is not in so vigorous a state as it has been. This is only given as a supposition." This phenomenon was treated

rather more scientifically by Mr. Robert Holland in the *Liverpool Naturalists' Journal* for November, 1867. He there tells us that the Cheshire farmers say of Wheat in this condition that it is "being weaned," and "pining for" or "feeling the loss of its mother." *B. M.*

New Garden Plants.

ODONTOGLOSSUM TETRAPLASIUM, n. sp.*

This appears to be a new type among *Odontoglossa* Iasanthia, only to be compared to *O. Veitchii*, a species lately described (p. 461). The panicle is widely diffuse, and the flowers are equal to those of a very good *O. odoratum*. I guess they were white and blue. It was discovered in Peru by Mr. Davis, and will, no doubt, soon appear in the establishment of Messrs. Veitch. *H. G. Rehb. f.*

STENOSPERMATIUM WALLISII, *Mast., sp. nov.†*

Under the provisional name of *Spathiphyllum Wallisii* Messrs. Veitch have lately exhibited one of the most remarkable and beautiful stove Aroids known to us, and which was introduced from Columbia by Mr. Wallis. It is, we believe, new alike to science and to gardens, and forms a new member of a genus including only three or four species, from Peru, Columbia, and the Amazon district. As a decorative plant (fig. 117) its points are, its Cordyline-like habit, thick rich green leaves, with more especially its slender, whip-like, erect peduncles, bent over at the top, and bearing a nodding spathe of ivory-white colour, like an open shell, and with an oblong spadix, which bears the same relation to the spathe that the clapper does to a bell.

This very beautiful and novel Aroid may be thus more fully described. Stem ascending, 2–3 feet high, terete, glabrous, of the thickness of the thumb, often provided with aerial roots which proceed from the nodes. Leaves crowded, each with a tightly convoluted amplexicaul sheath, with membranous edges and about $\frac{3}{4}$ inches long, surmounted by a petiole of about 1 inch in length, compressed from side to side, and slightly channelled on the upper surface. The blade of the leaf measures about $6\frac{1}{2}$ by $2\frac{1}{2}$ inches, spreads more or less at right angles, is coriaceous, dark shining green above, paler beneath; in form it is obliquely lanceolate, or ovate lanceolate acuminate, with the midrib depressed on the upper surface, prominent beneath, the veins and venules obscure, approximate, arching from the rounded subcordate base of the leaf to the margin. Peduncle slender, erect, somewhat compressed, longer than the leaf, from whose axil it springs, reflexed at the summit. Spathe $4\frac{1}{2}$ by $2\frac{1}{2}$ inches, widely spreading, slightly coriaceous, ivory-white, boat-shaped, acute, ultimately deciduous. Spadix about 2 inches long, nodding, shortly stalked within the spathe and wholly detached from it, cylindrical-oblong, obtuse, densely and wholly covered with hermaphrodite flowers. Perianth absent; stamens 4, filaments flat, ribbon-like, membranous, with a dilated base, connective deltoid; anthers 2-celled, cells widely divergent at the base, and ultimately confluent into a reniform, sub 1-celled anther, opening by a longitudinal chink at the top. Pollen grains whitish, elliptical or sub-spheroid, smooth, large, mixed with prismatic and polyedral crystals. Ovary oblong truncate, 4–6 sided, with a cushion-like stigma in the centre, 2-celled within, at the base (the upper portion of the ovary solid, cellular, and with numerous very large cylindrical cells, tapering at the ends, and sometimes more or less branched). Ovules 4–6 in each cell, anatropal, erect, attached to the base of each cell by means of a long slender funiculus. Fruit, probably baccate (not seen).

The crystals mixed with the pollen-grains, and the peculiar "closter"-like cells in the ovary, are worthy of notice; the latter are, however, not uncommon in other Aroids, as in various species of *Anthurium*. This plant is doubtless fertilised by insects, the large spreading white spathe serving to attract them. The flowers are also protandrous, i.e., the anthers and pollen are mature before the stigma of the same flower, a very common provision for ensuring that the flowers shall not be fertilised by their own pollen, but by that of some other flower. This is a fact that should always be borne in mind by those desirous of obtaining "crosses" by artificial fertilisation. Another point easily seen in this plant, though of course it is

no uncommon occurrence, is the fact that the petiolar portion of the leaflags behind, in its development, both the sheath and the blade.

The details in fig. 116 are:—A, spathe and spadix, natural size, showing the brown stain on former where rubbed by the point of pendulous spadix, and the transparent indentations of spathe caused by the pressure of flowers when in the bud state; B, C, D, top, side, and longitudinal section of flower, enlarged 4 diam.; E, stamen, enlarged 8 diam.; F, pollen, enlarged 160 diam.; G, the cellular tissue, long vessels, and two varieties of raphides found in walls of ovary and elsewhere, enlarged 40 diam. *M. T. M.*

SALLET.

Few branches of kitchen gardening have more curiosities, in proportion to their importance, belonging to them than salads. Their antiquity partly accounts for this. Of all food, uncooked vegetables are the simplest and the most primitive; for whenever carnivorous or piscivorous may have been the tastes of pre-historic man, necessarily, we may believe, would occasionally drive him to a diet of green leaves and

(Menage derives the word from the Latin, *salata*, or *sal*, salt; others from *salco*). Du Cange from *salgama*, which is used in Ausonius and Columella in the same sense; some add mustard, hard eggs, and sugar; others, pepper and other spices, with Orange peel, saffron, &c. Some define *sallet* more generally as a composition of plants and roots of several kinds, to be eaten either raw or green, blanched or candied, by themselves or mixed with others, and even occasionally boiled, pickled, or otherwise prepared and disguised, to render them more grateful to the palate. But this definition includes potherbs, &c., which the generality of authors deny to be any proper *salleting*.

The principal salad herbs, and those which ordinarily make the basis of our English *sallets*, are Lettuce, Celery, Endive, Cresses, Radish, and Rape, &c.; along with which, by way of furniture or additions, are Purslane, Spinach, Sorrel, Tarragon, Burnet, Corn-sallet, and Chervil.

The different tastes of mankind will not allow any certain mixture of these to be prescribed as most agreeable; but still, in mixing them, the relish of the several herbs is to be considered—those, for instance,

FIG. 116.—SPATHE AND STRUCTURAL DETAILS OF *STENOSPERMATIUM WALLISII*.

uncooked roots, which he would strive to render as palatable as possible by the teachings of traditional or hereditary experience. In pictures of pastoral entertainments, they naturally form part of the bill of fare. Milton must have meant salad at the repast

"Where Corydon and Thyrsis met,
Ate at their sav'ry dainties set
Of herbs and other country messes,
Which the neat-handed Phyllis dresses."

Hermits, too, have been supposed to live on

"Cresses from the brook and water from the spring;"

the date, however, of those vegetarian habits is conveniently vague. To approach a more determinate epoch, Evelyn's *Acetaria*, or *Discourse of Sallets*, should be known to most of our readers, at least by repute. A more restricted number would be cognisant of the account of salad given by Dennis de Coelogon, in his *Universal History of Arts and Sciences* (1745), which we therefore give for their enlightenment, as the salad season is fast approaching. Here, singularly enough, gardening or horticulture is treated of only as a branch of agriculture.

Sallet, or salad, is a dish of stable herbs ordinarily accompanying roast meat, composed chiefly of crude fresh herbage, seasoned with salt, oil, and vinegar

which are most hot and biting, as Cresses, Mustard, Celery, Tarragon, Chervil, &c., with those that are more cool and insipid to the taste, as Turnips, Rape, Spinach, Lettuce, Corn-sallet, Purslane, &c. By this means the herbs may be so judiciously mixed that the too strong taste of one kind may not overpower all the rest, and the insipid kinds be directly used to moderate and qualify the heat and pungency of the others, as the season of the year is more hot or cold, so as every *sallet* may not only be agreeable to the taste, but also physic to the body.

The gardeners call small herbs in *sallets* those which should always be cut whilst in the seed-leaf, as Cresses, Mustard, Radish, Turnip, Spinach, and Lettuce; all which are raised from seeds sown in drills or lines, from the middle of February to the end of March, under glasses or frames, and thence to the middle of May, upon natural beds warmly exposed, and during the summer heats in more shady places; and afterwards, in September, &c., as in March, &c., and lastly in the rigour of the winter in hotbeds. If they chance to be frozen in very frosty weather putting them in spring water two hours ere they be used recovers them.

In gathering small herbs, the best way is to pull them up by the roots from the hotbed. If the roots be left, and a second crop of *salleting* sown on the same bed, it will not prosper. In sowing second crops it is to be observed that seeds of the same kind

* *Odontoglossum tetraplasium*, Rehb. f.—Panícula ampla diffusa; multiflora, ramis primariis validis; bracteis spatheae oblongis acutis; ovaria pollicellata; cinctis ovumibus; sepalis tepalibus linearibus acuminatis, crispis, basi cuneatis; labelli carinis basilariibus oblongis acutis serratis; carinulis interjectis geminis, carina mediana prolescente distans labellum versus; falcatulis geminis strioque superstitibus; lamina oblonga acuta undulata velutina; columna clavata, lamella tertium non eguanza.
† *Stenospermium* *Wallisii*, Schott, Prod. Syst. Aroid. (1869), p. 236.
* *Wallisii*, *Mast.*, sp. nov.—Caudice assurgente ad nodos radices emittente; foliis approximatis basi vaginantiibus, oblique ovato-lanceolatis; pedunculis folio sulfutissime longioribus gracilibus; erectis apertis; spathe ovato-oblonga, membranacea, albidis albidis.—*Spathiphyllum Wallisii*, Hort. Veitch.—Columbia, Wallis.

be not sown in the same place; but the ground is to be eased by varying its burden, putting hot seeds where cold ones grew before, &c. Another rule is, that no plant be placed in the same spot where the same kinds have grown before.

Winter sallats are greatly improved by blanched Celery, which is a hot herb of a very rich flavour, raised from seed sown in March and April, in a well-exposed place, and transplanted six weeks after its first appearance into beds, where it remains till the middle of June, and then planted in trenches, 8 or 10 inches wide and as many deep, first pruning off the tops and roots. As they grow large they are to be earthed up, within 4 or 5 inches of the top, which is repeated several times, till they be fit for use. Endive blanching is much used in winter sallats, though it have neither taste nor flavour; it is cultivated much after the manner of Celery. Of Lettuce there are various kinds, the best are the Roman, Dutch Brown, Imperial, and Silesia kinds, all which cabbage well.

wanting; it is a cordial herb, though not the most agreeably tasted, yet a few leaves, or three or four of the tender tops, give the sallat a good relish; it is propagated from slips, taken from the root, and planted in March. Note, in the spring, Dandelion, blunched, which is gathered in almost every ploughed field, makes an excellent sallat, mixed with other herbs. Some, likewise, gather Violet flowers, Cowslips, and blossoms of Burrage, as part of the sallat furniture: others, Fennel and Parsley.

Dressing of Sallats.—The Celery and Endive are to have their hollow green stem or stalk stripped of all its outside leaves, and sliced in the blunched part, cutting the root into four parts. The other ingredient herbs, being exquisitely culled and cleansed of all faulty leaves, &c., are washed rather by sprinkling than sobbing them in spring water, laid to drain off all superfluous moisture, then shook and squeezed together gently in a coarse cloth, to dispose them to receive the seasonings, viz., the salt, vinegar, oil, &c.

PEACHES AND NECTARINES.

I FEAR we are very ignorant of arboriculture, of the theory of vegetation, and of the phenomena of plant life. We do not study and observe. To see a thing is not necessarily to observe it. "Observation" is intellectual sight. Locke has truly said, "We know a little, suspect more, and jump to a conclusion." People should not only observe but "read, mark, learn, and inwardly digest."

Peaches and Nectarines are my special hobbies, and I have studied them since 1852. I have now twenty of them under glass, and 124 outside of it. They are in fine condition; and though they are so exposed, there is not a single blistered leaf on the trees. Sir W. Marriott and Mr. Mansel Pleydell called on Friday, April 23, and I pointed this out. I have not disbudbed the trees at all. Probably this

FIG. 117.—STENOSPERMATIUM WALLISII.

They are commonly sown with other crops in March for summer sallats, and in August to be transplanted, or September to stand the winter, either to be cut for winter sallats or to cabbage early next spring for seed.

For the additional, or secondary sallat herbs, Burnet is a cool perennial herb, whose tender leaves, mixed with other herbs in the winter, give the agreeable flavour of a Cucumber. It is propagated by seed, sown in March. Corn sallat, raised at the same time and in the same manner, makes a good winter sallat furniture. Purslane, an insipid yet cooling herb, is admired by some in winter sallats; it is raised by seeds, sown in March, in a warm place. Sorrel is chiefly used in the spring, when the young leaves are very agreeable; it is raised from seeds, sown in March, usually in drills or rows. Spinach is a necessary ingredient in raw sallats, to be cut in a young state; but it is better for boiled sallats in the winter or spring; it is sown in March, April, or May, and again in August, in a place well exposed to the sun, that the leaves may be large enough for boiling in winter. Tarraron, of all others, should never be

The oil not to be yellow or high coloured, but of a pale olive-green, without either taste or smell; the vinegar perfectly clear, neither sour nor pallid; the salt to be the best ordinary bay salt, clean, bright, and dry. Some, indeed, recommend the essential salts and spirits of vegetables, or those of the alcalizate and fixed kind, extracted from the calcination of Balm, Rosemary, Wormwood, &c., and affirm that, without eating the gross sallat herbs themselves, we might have healing, cooling, generous, sallats wholly out of the salt-cellar.

Note, in the proportion of salt, pepper, and vinegar, regard is to be had to the season, constitution, &c.; the two first being best for cold, the second for hot stomachs and seasons. For a moderate sallat vehicle, to three parts of oil put one of vinegar, or lemon, or orange juice, and in the mixture steep slices of Horse-radish, with a little salt; occasionally add a little Guinea pepper and mustard, with the yolks of two eggs boiled, squeezed, and bruised into a mash therein; pour the whole on the herbs, stirring and mingling them till they be thoroughly imbibed. *E. S. D.]*

would not be seen in any garden in England. I think, therefore, a few observations, only as far as my experience goes, may be acceptable. I never write what I have not experienced. I look to the trees all the year round. It is impossible for a gentleman's gardener to do the same. He has generally too many things on his hands, too few labourers, and too few pumps: the great deficiency in our English gardens is water-power. One word on the management of the trees. The trees should be kept as far as possible equally balanced. The prosperity of the trees depends in a great measure on the equalisation of the sap throughout all the branches. This would probably be the case if the trees were left to themselves. The rush of sap is to the upright upper branches, next to the upper horizontal branches, so that the lower branches get less sap and move more languidly than those at the summit. If a tree is unbalanced by being strong on one side and weak on the other, the strong side only should be cropped and the weak side should be totally fruited; in this case the strong branches should be inclined, without twisting the branch, for that would cause gum, and the weak

side branches elevated and allowed to have all their leaves, which will draw the sap, and as many of the leaves on the strong side as could be spared should be taken off or cut in half. Over-fertilisation produces non-fruitification. Small well-ripened wood about the size of a slate-pencil is the wood that bears fruit. The slower the circulation of the sap the smaller and riper the wood will be, and greater will be the prospect of fruit, as the wood will be smaller and the fruit-buds more numerous. After a frosty night be careful not to remove the shading suddenly; if the sun comes out powerfully it will wither the blossoms before they have time to "set." In choosing Peach and Nectarine trees see that they are good at the point of union between the scion and the stock. This is most important, for if the trees are bad there they never can be good. Short pruning out-of-doors is more likely to produce good crops than long pruning, for they depend greatly on the ripening of the wood; and if you cannot ripen shoots 4 or 6 inches long, how can you ripen shoots 16 or 24 inches long? I am a short pruner for that reason. I disbud but little, and pinch the shoots mainly to two, four, or six, full-sized leaves; consequently I have many trees out-of-doors and under glass supplied almost wholly with *bouquets de Mai*. I have one Royal George under glass, well fruited all over, upon *bouquets de Mai*. How pretty such trees look when in flower.

Insects are now very busy, and should be looked after. Methylated spirit is the best remedy for scale. Dip a feather into it and touch them with the spirit: it kills them instantly. Mr. Rivers told me of it.

Syringing the trees for aphid. Stand sideways (not in front and syringe the first way and then the other. If the edges of the leaves do not least pull them off, squeeze, and burn them; syringing will not get them out of the curled leaves. Open the leaves and you will see a colony.

Disbudding.—I disbud but little, and never till the leaves are fully expanded. I can then select, taking off isolated leaves, if there are any. The bloated leaves are the effect of evaporation, cold, cutting winds, and heat. Trees should be supplied with water, which will enable them to keep up a supply of moisture equal to the evaporation.

Leaves and Skin are the first and second lungs, and the fruit must be kept clean. If the foliage is bad or scathed, the fruit will not be good. There must be a leaf collar with the fruit or beyond, or the fruit will be flavourless.

Over-cropping and Over-wooding.—Neither of these should be done. Three fruits in a square foot on a strong tree is as much as it should have. Freshly planted or weak trees should not have more than one fruit in the same space. Probably it would be best to let them have much less. If a sort is good, the bigger the fruit is, the better is the quality and flavour. You had better have one large Peach than two small ones. In this case you may only one stone, and in the latter two. Over-cropping esters flavour, and is injurious to the next year's prospect, because the rush of sap is to the fruit, and the tree cannot form bearing wood for the next season. Disfruit the trees at several times, and also disbud them at several times.

Gum.—This is the worst form of disease of all. It is occasioned by tight ligatures, by straining the branches, and by curbing the shoots all over the tree at one time. Disbud and stop the shoots at several times, or you will disturb the economy of the tree too violently and produce gum. If gum oozes out scrape it off and score the rind with your knife—an "empy house is better than a bad tenant."

Canker.—This is usually attributed to the soil here; but it is a disease externally caused by violations of the skin and rind, the roots have nothing to do with it. The Ribston Pippin and Moorpark Apricot are much given to it. Generally, but not always, it takes place at the knots. I imagine the rains lodge there, and the frost bites sharp where there is most moisture.

Nails and Nails.—I use matting, and not shreds, with cast-iron nails. There is, therefore, no occasion for drawing the nails, which leave holes for termite. Give the matting a twist, so as not to let the twig touch the nail, and be sure not to tie too tightly or the shoot above the tie will die, and gum will ooze out beneath. Cast-iron nails are only 6s. per 4 cwt. When they are in the way a slight tap with the hammer will break them off and leave the holes stopped up. I usually leave them in their places and simply cut off the matting. Just imagine the havoc gnawing pruners with shreds and nails must make in a wall!

Pointing Walls.—I have just had mine done, and it cost me a great sum, but the winter made it necessary. I used with the mortar Portland cement and blacksmith's ashes, and the work is famous. Our Dorset lime is not strong enough; it is the best lime is the Bridgewater lime. The winter has, indeed, been severe, but now we have passed the rubicon—

"For now the sullen winter's past,
No more we fear the northern blast;
Hark! The birds melodious sing,
And sweetly usher in the spring."

W. F. Radcliffe, Oxford-Fitzpaine, April 26.

A PLEA FOR MOSSES.—II.

The drying winds of March have told on those mosses that grow on trees, walls, or among grass, but our own in the glass dishes look as fresh as ever, and in damp woods and on moors they are still very beautiful. Many species are now in fruit, which renders the distinguishing of them much easier, and as it is always more satisfactory to note from plants growing in their natural positions, I shall try to describe those collected during the last week of March.

Bartramia pomiformis is lovely now, completely dotted over with its bright green erect Apples, and forms a great contrast at present to the other dried-up mosses on the stone dykes, but I observed its tufts were generally close up to the top of the retaining wall, thus getting shade and shelter from the over-hanging dead grasses.

Bryum capillaris (greater Bristle-moss) is also beautiful, often nodding fruit; the capsules are very transparent, and set on reddish orange setae—all the fresher when growing among the two little wall Ferns, *Asplenium Ruta-muraria* and *A. Trichomanes*. A 5-inch saucer with this pair of common mosses in, is at present a most "dainty dish" of fruit.

Little curled up dark green tufts of *Orthotrichum crispum* (curled Bristle-moss) with its minute terminal capsules, catch the eye on trunks of trees; it is a very distinct moss—the tufts are usually about the size of a halfpenny. On a stone wall, among the bright orange patches of that commonest lichen, *Parmelia parietina*, was the minute *Grimmia Doniana* (Donian Grimmia), the whole plant of which does not exceed an eighth of an inch in height, and is of a dark brown ticked with gold capsules; *G. pulvinata* looks quite a large moss beside it, with its pale yellow seed-vessels safely buried among its leaves (far would be a fitter word to use, and very like mice are the great curls of this moss!) Walking down a burn close to the stream, are nearly dry one commands both moss-covered banks and the hollow under the roots of trees, where one is sure to find finer specimens of the beautiful *Bryum ligulatum* than those got in January. It might pass for the favourite Killarney Fern, *Trichomanes*, or some exotic filmy Fern.

On the stones which water should cover are both the large and small *Fontinalis*; *F. minor* (Light-foot) has its capsules "growing out of the ends of the lateral branches, which is the most material distinction" between the two. It grows three or four inches long, while *F. antipyretica* (great Water-moss) is in waving dark masses of 8 or 10 inches. *Hypnum dendroides* (tree-like Feather-moss) is a great beauty; growing among the grass and rushes it catches the eye at once by its thick top of rich velvety green standing upright on bare stems, tree-like—it seldom stands in fruit; and in complex contrast to this is the common *H. undulatum* (waved Feather-moss), distinct in its young and full grown state, when the flattened and almost white branches are seen trailing down a damp bank. I did not find it in fruit; it reminded me almost of a *Lycopodium*. In fine fruit on trees and walls was *H. rutabulum* (common rough-stalked Feather-moss); the little bright brown capsules thickly dotted on the large masses of this most common do not give the moss a very attractive, and common also is *H. praelongum* (very long Feather-moss), not in fruit, but, as I found it, distinct from its very fine, almost hairy appearance, and light green, though it is a variable species. One great stumbling-block to the beginner is the very different situations the same moss will be found growing in, and of course its character altered accordingly. On the wet moor just now *Polytrichum commune* is the most attractive plant; 6 inches high the ends of its stalks terminated with a kind of "rosaceous cup" of a bright red colour, and on a dry bank is the same "common Hair-moss," too short to be plucked by the fingers, and requiring to be poked out with the point of the knife; true, its bright red cup and well known capsule are the same. "This cup is looked upon by Linnaeus as the female flower of this moss, but Haller is of opinion that it is only the term or origin of a new stalk, which frequently rises from the centre," and which again becomes sometimes profligate; and this is the opinion of botanists of the present time.

Then again, in a young state mosses, like Ferns, give little indication of which species they are, and treasures turn out the most common *Hypnum* or *Bryum*, or perhaps no moss at all, merely *Conferva*, like the pale green mould one finds soil anywhere, every-where. A lens, possibly, would prove the fact of a seedling moss, but I am sure, for amateurs, learning first without such aid is best; it will be many a year before they exhaust what should be known and seen by the naked eye. Linnaeus, we read, to the last seldom used a microscope; possibly this was a little weakness or boast of the great botanist, but there is no doubt the less paraphernalia the young student begins with the better. The want of this and that as

excuses for ignorance are far oftener cloaks for laziness and want of application, and we amateurs will learn more by teaching our own eyes to observe and see than we shall from erratic poking through with a lens.

The ground in an open wood, principally of Fir trees, is covered with large clumps of the dark green velvet *Bryum borum* (Swan-neck Thyme—Thread-moss), attractive in its young state, fitting tight to the soil, and when the handsome pendulous capsule is, as at present, in perfection, the fruit-stalk, though tall, is so slender that the eye catches the bright green seed-vessel and misses the setae. *Polytrichum juniperinum* (Juniper-leaved Hair-moss) likes the damp wood also, and is distinct with its arrow-head-shaped capsule standing erect. No bright-coloured gemme did I find on this *Polytrichum*. Close by on the sides of the wide open drains were patches of *Hepatica*. No greenhouse pots can be kept free from the Hepatic moss—*Marchantia polymorpha*—a real pest, which forms a tight green cake on the surface of the soil, most detrimental to the legitimate plant in the pot; and *M. conica* is of darker green, and larger patches—a most peculiar-looking plant. Tall transparent foot-stalks (some I measured were above 3 inches long) rising from the flat leaf-like surfaces, some with a black bead-like head (nothing so like them as the horns and eyes, commonly so called, of snails), and others burst with a yellowish four-sided open sort of flower—hardly possible to lift the patches without breaking the pale, clear foot-stalks, so very short-lived are they when taken home. Although not mosses, it was impossible not to be attracted by these *Liverworts*, now spreading out my booty on a felled Birch so as to select the best specimens, could I resist collecting the various lichens on that single trunk—tight-fitting circles of *Pertusaria communis*, light round the edge, of darker grey in the centre; *Parmelia olivacea*, greenish in colour, growing the same way, and both requiring a slice of the bark to come off with them; large fizzly tufts of *Usnea barbata* (Tree Hair), and of *Ramalina farinacea*, with flat fronds like stag's horns; *Cladonia deformis*, a mealy white horns growing among the others, all so utterly common that thinking of a damp climate and ill-drained land at once brings before one these particular greylichens. On an Oak stump were layers upon layers of *Polyporus versicolor* (Cock of the Woods), a very common woody fungus—according to age shaded in half circles of many colours, from pale lilacs, greys, fawns, browns, to almost black; and growing close to it were tufts of the black and grey horned *Hyopoxylon vulgare* (Candlewicks, as they are commonly called). After Mr. Smith's "confession," p. 398, funguses are not likely to be studied by the many; still they will come up among mosses to attract one's attention and interest as well as the lichens; and while passing among trees it is impossible not to know the escape from the green dust of that invisible fungus, *Chlorococcium*—that silent wight with gleebing, bird-nesting, fruit-stealing boys. *F. F. Hope, Wardle Lodge, April.*

THE CLEMATIS AS AN EXHIBITION PLANT.

THAT the modern varieties of Clematis admit of being grown into specimens will be readily admitted by those who saw the plants exhibited by Messrs. G. Jackman & Sons, of Woking, at South Kensington last year, or who witness the exhibition which opens to-day in the Regent's Park. Those, indeed, who avail themselves of this latter opportunity of seeing the first Clematis exhibition of any importance which has yet been held in public, will meet with a floral treat of which they can probably form no conception. If, however, the imagination can paint the effect which will be yielded throughout the month of May by upwards of 400 well-grown plants, in splendid condition as to health and vigour, and bearing a crop of over 20,000 flowers, then some idea may be formed of the display which is provided by the Messrs. Jackman in the gardens of the Royal Botanic Society.

To Mr. G. Jackman must certainly be accorded the credit, not only of first directing attention to these plants by raising C. Jackmanni, but also of showing the public how the Clematis ought to be grown in order to take position as an exhibition plant. His first essays were made with the late summer-flowering varieties, which required a totally different treatment to that accorded to those now about to be exhibited; in the former the cultivation proved to be a kind of struggle against the weakening influence of pot or tub culture upon plants which naturally strike their roots deep into the open soil, and ramble far and wide, blossoming as they go. To get plants of this habit to furnish with vigorous blossoms the necessarily ample space over which they had to be trained was a feat requiring considerable knowledge of the wants and habits of the plants, and was thoroughly

well accomplished, as the displays at the London and provincial shows of the last few years have borne full testimony. Last year Mr. Jackman sought for new laurels in another field, and won an easy victory, as many of the plants then shown at the Crystal Palace, at South Kensington, and at the Regent's Park, furnished sufficient evidence. This year the exhibition, being arranged for the month of May, will naturally consist mainly of the spring-flowering and early summer-flowering varieties, but to these, for the sake of the contrast of colour they afford, will be added a selection of the late kinds brought forward by forcing.

the occasion of the visit of His Imperial Majesty the Emperor of Russia, with the Duchess of Edinburgh and suite.

The plants were placed in what is called the Queen's Corridor, right and left of the principal staircase leading to the Royal box, and one of these, leading to the Imperial banquetting-room, in which the specimens of Clematis were shown intermixed with other plants, is represented in fig. 119. Of the plants themselves we need only say that their massive star-shaped blossoms of various hue were most effective in this combination, and elicited marked admiration from the Imperial party. The other and smaller

features of the floral decorations. This is sufficiently well shown in the illustration.

No one who cares for the Clematis, should fail to see this grand exhibition, upon which no small amount of skill and trouble have been expended by Mr. Jackman and his very efficient staff. It will, as we have already said, remain open nearly throughout the month of May—from May 1 to May 25—and in its successive stages will be well worth visiting as often as opportunity may permit, on account of the succession of varieties which will be brought forward as they come into blossom.

FIG. 118.—STAIRCASE LEADING TO THE ROYAL BOX, CRYSTAL PALACE, DECORATED WITH CLEMATIS.

With what success the plants have been treated will be apparent when we state that the larger specimens, which form considerably over half the number of those prepared for the show, cover a balloon-shaped wire trellis, measuring about 2 feet high, and nearly as much across, and that these carry flower-buds which average fully seventy per plant, and which in a large proportion of the plants mount up to upwards of 100 flowers each. Some of the later kinds indeed run up to 140 or 150 blossom-buds. One of these plants fully blown will therefore be, of itself, quite an exhibition.

We are able to give some idea of the effect produced by the Clematis when grown as an exhibition plant, by means of two engravings (figs. 118, 119) from photographs taken at the Crystal Palace last year, on

sketch (fig. 118) shows two of the plants which were honoured with a prominent position in the decoration of the staircase above referred to—a point which proved to be very difficult to set off to advantage, but which the happy thought of draping with the bold flowers of the Clematis, hit off exactly; the selected plants had flowers of a pure white and deep mauve colour respectively, and the admixture of these two colours proved exceedingly telling. Our figure represents these plants, after they had been taken off the trellis on which they had been grown, and had been trained around a thick iron column, which is one of the mainstays of the structure at this point, and which when covered with the blossoms of the Clematis in the manner indicated, instead of being an eyesore, was converted into one of the most attractive

Home Correspondence.

The Lambton Castle Vines.—The paper on Vine growing by Mr. Hunter in the *Gardener's Chronicle* at p. 499 is most interesting. Whatever a man writes on the culture of a fruit which he has brought to greater perfection than any man has ever done before, not only deserves but demands attention. The only question of interest to me is, To what part of his treatment is his great success owing? We cannot suppose the situation favourable, at any rate. Land of such a nature that it was necessary to build vineries on piles, is hardly the situation one would choose for a garden. Then, again, though in such a place a hard and impenetrable surface on which to lay a Vine border

might be and probably was a necessity—and granting the necessity, we see the arrangements for drainage were all that could be desired—still few would attribute Mr. Hunter's success to concrete under his Vine border. Many of us would say that though such an arrangement may be necessary in many places, yet it is always to be regretted. An impenetrable subsoil is a thing no one covets when farming, and a substratum made artificially so impervious as to cut off all capillary attraction is not what one would choose as the foundation of a Vine border. Then, again, the soil or rather compost prepared for Mr. Hunter's Vines differs little from what is generally recommended. Situation, soil, climate—there is nothing in any of these to prepare us for expecting bunches of Black Hamburg Grapes more than usual in weight. To what, then, must we attribute his astounding success? Is it to the fact that he every year disturbs his Vine border with steel fork? I should say his success is a proof how carefully the operation of forking has been performed and how good-natured a plant the Vine is, but I for one cannot look upon this practice as being good in itself. We know that old Vines are greatly benefited, when from improper management their roots have all left the surface of a Vine border, if the soil destitute of roots is carefully forked, and fresh turfy soil placed over the roots to a moderate depth. We also know that Vines may be carefully transplanted into a fresh border and receive little check the first season, and with advantage in future years; but that an annual disturbance of the roots of a Vine would be beneficial is what we should be hardly prepared to expect. If such treatment proves to be beneficial, then we may be glad that Mr. Hunter's groundless fear of wireworm has led him to the discovery—for I am quite sure his fear was groundless. Growing, as 10,000 thousands of pot Vines in fresh green turf, just cut from the field (full of wireworms, as a matter of course), either my men or myself must have seen a root injured by wireworm before this; but neither have we seen roots of Vines injured, or indeed, the roots of any tree or shrub, though every gardener knows how injurious those insects are to many plants and vegetables. Mr. Hunter may rest assured the wireworms were feeding on the roots of grasses in his turf soil, though they preferred his manure, which would have been glad of a sweet Apple, a piece of Carrot, or a Potato. Had they any taste for his Vine roots his Vines would have stood a poor chance indeed. According to my ideas we still have to look for the cause of Mr. Hunter's success; and I should be inclined to think it was chiefly attributable to ventilation and abundant supplies of water and manure-water. The more artificial the culture is the greater necessity there is for close attention; and we all know what a mess some people make of Vine culture in pots, or in heated borders, or planted altogether inside houses, or on beds of concrete. In such cases the requirements of a Vine must be furnished by the cultivator, as little is left to Nature. Mr. Hunter's paper shows his heart is in his Vine culture; the careful ventilation—the record of temperature taken four times a day—proves this. The strong points of his culture seem to me ventilation and watering. Strong, healthy foliage made under the influence of fresh air and a growing temperature would have a very different appearance, and would feel to the touch very different to foliage produced in an atmosphere more fitted for Ferns than Vines. Then, again, he must have the command of plenty of water and the means of readily warming it, seeing that he can put on 5000 gallons of water at a time in a tepid state. When we remember the ample drainage provided below his border, and that fully one-third of the materials of his compost was lime scraps, charcoal, and burnt clay, it is quite clear he could hardly give too much water; and nothing is more certain than that Vines generally get too little. Again, strong, healthy foliage, on which air plays freely, in a warm atmosphere, must take up and give off an enormous quantity of moisture; and when this water has passed through rich soil, or has been charged with manure, it must leave much behind in the wood and foliage of the Vines. With the results are so astonishing we must all be anxious to know to what they are due. There can have been no bad practice; the thing to know is, what there was so much better than that of acknowledged good cultivators as to produce Grapes twice as large as most of the best growers can show us, with all their skill. There are several points not very clear in Mr. Hunter's paper. He says, "At getting a cement and brick bottom to my satisfaction, and a 4 feet in height." I should suppose he means 4 feet from the surface; if so, what depth of soil is there in the border, and on what principle has he made 4 feet of it below the surface? He can hardly mean he has provided a mass of concrete 4 feet thick. Then, again, the size of the house is not given, or the size of border to which the water was applied. Again, what were we to understand by "a small house of Vines planted, void of natural soil, except a small quantity which was used to surround the newly-planted Vines," &c.? The compost used on a large scale by Mr. Hunter can hardly be

called a natural soil; what are these growing in? If also the nature of the soil from which the turf was procured had been stated, it would have been more satisfactory. It surely must have been a very heavy soil to bear one cartload of lime scraps, one of charcoal, and one of burnt clay, besides manure and bones, to only six cartloads of turf. *J. R. Pearson, Chilwell.*

—Mr. Hunter, of Lambton Castle Gardens, has once or twice drawn attention to the light rainfall in his neighbourhood, in connection with his successful Grape growing (see p. 499); but it is perfectly clear, in his case, that the rainfall may mean anything or nothing. Whether the water falls from the sky or from a watering-pot is of no consequence. The question is, How many inches of water did his Vine borders receive from all sources during the season? It is stated that 14,280 gallons have been given to one vine by the watering-pot, from March till July; but as neither the length nor the breadth of this border is given, these figures give no exact information. Perhaps Mr. Hunter will kindly supply this omission, and then your readers can judge for themselves. *Enquirer.*

Doronicum caucasicum for Ribbon Borders.—This plant helps to form one of the most effective ribbon borders imaginable. We have used it for that purpose for years, as well as for bedding, &c. At this time we have a walk 100 yards in length, with a ribbon border on each side, both being filled alike, and as follows:—The back row *Doronicum*, then a double row of *Anemone coronaria*, next a line of variegated Arabis followed by one of *Verbena* purple, and a bed of Golden Pimpernel about 3 inches wide next the Box, &c. I have not seen anything to surpass the above arrangement. *J. Grey, Nymanton, Stamford.*

The True Double English Daffodil.—I am afraid that Mr. Shirley Hibberd's definition of this plant at p. 535 will be rather apt to mislead, and, judging from his remarks, I cannot help thinking that he had doubted the accuracy of Mr. Worthington Smith's careful engraving at p. 500, which represents a phase of the true double-flowered English Daffodil correctly. Mr. Hibberd at p. 535 says:—"The distinctive character of this form is that the tube or crown is intact, the doubling taking place within it." But, unfortunately, this definition is insufficient, inasmuch as the corona frequently bursts open or is slit into irregular segments, and then the result is a Rose-shaped flower. On the other hand, the common double Spanish Daffodil frequently has the duplicate segments confined inside the corona, just as shown in Mr. Smith's figure, but then the flower is much deeper coloured and larger. The difference between the true double English Daffodil and the common double of gardens, fields, and orchards is very apparent when both are seen together, but the main distinctions of size and colour are difficult to define by descriptions. The true double English Daffodil is little more than half the size of the common double, the perianth segments being pale sulphur, and the coronal segments clear chrome-yellow. In the common Spanish double, on the other hand, the perianth segments are chrome-yellow, greenish behind, while the coronal segments are of a deep orange-yellow. When Mr. Barr rediscovered the true double English Daffodil last spring (1874), he kindly brought me two flowers to sketch. One of these flowers was rose-shaped, and composed of sulphur-tinted perianth segments, amongst which were distinguished the deeper yellow coronal divisions. The other form had the corona intact, the duplication of coronal and perianth segments being confined within its radius, and six of the perianth segments were quite normal and in their proper position. It is curious to note that the duplication of the true double English Daffodil in Mr. Barr's collection this year is confined to coronal segments only, as shown in Mr. Smith's engraving; but last year they had duplicate perianth segments also developed. I believe Mr. Hibberd is quite right when he refers to some of the monstrous many-centred flowers of *N. Pseudo-Narcissus* var. *grandi-plenus* as being in reality fused or coherent umbels on normal scapes, and I can quite understand that in some of the more plethoric flowers there are traces not only of duplicated foliage, but also of incipient bulbs. This state of things, however, is confined to the *grandi-plenus* form of *N. Pseudo-Narcissus* var. *grandi-plenus* form of *N. (Phillygne)* odorus, which also occasionally produces flowers having two or three centres, but then it is conjunctive with the metamorphosis of stamens into coronal segments, and often a multiplication of the perianth divisions. This extreme subumbellate state of duplication is shown in the true double English Daffodil, or, if so, I have never seen examples. Double *Fuchsias* are very different to double *Daffodils*, for in the majority of cases they have eight stamens, and the style quite normal, and often bear perfect seed as freely as the single kinds; indeed, if my memory serves me rightly, I believe one old purple-flowered variety, named Sir Colin Campbell, having duplicate

petals, fruits very profusely. This I believe is never the case with double *Daffodils*, and some of the single coloured species never fruit naturally, and can rarely be made to do so by artificial means. It must not be forgotten that both the plants here alluded to are but double-flowered varieties of *N. Pseudo-Narcissus*, not separate species; so no one need feel surprised if they are found to slide into each other eventually, just as is now the case with the single forms, from which they have in all probability originated. *F. W. B.*

Hardy Varieties of Broccoli.—In the midland counties Broccoli in general has been severely tested this winter, and some varieties have succumbed to the severe frost in the last week in December. Osborne's Winter White was the tenderest with me, being nearly all killed, but in the same plot Snow's Winter and Blackhouse's Early, with Dilcock's Bride, have stood well; but their coming in has been very irregular and much later than usual. In December had all their heads laid down to the north close to the ground, and a wisp of dry hay put on the head of every plant. This was done before the severe frost occurred, on the last days in December, and it saved them from being much injured. Where dry Fern fronds can be procured, these are still better than hay, as they are not so liable to be blown about by high winds. A nice break of *W. Excelsior*, the Leamington, and Cooling's Matchless Broccoli was done in the same way, and they are now coming in and showing nice white heads, but not so large as last year, and at least two weeks later. All the above varieties are excellent, and may be reckoned on as quite hardy, where a little attention is paid to preserve them in severe winters. The later sorts of Broccoli, such as Carter's Champion and Cattel's Eclipse, have not been laid down nor covered in any way here, and they have stood the winter quite unimpaired, and will produce a good supply in May and June. Kenne's Winter White and Lander's Late White Goshen are likewise two very late and hardy Broccoli as grown here this year. *William Tillery.*

The Prince of Wales Plum.—I believe the chief cause of the frequent losses of Prince of Wales Plum trees arises from their having been grafted on an improper stock. The stock alluded to is the common Plum, which I think is the scarcest of all Plum stocks, and perhaps the most difficult to propagate. Consequently the Mussel, Brussels, or Brompton are used, and these are obtained from suckers taken from old-established trees, and may be of mixed kinds and quite unsuited to the longevity of the Prince of Wales Plum, although it grows more vigorously upon these than on the common Plum. I am inclined to think the very fact of the robust growth tends to shorten its life. The Mussel stock is the least injurious of these improper stocks, but the only safe stock is the true common Plum. I cannot reconcile to my mind any of the causes assigned for its failure in the several letters that have appeared in your columns. Mr. Bréhat's plan for covering the trees with paper is simply ridiculous, when the great extent of land covered by this favourite Plum is considered. It would be an impossibility, and I believe it would at the same time be quite useless. I am more inclined to put my trust in the discovery made by Mr. Barron, of Borrowash, some years ago, in the matter of the dying out of the limbs of Apricot trees, which he fully convinced me was caused by October frosts catching the sap either before it had descended or before it became consolidated and the wood ripened. In the case of the Apricot, although the branch is struck in October it does not show the defect till the following summer, when the leaves are expanded and the fruit is about half an inch long, when the sun calls upon the tree to support the fruit, which it cannot do, but dies of apoplexy. It may be argued that if one branch is struck by frost why should not others suffer? To this I reply that frost always makes its own selections, and I believe it will be found that the most robust branches are affected first. And so it may be with the Prince of Wales Plum, for its being excited into excessive growth by a stock that is not on and then destroys it. That Cherry trees are thus affected in October I have not the least doubt, especially if the October frosts have been accompanied by wet weather. My observation goes to show that we do not attach sufficient importance to the destruction of vegetation by October frosts, and if protection is to be given to trees, October is the time to give it. Many a farmer can tell of the enormous loss the country suffered about eight years ago from the destruction of the Mangel crop by an early October frost: many a pit did I see opened the following spring showing a mass of putrefaction. *C. Lea, Hounslow.*

Mulberry Trees for Australia.—In your last issue a correspondent asks for information as to how he can best send the Mulberry to Australia—whether as cuttings or plants. At the present season neither mode would be successful, as the buds are just bursting; the best time to send the young trees is the month

of November, and any nurseryman would pack them suitably. If cuttings are sent they should be taken from well-ripened shoots of the year's growth, tied in small bundles, and both ends dipped in softened pitch or resin, and then packed in a case with layers of crushed charcoal between the bundles and cuttings. They should be sent from England in the month of November or December, and the case may be either soldered down or secured with a lid fitting rather closely. I am not aware of any useful variety of Mulberry not already in the Australian colonies; and it is just possible your correspondent may be giving himself unnecessary trouble and expense in sending out plants of which the colonists have an abundant stock. If your correspondent is desirous of sending out something useful to his friends or to those important colonies, I shall be happy to afford him information as to plants not very well represented at present in the Australian colonies. *W. Clarkson, Hayes, Kent.*

Picea concolor.—I have been much interested from first to last in Mr. Murray's remarks on *Picea concolor*, or, as he would call it, *P. grandis*, var. *concolor*, and the reasons he assigns for considering it so related. He informs us that he grounded his opinion on having seen *P. grandis* in its native Rocky Mountains with all the characters that this species presents; and he adds that he found "very great differences in the habit of trees of *P. grandis* growing side by side, and in some cases the leaves scattered thin and sparingly, and would be like another would have its foliage twice as thick; one would have long leaves, as in *lasiocarpa* and *Lowiana*; another quite near it would have them only half the length. And even in colour a great difference was constantly to be seen; one would be of a darker green, another yellowish olive, a third nearly white, and so on."

We who have been accustomed to look upon plants raised from seeds sent home from the Pacific coast and Vancouver's Island, have seen in them no such variability. In holding the opinion that this form of *Picea* is a variety of *P. grandis* Mr. Murray differs from Dr. Engelmann and M. Roelz, both trained botanists in the field, who, having seen it in its native habitat, consider it a distinct species; and M. Roelz at least thinks it more closely related to *P. lasiocarpa* of Hooker than any other known species, which opinion is certainly strengthened by all that I know of this Conifer. I have about fifty fully-matured leaves of it which I selected from among the seeds disposed of by the Messrs. Sander & Co., St. Albans, and they certainly indicate close relationship to *P. lasiocarpa*, but differ from its leaves in having almost the entire upper surface from edge to edge dotted with stomata, whereas the band of stomata that runs along the middle of the upper face of the leaves of *lasiocarpa* occupies not more than one-half the leaf-surface, the remaining portion from among the seeds disposed of by me. But this is not the case in *P. concolor*, the whole leaf-surface, upper and under, being covered with a whitish meanness. Now I know that Mr. Murray has elsewhere (*Proceedings of the Royal Horticultural Society*, No. 5, vol. iii.) expressed great faith in the number of lines of stomata as a specific character, and, taking him at his word, I now ask him whether this new form of *Picea*, with almost the entire upper surface of its leaves dotted and striated with stomata together with their length, shape, and disposition on the branches, comes not nearer to *P. lasiocarpa* than it does to *P. grandis* with its channelled leaves destitute of stomata in the upper face? Besides these leaves I have within easy reach a dozen or more two-year-old seedling plants of *P. concolor* that differ from *P. lasiocarpa* (*Parsonsiana* or *Lowiana*) of the same age, mainly in the way that I have already indicated, and in showing no signs of a channel on the upper face, and in being bluish white instead of pale green as in *P. lasiocarpa*. The hundreds of seedlings that we have of this new Conifer, now in the seed leaf, also differ from those of *P. lasiocarpa* growing alongside of them in that they have from five to seven seed-leaves (*P. lasiocarpa* having from six to eight), and in being of a beautiful bluish-white colour, certainly very distinct from any *Picea* that has ever before been raised in England. It matters not to the amateur who has this *Picea*, it may be more closely related to *P. grandis* than to *P. lasiocarpa*; but the case is different with those who are interested, pecuniarily and otherwise, in the cultivation of *Piceas*. To them a bluish-white form of *P. grandis* would certainly be an acquisition and a plant to be desired; but how much greater an acquisition, and how much more desirable, would be a hoary or bluish-white form of the already highly ornamental *P. lasiocarpa*, I leave them to answer. And now, just as words as to the probability of this *Picea*. The two-year-old plants that I have already referred to, in company with a number of plants of other species of *Picea*, been wintered in a cool house, but for the last four weeks or so they have been subjected to a little artificial heat, and the consequence is, that the plants of *P. concolor* are now bursting their buds, and exhibit about the same degree of advancement that *P. magnifica*, notably the

most tardy of known *Piceas*, exhibits; while others, such as *Picea* *Pinidora*, *Webliana*, and *firma*, similarly circumstanced, have made from 2 to 3 inches of growth, so that cultivators of this *Picea* need have nothing to fear from spring frosts. *George Syme.*

Horticultural Shows at South Kensington.—There seems to be some misapprehension among exhibitors as regards the 50 per cent. reduction on the prizes. Some are of opinion that it applies to the whole of the shows during 1875, whilst others believe that it does not include May 12, June 2, and July 7. This is a matter that ought to be clearly understood, seeing the effect that the fifty off has caused already. The Society must now be saving money. Last Wednesday's schedule offered £72 15s., and according to the awards only £3 7s. 6d. was given, so that we may conclude that the Society will not only soon be able to pay last year's prizes, but have a good balance at their bankers. *H. B.*

Araucaria imbricata.—We have not succeeded in growing a single plant to perfection in our botanic garden, which is situated upon a chalky gravel. They grow tolerably well for a few years, but then the whitish tomentous substance begins to form amongst the leaves at the end of the stem or branches. It extends, and the plants gradually die off. My idea is, that the chalk in the soil is the cause, but I should much like to know the experience of others. Several of the Fine tree will not grow in our soil. *C. C. Babington, Cambridge.*

A Perpetual Flower Garden.—Would any of your correspondents favour me with their experience? We have three windows commanding a small plot of ground in front of the house, facing west. I wish to keep this always supplied with plants in flower, especially in the spring months, and propose making a single tier of rock-work, so as to have pockets which will have some protection from sun, wind, and driving rain in a few of these, would be fixtures in the shape of small evergreens, such as *Stimmia japonica*, *Ledums*, *Gaultheria procumbens*, the dwarfest *Penstemon*s, &c.; the others would have empty flower-pots fixed in them; in these plants in pots, bloomed elsewhere, would be placed and renewed as required. I should think that by this means a constant succession of pretty flowers could be kept up as in a conservatory without very much trouble, and that the partial protection of the rock pockets would sufficiently protect from weather to prevent them becoming much ragged except from very hard frosts. If any of your correspondents have tried anything of the sort, and would communicate the results in your columns, I should be much obliged. *George F. Wilson, Heatherbank, Weybridge Heath.* [The empty pots might be plunged in cocoa-nut refuse with advantage. Eds.]

The Past Winter.—I think we may now venture to reckon up the gains and losses of the past winter, which I consider to have been one of the most trying that we have had for many years. I therefore send, according to promise, a list of plants of whose hardiness I was doubtful, with the results of the winter upon them. All have been equally unprotected except that some may have been in more sheltered spots than others. The following, I fear, are dead:—

- | | |
|---------------------------------|--|
| <i>Yucca filifera</i> | <i>Fuchsia Dominiana</i> |
| " <i>convexa</i> | <i>Boykinia occidentalis</i> |
| <i>Eucalyptus obliqua</i> | <i>Mediola geranioides</i> |
| " <i>angustifolia</i> | <i>Cheiranthus nuttalis</i> |
| " <i>corymbosa</i> | <i>Hypericum baleareicum</i> |
| <i>Callitris cupressiformis</i> | <i>Heuchera himalayensis</i> |
| <i>Convolvulus Cieserum</i> | <i>Erigeron glaucum</i> |
| <i>Statice echinoides</i> | <i>Solanum jasminoides</i> (in the open border). |
| <i>Salvia taraxacifolia</i> | |
- The following are all alive, though some of them have been more or less injured:—
- | | |
|---|---------------------------------|
| <i>Rosa aloefolia variegata</i> | <i>Callitriche involucrata</i> |
| <i>Ruscus androsylvanus</i> | <i>Chelidonium majus</i> |
| <i>Paeonia officinalis</i> | <i>Tricuspidata aurea</i> |
| <i>Lycium purpureum</i> | <i>Tubalgia allicata</i> |
| <i>Edwardia microphylla</i> | <i>Habranthus pratensis</i> |
| <i>Solanum jasminoides</i> (against a wall) | <i>Levins nurepensis</i> |
| <i>Richardia setiifera</i> | <i>Saxifraga Fortunei</i> |
| <i>Phormium tenax</i> | <i>P. mutata</i> |
| <i>Manfreda tricoctum</i> | <i>Cynometum Fortunei</i> |
| <i>Chionodoxa luteo-virens</i> | <i>Margyricarpus setosus</i> |
| <i>Pisonia Hillebrandii</i> | <i>Gerum capense</i> |
| <i>Valletta purpurea</i> | <i>Cyclophorus</i> |
| <i>Unbilicus Litanois</i> | <i>Psoralea Pourcei</i> |
| <i>Trostrotyx hispidentum</i> | <i>Kniphofia caulescens</i> |
| <i>Mutisia curatilis</i> | <i>Ecraonocarpus scaber</i> |
| <i>Iris fibrifera</i> | <i>Penstemon Palmeri</i> |
| <i>Perovonia Zandicherianum</i> | <i>Phlox pilosa</i> |
| <i>Cyclophorus</i> | <i>Diplazis glitiosus</i> |
| <i>Veronica Hillebrandii</i> | <i>Hypericum Coris</i> |
| <i>Polygonum Hillebrandii</i> | <i>Rubus australis</i> |
| <i>Statice Lentensis</i> | <i>Globularia mana</i> |
| <i>Geranium Bungei</i> | <i>Solanum minutum</i> |
| <i>Vitex Agnus-castus</i> | <i>Bellis rotundifolia</i> |
| <i>Arisarum vulgare</i> | <i>Cerculeacens</i> |
| <i>Senecio</i> | <i>Eupatorium angustifolium</i> |
| <i>Polygonum filifolium</i> | <i>Eulalia japonica</i> |
| <i>Phibiscus boxifolia</i> | <i>Begonia sageritoides</i> |
| | <i>Geranium tuberosum</i> |

In this list I should like to draw special attention to *Mutisia decurrens*. My plant was a small one, and I was very doubtful about leaving it out; but the winter has not only had no bad effect upon it, but the plant has been actually growing slowly but steadily all the winter, so that it has now shoots of this year's growth

of more than 8 inches. The plant may, therefore, be highly recommended as a hardy climber. Its flowers are very handsome, and its leaves very curious; their shape is very quaint, and each leaf is terminated by a long double tendril. I am so much pleased with the plant, that I would try the beautiful *M. ilicifolia* if I could meet with it, but I fear it is very scarce. There are many plants that have not yet sufficiently declared themselves to be placed in either of the above lists; but I can send you a supplemental list if you wish. I hope others will send you similar lists. *Henry W. Lilacombe, Hilton Vicarage, Gloucestershire.*

Primroses Changing Colour.—What is the cause of the common Primrose turning pink? In my shrubbery borders this spring a large proportion of the plants have produced pink flowers, having hitherto produced only yellow flowers. Many old plants have half their flowers yellow and half pink; some flowers appear to be in a transition state. The yellow and pink flowers on the same plants differ in shape, the pink being thinner flowers, with larger intervals between the petals. I gave the border which contains them a dressing of riddled garden heap, chiefly leaf-mould, in winter. I have often noticed the pink variety before, both wild and in cultivation, but I have never observed a similar transition. I have not the same doubt about this transformation as I had about that of the Daffodils. *C. W. D., Eton.*

Horticultural Exhibitions.—At a time when the metropolitan and provincial Societies are offering prizes at their exhibitions which, with the single exception of the Royal Horticultural Society's principal summer show, are of such paltry value as to produce nothing better than the mere shadow of what these exhibitions once were—and, to make matters still worse, in some cases the arrangement of the different classes such as to effectually prevent many exhibitors from showing—it is refreshing to point to what is being done elsewhere. Take Leeds, for example; and the advertisement of the prizes which the Society offers is a indictment of the prizes which the Society exhibitors deserve special mention. For twelve Roses, pots, not over 9 inches, £10, £6, £4; twelve stove and greenhouse plants, £20, £12, £8; twelve show Pelargoniums, £12, £8, £5; twelve Orchids, £12, £8, £4; Azaleas, Ericas, Ferns, hardy and exotic; fine-foliage plants; Zonal, Fancy, Bronze, and Variegated Pelargoniums; Fuchsias and other popular plants; numerous classes for rose and other flowers with fruit both in collections and single dishes, for all of which most liberal prizes are offered. In addition to which the Society finds horses free of charge to draw exhibitors' vans to and from the railway stations, and good roomy vans for those who convey their plants in railway trucks. This matter of horses and vans is a real advantage to exhibitors, who are too often victimised by the exorbitant charges imposed upon them when their position is resisted. In such horticultural exhibitions, which are held to be representative, are carried out in a dignified spirit, the money expended is simply so much thrown away, as they do little to advance the pursuit of horticulture, and the display never being sufficient to attract the public in numbers, a loss is generally involved. *T. Baines, Leeds, and Manchester* too, set a good example in this matter. Eds.]

Camellia reticulata.—This magnificent *Camellia* is now grand in the *Camellia* conservatory at Chiswick House. It has been literally sheeted with its gorgeous blossoms, but the requirements of Marlborough House are constantly denuding the tree of its large and rich blossoms. Planted by Mr. C. Edmonds in 1829, this tree has grown up under his constant supervision to the present moment, and probably he was never before so proud of it as he is this season. Size is always a main feature of the blossoms of this species. This year, notwithstanding the wonderful profusion, the flowers are of great size, and richly coloured—a striking hue of warm, red rose. The diameter of the flowers is really surprising, but the large bold petals—generally three and four deep—and the large bunch of golden anthers in the centre, require space to develop themselves. One turns with something like relief from the symmetrical blossoms of *C. imbricata* alba with their almost geometrical outline, and other compact flowering varieties, to the bold rugged grandeur of those of *C. reticulata*, and admires them all the more for decorative purposes. The plant at Chiswick House has outgrown the space allotted for it, and it seems to aim and twist itself in the hope of finding large quarters in which to make free growth. It necessarily contracted abiding place, though it spoils the beauty of the tree, does not in the least degree affect its freedom of flowering. It is difficult to imagine that a plant could bear more blossoms than that in question. Would that a new house could be built over it, with ample space in which to develop itself without restraint. It deserves to be let to some Mr. Edmonds man, to see his favourite plant flourishing under freer conditions, and yearly building up a yet more distinguished reputation. *A. D.*

HORTICULTURAL EXHIBITIONS, 1875.

MAY.

- 12.—Royal Horticultural Society, South Kensington. Meeting of Fruit, Floral, and Scientific Committees. Pot Rose Show.
- 14 to 21.—Manchester Botanical and Horticultural Society's Annual National Exhibition, at the Garden, Old Trafford. Manager, Bruce Findlay.
- 17 and 18.—Halifax Floral and Horticultural Society's Annual Exhibition. Sec., Leonard Kershaw, 20, Gladstone Road, West Hill Park.
- 20.—Royal Horticultural Society of Ireland. Early Summer Exhibition. Sec., A. Balke, 28, Westland Row, Dublin.
- 22.—Crystal Palace Great Flower Show. Sec., F. W. Wilson.
- 26.—Royal Botanic Society, Regent's Park. Summer Exhibition. Sec., W. Sowerby.
- 27.—Royal Horticultural Society, South Kensington. Meeting of Fruit, Floral, and Scientific Committees.
- 31.—Covevny and Warwickshire Floral and Horticultural Society's First Show of the Season. Sec., Thomas Wigston, 3, Portland Terrace, Lower Ford St., Covevny.
- 31 to June 4.—Bath and West of England Society's Exhibition at Crofton.

JUNE.

- 1 and 2.—Royal Western Horticultural Society's Exhibition at Plymouth. Hon. Sec., F. B. Bond, 16, Penrose Street, Plymouth.
- 2.—Royal Horticultural Society, South Kensington. Meeting of Fruit, Floral, and Scientific Committees. Great Summer Show.
- 9, 10, and 11.—Leeds Horticultural Society's Twelfth Annual Summer Show. Sec., James Birbeck, Delph Lane, Woodhouse, Leeds.
- 10.—South Essex Clerical Society's Exhibition at Leyton Sec., G. E. Cox, Leyton.
- 10.—Royal Botanic Society, Regent's Park. Summer Exhibition. Sec., W. Sowerby.
- 16.—Glasgow and West of Scotland Horticultural Society. Midsummer Exhibition. Sec., F. G. Douglall, 167, Caning Street, Glasgow.
- 16.—Royal Horticultural Society, South Kensington. Meeting of Fruit, Floral, and Scientific Committees.
- 17 and 18.—Lee and Borekheath Horticultural Society's Exhibition. Sec., C. C. G. Rogers, 2, Broom's Road, Lee.
- 18.—Scottish Pansy Society's Exhibition at Edinburgh. Sec., W. M. Welsh, 1, Waterloo Place, Edinburgh.
- 19.—Crystal Palace Rose Show. Sec., F. W. Wilson.

THE

Gardeners' Chronicle.

SATURDAY, MAY 1, 1875.

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY,	May 1	Opening of the Alexandra Palace (this day).
		Special Exhibition of Clematis at Regent's Park (until 24th).
MONDAY,	May 3	Mr. W. Balke's Special Show of Roses, Pelargoniums, &c., at Regent's Park (until 24th).
		Meeting of the Entomological Society, at 7 P.M.
TUESDAY,	May 4	Side of Ferns, Aloes, Agaves, Orchids, &c., at Stevens' Rooms.
WEDNESDAY,	May 5	Side of Poultry and Pigeons, at Stevens' Rooms.
THURSDAY,	May 6	Sale of a Collection of Established Orchids, at Stevens' Rooms.
		Meeting of the Linnean Society, at 8 P.M.
FRIDAY,	May 7	Sale of 5000 Bulbs of Lillium, Established Greenhouse Plants, at Stevens' Rooms.
		Exhibition of Plants and Flowers in the Kibble Conservatory, Glasgow (two days).

THE SPRING GARDEN at BELVOIR is always a thing to be seen with pleasure, and, if it be possible, this year more than ever. The long, dreary winter, the laggard spring, and continuous east winds, have irritated us to weariness. For such a feeling no more potent antidote could be found than a visit to the wooded slopes of Belvoir, enamelled as they are with a lavish flush of beauty, framed by noble trees in the tender hues of first opening buds.

This year, too, the extensive additions which Mr. INGRAM is making begin to tell, and beautiful as they now are, give promise of a yet more delicious prospect in years to come. In the old spring garden, which has so often been mentioned in these columns, the flowers are grown in more or less symmetrical beds on flat terraces, environed by fine trees, and, as it were, nestling beneath the terrace walls of the Castle, which in general aspect and in site presents no slight resemblance to Royal Windsor. The beds are "carpet beds" or "bouquet beds," and well deserve the latter name, for from the end of winter, or even earlier, till early summer, they are a dense mass of varied bloom. The variety is one of the chief points of interest: almost every day, certainly every week, some fresh flower opens, and, it may be, gives an entirely new aspect to the whole.

So thickly studded and so varied are the inhabitants of these beds, that enumeration would be wearisome; suffice it to say, that the general

principle in planting them is to have a centre of some striking foliage plant, such as a low-growing Yucca or a Veratrum—this last, by the way, a noble plant for such a purpose, giving a quasi-tropical aspect eminently bold and effective. The edging is of *Eunomus radicans variegatus*, Ivy, the purple-leaved *Heuchera lucida*, or the Golden Thyme or what-not. Between the centre and the edging, so constructed, is the "carpet"—and a rich carpet it is, satisfying the eye with a soft richness of colour, and a rainbow-like gradation of hues and tints utterly indescribable, but as different from the harsh glare of the eternal scarlet *Pelargoniums* as a sketch of RAFFAELLE'S is from the gaudy tinsel of a Roman Catholic church in the country towns of France.

The staple of the "carpet," the material of the "bouquet," consists of Aubrietias, Arabis, Primroses of all hues, Erica medieterranea and carnea, Myosotis dissitiflora, the yellow *Doronicum austriacum*, Golden Thyme, various Sedums, bulbous plants, Scillas, Hyacinths, Tulips, Pansies, Daisies, and many more.

We shall have some thing to say at another time as to certain special plants we noticed, and as to their fitness for special purposes; we shall have to note once more the compact strain of Wallflower with which Mr. INGRAM'S name has become associated—and a variety of novel seedlings, in particular a lovely Iris in the way of pumila; but we must not stay now to enter into details. We would prefer now to comment on the contrast between the spring beds on the terraces and the new development of spring gardening now in progress. Exquisitely beautiful and exceedingly interesting as the terrace beds are there is still a trace of formality about them—a "soppon" of "bedding out," which somehow does not seem to associate well with spring flowers. Still more pronounced was this feeling on viewing the "ribbon borders." Whether the same idea has occurred to Mr. INGRAM or not, we know not; at any rate, by the Duke's permission, he has evolved a spring garden on a scale and of a form which will put all similar attempts into the shade. Imagine the side of a steep and lofty hill scooped out like the combs on the South Downs; further imagine that an overpowering torrent has swept the side of the comb, laying bare the rocks, and exposing their stratification, which projects in bold masses; fill every cranny and every nook with spring flowers, with alpenes, with Ferns, with Sedums, or what-not—with striking plants, such as Yuccas, Arundo conspicua, double Gorse, *Arundinaria falcata*—clothe the hilltops with noble trees, and set the whole in a framework of forest scenery, with peeps of distant landscape and a lake at the foot of the hills, and you have some idea of what is being done at Belvoir. The idea is admirably carried out; the site is, as it were, made on purpose, the rocks are disposed as only a man with at once an artist's and a geologist's eye could arrange them: they have, in fact, the supreme charm of truthfulness. A cascade, were it only a tiny mountain rill falling from rock to rock, seems alone wanting to complete the illusion.

All this has been done by simply clearing away from the steep escarpment a quantity of old crowded shrubs and trees, and by artistically placing blocks of stone here and there—helping Nature, as it were. Deep pockets between the blocks, reminding one of the "pot holes" of the chalk, are filled with soil, and in this the plants are grown. "Only a rockwork on a large scale," some one will say; true, but what a rockwork! It is a Swiss hillside pasture transferred to the midlands, and with the flowers multiplied beyond measure in the transfer. If such be the impression now, when the work is new and unfinished, what will it be in the course of a few seasons when the plants

become established? We must, perforce, content ourselves now with this general notice, reserving comment on certain details till another occasion.

PROFESSOR NEWMAN and the members of the Vegetarian Society are making great efforts to proselytise and make converts to their peculiar doctrines. Let us say at once that to a large extent we sympathise with them. We believe that among the upper classes a great deal more animal food is eaten than is at all necessary or desirable. On the other hand, the poor and the labouring classes get, as a rule, far too little. We admit, too, that it is quite possible to live and thrive upon a pure vegetable diet. We know that whole nations do so. We admit and lament that our working-classes neglect or ignore forms of vegetable foods palatable, much cheaper, and as nutritious as any they get. We have seen dock labourers in Genoa, artisans in Florence and other Italian towns, making hearty nutritious meals of Lentils, Peas, and Pulse, nearly as nutritious weight for weight as meat itself, and very palatable, and have lamented that our own people should not have availed themselves of fare so excellent and cheap. Over and again, too, have we urged in these columns the increased production and consumption of fruit, and advocated the giving to cottagers a few perches of garden ground to provide his own family with vegetables. But, admitting so much, we cannot concede all that Professor NEWMAN asks. We acknowledge that the slaughter of animals is cruel, and that it behoves us all to do what we can to reduce that cruelty to a minimum; but the inevitable cruelty does not show that meat is not a proper food for man. If the vegetarians pushed their theories to their utmost limits they would neither eat nor drink nor breathe. Let them take all the care to exclude animal food they can do, the next tumbler of water they take may contain more animal life than they would care to measure. They can hardly draw a breath in some places without unconsciously inhaling minute forms of animal as well as of vegetable life. Fruits, Pulse, Flour, Sugar, and most vegetable substances are apt to teem with minute animals, and the vegetarians in strict logic should not eat them. True they may say that cooking destroys them, but what is the cooking but cruelty? Again, cooking is not always certain to destroy them. It may be said that all this is mere quibbling, that it is pushing matters to an extreme; but if so it is the vegetarians who compel us to present them with this *reductio ad absurdum*.
