yellowish-brown veins; and a row of rounded, bluish-black spots between every two veins; the eyes and legs are black, each joint of the latter being fringed with white. The caterpillar is about $1\frac{1}{2}$ in. long when fully grown, and is of a yellowish-buff colour. The head (with the exception of the crown, which is lighter), a shield-shaped spot on the first joint of the body, and various round spots on the other joints, and the upper part of the last joint are black; the round, black spots on the body are raised, with a fine, short hair growing from each. The mouth is provided with a strong pair of jaws; the body has twelve joints, the first three bearing a pair of small, black legs, the sixth, seventh, eighth, ninth, and last joints also bearing legs. The chrysalis is brownish-yellow, except at the ends, which are dark brown.

S. G. S.

Plant Vagaries.—In a lecture delivered on June 17 last, before the members of the College of the Sorbonne, Paris, by M. Alphonse Lavallée, Secretary-General of the Central Society of Horticulture of France, and possessor of the magnificent and altogether unequalled collection of shrubs and trees at Segrez, he mentions the following facts that may be interesting to the readers of THE GARDEN: 1. That the Liquidambar styraciflua in his arboretum, when planted as a single specimen, never exceeds the dimensions of a bush, but that when several of them are planted close together, so that in fact they almost crowd one another, they will all of them attain the dimensions of a small tree. 2. That shrubs and underwood generally will thrive and flourish when planted under Beech trees, but will not even live when planted under the shade of the Walnut. 3. That Nettles will only thrive in the immediate vicinity of human habitations, and that when these are removed the Nettles, which used to abound, almost immediately afterwards disappear also from the locality, but that, on the other hand, no member of the Orchis family seems able to exist in the immediate vicinity of man's abode, as particularly in Switzerland, when peasants' cottages are built on spots where these plants are plentiful, they all quickly disappear and cease to grow. He gives no reasons for these curious likes and dislikes, but merely states the facts as they have come under his notice. M. Lavallée, who is also Treasurer-General of the Central Agricultural Society of France, has also recently published a pamphlet, addressed to the members of that Society, recommending as a stock whereon to graft Vines that will not possibly be liable to the ravages of that dreaded Vine pest the Phylloxera vastatrix, the species of Vines which are indigenous to the different parts of Asia, where this pest is altogether unknown, in the hopes that as silkworms, which live and thrive on the leaves of the White or Paper Mulberry, will not touch those of

Morus nigra or Black Mulberry, so the Phylloxera may also not like the roots of the Asiatic species of Vine. The experiment is at all events worth a trial.—W. E. G.

NOTES OF THE WEEK.

Sonerila Hendersoni.—This winter-flowering plant and its varieties (six in number) now rank amongst the most attractive occupants of stoves in the London nurseries. Their foliage is richly marbled and shaded with silvery-bronze, whilst their flowers, which run through all shades of violet, mauve, and pink, are produced in great numbers. They are well adapted for growing in pans, baskets, or vases; and even in 3-in. pots, handsome, bushy, little plants of them may easily be had. Grown in the latter way, a number of plants, some of which bear over thirty spikes of blossom, form an attractive fringe to Palms, Dracænes, and other fine-leaved plants in one of the houses in the Pine-apple Nursery.

Three Good Autumn-blooming Plants may now be seen in Mr. Parker's nursery at Tooting. They are arranged in a long line, and consist of a dwarf Pampas Grass, and the late-flowering *Tritoma grandis* (planted alternately), edged on both sides with long lines of the purple-flowered *Aster Amellus*. The plants of the Pampas Grass are each furnished with numerous plumes, whilst the showy blooms of the *Tritoma*, which are borne on stout spikes, are produced in large numbers, and more are still being thrown up from the bottom. Planting in lines is not always desirable, but there are many other ways in which such plants might be arranged effectively.

Seaforthia elegans in Flower.—A fine specimen of this Palm has been in flower in the large conservatory in the Royal Botanic Gardens, Regent's Park, for several weeks past. Whether it will ripen seeds or not is uncertain, as it is rather late in the year; but a short time ago a specimen of this Palm flowered in the gardens at Endcliffe Hall, Sheffield, and is now ripening a crop of seeds. The same plant flowered last year, and a fine stock of young plants from the seeds was obtained.

Dicentra formosa.—This forms an excellent border plant during summer and autumn. It resembles the kind known as *D. eximia*, but is of a stronger and hardier habit of growth. It also flowers more freely, and its blossoms are larger and of a brighter rose colour. It forms an excellent band to a shrubby, or isolated clumps of it in raised positions produce a good effect. We lately saw a long line of it in Mr. Parker's nursery, where, backed up by a row of variegated Cornes, it had a fine appearance. In the rich, deep soil of the Tooting nursery it grows with great freedom, and flowers successively for several months. Its blooms are useful among cut flowers, and its leaves may be used in like manner as a substitute for Ferns.

Helleborus altifolius in Pots.—This fine early-flowering Christmas Rose makes an admirable pot plant in November. We lately saw it treated in this way in Mr. Ware's nursery at Tottenham, in which one plant in a 10-in. pot bore upwards of 100 buds and blossoms. Such plants may be obtained either by growing them continually in pots, or by planting them out during summer and lifting them and potting them in the autumn. It is a good plan to put a sheet of brown paper round the plant when the bloom-buds appear, allowing the light only to fall on its top. This brings the flowers well up among and above the leaves, which, if the plants be wanted for conservatory decoration, is very desirable. Under this treatment, too, the flowers come whiter than when exposed to very bright sunshine. This Hellebore might also be made to form an effective feature in the conservatory if planted in quantity in the autumn, so as to form an undergrowth to Palms, standard Chrysanthemums, and similar plants.

Bananas at Wimbledon House.—The finest cluster of Bananas we have ever seen, and perhaps the largest ever grown in England, may now be found in the gardens at Wimbledon House. From the same place, some few years ago, Mr. Ollerhead exhibited a cluster which weighed 97 lb., said to be the heaviest of this sort on record; and it is expected that that alluded to above will considerably exceed this weight. The kind grown is *Musa Cavendishi*, which, on account of its dwarf habit, is the best for small houses. The plants are growing in a raised bed in the middle of a span-roofed house, in good, rich, holding soil. A little bottom-heat is given, as are also copious supplies of water; indeed, if the plants be even once allowed to become dry, failure will be the result. The plants now bearing fruit were planted out last February, and consisted of medium-sized, strong suckers taken from the bases of old plants. Their stems are now at least 20 in. in circumference. The fruit will be ripe in January next, and from the base of the plant several suckers are encouraged to grow to supply the place of the old plant, which, after

the fruit is ripe is cut down, and the young plants afford another crop of ripe fruit in July or August next. When the July fruit is cut, the old stools are lifted, the beds re-made, and fresh suckers are planted. Thus, in twenty months from the time of planting, two good crops of fruit can be obtained. It is always best to have the bed parted off into square portions, in order that the plants may be brought on or planted in succession, as occasion may require.

Large Brugmansia arborea.—Mr. John Incombe has sent us a section of the stem of a plant of this *Brugmansia* lately cut down in his conservatory at Combe Royal, near Kingsbridge, which measures 25 in. in circumference. The wood appears to be of no value, but the section in question serves to show the size which this *Brugmansia* will attain when growing under favourable conditions.

Lapageria as Standards.—Few plants are better adapted for covering umbrella-shaped trellises than *Lapageria rosea* and its white variety. The flowering shoots can be tied so as to hang loosely and gracefully from the trellis, a position in which they can be seen to better advantage than when trained over balloon or pyramidal shaped trellises, on which we too frequently see them; moreover, as standards they can be employed in the conservatory to better advantage than in any other form, inasmuch as they allow of other plants being placed beneath them. We lately saw some very large specimens in flower thus grown in Messrs. Veitch's nursery, Chelsea.

Chrysanthemums at Chelsea.—There will shortly be a fine display of Japanese, incurved, and Pomponé Chrysanthemums in Messrs. Veitch's nursery, Chelsea. The plants, which have this year been grown more bushy, in order to secure a quantity of bloom rather than a few fine flowers, are arranged in a large span-roofed house, which will, in a week or ten days, be most attractive, as far as a show of flowers is concerned. All the best of the old, as well as many valuable new kinds, are here represented; and they will, in addition to producing a brilliant display, afford a good opportunity for selection.

Fast Budding of Fruit Trees.—Very few who are unacquainted with the art of budding will believe how rapidly it can be performed by experts. Some twenty years ago, when I first commenced the nursery business, it was thought that a man who budded 2000 Peach trees in a day was very expert, and if he did more than that he must slight his work. The number has been gradually increased, until now we can find occasionally a man who can bud 5000 trees in a day of ten hours. The largest amount I have ever heard of was done by our men the past season. My brother and two young men in our employ, with three tiers, six in all, budded and tied 40,800 Peach trees in three days of ten hours each. I have occasionally heard of a large number set in one day, but this is the largest number I have ever known budded in the time.—C. J. BLACK, in "Gardeners' Monthly."

Aster grandiflorus for the Conservatory.—This, one of the latest-blooming kinds of Michaelmas Daisy, is well adapted for lifting and flowering in pots in the conservatory. Its large flowers, which are of a very showy bluish-purple, supply a colour wanting in Chrysanthemums, and well-grown bushy plants of it would greatly enhance the effect of a mixed collection of Chrysanthemums, scarlet *Salvia*, and similar plants used for autumn indoor decoration. We lately saw fine, bushy specimens of this *Aster* in Mr. Parker's nursery, Tooting, just opening its bloom buds, and which, if lifted, would be well fitted to the purpose alluded to. Associated with this kind were also in flower *Aster terminalis*, *A. paniculatus*, *A. Novæ Angliæ*, the dwarf *A. discolor*, and *A. ericoides*.

"Art" in the Garden.—Our friend Mr. Meehan, of Germantown, has a sensation in his November monthly. In the description of a garden we read that "on both sides of the main drive is a broad expanse of lawn, unbroken by tree or flower bed, and of a verdure unexcelled; on each side of the same drive is a mammoth ribbon line bed, running a length of 800 ft.—the effect of these beds, when I saw them in the light of an August afternoon, in contrast with the velvet-like lawn, is something never to be forgotten, and it is doubtful if in all the experienced art of Europe they have ever been surpassed. One bed is described as containing 50,000 plants." We are, however, not very sorry that an ocean divides us from these "fine effects."

At the Royal Horticultural Society's meeting next Tuesday there will be a fine display of Chrysanthemums from Messrs. E. G. Henderson and other noted growers, and a good exhibition of vegetables is expected in competition for the prizes offered by Messrs. Carter, Sutton, and Hooper. Messrs. Veitch & Sons will, by special request, again exhibit an extensive collection of winter budding plants similar to that which excited so much interest at the last meeting.

NOTES FROM KEW.

Hardy Plants.—The most stately of all the plants belonging to the Natural Order *Lilacæ* are the *Yuccas*, some of which assume an arborescent habit, and afford a style of beauty peculiarly their own. Most people know the common Adam's Needle (*Yucca gloriosa*), but the variety *glaucescens*, which we now note, is not frequently met with. It has the habit of the type, but its leaves are very glaucous; like the common one, it produces its large and handsome panicles of whitish flowers at almost any season. *Phlomis ferruginea*, a handsome, shrubby Labiate, nearly allied to the Jerusalem Sage (*Phlomis fruticosa*), is a very desirable South European plant, which is quite hardy in this country, at any rate in the southern counties; even at the present inclement time of year its large, orange-yellow flowers are in full beauty. The very much wrinkled leaves are densely covered with beautiful, star-shaped hairs.

Greenhouse Plants.—*Justicia speciosa*, an Indian Acenthad, is now gay with its pretty purple blossoms; either for the greenhouse or stove this easily-cultivated and free-flowering winter decorative plant is very useful, and is well worth growing. *Marsaltia Heisteria*, a native of the Cape of Good Hope, is a rigid shrub of Gorse-like habit, thickly studded over with small, purple, Pea-shaped flowers; this pretty plant remains continuously in flower for several months. *Begonia natalensis*, another South African plant, flowers well in a young state; it has neat, light green leaves, white flowers, and is of good habit. *Cyrtanthus McKinnii*, a very lovely Amaryllid, from the Cape of Good Hope, has long, narrow, dark green, Grass-like leaves and scapes about 1 ft. in height, bearing umbels of long-tubed, white, deliciously-fragrant flowers.

Exotic Grasses.—The Batavian Sugar Cane (*Saccharum violaceum*) is a decidedly ornamental stove plant; the glossy leaves are purplish and the entire foliage is tinged with purple. *Reana luxurians* or, more properly, *Euchlæna luxurians*, a noble Grass from Venezuela, is now in flower, probably for the first time in this country. It is a tall plant with a superficial resemblance to Indian Corn, and, like it, produces its panicles of male flowers at the summit of the stem, and the female spikes in the axils of the stem-leaves. Much is expected from this as a forage Grass; and although it has failed somewhat in some places where it has been tried, many Indian planters speak in the most hopeful terms respecting it, as a single good tuft will afford sufficient food for a bullock for an entire day. Some of the Kew specimens are from 10 ft. to 15 ft. or more in height. *Gynerium saccharatum*, another Grass from Tropical America, makes an extremely handsome specimen plant where sufficient room can be afforded it; it has tall, Reed-like stems 12 ft. or 15 ft. high, and long, plume-like panicles of whitish flowers. A South European species, *Arundo mauritanica*, does well out in the open air during summer, provided it can command an unlimited supply of water. Under these conditions it gives us a very fine sub-tropical effect. In the old Lily house, the grand feathery panicles of this southern Reed, borne on stems 8 ft. high, are very beautiful.

Stove Plants.—*Randia longiflora*, a remarkable shrub or small tree from Sierra Leone, is a near relation of the *Gardenias*; the large flowers—the tube of which is nearly 1 ft. in length—are creamy-white, with the exception of a red patch behind each of the five stamens. *Aphelandra Sinitzini*, recently introduced from Peru by Linden, of Ghent, is a noble plant with large, leathery leaves, polished green above and purple beneath; the flowers, produced in fine spikes, are a splendid vermilion. *A. Porteana*, from Bahia, is another very showy and free-flowering plant, with spikes of very rich orange-scarlet. *Anthurium candidum*, introduced two or three years ago from Colombia by Mr. Shuttleworth when collecting for Mr. Bull, of Chelsea, is a charming and elegant stove Aroid; the peduncles, somewhat longer than the oval lance-shaped green leaves, are surmounted by a snowy-white spathe.

Orchids.—During the past few years a large number of *Masdevallias* have been introduced, and our gardens have been enriched by lovely cool house epiphytes, many of which are as remarkable for the peculiarity of the shape and structure of their blossoms as for their exceedingly rich colouration. Several are, at present, in flower at Kew. Of *M. Veitchiana*, first discovered by the late Mr. Pearce in the Cordilleras of Peru, Sir J. Hooker says, "In point of colour it is not only one of the most beautiful, but most singular of Orchids; for the vivid hue of the flower is due to the whole inner surface of the petals being studded with minute papillæ of a brilliant cadmium-yellow colour; these are largest and most crowded where the colour is deepest." *M. ignea* is a near ally of *M. Veitchiana*, and was originally imported from New Grenada in March, 1870, and sold at Stevens's Rooms. Professor Reichenbach, in describing it, says that the blossoms are "dazzling scarlet mixed with orange-scarlet; too dazzling to look at long." *M. Harryana*, introduced by

Wallis from New Grenada in 1869, has blood-red flowers, the sepals forming a yellow tube. *Oncidium excavatum* is a tall-growing and very free-flowering kind, with bright yellow blossoms, stained with brown near the base of the lobes of the lip. *Sarcanthus laxus*, a most floriferous and neat-growing little epiphyte from Moulmein, bears numbers of drooping spikes of small, but pretty flowers, the deep purple lip of which renders them conspicuous. The long-stalked, drooping spikes of the rose-coloured blossoms of *Mesospinidium sanguinum* are very charming, are freely produced, and last a considerable time in perfect condition. *Liparis spathulata* and *L. pendula*, both from India, make up in number of flowers and grace and elegance of habit for the small size of the individual blossoms; in colour these are greenish, but are borne in great profusion in drooping spikes. Their somewhat disagreeable odour is, however, a slight drawback. *Dendrobium bigibbum*, with its rich purple flowers, is certainly one of the most handsome of the Australasian Orchids, and *D. aquinum*, with its long, leafless pseudo-bulbs studded with blossoms (pure white, with the exception of the base of the lip, which is tinged with primrose), is not one of the least lovely of the Indian kinds.

—†

NOTES FROM AMERICA.

A FRIEND of ours who cultivates hardy plants in a remote corner of the New World sends us the following: Your horticultural journals should keep an American editor. I do not see how you manage to get so persistently wrong on American plants. Scarcely any of you mention an American native plant but what you get as far out of the way as the secular journals do when they touch our geography, politics, or social matters. What an amusing story you are telling about *Clematis Pitcheri*. No living mortal ever saw it in the country where it grows with a flower anything but purple, and a dull purple too. Then the "Revue Horticole" made matters worse by a coloured plate with scarlet flowers, about half or less the size of *C. Pitcheri*. One of your correspondents speaks of *Panicum virgatum* as growing 3 ft. high. A clump within fifty yards of where I write is taller than I, and I am 5 ft. 11 in. (or, as Pat said, 11 ft. 5 in.; I have forgotten which), and it tops me. Another writes of *Andropogon furcatus* as "graceful." We look upon it as the emblem of meanness. It will doubtless do in a botanic garden, but pray do not encourage people to plant it by calling it "graceful." Pray what can you have as *Helianthus divaricatus* that it should be called "fine?" It is just about as "fine" as a Jerusalem Artichoke and other coarse Sunflowers. If you wish for fine Sunflowers, take *H. orgyalis* or *H. Maximiliani*, and I will agree with you. One of your correspondents commends *Bocconia cordata*. It may behave differently with you, but here it is one of the worst nuisances ever introduced. It runs and comes up everywhere in the lawn. Another "spreader" is the Kentucky Coffee tree (*Gymnocladus canadensis*), about which Mr. C. M. Hovey writes so enthusiastically. My soil is very sandy, and this comes up from the root in a promiscuous manner. Still, what Mr. Hovey says otherwise is to the point, but I think I have found fault enough to show the need of an American censor. If you make me an offer, let it be a large one.

G. T.

[The *Clematis*, as it flowered in the Garden of Plants, most certainly had red flowers. Perhaps it is another species, or a distinct-coloured variety. *Panicum virgatum* is not one of the Grasses that has received kind treatment in our gardens, and we have never seen it so high as the plants mentioned by our American correspondent. Grasses are much influenced as to stature by soil and climate. What does our correspondent say to the other side of the question, as illustrated by such notes as this, which we cut from Vick's useful magazine? An American writes thus from Derby: "I will send a root or two of real English London Pride. Have seen both London Pride and *Lychnis* in the same garden, which goes as further proof of the truth of your statement, *Lychnis* is not London Pride, as some Americans claim."]

Nurserymen's Exhibits at Paris.—The following will give some idea of the extent of nurserymen's exhibits in the grounds of the Paris Exhibition. Passing recently through that portion of the gardens set apart especially for the above I noticed the following exhibited by one firm alone (that of Leroy, of Angers), viz., Apples, 492 varieties; Pears, 813; Plums, 153; Cherries, 131; Peaches, 145; Apricots, 43; Almonds, 18; Quinces, 10; Figs, 31; Raspberries, 30; Currants, 40; Strawberries, 102; Conifers, 310; Evergreen shrubs, 500; climbing plants, 125; plants especially adapted for peaty soils, 50; and deciduous trees and shrubs, 600, making a total of 3593 varieties. The whole were arranged very effectively in beds and borders, and, owing to their being crowded together, they could be easily examined by any one who wished to do so, each speci-

men being a very fair representative of its kind.—CHARLES DENNIS' *Southwark Park*.

THE KITCHEN GARDEN.

AERATING THE SOIL.

I ENTIRELY agree with all that Mr. Cornhill has said (p. 424) respecting the ridging of ground in winter or leaving it alone. Our soil here is of a stiff, retentive nature in winter, but bakes and burns in summer; and if it be stiff and lumpy in the spring, or run into a state akin to the consistency of clay with excessive moisture, it becomes almost impossible to crop it fitly or to reduce it to a pulverised condition. Ridging will do good if it be done whilst the soil is fairly dry in the autumn; but if the operation be left until it has become saturated with wet, then it will turn up in huge lumps, and in lumps it will remain unless severe frosts pulverise it. I would often like to have my uncropped ground neatly dug or forked over in the autumn, or during open weather in winter, but if I did have it so worked and a week or two of rainy weather succeeded, it would then look very much as though it had been rolled, and would run together in such a way as to make moving it in the spring heart-breaking labour. Where it cannot be ridged and it is intended to dress it with stable manure in the spring, it is far the wisest plan, even at the risk of being thought untidy, to leave it untouched, weeds and all, for the winter, and let the worms do the work of aerating, which they will perform much more effectually than human labour can. When it is purposed to grow Potatoes—our staple crop here—with patent manures, I like to turn up the soil in ridges from 2½ ft. to 3 ft. in width, and to allow it to remain rough and unkempt for the winter; then in the spring, when the soil has become fairly dry, have the furrows forked over, draw shallow drills with a hoe, plant the tubers, dress with the manure, and fork down the pulverised soil from the sides of the ridges to cover the seed. The remainder of the ridge can then be forked down at leisure either before or after the Potato plants appear. Planting of all kinds of hardy flowers, such as Primroses, Polyanthus, Pansies, &c., that should be done in the autumn, and in some cases must be, let the result be what it may, is, nevertheless, best done in the spring, as the rains of winter cause the particles of the soil to run tightly together, the roots are fixed as in a vice, and in the heat of summer the soil is baked so hard, that it is almost impossible to get it clean and usable. It is an undoubted axiom that the wetter the soil in winter the more will it bake in the summer; whilst a dry soil in winter, if it be of average depth, will be the coolest in summer. The more the soil is pulverised, the more the surface is disturbed and made fine, the more retentive is it of moisture; and, except when the winter has been severe and the frost has thoroughly entered the soil, the highest condition of pulverisation is found when the worms have had undisturbed action, and the ground has lain untouched till March, or until dry weather prevails. Recent winters have rendered the ground more difficult to work in the spring than was formerly the case. Then several weeks of severe frost did a large amount of good; now, mild winters and heavy rainfalls keep the weeds growing, render the ground close and heavy, and leave slugs, snails, and other pests in undisputed sway. I heartily recommend all who have stiff, clayey soils to cultivate to be careful how they move them in the autumn, lest they do more harm than good. A. D.

MEDIUM-SIZED TABLE POTATOES BEST.

THE size to which Potatoes shall be grown has been much governed by the supposed requirements of the exhibition table, and as long as mere size or bulk were favoured, so long did growers regard such tubers as the best to produce. But of late there has been a tendency towards medium size, allied to handsome shape and pleasing outlines, and, in spite of some occasional misjudgment, there can be no doubt that the general taste now favours such tubers, and is disposed to regard them as presenting a good idea of a table Potato, whether for show or consumption. It is an acknowledged axiom that Potatoes are grown to be eaten, and this is so far indisputable, although at present not a few are grown for exhibition. But Potatoes are only exhibited with a view to encourage the growth and production of

handsome, even kinds for the table, and, therefore, if some do not reach that destination, their exhibition tends largely to promote the growth and consumption of others. Potatoes being grown to be eaten, and as it is the usual English custom to cook them in a whole state, the question may well be raised, What is the best and most desirable size to aim at? Perchance many people are indifferent as to the average size of their table Potatoes provided they can obtain plenty for consumption; but this is hardly a view that will commend itself to those who have made the cultivation of the Potato a matter of interest and importance. Relative size, too, often means relative quality; and as a cooked Potato is an abomination if not good, so does it follow that the better it is the more enjoyable and pleasing to the consumers will it be. Tubers of neat, medium size, that is, weighing about four to the pound, come nearest to my estimate of a table Potato; but these would hardly meet the requirements of Potato judges, who yet look for sizes varying from 6 oz. up to 10 oz., and in a recent prominent case of judging tubers from 12 oz. to 14 oz. were put into the highest place, not because they possessed good quality, but because there was bulk, and the size was in accordance with the known character of the variety. Now, I hold that Potatoes should never be sent otherwise than whole to table, and to have this desideratum only even tubers of a medium size could be used. Potatoes cut before cooking never boil so evenly, nor look so well when dished up, nor have such excellence of flavour as have smaller whole tubers; and further, whilst the outer surface of the peeled Potato does nicely flake and present the mealy character that we all so much admire, the cut surface of the halved Potato never does. But there is more than this; large tubers contain a larger proportion of water in their composition; small tubers contain less. The nutritious properties of the tuber are found in the latter in a more concentrated form, and then a less bulk of such food suffices. My preference in point of flavour is decidedly in favour of kinds that have flesh much tinted with yellow. Many white kinds, such as Regents, Victoria, Dawes' Matchless Kidney, Snowflake, &c., will boil mealy and as white as snow, but there is not that piquancy of flavour that is found in the yellow-fleshed kinds. These latter, however, predominate amongst home-raised sorts, and, therefore, there are perhaps more really good-eating Potatoes than is generally believed. White is the prevailing colour of flesh of the American kinds, Brownell's Vermont Beauty being almost the only exception, and this is probably one of the best of that large section, when cooked. On the other hand, with us, starting with that old and favourite Kidney, the Ashleaf, we get yellow tints predominating, as is seen in such other delicious table kinds as the Lapstone, Early Market, Rector of Woodstock, King of Potatoes, Radstock Beauty, Blanchard, Grampian, Scammell's Glory, Woodstock Kidney, Covent Garden Perfection, &c., a few representing scores of Potatoes of the finest table quality having yellow-tinted flesh. Of all the kinds here named none gives large tubers, except under gross cultivation. All are garden kinds, and just such as should be placed upon a gentleman's table. That we are not retrograding in the production of quality in new sorts, Mr. Penn's Woodstock Kidney affords evidence; it is a most delicious table kind. And only just now I have discovered in a kind I have grown for two years, but not previously tasted, a veritable table gem than which I have not seen a more tempting sample when dished up than this is. It is a kind originally received from the west of England, and is known as Gloster Red. The skin is netted, of a dull purplish-red, with blotches of white; in shape it is flattish-round, and, although the tubers are not large, it is a great cropper. I think, in all my experience, I could back this kind when cooked against any Potato in cultivation, excepting, perhaps, Woodstock Kidney. If growers would be content to get less bulk with the large kinds, no doubt the table quality would be improved. "Mantum in parvo" is an excellent motto for a good but medium-sized Potato, and those who have tasted really good ones will turn with repugnance from those tubers that have nothing but size to commend them. A. D.

Late-sown Scarlet Runners.—Mr. Legge's experience with late crops of these Beans (p. 423) is unfortunate, but he should not on that account condemn the practice of late sowing generally, as many can bear testimony to the value of late crops of Scarlet Runners, especially those who have to supply large establishments with every vegetable luxury that is procurable, whether in or out of season, and with whom a continuous supply of Beans is as necessary as Potatoes. It is needless in cases of this kind to allude to the amount of nutrition contained in any given vegetable, as it is the demand that one has to satisfy; that overrules all considerations regarding individual taste. During autumn and winter, doubtless the Haricot would carry off the palm respecting nutritive qualities,

but, nevertheless, the green pods are much more in demand, just as green Peas are preferred to dry ones. Your correspondent draws too gloomy a picture of our English climate, as here, during the whole of October, we had an abundant supply of both Runners and French Beans from the open air, excellent both in quantity and quality; and, far from thinking it a waste of seed and labour, I should decidedly adopt the same practice in future. Moreover, I would recommend any one similarly situated to follow the same course, as they will (unless exceptionally unfavourably situated) be well satisfied with the result. To make one sowing of vegetables that are in such continuous demand as Scarlet Runners, and when the supply from these fails, calling the season for them over is not, I feel sure, likely to meet with general approval.—J. GROOM, *Linton Park, Maidstone.*

ANSWERS TO CORRESPONDENTS.

Acacias as Window Plants.—Will the Acacia thrive in an ordinary sitting room? Does it require any particular treatment? The leaves are falling off, though they are not dead.—W. G. [Acacia lophantha the kind alluded to, now so much used for decorative purposes, is one of the easiest of a proverbially easy family of plants to grow, but all of them are liable to the attacks of red spider which quickly destroys the vitality of the leaves and causes them to fall off. A deficiency of water would have the same effect, or, if grown in a house where gas was used, especially in apartments underneath but connected with the room in which the Acacia was placed, the plant would also suffer. If affected with red spider, damp the leaves and dress them over thickly with flowers of sulphur, especially the undersides, and allow it to remain on for a week, when it should be washed off, keeping it from getting into the soil.—T. BAINES.]

Wintering American Aloes.—Could the ordinary American Aloe be safely trusted out-of-doors in an open shed for the winter? or is it important to take it into a greenhouse or conservatory? I have two plants, one the ordinary form and the other variegated, and thought of putting them into an open shed, and covering the pots in which they stand with dead leaves. Would this be a safe proceeding?—L. K., *Surbiton.* [The American Aloe will only live, without protection, in the Channel Islands and in the most favoured parts of the south of England. It will be best, therefore, to winter your plants under glass.]

Canadian Wonder French Bean (p. 429).—This should be grown by all requiring forced French Beans. If planted out in well-heated pits with plenty of room, quinceux fashion, 1 ft. apart, and stopped occasionally, the result will be an abundance of fine, well-nourished, succulent Beans, much better than the best pot ones, however well grown, and this the whole winter through, whilst half the quantity compared with other varieties will make a dish. To plant thickly is to court failure as, doubtless, many have done. For summer crops, all those who have not done so, should try the effect of placing sticks to the rows as is done in the case of Peas or Scarlet Runners. This was accidentally discovered by a few plants helping themselves to the sticks of an adjoining row of Peas, and bearing much more abundantly than usual.—W. C. *Blenheim.*

White Azaleas in the Open Air.—In reference to the question relative to these living in the open air (p. 430), I may mention that we have some here in open beds that have evidently been out-of-doors for several years. Being in an elevated position, however, vegetation does not suffer from frost so much as it does in low-lying parts, but a few miles off and soil has also much to do with hardness. A plant, therefore, may often be hardy in one place and tender in another. Here we have Myrtles, Azaleas, Aralias, Camellias, Chamerops excelsa and humilis, Colletia cruciata, and numerous other plants flourishing in the open air that will not thrive even a few miles off. The plants named above are not only such as have withstood the last few mild winters, but such as have been out-of-doors for a good average term of years.—J. GROOM, *Linton Park, Maidstone.*

Forcing Seakale.—How soon ought Seakale brought ready for forcing to be covered after planting? and will bell-glasses do for forcing it as well as Seakale pots?—M. PARIS [It should be covered immediately after it is planted. Neither Seakale pots nor bell-glasses are necessary. Of course you know that the old way of carrying out the manure to the Seakale plot is not now practised in good gardens. On the contrary, the Seakale is carried to the heating material, as yours must be. In the London market gardens a frequent and easy way now is to plant it in a trench, about 3½ ft wide in which has been placed some stable manure and leaves, a few hoops and mats being thrown over this, and the whole covered well at the sides with good stable manure, and the top with straw. The roots are planted in the trench in lines a few inches apart. This saves the cost of the Seakale pots, &c. At Frogmore Seakale is forced in a raised brick trench near one of the houses, using stable manure; in fact, it may be forced in a variety of ways almost anywhere there is heat and darkness. As in every place, however, it is best to use the appliances at hand, the best way, perhaps, will be for you to put some of it in one of the little chassis which the French plunge so snugly to the rim in stable manure. There it would do admirably, some Cocoa-nut fibre or some light earth being placed over the crowns, and some litter thrown over the chassis day and night of course. It would, no doubt, do well, though, perhaps, not so quickly in the caves where the Barbe de

Capucin is grown so well for the Paris market. Seakale is a plant quite as hardy as Chicory, the roots of which afford Barbe, and, judging by the free, clean growth of this as seen in the Paris markets, under the same conditions Seakale would probably be grown with equal success. Why not try a few dozen in a box in some warm, dark corner of your dwelling house? There must be places in the neighbourhood of your hot-air chamber where you can find all the heat and darkness desired. It would be very handy and cleanly if grown in this way. Try it; putting the roots in a box with some light earth, or Cocoa-nut fibre, or leaf mould, covering the tops slightly with the same material.—R.]

Paraffin Oil no Cure for Slugs.—Seeing (p. 391) that paraffin oil was proved to be a cure for scale and green fly, and having heard that it was death to slugs, my heart rejoiced exceedingly, and as no mention was made of the proportion of oil and water, I thought I would try some oil alone. Six fine, healthy slugs were soon found, and they certainly did not like their bath; they shed their slimy coats, and started each on his own way. A friendly snail made his appearance, so I gave him a few drops; he frothed at the mouth a little and passed on. I administered a second dose to the slugs, but on returning in half-an-hour to look for their corpses, they had all fled. Possibly young plants watered with oil and water may be protected from the attacks of slugs, which may not like the paraffin, but that it is not fatal to snails or slugs unless put a-lique I have proved.—R. G. V.

Mildew on Roses.—Mr. Baines' remarks on pot Roses (p. 399) are invaluable to amateurs; but why does ventilation by means of side lights produce mildew? I am about to build a small Rose house, and am much interested in this matter. I have no doubt of the truth of the assertion, as doubts regarding side ventilation have always existed in my mind. Still, the observations of Mr. Baines seem to convey a greater knowledge of mildew than I possess, and enlightenment would greatly oblige.—JOSEPH POTTS, *Sunderland.* [The foliage of Roses, in common with that of other hardy plants when grown under glass with more or less fire heat, is comparatively much tenderer than the leaves of plants are that absolutely require artificial heat in this country, and if checked in the least they at once become fit receptacles for mildew. The external air is so much harsher and colder, except in summer, than that of the houses in which they are grown, that when admitted through side openings it at once affects the tender leaves and extremities of the shoots, and renders them liable to mildew, hence its presence under such conditions. But I should recommend Mr. Potts, in the construction of his house for Roses, to provide the means for giving side air, as some may be required in summer, and the house may at some future time be wanted for the growth of other plants besides Roses. In the erection of houses for horticultural purposes I always make such provision as will allow them at any time to be used for growing plants that may require treatment different from that of the plants for which they are first built.—T. B.]

The Catawba Graps.—Where can I get this Grape? I have inquired of various nurserymen, but without success.—C. E. [Try Messrs. Ellwanger & Barry, the great American nurserymen, Rochester, N. Y.]

Aralia Sieboldi in Flower.—"J. R.," Eastcott Cottage, Pinner (p. 430), is not alone as regards his Aralias flowering in the open air in October, as all our outdoor and conservatory plants of this Aralia are in full flower. The blooms resemble those of common Ivy.—J. G.

Erodium.—Seeing that "W." (p. 430) has put M. J. Sisley right as regards Erodium pelargoniflorum, allow me to point out a widespread error in the spelling of another Erodium, viz., *E. caruifolium*, which is generally written with a *v* instead of *z*, a hybrid word with no meaning. The name is taken, not from Carve, but Carui, the plant that yields the well-known Carraway seeds.—THOS. WILLIAMS.

Names of Plants.—*W. E. R.*—I too much shrivelled to be recognised; 2, *Passiflora princeps*; 3, *Adiantum trapeziforme*; 4, *Davallia elegans*. *V. T.*—*Virginian Poke* (*Phytolacca decandra*). *J. F.*, *Leogram*.—3, *Habrothamnus elegans*; the other specimens not being in flower, cannot be named with certainty.

Tuberous Tropæolums.—Mr. A. Henderson informs us that the seeds of these usually lie twelve months in the ground before vegetating.

Questions.

East Lothian Stocks.—I should be pleased to have the opinion of Stock growers as to the cultivation of these flowers—I mean as regards their hardiness and general management.—R. GILBERT, *Burghley.*

Scale on Epacris.—I have some large plants of Epacris infested with white scale. Can any of your correspondents give me a receipt that will effectually kill it without injuring the plants? Would paraffin-oil diluted with water be of any use?—W. M. S., *Manchester.*

Cutting Down a Large Screw Pine.—We have growing in the centre of the stove here, in an 18-in. pot, a large Screw Pine (*Pandanus utilis*). It has a bare stem at the bottom of about 8 in. or 9 in., and is 9 ft. high. As it is getting too large for the house, would some one kindly tell me: 1. Whether it would grow again if cut down? 2. When is the best time to cut it down? 3. Whether it would be best to cut it off close to the pot, or to leave a good long stem?—DEWSBURY.

Conservatory Ferns.—I should be glad if some correspondent would kindly give me a list of about a dozen good ornamental Ferns (not English) which would be suitable for planting out permanently in a shady, unheated conservatory.—S. CHAMP.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

ROSES.

NOTES BY AN OLD ROSARIAN.

THE Rose has had many chroniclers, from Sappho to Reynolds Hole; its praises have been sung in all lands, and in many tongues; it has inspired the poet's thoughts, has delighted the love-sick swain, and has ministered, alas! to the whims of tyrants; it has been, in our own land, the emblem of that civil war which laid low the bravest and best of our old nobility; but never was the Rose so extensively cultivated as at the present time; our Rose nurseries increase in number and size every day; the demand for it is insatiable, and from the cottager's garden to the nobleman's pleasure ground everywhere the Rose is grown and is reckoned the queen of all flowers. And should it not be so? Apart from all associations connected with it, it has in itself charms rarely combined in a flower—its delicious perfume, the brilliancy of its hues in some and the delicacy of its tints in others, its adaptability to succeed in all soils and climates, and the profuseness of its blossoms all combine to make it the favourite it is; and that would be, indeed, a strange specimen of humanity who would attempt to decry the Rose. Yet have I a complaint to make, not against the Rose, but against the way in which it is regarded now—the one point which seems above all others to be thought of in connection with it is its character as an exhibition flower. Like the lady at the Royal Botanic Show who, seeing one of Mr. Bull's valuable stove variegated plants, enquired, "Is it good for bedding out?" so now everything seems to be summed up in the praise of a Rose when it is said it is a fine exhibition flower. It is for this cause that the old-fashioned Roses are well-nigh banished from our gardens, every space therein which cannot be occupied by a Duke of Edinburgh or a Baroness Rothschild being grudged by most modern Rose growers. How rarely do we see the old Cabbage or even the common Moss! and yet what more fragrant than the one or beautiful than a bud of the other? For this cause Roses that have not an atom of scent in them figure largely in the garden. We confess to an admiration of Baroness Rothschild or Mons. Noman, but if they had not been exhibition Roses they could never have sustained the place they have. For this cause, too, Roses that have no more constitution than the inmates of a consumptive hospital are petted and coaxed in order that they may give a bloom or two, and then be consigned to the rubbish-heap, inducing, by their appearance on a "winning stand" on a show day, some less experienced grower to "order" them, only to see them pine away and die. For this cause some of the most beautiful Roses are spoken contemptuously of as Daisies or Ranunculuses, because they are so small; thus, in all the domain of the Rose Queen, there is not a more beautifully-shaped Rose than Comtesse Cecile de Chabillant, the only one that poor Marest ever raised, and yet it is gradually becoming less and less seen, until many a Rose grower will be ashamed to confess that he ever exhibited the flower, and all this because it is small. For the same reason a Rose almost unique in its colours, Souvenir de Dr. Jamain, is rarely seen, and many others are only tolerated because now and then they may give an exhibition flower. For

this cause, too, Roses are divested of all their buds save one, so that in the garden of the Rose grower whose soul soars not beyond the exhibition table, one never sees the Rose in its most beautiful aspect, like a comely matron surrounded by a bevy of lovely daughters—all must be pinched off save the one which is destined to figure at the show by-and-bye. Now I do not depreciate shows and show Roses. I believe the Rose would never have obtained the wide popularity that it has had it not been for our Rose shows; nay, it is because I value them, and more because I love the Rose, that I desire to raise my voice against a too exclusive reference to them in our Rose growing. I would write for those who desire to find a delight in the Rose, not merely those which modern intelligence and skill have added to our store, but those of former days of which poets sung and for which lovers sighed; nay, sometimes as I go out from my own garden, where the choicest and newest varieties are grown, I stand in admiration before a wild Rose, with only its petals and its golden anthers, which has festooned itself with a grace no training could give it, and wonder, after all, whether man has not rather spoiled than beautified Nature's work.

Those who took the trouble to look at the stand of old-fashioned Roses exhibited at the last meeting of the National Rose Society must have been surprised to find how many beauties had been overlooked in the rush for the larger and more brilliant novelties. Amongst those shown on this occasion were the following (I omit the half-dozen Teas): Scotch White, Fabvier, Cramoisie supérieure, Crimson China, Félicité Perpetuée, Aimée Vibert, Lamarque, Bourbon Queen, Old Cabbage, Yellow Provence, Madame D'Arblay, Ruga, Crimson Damask, Old Damask, Rosa Muudi (commonly called, York and Lancaster), Madame Legras, Chénédolé, Crested Moss, White Bath Moss, Fairy, The Garland, White Globe Hip, Comtesse de Lacepède, Village Maid, Rose de Meaux, Coupe d'Hébé, York White, Kean, Hypatia, Fulgens, Alba Félicité, La Ville de Bruxelles, Madame Hardy, Mrs. Bosanquet, Crimson Boursault, Blairi No. 2., besides some others of which even the diligence of Mr. Julius Sladden, of Chipping Norton, who exhibited them, could not discover the names; but it is evident from this list that there were many others which might have been added as coming within the terms named, *i.e.*, Roses known before 1840. The Austrian Roses were unrepresented. Amongst Gallica Roses, too, D'Agasseau, Boule de Nanteuil, and Adele Prévost might have been added. Then the Banksia Roses were absent, so that, if, as it is to be hoped, the National Rose Society should continue to offer prizes in this class, the zeal of cultivators and lovers of the Rose may rescue from oblivion some of those flowers our forefathers delighted in; and this need not be any retrograde path; if the lovers of herbaceous plants consider the re-awakened taste for the old-fashioned flowers of former days not a falling away, but an advance in gardening, seeing that there is more skill required for their cultivation than for the multiplication of thousands of Zonal Pelargoniums, and that the variety they exhibit is infinitely more beautiful than the best polychrome arrangement of the modern style, so at least the lover of Roses may claim that in seeking to bring back into our gardens many a discarded favourite, he is adding to that variety which even a Rose garden may be benefited by. If, then, in taking up the subject of the Rose, I wander somewhat from the beaten path, if I regard it less as an exhibition than as a garden flower (although I do not propose to leave it out in any of its aspects), I may perhaps be doing some little service to a wide circle of its admirers who, reading of all that seems necessary to obtain good flowers, despairingly hold up their hands and say I must

leave that to others. If I can show such that as much real enjoyment of the flower can be had from it in a quiet way as the most successful exhibitor ever had, and if I can induce some to try again many an old favourite which is now nowhere in the race, I shall feel that I am contributing something as a loyal subject to raise still higher the standard of our lovely queen.

ROSES IN MARKET GARDENS.

HYBRID PERPETUAL ROSES.—These are not grown in houses in nearly such large quantities as are Tea Roses, because to force them into bloom early in the year incurs much trouble and expense, and the blooms once cut from them, the plants are, comparatively speaking, done for the season; whereas Tea Roses keep on growing and flowering; and, moreover, their blooms are more valuable than those of any other kind of Rose. Mr. Ladds, of Bexley, grows Hybrid Perpetuals in larger numbers than any grower I know of near London; he has a house of similar dimensions to those already referred to filled with them during winter and spring. These furnish a quantity of blooms at Easter and keep up a supply until Roses become plentiful out-of-doors, after which time they will not pay for house room. The varieties principally grown are General Jacqueminot and Victor Verdier, these being preferred to all others on account of their perfectly formed and richly coloured buds. The plants are grown in the form of standards from 3 ft. to 4 ft. in height. They are planted during the summer in the open ground; and in the autumn, after being slightly pruned, are taken up and planted indoors in beds specially provided for them, and in this position they yield thousands of buds during May and June, after which time they are again planted outside. Sometimes the plants suffer in consequence of being thus suddenly turned out of a warm house into the open air even in April, but having the whole of the summer to recruit themselves they invariably give satisfaction. Mr. Maller, of Tottenham, has a long span-roofed house permanently planted with General Jacqueminot. The plants, which are on the Manetti stock, occupy beds on each side of a centre path running through the house. The ends of the shoots are yearly pegged down to the soil, which causes them to break freely and produce a dense thicket of strong shoots, each bearing large trusses of blossom. They are usually in flower at Easter when the blooms are of most importance. The only objection to this plan is that the house is made unavailable for other plants during the time the Roses are not in bloom; but anyone wishing to adopt this system might have the lights forming the roof of the house made so that they could be easily removed during summer and autumn and used for other purposes, and this would benefit the Roses by exposing them fully to the weather. Mr. Reeves, of Acton, grows all his Roses in 6-in. and 8-in. pots; they are brought into bloom in three successive batches, each consisting of about 1000 plants. The first batch come into flower early in March, when they fetch 9s. per dozen; the second in April, and the third in May. After blooming is over the plants are plunged out-of-doors for the remainder of the summer in a sunny situation. In autumn when wet weather sets in the plants are laid on their sides to ripen their wood. They are pruned in October or November, and the first hatch are placed in a cold frame until they break into growth and bloom buds can be discerned, when they are removed into a warm house, and replaced by the second lot. The

variety grown here is also General Jacqueminot. Early in June we often find in the market Hybrid Perpetual Roses in 6-in. pots offered for sale. Such plants are very dwarf and bushy, the foliage being clean and healthy, and each plant bears from five to eight good blooms. Plants like these are seldom found in private gardens, owing chiefly to the fact that gardeners force them too rapidly, or have not often suitable places in which to grow them. The great point to be observed in forcing Roses is to bring them on with as little heat as possible until the bloom buds are discernible, after which they will stand comparatively rapid forcing. Frequent syringing, fumigating, and plenty of water at the roots are also points of great importance in forcing Roses. A large quantity of cut Roses is supplied during summer by growers who deal in Roseplants, and as these are benefited by the removal of the blooms, a twofold purpose is thus served, and the money obtained for the flowers, which is from 15s. to 20s. per hundred, goes a long way towards paying for labour, &c. Some growers have, however, permanent plantations of Roses on the Manetti stock on purpose to supply cut blooms. In this case they are planted about 4 ft. apart in rows, the points of the strong shoots being yearly pegged to the ground. A warm border or open plot is selected for them, the ground is heavily mulched with half rotten manure, and large crops of flowers in early summer and late in autumn are gathered from them. The chief objection raised to the pegging-down system is that the ground cannot be kept clear of weeds; but when it is heavily mulched comparatively few weeds make their appearance. The best thing in use for the prevention of the green fly on Roses is a solution of Quassia chips; it is cheap, clean, and easily prepared. Among suitable kinds of Roses for outdoor planting in the way described the following may be named, viz., Alfred Colomb, Charles Lefebvre, Edouard Morren, General Jacqueminot, John Hopper, Boule de Neige, Gloire de Dijon, Lord Macaulay, Senateur Vaisse, Madame Chas. Wood, alba rosea, and Victor Verdier. Gardeners a few miles from London who grow outdoor Roses expressly for market in the shape of plants or cut flowers provide themselves with plenty of propagating pits and stock plants. For Tea-scented varieties, the cultivated seedling Brier is the favourite stock, and for that class of Roses it is superior to the Manetti. When the plants are grafted in winter and spring they are plunged in bottom-heat in close and shaded frames, and as soon as they have rooted fairly and have begun to grow they are repotted, and replaced in the same frames as before until root action has again fairly commenced, after which they are placed on the side shelves of the houses or pits to make room for others. They are afterwards potted as required, pinched when the shoots have a tendency to become too long, and gradually inured to a cool temperature. During this period they are kept moderately moist with tepid water, gently syringed overhead every fine day, and kept in as light houses as possible. Tobacco water or Quassia water are used to keep down green fly, and flowers of sulphur to keep down mildew. By the 1st of June these young plants are hardened off, so as to be ready for planting out. Beds are prepared for them in deeply-worked soil, liberally enriched with old manure and leaf-soil, and having an eastern or south-eastern aspect if possible. Here they are planted in rows at variable distances, and over their roots is placed a mulching of Cocoa-nut fibre, leaf-soil, or decayed manure. In planting it is an important point to bury the point of union of stock and scion in the soil, so as to encourage the emission of rootlets from the scion, thus giving the plants additional support. Such as are required for retaining in pots are re-potted

in a compost consisting of two parts rotten manure, one part leaf-soil, and three parts loam, and plunged out-of-doors in beds, and treated like permanently planted ones. The pot plants, as winter approaches, are brought indoors to be forced if necessary, and to supply scions for grafting. The permanent bushes remain untouched, with their mulching still round their roots, until the pruning season comes round in spring. The ground is then cleared of all prunings and hoed, and otherwise made properly clean; but at no time are the alleys between the Roses dug or even what is called pointed. A fresh mulching consisting of two loads of decayed manure mixed with one load of leaf-soil is then laid on thickly, and this keeps the roots moist, and near the surface. The result of this treatment, as might be expected, is healthy, vigorous plants and abundance of Roses. Before the buds begin to expand a small piece of bast matting is tied—not firmly—around each to preserve their symmetry and prevent their expansion; for as during the height of the Rose season blooms are cut daily, or at least three times a week, the quality of the buds is not thus impaired. They are cut early in the morning when the dew is on them, and in this way they travel better, and keep fresher than if gathered later in the day when they are dry.

C. W. S.

THE KITCHEN GARDEN.

IMPROVED ASPARAGUS CULTURE.

MR. W. ALLAN's instructions for the formation of Asparagus beds (p. 428) would, I doubt not, be found very useful to "An Elderly Amateur," who wishes to be informed respecting their construction after the most approved pattern—that is to say, if he desires that in due time his table shall be supplied with heads as big as thumbs; but if fingers would satisfy him, it is possible he might find it worth while to dispense with beds, and grow the plants singly in ordinary borders. Taking out the soil to the depth of 2 ft., and bringing in abundance of turf, crushed bones, and stable litter—all this can easily be accomplished where there are plenty of hands and ample means, and the conviction that all this is necessary if you intend to grow Asparagus is just that which deters those who have neither a long purse nor extensive grounds from providing themselves with this desirable luxury. They are, perhaps, aware that Asparagus does not yield produce that can safely be gathered till it has occupied the ground for four or at least three years. This they would put up with; it is the other difficulties that scare them. A single plant of Asparagus requires a space of at least one square yard to grow in, and, indeed, it soon extends its roots beyond that limit. Hence economy of space is promoted by planting Asparagus in beds, where the roots can cross each other, and in time become a tangled mass, and they would soon exhaust the ground in which they grow, unless they were most liberally supplied with stimulating nourishment. The Asparagus plant, if allowed sufficient room, requires no more manure than do the other garden crops; indeed, if sufficient attention be given to it by occasional top-dressings of salt, with a little soot or artificial manure, it will produce in the open quarters fine shoots and plenty of them; but, grown in this way, it requires more room than it does when planted in beds, and our object, of course, will be to ascertain how space may be economised. Here the plants stand in a single row about 34 in. from crown to crown, and 18 in. from a gravel path into which they can, and they do, send their roots on that side in search of nourishment. On the other they have their own border, which they share with Carrots, Broccoli, or whatever the crop may happen to be next them. But these are not allowed to approach the crowns of the Asparagus nearer than 3 ft., and the space left vacant is sometimes utilised by pricking out young Lettuces, Broccoli plants, &c., in it. It is important not to damage the roots by digging too near the crowns; the fork only should be used, and that very carefully, in the space

allotted to the Asparagus. It will be perceived that by this arrangement loss of space is considerably diminished, and there is no need whatever for an excessive expenditure of stable manure. An ordinary Asparagus bed takes as large a slice on of the manure heap as a crumpet does out of a pound of butter. The liberal supply of bones, turf, and manure with which the beds were at the first enriched, gets exhausted in the course of time, and then the plants have to depend entirely for their support on what is washed into the soil through the top-dressing by the heavy rains. Another advantage gained by the adoption of the system advocated relates to the choice of plants. One-year-old plants seem to be generally recommended with a view to results. I should, however, prefer a good admixture of plants of two years' growth. The number that fail will most likely be very small, and they can be replaced by others if they do not thrive. At the time of planting, or a little earlier, a sowing of seed should be made in another border for a supply of plants either to fill vacancies, if there happen to be any, or to extend the plantation if desired; but it will be found that considerably less than half the usual number of plants will be wanted if your Asparagus is grown in the manner herein recommended. The distance from plant to plant which Mr. Allan gives is very much greater than is usual with Asparagus grown in beds. Johnson's "Gardeners' Dictionary" (edit. 1870) directs that the plants should stand 1 ft. apart, and Mawe's "Gardener" (edit. 1868) makes the distance 10 in. or 1 ft., much too near for the plants to thrive. As to the depth at which they should be set, I think 3 in. will be found sufficient and more conducive to the growth of the plant than if it were put in deeper, and even a less depth I would recommend if top-dressings of fresh soil can be obtained. When making sowings of Asparagus, be careful that only a single seed is deposited in one place; laying the seeds at equal distances along a flat strip of wood and reversing the latter over the drill will facilitate this operation. You are not likely to want many plants; therefore allow them room enough, and they will be all the stronger in consequence. When the plants bear seed, if the tops are not removed before some of it has dropped, the seedlings produced must be removed as soon as they are discovered. In recommending this method of cultivating Asparagus, I assume that the soil in which it is tried is of fair average depth and richness, and in other respects suitable to the growth of the plant.

B. S.

VEITCH'S AUTUMN SELF-PROTECTING BROCCOLI.

We are now cutting magnificent heads of this Broccoli, which in all respects seems equal to Veitch's Autumn Giant Cauliflower, and as the qualities and value of this are so well known, no greater praise can be bestowed on it. This Broccoli, coming in as it does just now, when the season for Cauliflower is nearly over, and before such as Snow's, Osborn's, Backhouse's, or others can be had, fills up a gap that has always occurred in the supply at or about this season of the year, when there is generally a greater scarcity of choice vegetables than at any other time, as Seakale and other forced vegetables do not generally aid us much till after Christmas. Although this fine autumn Broccoli is very self-protecting, I find it always advisable to heel a good many in on a warm, sunny border, where they can be easily and quickly protected by throwing a few mats or other covering over them on the appearance of sharp weather. So cared for, the heads are safe, as, although there may not be frost enough to injure the white heads so far as to discolour them, the least touch always imparts a strong taste, and quite spoils their delicate flavour. I could tell a Broccoli or Cauliflower that had been nipped by frost by the smell after being cooked without seeing or tasting it, as the odour which they exhale is very disagreeable. Opinions on the utility of laying Broccoli appear to differ, but there is a great contrast between such as are grown in rich, enclosed gardens and those in poorer soils in open fields around London the stems of which are small in comparison and altogether of a harder and more woody nature. Such as these will stand when others would be killed outright; and although, no doubt, laying them checks growth and the size of the head they produce, it is much better to have a quantity of small one than to risk the loss of the crop altogether. This being so, I

would advise that a portion, at least, have their stems protected by sinking them in the ground, either where they are growing or some other spare, vacant spot where they can be put closer together, and set the land they occupied previously at liberty for some other crop earlier than it would otherwise be. As to which way the tops slope to the north or south, it matters little, as the weight of snow or cold is sure to press all the leaves down flat over each other, and it is these that then protect the stems and crown, and keep the little warmth there is in the ground by stopping radiation and preventing the frost entering. Standing upright in their natural position, the leaves fall away from the crowns, which is the most vital part of the plants, and leave them fully exposed to frost and the blast of cold, cutting winds, under which ordeal many of them must of necessity succumb.

S. D.

REMOVING THE SEED FROM ASPARAGUS.

THERE is in THE GARDEN (p. 429) a very good article on the growth of Asparagus. One direction, however, is omitted, viz., the carefully picking off all dropped seed, the ruin of the best bed ever made. Unless the bed be carefully swept every year the fallen seeds produce plants, and the consequence is that want of room causes progressive diminution of size, until at last the heads do not arrive at a greater girth than a quill pen; the roots get irremediably mixed, weeding cannot be satisfactorily done, therefore the bed that should have been in perfection twenty years after planting has to be destroyed in ten, and all owing to a little neglect in not carefully removing the seeds. As for management of Asparagus, the less said the better, for what applies to one soil fails in another, nor without considerable expense can any one arrive at perfection. As for forcing Asparagus, it is a mistake. We, in Dorset, every year try the plan of destroying part of an old bed, but the produce is colourless and flavourless, even if you do succeed in producing respectable-looking heads at a cost of twenty times their value. Give the beds, both in November and March, as much salt or brine as you can get; if happily you reside near the sea where there is a sandy beach, the Asparagus, equally with the Seakale, enjoys being well dressed from the coast, and at the same time there is an immunity from slugs and worms. The only questions not settled—Should a bed be made raised or flat? Should there be good drainage or none? of course, supposing the ground fairly dry. Should, as at Bath years ago, large patches be cultivated, or should only single lines be planted at a distance of 18 in. between each plant? Above all, never cut a head smaller than a man's little finger, nor ruin next year's crop by cutting at all after the first week in June, and, if an early season, not so late as that.

Litton Cheney, Dorset.

E. E. P. LEGGE.

Cloches and their Prices.—I was asked the other day a fabulous price in London for a cloche. Now, judging from what I saw in Paris, and from what I know as regards England, I am satisfied they can be manufactured and retailed equally cheap in both countries. There must be hundreds, like myself, who would gladly take their 200 or 300 16-in. cloches if they could get them at 1s. or 1s. 1d. apiece if they only knew where to get them. In the suburbs of Paris I saw acres on acres of them, and why they should be used in a drier and milder climate than our own and not in our own is a puzzle to me. For early Rhubarb, Seakale, winter salads, Strawberries, Tomatoes, Capsicums, &c., they are invaluable; you can protect against climate without nonnatural forcing. Light is as essential for flavour as it is for general growth, and a larger use of the cloche would enable many a market gardener to find a ready sale for salading, which, I believe, is largely supplied at present from France. My object in meeting this cloche question is to be able to extend my salad growing later towards winter and earlier towards spring than our climate allows.—KHODA BUX.

Veitch's Autumn Giant Cauliflower.—My gardener brought in on Wednesday (November 13) one of Veitch's Giant Cauliflowers, the weight of which was 8½ lb., and the circumference 42½ in. The weather has been very cold, with snow and frost; the latter obliged me to cut it before it had attained its full growth; it has, however, proved excellent eating. Is not this an unusual size in this inclement season, even for this giant kind? The seed of it was sown March 11, and the seedlings were pricked out May 1, and planted out June 19.—A. L. GODFREY, Kennett Hall, Newmarket.

Forcing Rhubarb and Seakale.—At this season of the year, when the forcing of such vegetables as these is occupying attention, it cannot be too strongly urged that many are deterred from attempting so simple an operation by the supposed difficulties of the under-

taking, whereas both may be most successfully forced in positions that cannot be otherwise utilised. Wherever boilers are fixed for heating hothouses, or buildings of any kind, there is, as a rule, some of the main pipes that must of necessity pass through positions where their heat is not required; all that is necessary is to make up a rough box of the desired size, and plunge the roots in light soil, covering the crowns with dry leaves, Fern, &c., and laying over the whole a lid to exclude light; keep the soil moist, and regulate the heat by raising or lowering the box, and as good a supply of Seakale and Rhubarb may be obtained by such simple means as from the most elaborately-finished structure built specially for the purpose.—J. G.

French Beans and Scarlet Runners.—Mr. Groom (p. 453) argues well, yet forgets that Kent is the garden of England, and that many experiments in horticulture may succeed in that county which would always fail where the stroke of the south-west wind comes; and if there be much water near the Beans, the earliest frost finishes them for culinary purposes, often causing the dry ones to rot. If I may offer a suggestion to a far more experienced cultivator than myself, it would be that cool frames, covered on frosty nights only, would furnish a constant supply of French Beans throughout the autumn. These Beans, however out of season to my taste, are as much out of place as the Telegraph Cucumber before salmon comes in. Last spring I had good success in forcing Strawberries, and they were valuable to send to a sick friend; I ate one, an Eugénie, and thought it very insipid. The only vegetation worth extreme forcing is that for ornamentation. All flowers pay well, and are as requisite to set off the dinner-table as to furnish a bouquet, or complete the dressing of a lady's hair.—EUGENE E. P. LEGGE.

— For some years I adopted the plan of late sowing, as recommended by Mr. Groom (p. 386), but for several years I have discontinued it. I now sow a full crop regularly about the third week in April always on ground trenched three spits deep and well manured, and, if possible, have the rows near the walks, so that the ground is only shaded on one side of the Beans; they are staked with freshly-cut Sycamore sticks 13 ft. long and from 1½ in. to 2 in. in diameter at their base. The sticks are put in much out of the upright, slanting from the row, and then they are brought together and made to cross each other, like the letter X, another stick rail fashion being laid along the upper angle to keep them in shape, as one stick springs against the opposite one; and, held by the rail, they withstand gales of wind, which, if staked in any other way, would render them useless, taking into consideration the height they are grown. The rows are upwards of 10 ft. high, and clothed with foliage and Beans abundantly every season until destroyed by frost. Of course, we have to gather them by means of steps, but the rows occupy no more ground than if only 6 ft. high. I make it a rule to stop the plants when 2 ft. or 3 ft. high, and once or twice afterwards; also to keep them gathered clean throughout the season, except those left for seed. The Sycamore sticks are only fit for Beans one season, as they would not stand wind when dry. Ash is the best, and will last three years; but the Sycamore underwood is plentiful hereabouts, and the thick end come in for Dabbias, &c., the following year, or they do for the labourers, who grow their Beans less strong, and are always glad to have a few Bean sticks. Carters' Champion is a fine sort for exhibition, many of the pods of which measure 8 in. long, but I think the old sorts, such as Painted Lady, &c., would produce an equal weight of Beans.—J. G., Exeter.

— I cannot agree with Mr. Legge's remarks (p. 423) respecting late Scarlet Runners. I always try to have them as late as possible, and also the dwarf French Beans, and, after forty years' experience, I never remember having any complaint as to their being out of season. On the contrary, I have found them even more useful than in midseason. This year we had the last dish of French Beans on the 2nd inst.; they were gathered (Oct. 30) from plants growing close to a south wall, the ground on north borders at that date being frozen. We also had a good supply of Runners through October; the last were gathered November 4, after several slight frosts. I had the last of them cooked on the 16th inst., being then plump and fresh, and all that could be desired. If Mr. Legge could have tasted them he would have said no more about Beans not being nutritious; and, as regards usefulness, I quite agree with Mr. Groom, that they are as much a luxury late as early.—W. DIVERS, Wierton Place, near Maidstone.

A New Early Tomato, the Alpha.—A basket of fruit of this variety was sent me on August 23 by Mr. Frank Ford, of Ravenna, Ohio, as the result of his experiments during several years in procuring a variety that combined excellence of form, colour, and quality, with earliness. Mr. Ford states that the specimens sent were gathered ninety-four days after the seeds were sown in the hotbed. For the rest, we can say that in form, colour, solidity, and good flavour, they are as good as the best.—"American Agriculturist."

DEATH OF JAMES McNAB.

MANY of our readers will be very sorry to learn, and it is with great regret we have to announce, that JAMES McNAB, long Curator of the Royal Botanic Gardens, Edinburgh, died there, last Tuesday. Lately apparently vigorous and in good health, many who knew him will be quite unprepared for the announcement of his death, which is a loss to horticulture, to the Edinburgh garden, and to Scotland, throughout which he was so well known and so greatly esteemed. A more fitting man to be curator of a botanic garden it would be difficult to find, being a great lover of plants and having a full knowledge of them and the essentials of their culture. The Edinburgh garden bore marks of this in many ways—in its rich collections of hardy plants and trees, in its Palms and other indoor plants, and reserve gardens, which were the richest we know of in any public garden. Having early made a good acquaintance with United States and Canadian plants by travelling in these countries, his knowledge of them was of such a kind as to be exceedingly useful to the curator of a botanic garden and to a landscape gardener. For twelve consecutive years before 1834 he served as an apprentice, journeyman, and foreman in the Edinburgh Botanic Gardens

with his father. Besides general routine work, his early life was much devoted to the preparing of plans of gardens, greenhouses, heating apparatus by steam and hot-water, as well as in the drawing of many of the plants which flowered in the Edinburgh gardens and nurseries from the year 1829 and onwards. These were figured in the "Botanical Magazine," Sweet's "British Flower Garden," and other works. The year 1834 was spent in travelling in the United States and Canada, and the records of the more interesting plants obtained in this journey are to be found in a series of papers published in the "Edinburgh

Philosophical Journal" for 1835, and in the earlier numbers of the "Transactions of the Edinburgh Botanical Society." In 1835 he was appointed Curator of the Caledonian Horticultural Society's Experimental Garden at Inverleith, where, besides the management of the garden, he had much practice in landscape gardening. This situation he held till 1849, when, on the death of his father in December, 1848, he was appointed Curator of the Royal Botanic Garden. At that time the garden contained only fourteen imperial acres. Since then the

history of the garden has been one of improvement, of extension, and of progress, largely owing to his work therein. In addition to the extensive practice of gardening, Mr. McNAB has often been a contributor to horticultural literature, as his writings, not only in THE GARDEN, but also in the transactions of the Botanical Societies of Edinburgh and elsewhere amply show. He did not, however, confine himself to strictly botanical and horticultural matters; on the contrary, his writings embrace numerous essays on Vegetable Climatology, landscape gardening, and arboriculture, all of which, if gathered together, would form many volumes. He was a corresponding member of several societies, both at home and abroad; also one of the original members of the Edinburgh Botanical Society, established Febru-

The Late James McNab.

ary 8, 1836, to the transactions of which he has been a frequent contributor ever since their commencement. Regretting his loss as one of the most advanced of the true school of gardeners, we have also to regret the loss of a valued contributor, his very last contribution to our columns being a reply to a question on Pandanus in this issue. His family will have the sympathy in their loss of all who knew him well, and we cannot express a better wish for the Royal Botanic Garden and its collection than that they may always be in the charge of men not unworthy to be successors of JAMES McNAB.

THE FLOWER GARDEN.

SUMMER AND WINTER BEDDING COMBINED.

Now that there is such a wealth of material in the shape of plants suited for the furnishing of flower beds in winter, there can be no excuse for these remaining empty after the summer-bedding plants have been cleared away, *i.e.*, if labour and the wherewithal to obtain the plants are forthcoming. Of course, it is useless to suppose that additional labour is not required to carry out both summer and winter bedding; but where this is allowed, or can be obtained for the asking, then I strongly recommend this kind of decoration being carried out to the fullest extent commensurate with means and demands. After several years' experience, I would not now give up my bit of winter bedding, even if challenged to do so by the withdrawal of the little extra expense which it entails. There are potent reasons why winter bedding should be encouraged. First, there is the season, when all around us is bleak, dull, and bare—leadens skies, leafless trees, flowerless meadows, and silent woods; all of which have a somewhat depressing effect on most temperaments. It, therefore, behoves us to endeavour to neutralise this prevailing dullness by making our gardens as cheerful as possible. Another reason, and one which, to those fond (as thousands are) of summer bedding, should be the great reason for adopting the system is the short period during which summer bedding continues in perfection, for the thought is continually haunting one that it will fade all too soon. The adoption of winter bedding, however, in my own case has obliterated such thoughts, and now one looks forward to and has a continuation of real pleasure derivable from both systems. Nor has this been the only result; others equally beneficial, perhaps more so, have, as it were, accidentally fallen in our way, and in this wise: It having been a *sine-qua-non* that summer and winter bedding must meet, compulsory ingenuity had to devise ways and means for the accomplishment of this result in the most effective and economical manner possible. This has led to our searching out and using as summer bedders many hardy plants which otherwise we should not have thought of using, but which are just as effective as tender exotics; nay, in some cases more so; and which when planted in the spring serve till the following spring, when they are taken up, divided, and replanted for another year. It is doubtless the endless labour connected with the short duration of summer bedding that has brought it into disrepute in some quarters, and one is obliged to admit very justly so, but if we can combine, as I intend we can, summer and winter bedding, then much of the opposition to formal parterre planting would cease. From the above it will be perceived that a sort of compromise, a give and take, a tender and hardy system of bedding is that which is here advocated. For instance, in summer planting a goodly number of the more handsome and showier growing Conifers and other shrubs should be brought into use for the filling of vases, centres of beds, and as dot plants in the larger beds. Amongst the best plants for this purpose are *Retinosporas*, *Thujas*, *Junipers*, *Cypresses*, *Biotas*, *Yuccas*, standard *Golden Yews*, standard *Cotoneasters*, variegated *Hollies* and *Euonymuses*. For lines and groundwork the following are most suitable, *viz.*, *Sedums* of many kinds, *Saxifrages*, *Sempervivums*, *Cerastium arvense*, *Mentha Pulegium gibraltarica*, *Veronica repens*, *V. incana*, variegated *Thyme*, variegated *Arabis*, and others. These hardy plants being worked in with the summer arrangements, and, so far as my own experience goes, with evident improvement to the tenderer subjects, give so much the less labour when the time for the winter arrangement arrives, a few days at the most sufficing for the clearing out of tender plants and replacing them with hardy ones. Amongst the best for taking the place of *Pelargoniums*, &c., are hardy *Heaths*, variegated *Ivies*, variegated *Periwinkles*, *Cotoneasters*, *Berberis*, *Aucubas*, variegated *Box*, variegated *Euonymus*, *Lavender*, common and variegated *Thyme*, *Pernettyas*, &c. W. W. H.

Wintering Gladioli Out-of-doors.—It having been suggested that bulbs of Gladioli when left in the ground over winter will start in spring quite as well as when taken up and replanted, allow me to add a bit of my experience in regard to this matter. I believe

it to be safer to take up the full-grown bulbs, as a very wet or a very cold winter might destroy many bulbs which could have been saved. I would not leave out any seedlings, but the young brood bulbs ought in every case to be left in the ground, or rather be replanted immediately after taking up the full-grown ones. These brood bulbs have a coat, which, when getting quite dry, hardens very often to such an extent that they must lie one year in the ground before they can start; whereas, when replanted in autumn immediately after taking up the parent bulbs, they will spring up freely in spring, and neither cold nor wet will injure them; on the contrary, these agencies will break the thick coating and allow vegetation to take its course in due time.—MAX LEICHTLIN, *Baden-Baden*.

AUTUMN-PLANTING GLADIOLI.

"DELTA" (p. 413) is probably right in regard to this matter. Most of the older species were, as a rule, left in the ground. For many years past we have also grown several thousand bulbs of *G. Bowienis*, a very showy, fine variety. For the last six or eight years we have left them in the ground, only taking them up to divide and replant as the roots get overcrowded or the soil becomes exhausted; the result has been highly satisfactory. The crop of bulbs is more numerous and finer than under ordinary treatment, and the plants flower with great vigour and profusion. Bulbs of other varieties have also been left at times. A dozen or two were overlooked in herbaraceous borders last year, and neither the wet nor the cold appears to have injured them. Many of the *G. Bowienis* are grown in rows, and our practice has been to form a ridge of fine earth from 4 in. to 6 in. high over the crown of the ridge. This performs two functions possibly equally useful to the Gladioli—it keeps them dry and also warm. The better sorts of Gladioli will not bear severe frost, and are readily injured by having their crowns frozen; consequently, those who plant in the autumn, or leave their roots for several seasons in one spot, should either plant rather deeply or cover the surface with powerful non-conductors, as suggested by "Delta," or earth them up for the winter, as here recommended. It is an easy matter to form a ridge over a row, or a mound over a patch of Gladioli that shall at once shut off the rains and exclude frost. On heavy or naturally wet soils, however, it might prove dangerous to leave Gladioli in the ground. For though, doubtless, many failures, and not a little of the disease which not seldom proves as destructive as it seems inscrutable, originate in excessive and unnatural dryness, yet it is equally true that the roots cannot live or remain healthy in saturated earth. Where a good many are grown, both systems, that of dry storing and autumnal planting, should be tried, for, with such a valuable plant as the modern Gladioli it would not be wise to trust all one's eggs in one basket. I venture to doubt whether there is much in "Delta's" idea of the greater hardiness of English-raised seedlings. All our finer Gladioli are the offspring of one or more closely-allied species, and the mere accident of the birthplace of seedlings has little if any influence in determining the hardiness or tenderness of the plants. After many years of careful attention to the subject, I have no faith in acclimatisation. For example, we have not one iota of verified truth to prove that either the Potato, the Dahlia, or the Scarlet Runner are any hardier now than on the first day of their introduction. As to the superiority of the Gladioli of the Messrs. Kelway, that is a fact patent to all cultivators, and is easily accounted for by their superior skill, special culture, and suitable soil and climate, without attributing any part of it to the greater hardiness of their many thousands of seedlings. D. T. FISH.

STEM ROOTS OF LILIES.

I HAVE been waiting since "Dunedin's" letter, regarding the positive hurtfulness, not to say mere uselessness, of the stem roots of *Lilium auratum* and *L. speciosum*, appeared in THE GARDEN of the 26th ult. in the hope that someone would take up the cudgels in defence of Dame Nature in this matter. I can imagine the surprise and horror of the dear old lady at this outburst of treason on the part of one of her most devoted sons. Hitherto she has been generally credited with an almost infinite variety of resource in adapting her provisions to the special requirements of each of her widely dispersed children; but to read "Dunedin's" letter one would imagine that this has been quite a mistake, or that at least the old lady is getting into her dotage and making great and ridiculous mistakes now. Up to the present Dame Nature has been supposed not only to provide for each class of her children, but also to look after each individual as well. Has "Dunedin" visited these Liliums in their native lands? because if he has not, how can he be sure that a mistake has been made in the special provision under notice, for that is really what his argument amounts to? To my mind, the presence of these stem roots in L.

auratum and *L. speciosum*, while they are wanting in *L. candidum*, at once suggests that the two former, in their native habitats, are under some condition which does not affect the latter in its native habitat, and I would set myself to ascertain wherein this different condition consists; and here I must admit that I disagree entirely from "Dunedin" in my estimate of the functions of the stem roots. I believe that they are where they are for the express and primary purpose of supplying the requirements of the flowers, and thereby taking the strain off the bulb at a time when, according to "Dunedin's" own showing, it and its roots are engaged in building up the successional bulb; and I further believe that in their native haunts these stem roots further serve the purpose of staying the long, wiry stems, and supporting them against the disturbing influences of the high winds which must sometimes visit these highland spots, and this steadying function must also be of immense value in keeping the bulbs and their brittle roots undisturbed. These stem roots act also as a thatch to preserve the bulbs and the delicate nursing successional roots from over much damp. The quotation with which "Dunedin" winds up his letter, from one whom he terms "a professional writer," is, I think, the common-sense view of the purposes of these stem roots. Where "Dunedin" is wrong is to expect the stem roots to continue their horizontal course when circumscribed in a pot. In this case they must either go upwards or downwards, and naturally they prefer to go downwards. If now and then one of them gets entangled in the scales of the new bulb under such conditions, that, I take it, is "Dunedin's" fault, not Dame Nature's; but I do not fancy the damage resulting therefrom is anything like so great as "Dunedin" would have us believe. My experience is that such stray roots, when they do occur, do no harm. "Dunedin" is entitled to all honour for the valuable researches by which he has established the true nature of the growth of *Lilium* bulbs, but I fear that in this matter of stem roots he has not pursued the same philosophical course of building up theory from actual facts. I believe that to cut off the stem roots, as "Dunedin" counsels, and thereby throw all the work of supplying the flowers, as well as the successional bulb upon the old bulb and its roots, will be found to gradually weaken the growth and diminish the size of the bulbs. "London Stone," I see, in your last number, asks the very pertinent question how "Dunedin" proposes to increase his *Liliums* "when he does not allow them to seed, and scrapes the stem in addition?" and I must confess I await his answer to this with some curiosity. It will be easy to arrive at the true nature of the functions fulfilled by these stem roots by a series of comparative experiments, and when "Dunedin" can place the results of such before us, and by them prove his present opinion to be right, I—and I doubt not many others—will accept the result cheerfully, but not till then.

A. S. O. N.

LILY GROWING.

"DUNEDIN" says (p. 433) that Mr. Dod "in saying that he gains a year's growth by buying a large bulb, is simply deceiving himself, and possibly others." Does any practical cultivator of the Lily believe this statement of "Dunedin"? I should think not. I am not going to dispute with "Dunedin" whether the old bulbs do or do not die annually, but this I will say, that the largest bulbs produce the strongest stems and the greatest number of flowers, as a rule, and a gardener, if he wants flowers, should certainly buy large bulbs, if he can afford to do so, for they are higher priced simply because they are believed to flower better. Practically speaking, Mr. Dod is quite right. "Dunedin" may call it what he likes, but by buying a large bulb, whether we gain a year's growth or not we at least buy the prospect, if not the certainty, of more flowers. I will cite a case in point; let "Dunedin" answer it if he can. A neighbour of mine bought a root of *Lilium auratum*; it produced a few fine flowers the first year. Finding the root larger at the end of the season, it was given a larger pot, and the following summer it produced a still better and stronger stem and more flowers, and this went on for two or three years, I forget exactly how many, till when I saw the plant it had a stem some 10 ft. or 11 ft. high and nearly as thick at the base as a young Larch tree, with a crown of fifty or sixty flowers upon it, to speak within safe limits, for, if my memory serves me rightly, the number was even greater. It was the grandest Lily I ever saw. Now, the question I wish to put to "Dunedin" is this: In whatever way that Lily bulb grew, it at least got larger every year (I reckoned it to be about the size of a child's head from what I saw of the top of it), and it produced a proportionately stronger stem and a proportionately greater number of flowers, and I submit that if I had judged it by its size alone, I would have judged correctly, and that by every year's growth it had upon it I would have been a gainer—that is, by each year's growth I should have had a bulb possessing greater flowering power, which is, I suppose, all Mr. Dod means by saying that he gained a year's growth by buying a large bulb. J. S. W.

AUTUMN FLOWERS IN HERTFORDSHIRE.

THE fine autumn with which we have been this year privileged has been unusually favourable to late-blooming flowers; indeed, I hardly ever remember to have seen them so fine. *Brogmansia sanguinea*, which has now stood four winters with me in the open border, had fifty-two expanded or semi-expanded blooms at one time rather more than a month ago; *B. lutea* has also been very fine. They began to bloom in July. I cut them to the ground with *Michaelmas Daisies*, and cover them with Cocoa-nut refuse till May. *Fuchsia cordifolia* has stood out six or seven years treated in a similar way, and has been full of bloom. *Ruta albiflora* has lived out for several years without any protection whatever, but, unless we have a fine and late autumn, it seldom blooms well; this year it has been perfection. *Exogonum purga* was in bloom till about a week ago. *Arctotis grandiflora* is not quite hardy, but it is a splendid bedding plant; its silvery foliage and great orange flowers are equally beautiful. It strikes freely from cuttings, if put in in July, and the old plants are easily lifted. *Salvia tricolor* has been a bush of bloom up to the present time, and *Leucocarpus salinus* has only just had its white berries blackened by the frost and rain. *Asteriscus maritimus* has held out bravely, and has only just succumbed; it is one of the very neatest and best of the dwarf, golden-yellow, perennial Composites. *Dahlia Cervantesi* has, as usual, been very handsome, and so have its congeners, which bear the names of *D. cocinea*, *aurantiaca*, and *lutea*, especially the last. It is so pretty and useful for decoration, that no garden ought to be without it. A little bush of *Enopatorium lignastrum*, which stood last winter, has been perfectly smothered with bloom. A very early form of *Narcissus præcox*, from Malta, has been in bloom for three weeks. An equally early form of *Galanthus nivalis*, which was collected for me by Lord Walsingham, either in Albania or the Ionian Isles, bloomed both last year and this in the middle of October. *Crocus Boryi*, *orphanides*, *medius*, *vitellinus*, *ochroleucus*, *nudiflorus*, *Elwesii*, *sativus*, *Cartwrightianus*, *Cam-bessedianus*, *serotinus*, *pulchellus*, *p. albus*, *Clusii*, *byzantinus*, *longiflorus*, *l. melitensis*, *cancellatus*, *tingitanus*, and *damascenus* have been in bloom, but it has been too cold for these autumnal Croci to open well.

H. HARPUR CREWE.

Drayton-Beauchamp Rectory, Tring.

ZINNIAS, SINGLE AND DOUBLE.

WHEN the late Dr. Lindley once termed the Dahlia "impish and inelegant" he, in all probability, intended to convey his impression that the course of improvement to which the flower had been subjected had resulted in the production of blossoms of decidedly monotonous character, in the rounded angles and in a uniformity of shape that presented but little in the way of variety. It is only an enthusiast with the Dahlia that will linger long over a stand of twelve, twenty-four, or thirty-six varieties, however finely the flowers may have been grown. The double Zinnia is passing through a similar course of improvement; single forms have become almost entirely lost in large, full, double forms; the size of many of them being nearly equal to that attained by many Dahlias. But the uniform perfection of shape is yet wanting in the case of the Zinnia, perfect as some of the flowers are; and, in addition to brilliant colours and variations in point of size, we also get differences of shape, which really lend an additional attractiveness to the flowers. A few years ago, and double Zinnias were a thing unknown. When the double forms did appear, they were warmly welcomed, because at that time double flowers were in fashion. The Floral Committee of the Royal Horticultural Society, a body which took a decided lead in encouraging the production of double flowers, and not without making some mistakes in doing so, have lately given first-class certificates to single Dahlias, some of which have been in cultivation nearly half-a-century, thus reversing its former policy to some extent. Perhaps, some day, the single Zinnias, which are in danger of being driven out of cultivation by the double flowers, will be recognised in the same way.

There is one good characteristic about the double Zinnias: they are not in some instances of such rank and unwieldy growth as the single types, and the process of dwarfing has gone hand-in-hand with that of multiplying the petals in the flowers. Careful selection also has done something in the way of inducing a better habit of growth, and it will be observed that it often happens that particular types of flower get improved both in habit and blooms at the same time. Some of the single Zinnias are very beautiful, such as the yellow, carmine, rosy-purple, scarlet, crimson, and orange. These, with the white, which is after all not a good white, will be always acceptable for their large showy blossoms and brilliant colours. I had an opportunity of inspecting in August last a large trial of Zinnias just as the flowers were at their best. There was quite a garden of them, for a few plants of each variety had been grown on in pots from the

seed bed, and, when they had established themselves, had prospered with great freedom, and each had formed a fine-branched specimen. This afforded a rare opportunity of ascertaining what the double Zinnia is capable of from a decorative point of view, and I must admit the result was in every way favourable to that form. What fine plants they make for cutting from, and the act of cutting induces growth, and renewed growth brings a fresh supply of flowers. In the case of the following varieties, which form the pick of the collection, the flowers were very large, almost on a par with some Dablias in this respect, handsome in shape, and associated with white and brilliant colours: Scarlet, very bright, one of the best; rosy-purple, very good; atro-purpurea, a fine box of deep purple; orange, bright and striking; yellow, coccinea, rather brighter than scarlet, a remarkable tint of colour; crimson, very fine; Karmesia, very fine carmine-crimson, large and full; and alba, fairly pure in colour, but not so fully double as the foregoing. There is what is termed a striped section of double Zinnias, but I have never seen any answering to the characters given to them, but I do not deny their existence; I simply state that I have not yet seen them. In some parts of the country cut blooms of both double and single Zinnias are much grown for show purposes, and there is as much rivalry in the efforts to gain first prizes as in the case of Dablias and Asters. While the Zinnia lacks the great size of the Dahlia, and the soft beauty and delicate colours of the Aster, it yet includes vivid tints and lustrous hues foreign to both these popular autumn flowers, and stands of well grown flowers of double Zinnias are most effective on the cut-flower table.

The Zinnia comes under the denomination of a half-hardy annual. The seed is sown in a gentle bottom heat in early spring, and the plants are hardened off and put out into the open ground to flower. Many spoil their plants by keeping them in the seed-pans and boxes till they are planted out, and in consequence the plants become drawn and grow tall, instead of fine, free-branched examples. When they are grown thus thickly together the roots cannot well form good balls with soil adhering to them, and when transplanted the plants are some time before they make a start, and when they do they seldom branch out. Those who care for Zinnias prick off their plants from the seed-pans into other boxes, or into a bed in a cold frame, where they are put sufficiently far apart to form good balls of roots. It is a good plan to put a few of the earliest of the plants, and grow them on to come into flower as soon as possible, so as to inaugurate a succession. The soil for the Zinnia should be of a light, rich nature. Leaf mould, manure, and a good sandy loam make an excellent compost. In this the plants root freely, and when they do this, they seldom fail to do well. D.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

How to Grow Ampelopsis Veitchii.—Most persons who have seen Veitch's Virginian Creeper must acknowledge its merits, but its beauty may be enhanced in a tenfold degree by allowing about three stems to grow, and cutting off all the side shoots close every spring, when young ones quickly grow out, covering the wall with a delicate foliage which is frequently mistaken for some new and beautiful Ivy; these branches, although so tender looking, last an astonishing time in vases or worn in the hair.—C. E. ISHAM, *Lampport Hall, Northampton.*

Ivies and Virginian Creeper on Tress.—Allow me to suggest that instead of cutting down the old trees at the back of the angler's house in Hyde Park, as has been recommended, that they be utilised to show the beauties of various Ivies, Virginian Creeper, and other climbers that will grow in London.—A COCKNEY GARDENER.

Pæderotæ.—These comprise a small group of dwarf Alpine herbs belonging to the Figwort family and nearly allied to the *Wulfenias*, of which we have two species in cultivation. There are also but two kinds of *Pæderota* in gardens, and by far the most ornamental of these is *P. Bonarota*, which is found amongst rocks, &c., on the Alps in various parts of Austria and Carniola. It varies greatly in height, being from 2 in. to 1 ft., which appears to be its maximum height. The stems are slender, bearing opposite, short-stalked, roundish, and sharply-toothed leaves. The individual flowers, which are rather small, vary from pink to a bright violet colour, and are borne in dense, erect, terminal racemes from 1 in. to 3 in. long, and are produced during May and June. Though it has been known to cultivators for upwards of sixty years, it is at the present time a very scarce plant in this country, and we are pleased to notice it included in the catalogues of some of the Continental nurserymen. It is synonymous with the *P. corulea* of Linnæus. *P. Ageria*, the other cultivated kind, is a much less showy plant. It grows from 1 ft. to 1½ ft. high; the lower leaves are small and roundish,

the upper larger, lance-shaped and pointed, whilst those of the middle portion, which are the largest, are ovate and tapering; all are unequally and sharply toothed. The manner of flowering is much the same as the preceding; the blossoms are of a pale yellow colour, and are produced in May and June. It is a native of the Alpine districts of Carinthia, Carniola, and various parts of Italy, from whence it was introduced to this country about half a century since.—W.

Dwarf Fuchsias.—Mr. Smith, of Newry, does well to call attention to the merits and beauty of *Fuchsia pumila*, a pretty little gem far too seldom met with. *Fuchsia globosa* on poor soil used to be almost as dwarf in habit, though, of course, with far larger leaves and flowers; and some twenty or more years ago *Fuchsia microphylla* and *macrantha* were popular bedding plants, though hardly hardy enough to stand the winter unprotected. These had small leaves and little tubular flowers, and were altogether very distinct and beautiful either in lines, groups, or small beds. These, with not a few other old favourites, seem to have dropped out of cultivation.—D. T. FISH.

Fuchsias for Planting Out-of-doors.—It is much to be regretted that growers of Fuchsias limit themselves almost exclusively to hybrids of garden origin, disregarding, or nearly so, the important species which we have had so long; for instance, it is seldom one meets with that fine old plant *Fuchsia fulgens*, and still seldomer do we see *F. corymbiflora* in good condition. Many years ago I met with both these in a garden a few miles from Windsor planted out in beds in the lower garden, the first named being from 6 ft. to 7 ft. high, the last one still higher. I think they were taken up in autumn and stowed away after the manner of Dablias, and they well repaid the trouble, as the flowers, like those of all the section, being of a pendent character, are not so effective when seen on small plants as on large ones, and both kinds can be raised from seeds. There is also a small variety very seldom met with, and for many years I lost sight of it altogether, but I eventually ran against it in an old garden in Surrey. It used to be called *F. parviflora* or *F. microphylla*. It is a pretty little kind, and ought to be more generally grown than it is, as it is a most abundant bloomer. There are also, I believe, one or two other species distinct enough for ordinary hybrids to be entitled to a place in collections, but the kinds which I have named are pre-eminently so.—A RETIRED GARDENER.

Lamium striatum.—This plant almost merits the designation of perpetual flowerer; indeed, I have known it to be in flower the whole year through, but that was when the winter was exceptionally mild. Its beauty, however, lies rather in the variegation of the leaf than in the flower. Early in spring, and even in the depth of winter, if the weather be not too inclement, the variegation is beautifully marked. It is just one of those plants which, if instead of being extremely easy of culture demanded heat and great care, would be very much prized.—J. CORNHILL.

Haberlea rhodopensis.—This is a charming little rock garden plant much resembling a *Gloxinia* in miniature, and it is also very interesting, as being one of the few hardy members of the *Gesneria* family. It forms dense tufts composed of numerous small rosettes of leaves which have the appearance of those of the Pyrenean *Ramondia* (*R. pyrenica*), each rosette producing in spring from one to five slender flower stalks bearing from two to four blossoms each nearly 1 in. long, of a bluish-lilac colour with a yellowish throat. It is found in the Balkan Mountains growing amongst Moss, &c., on damp, shady, steep declivities at considerable elevations. At present it is rare in English gardens, but it should be sought after by every lover of hardy plants.—W.

Hardy Flower Garden Plants.—Attention having been directed (p. 352) to the merits of the *Valeriana Phu* as a suitable plant for winter and spring decoration in the flower garden, might I ask if this plant is not the same as that sometimes called Marsh Valerian, a British plant inhabiting marshy places, and having white or pale-coloured flowers? I have not seen it for years, and was not aware that there was a golden variety of it, but as there is, I have no doubt that it is pretty. It has often occurred to me that if a bright yellow one could be given to the pretty foliage of the common roadside plant *Potentilla anserina*, called also Silver Weed or Goose Grass, it would be found to be a great acquisition in flower gardens, and possibly there may be more of our British plants which might be made serviceable in that way. For many years I had a pretty white-foliaged variety of the common *Colt's-foot*, which may be common elsewhere, and I believe that gem amongst plants, the variegated *Polymonium*, is only a variegated form of the wild species, and very likely several others of our wild plants might likewise be turned to good account in a decorative way. I remember once running accidentally against a wild plant amongst some hardy ones in a nursery-

man's collection, and, obtaining it, I found it was by no means a despicable one. It is called *Meum Athamanticum*, and has foliage much resembling that of some of the *Adiantums*; the flower is umbelliferous, and the plant is only remarkable for its foliage. And now-a-days, when fine-foliaged plants play so important a part in flower gardening, hardy wild ones should be sought after, being most easy of culture. The ordinary Stonecrop has been enlisted into the service, and also some Saxifrages, and doubtless the number might be increased. I expect some one will take up the case of the *Valerian* alluded to above, and I hope to see others of a similar character brought into notice.—A RETIRED GARDENER.

Saving Old Bedding Pelargoniums.—I agree with "Cambrian" (p. 412) as to his plan of saving old bedding Pelargoniums, having saved thousands every year in the same way; but, according to my experience, "Cambrian" has omitted the one thing needful, that is, as soon as they are put in the boxes they should be placed, if possible, in a gentle heat to give them a start, removing them when they begin to grow into a cooler place. If this be not done, a great many are liable to rot.—F. CANNELL, *Felthorpe Hall, Norfolk*.

Tritonia aurea as a Border Plant.—I have had this bulb in the open ground for the last three or four years, and have never noticed the shoots to suffer in the least from frost. The clumps grow stronger each year and flower more profusely, and they get no attention beyond what I give to the border in general. They are planted in a corner facing south and east, where they get the full benefit of all sunshine until between 2 and 3 p.m. I think they kept in flower this year for quite a couple of months. I have not found them to stray very much. They are planted at the foot of a sweet-scented Clematis, the roots of which may prevent them wandering to the extent Mr. C. W. Dod complains of.—F. J. ALEXANDER, *Fernlees, Gunnersbury*.

The Golden Chickweed in Winter.—In addition to this Chickweed (*Stellaria graminea aurea*) being one of the most useful yellow carpet plants in summer which we possess, it may also be made to form a dense, thick mass of bright golden leaves in autumn and winter. I lately noticed a large patch of it in the Wellington Nursery, which had been left undisturbed for years, as bright as I ever saw it in summer. This result is effected by allowing the plants to produce seeds early in autumn, and then cutting them down close to the ground, an operation which causes them to break afresh from the bottom and form a golden-yellow, close carpet in winter. Where hardy shrubs are employed for filling up flower beds in winter this would form an excellent undergrowth.—S.

Clematis Pitcheri.—I am glad to see that some of our American friends watch our horticultural proceedings, and that they set us right now and then, as far as nomenclature is concerned, in the case of plants truly American. I have made many enquiries, and have searched every work which I have come across to find out the name of the Clematis described as scarlet, and figured in the "Revue Horticole." I have applied for plants from several of the leading nurserymen in America of *Clematis Pitcheri* with red flowers (I was afraid to say scarlet), and they all say that they have never seen or heard of any such plant. Their description agrees with that given in Gray's "Manual of Botany," viz., "flowers dullish purple." It seems strange that such a mistake should have been made between two distinct kinds, for the plant in question is not *C. Pitcheri*, but a variety of *C. Viora* called *coccinea*, a plant sparingly found in a few localities in the United States.—A. P.

Arum Lilies (Callas) Out-of-doors.—I agree with both Mr. Hinds and Mr. Williams, that this *Arum* makes a much better plant treated as an aquatic through the summer season than managed in the ordinary way. We put some out here this year in much the same manner as that described by Mr. Williams (p. 432). We had a large flat bath made for the purpose in the shape of a half circle, which held eighteen good plants. This bath, which was 10 in. deep, was sunk in the centre of a border up to the rim; about 6 in. of good soil and old hotbed manure were then put in the bath, on which the plants were arranged according to their height; the bath or trough was then filled with water until it reached the rims of the pots. On each side of the *Arums* was planted a small group of variegated *Maize*, and in front of the bath were plunged some plants of *Agapanthus*; at the back were *Tobacco* plants. The *Arums*, which seemed to be quite at home, produced a very good effect. I was requested to let the plants remain out in the bath, which I did until the 12th inst., when they were brought in to all appearance a complete wreck. In the course of a day or two they recovered to some extent, but the finest of the foliage is very much spoilt through the frost, of which we had 9°. I state this to show that this *Arum* is not sufficiently hardy to withstand our winters out-of-doors, at least not in this locality.—H. ANDREWS, *The Hill, Salisbury*.

THE INDOOR GARDEN.

FUCHSIAS.

FROM much that has been written recently on these most useful plants, it might, so far as a portion of the views expressed are concerned, be inferred that Fuchsias had only recently come prominently under the notice of cultivators, and that the many uses to which they may be put had only now been discovered, or that they had in a measure been neglected or discarded and set aside in favour of other plants more ornamental, and generally better deserving of cultivation; yet nothing can be more erroneous or opposed to facts. I am ready to admit that Fuchsias are not now so well represented on most of the exhibition stages as they once were, and this despite the very substantial prizes that in some places are offered for them, but this is not difficult to account for by those who have taken the trouble to notice the spirit by which the best plant growers, in almost every part of the country where exhibitions are held, are usually actuated, that is, after a time a disposition to take in hand for exhibition only those plants that are the most difficult to grow. So general is this the case that amongst the best plant growers now existing, with many of whom I am personally acquainted, there is scarcely one who did not commence with the more easily managed subjects, such as Fuchsias and others of a similar character, and afterwards turned their attention to those things that need the most careful study as to their requirements and unremitting attention in administering to their wants. Were Fuchsias equally difficult to produce in perfect condition, they would doubtless be seen at all our principal horticultural shows. There is also another class of plant growers who care little about Fuchsias, or, in fact, anything else, unless it happens to be the plant of the hour. At one time it is tricolor and bicolor Pelargoniums that find favour; next it is zonais that take their place to the exclusion of everything else, until the contents of the greenhouses of those enamoured with them are as monotonous and painful to look upon, and as devoid of elegance in form as a field full of Poppies; now it is tuberous-rooted Begonias that are in fashion, which, in their turn, will, no doubt, be supplanted by the first available new subject or exhumed old one that can be made to answer the purpose of getting up a sensation. But this is not gardening in the legitimate sense of the term. That consists not in fleeting favour for this or that plant for a time, but none long, but in keeping on selecting and cultivating as many plants as are found really worthy of attention, and that afford the diversity of form, colour, and contrast generally that go to constitute the true charm of a garden either under glass or in the open air. So far from the cultivation of Fuchsias, as grown for general decorative purposes under glass, being on the decline, or ever likely to be so, it is simply the reverse; for, excepting the large and diverse family of Pelargoniums, taking them collectively, there are no plants so much grown as Fuchsias. Of this any one who is in the habit of moving freely about the country and seeing many gardens large and small cannot fail to be aware.

As to Fuchsias not being so much used for bedding as some other plants are, or their merits entitle them to, the reason for this is equally easy to see. After planting out in spring, they are not so soon fully in flower, nor do they ever furnish the same amount of colour as plants that bear their flowers erect; their natural drooping habit does not admit of this. But there are not many who have anything like a general knowledge of gardening matters who are not fully acquainted with their adaptability for planting out. There are few gardens, large or small, in which they are not more or less so used, except, perhaps, close to towns, where the plants selected are generally such as will make the greatest blaze for the short summer months. Fuchsias are, however, much superior to three-fourths of the tender plants that are usually bedded out in summer in every property worthy of consideration, and they have only failed to become popular through their not producing an even surface of colour that tells at some distance off, an indispensable condition with many in their choice of any plant for this purpose; but, as better taste prevails in these matters, I have no doubt their merits will be more appreciated. But, where Fuchsias are to

be thus grown, let me plead for better treatment than covering the surface of the ground occupied by their roots with Ivy, Periwinkle, or anything of a similar character. Ivy quickly impoverishes the soil to which its roots have access; it very soon weakens and destroys such plants as the common white and Turk's-cap Lillies, herbaceous Pæonies, Michaelmas Daisies, and Phloxes, all of which I have tried in an Ivy-covered bed, but, despite all the assistance that could be given them without cutting away the Ivy, they very soon perished, and the latter two, at all events, of the above-named plants, are so well able to hold their own against most others as to get considerably above their share of whatever food is within their reach. The proposed treatment of Fuchsias is about on a par with the usage they too often receive under pot culture, where, after a short start in spring, not unusually under Vines, or other light-obstructing influences, they are frequently relegated to out-of-the-way corners in conservatories or other structures where few things can live and have a good appearance. Some years ago I had a good-sized bed in a light, open position planted with Fuchsias of different colours, dark and light. The plants stood 1 yard apart, and between them in the inner portion of the bed were clumps of *Lilium bulbiferum* and *L. candidum*, and a few plants of the white and pink varieties of *Anemone japonica*, which required nothing more than some of the lower branches of the Fuchsias towards the end of summer being cut away to keep them from encroaching too far upon the surroundings. This was easily managed without showing at all that any cutting had been necessary. Hyacinths, Tulips, Crocuses, and Snowdrops occupied the outer edges of the bed, making a display in spring, and dying down before the Fuchsias had pushed their branches in a way to interfere with them. All that was requisite was to cut down the Fuchsias as soon as the frost destroyed their tops, and put about 8 in. or 9 in. of coal ashes over their crowns for the winter. This covering was removed in spring, a moderate quantity of manure slightly forked in, and the surface kept clear from weeds until the branches of the plants almost covered the ground. Thus managed, I never had a bed that gave so little trouble in proportion to its size, or that was altogether more satisfactory. The quantity of flowers which it furnished for cutting without their being missed was worth considering where cut flowers were largely in demand.

T. BAINES.

REGULATING CONSERVATORY CLIMBERS.

Now that the short, dull days of winter will soon have arrived, it is high time to give attention to the thinning and regulating of all kinds of conservatory climbers, in order that the light and air which they obstruct may be allowed to have full play for the benefit of the plants beneath them. Much judgment and discretion, however, are necessary in doing this, for without a full knowledge of the habits of the different varieties, and their mode of flowering, whether on the old or young wood, a good deal of mischief may be done. If we take the Bignonias, for instance, and remove the long, dependent shoots made during the present year, we take away the bloom that would appear in the spring; and the same would happen in the case of the Lapagerias and others; but to prune out such from Passifloras, Tacsonias, and similar plants is a work of necessity, in order to allow room for fresh shoots to occupy their places. Those of the current season having so far served their purpose, at least two-thirds of them formed during the summer may be removed, leaving the remainder till fresh growth has made some progress, when they too should be cut away, except such as are likely to be required for laying in to fill vacant places. This kind of treatment leaves just sufficient foliage to keep the roots slowly at work and the sap in circulation to feed the spurs and plump up the buds left near their base. The almost perpetual flowering character of *Tacsonia exoniensis* and *T. Van Volxemi* is such that it is impossible to cut away anything from them without sacrificing some bloom at the extreme tips of the pendulous shoots, and the only way to keep them in order is to be constantly regulating and encouraging the young ones, and gradually cutting out such as are getting too long or becoming exhausted. This will prevent undue crowding, and will allow their flowers to be seen to the best advantage. There is no way of growing these equal to having them in a lofty ridge with just the main stems made secure, and the lateral branches allowed to depend straight down overhead, which is far more natural and effective than any kind of training, however well it may be carried out; indeed, these and *Passifloras* are only adapted

to this mode of culture, and exceedingly graceful they are when well cared for and not allowed to get into a wild, entangled condition.

The great drawback to *Tacsonias* is their liability to scale, that often assails them to such a degree as to have the appearance of being splashed with minute spots of whitewash, and this kind of scale is, of all others, the most difficult to kill. The best remedy I have ever found is to paint the bark of their stems over with some Fowler's Insecticide mixed with clay so as to make a thin wash similar to what Vinea are usually dressed with, and this stifles them and keeps the plant free from attack for some time after. Paraffin used at the rate of a wineglassful to four gallons of water is said to be a sure cure, and if so, being so easily and quickly applied, as it may be by means of a syringe, it will be one of the greatest boons that cultivators have ever experienced. Lapagerias, like *Tacsonias*, are also very subject to the same kind of insect, and likewise thrips, especially if they happen to be in houses where the atmosphere is a little too dry, or other conditions not altogether favourable to their growth. Handwashing these is a difficult and tedious process, owing to the stiff and peculiar formation of the leaves, and here, therefore, the paraffin will be of rare service. It is to be hoped that those who have the opportunity will experiment with it, both alone and in connection with soft soap, Tobacco water, &c., and give a report for the benefit and guidance of others. If this be done carefully, and the quantities of each ingredient used and the effects produced noted and made public it would be of great service.

In regard to the general treatment of these latter lovely climbers, the thing is to encourage as much young growth as possible, and the way to do this is to give an abundant supply of water from the beginning of April to the end of October, which will assist it through its flowering period as well. In Chili, in its native habitat, it blooms during the rainy season, when the sky is dull and overcast, thus showing that it is fond of a good deal of moisture at that time; but if we look at the structure and immense substance of the flowers, they afford convincing proof that it must take abundant supplies to feed them. If well drained, and in a bed composed of rough, fibry peat, as they should be, it is impossible during the summer months to give too much water, as they will nearly grow in it if it be not stagnant or remain too long in the soil to cause it to become sour and inert. The shoots of *Lapagerias* flowering only once should be cut away when the blooms die off, unless it may be thought desirable to save any of them for seed. These come on pods of various lengths and sizes, and germinate readily when ripe, if sown in heat in sandy, peaty soil kept regularly moist. Next to those already mentioned, I think *Tecoma jasminoides*, one of the most desirable of conservatory climbers, but to get it to flower freely it must have a very light house, with full exposure to the sun, in order to get the wood well ripened. Even with these advantages it is often a shy bloomer when planted out where its roots can run unrestricted; and the way to produce the most satisfactory results is to confine it to a limited space, and keep it rather short of water during the early part of the autumn and winter. The habit of this, like the Bignonias, is to flower on the growth of the previous year, and the pruning, therefore, must be regulated accordingly.

Besides the general cleaning and regulating of all kinds of conservatory creepers, the present is the best time for adding to or renovating any old borders that may have become exhausted or the soil in an unsuitable state for healthy root action, as, owing to the semi-dormant condition the plants are now in they will bear more pulling about than at any other season. For the generality of them there is nothing better than good sods of fibry peat and loam chopped up rather coarse and a liberal supply of sand added to keep it open and porous. If from 6 in. to 12 in. of this mixture is given and a covering of the old soil laid over the top, it will result in a greatly increased state of health of the plants and a more floriferous habit.

S. D.

Salvia leucantha.—This beautiful and abundantly free-blooming *Salvia* is now a most ornamental plant for the decoration of the winter greenhouse, and is well worthy of more extensive cultivation than it receives. It is a native of Mexico, and is figured in Vol. LXXIII. of the "Botanical Magazine," t. 4318, but the plate by no means does justice to the beauty of the flower, as, indeed, the accompanying letterpress frankly admits, saying that the rich violet or lavender-coloured tomentum of the calyx and the pure white of the corolla cannot be well represented on paper. It has also the great merit of being exceedingly quick-growing and of the easiest cultivation, a small cutting of it given me by a friend (who brought it from Cannes, where it abounds) at the commencement of this year, which was only 3 in. in height when put out into the open border at the beginning of summer, having, by the time it had to be lifted again in September, developed into a large bushy plant, requiring a 10-in. pot to accommodate it, and it is now one mass of flowers.—W. E. G.

A DOUBLE-SPATHED FLAMINGO PLANT.

The "Revue Horticole" figures a variety of this plant, which it calls

Madame Jules Vallerand, a sort raised by M. Vallerand. It seems very like *Anthurium Daviesi*, raised in England, but that variety

Anthurium Scherzerianum var.

(figured in THE GARDEN, June 12, 1875) differs from it in having the spathe overlapped.

COOL-GROWN BOUVARDIAS.

THE best plants of these I ever saw were grown at Messrs. Fisher, Holmes, & Co.'s nursery, Handsworth, Sheffield. The plants of which I speak I saw about three years ago, and they were growing out-of-doors in a frame with the lights off, under the shelter of a Beech hedge. This would be about the end of August. When I saw them again it was at Christmas, when they were at their best—strong, sturdy bushes with such foliage and flowers as one rarely sees. Of course, they had been removed from their outdoor quarters some time after I saw them and pushed on afterwards in a kind of intermediate temperature. Previous to that time I had grown our own plants under glass all the year round, but I discontinued the practice, and with the results lately mentioned in your pages. I do not doubt Mr. Baines's success in growing his plants well in a stove during the winter (p. 436), but I do not think such treatment is necessary. Shoots made during the dull, dark days of winter in a stove temperature produce poor flowers, but those produced from hardy summer growth are sturdy enough and well developed, and if such plants be placed in a warm greenhouse about October, they will continue to produce flowers for a long while. A temperature of from 55° to 60° suits them best during the winter. I find a good deal of difference of opinion exists on the subject, even amongst the best growers, but there can be only one right way after all, and it is desirable that we should be certain what that way is. I find that Mr. G. Baker, of Coombe, Surrey, in the "Gardeners' Assistant," before referred to by me, recommends a temperature during the growing season of from 55° to 65°, and the "coolest part of the forcing house" in winter, in which structure only moderate temperatures are recommended. On the other hand, Mr. Baines, writing on the same subject in the same book, recommends a growing temperature throughout the summer of from 70° to 80°, a difference of nearly 20°. At the end of July he says the plants may be removed to a cool frame, but in order to have flowers throughout the autumn he recommends the plants to be again early introduced to a temperature of from 68° to 70° at night, with a proportionate rise in the daytime, which looks very like treating the plants to a stove temperature nearly all the year round, a kind of treatment which many others, as well as myself, find to be not only unnecessary, but positively injurious in general culture. Mr. Baker's advice appears to me to be the best and safest; but one is surprised to find such contradictory advice given on the same subject in such a work as the "Gardeners' Assistant."

J. S. W.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Hybrid Orchids.—Until comparatively recently the number of garden-raised hybrid Orchids existing might have been counted on the fingers. I well recollect the time, many years back, when it used to be said that Orchids were at least free from the hand of the hybridist. Mr. Dominy was the first to show to the world what it was possible to accomplish in this way when he raised the exquisitely beautiful *Cattleya exoniensis* from seed. But Mr. Dominy's labour in this particular direction did not end here, as has been proved by the many fine hybrids that have subsequently made their appearance from Messrs. Veitch's establishment, notable amongst which may be mentioned *Calanthe Veitchi*, and more recently the fine *Lælia Dominicana*, and there are still at Messrs. Veitch's hundreds of unbloomed seedlings. During the present autumn a considerable number of *Cattleyas* have flowered, remarkable for their elegant and delicate colours and long endurance. They are the result of crossing such kinds as *C. labiata*, *C. Loddigesi*, *C. Aclandiae*, and the above-mentioned hybrid, *C. exoniensis*, which is thus the parent of a second generation. The seedlings appear to be almost all autumn bloomers, which is a great advantage, looked at from a general gardening point of view, as in this way they add to the comparatively few that flower during the dull season. There are also a number of seedling *Masdevallias*, some eighteen months old, growing with the proverbial freedom of the species; from these something good may be looked for. These hybrids are not only highly interesting to those who make Orchids their especial favourites, but equally so to the many who take a broad view regarding the progress made in the cultivation of flowering plants generally.—T. BAINES.

Orchids without Heat.—In furtherance of what "C. W. S." (p. 376) has written on this subject, allow me to say that we have a house of Orchids to which no artificial heat has been applied for these last two years beyond what has been needed to keep out frost, and I give them all the air I can during hot days, even setting the door open. I find that they like all the air and light they can get; in fact, a cool greenhouse, in which *Fuchsias* and *Pelargoniums* will succeed, will suit most of the *Odontoglossams*, *Masdevallias*, *Occi-*

diums, *Lycaste Skinneri*, *Laelias*, *Pleiones*, *Cœlogynes*, and *Trichopilia*. The house in question is a span-roofed one, running east and west, and I find the less shade they have, without allowing the sun to burn them, the better. *Miltonia spectabilis* in this house has produced upwards of 100 flowers; it is well exposed, and grows vigorously. *Lælia Dayana* also does well in this house. The best plant I ever saw of *Dendrobium speciosum* grew in the open air during the summer time. We keep a large quantity of *Cypripedium insigne* in a cool frame all the summer, and plants of it are now coming very freely into flower. It is a plant that will bear as much rough treatment as an *Agapanthus*. About fifteen years ago I remember saying to Mr. Wilson Saunders, then at Hillfield, that the time would come when *Orobids* would be grown as easily as *Fuchsias*, and I am still of that opinion.—J. CROUCHER.

***Cestrum aurantiacum*.**—For training to pillars or rafters this fine climber is unequalled amongst autumn-flowering greenhouse plants, and it is, moreover, a plant requiring the simplest culture. It should be planted in a bed of rich soil, and be cut hard back in spring. Thus treated, it will not fail to produce every autumn a profusion of rich golden blossoms in long, drooping terminal branches which contrast finely with the bold deep green foliage. Though it is a native of Guatemala, it has proved itself capable of withstanding such winters as the last two in warm localities, with only the protection of a wall. If it does prove hardy it will prove a good addition to decorative wall shrubs, and a fit associate for *Habrothamnus corymbosus* and *H. fasciculatus*.—W.

Warming Small Greenhouses.—Allow me to describe a simple method which I have had carried out in my greenhouse, and which, after two winters' experience, I find to answer very well. For this system, however, it is necessary that there should be a fireplace in the house conveniently situated for that purpose. My greenhouse is a small lean-to against the gable of the house. My dining-room fireplace is in this gable, and I had the ordinary back of the fireplace removed, and a small boiler inserted in its place, which forms the back of the fireplace, and in which the water is easily heated to boiling point. From this boiler small pipes, about 1½ in. in diameter, are laid underneath the greenhouse stage. A small cistern is placed at the extreme end of the stage and connected with the hot-water pipes. This cistern compensates any small loss there is in the water during circulation or by escape of steam. The whole thing was done for a few pounds, and the after expense is nothing, as all that is necessary is on a frosty night to put a few shovelful of cinders on the fire, and this will keep it going until next day. A kitchen fire would, of course, answer still better, as the heat would be much greater.—S.

***Salvia* in Pots v. Planted Out.**—These form such useful plants for furnishing large conservatories where large masses of colour are required, that the most expeditious way of getting up a good stock of them is of importance when such structures are required to be kept gay during the winter and spring months. I have tried the plan of planting out such varieties as *splendens*, *Heeri*, and *gesneræiflora*, but although larger plants may be grown with less attention as to watering, &c., than by confining them in pots, I am convinced that more floriferous and altogether better plants may be grown by the latter method, as, being of a strong-rooting and gross-feeding habit, they become over-luxuriant if planted out in good soil; and, as is well known, a short-jointed, well-ripened growth is conducive to free flowering, it follows that pot culture is most likely to attain that end in the case of such subjects as the *Salvia*, and on the score of economy of labour there is not so much real as apparent saving by the planting-out system, as the extra attention of lifting, potting, and getting the plants established would nearly counterbalance the labour of watering, which is the principal objection to the pot system. It is altogether different with plants like the *Calla*, where the size and strength of the leaves determines the size of the flower, as in the *Salvia* a well-furnished head of flower is of more importance than the size of individual flowers.—J. GROOM.

***Abutilon Anna Crozy*.**—This new hybrid *Abutilon* has by far the brightest-coloured and largest flower of any of the new varieties which I have seen. Its colour is a fine deep purplish-rose, and its flowers are at least half as large again as those of *A. Boule de Neige*. They are most perfectly formed and of fine shape and substance. It is well worth adding to any collection of greenhouse plants. I received it by post in a small estate from a Lyons nurseryman, and do not know whether it is yet in cultivation in England or not.—W. E. G.

The White-flowered Weigela.—To all those about to order shrubs for out-of-doors or blooming in pots, I would say give this a trial. It is one of the most beautiful white-blooming shrubs grown.—J. C. F.

PLATE CLV.

JAPANESE PRIMROSES.

THE annexed coloured illustration of Japanese Primroses represents a race of hardy new forms of so much beauty and variety, that the wonder is they are not much more generally grown than they appear to be, especially as their value for house decoration ranks very high. We are indebted to the late Mr. John Gould Veitch for the introduction of *Primula cortusoides amœna* or *P. Sieholdi*, as it has since been designated. This was followed by the white variety, the Lilac form, known as *lilacina* (which is so distinct and altogether so unique in character as to rank almost as a species), and the rose and white variety known as *grandiflora*, the inner or upper surface of the petals of which is white, the reverse rose. Probably one or two of these are garden hybrids raised in this country. It appears inexplicable, but it is not less a fact that these fine forms were under cultivation in this country for a considerable time before new varieties were obtained from them. Probably this arose from the circumstance that *P. amœna*, which is most generally cultivated, rarely matures its seed. The other three are more free in this respect, especially the variety *grandiflora*. It is worthy of record that three almost simultaneous attempts were made to cross-breed from these fine hardy Primroses, viz., by M. Victor Lemoine, Nancy; Mr. James Allen, Shepton Mallet; and by Mr. A. Dean, Bedford. We have heard that M. Lemoine's new types are both fine and distinct, and that they have been much appreciated on the Continent. Mr. Allen has obtained some charming varieties, among them pretty lilac and pale mauve forms of *P. amœna*, and Mr. Dean has obtained a valuable break both as regards variety and colour. Three of these are represented in the accompanying illustration; that at the top is *laciniata*, a fine kind, remarkable for its large, bold flowers, which, as will be seen, are handsomely fringed on the edges, and of a rich, bright purplish-red colour, a tint difficult to represent on paper; that on the right is *purpurea*, a sort having large and finely-formed flowers of a bright mauve-purple, very distinct and handsome; and that on the left is *maxima*, a greatly-improved form of *grandiflora*, largely increased in size, purer in colour on the surface, and deeper on the reverse side. These were all awarded first-class certificates at South Kensington. Mr. Dean has also raised many other varieties of scarcely less merit, but the foregoing will sufficiently illustrate their value. One chief merit possessed by these new Japan Primroses is, that they bloom early, coming in about the month of April, when flowering plants are not particularly plentiful; another is, that they are remarkably free bloomers, throwing up, as they do, successional flower stems, and lasting a long time in perfection. For pot culture and cool greenhouse and conservatory decoration they are unequalled at the time of the year just alluded to. Their cultivation, also, is comparatively easy. The best soil for them is light, rich, free material, consisting of fibry loam, leaf-mould, pulverised manure, and some grit to keep it open. When grown in pots, the latter should be well drained, as the roots keep pretty near the surface; they are also impatient of excessive moisture, and, when planted in the open ground (for the Japanese Primrose is a perfectly hardy plant), they should be in thoroughly drained soil, or in raised positions on rockwork. The roots creep just below the surface and form eyes, by means of which any one variety can be easily propagated. The Japanese Primrose is a herbaceous perennial, which loses its leaves in autumn and winter, when it goes to rest, and breaks up again early in spring. R. D.

PROPAGATING.

LEPTODACTYLON CALIFORNICUM.—This lovely bright pink flowering plant would certainly be more extensively used in the flower garden but for the supposed difficulty as to increasing it. If a few plants be taken from the greenhouse and put into an intermediate house in January, they will begin to push out young shoots of which cuttings can be made in the manner shown in the annexed illustration. They may be inserted in cutting pots filled with peat, loam, and sand, and with sand on the surface; well drain and water, and let the bell-glasses be put over them; then place them on a gentle bottom-heat, and they will emit roots in three weeks; the glasses may now be raised a little at a time, till they can be left off altogether; they may then be potted off, set on a gentle manure bed, and they will be ready for planting out in May.

Cutting of
Leptodactylon
californicum.

H. H.

Propagating Tuberous-rooted Begonias.—I find that these useful plants are easily propagated by means of leaves. Leaf cuttings with the stalks adhering to them inserted in shallow pans of light, sandy soil, and placed in an ordinary propagating frame, made up of leaves and stable manure, soon root and put forth a shoot—a hint which may perhaps be useful to cultivators having limited accommodation, and who are anxious to increase any particular variety they may possess.—A. HOSSACK, *Ragley*.

Verbenas for Propagating.—Verbenas required for propagating purposes at the turn of the year should now be kept as cool as possible. By the new year they will be in fine condition for introducing into heat. They are very liable to the attacks of green fly and mildew, which, if not checked in time, will effectually cripple them. Dip them in Tobacco water, or fumigate for the former and dust freely with sulphur for the latter. For rapid, easy propagation, healthy and vigorous plants are indispensable; there is then no difficulty in working up a quantity from a limited stock.—J. CORNHILL, *Byfleet*.

Tuberous Tropæolums from Seed.—If properly treated, the seed of tuberous Tropæolums does not require twelve months in which to germinate. If sown in August they will come up freely in October. I have raised a great many of *T. tricolorum* and *azurum* without any difficulty in this space of time.—J. CORNHILL, *Byfleet*.

Colonial Museum for London and Proposed International Horticultural Exhibition for 1880.—On these subjects we have received the following from Mr. Wills, of Onslow Crescent, South Kensington: "I see by the daily papers that steps are being taken by the Council of the Royal Horticultural Society with the view of allocating as a site for the Colonial Museum, the situation which I had the honour of suggesting in my memorial to His Royal Highness the Prince of Wales and Her Majesty's Commissioners for 1851. I am extremely pleased to see that the Council have so quickly responded, and that they are anxious that the proposed Horticultural Exhibition of 1880 should be held. I for one shall be delighted if it should prove to be the means of stemming the torrent of adverse fortune which for many years past has enveloped the Royal Horticultural Society, and destroyed its usefulness as regards the advancement of horticultural science. It would also be a source of much gratification to all connected with horticulture if it should prove to be the means of the gardens at South Kensington remaining in the hands and under the control of the Council of the Royal Horticultural Society, and a great boon to the people who live near the gardens; it would also secure one more open spot for joyous recreation. It is, therefore, earnestly to be hoped that horticulturists of every degree will join hand in hand and all work with a will to carry out what will prove to be a grand national scheme. Now is the opportunity for developing an international horticultural exhibition worthy of the name of us. Let all now unite and feel that we have only one common interest at heart, namely, the advancement and maintenance of horticulture as a science worthy of our country. Let us prove to the colonies how worthy we are of their esteem, and to all subjects of foreign nations how delighted we shall be to see and entertain them. Horticulturists have been treated with every respect and kindness in connection with many of the great horticultural exhibitions on the Continent. Let us for once show our neighbours who are fighting the battles of horticulture on the Continent and elsewhere how much we have appreciated their kindness, and how

gladly we will be to welcome them to our shores in 1880. We shall secure the patronage and most valuable support of H.R.H. the Prince of Wales, which will be in itself a tower of strength, as all will admit who have seen to what a successful issue the great Universal Exhibition of Paris has been brought. It is not only horticulture and agrioniture that would benefit by the suggested amalgamation; it would also be the means of cultivating and improving the minds of millions of Her Majesty's subjects, thereby instructing them in the peaceful arts and sciences, a circumstance which could only be conducive to their future happiness and welfare."

GARDENING FOR THE WEEK.

Roses.

Climbing Roses.—Where climbing Roses are to be introduced to plant houses of any description, the present is a good time for planting them; but, desirable as it is to have Roses where they can be trained on the roof, to pillars, or in other positions in ordinary houses, especially where there is no structure that can be devoted to them alone, it is nevertheless well to consider the matter so far as regards the absolute requirements of the Rosos before introducing them. There are few, if any, plants that are more subject to the two greatest gardening pests, aphides and red spider, than Roses. If these be allowed for only a short time to have possession of them, they will injure the flowers and disfigure the foliage to such an extent as to make the plants more an eyesore than an ornament, to say nothing of their communicating the insects to everything in the house grown under them, on which they will live. For this reason it becomes a necessity all through the growing season to have recourse almost daily to a copious application of water, with either the garden engine or syringe. In their case no mere sprinkling will be found of much use; therefore, however desirable it may be to have Rosos grown in this way, their presence on the roof of an ordinary conservatory is not advisable where the body of the house is required to be kept gay by the continuous introduction of flowering plants, rendering the use of the water impossible without the manifest damage and disfigurement of the flowers standing under them. Insufficient forethought in this matter usually ends in disappointment. When they can be trained on a glass end of such structures, where the frequent applications of water will not fall directly upon anything of consequence below them, there with advantage they may be grown. Their close proximity to the light in a position of this sort will be another point in their favour.

Border for Roses.—To insure Roses lasting for any considerable time, the bed or border in which they are grown should contain sufficient soil to support them. Although a good deal of assistance may be given to the roots by the application of liquid manure, the annual removal of a few inches of the surface soil, and the replacement of it with new material, still these will not compensate for too limited an amount of space wherein the roots can extend. One of the first matters to be thought of is sufficient drainage. This should consist of several inches of material, such as brick rubbish broken fine enough, clean gravel or burnt clay ballast, and in addition to this there should be an outlet drain from the bottom; over this put thin turf sods with the Grass side downwards. These allow all the superabundant moisture to pass from the soil, and more effectually prevent the earth from washing into the drainage than any partially decomposed vegetable matter will do. Over them place the soil, which should consist of good strong loam, like that in which Rosos out-of-doors are found to thrive the best; to this should be added as much rotten manure as will make the whole a moderately rich bed for the roots to feed upon as soon as they begin to extend, but as the bed is of a somewhat permanent character, a couple of small spadeful of $\frac{1}{2}$ -in. bones to each wheelbarrowful of soil will be an advantage.

Selection of Plants, &c.—In selecting plants for a position of this sort, the most continuous blooming varieties will be found the best. *Maréchal Niel* is a general favourite, producing, as it does under favourable conditions, large crops of handsome flowers; yet I consider it anything but the best Rose for such situations. It is an extraordinarily vigorous grower, and, unless skilfully managed by a yearly reduction of considerable portions of the wood, to be replaced by strong new shoots, it becomes a thicket of small, comparatively weak spray, the greater portion of which does not flower. It also appears in many places to be somewhat short-lived, canker off at the base, or going wrong in other ways, whether grown on its own roots or worked on the usual stocks. Any of the freest-growing Tea kinds that are found to do well for indoor culture will usually be preferable to *Maréchal Niel*, giving that which is of very great importance in the case of Rosos in such positions,

viz., a longer continuance of bloom. There are no structures in which a general collection of plants is cultivated wherein Roses on the roof can so advantageously be grown as in a Camellia house, for here, if trained not too thickly, so as to darken the plants too much, the shade afforded by them during spring and summer would be rather an advantage than otherwise, and the free use of water required by the Roses would do no harm to the Camellias; but here, as in all other houses where Roses cannot be treated exclusively as they need to be in the matter of heat, they cannot be depended on to bloom at the time when the flowers may be wanted in the way in which they will do in a regular Rose house. Roses for planting out in this way should always be plants that have attained a good size and strength. The small weakly specimens that are sometimes used will, in all probability, be a year or two before they make much progress, and sometimes fail altogether, as when any plant possessing only a small amount of roots is thus placed in a considerable body of soil, the latter frequently gets into a sour, unhealthy condition before the roots are sufficiently numerous to take possession of it.

Planting Roses.—The plants should be turned out of the pots, and it is generally necessary to loosen the roots wholly from the soil, so as to lay them out full length in the bed. It is for this reason that it will be found better to plant such Roses when their growth is dormant than to delay it until further in the winter or till spring, when they would be to some extent under the immediate exciting influence of more or less fire-heat or increasing sun power, either of which would be inimical to their flowering next season, through the fact of the buds being all at once excited into growth before any progress at all had been made by the roots. Nothing is more suitable to use for such purposes than any examples that may be in hand or can be procured of Roses that are getting too large for pot culture, as by employing these there will be no loss of time, as they will bloom the ensuing season. No further cutting back will be required than shortening the strongest shoots slightly, or the removal of weak, useless growth. Before the plants are put in their places it will be well to wash them freely with Tobacco water, to which has been added a little sulphur, as, if even no living aphides or red spider can be detected upon them, the eggs of these may exist, which it is very necessary to destroy previous to their coming to life, for prevention is better than cure in their case, as fumigation often harms the foliage, which, like that of most other hardy plants, is more tender and susceptible of injury when grown under glass than out-of-doors. In the case of Roses planted out in situations such as these, or in houses where more or less fire-heat will be applied as the winter advances, where any renewal of the soil is necessary this may be immediately done, through which interference with the roots at the time when growth is commencing will be avoided, a circumstance that has a good deal to do with their ability to flower in the way desired. As much of the surface soil should be removed as can be done without mutilating the roots, replacing it with new material of a description like that recommended for the first formation, treading it down tolerably solid.—T. BAINES.

Indoor Plant Department.

Coleuses and Alternantheras.—Coleuses that are required for growing in pots or for bedding purposes will now need to be kept in a moderate heat. If there be a deficiency of room in the house or pit, where such subjects are to be wintered, cuttings may be taken from any large plants that exist, which will soon strike, if covered with bell-glasses in a genial temperature; the old plants may then be thrown away. Alternantheras that have been struck from cuttings, or plants that have been taken up from the flower garden and potted, should be kept in a growing temperature of from 50° to 55° in the night and supplied with water as required. If maintained in a healthy state through the winter, they will furnish an abundance of cuttings in the spring.

Vallotas.—These easily-grown, handsome, flowering bulbs should, during the next three months, be kept somewhat drier at the roots; yet, as they are an evergreen species, the soil must not be allowed to become completely dried up, or the leaves will flag, which will have the effect of causing them to turn yellow and fall off before their time, which would not only prevent their fully blooming the ensuing summer, but would also considerably reduce the strength and size of the bulbs. This is one of the best subjects for those who require plants in flower to decorate sitting-rooms. A 9-in. pot will hold four or five full-sized bulbs of Vallota that will continue in bloom for a month. It is easily grown and readily propagated, increasing quickly through the production of numerous offsets, which are formed every year at the base of the old bulbs. These, when about the size of large Peas, will have made two small leaves each and a small root or two. They should be placed, eight or ten together, in

6-in. pots, well drained, in ordinary sandy loam, in which they may remain for a year or eighteen months. Like the flowering bulbs, they must not receive so much water during the winter as in the growing season.

Violets.—If a few of these that have been prepared during the summer be now lifted with balls of earth so as to disturb their roots but slightly, and transferred to 6-in. or 7-in. pots, they also should be accommodated in a frame, from which, if required, they can be removed to the greenhouse, or a dwelling room where their fragrance will be appreciated. In all cases with plants of the above description that at this season are kept in frames, it is essential that they have abundance of air by removing the lights for a few hours on fine days, and tilting them when it is wet; if this precaution be not taken they will become drawn; aphides also increase much faster where there is an insufficiency of air admitted; dip or fumigate as soon as the presence of this pest is discovered.

Flower Garden.

Lifting and Storing Dahlia Roots.—In many parts of the country Dahlias have escaped being cut down by frost much longer this autumn than usual, and there is often a disposition to allow them to remain undisturbed as long as they continue to flower; but, as soon as the tops are destroyed by frost, the roots should at once be taken up. If, on the other hand, they are allowed to remain for a time in the ground the result is the latent eyes that exist round the base of the stems, and intended to form shoots for the coming season, are at once started into growth. To such an extent will this sometimes occur, that no eyes remain from which the plant can make growth in the spring, although the tubers may be quite sound. These dormant buds are very often destroyed by the following bad practice. When the tops are cut off at the usual distance of 8 in. or 10 in. above the ground, and the roots lifted and placed with the stems upwards, the sap continues to ascend, and oozes out where the tops have been severed, running down and keeping the remaining portion of the stem wet, which causes it to rot and turn mouldy right down to the bottom, and kills the buds at the base. To prevent this, the roots, when taken up, should always, for a time, be placed top downwards on a shelf in an empty Vinery or dry shed, where they will be beyond the reach of frost, or they may be hung up on nails in a similar position against a wall in any dry, airy building, the object being to get them dry without delay, after which they may be stowed away in any place where there is no possibility of their getting frozen, or of the roots becoming too dry and shrivelled, to prevent which they can be covered over with dry Fern or straw. At the time of taking them up, see that the names are legibly written on the labels, which should be secured to the stems with wire, as twine or bast, when used for this purpose, often rots during the winter.

Herbaceous Lobelias should now be taken up and placed either in pots or boxes as closely as the crowns can be got together, with a little drainage underneath, and just as much soil round the roots as will keep them moist; this will be found much better than heeling them in under stages in greenhouses or similar places, where they are too much in the dark, and receive an excess of water that drips from the plants above. These fine old, late, summer-flowering subjects are not nearly so much grown as they should be; they are easily managed, increase readily, take up but little room during the winter, and they will live through the winter anywhere out of the reach of frost.

Tritomas are not safe in the open ground from frost in many parts of the kingdom, and, even in the most favoured localities, if it be desired to increase them they should be now taken up, the crowns divided, placed singly in small pots, and plunged in coal-ashes in a frame where they can be so far protected as to keep the soil from being frozen; this latter precaution should always be taken, even in the case of plants that are quite hardy; when their roots are in a pot they suffer much more from frost than in the open ground; this at first sight may appear unaccountable, but the way it occurs is thus explained: When the soil is confined within the restricted limits of a pot, it has not room to expand when frozen in the same way as when in an unconfined position, the result of which is that an inward compression takes place which crushes the roots within it; from this it will be seen that even the commonest plant should not be allowed to have the soil frozen about its roots when so placed.

The Christmas Rose (*Helleborus niger*), with its improved variety, *H. niger maximus*, are well worthy of extensive cultivation, flowering, as they do, at a time when outdoor flowers are scarce, and during a festive season when they are so much required and appreciated. With but little care or attention these plants will continue to bloom throughout the entire winter should the weather prove moderately mild, and even during severe weather the protection of a

few hand-glasses or a frame will generally insure an abundance of fine, large, and pure white blooms from the beginning of December until the early part of March. Christmas Roses are of easy culture and by no means difficult to increase. Early in spring large roots or patches may be unceremoniously cut into moderately small pieces with a sharp spade and planted out singly, where they will soon become well established plants, and will flower freely during the following and succeeding winters. When all fallen leaves have been cleared from lawns and similar places, it may, in some cases, be necessary to again pass the mowing machine or the scythe over the Grass, and if the principal gravel walks, or those in immediate connection with the flower garden or the residence, are found to be considerably soiled through decaying leaves or worm-casts, or where the surface may have become covered with Moss, a portion of the surface should be scraped off and should be replaced with a thin coat of clean gravel, which will tend to give the whole an appearance of cheerfulness during the winter.

Lily of the Valley.—This favourite plant is seldom really well managed out-of-doors in this country, except by those who grow it for sale. To the fact of its naturally hardy constitution, enabling it to exist in any out-of-the-way place with the least possible care and attention, may be attributed its frequent neglected condition. The Lily of the Valley has the character of enjoying partial shade, and through an impression that this is necessary the position chosen for it is often so near trees or shrubs, the roots of which impoverish the soil to such an extent as to prevent it from receiving more than a quarter of the nutriment necessary to enable it to form stout flowering crowns. Another source from which a weakly state arises is through the plantation of Lilies of the Valley being permitted to remain too long without removal until crowded together in a way that precludes the possibility of their attaining the requisite strength to produce healthy and vigorous blooms. The present is a good time for planting; choose a piece of good ground completely away from the influence of the roots of trees, dig it thoroughly 15 in. deep, working in plenty of rotten manure; if the soil be heavy, add 2 in. or 3 in. of sand or road grit. In removing the plants from the old bed it will be well to select those with the strongest crowns for forcing this season, dividing the remainder of the strong from the weak, and planting them separately. Open shallow trenches 12 in. apart, allowing 6 in. between the crowns in the rows, cover with 2 in. of soil, on the surface place a mixture of rotten manure and leaf mould, for although the plant (being a native of Britain) is necessarily quite hardy, yet in common with all those that are moved in autumn, it is better to protect the roots from severe frost. Some growers plant early in the spring, just before the Lily in question begins to grow, but after trying both plans I prefer the present season for that purpose. Strong crowns are essential to the production of fine flowers; to insure these plenty of water is necessary in dry weather whilst the leaves are green in summer. Keep them quite clean from weeds; the plants will increase fast, and in the course of two or three years, when the ground becomes too full, take up, thin out, and replant. For forcing always select the crowns with round, plump buds, as these only will bloom.

Herbaceous Borders.—Most of the plants here will shortly be in a condition to have their tops removed; this is necessary for appearance sake, but is not justifiable upon any other grounds. The tops, although they may have no vitality in them, afford protection to the roots and dormant buds that lie thickly about the crown just under the soil. When the old flower shoots are removed, the crowns sometimes suffer in two ways, first, from the absence of shelter that would be afforded were the tops allowed to remain, and also from another and often more serious cause. In many cases the stems are hollow, and, when these are cut at 1 in. or 2 in. above the ground, they get filled with water down to the bottom, right to the very point where the buds are formed that are intended for the ensuing year's growth. To inflict as little injury as possible in this manner care should be taken in the first place never to remove the tops from a plant whilst there is any vitality in them; for, until dead, they must impart strength to the roots, and, when in a condition for removal, they should never be cut so close as is generally practised. Instead of severing them near the surface leave them 8 in. or 10 in. high; so treated they will not be an eyesore. In the case of anything that is at all tender a little dry Fern or litter may, with advantage, be placed round and over the crowns. All weeds should be removed by hand and the ground raked; but, in places where there are yet any leaves to fall from deciduous trees, anything in the shape of mulching over the entire surface should be deferred until all the leaves have fallen and can be cleared off; as, if the mulching is put on whilst the leaves are yet falling, it is afterwards a difficult matter to clear them off.

Indoor Fruit Department.

Vines.—Placing bunches of Grapes in bottles of water to preserve them during the winter is a system often practised, and under certain circumstances it possesses many advantages. In Vineries full of plants, and where there are many Grapes hanging, it is impossible to keep the atmosphere sufficiently dry to prevent the fruit from rotting, and in such cases it is much better to cut the fruit and bottle it than to let it spoil on the Vines. Many old Vineries, too, are far from being waterproof, and, consequently, ill adapted for keeping Grapes. Moreover, where there are only, as often happens, a few dozen pounds of fruit hanging in a large house, from which it would take a great deal of firing to keep out frost and damp for any length of time, cutting and bottling may be profitably resorted to. In cutting bunches for this purpose from 4 in. to 6 in. of the shoot between the main stem and the bunch should be removed along with the fruit. This piece of wood is placed in the mouth of the bottle, which may either be laid down in a slanting direction, so as to allow the bunch to hang over the edge of the shelf or whatever else may be best. Pint bottles suit most bunches, and they need not be quite filled with water; on the contrary, if the end of the shoot is covered that is sufficient. In order to prevent too much water from passing through the wood, the cut end may be half charred before it is placed in the water. A fruit room in which Apples and Pears keep well is a good place in which to put Grapes bottled in this way. The atmosphere about them should be kept dry, and the temperature should not be allowed to fall below 40°. They should also have air and plenty of light on all favourable occasions. Under this treatment few berries will decay, and their flavour will not deteriorate much. Grapes may also be kept by cutting the bunches as if for bottling, and running the cut end of the wood into a fresh Potato. Thus circumstanced, they may be hung up in a room like that to which reference has just been made. This plan is, however, not so good as bottling. When the bunches are cut for these purposes, the Vines should be pruned at once, and all cleaning required should be done. Grapes need not be cut merely for the purpose of relieving the Vines which do not suffer through fruit hanging on them, even until the buds begin to swell the following season.

Plant Vegetables.—What is one to think of learned and professedly scientific men who talk such nonsense as that quoted in THE GARDEN of last week (p. 450) from a lecture of M. Alphonse Lavallée, delivered before the members of one of the Paris colleges? First, we are told that "shrubs and underwood generally will thrive and flourish when planted under Beech trees, but will not even live when planted under the shade of the Walnut;" and, secondly, that "Nettles will only thrive in the immediate vicinity of human habitations, and that when these are removed the Nettles move too." Not one of these statements is true. In the first place, underwood does not thrive and flourish under the Beech; it is the worst tree in the forest for injuring and destroying such, for which reason sportsmen detest it, as cover cannot be grown where it is planted extensively. As to the Walnut, underwood take to it kindly. Not far from where I write there is a tall and shadowy Walnut tree, round the trunk of, and in close contact with which, Rhododendrons, Hollies, and Laurels form an impenetrable thicket, and they have been there for more than twenty years. With regard to Nettles, it is true they often take possession of waste heaps and places near dwelling houses, where they are not disturbed, but they just grow as well about the open skirts of the woods, and in the fields, and elsewhere, as I could show any summer, only in the fields and about the hedgerows the farmers keep them down as much as possible by cutting them over or putting a handful of salt on their roots, as I have often seen them do. It is such statements as those of M. Lavallée that help to bring the teachings of scientific men into contempt.—J. S. W.

The Gold Medal Boiler.—Mr. B. S. Williams gives an excellent account of this boiler, which he has used in his nursery for several years. It never gets out of order, and it burns any kind of fuel that comes in its way.

Mechanism in Plants.—I send you a tendril from a Passion Flower which is a perfect helix or spiral spring. The helix spring is in general use in the construction of various classes of machinery, and it is not at all improbable that the plant production in question, or some similar one, may have given rise to the adaption of its form to mechanical appliances.—J. A. H., *Gateshead*.

The Weather in the Midland Counties.—Already 11° of frost have been registered here, and a considerable depth of snow has fallen. Whether it is to be really a hard winter or not I cannot predict, but if so, we have not many berries for the small birds to feed upon. The foliage of many of our Oaks is still green, as was the case in the late autumn of 1860, which many have cause to remember. J. MILLER, *Clumber*.

TREES, SHRUBS, & WOODLANDS.

AUTUMN TINTS ON FOREST TREES.

BEAUTIFUL and distinct as are the leaves of many of the choice exotics which adorn our gardens and shrubberies, yet in the blending of the autumnal tints of our indigenous park and forest trees there is an appropriateness to the season which we look for in vain among the occupants of the close-shaven lawn; and as it is with the native trees that the forester has principally to deal, and to them that even the landscape gardener must trust for shades to produce his most permanent effects, a few remarks suggested by a ride through Surrenden-Dering Park, in Kent, on the 2d inst., when the noble trees with which that park is so profusely studded had attained the climax of their autumnal splendour, may interest the readers of THE GARDEN. Passing the front of the mansion, the only piece of "verdant sculpture" about the grounds is to be seen in the closely trimmed and compact Yew hedge which shelters the south terrace from the east and north-east winds. Looking thence across the west terrace, towards the garden front of the house, and through a network of the already bare twigs of a spreading *Acacia*, the yellowish-green of a handsome deciduous Cypress contrasts strikingly with the rich dark green foliage of a towering *Wellingtonia*, while rising behind and far above both is a dense and darker mass of Elm and Silver Fir. Near the centre of the lawn a fine Tulip tree presents a compact array of leaves of a somewhat pale orange tint, and close by an ancient Cedar forms a striking foreground to a belt of Oaks, which, in their turn, are overtopped by some stately Silver Firs. Near at hand a graceful Deodar rises from a profuse mass of Portugal Laurel, its bright green showing a well-defined outline against the dense and rolling masses of partially-withered Sycamores. Carrying the eye onwards, we observe a fine belt of Ilex, Beech, Spanish Chestnut, Elm, and Ash, enlivened by the last glories of a *Virgilia lutea* and the bright blue of a row of slender Eucalypti. Looking still further southwards, towards The View, from either side of which "grove nods to grove," we observe in the distance that from each of two fine stools of Oak half-a-dozen stately stems spring up, and these, crowned with all their summer verdure, stand out boldly against the russet tops of the trees in the distant Benacre Wood. Near the top of The View one handsome Beech tree, with its uppermost branches bare, and its lower ones clothed outwardly with an abundance of golden-coloured leaves, is being awayed gently by the wind, and still reveals within a wealth of verdure. From either side bright branches of Hornbeam protrude through the dark masses of Oak, and on the left a graceful Ash of the liveliest green stands amongst some wide-spreading Plane trees, whose yellow leaves descend in showers to mingle with those which already form a russet carpet beneath. A dense mass of Hornbeam intermixed with Oak and Ash bounds the park on the south, and here and there a Maple pushes forward a branch with leaves as pale a yellow as the first spring Primroses. Over a sheltered lake, which reflects the slender stems of a grove of young Oaks beyond it, hang an Aspen with its yellow and russet leaves trembling in the breeze, a Birch with bright stem and dusky top, and a low-branched Alder of the deepest green. Still further to the left, and standing midway between a grove of handsome and still green Oaks, and a cluster of exposed and purple-topped Beeches, a small-leaved Maple and a free-growing Hornbeam spring up together, and as the latter overtops and also flanks the former, the Maple in the full blaze of the setting sun looks like a mass of burnished gold surrounded by a framework of bronze. From the front of the mansion the view across the park to the east discloses the principal elements necessary for the formation of a perfect landscape, water excepted. Here is unity, uniform verdure, an undulating surface, and that variety in planting which divides the whole picture into several compositions. A few single trees of fine dimensions are to be seen on every side, but the greater part of the surface is covered with irregular clumps and groups, such as Claude delighted in introducing to his landscapes. The lights and shades which play upon these are heightened by the effects of judicious thinning, and the groups themselves are sufficiently profuse to

give animation without overcrowding, and thereby disfiguring the scene, while by their variety they gradually retard the vision until astonishment develops into admiration. One large clump in particular, which stands upon a distant eminence, and is composed of Beech and Ash in the foreground and Oaks behind, opens towards the spectator, so that the darker trees give an appearance of greater depth to the recess, while the more lustrous Beech and Ash glow as brightly in the sunshine as if some luminary had entered the recesses of the grove.

Leaving its splendour on the jagged porch:

There an Ash, light and airy, rises from the same spot as a dwarf and gnarled Oak, which it overtops; here a twisted Hawthorn at the foot of a tall Oak which it nursed up clings like a decrepid nurse to the foster child which no longer requires her assistance. Far away in the distance a sombre and apparently impenetrable mass of Firs, straight and formal in its outline, crowns the summit of the hill which overhangs Westwell, and favourably contrasting with this the lofty Beech Wood, which occupies the higher ground above Eastwell Park, stands prominent, the boles bright and the tops one glow of radiance, while here and there small clumps and single trees break away from the mass above and flow, as it were, negligently over the bosom of the slope.

A. J. BURROWS.

SEASIDE PLANTATIONS.

MR. BURROWS (p. 427) mentions a fact that has not been so often noted as one might have expected, viz., the difference in the hardiness of evergreen and other shrubs on the east and west coasts respectively of Scotland and England. On the west coast, near to the sea, and in places within reach of the spray in rough weather, I notice that the Sweet Bay, Golden Holly, *Arbutus*, *Laurustinus*, Evergreen Oak, *Aucuba*, *Hydrangea*, *Fuchsia*, and the *Tamarisk* everywhere succeed best, some of these, indeed, like the *Hydrangea*, *Laurustinus*, Sweet Bay, and Evergreen Oak, doing better near the sea than anywhere else, while among climbers the Ivy and the *Passiflora cœrulea* grow very freely. When we turn to deciduous trees, however, so far as I have observed, we find them thriving better on the east coast than on the west—probably because the gales are less severe. In and about the watering-places on the west coast, deciduous subjects, like the Beech, Elm, Laburnum, Plane, Hazel, &c., make some little growth annually, but they are hardly in leaf before their foliage gets blackened and withered by the blast as if a severe frost had passed over them; and this applies to the coast right away from the Solway Firth to Holyhead, at least, wherever the trees are exposed and not far from the sea, as I have myself noticed at different times. The tree that thrives best is the Willow, and on some Lancashire estates it is planted in belts on the seaward side of the plantations; it thrives amazingly and does not seem to be the least affected by the gales. On some parts of the east coast, on the other hand, mixed plantations of deciduous trees grow freely, and attain a good size quite near the seaside. If I remember correctly, such examples will be found on not a few parts of the coast between Edinburgh and the borders and farther south, and also on the shores of the Firth of Forth, up which north-eastern gales sweep with considerable velocity, but not so fiercely as the hurricanes do on the west coast. Shelter, indeed, seems to be the chief desideratum in seaside planting. Wherever the force of the hurricane is broken, there the trees are tallest and most luxuriant. The strength and frequency of the gales on the west coast may be guessed from the height and extent of the blown sandhills, which, on some parts of the Lancashire coast, extend in a lofty and unbroken line for many miles wherever the shore is flat and sandy; indeed, these hills now form a good shelter in themselves in some localities, and plots of farm and garden land are being taken up behind them where it would have been impossible to cultivate anything at one time. In one such locality, I am told, an enterprising market gardener has started an extensive Asparagus garden that promises to be a most successful undertaking.

J. S. W.

Lombardy Poplars for Lightning-rods.—Professor ASA GRAY sends us "American Agriculturist" the following note: The reason which lies at the bottom of the general belief, on the Continent of Europe, that lightning strikes the Lombardy Poplar trees in preference to others, is coming to light. Green herbage, and green wood—sappy wood—are excellent conductors of electricity. A tree is shattered by lightning only when the discharge reaches the naked trunk or naked branches, which are poorer conductors. An old-fashioned Lombardy Poplar, by its height, by its complete covering of twigs and small branches, and their foliage, down almost to the ground, and by its sappy wood, makes capital lightning-rod, and a cheap one. Happily no one can patent it, and

bring it round in a waggon, and insist upon trying it. To make it sorer, the tree should stand in moist ground, or near water; for wet ground is a good conductor, and dry soil a poor one. It is recommended to plant a Lombardy Poplar near the house, and another close to the barn. If the ground is dry, the nearer the well the better—except for the nuisance of the roots that will get into it.

THE FRUIT GARDEN.

WINTERING STRAWBERRY PLANTS IN POTS.

"CAMBRIAN" in his remarks upon this subject (p. 344) recommends that they should be left out-of-doors until the time when they are required to be placed in heat, but, judging from my own experience, I think it will be found that the grower will have to modify his practice according to the condition in which his plants may be. If they are thoroughly well rooted, then they not only do not receive injury from continuous rain, but really appear to revel in the extra moisture; whereas if the pots be not crammed with fibre they will suffer much from heavy showers. It is the custom in most establishments to lay or pot single crowns in 6-in. pots, employing a rich, unctuous compost, consisting of loam and manure. If strong runners be taken early, and the plants well attended to, they will probably be all that can be desired in the autumn; but it often happens that from various causes this result is not achieved; the pots do not become thoroughly full of strong roots by the time when the autumn rains commence; and from the fact of the rich manurial element of the soil being unexhausted many of the fine roots perish. Such plants I know from experience will often suffer so much that when introduced into the forcing house they fail to start with the requisite amount of strength. They should therefore be so placed that the amount of moisture which they receive may be regulated at will. Protection is not coddling. The former is sometimes necessary, the latter is at all times reprehensible. I prefer myself to place the plants in frames by the latter end of October, merely covering with the lights in heavy, continuous rains, or in very severe weather. Air should never be taken off unless the frost be very penetrating or accompanied by harsh, drying winds, as I have found that a continuance of biting, drying wind playing upon the foliage saps the vitality of the plants to such an extent that they are of but little service afterwards. More especially is this the case if the soil in the pots has become dry and frozen, the crowns then shrivel, and are thus quite incapacitated from yielding a crop. A large proportion of the Strawberry plants here are grown two and three years in the same pots, and it is found that they make roots of a description that no young plant can do, being of such a thick and wiry nature that no amount of rain can possibly injure, and when fruiting they may be set in pans, and the latter be filled up with water without fear of injury arising therefrom. These plants are oftentimes not much to look at; the crowns do not attain that grossness observable in young runners, but they mature better, and the extra strength of root causes them in the forcing season to far outstrip those of finer proportions. Owing also to the amount of manure water which may be administered, a much heavier crop is obtainable from them. I fully agree with "Cambrian" that dryness in the winter is fatal to fertility in the spring, but exclusion of light, if only for a brief period, I have found equally injurious. Some years back a number of good rooted plants were plunged in the open air. A period of hard frost set in, and they were covered with some litter. It froze night and day for upwards of a week, and when uncovered it could be easily seen by the yellow tinge of the leaf that the foliage had suffered. The effect of this deprivation of light was plainly observable at forcing time. When in frames the snow may be brushed off, and the plants do not suffer. I remember once allowing the snow to remain on some frames for a few days, thinking, as the frost was very severe, it would be some protection. I would never do so again; the foliage suffered even in that short time. I have always found that any deficiency in health in the leaf at starting time is sore to be attended by a languid root-action and a consequent falling off in the crop.

JOHN CORNELL.

The Ickworth Imperatrice Plum.—We are just finishing off our stone fruit dessert for the season with this excellent Plum, which is hardly equalled in quality by any other, rich as the Plum family is, in flavour and general excellence. Such Plums as the Jefferson, Coe's Golden Drop, and Reine Claude de Bavary leave little to be desired. And yet the Imperatrice has a vinous richness of flesh and flavouring that none of these possess. Of course, too, its extreme lateness renders it all the more valuable. We have had Coe's Golden Drop from ground cordons up to November, and the Imperatrice until now (the 12th), all from the open air. Plums in the middle of November are always highly appreciated, and yet the Imperatrice is but little grown.

Perhaps the chief reason of this is that it is a shy bearer. As a rule, the trees seem to fruit but little till they get old, nor then, unless forced into fertility by root pruning or confining. It is also a Plum that drops more freely after apparently setting than most others. It is well to assist the fruit through this critical crisis by copious root waterings and top syringings with the garden engine. The leaves seem almost as sweet as the fruit, and to attract aphides in unusual numbers; being also somewhat smaller than the leaves of most Plums, they are the more easily injured or eaten up. It is, therefore, of the more importance to watch for the first appearance of fly, and destroy it at once with Tobacco water, or a deluge of clean water applied with such force as to wash it off at once. Beyond this stage the Imperatrice Plums need no particular attention, only to leave the fruit on the trees till they are partially shrivelled. Their flavour is hardly developed till they reach this stage, and, indeed, not till after being gathered a week or two and stored in a dry Vinery, or other house or room in a temperature of 60° or so. The more, in reason, the fruits shrivel, the richer their flavour, though it is better not to carry the shrivelling process too far, as it reduces the size and injures the appearance of these most luscious of all Plums. Slightly shrivelled and served with light-coloured leaves, with the heavy bloom left untarnished and intact, there are few more interesting and useful fruits served at the best tables than these fine late Plums.

—D. T. FISHER.

The Ansault Pear.—This Pear, a French variety, is highly praised, and stated to be as good as any, if not the best of all, Pears.

Have any of our readers tried it? Those who describe it as above in the "American Agriculturist" are the best of judges.

PRUNING FRUIT BUSHES.

THE plan of cutting the young wood of Gooseberries and Currants close in to the main shoots, and leaving nothing but a few young spurs, is the mode of pruning most commonly practised, but it is questionable whether or not this is the best way of pruning to secure fine crops. I have tried bushes side by side pruned in this way, and others in which was left a good quantity of young wood, and the latter invariably bore the best crops, both as regards quantity and quality. Cutting most of the young wood off limits the fruit-bearing proportions of a tree very much, and I could name a good many instances in which aged bushes were killed altogether by annually persisting in cutting away all the young wood. The worst and common way of pruning bush fruits is to cut in all the side shoots to one eye or two from the old wood, and finish off by cutting the leading or top shoot some 2 in. long. The best and most fruit is produced by the few young buds that are left, and any one may understand that to leave more young buds would be a certain means of insuring more fruit. Besides, to keep up the strength of a bush or tree, it is ne-

cessary that young wood should be allowed to develop itself in some way or other, but, as a rule, this is not taken into consideration. I have said that close cutting is the worst way of pruning. Now, I consider the best way to be never to leave the wood too close together; leave the young shoots at least 4 in. long, and the top or leading shoot 10 in. or 12 in. long. Cut out some of the old branches every year, and allow one or two of the strongest of the young ones to take their places. Let those interested in the matter try this plan, and observe the result. The finest crops of Gooseberries and Currants which I have ever seen were growing in a garden not far from where I now am. The bushes had been allowed to grow so freely that they were in the form of small trees; the branches were not crowded, and the fine, large fruit was hanging in closely-packed rows and clusters, some 6 ft. in length. I am strongly of opinion that where the close cutting in of Apple and Pear trees is practised, as it is in many places, it is as injurious to the trees in the way of producing canker and other diseases and short crops as it is in the case of Gooseberries and Currants.

CAMERIAN.

GRAPES WITHOUT FIRE-HEAT.

Good Grapes may and have sometimes been produced in this country without the aid of fire-heat, and also without the elaborately-prepared borders, which are generally considered necessary for the roots of the Vines. Much of the success or failure, however, of such experiments will necessarily depend upon certain circumstances or conditions, such as the character of the soil, the situation, and the varieties of Grape Vine selected for the purpose, and, above all, the character of the season, which, unfortunately, the cultivator cannot in any degree control. To justify the expectation of the Grape Vine succeeding in the ordinary soil of a kitchen garden, it is necessary that the same should be of good depth, moderately rich, and neither too light nor too heavy, but if at all inclined to the latter condition it should be efficiently drained, and it is only in the south or south-eastern portion of the island that success can be very confidently expected. At all events, I should hardly think the experiment worth trial north of the Trent, nor yet in the moist climate of the western counties. The selection of sorts should be confined to the most hardy and the earliest ripening varieties, such as Royal Muscadine, Dutch Sweetwater, Grove End Sweetwater, or Early White Malvasia; Black Cluster, Esperine (an excellent variety, nearly equal to Black Hamburg), Frankenthal, and possibly a few other kinds.

At this place there is a span-roofed, unheated orchard house, 90 ft. long, 20 ft. wide, 12 ft. high in the centre, and 6 ft. at the eaves. This is planted with fruit trees such as Peaches, Nectarines, and Cherries. A paved path 3 ft. wide makes the interior into a central pit or bed of soil, while a border of soil 3 ft. wide occupies each side of the structure. Some eight or nine years ago it was resolved to train a single Vine rod to a strong wire over the centre of the pathway under the glass, and at a distance of 14 in. from it. The soil inside the house being devoted to the roots of the fruit trees, it was thought inadvisable to plant the Vines inside, and it so happened that on each side of the house was a gravel walk some 3 ft. wide; but as the Vines were to be planted more for the sake of appearance and to enliven leaves for garnishing than for any expectation of obtaining ripe fruit from them, it was considered unnecessary to be at much trouble with them. The gravel was therefore merely removed from a portion of the walk where a Vine was intended to be planted to the width of 4 ft.; the subsoil was then loosened up, one or two barrow-loads of good soil was placed upon it, and in this the Vines were planted, the rods being introduced to the inside of the structure through a hole made in the brick wall a little under the surface of the walk, while the roots were directed, as it were, to find their way into the soil of the open quarter or border, and this they certainly appear to have done. The disturbed gravel was again levelled in, the walk was rolled down, and no farther trouble as regards the roots has been found necessary. The wire stretched above the pathway was very soon entirely covered by the Vines, which are annually pruned upon the short spur system; the young shoots are all stopped at a joint beyond the bunch, and as soon as the shoots will bear it they are tied in close to the rod. No leaves are allowed to form upon the portion of the rods which lead to the wire, and they are consequently unobserved, while a single rod well furnished with fruit, passing all round a structure of such dimensions, has a very ornamental appearance, and does not in the least degree interfere with the development of the fruit trees planted inside the house. I ought to have stated before that the house in question runs north and south, and that the Vines trained above the east pathway are all of the Black Hamburg variety, while those over the west pathway are the Royal Muscadine. The latter has never once failed since the Vines became fairly established to produce an annual

crop of excellent fruit thoroughly ripened, while, on the other hand, the Black Hamburg, although they have never failed to carry a heavy crop of fruit, have not always thoroughly ripened it. Some seasons, however, and the present is an instance in point, they have ripened their fruit as well as could be desired. It gets jet black, carries a beautiful bloom, and its flavour is really very good, while it appears to keep better than fruit of the same kind in other houses which have had the benefit of fire-heat.

Culford, Bury St. Edmunds.

P. GRIEVE.

PEARS FOR THE NORTH.

In the Cleveland district of Yorkshire the small summer Pears are those mostly grown, especially for market purposes. I refer chiefly to the Green Chisel, Crawford, Citron des Carnes, Doyenné d'Ete, and Hessele, all of which ripen perfectly and realise fair prices. The fault of these Pears is, they are too small, and this fault is greatly increased by allowing the trees to bear too heavy crops. This is particularly the case with the Green Chisel and the Hessele, which are often so small as to be unealeable, but when fair samples are offered, these Pears sell readily at the highest prices and are the most certain croppers. The Yat is another handsome old Pear. Last year, when Pears were a failure here, the Yat bore a fair crop and this year a full crop of finely-coloured fruit. Beurré Giffard is a good Pear, but not much seen in the Stockton or Middlesborough markets. Of other well-known sorts of Pears grown here, Muirfowl Egg, Louise Bonne, and William's Bon Chrétien are the best, but they do not come up to the appearance of the same varieties grown in the south. On walls Beurré Diel and Winter Nelis come up to the highest standard of any Pears that I have seen in Cleveland.

CHAS. M'DONALD.

Stokesley.

It does not at all surprise me to hear, as Mr. Hinds asserts, that Gansel's Bergamot Pear does well as a eepalier, as that kind is well known to be a free-growing variety, but it would greatly surprise me to learn that fruit obtained from such trees in northern districts was ever fit for dessert. The fact, too, of Easter Beurré, Beurré Rance, and Ne Plus Meuris, grown as standards, having fruited freely with Mr. Hinds, as he states, is quite beside the question at issue, for no one doubts their free-cropping properties, but what is the use of having them in a collection if they never finish up fit to be eaten? That my condemnation of them, and others mentioned, as dessert fruits was right is proved by "J. S. W.," who fully endorses the greater part of what I said respecting the sorts enumerated and the amended list which I gave.

S. D.

New Grapes.—I am glad to see the Golden Queen Grape so well spoken of from so many different quarters, as most people of late have become very chary about planting fresh sorts, so great has been the disappointment many of those sent out during the last few years have caused. I cannot say anything myself as yet respecting the fruit of the Golden Queen, but that it is a fine, vigorous grower, having stout, leathery foliage, I can bear witness, as one which we have here has made a magnificent rod, and carries such leaves as always gladden the heart of any cultivator who takes any pride in his Vines. I was much struck some time ago with some bunches which I saw of the Aluwick Seedling; the berries were large, of a magnificent jet black, and carried that fine bloom so characteristic of well-finished Grapes. As I had not the opportunity of tasting it I should be glad to hear before planting it what some of our best growers think of it, as I do not care to incur the loss of time and space in trying any new kind that may have to be routed out or grafted just as it ought to be in full bearing; and no doubt there are numbers of others who have the same feeling in this respect as myself, and who are only waiting till they hear further trustworthy accounts from those who have this variety. In large places, where there are many Vineries, the loss of a rod is not often an object, but where glass is more limited and the demands for fruit great in proportion, it is a serious matter, and often puts growers to much inconvenience and trouble. To compare notes, therefore, is a great help.—S. D.

Mealy Bug on Vines.—Paraffin has been vouched for as a sure and safe remedy, if carefully applied, by so many practical men, that we may safely advise you to use it. As soon as the Vine leaves fall, clear the house not only of them, but also of all other plants that may happen to be therein, and give the stems of the Vines a good washing with the paraffin mixture, following this immediately by a thorough cleansing with pure water. To a wineglassful of the ordinary paraffin oil of the shops add 4 gallons of soft water; mix thoroughly and keep in constant agitation while being used. This may be done by allowing one person to draw and discharge again into the vessel, employing a second syringe for this, while another person draws while the liquid is thus agitated, and discharges it on the Vine stems and over all the woodwork of the house. Wherever it touches the mealy bug it is certain death. If on pruning you find any have been left behind give a similar washing later on, and afterwards paint with Gishurst Compound as a check upon other vermin.—"Gardener's Chronicle."

IN THE TROPICS.

WE are pleased to say that Mr. F. W. Burbidge is home after a long journey in parts of the Eastern Archipelago, exceedingly rich in interesting plants. The following extracts from a private letter from him, written on his way home, we feel assured, prove interesting to many of our readers:—

“How I did revel in the fruits obtainable during September in Singapore!—Durian, Langsat (here sold under the name of Duku) Bananas, with a richness and freshness of flavour and perfume utterly indescribable. One variety of all others is especially noble in appearance and excellent in taste, viz., Pisang Rajah, a Malay name signifying King of Bananas. Excellent Persimmons were in the markets; this is the Kaki fruit of China and Japan (*Diospyros Kaki*) which you know well. These fruits are imported to Singapore from Hong Kong and were in excellent condition, plump and unbruised, of a deep Tomato-like red colour with a delicate whitish bloom. The flavour is delicious, reminding one of a well-ripened Apricot, but with a slightly astringent after-taste. There is another tropical fruit, however, which this Kaki fruit still more resembles, viz., the large, Orange-like fruits of a caoutchouc-yielding plant called “Manungau” by the natives of the Malay Peninsula, and which is supposed to be borne by a species of *Willughbeia*. Rambutan and the Mangosteen were plentiful, as were also green Oranges and delicate pink-fleshed Pomoloes from Siam. The Pomoloes of the East are far superior to those of the West Indies, having, indeed, a rich, juicy, Grape-like flavour peculiarly their own. No one would detect a suspicion of the flavour of Muscatel Grapes in the Pomoloes now so commonly imported to Covent Garden Market, but the peculiar Grape-like aroma and flavour of the Labuan and Siamese varieties of this fruit can be likened to nothing else. Very fine samples of Apples from Australia were also obtainable, and Chinese Pears likewise imported were plentiful, but their texture is that of a hard baking Pear when first gathered, and their flavour is very inferior as judged by our own standard. There are two varieties of these, an Apple-shaped fruit with a long stalk, and a short-stalked, russet-skinned variety, which is kept fresh by immersion in water. A few other native fruits, such as Tarippe (*Artocarpus Blumei*), Jack fruit (*A. integrifolia*), Rose Apples (*Jambosa*), &c., made up the supply. Here, in Port Said, the fruit is nearly all imported from the islands of the Mediterranean, or from France, nor is the supply so limited as one might suppose, seeing that, save Water Melons, Dates, and Pomegranates, Egypt produces but little fruit. Pears come here from the Paris markets, as also do many vegetables. Apples, Plums, Custard Apples, Sweetwater and Almerian Grapes, Cadiz Melons, and Pomegranates were tolerably plentiful, good in quality, and cheap; as, indeed, fruit or any other food produce invariably is when there is a constant and general demand for it, as there is here and in other hot, thirsty lands. Nowhere have I seen better Pomegranates, and few fruits are more grateful during hot weather, especially if their crystalline red pulp be eaten with the addition of a little red wine and sugar. How is it that this, one of the most distinctly handsome and classical of all fruits, is so seldom seen on English tables, seeing that they are now so plentiful in our markets? Doubtless, however, they would be far more generally eaten were they obtainable in good condition during our hot season. A golden-flowered Cassia was very showy in some of the gardens, and the freshest of all green creepers was the German Ivy (*Mikania scandens*), so largely grown in America as a window plant and for covering screens in rooms. A long-leaved species of *Casuarina* was very noticeable, and trees of it might readily be mistaken for those of the long-leaved *Pinus*. Different species of *Casuarina* are common shore trees throughout the East, where they replace the Conifers of temperate and cold climates, and not in appearance only, for the peculiar sighing noise of the winds through a plantation of Scotch Pines is exactly reproduced by these plants.

“I have been, I believe, successful in sending home alive most of the plants which I have discovered, and if I can land those I now have with me alive I shall be almost satisfied with the results of my journey. We are gliding through the Canal now, and the fresh green creepers—feathery Tamarisk, with its light foliage and delicate rosy plumes, and the

masses of deep red-blossomed Oleanders—form a lovely contrast to the strip of blue sea-way and the red sandbanks on either side. It is hot here, but nothing compared with the Red Sea, just after one gets inside Cape Gardafni, where the thermometer indicated 110° in the shade under an awning on deck, and the temperature of the sea water was 92°. At Suez we got the first breath of really cool, satisfying, fresh air that we have had since leaving Singapore. Yes, the Tropics are hot at midday, and at times it does rain, but one never suffers from the sudden transitions of climate as in England. When I think of a thick yellow November fog in London, blanket-like in intensity, I shudder. Yet the tropical flowers, of which nearly all travellers (except Wallace) have said so much, cannot for a moment be compared with ours for general effect. For example, I do not believe I could name a dozen tropical flowers that have half the landscape effect of the Buttercups, Bluebells, Primroses, *Myosotis*, Violets, and the rosy-flowered *Lychnis* of English woods. During all my rambles in the East I have seen nothing fresh and spring-like—nothing like the gold of Daffodils on the young Grass, or the royal purple of an autumnal *Crocus* on its Mossy bed. This much is lacking in the forests primæval, and even in gardens—Eastern gardens—this unvarying sense of permanency in foliage and flowers is most evident; the same plants seem to keep up ‘dribblets’ of bloom all the year—the beauty of a ball-room belle in jewelled array, and jaded by a season’s festivities. There is the refined beauty, true enough—*Victoria Lilies* and other *Nymphæas* in open air pools, the pink-blossomed Sacred Lotus also, and the noble *Amherstia*, with its pendants of crimson and gold, and all in groves of tropical Palms; but it is astonishing how soon one tires of this—how much one longs to sniff the fragrance of Pinks and Wallflowers, to stoop for a Violet or two from a Mossy bank, or a Snowdrop from a cottage garden. There is no gainsaying this point—the most beautiful and satisfying of all flowers are those of temperate climes.

“In dried specimens I have done something, and have no doubt that there is a fair proportion of new plants among them, especially Ferns, Mosses, flowering plants, and Orchids. Mr. Veitch has kindly sent most of them to Kew, with the exception of those I have on board with me. One thing about collecting is that it is exciting work—exciting to find a good plant; and then comes the anxiety to hear of its safe arrival at home. You would like to look over my cases here now—nearly everything in good condition. I damp them down with a syringe morning and evening, and find the work highly interesting. It is astonishing how much gardening one may really do on board ship; indeed, this steamer is to me a sort of large ‘Wilson raft.’”

GARDENS IN THE WEST OF SCOTLAND.

Few places will more amply repay lovers of landscape gardening for a visit than the grounds of Earnock and Neilsland, the seats of Mr. John Watson, situated about twelve miles east of Glasgow, in the district of Hamilton. At the former place the quaint old garden is in itself a study, almost surrounded, as it is, by high rocks, evidently the remains of a quarry in bygone times. The surface is very irregular, and studded with old trees. In the lower part is a stream of water constantly flowing, which keeps the atmosphere moist and is conducive to the growth of trees and shrubs. Along the north side an old retaining buttressed wall exists; this was originally planted with fruit trees and flowering shrubs, but now it is a perfect picture, being densely clothed with the black Maiden-hair Fern (*Asplenium trichomanes*), some plants of which measure as much as 14 in. across, and all are in luxuriant health. Notwithstanding the quantity of this Fern growing here, no deviation from the original type is observable. This wall has at one time been formed to protect a terrace. The mass of damp soil behind (now covered with green Moss) renders it eminently fitted for the growth of Ferns. At various elevations in this remarkable glen numerous trees are to be seen, many of them of great age and standing singly. The trunk of one Scotch Fir measures 10 ft. 10 in. in circumference, rises 40 ft. in height without a branch, and is seemingly of a uniform thickness throughout. Several lofty Beeches may also be seen

here, the trunk of the largest of which measures 15 ft. in circumference. A large pendent Yew, the branches of which measure 150 ft. in circumference, was only 20 ft. in height. Many other trees were observed, such as the Hemlock Spruce, variegated Plane, and purple Beech, but they were by no means remarkable for size. Fine old clumps of the original Rhododendrons, such as *R. ponticum* and *R. Catawbiense*, may here be seen in the form of bushes of noble dimensions, and probably from this circumstance the grounds round Earnock House have of late years been richly adorned with one of the finest collections of all the newly introduced Rhododendrons known, both species and hybrid varieties, planted in large, irregular masses. These are all doing well, and are covered with flower-buds for next year's blooming. This portion of the grounds is also richly studded with trees, but none of them the age of those just noticed. In the neighbourhood of the mansion numerous groups of equestrian and other statues have been judiciously placed amongst the shrubberies, many of which were recognised as originally belonging to the Forest collection, which for several years was exhibited in Edinburgh, each being cut out of one block of stone weighing many tons; therefore, getting them into position must have been a work of considerable labour.

From Earnock I visited the neighbouring estate of Neilsland, belonging to the same proprietor. It also contains many fine old trees, standing singly or in groups. Here large boundary belts have been planted, which in a few years will have a striking effect. New Conifers have been largely introduced, particularly *Picea Nordmanniana*, *P. nobilis*, &c. These are planted at regular distances apart from each other, and also from the boundary fences; and if thinning out be carefully attended to, these long belts will in time become highly interesting. It was on this part of the property that I inspected that most ingenious and remarkable structure, the Swiss cottage, which stands on a rocky eminence on the edge of a deep ravine studded with vegetation varying from lofty Firs to dwarf Alpine plants. The rockeries in the neighbourhood of the cottage are of a truly picturesque character, and admirably constructed to give the appearance of natural rocks. Rock plants of every description are here freely interspersed on the sloping sides, and all doing admirably. This Swiss cottage and its adjuncts are certainly a wonderful piece of rockwork engineering, covering, as they do, a large extent of surface, reflecting great credit on Mr. David Mitchell, Mr. Watson's adviser in all matters of landscape gardening.

JAMES M'NAB.

Royal Botanic Garden, Edinburgh.

Rustic Bridge without Nails.—Mr. Livesey, of Stourton Hall, Horncastle, has sent a photograph of a rustic bridge, the design for which he copied from a small view in Vol. I. of THE GARDEN (p. 52). Everyone who sees it, he adds, is much taken with its neat and quaint appearance. It is of 27-ft. span, and crosses a narrow neck of water at the head of the lake where the supply comes in. We will probably at some future time have an engraving made of it for THE GARDEN. Along with the photograph of the bridge came another representing a very fine *Benrro Boac Pear*, trained horizontally and laden with fruit.

Todeas.—The culture of these handsome Ferns is in many cases limited on account of there not being in gardens suitable places in which to grow them. Any one, however, having a conservatory or greenhouse may easily cultivate them with little trouble or expense. Where beds exist in the conservatory, little semi-circular nooks may readily be formed in them by taking out some of the existing soil, and building all round with peat cut into convenient-sized turves. A sheet of glass should be placed in front and one on the top, and the Ferns, which may either be grown in pots or pans, and placed on a little white gravel, or planted out, will, if kept moist, grow vigorously, and, in some cases, succeed even better than those for which more elaborate provision has been made. The idea was suggested by Todea Ferns similarly situated in the large conservatory in the Royal Botanic Gardens, Regent's Park; there, overhung with the fronds of graceful Palms and other plants, they succeed well and have an interesting appearance. The walls of peat are rendered much more effective when covered with Club Mosses, small-growing Ferns, *Fittonias*, *Ficus minima*, and similar plants.—S.

NEW OR RARE PLANTS.

Abutilon igneum.—A very distinct and beautiful *Abutilon*, bearing the name *A. igneum*, was sent to the last meeting at South Kensington, by Mr. Barron, of the Society's gardens at Chiswick. It

Abutilon igneum.

has a large bell-shaped flower of a rich red colour, veined with velvety maroon markings. Its blooms and buds are borne profusely, and stand out free from the foliage, a quality in which the other species are rather deficient.

Masdevallia velifera.—The number of species now known of

Masdevallia velifera.

the genus *Masdevallia* is so great, and the variety of form and coloration they exhibit so diversified, that it is difficult to make a small selection. Fortunately, they require little space to develop their fa

beauty. Only one species was known to the authors of the genus, and Lindley describes only three in his "Genera and Species." In 1861 Reichenbach described thirty-six, but since then fifty additional species, probably, have been discovered, a large proportion of which are in cultivation. The present species is allied to *M. Mastodon*, and was originally described in the "Gardeners' Chronicle," n.s., ii., p. 98, by Dr. Reichenbach. It was discovered by Mr. Patin in New Granada, who sent it to Mr. Williams, of Holloway. Our figure was drawn from a specimen in Mr. W. Bull's nursery at Chelsea. The flowers are green outside at the base, shading into brown upwards, and yellow on the borders and tails, brown inside; petals light green; lip dark brownish-purple; whole flower shining as if varnished.—W. B. HEMSLEY.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

NOVEMBER 19.

ON this occasion some good collections of vegetables were shown in competition for the prizes offered by Messrs. Carter & Co., Sutton & Sons, and Hooper & Co. As regards plants, the chief feature was Mr. Wills' display of new fine-leaved *Dracenas*, which were remarkable examples of good culture, and among them were kinds the beauty of which has been hitherto unknown among *Dracenas*. These were effectively backed up by well-grown, healthy Palms, and edged with neat little plants of *Adiantum Farleyense*. *Chrysanthemums* from the leading growers, together with a bank of new and rare plants from Mr. Bull, made up a very attractive and interesting show considering the season of the year.

First-class Certificates were awarded as follows:—

Calanthe Sedeni (Veitch & Sons).—A hybrid, the result of a cross between *C. vestita* and *C. Veitchi*. Its flowers, which are borne in long, graceful racemes, are of a vivid rose-magenta, rendering it one of the most attractive *Calanthes* in cultivation.

Odontoglossum madrense (W. Bull).—A kind with sweet-scented flowers, having white petals, dark at the base, with a golden-yellow throat.

Cyclamen Mont Blanc (H. B. Smith).—A robust-growing kind with very large, pure white blossoms. One of the finest white *Cyclamens* yet exhibited.

Chrysanthemum M. Crousse (Jackson & Son).—A Japanese kind with curiously-formed, globular flowers of a crimson-bronze colour.

Golden Ilex scotica (A. Waterer).—A smooth, golden-leaved, very handsome kind.

Odontoglossum Alexandræ var. Perrini (Jaques).—A fine variety with violet-edged petals, the backs of the flowers being also purplish-violet.

Miscellaneous Plants.—Messrs. Veitch & Sons again showed an extensive and varied collection of miniature shrubs desirable for winter use in the flower garden. These were shown in round baskets filled with Cocoa-nut fibre. Among them were noticeable Bamboos, finely-coloured Mahonias, *Skimmia obovata*, *S. japonica*, *S. fragrans*, *Aucubas* (literally covered with berries), *Menziesia* (purple and white), *Retinospora plumosa anrea*, variegated *Aucubas*, *Yuccas*, finely-herried *Pernettyas*, *Erya latifolia*, *Cornus Mas* (finely coloured), *Ericas* in flower, *Andromeda floribunda*, *Hollies*, and other attractive hardy plants, all arranged in a most effective manner. Mr. W. Bull, Chelsea, sent an unique group of choice *Orchids* and other plants, which attracted much attention. The background consisted of graceful *Cycads*, the handsome arch-leaved *Curculigo recurvata variegata*, *Ferns*, &c., and in front of these were well-flowered examples of *Dendrobium bigibbum*, *Oncidium macranthum*, the Violet-scented *O. tigrinum*, the chocolate-flowered *O. crispum*, and the gold-laced *O. Forbesi*. With these were effectively associated the blue *Vanda cœrulea*, *Lady's-slippers*, *Odontoglossum Alexandræ*, *O. crispum*, *Lilium neilgherrense*, *Calanthes*, trumpet-leaved *Sarracénias*, and scarlet and white-spotted *Anthrums*, also bushy little plants of *Sonerilas*. In Mr. Wills' group of *Dracenas* the most attractive kinds were *D. Willsi*, *D. Bausei*, *D. Mrs. Wills*, a fine dwarf green and white-leaved kind; *D. terminalis alba*, the counterpart of the well-known *terminalis*, only that its leaves are white and green. With these were also *D. aurantiaca*, a striking kind, as were likewise *D. Cantrelli* and *D. Caustonii*; *D. Goldiana* was also well represented in this group. Messrs. Veitch & Sons showed a fine *Lady's-slipper*, named *Cypripedium Lawrenceanum*, from Borneo. It somewhat resembles *C. barbatum*, but is in every way superior to it, its leaves being large and handsomely spotted, whilst its flowers are large and beautifully striped.

Messrs. Veitch also contributed an extensive and finely-grown collection of *Chrysanthemums*, among which were a goodly number of Japanese kinds with large, handsome, and variously-coloured blossoms. All the best new and old kinds were also represented in other sections. For these a silver Banksian medal was awarded. Mr. Chas. Turner, Slough, likewise contributed a fine collection of *Chrysanthemums*, among which were some handsome standards, as well as plants grown in the ordinary way. To these a small gold Banksian medal was awarded. Mr. Cannell, Swanley, sent cut blooms of zonal *Pelargoniums* placed on a carpet of *Selaginella*

denticulata. Among the most attractive kinds were *Louisa*, rose; Mr. H. M. Pollett, white, with salmon eye; *Edoone*, bright scarlet; *M. Thompson*, magenta; *Lady Sheffield*, deep rose. The same exhibitor also sent pot plants of the white and salmon *Vesuvius Pelargoniums* to show their value in winter. The plants were very dwarf, bushy, and full of bloom. Mr. Gilbert, of Burghley, sent handsome cut blooms of double *Primulas* the names of which were Mrs. A. F. Barron, Marchioness of Exeter Princess, *White Lady*, and a deep, rose coloured kind named *Lord Beaconsfield*. Sir C. W. Strickland showed a flowering plant of *Coburgia trichroma*, to which a cultural commendation was awarded. From the Society's Gardens at Chiswick came a basket of plants of *Begonia Moon light*, loaded with large, graceful trusses of white blossoms, showing that when seen in masses this *Begonia* makes a charming effect at this dull season of the year. From the same source also came a collection of cut blooms of sixteen varieties of *Bouvardias*, a pink zonal *Pelargonium* called *La France*, and the nut-leaved *Abutilon igneum*. Messrs. Hooper & Co. sent groups of finely-flowered plants of *Begonia Froebelii*, raised from seed last spring. The plants were in 5-in. pots, had been growing out-of-doors all summer, were lifted in autumn, and to all appearance a good display of flower for several months to come will be the result. Associated with these in striking contrast was a collection of well-grown *Cyclamens*, the flowers of which varied from the purest white to the darkest crimson-purple and rose. The same exhibitors also contributed a collection of cut blooms of *Chrysanthemums*, the whole being backed up by well-grown Palms, &c. Mr. H. B. Smith, of Ealing Dean Nursery, sent a group of finely-grown *Cyclamens*, healthy, bushy in foliage, and well-flowered, the blossoms varying in colour from pure white through all shades of purple, pink, and rose. A collection of cut blooms of *Chrysanthemums* was shown by Mr. Turner, of Slough, which, on account of their large size and rich colours, was universally admired. A good collection also came from Messrs. Jackson & Sons, in which were several new kinds worthy of notice.

Fruit and Vegetables.—Vegetables were shown in large quantities. In competition for prizes offered by Messrs. Carter & Co., High Holborn, for ten varieties of vegetables, thirteen collections were exhibited. These exhibits were generally good. Veitch's Autumn Giant Cauliflowers, Cabbages, Onions, Potatoes, and Celery especially were noteworthy. Carrots and Parsnips being, as a rule, worm-eaten or rough in appearance. We noted that one exhibitor had apparently greased or oiled his Carrots, which gave them anything but a good appearance, indicating that "dressing" is even practised in vegetable-showing as well as in that of florists' flowers. The first prize was won by Mr. Pragnell, Sherborne Castle, Dorset, who had an even and well-grown collection, containing remarkable heads of Williams' Matchless Celery, clean and handsome, finely-shaped Carrots and Parsnips, well-ripened white Spanish Onions, shapely Beetroot, Turnips, and Potatoes. Mr. Miles, Wycombe Abbey, was a good second, but his Parsnips were rather overgrown, and the Cabbages too white; Onions, Turnips, Beet, Cauliflowers, and Potatoes were excellent. The third prize fell to Mr. Neal, gardener to J. Southby, Esq., Bampton, Oxon; and the fourth to Mr. Baker, Bampton.

In competition for the prizes offered by Messrs. Sutton & Sons, Reading, for twelve varieties of vegetables, there were six collections exhibited. The best in this case also came from Mr. Pragnell, and consisted of a similar collection to that already recorded, with the addition of a handsome brace of Tender and True Cucumbers and a fine dish of Brussels Sprouts. The second prize was won by Mr. Neal, Bampton, and the third by Mr. Iggulden, gardener to R. Baker, Esq., Orsett Hall, Romford. For prizes offered by Messrs. Sutton & Sons for a dish of their Improved Reading Onion there was brisk competition, the first prize falling to Mr. Neal, Bampton. Sutton's Magnum Bonum Potato was well represented, and there were also Potatoes shown in competition for the prizes offered by Messrs. Hooper & Co.

Mr. S. Ford, gardener to W. G. Hubbard, Esq., Leonard's Lee, Horsham, contributed a splendid collection of Apples, consisting of upwards of thirty dishes. These fruits throughout were even in shape and finely coloured. The most attractive kinds were *Devonshire Queen*, *Golden Reinette*, *Cox's Orange Pippin*, *Cherry Orchard*, *Cellini*, *Duck's-bill*, *Blenheim Orange*, *Poor Man's Profit*, *Court Pendu Plat*, and *Wellington*. The same exhibitor also sent three good bunches of *Lady Downes Grape*.

Grapes were contributed by several well-known growers. Mr. J. Atkins, gardener to Colonel Loyd-Lindsay, Wantage, contributed six fine bunches of *Muscat of Alexandria*, well finished as regards colour and bloom, and the berries were even and very large. Mr. Hows, The Gardens, Benham Park, Newbury, showed good examples of *Black Alicante*; and Mr. Wood, gardener to Lady Mastyn, Leybourne Grange, Kent, contributed good bunches of *Gros Colman*. Mr. Harrison Weir exhibited fairly good dishes of *Champion Muscat* grown in a ground Vinery. Mr. Gilbert sent a *Netted Victory* of Bath Melon, good in appearance and excellent in flavour. The same exhibitor also showed a brace of *Montrose Seedling Cucumber*, a small and handsome variety, very green, and specially adapted for winter use. Mr. Gilbert also contributed a handsome bunch of *Trebbiano Grape* finely ripened. Mr. Ross, of Newbury, sent nine well-grown fruit of smooth *Cayenne Pines*, and good examples also came from other growers.

The Chrysanthemum Show at the Aquarium.—This was an excellent show, both as regards plants and cut blooms. Messrs. Henderson & Son exhibited a large collection of finely-grown plants, among which were several new kinds. Messrs. Dixon & Co., of the Anhurst Nursery, Hackney, also contributed many well-grown plants and a stand

of dried Grasses. The best plants in the exhibition, came from Mr. Hall, Tulse Hill; they were very dwarf and well furnished with evenly-developed flowers and healthy leaves. Several good standard plants were shown which were effective, but pyramids were formal and stiff. A box of blooms of *Pelargoniums* was sent by Mr. Cannell from his nursery at Swanley. Cut blooms of *Chrysanthemums* were well shown by Messrs. Saltmarsh & Sons, Cheltenham, and other good growers. Messrs. Hooper furnished a fine stand of dyed natural Grasses and flowers, which attracted much attention.

ANSWERS TO CORRESPONDENTS.

How to Heat a Small Greenhouse.—I have a small greenhouse 16 ft. by 5 ft., and am desirous of knowing how best to heat it during winter. I have tried one of Deard's stoves, which answered very well, but it required a great deal of attention, and generally went out at night when it was most wanted. I have the water pipes passing through the house, but want a way of heating the water economically, and with as little trouble as possible. Perhaps some of your readers will kindly enlighten me on the subject.—A WELSH LADY. [The best manner of warming a greenhouse as above is by means of a hot water apparatus with gas boiler attached, or, if gas be unobtainable, by a boiler that will burn ordinary fuel.—GEO. DEAL.]

Cutting down a Large Screw Pine.—Dewebury (p. 454) will find that his large Screw Pine, if cut down, will grow again. It may be cut down at any time, and it is best to leave a few inches of stem.—JAMES McNAB, *Royal Botanic Garden, Edinburgh.*

—“Dewebury” will do well to get his joiner to make and fit a neat wooden box on the top of the pot in which his Screw Pine is growing; then fill up with soil suited for the Pandanus. In a few months, without risk of loss, he may cut the bottom pot away.—YORK.

—“Dewebury” will find that the best way to manage his Pandanus utilis, in order to induce it to break again, is to thrust a sharp-pointed stick into its heart and give it a twist, so as to destroy that portion of the plant and prevent its further growth in that direction, when it will at once set to work to form suckers, any or all of which may, after a short time, be taken off and struck, or the strongest and best situated be left, and the head cut away. The advantage of treating it in this way is twofold, as the beauty of the plant may be enjoyed just the same; and if cut down so as to entail the loss of the leaves, there would be great risk of losing it, as the chances are, owing to the loss of sap from bleeding, that it would never break again. In taking the suckers off, they should be pulled away with a heel, and have the rougher part of this trimmed off before inserting them in sandy soil, and putting them where they can get a good, brisk bottom-heat.—S. D.

Pruning *Magnolia grandiflora*.—Is it injurious to *Magnolia grandiflora*, growing against a wall, to cut any of its shoots back?—P. [No; a moderate pruning does no harm. Of course cutting off large branches will do more or less injury to any tree subjected to it, inasmuch as that cannot be done without inflicting a severe check on it. The pruning should be done in spring about the time when active growth begins.—E. H.]

Ferns for Planting in an Unheated Conservatory.—Mr. S. Champ (p. 454) will find the following kinds available for this purpose, viz., *Polystichum vestitum venustum*, *Woodwardia radicans*, *Adiantum venustum*, *A. pedatum*, *Lomaria gibba*, *Asplenium bulbiferum*, *Dicksonia antarctica*, *Pellaea rotundifolia*, *Cyathea dealbata*, *Todea pellucida*, *Cyrtomium carotidifolium*, *Athyrium Goringianum pictum*.—J.

—Many greenhouse Ferns, I have no doubt, might be successfully cultivated in a house without artificial heat, especially if the house be large in size and the plants not near the glass. The following list may be found to answer your correspondent's requirements. Many of them have been found hardy in some parts of England: *Dicksonia antarctica*, *Woodwardia radicans*, *W. orientalis*, *Woodia polystichoides*, *Lastrea Standishi*, *Lomaria magellanica*, *Pteris longifolia*, *P. tremula*, *P. eerrulata*, *Cyrtomium falcatum*, *C. Fortunei*, *Adiantum pedatum*, *Asplenium bulbiferum*, *Hypolepis repens*, *Nephrodium molle*, *N. m. corymbiferum*, and *Onychium lucidum*. In all cases good, strong plants should be obtained, or they should be kept in pots till well rooted and strong. A good many species about whose hardiness there may be some doubt might be wintered in such a house if covers of brown paper could be placed over them on cold nights whilst sharp weather lasted. With such care a good many greenhouse Ferns might, I think, be grown in an unheated conservatory.—E. HOBDAV.

—Mr. S. Champ (p. 454) may grow a great variety of Ferns in his cool house if it be well glazed with thick glass, and the sides of Fern houses may be well clothed with Ferns. In this way we have planted out on elevated blocks of stone gigantic *Woodwardias* that over-shadow the dwarfier ones, that is such kinds as succeed heat in deep shade. The following are all beautiful varieties, viz., *Pteris umbrosa*, *P. serrulata*, *P. critica albo lineata*, *Lomaria chilensis*, *Lastrea elegans*, *L. decomposita*, *L. Sieboldi*, and *L. Standishi*, *Balanium Culcita*, *Platylerium acicorne*, *Adiantum cuneatum*, and *Cheilanthes elegans*.—J. GROOM.

Alnwick Seeding Grape.—Is Mr. Hunter's Grape (p. 408) from the stock or kind sent out by Mr. Ingram, and distributed by Mr. B. S. Williams? or that grown by Mr. Bell, of Clive House, Alnwick? or are the

two identical?—J. PEED. [Allow me to say, in reply to Mr. Peed's inquiry, that I got the Vine of Alnwick Seeding grown by me from Mr. Bell, Clive House, Alnwick. A bunch of Grapes being forwarded for my inspection before sending it to the Fruit Committee contained an eye, and I made use of it. I am not in a position to say if that sent out by Mr. B. S. Williams is identical or not, not having seen the produce of his stock.—J. HUNTER, *Lambton Castle.*]

Fruit Culture (*Rhoda Bux*).—You ought to have kept off the frosts in spring from your fruit trees on walls, and it is even possible to do so on espaliers; also to have selected only hardy kinds that ripen well in your summers. You say nothing of the nature of the soil, as Quince and Paradise stocks are not good on all. You can expect no kind of success so long as your trees are devoured by American blight, which is equally injurious under all systems. As to your English trees, you probably cut and pinch too much. Allow the young trees to attain something like a natural fair development before pinching them much. The tying down does not injure the tree, but if the cordons are not well managed they are very unsatisfactory. We think, with you, that the little utensils for training should be sold as cheaply here as in Paris, but with trade matters of this kind we can scarcely meddle. When next about Paris you should see a few established fruit gardens, which give a better idea than those at the exhibition of what you desire.—V.

East Lothian Stocks.—Referring to Mr. Gilbert's note (p. 454), I may say that I have had these Stocks good from both spring and autumn sowings. The former were sown in heat in March, pricked off when large enough to handle and given every attention, with the view of securing good strong plants for turning out early in May. If treated as biennials, the seed should be sown in the open air thinly early in August, be pricked into boxes, or, better still, be potted singly in small pots, and wintered in a frame or pit. If shifted into 48-in. pots early in March, and planted out finally in April, allowing them plenty of space, a very fine and continuous bloom may be expected. I had the best bloom last year which I ever remember to have had; the plants, indeed, flowered continuously all through the winter and spring, and so gay and sweet were they that I was sorry when compelled to pull them up to make room for other plants. Occasionally the plants die in winter, especially if they have been crowded together and the weather happens to be wet and cold. Frost, if the weather be dry, does not seem to hurt them so much. If it is desired to have a continuous bloom they should be planted on a well-drained site, a little raised above the ordinary level, if possible.—E. HOBDAV.

—Sow under a hand-glass or in a cold frame early in March. When fit to handle, prick off the young seedlings into light, rich soil in a cold frame, and when 3 in. or 4 in. high—say, about May 1—plant them out. Sometimes they stand the winter in Scotland, and bloom splendidly early next season; but the best way to save seed is to pot up the single kinds in September, winter them in a cold pit, and plant them out in spring after severe frosts are past. In cold localities they require to be sown in heat in February, in order to get them to bloom well the same season. For flowering early in pots, sow in the open ground about the 12th of August, and pot them when they are 2 in. or 3 in. high. They form very fine decorative plants in pots early in spring. We have often lifted large plants of them in September for making specimens to bloom the following spring, and they are well worth the labour and attention.—D. THOMSON, *Drumlanrig.*

Scale on Epacris.—In answer to “W. M. S.” (p. 454), allow me to state that we have found nothing to equal Abyssinian Mixture in which to dip plants infested with thrips or scale, taking care to keep it from the roots; it will not injure the foliage.—W. H. G.

—Paraffin, mixed at the rate of a small wineglassful to four gallons of water, will kill scale and does not appear to harm the most tender foliage. Your correspondent will therefore be quite safe in using it at least of that strength on his Epacris, and if he does so in hot, soft water, he will find it will mix better and be more effectual than if applied cold. With such hard-leaved plants as Epacris are the heat of the water may be as great as the hand will fairly bear, as in passing through the syringe and air, in applying it, cools down considerably, and the hotter it is, so as not to endanger the safety of the plants on which it is used, the more satisfactory will its effect be, and the same may be said of all the insecticides. In using paraffin for the purpose of destroying scale, &c., the water should be kept constantly agitated either by rapid stirring or, better still, by some one taking up a syringe and returning it again with force into the vessel, so as to drive any paraffin that may, from its greasy nature, be floating on the top into the water, and while this is being done a second person can be putting it on with another syringe. If not managed in this way its distribution is likely to be very irregular, from the cause already specified, and therefore some part of the plants would get more than their share and of greater strength than would be safe for them. Fowler's Insecticide, Abyssinian Mixture, Gishurst, or any of the mixtures of similar character that are now sold will, if used in hot water at the rate of 4 oz. per gallon of soft water, destroy scale, but the plants should, when applying it, be laid on their sides and left in that position to drain for a time, in order that none may get into the soil.—S. D.

The Red-berried Elder.—Does this come true from seed? and have the berries the same qualities as the black-berried or common variety? I should be glad if Miss Hope or some other correspondent would kindly forward me some seeds. That lady's pithy description of the bushes looking like *Pyrus japonica* in full flower makes one long to raise and plant the red-berried Elder in quantity. I have not found sheep urr habits troublesome to the common Elder. The immunity or otherwise, however, of this or other shrubs from their ravages often depends

on the scarcity or abundance of food, or other plants that they may prefer to those that escape, in any given locality. Hence the difficulty of being assured at times that any particular plant is safe against the nibblings of sheep or the ravages of rabbits.—D. T. FISH.

Arbutuses from Seed.—Can these be raised from the berries now ripe? if so, what time ought they to be sown?—A REGULAR SUBSCRIBER. [When the berries are gathered, the seeds should be separated by washing and carefully dried. March is certainly the best time for sowing, which should be done either in pans or frames.—W.]

Lamp Heating.—I am surprised that only one answer has been given to the inquiry (p. 275) as to the adaptability of a lamp for heating, or rather for excluding frost from, a small greenhouse; and, as I used one for years, possibly a short account of my experience may not be out of place. My greenhouse, 10 ft. by 7 ft., had the worst of aspects, viz., facing due north, and had no sunlight from November to March, but, with the help of a duplex paraffin lamp stove, which can be bought for about £1, I managed to exclude frost during some sharp winters. The principle of the stove is the same as that of a duplex lamp, the difference being that metal is used both for chimney and casing; the reservoir holds two quarts of paraffin oil, and will burn (if needed) for thirty hours, though it should be trimmed after every twelve hours, if possible. The chief points to be attended to are: Never to relight the burners without cutting the wicks, to keep the reservoir full, and to be sure not to let the lamp stand in a draught, or a day's amusement may be found in washing the leaves of the plants. If properly trimmed and kept clean, there is no smell from the oil, and the plants do not suffer in the least from the fumes. There is a reservoir for water, which evaporates as the lamp burns, but this I hardly ever use, as a dry heat is wanted to exclude damp, which does more harm to Pelargoniums than cold.—R. G. V., *Shepherd's Bush*.

Names of Plants.—J. T. Hardwicke.—1, *Polypodium glaucum*; 2, *Lastrea tenerianae*; 3, *Pteris incisae*; 4, *Blechnum occidentale*.

Questions.

Morello Cherries.—I have two Morello Cherry trees trained against the back of my house having a direct north aspect, as recommended in THE GARDEN, September 7 (p. 222), and three with an eastern aspect, but shaded by the house. For the last fourteen years they have bloomed and fruited well, but, just when beginning to ripen, nearly all the fruit withers and drops off, so that in no one year have we had two quarts of ripe fruit off the five trees, which have attained a considerable size. It is a clay soil. Can any of your readers suggest a reason for the failure?—G. ATKIN.

Weeds.—Can any of your readers tell me the best way of getting rid of weeds in a large herbaceous garden many years neglected? There are beds of shrubs and old plants, also a great many bulbs and bulbous roots which were only planted last spring.—R. D., *Dolgelly*.

Jerusalem Artichokes and Rabbits.—Can any of your correspondents inform me if rabbits will meddle with Jerusalem Artichokes if planted in a wood where they abound? I have a piece of ground here on which Potatoes have been grown so many years in succession, that they now scarcely reproduce their own seed, and I thought of planting it with Artichokes, if they will be safe from rabbits.—W. V., *Boro'bridge*.

Icehouses.—Which is the best form for the bottom of an icehouse? The one here has a flat bearded bottom, with holes formed in the centre, and a space of $\frac{1}{2}$ in. around the outside between the walls and the boards. Would it not be better if the boards sloped from the wall to the centre, with a grating placed there to carry off the water? I might mention, perhaps, that there is a drain in the centre underneath the boards, and that the latter are fixed like those of an ordinary floor; therefore, the space underneath is quite hollow.—W. V., *Boro'bridge*.

Hybridising and Propagating Clematises.—Being fond of Clematises, I have now some seventy varieties of them under cultivation in my garden, and I am anxious to obtain some new combinations by hybridising. Will any of your correspondents who have done so much already through your columns to spread a love for the Clematis amongst amateurs be so kind as to give me some practical hints about the matter, as well as about the best mode of propagating Clematises?—WM. KRAHNSTOVER, *Baden-Baden*.

Salvias in Small Pots.—Most of us are acquainted with the usefulness of the good old *Salvia splendens* for autumn blooming, and with *genuiflora* for spring decoration in the form of large plants. But let me just say a word in favour of *S. splendens* in small pots. Take off some good strong cuttings the first week in July, put three round the side of a 5-in. pot, and put them into a moist pit, such as a Cucumber pit. When struck, pinch out the tops, and after they break shift them into 6-in. or 8 $\frac{1}{2}$ -in. pots, giving them a place in a cold pit or greenhouse, where they will soon make good plants. When they begin to bloom give them some encouragement, putting them into a warm house as the days get cold, and the grower will be rewarded with some excellent small plants for conservatory or indoor decoration. Let me just say that *S. miniata splendens* and *splendens alba* are both good *Salvias*, and worth everyone's growing. They are much dwarfier and bloom earlier.—J. C. F.

NOTES FROM KEW.

HARDY SHRUBS.—Though not in flower at the present time, three North American shrubs amply deserve notice on account of the beauty of their decaying foliage. The Blue Tangle or Dangleberry (*Gaylussacia frondosa*) is especially attractive, its slender branches being well clothed with bright crimson-scarlet foliage; in summer the leaves are green above and glaucous beneath; the sweet and edible fruits are dark blue with a white bloom. The dwarf Huckleberry (*Gaylussacia dumosa*) has summer leafage green on both surfaces; at present its leaves are also finely coloured, the scarlet being considerably toned down by an admixture of bronze; the fruits of the latter are black, whilst the blossoms of both are white, tinged with red. *Leucothoe coriacea* is another neat-growing Heathwort, with leaves now bright red. The foregoing have been very conspicuous for several weeks past, and still retain their leaves. All would come in useful for making gorgeous masses of autumnal colour quite close to the ground.

GREENHOUSE PLANTS.—*Daphne papyracea*, with its bright green, lance-shaped leaves, and with the tips of its twigs burdened with clusters of long-tubed, pure white blossoms, is a neat-habited and free-flowering plant; it is a native of India, where a paper is manufactured from its bark, which, on account of its great durability and immunity from damp, is much used in some parts for deeds and records. *Moræa edulis* is a charming South African Irid, with Rush-like leaves and flower stem, 1 $\frac{1}{2}$ ft. to 2 ft. high, bearing beautiful pale blue blossoms, each of the three sepals having a yellow blotch in its centre.

STOVE PLANTS.—*Stephanophyllum Baikiei*, a highly interesting and beautiful Acanthad, first flowered in this country just twenty years ago. It was raised from seeds taken from a dried specimen collected during Baikie's Niger Expedition by Barter, the botanist, who accompanied the expedition, and who fell a victim to the deadly climate in July of the following year. The plant is of pretty good habit, and its fine, curved, tubular, scarlet blossoms are freely produced in large terminal panicles. *Thunbergia Harrisii*, a native of Moulmein where, in some parts it forms the brightest ornament of the jungle, makes a handsome stove climber, easily kept within due bounds. The blossoms are borne abundantly, even by young plants. In colour, the limb of the corolla is a bright purplish-blue above, very pale beneath, fading from yellow into white at the throat.—†

Hydrangeas in Pots.—These are most useful plants, especially for all concerned with the plant decoration of rooms. They are not half so much grown in private gardens as they deserve to be, this being in part owing to an impression that they are difficult to flower freely, some thinking that it is necessary to have large plants to secure an abundant bloom. This is not so, however. If properly grown no plant is more certain to bloom freely, and in any sized pot, from a 4 $\frac{1}{2}$ -in. upwards. The grower may easily secure good plants in bloom every week in the year, so every one may suit himself with the size of plants and their time of blooming. Here we have not been without good plants during the last twelve months, and at the present time (Nov. 20) we have some handsome plants in 5-in. pots with heads of bloom 8 in. in diameter, while the plants themselves are not more than 1 ft. high. Few plants will stand such an amount of ill treatment as these flowering Hydrangeas, which will even live in dark places for a long time, and even withstand the influence of gas. Their usefulness in this way is shown by the numbers that are grown for Covent Garden. Those who have to furnish London rooms with plants know best what is useful in this way. When some flowers are pink and some blue the effect is of course the more valuable. With your permission I will at some future time state my way of cultivating these plants.—J. C. F.

Burnt Clay.—Since this is a material of great value in the amelioration of heavy clay soils, a brief explanation how the operation of burning is carried out may be useful to the inexperienced. About London the work is done at any convenient season, but preferably in autumn and in dry weather. The soil is dug out to a depth of 6 in. or 8 in., then a thick layer of brushwood is placed on the ground, and over that a layer of fine breeze or coal; this is followed by a layer of clay, then more breeze, followed by more clay, and so on, until a heap or ridge is formed. The brushwood is then ignited, and this fires the breeze or coal, and the whole heap gradually becomes a burning smouldering mass. Care must be taken that the fire does not burn through at any point. The cost in the neighbourhood of London is about 3s. a yard.—"Florist."

NOTES OF THE WEEK.

Vanillas at Syon House.—These bear, if possible, heavier crops at Syon House this year than we ever remember to have seen them. Some of the bunches number as many as fifteen pods, each of which measure nearly 9 in. in length. The plants now in fruit are growing in a narrow border filled with corks and brick rubbish, on which are placed a few inches thick of peat, and under which run hot-water pipes, from which a little bottom-heat is obtained. Several more Vanillas have also lately been planted in a shallow box set on a shelf on the back wall of one of the houses, the plants being trained along the wall and on a slanting piece of woodwork forming part of the roof. In this position they have grown amazingly, and they will no doubt bear good crops of fruit. Moisture, warmth, and sunshine appear to be important points to be observed in the culture of the Vanilla, but the most important of all is the perfect fertilisation of the flowers when they open.

Hydrangeas in the South of Ireland.—It is really astonishing to see the Hydrangeas hereabouts. I was curious to count the number of flower trusses on one plant, and found them to be 385. I also measured one or two of the largest trusses, and found them to be not less than 15 in. in diameter. This was a blue-flowered plant, and its circumference was 74 ft. It is not by any means uncommon to meet with Hydrangeas hereabouts much larger than the one here alluded to. A friend told me a few days since he had counted not less than 950 trusses upon one plant.—*JOSIAH JEFFREY, Derry, Ross Carberry, Co. Cork.*

An Alps Garden under Glass.—Mr. Joad, of Wimbledon, has lately had a rockery constructed under glass by Mr. Pulham, of Broxbourne, on which are planted many of the rarer and more beautiful of Alpine plants. The house is a span-roofed one, and the stones are built up in such a way in the middle as to give it a natural cave-like appearance. All round the house, too, stones are placed, in which are left deep pockets filled with soil, in which the plants are growing. The plants have, as yet, made but little progress, but when fairly established this will prove a very interesting house. The plants can readily be watered by means of a perforated pipe fixed along the middle of the house close under the roof, and to which a tap is fixed, so that the plants may be subjected to a fine spray of water whenever that may be desirable. In the same garden are also houses planted with half-hardy plants, and herbaceous plants are likewise grown to some extent out-of-doors. Altogether, this garden is a most interesting one.

Pine-apples in Covent Garden.—The culture of Pine-apples at St. Michael's for the English market appears to be on the increase, judging by the quantities of fruit now to be found in Covent Garden; their quality also seems to be improving yearly. At the present time really handsome, well-coloured Pines, weighing from 5 lb. to 8 lb., may be bought at prices varying from 10s. to 15s. each. This must in time put a stop to Pine growing in England, as far as autumn and winter fruits are concerned, but during what is termed the London season, a time when all kinds of fruits are in most demand, foreign Pines are scarcely obtainable, and good English Queens fetch more money per lb. than it takes to buy a whole fruit of the Smooth-leaved Cayenne at this season of the year.

Dipladenia boliviensis in Winter.—This is one of the best stove climbers which can be grown for supplying cut blooms during the autumn, winter, and spring months. We lately saw plants of it in the gardens at Syon House flowering freely, the blooms being very white, with a rich golden-yellow throat. The plants were trained on single wires placed across the house at good distances apart, a method by which comparatively little light is kept from the other occupants below, whilst a good effect is the result, and a supply of cut flowers of the choicest description is obtained when they are in most request and most valuable.

Orchid Houses in Winter.—At the present time the Orchid houses in Meera, Veitch's nursery, Chelsea, are as attractive as at any other season of the year; and, this being a comparatively flowerless time with other plants, Orchids are now doubly valuable. A fine specimen of *Cattleya exoniensis* bears from eighteen to twenty gorgeous blossoms, and associated with it are also *C. Dowiana*, *C. labiata*, and *C. elegans*, all finely in bloom. In one corner of an Orchid house an effective display is made by means of *Calanthe Veitchi* and *C. vestita*, intermixed with *Oncidium varicosum* and *O. Forbesi*. Amongst these are also suspended finely-flowered plants of the beautiful *Dendrobium formosum giganteum*. Quite a floral avenue is likewise formed in one of the houses by *Calanthe*, the showy blue *Vanda corulea* and *V. suavis*, *Odontoglossum Ruezli* (growing in small pans suspended from the roof, the flowers of which are very

large and finely coloured), and various *Dendrobiums*. The charming *Burlingtonia fragrans*, growing on long blocks of wood, is bearing a rich profusion of graceful racemes of ivory-white, sweet-scented blossoms. In a long corridor, occupied on each side with fine-leaved *Dracenas*, *Palma*, *Begonias*, *Crotons*, &c., yellow-flowered *Oncidiums* in pots, and *Dendrobium formosum giganteum* on blocks suspended among the graceful leaves of the *Palma*, &c., have a charming effect at this season of the year.

Asparagus decumbens.—This makes an elegant basket plant in winter. Its foliage is light and feathery; it assumes a pendent habit, and, being of an intense green colour, when well grown it is effective either in the conservatory or dwelling house. We lately saw plants of it grown in pots in one of the houses in Mr. Ware's nursery, Tottenham, on a shelf, to which they formed a green and elegant curtain.

Passiflora quadrangularis in Fruit.—In addition to the fine effect which this climber produces when in flower during summer, it is by no means unattractive in winter when in fruit. Only as many fruit as the plant will conveniently carry without sustaining injury should be left; these will attain the size of a swan's egg, and when they assume a transparent cinnamon colour they are very handsome. We lately saw a plant of this Passion-flower in fruit at Syon House.

Bouvardias at St. John's Wood.—There is just now a good display of Bouvardias in the Pine-apple Nursery. The plants, which consist of the best cultivated kinds, are arranged on stair-like stages in a large span-roofed house, where some hundreds of them, with flowers of various colours, have a good effect. They are the produce of cuttings struck in spring, planted out-of-doors in light, rich soil, kept well supplied with water, mulched during summer, lifted in September, potted, and, after being set in a cold frame shaded from bright sunshine for a week or two, placed in the house which they now occupy. All Bouvardias may be successfully grown in this way, a plan which produces far larger and more healthy, free-blooming plants than pot culture. Plants cut back after flowering, and planted out in spring, might be grown into large specimens, which in the conservatory, at this season of the year, would be most desirable. If, after being potted, the plants are kept in a healthy, growing condition, and the flowers cut as they open, a good succession of bloom may be obtained all through the winter months.

Epiphyllums on Pillars.—These look well clothing pillars or supports in the conservatory or warm greenhouse. They are easily brought into the required form for this purpose, and they may either be grown in pots or be planted out, but the former way is the best, inasmuch as the plant can be removed when out of flower and replaced by something else. We lately saw some plants similarly situated in flower in a garden near London.

Luculia gratissima.—This beautiful plant is, it is satisfactory to find, being brought into more extensive cultivation than has hitherto been the case. For some years past it has been a scarce plant, even in the best nurseries, but it is not at all difficult to find at the present time an abundance of thrifty young plants of it in most of the London nursery gardens.

Asplenium nobilis.—This is a graceful Fern, with light, lace-like pinnae and arched fronds, which somewhat resemble those of *A. viviparum* or *A. lineatum*. It is well adapted for growing in small pots for the decoration of vases in the greenhouse.

Bignonia venusta.—This old-fashioned but still excellent plant is now finely in flower at Syon. It is trained over the rafters of a half-span-roofed house, from which long festoons of its brilliant orange blossoms gracefully depend. Such a charming plant, flowering abundantly at this season of the year, might be more frequently met with under the same conditions than it is, for few climbing plants are more worthy of a place in the conservatory, however small that structure may be.

Prize Vegetables.—The extensive collections of vegetables shown at South Kensington on Tuesday last are such as are likely to have a good effect. It has too often and too long been a defect of London shows that kitchen garden products were not illustrated thereat. Mr. Pragnell, of Sherborne Castle, Dorset, who has for the past year written the "Diary" in the pages of THE GARDEN, won the first prize in the two great classes. The many important prizes he has won during the last seven years, where the competition was of the keenest, leave no room to doubt that he is the best of vegetable growers.

The *Victoria Regina* in the Regent's Park is now very fine. It has thrown up this year thirty-nine blooms, and some are yet to come, the plant being as yet as fresh as at any time during the season.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—Shakespeare.

THE INDOOR GARDEN.

PLANT ARRANGEMENT IN GREENHOUSES.

THIS is a matter about which it is difficult to write. The subject cannot be comprehensively treated upon paper, but anyone who has visited many small gardens at different seasons of the year must be aware that the quality of the plants and the way in which they are often arranged in greenhouses leave much to be desired. Large and handsome greenhouses are frequently built contiguous to villa residences. The gardens in the neighbourhood of large towns are necessarily small, and do not admit of much space being devoted to pits and frames in which to cultivate plants, and without such adjuncts there is much difficulty in keeping the house gay with flowering plants. In the construction of such houses, the architectural effect is studied at the expense of those conditions that would conduce to good culture. The best houses are those with span roofs, and of such a size that the plants intended to be cultivated in them should not be far removed from the glass. As a rule, the further plants are from the glass, so much the more difficult it is to keep them in a healthy condition and well furnished throughout with leaves. Houses over 16 ft. wide should have a central stage and platforms round the sides on which to place the plants. If one side of the glass structure be attached to the house, I would still have it of the span-roofed form, and the raised platform could be carried round the house all the same. This platform should be about 2 ft. 6 in. in height, the side stages to be reserved for small and medium-sized plants. A row of large specimen plants might be arranged along the centre of the middle stage.

Let us now consider what would be the best plants with which to furnish such a house and keep it gay without much extraneous aid. What are usually termed hard-wooded plants are rather difficult to keep in health when mixed up with a miscellaneous collection of rapid growing plants, such as Pelargoniums, Cinerarias, Calceolarias, &c. A most useful class of plants are the Epacrises, nearly all of which are winter-flowering, and they have the merit of lasting long in flower. A selection of the best varieties will maintain a succession of bloom from January till June; the flowers also last a long time in a cut state, and the colours are such as usually give the greatest satisfaction. The pure white *E. candidissima* is very beautiful, and *E. hyacinthiflora carnea* produces beautiful spikes of flowers. There is also a fine variety named *fulgens*, and *E. Kinghori* is a compact-growing, free-flowering sort. These blossom early. Amongst later kinds that continue the blooming period until June may be named *E. Eclipse*, the flowers of which are very long, bright crimson, with a blush or white mouth. *E. miniata splendens* is perhaps the best of all: this variety and *Eclipse* are well adapted for exhibition purposes. When these plants are of small size they ought to be arranged on the side stages near the glass, and as they grow larger they should take their places in the centre.

Azaleas of the Indian and Japan sections should also be grown by the owners of small gardens. Those with decided colours are the most useful, and if only a few can be grown the pure white *A. Fielderi* should be amongst

the Indian sorts. One of the latest in flower is *Brilliant*, which should also be grown. These Azaleas flower without the aid of artificial heat in May, June, and July. Standards with round heads are very useful, and form a distinct feature. Camellias cannot be dispensed with in any house if it be at all adapted for their culture. They are so hardy, and when their management is understood they require no more attention than common plants. The old Double White and the pure white variety named *Fimbriata*, with fringed edges to the petals, produce superb flowers. *C. imbricata* is an old sort with well-formed crimson blossoms. *C. Reine des Beautés* has flesh-coloured flowers. *Countess of Derby* is a beautiful white kind striped and flaked with rose. The above selection of hard-wooded plants may remain in the greenhouse during the whole year, except in the months of July, August, and September.

Roses in pots constitute an indispensable feature in the greenhouse, and for this purpose small plants in 8-in. pots may be grown; they might be protected during winter and early in spring with glass lights in a place fully exposed to the sun, and be removed to the greenhouse when the buds are well advanced. Hyacinths, Tulips (of the early flowering Dutch sorts), and Polyanthus Narcissus, potted from September till the end of November, will, with but little trouble, yield a succession of flowers. Those to bloom early should be removed to the greenhouse about the end of November, and the latest about the end of January. *Mignonette* in pots trained as standards or bushes, and in pots from 5 in. in diameter to 11 in. according to the taste of the owner, is always welcome, and *Cinerarias* in all their varied colours form a brilliant feature from Christmas until the end of April. Seedlings are the easiest to manage, and their size should be regulated by that of the house. Neat, bushy plants may be flowered in 6-in. pots, and large specimens in 8-in. ones. *Calceolarias* require very similar treatment; and if a frame can be spared for the one, with its back to the south, the same will answer for the other. Their desperate enemy is green fly, a pest which must not be allowed to establish itself.

The culture of stage and fancy *Pelargoniums* is well understood, but, nevertheless, one often sees the plants badly cultivated, the stems drawn, and the leaves spotted. No plants are easier managed, but they must be kept in a light, airy place, and free from green fly. They succeed the *Cinerarias* and *Calceolarias*, being in flower through the months of May, June, and July; the zonal section succeeds these, and, with good management, are in flower until November, when the different sections of *Chrysanthemums* take their place. A collection of plants, such as I have just enumerated, will keep a greenhouse gay all the year round, with the aid of a few cold frames. *Liliums* have not been included, but a selection of them will last in bloom for three months. *Phloxes*, *Carnations*, and *Picotees* will also flower during the months of July, August, and September.

As to the method of staging the plants, the large ones, as I have already said, must first be placed in the middle of the centre platform, with a row of dwarf plants along the edges. The usual and easiest way is to allow the intervening space to be filled with plants that form an almost unbroken surface, falling from the centre to the edge. If this arrangement be carried out the formality ought to be broken up by introducing tall plants here and there at intervals. Standard Azaleas answer for this, and *Mignonette* trained as standards also answers well; so do *Phloxes*, perpetual-flowering *Carnations*, and, in their season, neat plants in 6-in. pots of standard *Chrysanthemums*. In large houses the hardier Palms may be

introduced with excellent effect, and in all cases flowering and fine-foliaged plants should be judiciously mixed, and a distinct class of plants should be grown on the different stages. On the front and end portions should be placed the hard-wooded Cape and New Holland plants with hair-like roots. These increase rapidly in size, and if good specimens be desired, they must not be overcrowded with other plants. If the pots be as large as 12 in. in diameter, dwarf plants, both flowering and fine-foliaged, may be arranged underneath them, but they should not be allowed to grow close to the branches of the specimens. The back stage near the residence will be much shaded by the centre stage, and more so by the wall of the house. Green-house Ferns and Camellias may entirely fill that portion; they will form a distinct and pleasing feature, and if more Camellias be wanted, they might be grown on the back part of the centre stage. Avoid overcrowding in all cases. Cleanliness is imperative. Let the pots be quite clean, and all decaying leaves be removed as soon as they are perceived. Fumigate the moment the least trace of thrips or green fly is observable.

J. DOUGLAS.

GARDENIAS, THEIR CULTURE AND PROPAGATION.

In most gardens of any considerable size few or more Gardenias are found. They are the sweetest of all flowers, and perhaps the most highly appreciated of any. Their odour is peculiarly rich and satisfying, combining that of the Stephanotis and the Rose. The colour of the more popular sorts is the purest white, which renders them the more valuable for bouquet and other purposes. Gardenias, however, if crushed or when about to fade change colour, but even when thus discoloured by time or accident they retain their sweetness. Considering the almost unparalleled popularity of Gardenias, it is surprising that they are not more and better grown in private gardens than they are. The Gardenia is assuredly one of those plants that is better grown in and around the metropolis than in the provinces. The finest Gardenias which I have ever seen have been in some of the London nurseries and in Covent Garden Market. The varieties most generally grown for market purposes are *Gardenia florida*, *f. variegata*, and *Fortunei*. On the whole, I prefer Fortune's Gardenia; the flowers are larger than those of *florida*, and it also flowers more freely. The habit and constitution of the plant are also all that can be desired. It may, however, be remarked in passing that the variegated variety of *florida* flowers more freely than the normal type, and produces flowers almost equal in size and sweetness to *G. Fortunei*. There is a larger flowered variety called *G. radicans major* which produces flowers nearly as large, though not so finely shaped as those of *G. florida*. The variegated variety of *G. radicans* is almost worth growing as a fine-foliaged plant, and it flowers as freely as the green-leaved or normal type. The *Gardenia citriodora* is a plant of a character quite different from either of these, and is comparatively rare in cultivation. It is, however, very fragrant, with a strong suspicion of Orange blossom about the perfume. The flowers are also single. The old *G. radicans* is also a useful free-flowering variety much prized for bouquet making. *G. Stanleyana* is different in habit and flower from all the others, but as regards completeness it should hardly be named with them. It is a highly ornamental stove plant with large trumpet-shaped flowers something like those of a *Datura* or *Brugmansia* about 8 in. long and 5 in. across. Its colour is peculiar, the interior being a sort of reddish-brown approaching to crimson and margined with white. The place for this variety is the rafter, wall, or roof of a stove, as it delights in heat and moisture, being a native of Sierra Leone. The other varieties, with the exception of *G. citriodora*, which comes from Natal, are natives of China and Japan. The whole of them are, however, shade and heat-loving plants when in full growth; and the best places in which to grow Gardenias in perfection are close pits or houses where an atmosphere bordering on saturation and a top and bottom-heat of 65° or so can be maintained while they are making their growth and opening their flowers. Under

such favourable conditions the foliage and flowers will be almost as large again as under drier and cooler treatment.

After flowering, Gardenias should be shifted into fresh pots if needful, and any pruning or training required should also be attended to. Under good culture, however, Gardenias can hardly be said to need either. Even the flowers should be gathered singly and mounted; as if cut with branches many shoots would be cut off, each of which in the natural course of things would have developed into a flower-bud. Pruning in the same way, by diminishing the number of the shoots, reduces the flowering capacities of the plants, and should be indulged in as little as possible. After the growth is completed and partially ripened, all the hardier varieties, such as *florida*, *Fortunei*, and *radicans*, may be placed for a few months in cold pits or even in a sheltered position out of doors throughout the warmer summer months. The comparatively sudden transition of the plants from cool to warm quarters quickly develops the flower-buds, as Gardenias bear forcing well, and seldom drop their buds, unless exposed in a dry atmosphere as well as to a high temperature. At one time the belief was almost universal that manure heat was necessary to the perfect culture of Gardenias; and doubtless many fine flowers were grown in manure beds by our fathers and by some of us in our younger days. Great merit was attributed to the ammonia not only in developing the size of the flowers, but also in filling them with fragrance; and, considering the close affinity between ammonia and some of our scents, this idea had a scientific basis to rest upon. But doubtless the chief use of the manure heat was the maintenance of a genial atmosphere around the roots and tops of the plants. Certain it is that Gardenias are now generally grown as well or better without manure heat than ever they were by its aid; and one of the best means of keeping up a constant supply of these sweet flowers is to devote a house for their cultivation, and plant them out in borders. Low span-roofed houses, with heated borders on either side of a central path, are, perhaps, the most handy for the wholesale culture of Gardenias; but lean-to houses also answer well. In the case of the latter, the whole of the back wall may be covered with the plants with several rows of dwarf plants in front. Houses of this sort will produce an immense quantity of flowers, for Gardenias may be forced into producing two crops in a year. They flower on or near the extremity of the young shoots, and as young shoots are produced and ripened the development of the flowers follows as a matter of course on the application of sufficient heat and moisture. Gardenias planted out also yield a long succession of bloom. The flowers being gathered at different times, the young shoots are also formed at different seasons, and large, well-established plants under liberal treatment thus get into a very useful way of semi-perpetual flowering, which enables the cultivator to gather many a welcome flower at almost any season. But of course Gardenias, by means of changes of temperature and treatment, may also be made to flower but once in a season, as is mostly the case with those cultivated in pots. Whichever mode of culture is adopted, the best soil for Gardenias is equal parts loam, leaf-mould, or thoroughly sweet and well-decomposed manure freely mixed with sharp silver sand. I am well aware that many prefer peat to manure or leaf-mould, and, no doubt, Gardenias do well in loam and peat, but they do better with the manure or leaf-mould. The drainage should be ample, but not excessive, as the Gardenia loves moisture when in full growth. When the pots or borders become full of roots, few plants enjoy manure water or turn it more rapidly to good account than Gardenias. Everything, however, approaching to over-feeding or over-saturation must be avoided.

The Gardenia has one failing, and that is, it is very attractive to mealy bug, and once this pest gets established it is difficult to eradicate. The surest means of keeping the plants clean is to mark the first bug and touch him with paraffin oil; this oil seems to kill at once. Thrips, aphides, scale, &c., are the result of errors of cultivation mostly, and will not occur under the above treatment. Soap may, and paraffin or a touch of turpentine will, clear them off at a single dressing.

Few plants are more easily propagated than Gardenias. Small pieces of the young ripe wood, inserted in silver sand, either under or without bell-glasses, in a sharp bottom-heat of 80° and a moist atmosphere, root readily. When rooted, pot

off singly and grow on in a brisk temperature until the plants become large enough to flower, stopping or training if needful to form dense bushes—the best of all forms for Gardenias in pots. Much time is gained by this tropical treatment of young Gardenias, and the plants seem the healthier and flower the freer for it afterwards. One word of caution may be given to those who have not handled many Gardenia flowers. They are remarkably easily injured by careless gathering or rough handling, and every bruise will show and tell before many hours are over. Gardenias also look best mounted with their own leaves; the larger varieties of Myrtle form the next best setting. They associate admirably with delicate pink Roses, red Camellias, the softer pink and more delicate scarlet Pelargoniums, red or scarlet Spiræas, pink Lilacs, bright-coloured Pinks, Euphorbias, Begonias, Cyclamens, Primroses, Heaths, Calanthes, Dendrobiums, and other Orchids, &c.; while for a bridal or other wreath few flowers can equal in sweetness and graceful beauty Gardenias, white Spiræas, white Roses, and Lilies of the Valley, the Gardenia citriodora being used in such a wreath in lieu of Orange blossoms. D. T. FISL.

TORTURED CHRYSANTHEMUMS.

I HAVE for many years been an admirer of the Chrysanthemum, having been much struck by the beauty of the plants at a show I once saw in a country town. These were, as a rule, strong, well branched and clothed, and carrying on each from twelve to twenty blooms in different stages of development, hanging with their natural grace from the ends of the branches. Not having seen an exhibition of Chrysanthemums since that time, I determined this week to visit the show at Bristol, expecting to see again these graceful forms with the improvements in size, colour, and growth which might naturally have accrued during twenty years of careful cultivation. There was never a more complete disenchantment. On entering the room I beheld numerous stands of plants, some tortured into the shape of an umbrella, others of a gigantic pork pie, but all having their convex surfaces covered with fine blooms, from thirty to fifty in number, but all in precisely the same stage of growth, and staring in the most unnatural manner straight up to the ceiling. Except, perhaps, in a stand of show Dahlias, I never saw floriculture so at war with æsthetics. I ask you to allow me to enter a protest against such treatment of my old favourites, not only on that ground, but because it must, I should think, tend to discourage their cultivation by amateurs and others who may, from seeing them thus elaborately tormented into strange forms, suppose that their natural habit is ungraceful or unpleasing. The misplaced industry displayed in the production of such specimens is, in fact, no proof of good cultivation, as we all know that it is easier by manuring and disbudbing to persuade a Chrysanthemum to yield large, full flowers than to keep it in a robust, well-balanced form, capable of showing off its blooms to the best advantage. There is also a drawback to showing all the blossoms of a Chrysanthemum in their full development, in the circumstance that most of the favourite exhibition sorts being of incurved form, the backs of the florets only appear; and these surfaces being, in all, except the white and yellow varieties, more or less suffused with grey, the beauty and distinction of colour are, in the darker kinds, almost lost. It possibly arises from the fact that only a few kinds will bear the necessary manipulations for being twisted into specimen plants that a Chrysanthemum show (at least, the one I saw) presents so little variety. I had fondly hoped to make acquaintance with new flowers, or some of those beautiful sports from the older sorts for which the Chrysanthemum is remarkable, but no; with the exception of one or two new Japanese varieties among the cut blooms, stand after stand consisted of a repetition of the same flowers, so that if about a dozen I could name had been excluded, the stands would have been left bare. May I, in conclusion, venture to suggest that you might, if you concur with these remarks, give a figure of a specimen Chrysanthemum plant as it should appear? I cannot but think that your efforts of pen and pencil would go far to rescue our most beautiful winter flower from the barbarous usage to which it is now subjected by those who exhibit it. J. P.

ORCHIDS FOR COOL HOUSES.

SEVERAL correspondents having requested me to furnish a few details respecting Orchids which will thrive in a low temperature, I willingly do so, and I do it the more readily because I am sure that when the subject becomes more generally understood many admirers of Orchids, who have greenhouses, or even slightly heated pits, but who are deterred from attempting their culture by an impression that the temperature at their command is insufficient, will willingly try their skill when they can be made to understand that they can commence with every probability of success, and provided ordinary care be exercised, without the risk of losing their plants. The great argument (apart from the acknowledged beauty of the flowers) in favour of the culture of Orchids is that although the plants are rather higher in price than those of other classes, when good Orchids are judiciously purchased and carefully cultivated, the money expended in them is only invested, the plants being generally worth more each year. In a few cases where the accommodation has been very limited I have succeeded in getting the owners to make the attempt, and in every instance it has been found that not only was sufficient heat at command, but that the temperature formerly kept up was even too high to suit many of them. I was formerly induced to give the subject of cool treatment of certain Orchids more attention by a passage in a letter from my brother, then in Mexico, in which he urged that he was sure, from his observation in the Tropics, that we gave Orchids generally too much heat and too little air. Among other things he mentioned that at a certain season he invariably found ice in the hollows of the leaves of the Agaves growing in close proximity to the Orchids early in the morning. I consider we have been rather long in arriving at a correct conclusion with respect to the cool treatment of many Orchids when we call to mind the number of cold-loving or cold-bearing plants which we have found in the same regions, such as Calceolarias, Verbenas, Fuchsias, Lobelias, Bouvardias, Mutisias, Rhododendrons, Bambusas, and a host of others, many of which are quite hardy with us. As regards my own experience, extending over a period of twenty-four years, I must say that I have seen but few Orchids under cultivation killed or permanently injured by cold even under the most trying circumstances. Through failure of the heating apparatus, &c., on two or three occasions I have seen 4° of frost in the cold Odontoglossum house (a thing not to be imitated or approached), while on the other hand I have seen a great many Orchids killed or rendered valueless by excessive heat and want of air. In furnishing the annexed lists I shall confine myself to those showy varieties with which anyone who may be induced to grow them will be delighted when his care is rewarded by the production of their flowers. I shall also only mention such kinds as I have myself successfully treated in the manner described.

Before enumerating the varieties, however, it would be better to say that the successful culture of Orchids does not altogether depend on the temperature; there are other conditions not requiring much skill, but equally necessary, which I will set down in as few words as possible, viz., that cool treatment be regularly persisted in and the house not allowed to rise more than 10° above the minimum by day, except by sun-heat. On bright days when the sun gets power, heat should be shut off from the pipes and a little air given at top and bottom until the sun is off the glass, when the air should be taken off and the heat turned on again. The valve regulating the heat should be carefully studied, so as to know exactly how much it should be turned in order to get the required heat, for if turned full on the circulation is generally too rapid and the heat thrown off too strong, in which case the plants rapidly decline. That the plants be watered with cold rain water only, and never watered overhead or syringed summer or winter; watering overhead keeps the plants up by means of the top and does not encourage them to root as they do when watered in the pot and aided only by the moisture in the air. That during winter the distribution of water about the house for the purpose of evaporation be kept well in hand, so that at night and even during the daytime in severe weather the house is comparatively dry. That the plants be grown on open stages at a distance, where practicable, of from 1 ft. to 4 ft. from the glass, and in full light; where fixed open stages are not available, the

plants should have a temporary wooden stage erected for them over the close stage by placing boards about 6 in. wide (at progressive heights) on bricks, an inch or so of space being left between each board, or by placing the plants on inverted flower-pots, raising them to the required height in order to allow of the air playing freely around them. Stagnant damp in winter is more fatal than cold, and to avoid this, means should be provided for giving a little air at top and bottom. This latter I provide for by removing a brick as near the ground as possible in every 4 ft. run of the house, and one at either end. These air-holes I leave open summer and winter. That the cultivator keep an eye to the last matured growth, and immediately water any plant showing the least sign of shrivelling as regards such growth, taking care not to overwater a plump plant. That care be taken not to hang baskets or blocks over the plants on the stages, and to distribute them sparingly, frequently changing their relative positions, taking them down to water them, and allowing them to drain before being replaced. Where Orchids are to be grown as cool as possible, it is best to have them potted or basketed in two-thirds fibry Orchid peat in lumps, and the remainder living Sphagnum Moss, without admixture of sand in any case. I find that roots sent out into the peat are more easily kept good under adverse circumstances than those in any other material. The Sphagnum Moss, however, is useful, particularly in summer, through its growing and keeping a healthy moisture around the plant.

The first list, from which I have excluded those varieties which appeared to me to be doubtful or difficult, comprises Orchids which will thrive in a minimum temperature of from 40° to 45° Fahr.; the 45° to be considered as the general minimum, with a possible fall to 40°. Those marked *b* should be in baskets or on blocks. The Mexican and Guatemalan varieties to be kept drier than the majority of the others.

Orchids thriving in a minimum winter temperature of from 40° to 45° Fahr. :—

Angræcum falcatum <i>b</i>	Lissochilus Horsfallii

transparens <i>b</i>	the varieties
Wardiannum <i>b</i>	Zygopetalum—all the varieties

Along with these may also be grown many of the varieties enumerated in the preceding list, if care be exercised—some of them, such as Cypripediums, Dendrobiums, and Oncidium, even with advantage.

The cultivator should water these varieties as little as possible throughout the winter consistent with preserving the plants in a plump condition, so as to retard as much as possible the young growth until the days begin to lengthen; but any plants which will grow should have the best possible place and attention given them, each plant being treated by itself and without regard to the condition of the others. On the care given to the individual plants depends the success of the whole. It is of the first importance that the plants should be obtained from some nurseryman on whom reliance can be placed that they have been fairly treated, and not grown in any unnecessary heat. During the present winter we mean to make a trial with some of the varieties enumerated in the first list in an unheated house (where they are at present), and respecting which I hope to give an account in the spring.

JAMES O'BRIEN.

Pine-apple Nursery, Maida Vale.

Bamboo Mat Shading.—Concerning this, one of the best of shading materials for glasshouses, Dr. Wallace, of Colchester, writes to us as follows: "We have had this shading in use for the past five years, and we find it to be just as good now as when first put up. We have just got over, after much trouble, a small consignment of these Bamboo mats for introduction as Orchid-house shad-

ing. They are, perhaps, the cheapest shading out, being about 3½d. per square foot; they only require a small roller at the bottom to stiffen them, and they roll up on the principle of the Cunningham mode of reefing sails."

FERNS FOR PLANTING IN COOL CONSERVATORIES.

MR. CHAMP does not say whether he requires the Ferns for which he asks (p. 454) for rockwork or otherwise, but the following are the best of any I know, and I do not think the list can be improved: The first I would specially recommend is *Woodwardia radicans*, a grand Fern, having handsome drooping and gracefully-arching fronds, which, when the plant is fully established, grow from 3 ft. to 6 ft. long, and keep in a fine, fresh-looking condition the whole of the year, and unaffected by sharp frost. Although tolerably hardy, it will be quite as well to protect the crowns by means of dry leaf soil or Cocoa-nut fibre if the temperature of the house ever runs down much below 30°, otherwise the soft embryo fronds are apt to sustain injury. Being naturally of a very pendulous habit, it should be planted high up in the rockwork, and allowed plenty of room and soil for its roots to ramble in, or if grown on the flat, it will be necessary to stake and tie up the fronds a little to keep them from spreading flat on the ground. Good rough lumps of loam and peat with plenty of water all through the summer will grow this fine Fern in perfection, and anyone requiring a handsome ornament for a large elevated vase or basket will find this one of the very best plants they can use. Protected in the manner above mentioned, it will live out in the hardy Fernery, and there forms an exceedingly ornamental object, and very distinct among others. Next to the *Woodwardia* in point of merit is *Lomaria chilensis*, a truly noble species, having smooth, dark green fronds, from 3 ft. to 4 ft. long, rising from a large, scaly crown that creeps along the ground or over the edge of rockwork, to which it clings with great tenacity, and soon spreads over a large space. *Lomaria magellanica* is another fine Fern, the fronds of which rise from a densely-covered crown of a massive tree-like stem, and are very broad and gracefully arching; when fully grown it forms altogether a fine object, but is not quite so hardy as the preceding. *Cyrtomium falcatum* is quite an acquisition either indoors or out, and is as distinct and striking among Ferns as the Holly is among evergreens, the fronds being much of the same character of that well-known shrub so far as regards their thick texture, and rich dark green glossy appearance. This fine Fern is sufficiently hardy to stand out in favoured localities without protection, and should be in every Fernery. *Adiantum pedatum* is another Fern of rare merit, and the only drawback it has is that it is deciduous, but for all that it ought to have a place even among the most select, as the delicately-tinted green of its beautifully radiating fronds makes it a very conspicuous object wherever grown. *Lastrea Filix-mas cristata* is a highly ornamental Fern, having fronds about 2 ft. long, the margins of which are beautifully crested up their entire length, and terminated with more densely tufted points, the weight of which causes them to arch over in the most graceful manner possible. *Lastrea opaca* is likewise a very fine Fern, and a somewhat recent introduction from Japan. This has fine spreading, deep green fronds that always look the picture of health on account of their bright polished appearance. *Lastrea Standishi* is another remarkably fine species from the same country, and quite distinct from the foregoing, the fronds of which are very large, of a pale green, and most elegantly divided. *Lastrea Sieboldi* is also a fine variety of this numerous family of Ferns, having spreading, very broad, triangular, deep green fronds rising from a strong crown after the manner of *Cyrtomium falcatum*. *Lastrea Gollieana*, too, is a strikingly ornamental kind, and well worth growing in any collection where space can be afforded. *Polystichum falcinellum* is one of the finest of the *Polystichums*, and this, with *P. pungens* and *P. Branni*, are the best of the exotic varieties of these that obtain much size. *Asplenium lucidum* is one of the most showy of Ferns, and makes a remarkably fine bold plant where it can have plenty of room to develop itself properly. *Dicksonia Calcita* is likewise a very grand Fern that makes noble fronds 4 ft. to 6 ft. long, of a fine bright green colour, which, when fully matured, and in a fertile state, are thickly dotted on the under side with dark brown spores that add much to their ornamental appearance. *Davallia canariensis*, better known as the Hare's-foot Fern, is a general favourite, and does remarkably well where it can have just a little shelter during very sharp weather. *Pteris cretica*, *P. c. albo-lineata*, and *P. scaberula* are all sufficiently hardy to succeed in such a position as that your correspondent names, and are considered quite choice even among the best of greenhouse collections. If deciduous kinds are not objected to, *Struthiopteris germanica* is sure to please, as the fine fronds it makes are regularly arranged just like the feathers in a shuttlecock, and droop over at the points in a graceful

curve, thus giving the plant a very stately look, and making it a most conspicuous object wherever it may be placed. *Onoclea sensibilis* is also a very beautiful Fern of a fast-spreading habit, but it is one that likes plenty of shade and moisture and a loose soil in which it can ramble freely. S. D.

COOL-GROWN BOUVARDIAS.

"J. S. W." (p. 465) has done well to direct attention to the matter of growing these lovely flowers in a low temperature, because this points directly to their being within the reach of cultivators generally; whereas growing them in a temperature of 70°, 80°, and 90°, with fire-heat during the greater part of the year, must not only limit the number of plants grown in many places, but would deter thousands from even attempting their cultivation. My experience is that *Bouvardias* are plants that may be grown as easily as *Chrysanthemums*. They may be brought to perfection with little more heat than that afforded by a cold frame; indeed, after the plants have done flowering they may be placed in a frame. Here they will start into growth in March. The young shoots may then be made into cuttings, and rooted in a top and bottom-heat of 60°, in which they may be grown until May, either in a frame or house; but after that time they may be hardened off, and the earlier in June they are placed entirely out-of-doors the better. If they are not planted out the pots should be plunged in ashes, or something of the kind, in a situation fully exposed to the sun. This is of far greater benefit to them than a high house temperature at any time, because when the plants are grown under cool treatment and fully exposed to the sun there is not the slightest danger of their not flowering satisfactorily in autumn in any heat between 40° and 50°. It should be fully understood that they are greenhouse and conservatory plants and not stove subjects, a fact which cannot be made too widely known by all who wish to extend the cultivation of these fine-flowering plants.

CAMBRIAN.

—"J. S. W." is right in saying that a good deal of difference of opinion exists as regards the treatment of *Bouvardias*, but he is not equally correct when he says that there can be only one right way. What the right treatment should be is simply determinable by the end sought to be obtained. Those who have not the means or inclination for keeping their plants warm enough to obtain from them the greatest quantity of flowers they are capable of producing through the winter season will be satisfied with the results of cooler treatment, but in writing what I did on the subject I was simply suggesting treatment based on what I had proved in practice to be calculated to give the best return, viz., the production of the greatest quantity of fully-developed flowers. "J. S. W." says shoots made during winter in a stove temperature produce poor flowers. Of course they do, but this only applies to some plants, not to all in cultivation by a great many, that is, if the grower be properly up to his work and treats them so as to impart to them the vigour indispensable to the development of flowers possessing sufficient substance. I have reason to believe that there are few who have been engaged in the cultivation of any considerable number of plants that have subjected many of the different species which they have grown to such a wide range of temperature from that which is generally looked upon as below the orthodox minimum to the opposite of being too high as I have done, especially the latter, by subjecting them to more heat than it is often supposed they would bear or do well with; but the heat which a plant will bear and do the best under I have found to be quite as much determinable by the condition of the plant, consequently upon its general treatment from the cutting pot upwards, as upon the country from which it comes, and this especially with such plants as *Bouvardias* and others similarly used that are generally grown up from cuttings in a year or a little over, flowered, and then thrown away to make room for others grown in a like manner to take their place, or otherwise headed down and grown on for a second season. T. BAINES.

Pot-Chrysanthemums for Exhibition.—It cannot be conceded that the *Chrysanthemum*, as grown in the ordinary distorted form for exhibition, in the shape of an even, compact bush or as trained down like an inverted saucer, possesses either grace or elegance. Growers of plants for exhibition are seldom concerned as to free or natural growth; their great object is to show as much bloom as possible, and in doing this invariably do it in a most formal way. The *Chrysanthemum* has naturally a habit that does not well accommodate itself to the purposes of the exhibitor, and therefore there must be pinching, depressing, distorting, and training to secure the required dwarfness and the proper outline. In no form, as exhibition plants, are they more pleasing than when shown as standards, if the growth be natural and the heads carefully, but not stiffly, arranged. Some

standards grown by Mr. Levesley appear to me to exceed in elegance and beauty all his fine-trained plants; each stem is about 2½ ft. clear, and the pyramidal head of foliage and bloom about 3 ft. in height. Such plants as these would have a superb effect if grouped amidst a bank of fine-foliaged plants. In the large-flowering trained plants special formality is added by the peculiarly formal or ball-like form of the flowers; and when a plant is seen in which a roundish form of training is aimed at, and all the shoots, topped by a large round flower, are tied up with extreme rigidity, it must be admitted that it requires a considerable amount of the florist's enthusiasm for perfect blooms to enable one to become entranced with the plants as a whole. That good effective plants of *Chrysanthemums* can be grown in pots with a minimum of training there is no doubt, as is evidenced in plenty of gardens where showing is not the order of the day.—A. D.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Cheap Basket for Ferns and Orchids.—Few baskets can be made more quickly or cheaply than those formed of virgin cork. Suitable pieces, cut in equal lengths, can easily be made into a round basket by means of strong wire, and a bottom may be fixed in a like manner. Club Mosses and *Ficus minima* grow readily on cork, and an elegant green basket can thus be obtained, which, if filled with Orchids or Ferns when suspended from the roof, has a fine appearance.—S.

Watering Camellias.—Many who have well attended to their Camellias during the summer and autumn are apt to cause themselves irreparable loss in the matter of bloom by neglecting to water them properly at this season. Those rules which apply to most hard-wooded plants with respect to watering in the winter do not hold good in the case of Camellias. They must not stand dry, and if they once become so, water them twice in the interval of a day, so that the balls may become thoroughly saturated. In dull, damp weather, when judging in the ordinary manner is deceptive, tap the pot; a clear ringing sound denotes the necessity of a good moistening. Bud-dropping is extremely vexatious, and a want of moisture at the roots and a too confined atmosphere are fertile sources of mischief in this way.—J. CORNHILL, *Byfleet*.

Growing Palms in Loam.—Though generally found growing in peat, nearly all Palms succeed equally well in loam. We lately saw examples of *Cocos Weddelliana* in Mr. Peed's nursery, Norwood, growing entirely in yellow loam, and seldom have we seen more healthy plants, the foliage being much darker and more glossy than that in plants grown in peat.—S.

Winter-flowering Pelargoniums.—These were well represented at South Kensington on the 19th ult. by a fine group of dwarf, well-flowered plants of the Vesuvius type, named respectively Salmon and White Vesuvius—kinds similar in all respects to the original Vesuvius, except in colour. They were shown by Mr. Cannell, of Swanley, and were of a useful size for decoration, and probably more serviceable for supplying cut flowers than large specimens. I also noticed some very fine bunches of cut blooms of the best varieties, the colours of which were extremely rich, and certainly better than can be had during the hottest months of the summer. This is probably owing to the blooms having more time to develop their full beauty, a cool, dry atmosphere and subdued light being apparently more favourable for this purpose than a maximum amount of sunshine. As regards culture, the principal points are growing the plants during summer in some fully exposed situation, so that the growth may be firm and well matured, and keeping all blooms pinched off in order to concentrate the energy of the plants in the wood. About the end of September the plants should be transferred to a light, well-ventilated house, where a little fire-heat can be applied sufficient to create a light, buoyant atmosphere, with plenty of ventilation on all favourable occasions. As the blossoms expand a little artificial manure applied in a liquid form will greatly assist the development of the blooms. The many beautiful varieties that have been raised during the last few years fully attest the successful results of careful hybridising, as both in habit of growth, sturdiness of footstalks, and substance and form of petals, one would scarcely credit that they are the descendants of the ragged, flimsy flowers of olden times.—J. G., *Linton Park*.

Violets in Pots.—Violets are just now unusually plentiful for the time of year. We may, however, possibly suffer from a dearth of them later on in the season. If the convenience of a cold frame can be had, or a space in the greenhouse accorded them, a few potfuls taken up now will be found very acceptable, when there are none to be found out of doors. A pot full of Violets in a room, or a few in the conservatory, afford a delicate and refreshing odour.—J. CORNHILL.

TREES, SHRUBS, & WOODLANDS.

PINUS INSIGNIS.

My experience with this Pine is, that it is often planted in too sheltered positions, and, consequently, gets much injured from making spongy growth. Being about one of the first to commence growing in the spring, it is liable to be injured by frost in May, and again early in winter; vigorous young plants often make a second growth, which rarely ever gets matured, and the consequence is, that if the winter be severe they succumb. There is at Ashburnham, in Sussex, a very fine plantation of this tree, which was planted about the year 1840, and, with very few exceptions, all have survived. The position is a northern one, on a stiff clay, previously well drained. These trees cannot be termed perfect specimens, owing to their being planted too thickly, but, taking the plantation as a whole, they are very fine, and have a pleasing effect when viewed from a distance; many of them are from 40 ft. to 50 ft. high, with good trunks. The exposed situation occupied by this plantation has a tendency to check luxuriant growth, and to encourage compact, well-ripened wood, and, moreover, abundance of cones, from which large numbers of plants have been raised. Young trees of this Pine are so frequently "coddled" in pots for years after being raised from seed, that it is almost impossible to disentangle their roots; and if they be planted with the balls entire, they will not withstand a strong gale. When grown in pots or boxes when young, the roots should be shaken out thoroughly every season, with as little damage as possible to the rootlets. By this method they will be found to flourish much more satisfactorily than when planted permanently, because the roots will be more pliable, and readily spread out without injury. Another mistake is often committed in not planting this Pine out permanently when about 3 ft. high, as when larger it cannot be so safely transplanted. As regards the value of the timber, I cannot speak practically; still, in the case of several trees which were cut down, it was found that they contained a good amount of resinous matter, and that the timber was pretty hard, but not so close grained as Scotch Fir.

A. HOSSACK.

Ragley, Alcester.

—Rich and beautifully green as is the colour of *Pinus insignis* where it succeeds, it is in many places one of the most disappointing of Conifers, and should never be planted unless in sheltered situations, as, where the wind gets at it, or it is exposed to severe cold, its foliage gets sadly browned and its growth stunted, a condition in which it is anything but ornamental. Mr. Baines has, therefore, done well in warning intending planters against its extensive use. No doubt, it will do well in the southern or south-western counties of England, and, I remember, some twenty-seven years ago there used to be a very fine specimen of it at Bowood, but how it fared in the sharp winter of 1860-61 I have not heard, or whether it is now in existence or not. *Pinus Cembra* comes nearest to it of any *Pinus* I know, as regards colour and habit, and, being of a more limited growth and exceedingly hardy, is well adapted to take the place of *P. insignis* where that variety cannot be grown. For small pleasure grounds or villa gardens where space is circumscribed, this is one of the best of Conifers to use, and shows up in most pleasing contrast with the silver-grey of the Deodar or any other light foliage of similar character. My favourites amongst Conifers for planting as single specimens where space can be afforded for them to develop themselves are *Picea nobilis*, *P. Nordmanniana*, and *P. cephalonica*, all truly noble objects; the latter, however, is somewhat tender, and should only be planted in positions where the sun does not shine on it in the morning so as to excite early growth or cause a too rapid thaw after severe frost, as that is how the soft, prominent buds generally get injured. *P. nobilis* and *P. Nordmanniana* will endure almost any amount of frost, as will also *P. grandis*, which is another very fine Conifer that should have a place even in the most select collection. *P. austriaca* is, as Mr. Baines states, one of the most valuable of Conifers, and so hardy that it will succeed almost anywhere; besides which, its timber is of great use for the roofing of sheds and other building purposes of a similar description. For growing for ornament as well as for profit none surpasses *Abies Douglasi*, the growth of which in free, loose soils is as rapid as that of the Larch, and the tree, containing as it does so much resinous matter, would, no doubt, form sleepers for railways and telegraph posts quite as or even more durable than those obtained from the latter. The wood of the Douglas Fir when cut down is remarkably heavy, and were it only better known and more plentiful, it would not be long before planters would turn their attention to it and grow it extensively. With those who preserve game, the Spruce is a favourite, as pheasants are known to be fond of its friendly shelter, and cannot be seen in it by poschers at night, but as the Douglas Fir sends out its branches in the same horizontal way, it is just as useful for the same purpose, and of far more value in every other respect.

S. D.

AUTUMN AND SPRING PRUNING OF TENDER SHRUBS.

It seems to me that a good deal of discrimination is necessary in the pruning of certain kinds of the more tender shrubs. I do not believe it is at all safe to prune trees or shrubs that are apt to be injured by frost in the autumn; Roses, for example, which are newly planted if pruned in November or at the time of planting, are far more likely to suffer or even die than those which are left unpruned. For this reason I have long since discontinued pruning newly-planted Roses, feeling quite certain from past experience that it is by far the safest plan. Nor is it advisable to prune tender varieties before spring for the same reason. In some way or other the pruning enfeebles them, and of course the more severely the plants are pruned, the more likely they are to suffer. I have an impression that more Roses die the first and second year after planting than at any other period of their existence, and I have little doubt that they die because they are usually sent from the nursery with such poor roots, in the case of the Brier at least, which has a root more like the head of a walking stick than anything else. It is often recommended to cut down Laurels and evergreens at this season, but such advice is questionable. It can be no benefit to a plant to be headed down at the approach of winter, during which time the naked stems will be exposed to all the vicissitudes of our changeable climate at its worst season. I find that bushes cut down at such a time do not heal over so quickly as those cut over when the sap is just beginning to rise, and this applies to old and feeble trees more than to young ones in vigorous health. The stems, instead of growing away at once, as they do after spring pruning, have to remain in a dormant condition all the winter and during the following summer; instead of healing over the bark decays and the wood dies back. The fresh break of young shoots becomes vigorous when decay is partly arrested in the bark, but it goes on down the centre of the limb, often with bad consequences to the tree a few years afterwards. But no kinds of plants exhibit the bad effects of being cut back at the beginning of winter more than some of our common herbs, at least in cold soils and cold localities. The Lavender, if cut down to a stump in October, frequently dies off to the root, while the Sage is invariably killed under the same treatment. Winter Savory, too, often dies under the same treatment, and even the hardy Thyme, when all the green shoots are cut away, goes off in cold winters; while, on the other hand, all three survive when their summer's growth is left upon them, even in the worst winters. This I have observed so often as to remove any doubts on the subject, and it is the same with many kinds of tender shrubs.

J. S. W.

WOODLAND WORK FOR DECEMBER.

WEATHER permitting, the planting of deciduous trees of all kinds may still be carried on in the woodlands; but, with the exception of the hardier sorts, no evergreens should now be removed, and those of a large size, which have been lately transplanted, may receive a good mulching to keep out frosts. In exposed places some tender evergreen shrubs, such as the Magnolia, should have a covering of mats during severe frosts. Now is a good time to secure abundance of leaves for rotting, to examine and clear out shrubberies, and to plash hedges which, from previous neglect, require this mode of treatment; but no hedge of an evergreen kind should now be meddled with. Hedges of Hawthorn may still be planted upon the level in fairly dry soils, and upon a raised bank or dyke on clayey lands. As the Hawthorn does not flourish upon very light sandy soils, when planted upon these a compost of part clay should be well worked into the land, and it may be desirable to mix a few Beech plants with the Hawthorn. Upon heavy clay soils an admixture of lime and road-scrapings will be found advantageous to the young Quicks. Three-year-old plants which have been two years transplanted, will generally be found strong enough.

In cutting off young plantations for the first time, great care should be taken to use only good cutting tools and to finish off the work well. In thinning screen plantations the woodman must, to a great extent, be guided by the depth or thickness of the belt. When it is narrow the removal of any considerable number of trees would mar its effect; but when its extent will permit of such treatment, the best way to secure a permanent screen is to keep the front trees well thinned out from the commencement, so as to allow them to branch low. By such means also a gradual increase in the height of the trees from the front line to the centre is secured, as those in the interior, from being more crowded, are the more rapidly drawn up.

This is a good time to scour out all open ditches in plantations, and to distribute the soil evenly among the young trees, as by this means the fallen leaves are at once fixed, so that they decay *in situ*, instead of drifting and filling up the watercourses or choking pin-

nocks and culverts. New ditches should also be cut where required. Though great attention is paid to letting off water from young plantations the ditches are often allowed to fill up as the wood gets older but as the roots of trees penetrate deeper into the soil the necessity for removing stagnant water increases, and instead of the water-courses being allowed to fill up they should be gradually deepened. This is more especially the case with plantations of Larch and Spanish Chestnut. Unsoundness of timber is frequently caused by the presence of too much water in the soil in which it grows.

One of the principal operations of the month will be the felling of timber. Where the trees to be cut down stand singly they may be grubbed, and in some cases a little more measurable timber may be secured by this method; but in close plantations grubbing cannot often be carried out without interfering to some extent with the roots of the "stores" or of the underwood. Here the cross-cut saw is decidedly the best implement when placed in the hands of experienced and expert workmen. But timber felling in such situations is an operation which requires both skill and judgment in the workmen. Having fixed upon the position in which the tree is to be laid, they must next compare the size of its head with the available clear space beneath, and lop off branches where necessary, both to equalise the balance of the head and also to prevent damage being done to the "stores." Then a triangular notch should be cut into the bottom of the trunk close to the surface of the ground, on the side towards which the tree is to fall, and exactly at right angles with the line of fall. Next, the saw should be inserted on the opposite side, the cut being kept open so as admit of its working freely, by wedges placed behind it, which may be driven home from time to time as required. Whenever the saw bids more on the one side than the other the wedge immediately behind that part should be tightened. By such means a skilful workman will, upon a calm day, place almost any tree within a few feet of the line selected for its fall. But on all occasions, and more especially in windy weather, or where the plantation is thickly stored, a guide rope is desirable; it takes but a short time to fix, and often prevents damage. In dry weather dig young plantations of Birch, &c., and clean hedgerows. In the nursery continue trenching, laying the soil as roughly as possible in ridges; also dig among young plants and undercut or remove the tap roots from strong Chestnut and Oak which are to remain another year in the lines. Collect cones of various kinds, and examine well the rot heap, giving it a little additional covering to keep out frost.

A. J. BURROWS.

NOTES & QUESTIONS ON TREES, SHRUBS, & WOODLANDS.

Honeysuckles on Fir Trees.—In our shrubby borders and woodlands we have some fine Honeysuckles that have been planted near the bare stems of Scotch and other Fir trees, and supported until they reached the lower branches; after that they support themselves and make a fine display. Some of the Clematises would also look well in similar positions.—J. GROOM, *Linton Park, Maidstone.*

A Pretty Combination.—I saw from a distance this season a large specimen Irish Yew, about half-way up which a branch of Guelder Rose had grown through it and developed its flowers on the front of the Yew. Nothing could have been happier or more distinct; the flowers of the Guelder Rose looked beautifully against the dark green background.—T. SMITH, *Newry.*

Irish Yews.—I agree with Mr. Groom (p. 428), that Irish Yews left to their own unrestricted growths are apt to look unsightly. Now and then, a few of them left to Nature have, however, a grand, massive appearance, but they are apt to be disfigured and ruined by snowstorms, Moss, and heavy rains. To preserve them as pyramids, they must either be frequently tied in, which involves much labour, or confined to a single leader from the first. Treated thus, and all offshoots forced into secondary importance by persistent pruning, the Irish Yew becomes and continues one of the most beautiful and natural of all pyramidal shrubs and trees.—D. T. FISH, *Hardwicke House, Bury St. Edmunds.*

The Trees in Sackville Street, Dublin.—It is with pleasure we observe that those wretched-looking trees which have been disgracing this fine street for the past three or four years are about being removed, and their places occupied by others, which we trust will have a longer and more prosperous career. It is but right to state that this is due to the public spirit of one who has ever been ready to aid in any enterprise likely to promote the cause of horticulture in this country. It is scarcely necessary for us to say that we allude to Mr. Niven, of the Garden Farm, Drumcondra, who has generously presented the trees to the citizens free of charge, merely stipulating that the Corporation make the necessary preparation for their reception.—"Gardeners' Record."

HORTICULTURE AT THE PARIS EXHIBITION.

AMONG the various districts round Paris devastated by the Franco-Prussian war that of Vitry suffered terribly. One morning in March, 1871—the week when the Commune began its work—I saw a nursery garden there, belonging to M. Defresne, which was the picture of desolation—not a tree or shrub over the many acres covered by the garden that was not cut down to within a few inches of the ground. In the house, recently deserted by the soldiers, no one was visible, and the rooms, piled with rubbish, were like nothing so much as ill-kept manure heaps. Some of the finest groups of evergreens and other trees and shrubs in the grounds of the present Exhibition came from this same nursery at Vitry—just such masses of graceful and rare specimens as the Waterers or Veitch could select from their best collections. This case is typical of the resurrection of France. In no way is her recovery more marked than in the vast zone around Paris which was cleared of houses and gardens to allow of the defence, and in the still wider district ruined in whole or in part by the operations of the two contending armies. Only those who saw this desolation can know what war meant to the inhabitants of the suburbs of Paris, and can fairly estimate the happy change and the progress that have since taken place. The result is not only gratifying to all who know and like France, but also as proving that even the blighting demon of war is not potent for lasting evil in the face of the efforts of a laborious and intelligent population. The results alluded to were very evident at the Exhibition, where, notwithstanding none but the most trifling concurrence from other countries, the horticultural and arboricultural interest was very considerable.

As to the general design of the extensive series of gardens round the Exhibition, it would be captious to have expected much where so many wants had to be provided for and where so many buildings were placed in the grounds. Yet it would probably have been difficult to dispose of the gardens to better advantage, excepting the portion immediately in front of the Trocadero Palace. The general effect of this pretentious building—far from happy in the effect of its central mass—is interfered with by the arrangement of the “garden” in front—a gigantic basin with water squirting up, and brazen heads vomiting water, large brazen casts of animals on the margin of the basin, and water tumbling down a series of steps on each side of the basin and central cascade—these helped to destroy any good or dignified effect the building might otherwise have had. These poor theatrical effects—for they really have nothing to do with the art of garden design—are deeply embedded in the mind of the ordinary landscape gardener, and also by such architects as attempt the laying out of gardens—always greatly to the detriment of the gardens. One of the blemishes of the many and fair gardens of Paris is, indeed, this weakness for unmeaning stone ponds of water. Wherever a large open space exists at a crossing a circular pond-basin is pretty sure to be placed there. Recently one of these huge basins has been placed behind the Trocadero building, a big pool with an immense rosette of water-pipes in the centre like a pile of old bottles on a stage, the whole surrounded by a common ribbon border and occupying a space that might easily be converted into a charming little lawn with groups of trees and shrubs and flowers. At first sight it might appear difficult to attempt the formation of artificial water in the grounds of a big show, given for a season only, yet it has been attempted here, and, with the exception of one point, very well done. Its one fault is the hardness, baldness, and formality of the margin, following too often false and conventional lines. The error is the more noticeable from the fringe of rock gardens which spring from the water in parts, and from the little cascades, and stepping-stone bridges being very natural and graceful in form. Much of the rockwork at the Exhibition is extremely well done, and there is an immense extent of it, considering the labour and expense involved in the formation of even a small portion. Considering the absurd crudities with which, under the name of rockeries, gardens are often disfigured, the effect of the various artificial rock gardens at the Paris Exhibition can scarcely fail to be beneficial in their effect on garden design. The big flanking rock garden to the right of the Trocadero is particularly worthy of remark, well answering its purpose of

concealing a very steep and high bank, which otherwise would have been difficult to deal with. The whole of the rock gardens were most gracefully draped and garlanded with climbing and trailing plants surprisingly fresh and vigorous considering the short time since planting.

The grounds were adorned with a vast number of ornamental trees and shrubs, which displayed a freshness and vigour sufficient to make light of all transplanting difficulties. At no exhibition of the kind hitherto organised has anything like the immense number of trees and shrubs been seen, individual nurserymen sometimes occupying or embellishing more than an acre of ground—making, in fact, an exhibition of his own. Thus one of the Leroys, of Angers, showed 500 kinds of evergreen shrubs. The France most of us are acquainted with is not like much of England, a country loved of evergreens; yet she, too, has important districts favourable for their development in Touraine and in the west and south. Considering the greater love for gardening among English people, it is noticeable that there is a taste for a greater variety of ornamental trees among the French who take any interest in planting. This is a healthy sign, and there are many rich collections in the nurseries which supply the growing taste for planting. As an example of the riches of some of the collections, one nurseryman showed specimens of 600 shrubs not evergreen, *i.e.*, those that lose their leaves in winter. Although we want careful selections mainly rather than very full collections, it must, nevertheless, be of the greatest importance to a country to possess such rich collections. In them new kinds may be found and tested from time to time to suit various requirements, soils, and tastes. It is in France at the present time that probably the richest collection of trees and shrubs existing has been brought together in the country seat of M. Alphonse Lavallée, President of the Central Horticultural Society of France. This gentleman, who has taken up the arboricultural question with much spirit and knowledge, has planted in his place at Segrez, Seine-et-Oise, between 5000 and 6000 kinds of trees and shrubs in the open air. As many important new species, and even unnamed species, are already growing in this collection, some of them likely to be of great importance from the point of view of ornament and usefulness, the owner, who has gathered the collection at great cost and labour, is likely to be a benefactor to his country and to the gardens and groves of Europe. The taste for planting rare and ornamental trees was one that long distinguished English gentlemen—perhaps more than any other—and it is greatly to be regretted that any cause should have tended to weaken this taste during the past twenty years. The deciduous trees of northern and temperate countries—those which must ever be the most important in Britain generally have been, beyond the most common kinds, neglected for years. In no country in the world are there such admirable opportunities for the effective planting of trees as in the country seats and parks of the United Kingdom, so large and so varied in surface as to admit of really effective and artistic grouping and massing. Therefore, while it would not be wise to imitate M. Lavallée exactly in his collections, it would be beneficial to the individual and the State if country gentlemen would sometimes, in addition to their general planting, take up say one family of trees and illustrate it in all its forms in their grounds. Thus, for example, one might take Oaks—and we have never seen any park or garden in which the species and varieties of Oaks were illustrated as they deserve—another Maples, another American and European Hawthorns, and so on. No exhibition and no botanic garden has ever yet done justice to the nobler trees, which can, indeed, only be seen in their stately beauty and true character where there is plenty of space around. Few expenditures usually prove more gratifying than those incurred in planting in such positions.

To the trees in the grounds someone has had the happy idea of introducing tall Bamboos from Algeria and Japan to grace the exposed Trocadero, and, though these have scarcely borne the transplantation so well as the inhabitants of northern gardens, with which the place abounds, they, nevertheless, are tall and graceful, and give those who have not seen sub-tropical countries some idea of the elegant forms of the giant Grasses called Bamboos. And it must not be supposed that these Bamboos have no practical interest from our point of view. Those

familiar with some of the best gardens in the south of England and Ireland will remember many a graceful tuft or brake of one kind of Bamboo, which, in these mild districts, attains a height of 20 ft. Of recent years, a number of Bamboos from the cooler regions they naturally inhabit have been proved to be quite hardy in the severe climate of Paris, and it is most probable that all these would prove hardy in the south of England, and would add to the many charms of its gardens. In Paris we have the most striking of all experiences of transplanting, whole streets of trees being now moved every year with facility. At the Exhibition thousands of trees grown to a good size for street planting, and even specimen trees, were moved so successfully, that but few died, and the whole kept in admirable health; indeed, few

everything together in a mass, and leaving all the finer types either to perish or to be drawn up and dwindled under the shade of the coarser and commoner species. We go to much trouble to keep hothouses for growing exotics into specimens, but few try to secure the natural and fair development of the hundreds of lovely shrubs and low trees hardy in our climate. The practice referred to secures a fair chance to the plant to assume its full size and natural habit. It also, when carried out near shrubberies, fringing them as it were with little groups and colonies, and single adventurers that have grown by themselves away from the mother colony, as it were, destroys effectually the hard, ugly cut margin which is the common "finish" of the greater number of shrubberies. The rude mismanagement of the shrubbery, in-

Plan of the Garden of the Trocadero Palace.

things more remarkable in the planting way have been seen than the extraordinary health of the many thousands of trees, and shrubs, and shrubby climbers which adorned the grounds of the Champ de Mars and Trocadero. We are all so apt to be content with a scarecrow appearance in our shrubberies for a year or so after planting, that it is interesting to note what has been done here; abundance of water has had of course much to do with it. Speaking of shrubberies, the practice in French gardens of frequently placing shrubs singly or in little groups, or colonies on the Grass apart from what might be called the shrubbery, is well worthy of mention, and instances of it were to be seen in the grounds. Shrubberies everywhere are too often the grave of many of the most beautiful shrubs, owing to the common habit of crowding

deed, is one of the things that must be changed if our gardens are to afford the beauty of which they are capable. The habit of placing all the taller kinds in the centre, and then rounding down the whole gradually to the edge all round so as to secure a pudding-like effect, the planting of quantities of Privet, Laurel, and other common trees and shrubs everywhere as undergrowth, so as to effectually produce a wearisome monotony, and to prevent most people from taking any interest in shrubs or trees at all; the laborious and fearfully destructive practice of lopping in the branches and mutilating the roots of established shrubberies by digging every winter, the results of which may be studied at any time in the extensive shrubberies of the West-end parks; the hard formal margin often surrounded by a formal line of some

wretched clipped "bedding plant;" the overcrowding to the death or disfigurement of many species—all these are orthodox practices, but are, nevertheless, wholly wrong, costly, and direful in their effects on our gardens and on the home landscape. The overcrowding and mutilation, which we so often see in our shrubberies, may be seen here in the streets and avenues. The skill of transplanting the trees is remarkable; their after-life such as prevents them ever assuming a natural or fair development. They are crowded so much that an annual mutilation by pruning soon becomes necessary; and as this pruning is apt to interfere with the natural form of the tree, and to make them all too much alike, the result in the end is a needless monotony. This is not only seen in the narrower streets of Paris, but also on the quays or open avenues. Although we have only begun planting quite recently in London, the trees on the Thames Embankment will very soon surpass those in Paris, unless the same system is pursued of leaving all the trees planted to ruin each other. By bold and prompt thinning we shall soon have finer trees in London than in Paris.

The forest department of the Exhibition was very interesting, particularly as represented in a large and handsome wooden structure in the Trocadero grounds. Here the woods that meet the different classes of wants, forest tools and implements, books, herbaria, models, plans, forest animals, birds, plants, and insects were admirably classed and grouped. Unusually interesting were documents, models, and plans concerning the re-wooding of the various mountain districts of France, long bare owing to inconsiderate cutting at one time, and kept so in many cases by the swift action of rains and torrents on the unwooded surface. The great interest shown in this subject in France is, no doubt, owing to the large extent of now bare territory, which, re-planted, would add to her resources. If in our case the area that has to be planted is smaller, there is the greater need to make the most of it, and this question of re-wooding the hills is of importance for every country. In France the Government seem quite awake to its importance, and there are numerous young trees in the grounds from the State nurseries, and beautiful and useful herbaria or collections of forest trees, shrubs, and plants made by Government foresters. The appearance of this forest house, and also of the Swedish wooden house nearly opposite to it, in the Trocadero grounds raised the question as to whether the merits of wood for building the walls of houses are sufficiently valued. Ugly and dismal-looking wooden houses no doubt exist, as they do in all materials, but the appearance of several wooden houses in the grounds spoke eloquently of what they are capable in the hands of good designers who understand how to build a house in this way.

No less important than the forest and ornamental trees were the fruit trees, particularly to France, in which the growth of hardy fruit for both home use and exportation has assumed such large proportions. There were whole gardens of well-trained fruit trees at the exhibition, and these, like their fellows of the grove and shrubbery, were in wonderfully good health, and many of them bearing fruit, although, in most cases, only transplanted to the Champ de Mars in the month of April—another proof of what is possible by means of careful transplanting. In England there are not a few who attribute the excellence of France in the culture of hardy fruit to the climate—the fact being that the climate of northern France is an extremely difficult one for the fruit grower, and, on the whole, not a whit better than that of Kent or Sussex. The real cause is a thorough knowledge of fruit trees in all that concerns their increase and training, a most careful selection of kinds likely to be profitable, and—major cause of all—because a great many more fruit trees are planted in France than in England. There is no reason why we should not supply our own markets with the Pears we import from northern France and the Apples we import from the United States. As to the ground required, there is as much wasted by useless trees in hedgerows as would supply all our markets. The small acreage now occupied by orchards in the United Kingdom explains how it is that American Apples now find their way at paying prices to even small towns in Ireland and Scotland. It cannot be said that the rural economy of the country is in a healthy state

when immense sums are sent out of it for produce that may be grown quite as well at home. No doubt some who do try find a difficulty in disposing of their produce advantageously, but that is often owing to growing too great a variety of kinds and unsuitable kinds, and it is also sometimes a question of market arrangements, which may in time be altered for the better. The care the Americans and the French take in rejecting all the varieties not really good and profitable in their respective localities is well worth our attention—liable, as we are, to seek many kinds. These, even if they prove good, are often needless, and prevent attention being concentrated on the few that unite all obtainable good qualities. The serious way in which fruit culture is studied by nurserymen in France may be gathered from the fact that one house alone showed young trees of over 800 kinds of Pears, and 492 kinds of Apples. Nobody would probably recommend that even a tithe of these should be grown, but the collection represented a really laudable attempt made to study and describe the merits of all the known varieties which have been considered worthy of names, and which occur in cultivation in various countries. This attempt was made most successfully by the late A. Leroy, of Angers, whose successors have sent so many important collections to the Exhibition. The fruit trees sent by growers in the Paris district and from Troyes were of more importance practically to us, because showing modes of training and varieties likely to be useful in cold districts. Among the modes of training, those in which a few stems ascend vertically and quickly cover a wall or trellis are worthy of adoption with us instead of the old, horizontally-branched tree, which takes so many years to complete, and by which system the walls are usually half bare. Simple and effective means of protecting wall fruit trees in spring by wide, temporary copings are also worthy of general adoption with us to secure regular crops of choice wall fruit.

As to the flower gardening of the Exhibition, it was interesting and extensive to a degree scarcely conceivable—every little structure of the many hundreds in the grounds being garlanded or fringed with flowers in addition to those arranged by the Administration or by the many exhibitors. Quantities of Roses had been planted, and bloomed fairly well, the ground beneath them being often carpeted with *Verbenas* or other dwarf flowers. This resulted in pleasing mixture and variety, and, better still, covered the naked earth too often seen beneath Roses and other plants in summer, even when the whole earth out of gardens is green. Ribbon borders were numerous and not ugly when relieved by fine-leaved plants, but nearly always made hard towards the edge by having some wretched plant stumped to the ground with the scissors or some other implement to keep it low. Here and there were great masses of one plant in one bed, mostly chocolate-coloured, and forming one flat mass, without light, or shade, or variety, or grace of any kind. The recent "carpet" phase of bedding out was also prettily illustrated, like all other beds set in the freshest Grass. It is one of those passing and not wholly admirable fancies which attract attention as we go slowly forward to attain what is perfectly attainable—all the varied glory of colour without sacrificing light and shade and form, and without geometry.

One of the best lessons the Paris gardens teach is that of the market gardening close round the city; these, however, few attempts had been made to illustrate at the Exhibition. Several little plantations, however, showed the culture of Asparagus, and, without going so far as Argenteuil, the English visitor could see that the French grower has one where we have from ten to thirty plants. It was shown in two of the principal ways it is grown; firstly, in single lines about 4 ft. apart, the roots being about 3 ft. apart in the lines; and, secondly, as isolated tufts among the Fig trees or Vines, the distance in this case being much greater than in the preceding one. The Asparagus culture is worth considering, because immense quantities are imported to the London markets every year. The demand is increasing every year, and our home production is utterly inadequate to meet it. Quantities of Asparagus were sent to the London market during the past spring from remote parts of France, and even from the neighbourhood of Madrid. Asparagus very quickly loses quality if exposed to the air; and it need not be matter for surprise if Asparagus gathered in the Madrid region, sold in the markets there, transported over

THE LIBRARY.

FAMILIAR WILD FLOWERS.*

such a length of railway or sea, and eventually, perhaps, exposed several days in London before it reaches the customer, should be a tough and tasteless commodity. Yet such finds a good market in London and others of our large cities. But it is just as necessary to grow Asparagus abroad for the English markets as it is to grow Hawthorns for our hedges there. There is no reason why the foreign Asparagus should not be driven out of the London market by the home-grown produce. To compete with it, however, in this branch, we must adopt a better method of planting, and cease the expensive method of needless and heavy manuring before planting which has hitherto been the rule. This is found to be quite needless in the cultivation of this vegetable at Argenteuil, where it is grown better than anywhere else. As in connection with this subject the question of green *versus* blanched Asparagus is often raised, it may be pointed out that the question of cultivation has little to do with that of blanching, and that the true mode of culture may be adopted without interfering with anyone's tastes or prejudices in that way.

It is to be regretted that little of the wealth of English nurseries and gardens was to be seen here, so far as outdoor gardening is concerned. This is understood to be owing to some mistakes as to the time of entering—no doubt, arising from the want of any home organisation to look after the interests of exhibitors. Whatever the cause, a mistake was made. No gathering in Europe attracts so many intelligent visitors from its most remote parts as a Paris exhibition; and the like of the now past one cannot be looked for years to come. Even recently, notwithstanding recent troubles in Russia, a curator of a botanic garden from Tiflis and other remote parts of Russia might have been seen preparing to add to their collections from those shown at the Exhibition and about Paris. English horticulture is rich in specialties; and it would have been for the benefit of the country and of horticulture if these had been shown. In coniferous trees; in evergreen shrubs; in Rhododendrons; in Lilies and hardy bulbs generally; in large collections of ornamental herbaceous plants; in hardy Alpine flowers; in fruit (culture under glass and as adapted to all cold and northern countries); in Orchids; English gardens are far richer and more advanced than any others; and it is in all ways a mistake that this superiority was not shown at the Paris Exhibition.

Among the few things shown from this side may be mentioned the illustration of Mr. Wills's spirited and tasteful way of arranging indoor flowers, and Mr. Lascelles' wooden curvilinear greenhouse. Mr. Lascelles has shown that wooden plant houses may be made in the curvilinear form as well as iron ones. This is an important improvement, as the hideous angularity of ordinary greenhouses makes them far from agreeable objects in the ornamental garden. The handsomest glass houses yet erected in this country are, in whole or in part, of curvilinear iron; and hitherto the free adoption of the curvilinear lines has only been prevented by their being necessarily in iron, to which material many horticulturists have objection. What English horticulturists might have done may be illustrated by Mr. Wills's success at the Versailles Exhibition, where he won fifteen first prizes, the prize of honour, and a valuable Sevres vase offered to the nurseryman who contributed most to the success of the show.

Bedding Violas.—The past summer—I may certainly write of it now in the past tense—has been one of the best known for a long time for all kinds of bedding Pansies and Violas, the display of bloom having been singularly beautiful. Some of the northern kinds that as a rule do not stand our hot summers well have been very effective, that curiously coloured kind, Queen of Lilacs, particularly so. The very best only of a number have been as follows: Whites, Vestal and Profusion; yellows, Crown Jewel, Yellow Boy, and Sovereign; blues, Blue Beard, Improved Blue Bell, Royal Blue, and Blue King; lilacs, lilacina and rubra lilacina; purples, Mulberry, Clevedon Purple, and Syrian Prince; and of black kinds, Othello. A rich bluish-purple kind, Holyrood, a robust grower, has been very effective, and a pretty little striped kind, named Charmer, has also been very pleasing. A cool moist summer here suits these plants admirably. A hot dry summer suits them in the north. Now the plants are making a very robust growth, and if some of the strongest shoots were cut away the new growth would give an abundant late autumn bloom.—“Gardeners' Magazine.”

FROM an educational point of view there is perhaps no worse method of beginning the study of the plant-world than by identifying a few specimens by means of plates. It is too apt to take the place of a thorough examination of the structure of the plant, which should be the first work of the beginner. There will always, however, in all probability, be a large class of people—children, ladies, foreign visitors, and other amateurs—who do not wish to study botany, but merely to know the names of a few conspicuous flowers. For their purpose coloured plates are a desideratum, well drawn and well coloured. The forty coloured plates are by far the most important part of the gaudily-bound but weak-backed volume, the preparation of which Messrs. Cassell have entrusted to Mr. Hulme. Mr. Hulme is, we believe, Art Master at Marlborough, and we think our memory does not deceive us when we say that he has previously published a volume of designs, drawn from flowers, of a semi-“conventionalised” form. This will account for his obvious penchant for full-faced blossoms in the otherwise admirably-drawn series before us. The colouring, however, is little better than that of Miss Pratt's well-known works, the foliage being almost invariably too blue. It would have added much to the value and clearness of the representations if occasional dissections and, perhaps more important still, outline sketches to show the habit of the whole plant, as in many plates in THE GARDEN, or, as in the cases of the Meadow Crane's-bill and the Burdock, an outline of a larger leaf in the background had been introduced. It is perhaps of little consequence that the forty-four plants described are arranged in no order, and an excellent descriptive summary occupying eleven pages has to do double duty as index, but we cannot but regret the meagreness of the 160 pages of letterpress. A good deal about the etymology of names and a few quotations from old writers as to alleged medical virtues are their main features. Several opportunities, such as two Roses, the Apple, the Poppy, and the Cuckoo-pint, for the suggestion of interesting lines of improving accurate study are neglected. We find no reference to cleistogone flowers under the Violet, to the suppressed peduncle, the axial placenta, or the dimorphic flowers, under the types of the Primulaceæ, to the Potato under Bittersweet, or to insect fertilisation under Orchis. The structure of some of the flowers is briefly alluded to, but we look in vain under Daisy or Corn Marigold for even a warning as to the nature of the “flower,” as Mr. Hulme terms the inflorescence of the Compositæ; nor do we get similar information ament the Grasses. Recognising the value of a work on some such plan as the present, we can only express a hope that in the second series there may be more letterpress with more in it, and that the colouring may better represent the powers of modern chromolithography.

G. S. BOULGER.

11, Burlington Road, Westbourne Park.

The Album Van Eeden, published in Haarlem, maintains its position amongst illustrated floral publications, and appeals directly to lovers of hardy bulbous plants. The present number contains six plates of bulbous flowers, natural size and admirably executed. Plate 70 represents Hyacinth King of the Blues and Madame Vander Hoop; plate 80, a group of Tulips, including elegans, retroflexa, cornuta, persica, and the Green Tulip (*T. viridiflora*); plate 81, double and single Snowdrops, combined with *Scilla sibirica*; plate 82 does ample justice to one of the finest forms of *Lilium davuricum*; plate 83 represents *Iris persica* and the curious *Iris tuberosa*; plate 84, a group of late Tulips. The letterpress is in Dutch and English.—P. B.

Elaborate Castings.—At a recent meeting of the Metropolitan Board of Works it was stated that the damage done to the railings on the Thames Embankment had amounted, for some time past, to £200 a month, or £1200 a year! The damage is done by boys, who break off the elaborate castings by wholesale. We confess we are not very sorry for the elaborate castings, and trust this case may be a warning to avoid them in such cases in future.

* “Familiar Wild Flowers.” Figured and Described by J. F. Edward Hulme, F.L.S., F.S.A. First Series. With Coloured Plates. London; Cassell, Potter, & Galpin.

PLATE CLVI.

WINTER-FLOWERING IRISES.

This week our plate represents three charming winter-flowering hardy plants, the value of which, either for indoor or outdoor decoration, can scarcely be over-estimated, for, combined with much beauty, some of them exhale a delightful fragrance, rendering them very welcome additions to other out-door flowering plants at this dull season of the year. Beautiful as the kinds are which we illustrate, they are not so handsome as others in cultivation, but, unfortunately, such kinds are as yet more or less rare. The majority of these winter-flowering Irises belong to the genus *Xiphion*, a section distinguished chiefly by the existence of a bulbous rootstock. Though all have been generally known under the name of *Iris*, it is, perhaps, advisable to coincide with the most recent authoritative revision, and it will not materially disturb the existing nomenclature if we note the principal synonyms, though of these some kinds are encumbered with many.

Long-tubed Iris (*Xiphion planifolium*, of Miller; syn.—*Iris alata* and *I. scorpioides*).—This old-fashioned yet beautiful kind, which is represented on the right in our plate, has long been known under the appellation of *I. alata*, but according to priority of date it must range under the first-mentioned name, as this was applied to it by Miller so long ago as the end of the last century, it having been commented upon in his "Gardeners' Dictionary." It forms tufts of about half-a-dozen rather broad and recurved leaves that are partially developed at the time of flowering, which generally begins in October, and generally a repetition of it at about Christmas time. It inhabits various parts in the vicinity of the shores of the Mediterranean region.

Persian Iris (*Xiphion persicum*, of Miller; syn.—*Iris persica*).—This, another old inhabitant of gardens, may be found depicted on the left of our plate. It appears to have been an object of culture for upwards of three and a half centuries, as it was alluded to by Parkinson in 1627. In addition to the showiness of the blooms, it possesses a delicious perfume much resembling that of Violets. Its geographical distribution extends from Asia Minor to Persia, and is found as high as 6000 ft. elevation. This kind, and also the preceding, are admirably adapted for Hyacinth glasses, as previously mentioned. In the open air in warm situations it commences to flower in February.

Netted Iris (*Xiphion reticulatum* of Klatt; syn.—*I. reticulata*).—This charming kind is undoubtedly the finest of the whole group. It grows in erect tufts, with leaves four-angled and slightly glaucous, about 1 ft. high at the time of flowering, but they do not attain their full dimensions till May. The flowers slightly overtop the foliage, and are about 3 in. across, with narrow, erect standards of a deep violet-purple colour; the falls are also narrow, a shade lighter in colour, and dotted with bright violet spots, and they have a deep yellow line running through the centre; the flowers are, moreover, very fragrant, which much enhances their beauty. It is a native of the Caucasus, Kurdistan, &c., and is found at considerable elevations in the mountains of Armenia.

The variety *Krelagei*, of Regel, has flowers of a much duller hue and less fragrant, therefore it is inferior to the type, but this is in some measure compensated by its flowering at least ten days earlier, which is usually about the end of February.

Lebanon Iris (*Xiphion Histicus*, of Hooker).—This very distinct and showy kind is also one of the rarest, having only been in cultivation a few years. It justly merits the encomiums that have been passed upon it at various times in THE GARDEN. It somewhat resembles the Netted Iris, but is rather taller. The leaves are awl-shaped, quadrangular, and glaucous, developed at the same time as the flowers, which are about 3 in. in diameter, stemless, but with a tube from 2 in. to 4 in. long, of a rich purple colour. The standards are narrow and erect, of a plain lilac colour, the falls broader, of a paler shade, copiously and very conspicuously blotched with deep lilac purple, and with a bright golden crest through the centre. It flowers much earlier than the preceding, generally commencing at the end of January, and, like it, exhales a very sweet perfume. It is a native of Palestine, inhabiting the Lebanon range and Mount Gerizim. It was first sent to Kew in 1873.

Caucasian Iris (*Xiphion caucasicum*, of Baker).—Though this kind has been an object of culture for many years, it is far from

being common, probably on account of its flowers not being very showy. The stems bear from one to three flowers, and from four to five sharply curved and rather broad leaves. The blossoms, which are produced in February and March, are about 2½ in. across, and of a pale yellow colour. It is a native of the Caucasus and North Persia.

Turkestan Iris (*Xiphion Kolpakowskyanum*, of Regel).—This is a new claimant for public favour from Turkestan, introduced through the instrumentality of Dr. Regel, of St. Petersburg. The flowers, which have been produced in this country, are described as being very beautiful. It has from two to three leaves, lance-shaped, and rather short. The flowers are stemless, with the limb pale lilac, shaded with white. The falls are ovate in shape, tapering to a sharp point at the base; the colour is pure white with bright lilac tips, and keel feathered with purple towards the base. The standards are pale lilac and freckled with white. It appears to flower at about the same time as the Netted Iris, but on this point we cannot speak with certainty. We hear that a goodly importation of this beautiful hardy plant is in the country, and we hope ere long that it will be as common as its congeners.

Long-styled Iris (*I. nunguicularis*, of Poirer; syn.—*I. stylosa*).—This handsome kind, which occupies the central position in our plate, is a member of the group of true Irises, and is one of the beardless section, but few surpass it in beauty, and, on account of its early period of flowering, viz., the beginning of the year, it should be an indispensable plant to every collection, large or small. One detractive point is that the flowers are stalkless, and nestle amongst the foliage, but they are admirably adapted for cutting, in which state they last good for some time, and even buds expand very freely in water. It is a native of Algeria, and was introduced about thirty years ago.

As regards culture, when grown in open borders these Irises should have a warm and sheltered situation, say under a south wall, and they will be found to succeed in any ordinary garden soil, provided it be not too stiff. It is advisable to place a thin layer of Cocoa-nut fibre refuse or some similar material to serve the purpose of protection during severe weather, and to prevent the flowers from being bespattered by mud during heavy rain. Some kinds produce seeds very freely in some seasons; these should be carefully collected, and, when well ripened, should be sown at once; and this will be found to be a wholesale mode of increasing the stock, as they will make strong flowering bulbs in about three years. Several of them, and especially the Netted Iris, are perfectly amenable to slight forcing, and by this mode their beautiful blossoms may be obtained several weeks earlier than their natural time. For this purpose good flowering bulbs should be taken up and potted in September or October, putting about five in a 6-in. pot, and kept in a cold frame till about the end of November, when they may be removed to a slightly warm house or frame. Another mode is to grow them with the bulbs placed in glasses of water, after the manner of Hyacinths. Of course, under such treatment they do not acquire such vigour as when grown in the open air, but they are very suitable in this state for enlivening living rooms, &c., a mode of culture in practice since the time of Miller, at the end of the last century. W.

[The plants from which our plate was prepared were furnished by Mr. Ware and by Mr. P. Barr.]

The Woolly-leaved Iaula (*I. candida*).—Though not possessing very showy flowers, this is a distinct and handsome plant. It grows to about 1 ft. high, and has rather large, short-stalked, ovate leaves, which are covered with a dense white down. The flower heads, which are yellow, are borne on the ends of the branches, and they are also produced from the axils of the leaves about mid-summer. It is a native of Candia, and was first introduced in 1714.—W.

The Celtic Valerian (*Valeriana celtica*).—This is an old-fashioned garden plant, having been cultivated so long ago as 1749. It should be included in the Alpine class, as it grows only 3 in. to 6 in. in height. It has a creeping rhizome, producing small tufts of root leaves somewhat oval and tapering in shape. The stems, which are slender, bear a few scattered small leaves and terminal loose racemes of flowers, which are very numerous but small, of a reddish tinge on the outside and white within. Besides its prettiness it is interesting on account of the aromatic odour of the long, fibrous, black roots. In a wild state it has a wide range of distribution, being found on the Alps from France to Italy.—W.

GARDEN DESTROYERS.

THE APPLE WEEVIL.

(ANTHONOMUS POMORUM.)

THERE are, perhaps, few insects which are more destructive to the Apple crop than this little weevil, which, unfortunately, is far from uncommon in this country. Its ravages are no doubt frequently attributed to that much-talked about and maligned combination of circumstances generally known as the weather, for, when the Apple blossoms suddenly wither or die without any apparent reason, it is always said to be a cold wind or frost which has done the mischief; whereas, it will often be found that these blossoms contain the grub or chrysalis of this weevil. As the grub requires a shelter from the sun and rain if the blossoms open fully before the eggs hatch, the grub will not live, so that in fine, mild weather, when the blossoms open quickly and together, the ravages of this insect are not much felt; moreover, the weevils have not so much time in which to lay their eggs. In cold, wet weather, however, the buds which have begun to swell are frequently retarded and prevented from opening for several days, which gives the insects plenty of time

The Apple Weevil (*Anthonomus pomorum*).

to lay their eggs and for the latter to hatch. Kollar mentions, "that in 1816 the blossom buds were attacked by these insects for nearly three weeks, owing to the cold and rain having checked the flow of sap, and that scarcely a bloom was to be found that was not pierced. No wonder that there was no Apple crop that year!" The beetles leave their winter quarters, which are generally under stones and leaves or the loose bark of the trees. In the spring after pairing the female searches for such Apple buds as are beginning to swell. She seems to be very particular in her choice, often carefully examining several before she can find one to suit her. When one is selected, she bores a hole into the centre of it with her long beak or nose, at the bottom of which she forms a kind of chamber, and then deposits an egg in the hole, which she pushes down with her beak. The entire operation of laying the egg and boring the hole is said to occupy three-quarters of an hour. She then seeks another suitable bud, for she never lays two eggs in one hole, or bores two holes in the same bud. It is not known how many eggs a weevil lays, but the number must be considerable, as so few of the insects are found compared with the number of blossoms destroyed. The grubs are hatched in the course of five or six days, and at once begin to feed on the pistils, stamens, and ovaries; the buds, however, continue to swell and the petals to open. When almost expanded the growth suddenly ceases, and the petals wither, shrivel, and form a kind of covering to the now almost empty bud, in which the grub or chrysalis may be found. The former attain their full size in about a fortnight, and then assume the chrysalis state, from which the perfect insect emerges in about a week. The transformations are completed very rapidly, only about a month elapsing from the laying of the eggs to the appearance of the

beetle, which feeds on the leaves of the trees during the summer, when it is seldom to be seen. In the autumn they leave the trees and find more sheltered places in which to pass the winter. As may be imagined, there is not much to be done to destroy these insects on large trees; the boughs may be well shaken, when many of the beetles will fall off, and, though they will reascend, it will take them some time to do so. From dwarf trees and espaliers they may be picked off, and as they usually crawl, and do not fly, this can be done without difficulty. Any flowers which have been attacked should be at once gathered and destroyed, as in this way their numbers the next season will be much lessened. Any stones, leaves, or rubbish which happen to be near the trees should be removed in the autumn, and any leaves, bark, or Moss scraped off the trees, for in such situations the weevils pass the winter. This species occasionally attacks the blossoms of Pear trees, but it usually confines its attentions to Apple trees. The beetle is from 1-8th to 2-10th of an inch in length, and is of a dark brown colour, covered with a greyish down; the wing-cases are somewhat reddish, with two oblique black bands towards the apex, the space between which is whitish. The head is produced into a long, slender, curved proboscis or beak; in the middle of which are the antennæ, which are 12-jointed, those towards the point forming quite an angle with the basal ones. The grubs are nearly white, with black heads; they are very small, fleshy, and have no legs; they are, however, provided with two rows of retractile, fleshy tubercles instead. The chrysalis, as is usual with beetles, is not complete, the limbs of the future insect being visible through the covering membrane. S. G. S.

THE PELLETIER WASP TRAP.

ONE of the most seductive traps for the wasp is that invented by M. Pelletier, and a glance at the accompanying illustration will show that in simplicity it rivals any of the wasp and fly-ensnaring devices which from time to time have been described in THE GARDEN. Although the illustration almost "tells its own tale," it may be as well to mention that the trap consists of a broad-necked, corked bottle having a number of holes all round it, cut in such a way that the wasp can easily enter, but with the greatest difficulty escape by them. Immediately opposite these funnel-shaped apertures

Pelletier Wasp Trap.

there is suspended in the middle of the bottle a small brass vessel containing honey or some other material serving as bait. Attracted by its scent, the wasps attempt to get at it, but as the trap is completely closed above, and has only diminutive perforations elsewhere, these efforts prove fruitless, and after a while the insects fall exhausted into the water occupying the lower half of the bottle and are drowned. When honey is the bait employed, and a proper amount has been put into the suspended vessel, it rarely happens that a second supply is needed during the same season. All that is necessary in most cases is to stir the honey about from time to time, and thus cause it to emit a stronger smell. As to the water in the bottle, this will now and then require renewing. There are many ways in which the Pelletier trap can be used; whilst it is, of course, mainly intended for garden and orchard use, attached to walls, trellises, or espaliers, on which any kind of fruit is trained, it has also been successfully employed indoors as a fly-catcher, a small lamp or lantern being substituted for the honey vessel at night, so as to make it continuously operative. T. S.

Pelargonium Comte de Morny.—This, although an old kind, is one of the best of zonals for small beds, inasmuch as it is of a close, compact habit and very floriferous. The colour, too, is peculiarly soft and pleasing, and serves to tone down the more brilliant kinds. For pot culture it is very suitable, more especially for late autumn decoration.—J. CORNHILL.

GARDENING FOR THE WEEK.

Orchids.

Anæctochili.—These most exquisitely beautiful of all handsome-leaved plants have baffled more cultivators who have attempted their growth than perhaps any plants in cultivation. The insignificance of their blooms is such as to render these of no value or importance; consequently, they are very rarely treated in the way that other Orchids are which are grown for their flowers, and it is often the aim of the cultivator to increase them as fast as he can by keeping them on growing more or less, or with only a very short period of comparative rest. From my own failures, as well as success, in the cultivation of these plants, added to what I have observed with many other growers, I have arrived at the conclusion that the want of sufficient rest produces the weakened condition that tends to their destruction. Whenever they have continued to do well for any considerable number of years, I have invariably noticed that it was in cases where they were subjected to a much longer rest than they usually receive—sometimes, through the inability of the growers to give them, during the winter, as much warmth as they would have done had they been able to choose in the matter, or that the countries they come from, especially all the golden-veined varieties, would lead us to suppose that they absolutely require. From my own experience, I am led to the conclusion that there is no safe means of resting them, but by a diminution of the temperature that will stop growth, for it must be borne in mind that they are not epiphytal to the extent that the majority of other Orchids are; growing as they do naturally upon the earth, or a very little elevated above it, they cannot be expected to bear drying at the roots, as many species will, and I have always found when the material in which they are placed gets quite dry the partially-developed roots never extend freely afterwards. My impression is, that if for the next three months they are kept with a night temperature of 50° to 55°, that it is much more conducive to their continued healthy condition than if warmer; at the same time, the material in which they are grown should be kept slightly moist, but, as a matter of course, not nearly so much so as in the growing season, and a little air should be admitted for a time every day by tilting the bell-glasses and giving them a tolerably light position. Those who have been used to keep them much warmer than this may find a difficulty in mustering courage enough to keep them so cool, but their unsurpassing beauty is such that they are worth any amount of attention on the part of those who are fortunate enough to have a representative collection, and it is quite clear from the numbers who have grown them well for a time, and at whose hands, without any change of treatment, they have become diseased and died right off, that the comparatively hot treatment to which they are often subjected all the year round, however it may stimulate growth and size for a time, ultimately induces a weakened condition, such as leads to their destruction.

Brassias.—These are not near so fashionable, or find favour with so many growers, as the numerous plants possessing more showy colours; but there are several of them that are worth growing, especially where large spikes of flowers of an enduring nature are required for cutting. As a matter of course, they last still longer on the plant. A good many of them are from the West Indian Islands, and, like most other Orchids from these parts, succeed much better with more air and a drier atmosphere during the growing season than the majority of Orchids are subjected to, without which, as well as more light than many species will bear, they do not flower so freely as they are capable of; they also bear being kept very dry at the roots for a considerable period through the winter. In most cases their season's growth will now be quite finished, and they should be allowed to get quite dry, requiring little or no water for the next three months.

Cyrtopodiums.—These belong to a select family, with only a few representatives, found both in the West Indies and tropical America, not nearly so much grown as they deserve to be; but their absence from the houses of those who cultivate general collections may be accounted for from their usual disinclination to flower, unless, like the last-named plants, the Brassias, but to even a greater extent, they are treated through their season of growth to a large amount of air and light, which is synonymous with a drier condition of the atmosphere than is often kept up in Orchid houses. Yet the immense spikes of flower which they produce, equalled in size by no other Orchids that I at present recollect, their general attractive character and the very long time they keep fresh, render them worthy of more general cultivation. Where grown, their growths will mostly be about completion, at which time they should be gradually dried off, for if the soil were kept moist for even a short time after the current growth was finished, with me they always started into second growth, which seriously diminishes the chance of their flowering. *C. punctatum* and *C. Andersoni* are both handsome species.

Cattleyas.—Where a considerable number of these are grown and have a house to themselves, most of the species will now be about finishing their growth; the spring-flowering kinds will now require being subjected to dry treatment at the roots, continued longer or shorter proportionate with the time they are wanted to come into flower; if kept moist, even in a comparatively low temperature, the growth buds at the base of the current season's pseudo-bulbs will show a disposition to start; too much moisture at the roots with the majority of these plants is most injurious to them; as they are much more impatient of the material in which the roots are placed holding anything but a very slight amount of water through the winter than most Orchids, any approach to a wet state will cause their wholesale destruction. If the plants have been grown under conditions of sufficient light and not too much moisture in the atmosphere, or, at the root, it may be presumed that they will have plenty of roots, in which case they will bear for a considerable time an all but dry state of the soil without shrivelling to do any harm. It is only the soft, spongy-grown examples of these plants inadequately furnished with roots that are disposed to shrivel when subjected to the necessary dry treatment during the winter. The charming *C. labiata* will either now be in flower, or approaching that state; it is not well to submit this plant to too low a temperature whilst in bloom, or after the flowering is over, as, when so treated its thick, fleshy bloom-stems often have a tendency to rot down and destroy the leaves and bulbs which have produced them. Of *C. crispata* there are several beautiful forms that are well worth cultivation, although with many it is not a favourite, on account of the character it gets as being a shy bloomer; but, like many other plants this is simply attributable to its often not being treated as it requires; if grown too hot and moist, with little air and heavily shaded, it will not flower freely. Many plants of it will yet be far from having completed their growth, but the warmest end of the Cattleya house where a night temperature of about 50° is kept up will be quite hot enough for them. They should, until growth is completed, receive just so much water as will keep the material in which the roots are in a slightly moist condition, but considerably drier than during the summer season, by which means many of the old roots will retain their vitality. Much of the strength and vigour possessed by these plants, as in most other Orchids, is very much dependent upon the length of time their roots live, although, according to the nature of Orchids, a portion decays annually.

Lælias.—*L. purpurata*, and any others that make their growth similarly through the winter, should, if possible, be moved from the Cattleya house and set amongst the East Indian species or in any structure where a temperature some degrees higher than the Cattleya house will be kept up, otherwise it is almost impossible to induce these Lælias and like plants to make full-sized growths. Where such convenience does not exist, they ought to be placed at the warmest end of the Cattleya house, and means taken, by giving all the air admitted at the opposite end, to effect as much disparity as possible in temperature between the plants that have completed their growth and those that are progressing. *L. anceps* and *L. autumnalis* now in flower, or coming on, should be kept in an atmosphere sufficiently dry to preserve the flowers from spotting without approaching that moistureless, parched condition that Orchids in bloom are frequently subjected to, under an impression that it preserves the flowers longer, but which, in reality, is not the case, as they at all times require more moisture present in the air that surrounds them than the majority of other plants. The fine old *L. Perrini*, as soon as it goes out of flower, should be allowed to become quite dry at the roots, and kept in such condition until the time arrives for starting it into growth in spring.—T. BAINES.

Indoor Plant Department.

Stoves.—The average minimum temperature of the stove at this season should range about 60°, though, generally, the warmest part of it is a few degrees higher. Ventilation should be given at the top on fine days, cold currents being always avoided, and the sashes should be closed early in the afternoon. All evergreen plants should be kept moderately moist, but, if anything, a little on the side of dryness; keep deciduous ones rather dry, and the syringe should now be scarcely or ever used. *Caladiums*, *Achimenes*, *Gloxinias*, some *Alocasias*, *Kamperferias*, *Gloriosa* Plants, and some others, must be kept dry in their pots till spring, when they should be re-potted and started in a little bottom-heat. The varieties of *Epiphyllum truncatum* and *Russellianum* are now in full beauty, and may be transferred to the coolest part of the stove. *Apelandra Roezli* is now also one of the gayest of stove plants, and requires plenty of water. The earliest of the *Poinsetias* will by this time have developed their brilliant floral leaves, and must be kept in a warm place and have plenty of water, otherwise they are apt to lose their foliage. Keep succession plants in brisk heat, also those of *Euphorbia jacqui-*

niæflora, the flower buds of which are now set. *Asystasia capensis* and *Torenia asiatica* make fine winter-blooming plants for baskets, and require no care beyond dipping them occasionally in Tobacco water, as the *Torenia*, especially, is rather subject to green fly. Amongst other plants now in flower in stoves are *Strelitzias*, the yellow *Justicia calycotricha*, the drooping *Thyrscanthus Schomburgkianus*, the white *Cestrum diurnum*, *Medinilla farinifera*, the old-fashioned blue *Eranthemum pulchellum*, the beautiful white *Pan-cratiun caribæum*, *Eucharis amazonica*, *Begonias*, *Poinsettias*, *Melastoma malabathrica*, *Pitcairnia odorata*, *Bilbergia splendens*, *Rondeletia speciosa*, *Euphorbia Bojeri* and *splendens*, *Mussaenda frondosa* and *Inteola*, and many others. If *Ixoras* have broken well they may now be potted without disturbing the roots further than removing a few inches of the surface soil, and use pots 3 in. larger than those they previously occupied, and only good peat and silver sand as a compost. *Dipladenias*, too, if they have broken well should be repotted, but in their case the old soil should be shaken well away from the roots without hurting the latter, and they should be re-potted in good open peat and plenty of sand. Both *Ixoras* and *Dipladenias* should be kept rather dry after this shift. Keep *Allamandas*, climbing *Clorodendrons*, and *Boogainvilleas* quite dry at the root; winter them in a temperature of from 50° to 55°, and neither cut nor prune them. Plunge well-rested plants of *Eucharis amazonica* in a brisk bottom-heat, in order to induce them to flower. Pot young plants of *Cyperus alternifolius* for decorative purposes next year, using a rich soil and give them plenty of water.

Ferns and Lycopods.—Ferns should now be in a state of rest, which is better secured by a low temperature than by absolute dryness. A temperature of from 55° to 60° minimum is sufficient for stove varieties, while mere exclusion of frost will suit greenhouse ones. Such as are producing young fronds should be kept at the warmest end of the house, and should at no time lack water. Tree Ferns, too, should always have a good supply, for the surface-soil about them frequently presents a moist appearance when beneath it is injuriously dry. Cut away only such fronds as are quite dead. Hardy Ferns grown in pots should be placed in frames, on back stages in greenhouses, or plunged out-of-doors where water cannot lodge about them. Now is an excellent time to clean such plants of thrips and scale; when they have been thoroughly freed from these pests, the young growths come up vigorously, and have a much better chance of development than when old fronds, infested with insects, are present. Fumigating Ferneries, too, may now be beneficially practised, even oftener than in summer, inasmuch as the fronds in winter are harder and better ripened than in summer, and, consequently, less liable to injury. A good stock of young Ferns should be kept in a brisk, moist temperature for supplying cut fronds for furnishing purposes, and for filling ornamental baskets. Where spores have germinated, and have made a little progress, they should be pricked off in small patches at first, and afterwards, when a few fronds have been formed, the plants may be potted separately. Club Mosses also form good decorative subjects, the small kinds, like *Selaginella denticulata*, *Kraussiana*, and delicatissima being available for edgings, and the larger ones, like the varieties of *formosa*, *Africana*, *inequalifolia*, and others, make good substitutes for Ferns when kept growing, but when cut they soon fade. They may likewise be kept growing all through the winter, for as they grow so quickly, and can be propagated so readily, there is no necessity for resting them. Although they like plenty of water, even in winter, stagnant moisture is injurious to them.

Roman and other Hyacinths.—Where the beautiful small-flowered Roman Hyacinths are grown in considerable quantities, a second lot should now be placed in warmth to bring them into bloom. Where a good supply of flowers is required from the present time up to the close of the year these small free-blooming bulbs are invaluable, their natural early-flowering habit enabling us to have them without much forcing; when put in heat, the temperature should not be kept too high, a common practice, but, nevertheless, a mistake, as it draws the spikes up weakly, a circumstance which not only injures their appearance, but renders the flowers incapable of lasting nearly so long; a temperature of 55° at night, and 10° higher in the daytime, is sufficient. If a continuous supply of large-flowered Hyacinths, Tulips, and Narcissi are required until late in the spring, the latest roots should at once be potted; it is not well to defer this longer, as the bulbs are beginning to grow, and should not be longer kept out of the soil; when potted, treat them as advised for those put in earlier, *i.e.*, place them in a bed of coal-ashes, a few inches in thickness, filling up between the pots, and covering all over 5 in. or 6 in. in depth with the same material; they will succeed in the open air, or in a cold frame should such be at liberty; and in the latter they can be easily protected from frost.

Pelargoniums.—Show varieties of Pelargoniums, as well as fancies, that were cut back after blooming, shaken out, partially dis-rooted, and placed in smaller pots, will now require moving into others a little larger, in which they are intended to flower. The size of the pots should be determined by the strength of the plant and the purpose for which they are required. Eight-inch pots are sufficient for the largest specimens. If wanted, Pelargoniums may be grown 5 ft. in diameter in pots of the size just named; for ordinary decorative purposes 7-in. pots will be large enough. Grow them in good loam, enriched with about one-fifth of well-rotted manure; to which add a moderate quantity of sand. In potting, ram the soil tolerably hard; if it be left loose the plants form comparatively few roots, and run a great deal into leaf, instead of flower, in the spring. Water them sparingly through the winter, never giving it until the soil has become almost dry; and then in sufficient quantity for it to make its appearance through the bottom of the pots. Keep the shoots well tied out, and the plants in the lightest situation available, elevated close to the roof glass, with a night temperature of from 40° to 45°.

Flower Garden.

The rainfall during the greater part of the present month has been greatly in excess of the average, and, on heavy land, the soil is still in a very wet condition. In all cases, however, where it is not too much so, and while the weather continues open, planting operations may still be proceeded with. In planting ornamental trees of all kinds it is necessary to take into consideration the habit of growth, and the form or outline which the various specimens are likely to assume when they arrive at a partially or a fully-developed condition, in order that they may be so arranged as to suit the positions they are intended to occupy. Many instances may be found in which such trees as the Cedar of Lebanon have been planted so near to the mansion or dwelling house as to have the effect of completely dwarfing the building. Similar mistakes are also being made in reference to the Wellingtonia and the Douglas Fir. Trees which are likely to attain an altitude of, say, 50 ft. or 60 ft. in the course of twenty or thirty years should not be planted nearer to a residence than 100 ft. or 150 ft.; therefore, wherever grounds are circumscribed in extent trees of smaller growth should be used. Amongst the many ornamental plants which do not attain gigantic proportions may be recommended the *Cupressus Lawsoniana*, *Cryptomeria elegans*, *Libocedrus decurrens*, *Thuja borealis*, *Thuja Lobbi*, *Thuja elegantissima*, golden-striped Yews, variegated Hollies, &c.; and even *Picea nobilis*, *P. lasiocarpa*, and *P. Pinsapo*, together with *Pinus insignis* and *Cembra*, all of which seldom attain great dimensions. Among meritorious varieties of deciduous species the beautiful *Taxodium distichum* should not be overlooked. The *Acer Negundo variegatum*, the Tulip tree, *Rose Acacia*, the *Cornelian Cherry*, the *Maiden-hair tree*, and the various varieties of *Cratægus*, such as the double and the single-flowering scarlet and pink Thorns, are all well deserving of attention.

Bulbous Plants.—In far the greater number of gardens many more bulbous plants than are usually seen might, with advantage, be grown. Their distinct forms and pretty colours are an interesting and pleasing feature during the spring months. Nothing, in their way, can be more beautiful than the varieties of *Erythronium* (*Dog's-tooth Violets*); those who intend growing these should procure *E. giganteum* or *grandiflorum*, a fine red variety; *E. album majus*, a very large-flowered pure white, much superior to the old white variety; *E. americanum lanceolatum*, yellow, a very distinct and desirable kind; *E. atro-roseum*, a deep rose-coloured kind; *E. purpureum majus*, with large mauve-purple flowers; *E. giganteum album*, splendid white, bearing eight or ten flowers on a stalk; *E. giganteum flavum*, fine golden-yellow. Either grown together in a bed or in good-sized patches, at the front of the herbaceous border, these plants have a charming effect, not alone for the beauty of their flowers, but their handsome mottled leaves are very attractive; they should be planted without delay. Hardy kinds of *Ranunculus*, such as the Turban varieties, may now be planted in situations where the soil is dry; but the more valuable sorts should not, except in very favourable positions, be planted yet, as they are apt to suffer from wet by lying too long in the ground. Where a succession of handsome hardy flowers is held in estimation, single *Anemones* should be largely grown, the plants, from their compact habit and the continuous brilliant-coloured blooms which they produce being almost without a rival; the single scarlet variety is most effective, commencing to flower in a mild season during the first month in the year. *Anemones* like a moderately rich, free soil, and if grown in clumps in the herbaceous border should occupy a front position on account of their dwarf habit of growth. A very pleasing effect may be produced in spring by planting large masses of *Snowdrops*, *Crocuses*, and *Daffodils* in the Grass in distant parts of lawns, in Grass

plots in out-of-the-way corners, or in front of shrubby borders, and under trees. These may be either planted in patches or dispersed 6 in. or 8 in. apart over the available ground. The places chosen for plants of this kind should not be in too close proximity to the dwelling, as the tops ought not to be removed in the spring until after they are dead, which, in a very prominent position, would be unsightly. Where any of the above plants are to be so arranged they should be planted immediately. Crocuses and Snowdrops may be put in by making holes with an ordinary dibber, covering the bulbs with a little loose soil; for Daffodils, holes must be made with a spade, but whichever way the planting is effected it can with ordinary care be done even on Grass without having an unsightly appearance.

Indoor Fruit Department.

Vines.—When the earliest-started pot Vines produce young leaves do not increase the bottom-heat in which they are placed, but raise the day air temperature to 65°, and at night it should be 58° or 60° when the weather outside is mild. As soon as the shoots are 2 in. long the canes should be suspended nearer the roof than they have been during the time when they have been breaking. Admit a little air on all fine days, and on all such occasions the Vines may be well syringed when the ventilators are usually closed. If the pots are placed near hot-water pipes the soil in them will become quickly dry when strong firing has to be resorted to, and they should be looked over daily and well supplied with clean water whenever indications of drought show themselves. During cold nights, when much fire heat is used, the pathways and other surfaces should be kept moist to prevent dry air from injuring the tender shoots. A second batch of pot Vines may be got in readiness to place in heat about the 1st of next month; clean and surface-dress them as was directed in the case of the others. The different varieties of Black Hamburgs, which include the Frankenthal, Dutch, Mill Hill, and Victoria kinds, are those which still give most satisfaction as early black kinds, and Royal Muscadine, Foster's Seedling, and Buckland's Sweetwater among white varieties. Later varieties take longer to gain maturity than those just mentioned.

Pines ripening too quickly for consumption, or requiring to be kept for any special purpose after they are ripe, may be kept in very excellent condition for a month or six weeks, say in a room in which there is a temperature of about 40°. Both plant and fruit should be thus circumstanced, unless where any valuable suckers are attached, and are likely to be sacrificed. In this case the fruit may be cut and hung up crown downwards in the same room, but, under all circumstances, it is best to cut the fruit, and remove the plant and fruit before they are quite ripe. Watering must now be done with great care; feel each ball with the hand to ascertain if it really needs water. Look over Queens that are resting, and, unless they are next to being dust-dry, do not give them any water. When a very fine day occurs, airing Pineries should receive attention, just the reverse of that recommended for early Vineries. The front ventilators should in this case be opened. This mode has the very desirable influence of preventing the plants and crows from becoming over-drawn.

Peaches and Nectarines.—If the pinching and thinning of Peach trees has been well followed up throughout the summer months, little pruning will be necessary now; still, where not done, the usual winter pruning will require attention, except in the latest houses, in which the foliage is not yet down. Ordinary fan-training is that which is most practised, and also that by which a tree is best kept in health. Severe cutting of Peach trees, especially strong branches, should be avoided as much as possible; but, if the wood in a tree has been allowed to get too thick, which is a common fault, instead of nibbling away at the smaller twigs, branches of the older wood should be cut out, always having an eye to bringing up a succession of young wood from the bottom. In young vigorous trees care must be taken to preserve well-ripened twigs covered with buds, cutting out the green soft branches, if thinning is necessary; but they must be retained if filling up is required. Some varieties, such as Rivers' Orange Nectarine and the Pine-apple Nectarine, are of a more dense and twiggy growth; and some, as the Nobless Peach, are more given to lengthy growth than others; consequently, more caution is required with the latter. In tying the trees see that every shoot has room to extend itself when growth shall have commenced, else there will be confusion and overcrowding in spring. Never shorten the bearing wood of a Peach tree. In late houses the foliage will be falling fast; keep all dry, and husband sun-heat; the foliage will fall while quite green through sheer lowness of temperature and damp. I like to see Peach leaves ripen yellow, like other foliage. The wood of dwarf trees in pots, or planted out, will want thinning and tying down in order to bring the trees into shape. Some sorts yield to this treatment well, others are more stubborn. Pendulous-growing sorts make

handsome trees managed in this fashion; and, with fruit hanging down to the ground, they have a fine appearance.

Pits and Frames.—See that the occupants of cold pits and frames receive plenty of air when the weather is not frosty; the object now is to restrict growth as much as possible, as the less progress the occupants of such structures make the harder they will be. This not only applies to plants in pots, but also to subjects like young Lettuces and Cauliflowers. Either in frames or under hand-glasses or cloches, inattention to this matter of giving air is frequently the cause of these plants dying outright, or suffering seriously when long-continued frosts occur.

Kitchen Garden.

Globe Artichokes should now be protected; if these, after the heads have been used, had the old stems cut away, the young growth at the bottom will be in a robust state, capable of enduring even the most severe winter with a little protection. The best and only material they require is about 1 ft. of dry litter placed lightly round the young shoots, but not over them, leaving the largest leaves just above the litter; round this place 9 in. of soil two-thirds as high up as the litter in the form of a slight Celery ridge, but not drawn up so close. So managed, I have never had this vegetable injured in the least, even in damp, heavy soil. In planting Artichokes the rows should always be so far apart—5 ft. is not too much—as to admit of the soil required for this protection being taken from between them, without going so deep as to leave the roots insufficiently covered. Where the rows are near together, it will be necessary to bring the soil from elsewhere. In this case, coal-ashes, if at hand, will answer the purpose in every way.

Peas.—Those who reside in the southern or western parts of the kingdom, or in any favourable locality, not far from the coast, where severe and protracted frost is not usual, and where, in addition, the soil is of a light nature, may now sow a few early Peas for the chance of having some a little more forward in the season than by later sowing. Choose a situation sheltered from the north and east winds, with the ground, if possible, sloping to the south. Dig it well, and mark out the rows 4 ft. apart; in opening the ground for sowing, do not go above 2 in. in depth, for, if the Peas are put in deep at this season, they are liable to rot. Sow considerably thicker than would be required in the spring to make up for such as may not vegetate, or that suffer from the attacks of slugs; cover with the soil in the usual way, and over the top put a couple of inches of fine coal-ashes. This will not only act as a protection from frost, but also prevent slugs from penetrating the ground and devouring the young sprouts as they are pushing up through the soil. On ground that is much infested with slugs there is great difficulty in keeping these early-sown Peas from being eaten, and if, in addition, the soil is of a wet retentive nature, it is better to defer sowing until after the commencement of the new year.

Extracts from my Diary.

December 2.—Putting a batch of Keen's Seedling Strawberries on shelves in early Peach house. Cutting down old fruit trees, grubbing up their roots, and trenching the ground ready for large specimens. Washing Vinery lights ready for painting. Finishing pruning and nailing Plums and Cherries on north walls.

Dec. 3.—Cutting all Grapes in the Mrs. Pince house, and putting their stems in bottles of water in the Grape room. Giving early Peach house a good watering. Covering up a small piece of Parsnips to save them from frost. Moving large shrubs from nursery to pleasure grounds.

Dec. 4.—Looking over all seed Potatoes and removing any that are going bad. Tying mats ready for protecting. Making labels and pegs. Cutting shreds and pointing nails. Sorting Peas. Cleaning seeds. Looking over Onion store, and removing any that are bad.

Dec. 5.—Sowing Mustard and Cress. Putting a few more Hyacinths into gentle heat to get them forward. Commencing pruning and nailing Pears on east and west walls. Root-pruning Apple and Pear trees growing too grossly. Getting manure on to land whilst the weather is favourable.

Dec. 6.—Putting in 100 pots of French Beans. Making a new Mushroom bed. Clearing up flower borders, forking them up, and planting them with bulbs and spring flowers. Pruning Gooseberry and Currant bushes. Turning up together leaves and long manure for hotbeds. Deep treading as fast as the weather will permit. Looking over all the Pines, and giving them a little water where required.

Dec. 7.—Looking over Grapes in bottles, taking out any bad berries, and filling up the bottles with water. Looking over fruit room and removing all fruit that is beginning to decay. Fruit in use for dessert: Pines, Grapes, Pears, Apples, Medlars, and Nuts.—W. G. P., Dorset.

ROSES.

ROOT AND SHIELD GRAFTING.

(Continued from page 448.)

ROOT-GRAFTING.—This is a system which deserves to be more extensively practised (see figs. 20, 21, 22). It ought to be of great service to Rose growers, especially as regards kinds susceptible to the effects of frost, such as Tea, Bourbon, and Bengal Roses, as well as certain Bourbon Hybrids. It is a well-known fact that Rose trees are killed by frost. When grown on free stocks they sometimes spring up again, but when grafted on a Brier stock the latter alone survives, not, however, in all cases. The varieties best for the purpose are the Hybrid Perpetual, Manetti, and Cabbage Roses. Root-grafting may be performed in both spring and autumn, but autumn grafts have the best chance of success. The roots are cut into lengths from $2\frac{3}{4}$ in. to $3\frac{1}{4}$ in. long, taking care to preserve the rootlets intact; the slips should be from 1.5th to 4.5ths of an inch in diameter; the smaller ones are cleft-grafted or tongue-grafted. The scions to be grafted should have two eyes; they are cut slantwise for the length of 4.5ths of an inch, the slant commencing at 1.5th of an inch over the lower eye. The graft is pushed into the slit in the root, so that the eye is a little below the part where it is cut off. The bark of the graft and scion are brought into contact, and the junction is tied and waxed in the usual way. The eye is introduced into the root in order that it may draw up the sap and favour the striking and future development of the graft. The grafted roots are placed in a frame

Fig. 20.—Root ready to receive the graft.

Fig. 21.—Grafted root.

upon a layer of 9 in. of dry stable manure and garden soil mixed in equal parts. This compost ought to be prepared at least a week before it is required for use. A small trench of about 5 in. in depth is opened up all along the upper portion of the bed of the frame, and the grafts placed in it at a distance of $1\frac{1}{2}$ in. from each other, and in a slanting position. The first trench being filled, a second is opened at about $2\frac{1}{2}$ in. below it, the second being filled up with the soil taken out of the first, and so on until the whole of the frame is full. An ordinary frame will hold twenty rows of grafts, each containing fifty plants, that is to say, 1000 in all in a very small space.

The sash is then put on, and if we are grafting in spring it is covered over with a straw mat; if in the autumn, with dry leaves. Watering must be moderate, and should only be given when the soil is very dry. The amount of water given should be increased as the shoots on the grafts grow stronger. The

Fig. 22.—Grafted root.

grafts may pass the winter in the frame if we are careful to heap up around it a mass of equal parts of stable manure and well-dried dead leaves. We may also place the grafts in the propagating house, putting them first under bell-glasses and keeping them at a temperature of from 50° to 58° ; later on, when they are properly united, they must be removed to larger pots and placed in a cool house. Whatever may have been the plan on which we have kept them, we may transplant them into the open ground as soon as hard frosts are no longer to be feared. Root-grafting has the advantage of being capable of being performed under cover on days when the weather prevents us from doing anything in the open air. It also does not need a store of stocks, besides which it yields plants which, when once placed in a permanent position, very soon become fine bushes.

SHIELD-GRAFTING.—A shield-bud is an eye or rudimentary bud which is taken off the shoot where it has grown, in order to be applied to the branch or shoot of some other species or variety. This operation can only be performed on plants when they are full of sap; but the results are different according as we perform the operation in the summer or autumn. In the first case the shield-bud or eye may at once develop into a shoot and bloom; in the second, the eye seems, as it were, to go to sleep only to wake up in the following spring. Hence arises the difference between growing and dormant eyes. The method of taking off the shield-bud and of placing it on the stock prepared to receive it being the same in every case, we give the following details concerning it before proceeding to describe other modes of grafting. In taking off the bud we hold the branch with the left hand, the larger end towards the wrist, keeping it steady between the finger and thumb. The grafting-knife is held in the right hand, and kept firm by the four fingers, which must be closed upon it. The thumb of the right hand is pressed against the

shoot just under the eye which is to be cut out, so as to strengthen and direct the movements of the hand. The blade of the grafting-knife is then inserted at about 3.5th in. above the bud, so as just to pass through the bark. The blade of the knife is now carried in a downward direction past the bud, separating it partially from the shoot, and leaving attached to it a strip of bark about 1.6th in. wide and stopping at about $\frac{1}{2}$ in. below the eye. The blade of the knife must now be gently withdrawn sideways, and the bud entirely separated from the shoot by cutting off the loose strip of bark with the eye attached by a transverse cut from the outside. This is shown at D and E, fig. 23. Take hold of the bud by its petiole, and, turning over towards yourself, slice off the thin layer of young wood which may be noticed on the upper portion. This operation is greatly facilitated by slightly bending the upper part which has been cut slanting, when the young wood will separate from the bark, and may be taken off with the point of the knife. This operation must be performed with great gentleness and care, so that we may not injure the root of the bud. Rather than run the

risk of injury, we may even leave a small portion of the young wood adhering to the bark, especially when the sap is strong in the shoot. To graft the shield-bud on the stock, we must previously have made two incisions in its bark at right angles to each other in the form of a T, the upright cut being parallel to the stem of the stock. The horizontal incision should pass half-way round the stem, and the vertical incision from 1-5th in. to 1-2-5th in. in length. These two incisions should just pass through the bark of the stem or stock and no more. We must next separate the bark from the stem along both sides of the vertical cut with the spatula of the grafting knife, so as to allow the strip of bark attached to the bud to be introduced. Holding the bud in the left hand by its petiole, we insert it underneath those portions of the bark which have been lifted up by the spatula, pushing it gently downwards as far as it will go, and pressing it firmly into contact with the young wood of the stock. When the upper portion of the bark of the bud rises beyond the horizontal incision, it is cut off level with it. The shield-bud being in its place, the junction is bound round

Fig 23.—Shield-grafting.

with worsted, as shown at B and C, fig. 23. A double layer of worsted is first wound round the upper part of the graft so as to bind the angles made by the two incisions firmly together, continuing the operation downwards past the lowest part of the vertical cut. The end of the worsted is passed through the last loop of the ligature and drawn tight. The ligatures are allowed to remain on the grafts until the stock is ready for pruning, which, as we shall see further on, takes place about a fortnight or three weeks after budding in the case of growing eyes, and not until the spring when dormant buds are grafted. To remove the ligatures, we cut through the worsted on the opposite side of the stock to that where the bud is placed so as to avoid all chance of accidents. It has been proposed to remove shield-buds from the parent plant with horse hairs and to replace the worsted ligature by sheet lead or india-rubber bands. These pretty contrivances are only amateur's fancies, and not worthy of the attention of the practical workman, who cannot afford to lose his time, having frequently to graft seventy or eighty stocks in an hour. J. LACHAUME.

ROSES ON GRASS.

Now that croquet has died a natural death, and lawn tennis is considered by many too great exertion in hot weather, and by others only suitable for very young people, lawns will again become sources of delight to all true lovers of flowers. I am not writing for those able to devote 20 rods of Grass for the purpose of amusement, and yet possess their half acre for the growth of perennial, biennial, and annual flowers. Once more our Grass will be relieved from its sameness by beds of flowers many tinted, according to the taste of the owner. Roses, Pelargoniums, Verbenas, Calceolarias, Ageratum, &c., will resume their way—delightful way, both from their beauty and fragrance. I am now about to turn my croquet lawn to a better purpose, viz., plant it with several dozen standard Roses, at distances of not less than 9 ft. apart, for I am convinced that all standards thrive better singly than massed. My plan of planting will be as follows: I will lift the turf at least 2 ft. square, and remove the soil to the same depth; then make provision for good drainage by using from 4 in. to 6 in. of broken flint or other material easily procured. If turf can be spared I will cover the stones with it, always remembering that the Grass must be downwards; there then will be left at least 15 in. for good soil to nourish the roots, independently of the gain from the space intervening—by no means to be despised where Roses are 9 ft. apart. As to the after treatment to ensure good blooms, both in November and March a little thoroughly rotten manure will be dug in, but not deeply. On no account should the soil be made too rich, for at any time in the summer some liquid manure can be added, or a table-spoonful of some artificial manure (such as Standen's) may be watered in. Excessive generosity to all Roses only tends to over-great growth of wood. I have often seen a shoot of improved Devonianensis from 8 ft. to 10 ft. in length, and seldom are there in such cases many blooms. The same thing may be said of Cloth of Gold and Maréchal Niel; the two latter shy bearers, except under glass. As to pruning, most people begin much too early; the season must be some guide, and the milder it is the later should the knife be used, else the flowers will be premature and at the proper showing time absent.

Litton Cheney, Dorset.

EUGENE E. P. LEGGE.

The Old Pink China Rose.—I have been much interested in the remarks on old-fashioned Roses in "Notes by an Old Rosarian" (p. 455), and would like to ask how it is the old pink China is not more planted. It is nearly always in flower, and at this season of the year the buds are beautiful. In a small garden not far from where I am writing there is a large bush of this delightful old Rose with dozens of flower buds out in various stages of development, and it is rare, indeed, to find it altogether flowerless. It does not require much pruning or training. The shelter of a wall seems to suit it admirably. The best plants are generally found against old-fashioned cottages, where the eaves project to keep off cold rain and snow. In such positions, where the roots are not often disturbed, I have seen well-furnished plants as much as 8 ft. or 9 ft. high. It is a good border Rose, too, but does not attain to so large a size in such situations as against a wall. Planted in good mellow soil, well drained, and the plants not dug amongst, but well mulched instead with old manure or leaf-mould, a good mass of this Rose would be a sight worth seeing. It is very easily propagated by means of cuttings struck under handlights.—E. HOBDAV.

Mildew on Roses.—I find nothing equal to Ewing's Mildew Composition for clearing Roses of this fungus. Our garden being in the middle of a wood which is full of decaying vegetation, we have an opportunity of giving it a good trial.—F. CANNELL, Felthorpe.

Tropæolum canariense (aduncum) Seed.—Probably seedsmen are scarcely acquainted with any other article of their trade that varies so much in price as does the popular annual so called. It should, however, be noted that it is not Tropæolum canariense at all, but P. aduncum, the error having, no doubt, originated from its being popularly called the "Canary Creeper," from its yellow flower. In 1876-7 the wholesale price was from 9s. to 12s. per lb. In 1877-8 it went up to as much as 20s. per lb.; and this season there is a material advance in the price over that of last year. This Tropæolum is always in demand, and about once in three or four years there is a scarcity. A long, hot, dry summer will seriously circumscribe the harvest, and the same experience holds good in the case of the past cool, moist summer. In all probability this is owing to the ravages snails, slugs, &c., made among the young plants. The uses to which this pretty Tropæolum is put to in gardens are many. One of the most striking and effective was witnessed at Muckross, Killarney, a few years ago, where hedges of the Scarlet Invincible Sweet Pea, and the Canary Creeper, intermixed, were, as also at Culford, in Suffolk, one of the features of a place full of horticultural interest.—"Gardeners' Chronicle."

THE FLOWER GARDEN.

DISA GRANDIFLORA IN THE OPEN AIR.

HAS the out-door culture of *Disa grandiflora* ever been fairly tried in suitable localities in the southern and western shores of England, in the south of Ireland, or on the west coast of Scotland? When we know that the numerous North American *Cypripedia*, *Darlingtonia californica*, *Hyacinthus candicans* (Cape), *Aponogeton distachyon* (I have been shown a pond in the Isle of Wight where this plant was in flower during the winter months with a thin coating of ice and snow on the surface of the water), and many other plants, once thought to require protection, can in our climate be safely left to take care of themselves during our long winters, if only planted in situations suitable to their requirements, we may fairly, I think, expect, when we consider the peculiarities of habitat in which *Disa grandiflora* flourishes, and which I will proceed at once to discuss, that it will very shortly be added to the list of those plants which in many parts of our islands, where their peculiarities can be easily and suitably ministered to, are successfully cultivated without any protection. Allow me, then, to recall attention to Mr. Henry Buckley's vivid description (Vol. XIII., p. 275) of his visit to Table Mountain. It is there stated that at an altitude of not less than 3000 ft. above sea level, "less than a quarter of a mile brought us amongst quantities of *Disa grandiflora*; and well may Harvey term it 'the pride of Table Mountain,' for it would be difficult to find a handsomer or showier flower; and when you see a dozen or fifteen of its brilliant-coloured blooms clustered together, it is a sight not readily to be forgotten. The intensity of its colour exceeds that of any wild flower I have ever seen, the Snow plant of California, with its rich colour contrasting with the spotless snow, excepted. *D. grandiflora* grows most plentifully on the sides of the narrow watercourses which intersect the plateau, the sides, as a rule, being nearly upright, although we saw numbers on the face of large rocks where water was trickling down. The soil it grows in is a sandy peat, and it may almost be said to grow in the water, the soil being so wet; and as this is the driest month here, it is clear that the roots are always in wet soil, and I believe they never rest, as examination showed that they were even now pushing forth new growth." I am also favoured with an account from a correspondent resident at Cape Town exactly tallying with that of Mr. Buckley as to soil and locality. He writes: "This very beautiful Orchid is always found growing on the margins of ever-flowing rivulets and ledges of waterfalls; their roots are always under water, and frequently for days together are entirely submerged. In June, July, and August"—corresponding to our December, January, and February—"they are frequently covered with snow and hail. In 1878 they were, to my knowledge, so covered twice. I have frequently found ice on the slopes of Table Mountain 2000 ft. below the *Disa*'s haunts. The water on Table Mountain is cold, even on the hottest day in summer. The Table is frequently covered throughout the year with cloud or mist, and it frequently hangs on for four or five days, and at all such times the temperature is very low. In May, 1876, I was on the mountain for eight hours in a mist that came off the sea from the north-west; it was very, very cold. During our hottest months the Table is most frequently covered. At that season the cloud comes from the south-east with a very strong wind, and is even colder than in our cooler months. I have always found the *Disas* growing in sphagnum, peat, and sand. I have been on Table Mountain in midsummer, but have never found it so hot as in Cape Town. I have every belief that the *Disas* would grow well out-of-doors in the south of England by the side of a running stream."

It is to be specially remarked from these accounts—both furnished by eye-witnesses—that even in its native habitat this glorious Orchid (one of the most beautiful of all) is mainly found on the banks of rivulets, or where water is constantly trickling downwards. Likewise that not only in winter is severe cold experienced there for three months equal to or greater than any which is felt in many of our southern and western shores, but that even in summer, when the plants are in full luxuriance, they are for days exposed to a low temperature, cold winds, and the chilling effects of wet mist. *Primâ facie*,

we might, therefore, I think, fairly infer that if in snitable sites, viz., the banks of rivulets, little beds of sandy peat and sphagnum be provided for it, this glorious Orchid may easily be acclimatised with us as an outdoor plant. It is also clearly to be inferred that it must not be planted in shady spots; for, according to our correspondents, while its roots are in wet soil its foliage is in full sunshine. That it, if successfully acclimatised, would be one of the finest additions to the list of our outdoor plants is evident from its description in Williams' "Orchid Manual"—"This gorgeous Orchid grows to the height of 1 ft. to 1½ ft., bearing on the top of the stems from two to five beautiful scarlet flowers in June and July. The blossoms last a very long time in perfection. The flowers are from 2 in. to 3 in. in diameter. The variety called *Superba* has flowers more than 4 in. in diameter, of a bright scarlet and crimson, veined with pink." Surely to acquire such a brilliant flowering plant is well worth a trial?

Colchester.

A. WALLACE, M.D.

WINTER BEDDING PLANTS.

THOSE who attended the Royal Horticultural Society's meeting at South Kensington on the 19th inst. had a rare opportunity of inspecting a most extensive and varied collection of hardy plants, suitable for furnishing flower beds in winter, shown by Messrs. Veitch. They were arranged in three long rows, filling the spacious entrance to the council room, and, as they were in circular, flat baskets, they afforded a good idea regarding the effect which they would produce when planted in the positions which it might be desirable to decorate. The advantage of using plants of the class exhibited is, that a really good effect might be produced at once, i.e., immediately the summer bedding plants are moved, and by blending the winter and spring gardening by adding a margin of early flowers and mingling the bulbs with the dwarf plants, a really fine display might be insured throughout the whole season with this additional advantage, viz., that whereas most of the ordinary spring and summer flowering plants are useless and cast away as soon as their beauty is past, the plants in question being of a more permanent character increase in value. When grown too large for the purpose under notice, they come in for filling up shrubberies and permanent evergreen beds. Many, too, form beautiful single specimens, and if allowed space in which to develop themselves, become objects of interest for many years. Conspicuous amongst variegated plants were several kinds of *Eunymus*, *Hollies*, *Ivies*, and *Aucubas*, the latter loaded with berries, which unfortunately do not colour early enough out-of-doors to be effective for winter work. Of *Skimmias*, some excellent plants were shown both in fruit and flower; but of berry-bearing plants, one of the best was *Pernettya macronata*, which was quite loaded with purplish fruit. Amongst the best flowering plants were the well-known *Laurustinus*, *Menziesias*, and hardy *Heaths*, but, according to my idea, the baskets of *Retinospora plumosa* and *R. obtusa aurea* (the latter a beautiful golden Conifer) carried off the palm; nothing, in my opinion, can excel these lovely hardy plants, especially in winter when every small branchlet bends beneath its drop of dew, or is crested with hoar-frost. † Dark-foliaged plants, from the well-known *Berberis Aquifolium* to the choicer introductions of a more recent date, were too numerous to advert to in detail. I need only add that those who have a garden which they wish to make enjoyable "all the year round" will find plenty of variety amongst such plants as those to which I have just alluded, and they are obtainable at a price that does not prohibit their almost universal cultivation. J. GROOM.

— Messrs. Veitch's collections of dwarf shrubs for winter bedding are doubtless charming; but, alas! they are beyond the reach of poor folk. Permit me, therefore, to describe a bed here, which is exceedingly effective now, and will be still more so in spring. The bed in question is circular; the centre is a round block of *Viola Golden Queen*, interspersed with a few *Tulips* of the variety called *Kaiser Kroon*; next comes a broad band of *Ajuga reptans purpurea*; next a single line of variegated *Arabis*; then a double row of *Viola Blue Bell*; and lastly, as an outside edging, a line of *Golden Feather*. It would be difficult to heat this bed, either as a winter or spring arrangement. All the plants used are cheap and easily propagated, with the exception, perhaps, of the *Tulips*, which are a pure luxury and quite unnecessary. A thin mulching of Cocoa-nut fibre keeps all snug, and adds considerably to the harmonious colouring of the whole.—HERBERT MILLINGTON, *King Edward's School, Bromsgrove*.

Saving Old Bedding Pelargoniums.—Mr. F. Cannell (p. 463) is mistaken in thinking I have omitted the one thing needful (p. 412

to preserve these successfully. Had I said anything at all about heat, I would have said avoid by all means putting them in heat, especially at first, because if one begins with heat in October, it must be continued on during November and December, and probably for months longer, or the growth made first in "heat" will be worthless in spring. As soon as ours are put in boxes, they are placed in a Vinery in which the ventilators are open every day, and night too in mild weather. With the air circulating about them in this way not one of them "rots," and the growth which every one makes is not easily checked.

—CAMBRIAN.

EAST LOTHIAN STOCKS.

THESE Stocks are, without doubt, grand decorative summer plants in the north, where the cooler season seems to suit their growth and development; but Burghley is rather more south than north, and the treatment that answers it in the home districts will doubtless be found the best at Stamford. In the neighbourhood of London the East Lothian Stocks, which are a more robust strain than the well-known Market Intermediate, thrive and perfect themselves best when sown late in the autumn in cold frames, are allowed to stand in the seed bed for the winter, and are planted out when strong in the spring. In this way an earlier bloom is ensured, and, of course, a much longer period of flower. Under the thin, but nevertheless efficient, protection of a glazed light, Stocks will withstand a good deal of frost, and if very hard weather ensue, a mat or two or some Fern covering will keep them out of danger. An undoubted advantage is found if some of the strongest plants from the seedbed be pricked out, with a few inches distance between each, into another frame, or into small pots, as these transplant more readily and are sooner established than they otherwise would be. Plants thus wintered, put out into rich soil, will make good growth, and will bloom profusely; indeed, if kept moist in warm weather, they make superb bedding plants, their rich and well-defined colours furnishing hues that are not more finely displayed by any other bedding plants. Many growers of these Stocks, however, treat them as annuals, and sow them in bottom-heat in April and plant them out into the open beds in May. When this is the case the plants do not attain to such size, neither are the spikes so fine, but there is a large amount of bloom produced, and it continues so late into the year that in mild seasons these Stocks have furnished bloom at Christmas. Spring-sown Stocks should not have such rich soil, but will perhaps require even more moisture, as if the growth be once checked the plants rarely are so fine as would have been the case had the growth been free and continuous. The origin of this fine race of stocks seems to be somewhat obscured, but that East Lothian is the locality from whence they sprung there can be little doubt. Judging by the habit, growth, and colour of the flowers, they have some affinity to the Queen Stock strains; and, indeed, they are exactly intermediate between these and the Ten-week kinds. The old Queen Stocks have scarlet, purple, and white flowers; the East Lothian kinds have similar colours, but somewhat intermixed, that is, brighter in the dark colours and purer in the white kinds. The plants have a robust, compact, but branching habit, in this respect exactly corresponding with the growth of the Queen kinds, but that of the latter is coarser, yet more hardy; indeed, these latter are the hardest of the Stocks, and no doubt many of them are sold as Lothians. In another respect the Queen kinds are most valuable, because, being hardy enough to withstand in the open severe weather, they begin to bloom early, and will make grand masses of colour in April and May. Large breadths of the rich purple kind, commonly—but incorrectly—called the Twickenham Purple, are grown in Middlesex for the London market, the proportion of doubles being about 75 per cent. I think growers in the south of East Lothian Stocks would prefer the Queen kind for borders, whilst the others are undoubtedly best for the filling of beds and for producing a rich summer display.

A. D.

Tritonia aurea—Your correspondent, Mr. C. W. Dod, in his most interesting articles on growing the above-named plant outdoors, remarks that when treated as a greenhouse subject he finds the leaves wither and dry up prematurely without any apparent cause, but if he will examine them closely he will see that their dry, flabby look is owing to the presence of red spider, an insect to which this plant, more than almost any other, seems particularly liable. When grown in pots, unless under special treatment, it is almost an impossibility to keep it free from the ravages of this insidious pest, and the only way I have ever been successful in is in placing the plants in cold, damp frames, where they get plenty of air and never suffer from want of moisture at the roots all through their period of growth, for if this takes place so as to give them a check the enemy is quickly on them. As soon as winter is over the best way to treat them is to

plunge them somewhere out in the open where they are subjected to rain and light dews, and can have a syringing overhead occasionally during dry weather. Under glass the aridity of the atmosphere is too much for them, and I have never yet seen healthy green foliage on any at the time of blooming that had been in confinement longer than was necessary to bring out the flowers; but since we have managed them in the manner just stated, the leaves last fresh and bright-looking till they begin to ripen off naturally, and, as soon as they do this they require repotting, which should be done by giving them a shift into a size or two larger without disturbing the balls, or by a simple division if the object be to increase the stock, or, it be desired to confine them to the same sized pots, as the less they are pulled about the better they succeed, on account of the way their roots and stolons get intertwined and matted together. We are now planting spare stock out close to a sunny wall, a position the *Tritonia* does well in and affords plenty of flowers for cutting. When grown in the open, I find that the mulching of the ground is a great help to it, as a few inches of leaf soil, Cocoa-nut fibre, or anything of that kind will keep out a good deal of frost, and, when protected in this way, the plants will pass the hardest winter in safety.—S. D.

I can add even stronger testimony to the hardness of this plant than that adduced by Mr. Alexander (p. 463). Four years since I placed three clumps of it in a north border with the idea of thus lengthening the blooming season. Each succeeding year has brought forth more vigorous shoots and a greater quantity of flowers, lasting till the end of October. I must add that the natural soil is a cold and somewhat wet clay, and the bulbs have not for the last two years had any protection from frost whatever. So, although undoubtedly they would be more successfully grown in peat, yet this is a proof that they will do more than exist in clay.—E. FARRER
Petygards Hall, Swaffham, Norfolk.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Fuchsia pumila.—I am glad to find this very pretty miniature plant creeping to the front again. I remember bedding it out thirty-five years ago, and I have carried it about with me ever since. Bedded in small beds by itself, or used as an edging to beds of the larger *Fuchsias*, it is simply charming. I am afraid that *F. microphylla* will, as an outdoor plant, be found more enrious than useful. There is another with more minute foliage still, viz., *F. thymifolia*, and I have long cultivated a pretty variegated form of what is known as *F. occoines*, but which is, I believe, *F. virgata*; this I call *F. triolor*, from the very constant and varied tints of its foliage. It is not so coarse as the type, and truly hardy.—T. WILLIAMS.

Arum Lilies (Callas) Out-of-doors.—Referring to the remarks of Mr. Andrews (p. 163) on this subject, I may mention that I have had in my garden pond for more than twenty years past a large number of *Arum Lilies (Callas)* all the winter long, and I have never lost a plant. A moderate spring flows through my pond, which is not frozen over, unless with a smart frost. They increase from year to year spontaneously from seedlings, as well as laterally from the old roots, which are planted in the natural soil and kept down by a few large stones. We have had from fifty to one hundred blossoms out at one time, and the fine, tropical-like leaves are as yet untouched by frost, and are highly ornamental.—BURWOOD GODLEE, *Leighside, Lewes.*

Valeriana Phu.—In answer to the inquiry about this plant, I may state that it is not known as British, but is a native of Germany. In its ordinary form it is a plant of no great merit, being decidedly coarse. The British plant, supposed to be identical with it, is *V. officinalis*. The variegated *Pulemonium* is certainly a form of the British *P. coruleum*. I have grown the *Menis Athamanticum* for years, known by the strange name of *Bald-money*. It has a very delicate Fennel-like appearance, and is remarkable for its multipartite, hair-like leaflets, but certainly not like an *Adiantum*. Its beauty is best appreciated when grown in a pot.—T. WILLIAMS.

Winter Quarters for Echeverias.—Where room under glass is scarce, flower garden *Echeverias* may be stored away in a shed or tool-house. If packed closely in boxes they will need no water during the winter, and will endure uninjured from 10° to 15° of frost. If the winter be exceptionally severe, a mat or two thrown over them will be sufficient to insure their safety. I have kept them in this way when the thermometer has registered 15° and 20° some nights in succession.—J. CORNHILL.

The White Azalea Planted Out.—We shall be greatly obliged to any correspondents who will inform us as to the districts in England, Ireland, or elsewhere in which this well-known shrub flourishes in the open air.

NEW OR RARE PLANTS.

THE FRUIT GARDEN.

Acrostichum peltatum.—Though not new in cultivation, this elegant and curious little Fern is so rare as to deserve bringing under the notice of our readers. It belongs to a section of the genus *Acrostichum*, called *Rhipidopteris*, including two other species. The accompanying engraving represents a small portion (natural size) of a plant bearing one fertile and one sterile frond. In a wild state it creeps over rocks and the moist trunks of trees, the slender, trailing stems attaining 1 ft., 2 ft., or more in length, and interlace so that the fronds form a dense carpet. If not commonly seen in our Ferneries, it is not rare in a wild state, as it inhabits the sub-tropical, mountainous regions of America, from Mexico to Ecuador and Guiana, and it is also common in the West Indies. The other species are, *A. fœniculaceum*, a native of Ecuador and Peru, having rather larger, barren fronds divided into thread-like segments, and *A. flabellatum*, from the same region, with the fronds divided into

Acrostichum peltatum (natural size).

three or four broad segments. Mr. Ley, of Croydon, from whom the plant figured above came, finds it to succeed on a shelf in a warm greenhouse, potted in rough peat and small pieces of sandstone.

Phajus Dodgsoni.—A handsome species or variety allied to *P. albus* ("Botanical Magazine," plate 3991), but much superior, the petals being pure white and the interior of the labellum yellow, with red-brown longitudinal lines. This and *P. alba* differ from most of the other species of the genus in having an erect, leafy stem terminating in a pendent raceme of flowers. *P. Dodgsoni* is one of Mr. B. S. Williams' importations from the East Indies. Mr. Williams was awarded a first-class certificate for it by the Royal Horticultural Society in August, 1877, not 1871, as inadvertently stated in the "Floral Magazine."

Saxifraga Schmidt.—The "Gartenflora," plate 916, contains a figure of a *Saxifraga* under the above name, and belonging to the same section as *S. crassifolia*, from which it differs, Dr. Regel states, in its "denticulate ciliate," fringe-toothed leaves; from *S. thysanodes* (Lindley) by its glabrous leaves; and from *S. ligulata* and *S. ciliata* by its paniculate flowers, similar to those of *S. crassifolia*. Messrs. Haage & Schmidt sent this plant out under the name of *S. thysanodes*. Dr. Regel at first took it to be *S. crassifolia*, but besides the difference indicated above, it is a much tenderer plant, and may, perhaps, prove a variety of *S. ciliata*. As an ornamental plant it is inferior to several others of the same group. The same number of the "Gartenflora" also contains a coloured figure of *Acemons nemorosa* var. *Robinsoniana*, and an uncoloured plate of *Dieteria coronopifolia*, an asteroid composite with large blue and yellow flower-heads, a perennial with the leaves pinnately cut into narrow segments flowering in autumn, and very hardy.

W. B. HEMSLEY.

FRUIT TREES IN AUTUMN.

The importance of manuring cannot be over estimated by those who desire to have healthy trees, and good sound fruit. After a tree has thoroughly matured its produce, it is much exhausted and requires nourishment; it is, therefore, in the best condition to benefit by a judicious application of well-rotted manure. When the juices are no longer absorbed by the fruit, they are directed towards the buds containing the embryo crop of the following year, and on the fact, whether such buds are well fed or starved, depend both the quality and quantity of the future fruit. Any one who is in the habit of observing the manner in which the same varieties of fruit are grown in various gardens cannot fail to have noticed a great diversity between those which are well grown and those badly grown, some being fine and abundant, others scanty and inferior. Now, it should be borne in mind that trees continue to derive nourishment and support from their roots during the whole winter; in fact, they are storing up vigour and strength to carry them through the trying period of blossoming and setting. This is especially the case with Peaches, Nectarines, Pears, Apples, &c. Unsuccessful setting and stoning, and consequent failure of the crop, are too frequently attributed to bad spring weather or late frosts. The real cause of these disasters must, however, be sought for, for the most part, in weakness and want of vitality—the result of bad and injudicious feeding. Proper mulching in autumn would have done much to supply these deficiencies. The manure should not be (as I have often seen it) heaped round the bole of the tree (perhaps for a considerable way up the stem), thus encouraging the growth of suckers from the original stock, and doing mischief instead of good, but a small portion of soil should be removed from the roots as far as they extend; the manure may then be applied, but not allowed to come in direct contact with them, and the soil should be raked back over the manure. By this process the roots are induced to come to the surface for their food, and become matured by the warmth of the summer sun. The manure should be good material, containing nourishment in a soluble state, whose beneficial substances can be washed down by rain or artificial watering. I repeat that the manure should be good. Too often it is rendered poor and useless by over-fermentation. Manure is best rotted by means of slow and moderate fermentation. If the heat be too great, the ammonia is driven off and the manure becomes littersy, dry, and inert, and consequently of little value; but when it is properly fermented, the ammonia remains absorbed, and is nutritious and highly beneficial. Trees derive very little good, if any, from fresh or unfermented manure. To heavily manure a tree every third or fourth year (the common practice) is not advisable; it should be done moderately every year. Nature herself points out to us the best seasons for this top-dressing. She spreads a thick litter of fallen leaves over the roots, thus giving nourishment in autumn and protection in winter, while in spring and summer a carpet of green grows up around the trees, thus preserving moisture and preventing evaporation. So should we in like manner in autumn and winter feed and protect and in spring and summer top-dress, to retain the dews and rain, and to prevent dryness.

W. N.

Hillside, Newark.

Quickly-grown Smooth-leaved Cayenne Pines.—On the 17th June last I removed from old stools two suckers which had started and nearly done flowering. They were potted in 10-in. pots and plunged in a bed of leaves. On the 12th of October the first fruit was cut; it weighed 7 lb. 7 oz. The second was cut on the 21st of the same month, and weighed 6 lb. 6 oz. From the time they were removed till they were cut they were subjected to scarcely any fire-heat.—M.

Late Plums.—I quite echo the opinion of Mr. Fish (p. 471) as to the value and excellence of Ickworth Imperatrice (Knight's No. 6) as a late Plum. I have grown it for many years, and find it all he describes it to be. As a standard it seldom bears oftener than once in three or four years to any extent, but from a trained tree on a suitable wall (west I find best) it is more fertile. Too much cannot be said in favour of Coe's Goldea Drop as an excellent late Plum, bearing well in all forms, but best on a wall. As a very late

ordinary sort, Wydale lasted here till the 18th inst. in the open, and is a profuse bearer; not at present much known.—W. RODEN, M.D., *Kidderminster*.

NOTES OF THE WEEK.

Stenocarpus Cunninghamii.—This handsome Protead is now in flower in the gardens at Perryfield, near Godstone, where it has been for twenty years without, until now, producing blossoms. In its native country this species forms a lofty tree, having a bright red and yellow inflorescence, and long, handsome, leathery, Oak-like leaves, deep shining green above and pale green beneath. Where opportunities exist for growing plants of large size a place should certainly be found for this *Stenocarpus*.

Callipsyche aurantiaca.—This is an Amaryllid not often met with, but it is one which might be grown with advantage for mixing with Ferns or Mosses at this time of the year. Its tubular-shaped flowers, which are produced whilst the bulbs are leafless, are borne in whorls on long fleshy stalks, and are of a bright golden yellow. We met with it in Messrs. Henderson's nursery at Maidstone.

A Powerfully-scented Orchid.—*Maxillaria picta* is well worth growing if on no other account than for its pleasant and powerful perfume. It is not by any means one of the most attractive of winter-flowering Orchids, but a few plants of it in flower placed in a conservatory will scent the whole house. We lately saw plants of it blooming freely in the Holloway Nurseries.

Ipomœa Horsfalliæ.—This old-fashioned stove climber, which flowers freely in a warm greenhouse all through the winter, is not so common in gardens as its attractiveness and easy culture would lead one to suppose it would be. It should be trained under the roofs of houses on wires about 1 ft. or 18 in. apart, so that it obstructs little light from the other occupants of the house below it. There is also a kind named *I. cœrulea*, which flowers at this time of the year, and which might be associated with *Horsfalliæ*, as its sky-blue flowers would contrast well with the rich magenta-coloured blossoms of *I. Horsfalliæ*. Both kinds are now in flower in several places about London.

Lælia autumnalis.—A fine variety of this Orobid is now in flower in Mr. Williams' nursery, Holloway. It is one of the best of winter-flowering Orobids, and one which thrives well in a cool house. It may be grown with equally good results either in pots or pans, or on blocks of wood or cork, and on that account may be made available for any position in which it may be desirable to place it. With it are associated finely-flowered Oncidiums, such as *O. Forbesi*, *Rogersi*, and *tigrinum*, and a variety of *Lady's-slippers*; also the wax-flowered *Maxillaria venusta*, stalwart *Vandas*, and pretty *Odonoglossums*, all of which, intermixed with Ferns and Grasses, have a charming effect.

Japanese Chrysanthemums.—Notwithstanding that these are, from an artistic point of view, much more beautiful and graceful than the incurved and Pompon-flowered kinds, we notice that but few plants of them are exhibited at Chrysanthemum shows. Blooms of them are shown in a cut state in limited numbers, but about 90 per cent. of the Chrysanthemums shown are ordinary kinds. Whilst some of these, as regards form, are almost perfection, a little more attention might nevertheless be paid with advantage to the fine Japanese kinds now to be found in good collections. Their flowers possess a brilliancy and variety of colour not to be found in other plants, and from a decorative point of view they are infinitely more effective. There are good displays of Japanese kinds just now in several of the principal London nurseries.

American Camellias.—Cultivators, as a rule, are not aware of the advance which has lately been made in the production of seedling Camellias in the United States; Wilder's *Jenny Lind*, Mrs. Abby Wilder, and a few others are well known; but the very remarkable seedlings of Messrs. Hovey, of Boston, not yet "let out," appear, from all reports, to eclipse any yet produced. These seedlings have been frequently exhibited before the Massachusetts Horticultural Society, and one of them has been awarded a gold medal (£12). In a recent number of their "Transactions" we find the following descriptions of three of the finest: "*Mrs. Anne Marie Hovey*.—This beautiful variety continues to maintain its character of producing a great variety of colours on the same plant; indeed, entirely new combinations of colour are displayed by it every year, the marbling, spotting, pencilling, blotching, tinting, edging, and dotting of the various flowers have no parallel among plants. C. M. Hovey.—This is a very fine scarlet Camellia; of precisely the same tint as that of the bracts of *Poinsettia pulcherrima*; in size it measures from 5 in. to 6 in. in diameter, and in form is remarkable for its great regularity and

depth, as well as its petals, which are bold without a notch or serrature; the growth is vigorous, the leaves large and glossy, and the plant has a fine, bushy, branching habit. C. H. Hovey.—This is the dark variety so frequently exhibited, and now first named. Its colour is quite new, resembling as nearly as possible that of *Lord Raglan Rose*, or some of the new dark crimson-shaded *Roses*, a colour never seen in any *Camellia* yet produced. The shape is perfect, the petal as round as if cut with a compass, and the habit vigorous, bold, and spreading." We understand that Messrs. Hovey have placed in the hands of Mr. Stevens a few of the plants of these magnificent varieties for sale, affording an opportunity for cultivators to add them to their collections.

Royal Botanic Garden, Edinburgh.—We learn that Mr. Sadler, well known in connection with this garden, has been selected for its curator in the room of the late Mr. James McNab.

Dendrobium bigibbum album.—This is now in flower at Holloway. The plant is exactly the counterpart of the rose-coloured kind, whilst its blossoms are white, delicately flushed with violet. When well known, it will no doubt be grown as largely as the rose-coloured variety.

Japanese Primroses in Norfolk.—The Rev. Mr. Nelson informs us that these plants (of which several improved varieties were illustrated in colour in THE GARDEN of November 23) flourish freely in the open air in his garden at Aldborough, in Norfolk, among the herbaceous plants in borders.

Chinese Primula Ruby King.—It is no exaggeration to say that this is the most beautiful of all Chinese Primulas. It is now in flower in Messrs. Sutton's nurseries, Reading, and the whole of the plants show a remarkably even dwarf habit. The stems are stout, and of medium height, bearing large trusses of fine blooms, many of which are 2 in. in diameter, finely fringed, and of an intense purplish-magenta, a colour to which no artist could ever do justice. Whenever this grand strain shall become common it must inevitably displace all other purple-hued kinds.—A. D.

Sophranitis grandiflora.—This charming winter-flowering Orchid succeeds in no way so well than when grown on pieces of virgin cork suspended from the roof of the house in which it is grown. It soon covers the cork, and has a fine effect in winter when studded with brilliant scarlet blossoms. It grows well also on the stumps of Tree Ferns and in shallow pans. Its blossoms are well adapted for button-hole bouquets, few flowers lasting in a cut state in good condition for so long a period. Under all the ways just described, plants of this *Sophranitis* may be found in flower in Messrs. Veitch's nursery, Chelsea.

Chaumontel Pears in Covent Garden.—Fine examples of this excellent Pear are now offered for sale in great abundance in the Central Avenue, Covent Garden. They are imported from Jersey, and are well coloured and ripened. Considering the value of this Pear, it is surprising it is not more grown in English gardens than it is. In cold districts it will not succeed, but where a warm, sheltered place could be found for it, good examples might be obtained; or it would be well worth the expense of a glass-covered wall.

Recreation Ground for Torquay.—Sir Laurence Palk, M.P., has offered to the Torquay Local Board of Health a beautifully situated piece of land as a recreation ground for the nominal rent of 2s. 6d. per annum.

Street Trees.—A contract has been entered into by the local authorities with Messrs. Goff & Sons, nurserymen, Old Kent Road, to plant St. George's Road, Southwark, with Plane trees, from the Elephant and Castle to the Westminster Bridge Road; also to complete the planting of the Blackfriars Road up to the approach to Blackfriars Bridge.

National Rose Society.—We are informed that the annual meeting of this society will be held, by the permission of the Horticultural Club, at their rooms on Thursday, December 12, and that the anniversary dinner will be held at the same place on that evening. The Hon. and Rev. J. T. Boscawen, Vices-President, will preside.

National Auricula, Carnation, and Picotee Societies.—The date of the exhibition of Auriculas (southern section) was fixed the other day for Tuesday, April 22, 1879, in the gardens of the Royal Horticultural Society, and that for the Carnation and Picotee Society for Tuesday, July 22, at the same place; the schedules of prizes for 1878, for each flower respectively, are to be repeated.

Royal Horticultural Society.—The meetings and exhibitions of this society for 1879 have been fixed as follows:—Meetings—January 4, February 11, March 11 and 25, April 8 and 22, May 13 and 27, June 10 and 24, July 8 and 22, August 12 and 26, September 16, October 14, November 18, December 16. Shows—Great Summer Show, May 27 to 30; Whit Monday popular Show, June 1; Rose and Pelargonium Show, June 24.

ANSWERS TO CORRESPONDENTS.

. All correspondence should reach us early in the week to ensure attention in the current number.

Plant-covered Walls.—I wish to cover the back wall of a stove with *Ficus repens*, and have *Ferns*, *Begonias*, &c., growing, as it were, out of it. What is the best way to prepare the wall for holding soil for the above? Will cork bark or clinkers be best? and how shall I fasten them?—M. C. [Your best plan would be to get a strong wire trellis, the wires crossing each other so as to form squares or diamonds at distances of, say, 4 in. or 5 in. apart. This should be secured to the wall by means of stout iron staples, or stays, so as to leave about 6 in. between the wall and the trellis. Into this space pack good turfy loam, peat, and flaky leaf-mould, beginning at the bottom and planting the plants as the work proceeds. Sphagnum Moss may be used for the front, or, still better, plant it with *Selaginella denticulata*.—S.]

Morello Cherries Falling (p. 477).—On heavy clay soils it is not an uncommon occurrence for Morello Cherries to fall off just about the time the last swelling begins. I look upon it mainly as a question of stagnation of growth induced by the failure of the root action at a critical moment. If your correspondent can alter the character of the soil by working in gritty material, such as road scrapings, burnt earth, a little old mortar, or broken bricks, they would help to open it; and any old turf available might also be added. If possible, the extremities of the roots should be lifted carefully, some of the clay removed, and the trench filled up with better, lighter, and more gritty soil. Clay is about the worst kind of soil for Cherries. As the trees are planted against the dwelling-house, I suppose the site does not require draining.—E. HOBDAK.

Paraffin as an Insecticide.—Allow me to offer a word of caution to the initiated in the use of paraffin. While finding it invaluable for eradicating scale and mealy bug from the *Stephanotis* and *Gardenias* without injury, some plants of *Ixoras*, *Croton*, and a *Lomaria gibba*, dipped a month ago, are now quite denuded of foliage and seem as near dead as possible. I used a small wineglassful of paraffin to a 3-gallon pail of rain water, well mixed together. Probably in dipping the plants much more of the paraffin adhered to the foliage than if it had been applied by means of a syringe; hence the damage. I shall, therefore, for the future apply it with the syringe only.—H. HARRIS, *Denne Park*.

— I notice (p. 476) some remarks on the use of paraffin to destroy scale, &c., on *Epicurises* and other plants. Did any of your correspondents ever try one part paraffin to three parts soft soap, and then dissolve in hot water? It makes an emulsion which does not separate for some considerable time.—W. A. S.

— I notice (p. 476) mention made of the use of paraffin as an insecticide. I conclude your correspondent means paraffin oil or petroleum. The experience of others has been given in its favour in previous numbers. I tried it in the summer, mixed with water in the proportions recommended, on a *Mayduke* Cherry tree infested with the black aphid with the following result: I applied it twice with a syringe; it had no effect on the insects, but it injured the foliage. I have tried other insecticides, including *Gishurst's* and *Fowler's*, with no better success as regards the destruction of the black fly, and I shall be obliged to any one who will tell me how to get rid of it.—B. S.

Will Rabbits Eat Jerusalem Artichokes?—Mr. W. V. Boro'bridge (p. 477), may rest assured that rabbits if numerous will nibble off the young tops of these artichokes when they first come up. If he could fence them in with wire netting temporarily till the stems were becoming firm and hard, they would afterwards escape. Perhaps the best plan would be to put a permanent fence of galvanised netting round, and then crops of all kinds would be safe. If the land was worth anything it ought to pay for it, and it is worth something to be free from the annoyance of seeing the plants eaten off.—E. HOBDAK.

— We have a large patch of Jerusalem Artichokes, to which thousands of rabbits have free access, and I have never seen them touch a single root.—CAMBRIAN.

— In answer to "W. V.," Boro'bridge (p. 477), I am pleased to be able to state that I never knew rabbits to eat the stems of these plants. In re-establishment these were a speciality and largely consumed for soups and other purposes. The garden being rather small, and these plants being too tall and rather rubbishy for a kitchen garden, about an acre of ground was devoted to them beside an unfenced wood abounding with rabbits. They never interfered with the plants, but used to attack the root occasionally in unusually severe weather. As these were left in the ground and taken up as required for use, the plan was adopted of earthing them up with about 6 in. of soil, and the roots were seldom attacked by the rabbits afterwards. I have also frequently seen Jerusalem Artichokes grown on the sides of farm fields, and never saw them injured to any serious extent by either rabbits or hares, so that I think your correspondent may safely try Artichokes on his Potato land, so poor and sick of the crop, that it does not return the seed planted, though he must not expect a much better return of Jerusalem Artichokes from such poverty-stricken land, as they surely need good soil to grow a clean or profitable crop. Considering how palatable this vegetable is, and what a general favourite it is when well cooked and served with white sauce or melted butter, and how, as a soup, the Artichoke may be said to rank among vegetables almost as highly as the turtle among fish, it is surprising how little and in how small quantities the Jerusalem Artichoke is grown.—D. T. FISH.

Heating a Small Greenhouse.—"A Welsh Lady" (p. 450) would find a small conical boiler to be by far the easiest to manage for her purpose. Coke only should be used as fuel, and it should be broken up into small pieces, rejecting the dust. In frosty weather get up a good fire, so as to thoroughly heat the pipes; then at eight or nine o'clock, as may be convenient, fill up to the top with fuel, put in the damper to within 2 in. or 3 in., and a steady fire will be maintained all night. Saddle boilers are not so suitable for small structures; they require more fuel and a great deal of attention to keep the fire up.—J. CORNHILL.

A Wild Orchard.—After reading in THE GARDEN of November 16 about the Bullace there named and the Cranberries, the idea struck me of adding unto our orchard in Sussex a "wild orchard" with fruit trees such as follow, viz., Quince, Medlar, Mulberry, Bullace, Crab, *Pyrus Manley*, Barberries, Blackberries (the large kinds for preserving), Filberts, and, in a suitable place, Cranberries. All these, besides the interest of cultivating them, would yield fruit for preserving, &c. For instance, we have old-fashioned receipts for making an excellent Bullace cheese, Crab jelly, Quince jelly, &c. I venture to trouble you with a view to asking if you can suggest any other similar fruit-bearing trees or shrubs, as we should like to carry out our idea well? Our house is in Sussex between Midhurst and Haslemere.—CHARLES S. R. [An excellent idea! There are many fruits which could be grown this way that people do not usually give space to, and this applies to the varieties of cultivated fruits, as well as species that are never cultivated. The Natural Order to which most of our fruit trees belong contains many other species not without merit as fruits scattered throughout the temperate regions of the northern world. These trees and shrubs happen also to be most beautiful flowering trees and shrubs in spring, and are well worthy of culture on that account alone. In Japan, North America, and even the continent of Europe, one frequently sees fruits that are never seen in our gardens; such fruits will be quite at home in the wild orchard. For the sake of growing one family of fruiting bushes alone—the fruiting Brambles of America and other countries—a considerable piece of ground might be profitably devoted. Even amongst the English wild Blackberries there is considerable variety and a good deal of unrecognised merit, as anyone may see by visiting the Cambridge Botanic Garden. Such plants can only be grown fairly where there is considerable space. If so much beauty and interest, and even good fruit, may be found in one neglected family, it suggests how interesting the subject is when considered in relation to the great number of our hardy fruit trees and shrubs. We feel sure that some of our readers can help you with suggestions or with lists. It has just occurred to us that a good feature of such a garden would be plantations of such Apples and Pears as are most remarkable for the beauty of their flowers alone, some being much more striking in that respect than others.]

Icehouse Floors.—In answer to "W. V.'s" inquiry (p. 477) about these, the mere form is of little moment provided it be dry, and there is no possibility of stagnant water resting in it. Most of the best icehouses are egg-shaped, the egg, as a rule, standing on its narrow end. Of course in such the grating is on the lowest part, that is, the middle of the floor. The weakest part of such icehouses is that they are generally too narrow for their depth, thus exposing an undue amount of external surface of ice to the action of the walls. The ice keeps equally well or better in square houses, and the larger these are the less waste. These sometimes have a floor raised in the centre and sloping to the sides; in others the centre is sunk and the sides raised; and in yet others the floor is made to fall to one side or corner. In all cases a porous, hard bottom is preferable to a boarded floor, which soon decays, and has no special merit as an ice preserver.—D. T. FISH.

— It matters little how the bottoms of icehouses are formed, so long as the wood trellis, grating, or whatever is used for carrying off the water is efficient for the purpose intended; but there is one thing of great importance connected with it, which is—that the drain be so formed as not to admit air to the house, otherwise the ice, from having the temperature raised around it, wastes at a great rate, as it also does if the water cannot get freely away. A house to be perfect should be air-tight, by having close-fitting doors, and passages leading to the well where the ice is packed that can be filled with straw pushed together in a body, and every time any one enters the outer door ought always to be closed before the inner one is opened, as then the external air is excluded. If this be done every time ice is got out, and the passages are made secure in the same way by using plenty of straw, the loss through thawing is very slight. A good way of carrying the water off is to use a swan-neck or *U*-shaped bend, in which some of the water always stands, and thus prevents air from entering the house, as it would up an ordinary drain.—S. D.

Clearing a Herbaceous Garden of Weeds.—It is a pity that "R. D." (p. 477) did not take radical means of getting rid of the weeds before planting his bulbs and bulbous plants last spring. Few practices are more unwise than the planting of valuable plants among strong herbaceous weeds, and many old shrubbery borders and beds of herbaceous plants have been allowed to degenerate into something little better than "weederies." Such grounds should be carefully trenched, dug, scarified, burned, or fallowed, and every root and branch of weed, as far as possible, picked out and removed before committing valuable bulbs and other herbaceous plants to it. Dirty beds and borders can hardly be cleared of weeds after planting without inflicting very serious injury on the plants. A good deal may, however, be done by incessantly pegging away at the weeds the moment a root or branch of one appears, and with perennial weeds each head or stem should lead the cultivator to find and destroy a root or underground stem; and the work of destruction must be set about systematically, and pursued continually at all seasons and under all

circumstances until not a single weed is left. This labour, however, is very great, and it is much easier to clear the ground of weeds before planting than afterwards. If "R. D.'s" weeds are only annuals they are much easier destroyed. Not a few garden soils are so thoroughly stocked with weeds that it actually seems as if the earth was a sheer mixture of weeds and soil rather than the latter only. At every touch, in all seasons of the year, crop upon crop, and crop over crop spring up in perpetual succession. The remedy is, however, simple and easy enough if only persevered in. Scarify the entire surface of the ground every fortnight throughout the growing season, and any soil, however fully seeded with weeds, must ultimately be exhausted of its stock of seeds and cease growing weeds.—D. T. FISH.

Cloches—Since you published my remarks on cloches (p. 458) I have succeeded in getting them delivered from France free into my carts in Southampton Docks at 1s. each (40 centimetres=16 in.) without knobs. The Aire & Calder Co. for 16 in. cloches ask 1s. 11d.—A. T. T. PETERSON, *Lymington*.

Names of Plants.—*Anon.*—Your Grass is some species of Panicum, but it is impossible to name any member of such a large genus without having perfect specimens and knowing the native country, &c. *H. J. ROSS.*—*Bolbophyllum cupreum.*

Questions.

Lamium striatum.—What is the *L. striatum* of Mr. Cornhill? Can it be something new? I never heard of it, nor can I find any mention of it. Has not Mr. Cornhill *L. maculatum* in view when he wrote his remarks? It has exactly the same variegation as described. There are two varieties of it—*L. maculatum album* and *L. maculatum anreum*; the last is a gem. Both, however, are considered varieties of the White Dead Nettle, to which also *L. rugosum* and *levigatum* are now joined. The finest of the genus is *L. Orvala*.—THOS. WILLIAMS.

SOCIETIES AND EXHIBITIONS.

VEGETABLE AND ROOT SHOWS.

SEVERAL of our large seed-producing firms have during the past few years held shows for the exhibition of roots and other farm and garden produce. Such exhibitions tend to advance the quality of both garden and farm produce, as by frequently sowing seed from these prize roots the stocks in time become improved.

Messrs. Sutton & Sons opened an extensive root and vegetable show on Saturday last, in their large warehouse at Reading, where roots of excellent quality and great weight were shown. The display of Mangolds was remarkable; one Mammoth weighed close on 50 lb., and Globes measured nearly 4 ft. in circumference. Swedes and other Turnips were perfect in shape and quality, though somewhat less in number than last year. The cold wet season setting in just as these were bulbing stopped the growth, and early-sown ones are not equal to those put in later. To this show all the principal growers in the Kingdom sent specimens. The following are the weights of Mangolds in some of the prize collections: Twelve Long Reds weighed 406 lb.; twelve Golden Tankards, 377 lb.; and twelve Yellow Globes, 315 lb., or a gross total of 1098 lb. One enormous root girthed 3 ft., is 3 ft. 3 in. in length, and weighed 47 lb. The sewage class was a remarkable one. The following are the weights per acre (Mangolds) as the crop was lifted: Sutton's Mammoth Long Red, 110 tons per acre; Sutton's Golden Tankard (yellow fleshed), 88 tons per acre; Sutton's Berkshire Prize Yellow Globe, 77 tons per acre; and Sutton's Yellow Intermediate, 77 tons per acre. There was also a grand show of Potatoes, vegetables, Cabbages (weighing over 56 lb. each), Carrots, Gourds (162 lb. each), &c. The prizes offered for collections of vegetables induced a capital competition. The first prize was won by Mr. Wildsmith, Heckfield, with a collection so good that it could hardly have been surpassed. The twelve kinds comprised large and perfect heads of Veitch's Giant Autumn Cauliflower, dwarf green-crowned Savoy, splendid Brussels Sprouts, good Asparagus, Hathaway's Excelsior Tomatoes, short but handsome Master's Prolific Cucumbers, Sutton's Red Beet (perfect samples), Improved Stalant Parsnips (the best in the show and of perfect form), very handsome Trebons Onions, clean and good pink Celery, scarlet Intermediate Carrots, and Red Strap-leaf Turnips. Mr. Wildsmith also sent for exhibition a large basket of the Autumn Cauliflower, to show that at least at Heckfield it had been no failure. In the competition for twenty sorts of Potatoes Mr. Ross, gardener to C. Eyre, Esq., Welford Park, Newbury, was placed first, and Mr. Wildsmith second. The Potatoes generally were finer than last year, and were much more admired than the field roots. Several thousand people visited the show during the day.

On the 23rd inst. Messrs. Carter & Co., High Holborn, opened their exhibition at the Agricultural Hall, and it may be classed as one of the largest of the great autumnal shows of the season, occupying, as it did, the whole of the gallery—quite one-third of the entire structure. Notwithstanding the complaints in many directions of the indifferent season, Messrs. Carter & Co. succeeded in bringing together an extraordinary collection of magnificent roots, all of which, it must be borne in mind, have been grown by their customers under ordinary cultivation. These included some of the largest Mangold Wurtzels that have ever been seen in England, and an additional interest attached to this section of the show from the fact that these roots have been sent from some of Messrs. Carters' customers in the Dominion of Canada. Amongst other roots in this collection there were eight of Carters' Mammoth Long Red, turning the scale at the weight of 430 lb., or an average of about 54 lb. per

root; there was also one root of Carters' Warden Yellow Globe Mangold, weighing 60 lb., and one root of Carters' Mammoth Long Red Mangold weighing 63 lb.; there was also one extraordinary root of Carters' New Yellow-fleshed Tankard Mangold which turned the scale at 32½ lb. Turnip classes, as at all other exhibitions this year, were but moderately represented; this will be easily understood when it is remembered that many of the Turnip crops standing at the present time were not sown until August, or at any rate the earlier-sown crops failed to produce a plant in consequence of the unfavourable season. There were, however, some splendid roots of Carters' Pomeranian White Globe Turnip from several well-known farms. Collections of vegetables were well represented, the best twelve dishes being shown by Mr. Pragnell, Sherborne Castle, who had excellent examples of Carters' Heartwell Cabbage (the best kind known for autumn and winter use), Carters' Maltese Farnip, Pine-apple Beet, Schoolmaster Potato, Carters' Selected Brussels Sprouts, Celery, and Tender and True Cucumber. Mr. Iggulden, The Gardens, Orsett Hall, Romford, won the second prize, and Mr. Neal the third. Collections of Potatoes were also shown by the best growers, among which were noticeable a sackful of Carters' Magnum Bonum from the Prince of Wales's garden, excellent in appearance and quality; also Carters' American Breadfruit, Main Crop, and other good kinds. Mr. Pragnell was awarded the first prize for the best twelve Onions, a class in which there were fourteen competitors.

The annual show of roots, cereals, and vegetables grown from seed applied by Messrs. Webb & Sons, of Wordsley, Stourbridge, was held this year at Birmingham, in the large building known as Curzon Hall. It was the most important exhibition of the kind which has yet been held in the midland counties. The entries numbered over 1600, and the total number of specimens reached 25,000, many of them of great excellence. The collections comprised sixteen classes in the division for specimen roots grown without sewage cultivation, and three classes for roots grown with sewage cultivation. Webbs' Imperial Swede was the leading sort in the show, it being a kind which succeeds equally well in all localities. About 6000 specimens were shown, many of which were of large size and perfect form. White and green Turnips and Mangolds were well shown, the best Mangold being a new kind named Webbs' Kniver Yellow Globe. Potatoes and collections of garden produce were likewise shown in large numbers, and added greatly to the interest attached to the show.

Liverpool Chrysanthemum and Fruit Show.—At the exhibition of Chrysanthemums and fruit held in St. George's Hall, Liverpool, on the 20th ult., there was a brisk competition in several of the classes for cut flowers, trained plants, and also for fruit. The premier prize of five guineas (especially subscribed by Liverpool gardeners) was won by Mr. Tunnington, gardener to Charles McIver, Esq., Calderstone, who staged a unique exhibition, well proportioned, and far ahead of anything else in the show. Mr. Peers, gardener to R. Rayner, Esq., had blooms of extraordinary size, but rather loose and irregular, several of the flowers being past their best; and Mr. Elliott, gardener to W. G. Bateson, Esq., had a very good stand, which gained third place. Trained plants were well shown by Mr. John Hughes, gardener to R. G. Moran, Esq., and Mr. Phythian, the varieties being Mrs. George Rundle, Prince Alfred, Nil Desperandum, Barbara, Mrs. Dixon, and Sir Stafford Cairey. Flowering and fine-foliated plants were exhibited in good form by Mr. Peers and Mr. Cromwell, the former having a fine bush of the old Plumbago rosea in his collection. Mr. John Hughes had some splendidly-grown Primulas highly coloured; Epiphyllums and other flowering plants were also shown in good style by several exhibitors. Fruit was not shown in such large quantities as usual, but in many respects the quality was equal, if not superior, to what I have seen in former years, especially the superb bunches of Black Barbarossa Grapes contributed by Mr. Playfair, gardener to H. H. Nicholson, Esq., and the Alicante and Mrs. Pince exhibited by Mr. Macmaster, gardener to W. Just, Esq.; the bunches of Mrs. Pince, indeed, were perhaps the most creditable specimens of Grape culture in the show. Muscats and other white Grapes were admirably shown by Mr. Jamieson, gardener to the Earl of Crawford, and other local exhibitors. Pears and Apples (of which there was not half the quantity I have seen at former exhibitions) were very fine, the most noticeable varieties present being Marie Louise, Louise Bonne of Jersey, Easter Beurré, Beurré Diel, Napoleon, Beurré Clairgeau (a grand exhibition variety), Glou Morcen, Passe Colmar, and Ganeel's Bergamot. Williams' Pitmaaston Duchess was the largest fruit in the exhibition.

Cork Chrysanthemum Society.—The annual exhibition of this society was held in the large hall of the Corn Exchange on the 21st ult. The hall was well filled with plants and the show was the best ever held in the south of Ireland, both plants and cut blooms being of unusual merit, the weather previous to the exhibition having been most favourable for the growth of Chrysanthemums, which have now become universal favourites. The large flowering section was a splendid collection; the Pompones very fine, and the Japanese varieties exhibited by Mr. Cantillon attracted much well deserved attention. A leading feature of this show was the fine collection of cut blooms exhibited by Mr. James L. Lyons, which for size and beauty have never been surpassed. They were subjects of universal admiration, many of them measuring from 5 in. to 6 in. in diameter and beautifully incurved. Conspicuous amongst them were magnificent blooms of Jardin des Plantes (yellow); Empress of India (white); Globe (white); General Bainbridge (bronze); Boadicea, George Gleony, Mrs. George Rundle, Mrs. Dickson (sulphur, extra fine); Venus (blush); Lady Telford (purple tipped); Miss Mary Morgan (blush); Baron Beust, and Chieftain.

SATURDAY, DECEMBER 7, 1878.

[Vol. XIV.]

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

THE FLOWER GARDEN.

NEW TUBEROUS-ROOTED BEGONIAS OF 1878.

HAVING again grown in the open air during the summer now drawing to a close all the new varieties of the above-named most beautiful and highly ornamental plants that I could gather together during the early part of this year from their various raisers at home and on the Continent, to the number of thirty-six varieties with single flowers and three with double, and having carefully compared these novelties with the finest varieties of former years growing side by side with them and under exactly similar circumstances and treatment, I shall now proceed to state briefly, for the information of those of your readers who take an interest in this class of plants, the opinion I have formed of the respective merits of each of these new varieties in the hope that my remarks may not be without some practical use in enabling them to select for themselves for next year's growth those only that deserve a place in a really choice collection. Of the thirty-six single-flowered varieties above mentioned, five were sent out by the well-known Ghent house of Louis Van Houtte, named respectively—1, P. E. de Puydt; 2, Leopold II.; 3, Edmond Claus; 4, Adolphe Dubois; 5, Pearcei vitellina. Of these the first is certainly one of the handsomest and most distinct of all the new varieties of this year, being of extremely vigorous habit of growth, and producing in great abundance immense flowers of the finest substance of a somewhat lighter shade of blush than Lemoine's Diamant, but opening much more than those of that variety, their only fault being that their footstalks are not sufficiently strong to hold them in an upright position, so that, unless supported by forked sticks, they are apt to fall about over the plant; otherwise, this would be incontestably a first-class variety, and will still doubtless be much admired and sought after by many.

LEOPOLD II. is almost, if not altogether, identical with Fontaine's Lelia of last year, so need not be added to any collection where that beautiful variety already is. EDMOND CLAUD is a variety of considerable beauty and merit, of a spreading and branching habit of growth, and producing medium-sized flowers, much resembling in shade of colour those of Lemoine's fine variety of this year named Charles Baltet, but smaller in size than the blooms of that variety, though perhaps a little more brilliant in shade. ADOLPHE DUBOIS is a pretty variety, producing freely creamy-white blooms rather under the medium size, and with a reddish shaded outside to the petals; its habit is good, and its merit about second rate. PEARCEI VITELLINA is of low-growing and spreading habit of growth, producing dark green, pointed, and deeply-marked foliage, like its parent Pearcei, and medium-sized, deep orange flowers, the females, however, being wretchedly thin and poor in shape; and, except for its novel shade of colour, this variety has hardly any merits to recommend it.

Herr Otto Froebel, of New Münster, Zurich, sent me four varieties, named MONTE ROSA, a fine, strong-growing, tufty-habited variety, with well-formed blooms, of good substance, and of a pleasing blush shade of colour. SOLFATARA, a variety which, when good, is very fine indeed, of extremely vigorous habit of growth, and producing in great abundance large, well-formed blooms of a clear primrose yellow, a great acquisition; it seems, however, to vary greatly, as out of three plants, all growing in the same bed and all received direct from the raiser, only one is really fine, the second having smaller-sized blooms of a paler shade of yellow, and being decidedly less vigorous in growth, and the third producing blooms of a washy-whitish hue, and being altogether worthless. The same variation also appears in this raiser's Mont Blanc, which is sometimes almost pure white and sometimes of quite a rosy-blush tint, but usually in this latter state of such wretchedly delicate habit of growth as to be quite worthless. MEMORIA VAN HOUTTEI is a seedling apparently from diversifolia, which it much resembles in colour of foliage, but it is of much more close and tufty habit of growth; the blooms are small and poor and of a deep carmine shade of colour; but as it drops all its male

blooms unopened when grown in the open air, it can only be of any use for greenhouse culture. ORANGE is small, poor, and altogether worthless.

M. Victor Lemoine, of Nancy, sent me four new varieties this year, and I may also describe a fifth, which failed to bloom for me last season; they were JOHN LAING, a very fine variety, with vigorous but compact habit of growth, and producing, on stout footstalks well raised above the foliage, an abundance of finely-formed cupped blooms of a clear light red and of excellent substance. RAPHAEL DE SMET, certainly one of the finest, if not the best, of this year's novelties, of most vigorous and branching habit of growth, and producing an abundance of immense blooms of a fine, deep, rosy-purple shade of colour on long footstalks, and perhaps, individually, the largest of any known Begonia; this should be in every choice collection. CHARLES BALTET, a lovely variety, of open, spreading, branching habit of growth, and producing large, well-opened, deep crimson blooms closely resembling those of Van Houtte's Edmond Claus above described, but of larger size and finer substance. CHARLES BOINET is apparently quite a worthless variety. TROPHEE.—This is a most strikingly beautiful and also a most curious variety of low and tufty habit of growth, with dark, glaucous foliage, and altogether much resembling in habit the Jules Janin of the same raiser. This variety produces only female flowers in a perfect state, but these are of immense size and substance, and of a most lovely and glowing shade of deep carmine, and they are produced on short, stout footstalks in pairs, each pair having between them an abortive male flower without any organs whatever, and usually enveloping the base of both female flowers somewhat in the manner of a Hose-in-hose Primrose. Altogether a fine and exceedingly interesting variety, well worth cultivating.

M. Lequin, of Clamart, sent three varieties, of which ROSEA GRANDIFLORA is a very fine kind, of compact habit of growth, and producing fine, large flowers of great substance and of a most pleasing shade of light rose colour. MADAME MALET and Mlle. E. LEQUIN are both of branching and low-spreading habit of growth, with smallish blooms, which are creamy-white within and of a reddish tint outside. They are hardly distinguishable one from the other, save for some slight variations in the foliage, and are certainly of not more than second-rate merit.

M. Nodot's CECILE GENTE is a small, whitish-flowered variety, of good, upright habit of growth, but of no other merit whatever.

M. Jacob Maquoi's MONSIEUR DIEUDONNE MASSANGE resembles Van Houtte's Paul Masurel with rather smaller blooms, but has little, if any, new or fresh merit.

Messrs. Thibaut & Ketteleer, of Sceaux, sent one variety named BRILLANT, a name which it well deserves, as it is really a very fine and most striking variety, of completely upright and densely compact habit of growth, resembling a pillar, and producing all over it an abundance of fine large flowers, all of which are males and of a most brilliant shade of scarlet; this should be in every collection, being specially adapted for a specimen plant.

M. Bertier-Rendatler, of Nancy, sent one variety, Da. SAVOURET, of only indifferent merit, much resembling in colour Vincent's Reine de Bougival, but by no means so free blooming.

M. J. B. A. Delenil, of Marseilles, sent five varieties, of which LE PROCEEN is an exceedingly beautiful one, of first-rate merit, with immense flowers of a novel and beautiful shade of deep rose, produced with great freedom and of a vigorous and branching habit of growth. M. ROUGIE SARRETE is said to be sweet-scented by its raiser, but whether the son in these parts was not powerful enough to develop this peculiarity, or the plant was not strong enough, I failed to perceive any perfume whatever, but may perhaps be more fortunate next year when the plant gets stronger. MULTICOLOR is dull and of no merit whatever. DANAE unfortunately failed to grow with me at all, so its merits, whatever they may be, must be discussed among the next lot. MISTREA seems by nature especially tardy in starting into growth, not showing any signs of life till the end of August, and only forming a small plant too weak and late in coming to maturity to bloom this season, so must, like the last-named variety, be described among the novelties of 1879.

M. Crouse, of Nancy, sent two varieties—JULIE CHAMBAULT, a deep rose-coloured variety of no special merit whatever, and HELLEBORIFLORA, a low-growing, tufty-habited variety, producing an abundance of smallish flowers, the interiors of which are pure white, but the outside have a reddish rim round the edge; a rather pretty, but hardly more than second-rate variety. It was, however, very pretty and continuous blooming when lifted into a pot for the greenhouse.

Herr Ernest Benary, of Erfurt, sent five varieties, of which NE PLUS ULTRA, though decidedly an exceedingly distinct and fine variety, yet, I think, hardly deserves its very pretensions name. It is of erect and widely-branching habit of growth (as most accurately represented in a finely-coloured lithogram, prepared and distributed

by the raiser as an advertisement of his plant); the male flowers are of very large size, and of a deep shade of scarlet, very pendulous in habit. This variety is also said to reproduce itself absolutely true from seed. ORANGE PERFECTION certainly does not deserve its name. DEFIANCE is a fine, vigorous-growing plant, producing medium-sized flowers of a deep scarlet shade. FLORIBUNDA ROSEA is also a vigorous, tall-growing variety, producing good-sized and well-shaped blooms of a pleasing shade of deep rose colour. MONT ROSE is a somewhat less vigorous grower, producing medium-sized blooms of a deep pink.

Messrs. Veitch, of Chelsea, sent two varieties, MONARCH and QUEEN OF THE WHITES, the former of which is a vigorous-branching habited grower producing freely fine medium-sized blooms of a brilliant shade of scarlet. The latter, originally found as a chance seedling among a pot of *B. roseiflora*, is incontestably the purest white that has yet been sent out; it has also this curious difference from its parent, that whereas that is exceedingly shy to bloom, this is very free-blooming indeed, quite small plants producing three and four good stems bearing three blooms each. The foliage is of the distinct round and corrugated form peculiar to *roseiflora*, and the flower stems rise as in the case of *B. Veitchii* direct from the tuber, the plant being entirely stemless, and only, therefore, increasable by seed or root division.

M. J. Vincent, of Bougival, sent one variety, named JAUNE SERIN, of low-growing and compact habit of growth, with hairy stems of a most free-blooming character, and producing medium-sized blossoms of a clear, pure, canary yellow. It well deserves its name, being one of the prettiest varieties that has yet been sent out, but from its extreme floribundity it affords but very few cuttings, and will consequently be slow to increase.

Only three new double-flowered varieties flowered with me this season, all raised and sent out by M. Victor Lemoine, of Nancy, and named respectively MARIE and EMILE LEMOINE and ORNEMENT. The first-named is decidedly the largest-flowered and most fully double of any variety yet sent out, the fully-developed male blooms resembling more those of a Hollyhock with several flower facets than those of a Begonia; it will also by many be considered the most beautiful, though some will, perhaps, prefer the fine glowing scarlet of *Gloire de Nancy*, which it most resembles in shape. Its colour on opening is pale rose, usually with a white centre, but, as the flower develops, the white fuses into the rose colour, which assumes rather a deeper tint. It is so extremely free-blooming that the plants do not grow to a large size, but when cuttings can be obtained they root freely, so that this very fine variety should soon become plentiful, and be included in every choice collection. As in *Gloire de Nancy*, so with this variety; the double flowers largely preponderate in number over the female singles. Emile Lemoine resembles in habit of growth and shape of blooms the first double variety sent out by M. Lemoine, and named after himself Lemoine, but it is rather a stronger and more vigorous grower, and the colour is two or three shades deeper red than Lemoine; the double flowers are usually rather thin in the centre when fully developed, and, compared with the exquisitely beautiful last-named variety, this can only be called of, at most, second-rate excellence, though its fine, deep colour and freedom in producing its blooms will, doubtless, find it many admirers. Ornement is a charming variety of low and tufted, compact habit of growth, and producing an abundance of flowers of a clear, pale rose colour, the males of which, though, for the first month or six weeks of the season after being headed out, are only semi-double, and occasionally drop in a bud state unopened; still, as the season advances and the plant increases in strength and vigour, they lose both these faults and become fully and most beautifully double.

M. Van Houtte, of Ghent, sent out this year his first double-flowered variety named Charles Rogier, but though I got a couple of tubers at the commencement of the season, one did not grow at all, and the other not till too late to bloom this year. Among the five novelties to be sent out next season by this house is the first double yellow, as yet unnamed, which should be a great acquisition.

W. E. GUMBLETON.

Autumn-planting Gladioli.—I am pleased to see Mr. Fish taking up the subject of autumn-planting Gladioli (p. 460); I feel convinced that being out of the ground is very injurious to their well-being. If the bulbs were planted rather deeply in the first instance, there would be no necessity for taking them up every year, as they would be beyond the reach of anything like frost to hurt them, even enjoining we experience a severe winter. If cultivators of Gladioli were to try this plan, they would find that these showy flowers would prove much hardier than it has hitherto been thought they were. The bulbs forming above the previous year's bulb naturally tend to come nearer the surface; nevertheless, it would be safest to plant too deeply. Of course, if in unsuitable soil, the safest plan is to take them up and keep them in dry earth or sand.—J. S. T.

SELECT SPECIES OF PENTSTEMON.

MANY valuable introductions have of late years been made to the list of cultivated Pentstemons, principally through the instrumentality of Mr. Thompson, Ipswich, and we know that many more still exist in the rich storehouse of the Far West waiting to be introduced. Within the past few years much has been done also in regard to the improvement of the Pentstemon by judicious selection of seminal varieties of the old *P. Hartwegi* and *P. gentianoides*, which, though they possess a wide variation in colour, lack the beautiful clear blue which we find in some of the species, and therefore have a somewhat monotonous effect. These garden varieties, or so-called hybrids, may be ranged under two series of colours—those from *P. Hartwegi* belonging to the red flowered set, and those from *P. gentianoides* to the purple-flowered class; and, strange to remark, these series of colours will be found to run strictly parallel with other structural peculiarities. As regards culture, the species have, unfortunately, gained the reputation of being somewhat difficult to manage, as some, especially those of the shrubby section, show a remarkable tendency to suddenly die away when apparently they are in robust health. In order to ensure ordinary success, thorough drainage of the spot in which they are planted is a primary consideration, as it is a well-known fact that these, as well as a host of other Californian plants, suffer more from excessive moisture at the roots than from the coldness of our winters. The soil which I find best suited for all Pentstemons consists of good friable loam with an admixture of well-decayed leaf mould and sharp sand. It is specially advisable in the case of Pentstemons to have, in addition to the border specimens, a few plants in cold frames, in order to be able to fill vacancies, should they occur. They may be propagated either by means of cuttings or seeds. The former mode applies chiefly to the shrubby kinds, which strike freely in spring; and in favourable seasons seeds are freely produced from those from which it is not practicable to obtain cuttings. The following is a descriptive list of a few of the best kinds:—

Palmer's Pentstemon (*P. Palmeri*) is undoubtedly one of the finest yet introduced. When well grown it attains a height of 4 ft., and even 5 ft. It has stalked, oblong root-leaves, very glaucous and sharply and irregularly toothed; the stem-leaves are somewhat heart shaped and stem clasping. The flowers are produced abundantly, and form a stately, pyramidal head, each blossom being about 1½ in. long, with a much-inflated tube, contracted at the base and with a wide, spreading mouth. The colour of the two upper divisions is almost crimson, the tube and the other divisions are of a much paler hue, and each pencilled with a distinct purple streak. It flowers about midsummer, and forms one of the most effective hardy plants with which I am acquainted. It is a native of Arizona, and is also found at considerable elevations on the West and East Humboldt Mountains, Nevada. We may therefore reasonably expect it to be as hardy as many other kinds from that region. It is of rather recent introduction, hence its comparative rarity in gardens, but when better known it will inevitably become a popular favourite as it richly deserves. It was introduced by Mr. Thompson.

Cobæa-flowered Pentstemon (*P. Cobæa*) is one of the handsomest of the yet introduced kinds. It grows about 2½ ft. high, and has broadly ovate and sharply-toothed root-leaves, the upper ones somewhat heart shaped and stem clasping. The flowers are very large, being nearly 2 in. in length, with a much-inflated tube and a spreading limb about 1 in. across. The colour is pale purple distinctly pencilled with red streaks and delicately suffused with yellow, with the base of the tube of a creamy-white. They are freely produced in long, leafy racemes late in autumn. As well as being one of the most beautiful, this is one of the rarest of Pentstemons. It may, however, be found in several collections of hardy plants near London, and thrives vigorously and generally quite unprotected, but it is very difficult to propagate in quantity. It does service in trade lists for several spurious kinds, but it can be readily recognised when in flower by the above brief description. It is a native of the interior of Texas, and was introduced about forty years ago.

Blue-flowered Pentstemon (*P. cyananthus*).—This, though considered by some to be a variety of *P. speciosus*, is, however, for horticultural purposes very distinct and a most lovely kind. It is of erect growth, attaining 3 ft. to 4 ft. in height, with the root leaves broadly ovate and pointed, the upper ones stem-clasping and variable in size. The flowers form dense spikes 1 ft. or more in length, composed of short stout stalks, bearing clusters of flowers

1½ in. in length, with the tube of a reddish or purple tinge, and the spreading divisions of a bright azure-blue colour, rendering it one of the most showy kinds in cultivation. It flowers in May and June in favourable seasons. It inhabits the upper valley of the Platte River, in the Rocky Mountains, and was introduced from thence to our gardens in 1849. The newly-introduced variety *Brandegei* is a decided improvement on the type, being of a more robust habit, and its flowers brighter coloured.

Azure-flowered Pentstemon (*P. azureus*).—This is a well known and very effective dwarf kind with numerous erect branches; the lower leaves are somewhat heart-shaped and broader than the upper ones, which are narrowly lance-shaped, and all have smooth edges, and are slightly glaucous. On the upper half of each branch are borne in a crowded, racemose manner the numerous blossoms so arranged as to appear in whorls, being nearly stalkless. The blossoms are rather large, and of a clear, violet-blue colour, which is much deeper in the divisions than in the tube. It was introduced in 1848 from the Sacramento Valley, in California, where it was found in dry river beds, and also at considerable elevations on the mountains in the vicinity. It begins to flower with us towards the end of summer, and continues to produce its blossoms for a considerable time.

Variable-leaved Pentstemon (*P. heterophyllus*).—This shrubby kind is related to the preceding, being of dwarf habit and having numerous branches. The leaves are rather glaucous, the

Pentstemon heterophyllus (Vilneria).

lower ones being from 2 in. to 3 in. long, narrowly lance-shaped, the upper ones both short and long. The flowers are produced singly or in pairs from the axils of the upper leaves, and are 1½ in. long, with the tube suddenly narrowed at the base. They are of a pink-lilac colour in the type, but seminal varieties are very liable to vary. It was found and introduced by Douglas in 1834 from California, but was soon lost to cultivation. It was subsequently re-introduced by Hartweg from the valley of the Sacramento River, Upper California.

Jaffray's Pentstemon (*P. Jaffrayanus*).—This remarkably showy kind is, I consider, the best of the blue-flowered class. The very glaucous, broadly lance-shaped foliage contrasts finely with the bright, clear blue blossoms, which are borne in profusion during the greater part of the summer. Another point in its favour is its rather dwarf and compact habit, a feature generally sought after in select border plants. It inhabits various parts in North California.

Scouler's Pentstemon (*P. Scouleri*) is a sub-shrubby kind of rigid habit with narrow, toothed leaves; it produces compact racemes of large purple flowers in May and June, and is a native of the Kettle Falls, Columbia.

Diffuse-flowered Pentstemon (*P. diffusus*).—This beautiful kind formed the subject of a coloured illustration in Vol. X. of THE GARDEN. It is a semi-shrubby kind, from 2 ft. to 4 ft. high, with shining, ovate, and pointed leaves, irregularly and deeply toothed. The flowers, which are about 1 in. long, have the tube and lower divisions of a violet-purple colour, the two upper ones bordered with deep blue, and they are freely produced, forming a large, loose, many-branched head. It flowers throughout the greater part of summer and autumn. It inhabits the vicinity of the Columbia River and other places in North-western America. Its near relative, *P. Richardsoni*, much resembles it, but is inferior to it in point of beauty.

Showy Pentstemon (*P. speciosus*) is a remarkably handsome kind, with lance-shaped, slightly glaucous root-leaves, those of the stem being narrow, stalkless and slightly wavy at the margins. The stems grow to 3 ft. or 4 ft. in length, on two-thirds of which are arranged in a whorled manner the many-flowered clusters of its beautiful sky-blue flowers, varying to a reddish hue. It inhabits the banks of the Spokan River, in North-west America, and was introduced by Douglas about fifty years ago.

Shining Pentstemon (*P. glaber*).—This is nearly related to the preceding, but is of dwarfer growth, with tufts of narrow, spatulate, and shining leaves. The flowers, which are of various shades of purple, are borne in crowded spikes about 1 ft. in length, and are produced early in summer. On account of its short stature it is better suited for rockwork decoration than the majority of the other kinds.

Large-flowered Pentstemon (*P. grandiflorus*) is an extremely handsome kind, nearly related to the two preceding, growing about 3 ft. high, with shining, oval, lower leaves, those of the stem clasping it and roundish. The flowers, which are large and very showy, being of a beautiful pink colour, are produced from July to September. It is a native of the plains of Missouri.

Murray's Pentstemon (*P. Murrayanus*).—Besides being especially attractive when in flower, this fine kind, when well grown, is very handsome in foliage, having broad and very glaucous lower leaves, and large, stem-piercing upper ones. The blossoms are narrow and of a bright scarlet colour, freely produced on terminal branches in a racemose manner. It is also a native of Texas, and is now to be frequently met with in gardens.

Centranthus-leaved Pentstemon (*P. centranthifolius*) greatly resembles the preceding, but has much narrower leaves. It also appears to be more manageable in cultivation than *P. Murrayanus*, and it is almost as effective.

There are several other very fine kinds that are now tolerably common, and therefore need no description, such as the old *P. barbatus* and its gigantic variety *Torreyi*, *Campanulatus*, &c. Others, again, there are which are rare on account of being of recent introduction, such as the beautiful *P. secundiflorus*, *lætus*, &c. W.

ROCKERIES AND ROCK PLANTS.

The rockery, if well arranged, well planted, and well cared for, forms one of the most interesting features of a garden. It need not be large, it need not even be picturesque to inspire interest; indeed, many places are not adapted, from the nature of their surrounding circumstances and localities, for creating and properly displaying bold, picturesque effects. In such cases imitations of natural cliffs or the rugged scenery of Alpine regions are quite out of place. It often happens when we try to imitate the wilder moods of Nature, we fail to grasp the subject from want of study or training; and the result produced is far from satisfactory. Unless the natural conditions be favourable, it will be better, in the formation of rockeries, to adopt some less ambitious scheme than to perpetrate a bad copy of the upheaval of strata in some early period of the world's history. It is comparatively easy to secure the conditions under which the plants we wish to cultivate will thrive in some unobtrusive manner that will fit in almost everywhere. There are, of course, numberless places in a country so varied in surface and geological formation as ours where a natural and most interesting rock garden might be formed on either a large or a small scale in every way adapted for the culture of many species of plants where aspects could be obtained suited to their varied wants both as regards shade, sunshine, or other matters of cultural detail. There are positions in not a few gardens where the natural rock is so near the surface, that a very little labour in excavating would lay it bare, and where it would not be difficult to select some shelving hillside where precipitous cliffs, rude terraces, and winding stairs might be hewn out of the solid rock, and with the displaced fragments might be formed rocky mounds to suit the special requirements of every Alpine or other plant that will thrive in our climate. If a stream of water could be led to the summit of the cliff by an underground channel or a pipe, a very little amount of ingenuity would arrange a graceful and natural descent, illustrating in its course the beauties of cascade, rippling stream, and silent pool. The presence of

water in a rock garden of any extent is a great help (I had almost said a necessity). Many Alpine plants love moisture; indeed, I think a lack of moisture in our short bursts of dry, hot weather is one of the main reasons why some of the species are found difficult to cultivate. Where water can be had, the pond for aquatics and the quivering bog for marsh plants may be made specially interesting, and will appropriately find a place in the rock garden, or in its vicinity. Where the rock garden is large, scope will be found for much skill and judgment in selecting and grouping the shrubs, to give elevation to certain points, to deepen the shadows of others, and generally to relieve and give tone to the masses of rock. I think a rock garden should not be all seen from one point of view. The most interesting and pleasing gardens of the kind which I have had an opportunity of visiting had special points of view, where separate and distinct groups of objects could be enjoyed, but, in addition, there were many details cropping up at every turn—here it may be a choice group of Cyclamens near the friendly shelter of some jutting rock; further on, perhaps, a mound of rare Primulas or some equally interesting family, and in the arrangement of the surface, breaking it up into details, if I may so term it, suitable shrub or tree growth must play a prominent part, in proportion, of course, to the extent of the place. The trees and shrubs employed should consist mostly of evergreen species. There may be positions for the Mountain Ash or the Silver Weeping Birch, but the smaller forms of Coniferæ will predominate, and some, like *Abies clanbrasiliana* and *A. pygmaea*, are especially suited for rockeries on a small scale. The more extensive the rockery the more scope will be given for the creation of scenic effects in the arrangement of the trees and shrubs, both in its interior decoration and also in making backgrounds and boundary lines. The Clematis, the Ivy, Periwinkle, St. John's-wort, *Pernettya mucronata*, Cotoneaster, Sea Buckthorn, Rosemary, and similar plants may be used in groups of sufficient numbers to give character to particular spots. Arches of undressed stone may in some places be appropriately introduced, but there should in everything be a certain easily recognised fitness or necessity for whatever is employed, otherwise such things have a grotesque appearance. Thus an arch may be employed to span an entrance to the rock garden, or to form a connection between two groups of rocks on each side of a path that seems to require the existence of an arch to finish the group. Arches should be clothed with wall plants, of which there are many species that will grow on rough stones with but little more food than is supplied by the atmosphere. A creeper or two should be planted in addition to help to clothe and so reduce its conspicuous proportions. Shady positions may be created for Ferns and other plants that love shade, and the Alpine peak may also be introduced, if desired, clothed with suitable vegetation, gradually diminishing in stature from the base upwards, till the summit is lost in perpetual snow, which may be represented by the white-leaved *Antennaria*.

In small gardens or elsewhere, if there be no scope for the creation of picturesque scenery without offending correct taste in such matters, it will be better to strive only to make the position as suitable as possible for the plants which it is intended should be cultivated. This, of course, should not be lost sight of, but it often is when seeking to copy from Nature in any arrangement or grouping of stones for the production of scenic effect. Beds for Alpine plants should have an open, airy situation. Every beginner, no matter how much he may have previously read or studied, will find that practically he has much to learn, especially in the culture and management of rare kinds of plants. The latter have their whims and fancies, and some Alpine gems that grow like weeds on the bleak mountain side will not take kindly to every place, no matter how much care or pains may have been taken with them. The best kind of knowledge is obtained by direct experiment, and all who excel in anything must have laid the foundation of their skill in that way. A rockery on a small scale may be created, in every way suited for the cultivation of what are termed Alpine plants, by raising mounds of good soil and partly covering the surface with stones, vitrified bricks, or clinkers. The largest pieces may be partially bedded in the soil. When the stones, or whatever materials used, are

satisfactorily arranged, the cavities between them should be filled up with good soil to suit the different plants. Equal parts of loam and peat will suit most of them, but for some species a larger proportion of peat should be used, and fragments of stone or gritty matter should be mixed with it to keep the soil open and to secure efficient drainage. When the mound or bed has had time to settle, the planting may be commenced, and it is now that some knowledge of the antecedents and habits of the different species is desirable, in order to select proper and suitable sites, to give the small, delicate species a sheltered nook on the lee side of some large stone, and to plant the strong grower near the base of the work, where it cannot overhang and smother up its weaker neighbour. There are some kinds that delight to grow on a rocky ledge and overhang its outward face. Some love shade, and may be planted where some shelter from the sun's hottest rays can be had; others, again, love sunshine, and will revel in its fiercest beams.

After all that may or can be written or said on this subject, there is no royal road to the acquisition of this or any other kind of special knowledge, and there is no better way of becoming actually acquainted with Alpine plants and the best mode of cultivating them than by commencing with a small collection, and as one's knowledge and interest increases to keep adding to it; and as beds or mounds of Alpine plants need not assume any geometrical plan, we can add a bed or two any time we may think proper to do so. In this way we shall have time to become acquainted with all our favourites, to keep a close eye upon each, and if one looks unhappy to ascertain the cause and supply the remedy; indeed, the plant itself, if the symptoms are intelligently studied, will supply all the information we require to form a correct estimate of its condition. Planting Alpines on raised beds or mounds is a much more interesting way of cultivating them than in the level border, even in the case of such kinds as succeed under ordinary border culture. In the first place they are brought nearer the eye; study is made more easy and interesting; and in the periodical digging and hoeing of borders many choice plants are often seriously injured from want of care. Then, again, in winter it is the constant damp rather than the cold that injures the natives of the snow-clad regions, and on a well-drained mound of rockwork this source of danger would be mitigated or altogether removed.

E. HOBDAV.

Sempervivum fimbriatum.—Few readers of THE GARDEN will probably be acquainted with the fringed *Sempervivum*. I met with it in the Tyrol in the autumn. It may be said to be fringed and ciliated throughout all its parts—rosette leaves, stem leaves, and perianth. The flowers are in a close corymb, greenish-yellow in colour, and bell-shaped, and the segments of the perianth are fringed with processes at the tip, much after the fashion of our *Menyanthes*. I found it on the green-slate formation, or, to be more strictly correct, where the green-slate and micaceous clay-slate converge. It is a rare plant in the Tyrol, and, in corroboration thereof, I may state that Hanemann had no personal acquaintance with it when he published his "Flora of the Tyrol." If it had but the vivid colouring of our Alpine *Sempervivums*—such as *montanum* and *arachnoideum*—it would soon meet with attention. As it is, its shaggy dress and bell-shaped flowers form its chief attraction. There are two other still rarer species in the Tyrol that have more or less of shagginess, but *Sempervivum fimbriatum*, or *hirtum*, as it is also called, carries the palm.—PETER INGBALD, *Hovingham Lodge, York*.

Bouvardias Planted-out in Summer.—Whatever differences of opinion there may be as to the way in which these useful plants may be grown, there can be no doubt that good plants can be had by planting them out during the summer months. The best *Bouvardias* I ever saw were a quantity grown in one of the London nurseries in 1877. They were planted out and lifted in September, fine strong plants, ranging from 6 in. to 18 in. through, plants that would satisfy even an enthusiast. My own experience this season confirms the foregoing remarks; on some plants so treated there are from twelve to twenty good heads of bloom, and they have never been in a higher temperature than 55° (fire heat) since they were out of the cutting pots. Why, therefore, should we grow *Bouvardias* in high temperatures, when good plants of them may be grown as just described? They possess two advantages over those grown on the warm system, viz., they require less labour, and the blooms last longer in good con-

dition, both in a cut state and on the plants, rendering the latter better adapted for conservatory or house decoration than they otherwise would be.—J. C. F.

CALYSTEGIA SYLVATICA.

AMONG the plants dangerous for the garden, but too beautiful to be thrust out of it, are the two varieties of the large climbing Bindweed (*Calystegia sylvatica*). No plants form more beautiful and delicate curtains of foliage and flowers, and none grow more vigorously in any soil. The wild garden is the place where these are most at home, and where their vigorous roots may ramble without injury to other things. Among

Calystegia sylvatica,

bushes or hedges, or over railings or on rough banks they are charming, and take care of themselves.

LILY CULTURE.

In a previous paper I made a few remarks on the all-important functions of the bulb and the roots in relation to the nourishment and growth of the Lily, and among other things I said: When the flowers of the blooming plant begin to fade, it is a true sign that the roots of that bulb have done their work, for they also will be found to be decaying, if not already dead. The scales of that bulb, having expended all their elaborated sap on flowering and seeding, will also be decaying, though they will not, in many cases, dry up and altogether vanish for some months to come. The cause of this retardation in the decay of the scales of the dead or parent bulb, I will now, as a continuation of my reply to Mr. Dod (p. 433), proceed to explain, as nothing has tended more to mislead Lily growers than this very part of our subject. It is this, in fact, that has misled some very intelligent cultivators, and has induced them to say that when repotting they have never discovered traces of a decayed old bulb, and it has also been the principal cause of making many believe that the plant is a perennial. If we take up a newly-imported *L. auratum* bulb, the question is, what do we hold in our hands? Answer—The bulb of the past season, or parent bulb, which died

soon after the flowers faded, but which is still preserved in a rough state by the persistent walls of the empty cells. I have said in my last paper that these cells, where the sap is stored up and elaborated into nourishing matter, number not less than 300,000,000 in a medium-sized *L. auratum* bulb, and that, in fact, the whole life of the plant is that of the cells which compose it, for in them and by them its products are elaborated, and all its vital processes carried on. If, therefore, the cells number 300,000,000, we must have 300,000,000 of cell walls, composed of what is called cellulose or cellular tissue. These cell-walls which make up the tissue or fabric of the bulb, and which remain unaltered, and perform some offices long after life has departed, are composed of three elements—carbon, hydrogen, and oxygen, and are insoluble in water. The epidermis, or external skin of the bulb scales, consists of one or more layers of empty, thick-walled cells, cohering so as to form a firm and close membrane, preserving to a certain extent the shape of the scales and apparent bulk of the bulb, though after the nourishing matter in the cells has been exhausted, the scales contract somewhat in their interior, and consequently open wider apart from one another, like withered Fir cones, as we see when we examine imported bulbs. In such a case the roots of the parent bulb are dead, and the bulb itself is dead. If this be doubted it is easily proved. Cut any of the scales into thin slices and place them under a microscope. It will then be seen that not a vestige of elaborated sap remains within the cells, in consequence of their having been completely emptied of their contents when the flowers faded.

Lily Roots.

With regard to the roots which we see attached to imported bulbs, they do not belong to the parent bulb, but to the new bulb, which is within the parent bulb; but they are of no use, as it is impossible to lift a bulb out of the ground, even only two or three weeks after the flowers have faded, without depriving the main or new roots at their extremities of all that is most valuable. I have said: If a *Lilium auratum* bulb be planted in congenial soil, it will prolong its roots to a great depth, and these roots will branch out into numberless rootlets, and these rootlets into fibrils covered with innumerable root-hairs (seen under the microscope but not by the naked eye), which increase to a very great extent the absorbing surface, especially if the soil be deep, free, and friable. The minute fibrils of the root, near the lowest extremities, are those which are chiefly concerned in taking up nourishment from the soil. The thicker parts near the bulb are, comparatively, of no value for this purpose, for as the lower delicate parts spread and elongate deeper into the soil, the thicker parts, becoming older, a kind of skin or epidermis is formed on those parts, through which absorption does not take place freely. These multiplied fibrils, though invaluable, are nowhere to be seen in connection with the roots of imported bulbs, nor, in fact, in connection with the roots of any bulbs lifted late in the season; for they are of so delicate and fragile a nature, that they give way to the slightest pressure in lifting the bulb, necessitating the growth of an entirely new set of roots before the new bulb can send up its stem, thus retarding the blooming season, as well as impairing in quality the bloom of the next season—the source of many complaints on the part of those who cannot account for such Lilies blooming worse in the first than in the second season. The Japanese are reported to be very clever Lily growers; but they are much too clever in some things, especially in their treatment of the bulb and its roots. Not knowing the change of character in the bulb scales in the autumn, “they take the bulb out of the ground or pot soon after the stem has withered, and remove all the roots. It is then exposed to the air about ten or fifteen days and replanted sideways, in order that the water may not lodge between the scales, which might be the case if the bulb were placed upright.” This idea of planting a dead bulb (which they no doubt think is alive) with so much care, might be looked upon as something ludicrous, were it not that this method has been imported into this country, and has found many imitators, greatly to the hindrance of real progress in Lily culture. Just fancy this dead bulb being planted sideways to prevent water from lodging between the scales, when I have this moment explained that the skin of the scales is composed of a material “insoluble in water,” and to which water can do no harm. Besides, in planting the dead parent bulb sideways, they also plant the new bulb, within it, in the same position, making it absolutely necessary that its stem and roots should start horizontally, depriving the bulb, unnecessarily, of a certain degree of strength, before the stem can be made to rise up, or the roots to turn downwards. We are also furnished with many other examples (which easily find imitators) where the greatest care is taken of the old decaying bulb, without a thought being given to the new bulb within it, the only vital part, and the only part, too, that will bloom next season, if not destroyed, because it happens to

be out of sight, unless sometimes at its very apex. We are told also that the best houses in the trade in this country, send out their Lily bulbs "with all their roots intact," packed in damp Moss or other material. This is simply a work of supererogation; for these roots, being the roots of the new bulb within the old or parent bulb (not the old roots) must die; and, therefore, their extremities being destroyed, it would be much better to prune them off at once to within 1 in. or so of the base of the bulb. This applies equally to Lily collectors when sending bulbs to this country.

When are Lily Bulbs at Rest?

MR. T. BAINES (p. 433) in opposition to my teaching says: "The decay of the old bulbs and formation of new ones internally, is nothing more or less than what takes place in all bulbous-rooted subjects. In the case of all the scale-formed ones Nature effects her work much in the same manner—that is, a greater or less gradual throwing off and decay of the outer portion." Now, whatever Mr. Baines may mean by introducing "all bulbous-rooted subjects" along with the Lily, I know not, but this I do know, that with regard to the Lily itself he is altogether wrong. If he had paid attention to the natural economy of Lily growth, he would have seen that there was no such thing as "greater or less gradual throwing off and decay of the outer portion." He adds: "'Dunedin's' recent teaching has the misfortune of neither according with theory nor practice." Let us see if Mr. Baines' knowledge of the subject is more profound. He says, "If you do anything to any plant of these (*L. speciosum* and *L. auratum*) or such as are of a like nature, that shortens the duration or hastens the decay of the leaves before their allotted time, you inevitably weaken the plants." This I deny. I entirely agree with Mr. G. F. Wilson that "Lily bulbs should be moved when most at rest." The question then is, when are they most at rest? Not, certainly, as Mr. Baines says, "as soon as ever the leaves have decayed and fallen off naturally." It has been proved beyond a doubt that soon after the flowers of the parent bulb have faded, the roots of that bulb having done their work, will be found to be decaying, if not already dead. The scales of that bulb will also be decaying, though they will not in many cases dry up and altogether vanish for some months to come. The cause of this I have already explained in this same paper. We have, therefore, now only the stem to dispose of. If Mr. Baines had carefully examined the stem at its junction with the bulb, he would have found that it was much contracted and dried up, compared with what it was above ground. If he had cut off the stem close to the bulb, and had placed a slice of that part of the bulb under a microscope, he would have seen that there was not a single particle of elaborated sap in it, for this reason, that the cells of the bulb were completely emptied of their contents soon after the flowers faded. It is thus that Nature has laid it down as a law, that as soon as the cells are emptied of their contents, the whole of that plant perishes, leaving it to the new bulb to carry on the succession untrammelled by anything that has gone before. Further, if, at this time Mr. Baines had carefully removed the bulb away, without disturbing the stem, he might have planted that bulb in a pot or in the open ground with the very best prospect of an early and superior bloom from the new bulb next season. It is thus that Nature has decreed, that, as soon as the bloom is over, all nourishing connection between the bulb and the stem must cease. As regards the stem that would be left standing, it would have gone on keeping green for some weeks longer, its nourishment being supplied by its own stem roots. This is no mere theory, but a description of simple experimental facts which have been repeated over and over again, and no longer ago than last September in the case of *L. speciosum*, and October in that of *L. auratum*. Green leaves on the stem are no proof whatever that vitality exists between the bulb and the stem. It is simply a proof that those particular stems have a tendency to throw out stem-roots, and that those roots, from the nourishment they draw from the soil, assist for some time in keeping the leaves green. It is therefore clear that Mr. Baines has formed a one-sided theory from "*L. speciosum* and *L. auratum*, or such as are of a like nature." He, in fact, acknowledges as much, for he says: "I have not grown nearly all the Lilies now in cultivation." Had he done so, he would have seen that the leaves of those which send out no stem-roots "decay and fall off naturally" soon after the flowers have faded, simply because they have no stem-roots to keep them green.

Stem Roots.

In reply to "London Stone" (p. 431) allow me to inform him, with regard to his question about the increase of Lilies, that during this last season I lifted and replanted more than 200 bulbs very soon after the different kinds went out of bloom, and I gathered from them many more bottom-root offsets and small bulbules than I (as an amateur in a suburban garden) could make use of. As to seeding,

I leave that to the trade, for this reason, that the new or successional bulb gains in strength and size by not allowing the plant to run to seed. With respect to the mop-like growth of his *L. auratum*, it is a very bad sign indeed, but more common in pots than in the open ground. Some think that the stem roots assist the plant at the time of flowering, but those who entertain such ideas are unacquainted with the fact that bottom and stem roots—below the bulb called primary, and above the bulb called secondary roots—are composed of a different tissue or organization of parts, and that their absorbing powers are of a totally different character; and, moreover, that the sap drawn up by stem roots has no assimilated flower nourishment in it. In the beginning of last October a nurseryman sent me six pots for inspection. They were 6-in. pots, and in each pot there was a *L. auratum* bulb just out of bloom. The stem roots in thousands literally made a frightful exhibition. They had run over the edges of the pots, they had also run down the inside, twining themselves in and out among the bulb scales, completely exhausting the soil, and, cannibal-like, sucking the sap from the new bulbs to such a degree as to leave them not the sixth part of the size they should have been. A friend, an amateur Lily grower, happened to call at the time and saw them. As to the mop-like growth of the stem roots being "admirable protection" to the bulbs: as this is mere theory, I can only advise "London Stone" to look upon them as his greatest enemies if he desires to have a good bloom the following season. His "strong garden soil" (evidently too strong) had, no doubt, a great deal to do with the luxuriant growth of his stem roots, and, therefore, he should bear in mind that stem roots are not the normal condition of the genus. There are some species that send out no stem roots, there is a large number that send out but few, and there is a smaller number, like *L. auratum*, that send out large quantities, provided they are encouraged so to do, by rich soil and top-dressings, or, in other words, by ungenial soil and misdirected cultivation. As "London Stone" thinks that my views on the subject of stem roots are erroneous, I may tell him and others that I build up no theoretical views whatever, but simply endeavour to explain, to the best of my ability, what experimental researches have placed before my eyes.

If "A. S. O. N." and "J. S. W." (pp. 460—461) will be kind enough to put to me any distinct and definite questions, without being enveloped by extraneous matter, I shall be happy to answer them to the best of my power. But, above all things, let them say whether they believe in the perennial theory or in the successional bulb system; for, without knowing the exact ground upon which we stand, we may be spending time in working at cross purposes.

DUNEDIN.

ISOLATED PLANTS IN PLEASURE GROUNDS.

PERHAPS no one branch of ornamental gardening more requires the exercise of taste and judgment than does that which deals with the isolation of single plants. Beautiful as fine-foliated plants are when massed, and necessary as this arrangement may be to insure in certain situations effects of an imposing description, we yet turn with relief and renewed interest to a single finely developed specimen. Room to grow and spread in a free unrestrained manner is what every species of plant requires before it can fully display its full decorative capacities. Many fine-foliated plants, indeed, utterly fail to give any adequate idea of their true worth and beauty when crowded together. In such plants as the *Ricinus*, the *Wigandia*, the *Acanthus*, the *Palm*, we lose the distinctive leaf beauty and characteristic growth which distinguishes each kind if planted in formal ranks or crowded groups. Yet, pleasing and picturesque as is the effect of isolated plants upon stretches of verdure, it is a fact that it is very easy to overstep the mark and defeat the end in view, by creating monotony where diversity really is sought for. With many the practice of dotting a plant here and there becomes a passion, and the turf is eventually so studded with large and small specimens that there remains scarcely any free open expanse of verdure. In large places there is of course great scope for thus utilising our finer forms of ornamental-foliated and flowering plants; but in places of a comparatively small area isolation must be confined to very narrow limits, or the effect will be the very reverse of pleasing; and those plants which are to be isolated should be so placed that their full outline comes easily under the eye, for they should never be made the means of obstructing the view of other portions of the pleasure grounds. When placed in the centre of the lawn, the effect of such plants is too often obtrusive and glaring; whereas, standing in the proximity of, and backed up by, dense and taller-growing subjects, and yet far enough away to insure plenty of light and sun, the effect is one of a most satisfactory description. The gradations of light and shade and the diversity of growth and leafage, as exhibited by woodland scenery, are here fairly imitated. The isolated plant thus indicates the termination of the forest—the

point where the vegetation ends and the open prairie commences. Scab effects as I have here sought to convey may be easily seen in parks or on unreclaimed lands, where pieces of wood alternate with open breezy expanses of grass or common. We there see small trees and clumps of undergrowth straying away, as it were, from the main body, yet still near enough to remain within its influence and shelter. The open glade comes up to this lower growth, and runs in amongst it, reaching up here and there to the very stems of the larger trees, thus affording little scenes of a charming character. Such natural effects may be easily introduced into our gardens, even into the smallest. We have only to choose suitable subjects, and arrange them according to the space at command. Those who have but small gardens may recollect that it is really not the number of specimens which constitutes the charm in this method of planting, but the state of perfection to which each one is brought by careful culture. Half a dozen suitable subjects judiciously placed, and well attended to, will reflect more credit upon the grower, and afford greater satisfaction, than an indiscriminately arranged plantation of half-developed plants.

J. CORNELL.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Hardiness of *Lycopodium denticulatum*.—This has been growing out-of-doors here in the hardy Fernery for two years, and it looks equal to any which I have seen coddled up indoors. Associated with *Ferne*, *Sedums*, *Saxifrages*, &c., on rockwork, it is simply exquisite.—D. S. GILLET, *Weybridge*.

***Stellaria graminea aurea* as an Aquatic.**—This little golden Chickweed makes one of the prettiest aquatic plants for small lakes, where the water is clean, that can possibly be found, and it is also one of the easiest to cultivate. All that is needed is to put bits of it in the water and to make them to sink to the bottom; no pot or soil is required. They will soon start to grow, and in a few weeks will reach the surface. Treated in this way the leaves are twice the size of those grown in the flower garden.—W. WRITING, *Shot Tower, Newcastle-on-Tyne*.

***Callas* Out-of-doors.**—Three years ago I flowered *Callas* in a shallow pond, where I thought they would be permanent, but, to my disappointment, after the first season of blooming, in the month of July, they gradually decreased in size, and ultimately died. I may mention that the pond was supplied from the River Thames.—D. S. GILLET, *The Heath, Weybridge*.

Bulbs Wintered Out-of-doors.—After ten years' experience I am assured that *Snowdrops*, *Crocuses*, *Hyacinths*, and even the *Gladiolus* do better left in the ground than lifted, provided sufficient nourishment be given to the roots without disturbing them. Never had I finer blossoms than some which I had from bulbs that had been planted four years, and they were nearly as early as those from forced bulbs, nor, except in the case of an unusually severe winter (or rather severe early spring) can such bulbs come to harm.—E. E. P. LEGGE.

Brick Edgings.—For an edging suitable for any position where a neat and durable one is required, few of the ornamental tiles look so well, or are able to stand wear and tear better than ordinary building bricks. If these be neatly laid at first, sloping to the walk so as just to show the $\frac{1}{2}$ in. face, they will look as well after twenty years' wear as they do the day on which they are laid, as moss or any growth adhering to them is easily removed when the walks are hoed. For shrubbery walks under the drip of trees, where live edgings are an impossibility, edgings of this kind will be found very satisfactory, combining as they do utility and economy.—J. G.

***Lilium speciosum rubrum* with White Flowers.**—In a garden near Amsterdam a plant of *Lilium speciosum rubrum* produced this summer nine flowers, of which the first, third, fifth, seventh, and ninth, counting from the bottom upwards, were of the usual colour, but the second, fourth, sixth, and eighth were pure white, like those of the Dutch *L. speciosum album*. The plant in question has been two or three years on the same spot without being transplanted. In 1877 it yielded five flowers of the normal character. The place in which it is growing is a turf, sulphury fen containing a variety of soils, in some of which the flowers of plants are very much inclined to vary temporarily in colour. I should like to know if a similar variation in the flowers of *Lilium speciosum rubrum*, or in other sorts of Lilies, has been observed elsewhere.—J. H. KRELAG, *Haarlem*.

The Alpine Sparrow-wort (*Passerina nivalis*).—This is an interesting dwarf Alpine plant, nearly allied to the *Daphne*. It grows to about 1 ft. in height, clothed with a profusion of narrow and pointed leaves, which are interspersed with a copious supply of *Mezerium*-like blossoms. It is found at very high elevations on the Pyrenees.—W.

TREES, SHRUBS, & WOODLANDS.

STREET TREES.

I HAVE read in THE GARDEN (p. 500) that a contract has been entered into to plant with Plane trees St. George's Road, from the Elephant and Castle to Westminster Bridge Road; also to complete the planting of the Blackfriars Road up to the approaches to the bridge. The planting of trees along the margins of streets is a matter of great importance, not only on account of the cheerful aspect produced by their colour and shade, but also from a sanitary point of view. Some few medical men may object to the planting of trees on the ground that decaying vegetable matter is dangerous to health; but, surely, such objections are frivolous and easily overcome, being simply a question of scavengering. The power exercised by a given quantity of healthy foliage in the purification of the atmosphere, during its period of growth is vastly in excess of any vitiation it may cause by its decay in autumn. However, my purpose is not so much to discuss the merits of trees in streets from a sanitary point of view as from an arboricultural one. In No. 321 of THE GARDEN I gave a description of what I considered the best method of planting, staking, and guarding trees in streets, to gether with the best varieties for populous towns; to my opinions there expressed, I have nothing to add, so far as those particulars are concerned; but, seeing that in various parts of London the local authorities contemplate the planting of trees along the sides of streets, I wish to again call attention to the necessity of planting really suitable trees for the purpose. So much carelessness or want of the right sort of knowledge has been shown in this matter that a section of the public has become tired of the subject in consequence of the expense and subsequent failure. If we wish to succeed in enlisting the favourable opinion of the public regarding street trees, our first and principal aim must be to succeed in the object which we have in view, viz., to form lines of trees along the sides of our streets, which, from their nature are suited to withstand the murky atmosphere inseparable from large towns, trees which will grow with reasonable rapidity, and produce an abundance of healthy foliage which will remain in good condition until October. These are the conditions which the public have a right to expect, and for which they are called upon to pay in the shape of rates. Since, therefore, the planting of street margins devolves generally upon public bodies, it seems to me to be necessary to employ competent persons to carry out the work. Too often it is placed in the hands of the surveyor who, as a rule, has no knowledge to fit him for the purpose, and it is carried out by labourers who are perfectly ignorant of what is required. Consequently, failure is almost certain, or, at all events, but a poor return for the outlay is the result. None but really good trees should be planted, and the necessary preparation for their reception should be thoroughly made. Even though the expense may appear somewhat large at first, I am perfectly satisfied that the result will more than repay it, and, what is of great importance, several years will have been gained through making a good beginning. An instance of this will be evident to anyone who will pay a visit to the Victoria Embankment. Here is a case in which good trees were purchased in the first place, ample provision made for planting, and the work carried out under competent supervision. The great fault, perhaps, which was made was, that double the quantity of trees necessary were planted, the cost, of course, being in proportion. These extra trees should be removed without delay if this avenue is to become what it bids fair to be, one of the finest to be found in any European town. Everyone has such reluctance to uprooting well-grown trees that I would recommend that trees should be planted at first at the distances at which they are to remain. In the case of the trees on the Victoria Embankment, it is my opinion that they might be removed and transplanted with perfect safety. Public bodies would do well to consider these remarks, and let the cost of trees and tree guards be somewhat more proportionate than hitherto. The latter may be replaced at will, but a few years' growth upon the trees means so much time. Generally, tree guards or fences may be expensively elaborate, but should the cost of the trees exceed a few shillings each, it is often looked upon by the uninitiated

unnecessary expenditure. No greater error than this can be committed, and if, by giving expression to these opinions, public bodies may be induced to take up the matter earnestly and fairly in favour of the trees, my object will have been gained and myself amply rewarded. Absolute success would be the result, which would certainly be a satisfactory return for any reasonable outlay which might be made in respect to purchasing and planting trees on street margins. C. DENNIS.

Southwark Park.

WALL PLANTS.

A WRITER IN THE GARDEN (p. 415) mentions several plants as being suitable for planting against walls, to which I think a few additions might be made with advantage. I therefore give the names of two or three which I have used for the purpose many years ago. Some of them are perhaps too tender for every situation, but as I give the result, the planter can exercise his own judgment in the matter:—

Clianthus puniceus, a fine New Holland plant, is but seldom met with now-a-days in good condition; the fact is, that when grown under glass it becomes so sadly infested with red spider as to be very unsightly; therefore, after straggling with it as an indoor plant for many years, I at length planted it out against a south wall fully exposed, where it grew well and became clothed with foliage of the brightest green, and flowered abundantly the ensuing spring. I believe I partly covered it up with a mat during some very bad weather the first winter, but subsequently it received no protection, and the result was a severe winter killed it; this was a great many years ago. Subsequently, however, I planted another one outside, and managed to keep that alive for several years by covering it up with a double mat in very hard weather, but an unusually hard winter (1866-67) also caught it; nevertheless, on account of its beauty when in flower, I consider that it well repaid me for the loss which its destruction entailed, for no plant of the kind that I had ever seen flowered so profusely. This may be accounted for by the fact of the wood being well matured and the situation being a dry and sunny one. The plant was quite 12 ft. high and of proportionate width, and covered the space which it occupied with a dense mass of foliage of the deepest green, and its clusters of flowers were of the richest coral. I can strongly recommend this plant to all having a favourable position.

Edwardsia grandiflora.—This is also, I believe, a New Holland plant, and more hardy than many imagine. Out-of-doors it assumes quite a deciduous character, and, growing by the side of the *Clianthus* just alluded to, it did not seem to suffer in the least from the severity of the winter and flowered freely, its blooms having a peculiar insect-like appearance.

New Zealand Veronica.—This, on a low wall, flowered most abundantly late in the season, and under a mat in very severe weather it survived several seasons, until it became too large for the situation which it occupied, and had to be done away with.

Ceanothus azureus.—This is well worthy of a place on account of its handsome flowers, as are also some others of the same genus.

A RETIRED GARDENER.

Beech Trees and Underwood.—Surely "J. S. W." is talking rector nonsense than M. Alphonse Lavallée in asserting that "underwood does not thrive and flourish under the Beech," and as to Beech being "the worst tree in the forest for injuring and destroying underwood" it is simply incorrect. "J. S. W." should be free of absurdities like these, ere he imputes nonsense to men such as M. Alphonse Lavallée. As to the Walnut, I have no doubt M. Lavallée was speaking of a wood—Walnuts in numbers and not a single tree. A single tree is no proof of whether underwood will grow in woods under many Walnut trees, because the surroundings of a single tree are free and open. At the same time I believe underwood would grow under Walnut as well as under Beech in this country.—H. KNIGHT, *Floors*.

The White Indian Azalea Out of doors—With reference to this matter (p. 498), I may say that, during the present autumn, I have seen large, healthy plants of this Azalea at Hewell Grange, Worcestershire, and I remember there were specimens of it in the grounds there thirty years ago. There are also very handsome specimens of *A. amona* growing near, covered with well-developed flower buds. I am surprised that this latter kind is not more freely planted than it is, as it is quite hardy. Altogether, the collection of trees and shrubs at Hewell is a most interesting one. The soil is especially suitable, and the thinning out of inferior plants to make

room for better and rarer kinds has been judiciously carried on for a long series of years without intermission. I saw also in the grounds at Battle Abbey a large bed of white Azaleas, but, on the whole, the plants were not so healthy as those which I saw in Worcestershire. I rather think the south-west wind from Beachy Head and Eastbourne would come across the spot where they were planted with considerable force at times, and would, no doubt, at that distance, be impregnated with salt. I remember also when I was at Hillsboro' Castle, Co. Down (about 10 miles from Belfast), there was a bed of these white Azaleas growing in a sheltered part of the grounds. This was in the year 1853. I believe, too, I have seen them planted out at other places. Like Camellias, there are many localities in which they keep in fairly good health, but their flowers are delicate, and our springs are frequently unpropitious. It is not often they can be had in such good condition as under glass.—E. HOBDDAY.

—Twelve years ago, several dozen fine plants of this Azalea were growing in the sbrabbery borders in the gardens at Woolton Hayes, Liverpool. They were planted in beds of peat, and placed in prominent positions in front of Rhododendrons and Kalmias. I saw these plants pass through three winters unprotected and undamaged by frost or damp, and in strength of growth and profusion of flower they were equal to any plants I have ever seen in pots.—J. ROBERTS, *Gunneryburg Park*.

—There is a very fine white Azalea in the garden attached to the Goat Hotel at Beddgelert, and we have a small one here, within 4 miles of Snowdon, and 600 ft. above the sea. We consider it to be quite hardy, and I know it also grows well in the south part of Carnarvonshire.—ELLEN DARRISHIRE, *Penygroes, Caernarthenshire*

—For these last forty years, and I know not how much longer, the white Indian Azalea has done well without any protection in the garden here. It is planted in a sheltered place in rather light soil, with a good natural drainage in the sandstone rock. The plant blossoms fairly well every year, and it has borne frosts which have killed Bay trees to the ground. Situation, 40 miles south from London, on Hastings road; 200 ft. above the sea; and about 70 ft. from the bottom of the valley.—WM. MORLAND, *Lamberhurst Court Lodge, Kent*.

—Both the white and the old lilac varieties are growing most luxuriantly in the arboretum at Longmead, Bishopstoke, Hampshire. These, I believe, are single plants, and, to the best of my recollection, their diameter was from 10 ft. to 11 ft. The only protection which they received was in spring, when the buds began to expand; several long poles, stuck into the ground, were bent over them, and either mats or tiffany were thrown over the poles at night, and taken off in the daytime.—D. S. GILLETT, *Weybridge*.

—With regard to planting out Azaleas, I would say, yes; plant out the whole of your spare stock, and rest assured that it will grow and thrive too; but, as for its flowering well outside, I would not be so positive. I have seen several beautiful specimens of the white Azalea growing on the side of a hill in a north-west aspect, in Greenwood Cemetery, Brooklyn, U.S.A., where the temperature falls far below the average winter registerings, even in the north of Scotland, looking the picture of health, and one sheet of bloom. There can be no doubt that the hot summers experienced there are most conducive to its flowering properties, inasmuch as they thoroughly mature both wood and buds before frost sets in; otherwise, I cannot see how the plants could survive.—J. KNIGHT, *Reading*.

—In answer to the question with regard to the white Azalea flourishing in the open air in England, Ireland, or elsewhere, I beg to say that I planted at Lamorran many of these Azaleas in the year 1852 on a north bank, and have not lost one plant since, although I have seen the thermometer certainly on two occasions below zero (Fabr.)—J. T. BOSCAWEN.

—In the gardens at Singleton, Swansea, close to where I am writing, the white Indian Azalea has been planted in the shrubberies for a number of years, and it flowers and does as well in every respect as any Rhododendron.—CAMBRIAN.

—I have plants of this Azalea which have been in the open air without shelter for these forty years past, and, though the plants are still small, they are covered with pure white bloom every spring. The white Azalea is hardy in the open air anywhere in Cornwall, and many other varieties flourish here equally well.—J. J. R., *Penrose, Helston*.

—Eight or nine years ago a plant of the old white Azalea was planted out against a wall with a south-east aspect here, and it has not been injured by any frost that has occurred since, though it has never received any protection. A south-east aspect in this cold, damp valley may be considered the very worst for tender plants, because the sun strikes them earlier on that aspect than any

other; therefore, a south-west wall would give all tender plants a better chance.—D. THOMSON, *Drumlanrig, Thornhill, Dumfriesshire.*

— We are near the sea, but very much exposed to west and north-west winds. This season our white Azaleas (of which I gave you an account, p. 485) are again well set with bloom; in fact, on every shoot there is a bloom bud. They never receive any protection whatever, and for a week back we have registered from 7° to 13° of frost every night.—JOHN MOSSISON, *Narrowwater Castle, Warrenpoint, Co. Down.*

— The white Indian Azalea exceeds here out of doors splendidly. We have a quantity of it growing in the Camellia garden; one clump of it is about 10 ft. in diameter. They produce annually quite

THE INDOOR GARDEN.

ADIANTUM HENDERSONI.

THIS is an elegant and distinct Fern, and in habit unlike any other Adiantum. In the graceful arrangement of its foliage it greatly resembles the ribbon Fern (*Pteris serrulata*), and in the lovely rose tinges of its younger fronds, it calls to mind the coloured foliage of *Pteris tricolor*. As the fronds mature the rosy line changes to a coppery tint, which, in its turn, gives place to a pleasing shade of green, but as the plant is

Adiantum Hendersoni.

a mass of bloom, of fine form and substance. The plants receive no protection whatever. Some are out in open spaces, others in borders by the walls; but all grow and flower as freely as the hardiest Ghent varieties. The soil in which they are growing is mostly loam, with a little bog-mould of rather a toughish, retentive character.—JOHN EINSELA, *Castlemartyr, Ireland.*

Hodgins's Holly.—The well-known *Ilex aquifolium* Hodginsi is the best of Hollies for town gardens, and a very fine Holly anywhere. Usually when Hollies are planted in smoky and confined places the common typical form of *I. aquifolium* is chosen, and it does very well. But Hodgins's beats it every way. It is more noble in leafage, richer in colour, denser in habit, and more rapid in growth. I am really surprised at the progress of this variety in my collection, which, being extensive, affords me abundant opportunity for comparison. Not one of our Hollies, the varieties being nearly seventy in number, has in the course of nine years made such growth as Hodgins's—"Gardeners' Magazine."

evergreen it is seldom to be found without fronds possessing all the colours just named. It was imported from New Granada, and requires to be grown in an intermediate house. Messrs. E. G. Henderson & Son, of the Pine-apple Nursery, Maida Vale, from a plant in whose collection our sketch was taken, first distributed it. For vases or baskets it is a desirable Fern, and as a pot plant it is well worth adding to even small collections. S.

Linum trigynum in Winter.—The bright golden flowers of this East Indian Flax are very striking at this season. It is a plant easily grown, but not nearly so common as it ought to be where winter flowers are so much in demand. Cuttings of the young shoots taken in spring root quickly under the same conditions as those under which

ordinary soft-wooded plants are struck. They should be potted off when rooted, and grown on in the warmth of the hotbed for a time, occasionally pinching a runaway shoot to induce a bushy habit, and giving the plants more pot room as they seem to require it. As the season advances move them to the greenhouse, and, finally, in July move them to a cold frame and give them plenty of air. Their great enemy is the red spider, for which the best and only antidote is to encourage a regular, steady growth, and to give plenty of water at the root and over the foliage too when the weather is warm. Pretty little flowering plants may be grown in one season, and although the individual flowers do not last long, they open so freely in succession that the fallen ones are not missed. When planted out in a conservatory border in a light position it assumes more the appearance of a shrub, and is more effective than when confined to a pot. It will succeed in a compost consisting of two-thirds turfy loam, one-third leaf mould, and sand sufficient to ensure the necessary porosity.—E. HOBDAY.

WATERING AND THINNING CAMELLIAS.

NEARLY all Camellia plants, if in good health, will set more buds than they ought to be allowed to carry to perfection; in fact, if left on, they seldom do retain them all till they open; and not unfrequently over-loading the plants leads ultimately to weakly growth and small flowers. Therefore, wherever the flower buds have set thickly, they should be thinned, leaving one, two, or three buds on each shoot, according to its length and strength. In but few cases should so many as three buds be left. One bud will be sufficient on all shoots not more than 5 in. or 6 in. long. A plant thickly studded with well-ripened shoots carrying one bud each will in the aggregate bear an enormous number of flowers. Nowadays, in using Camellia flowers for bouquet making, there is no necessity to cut the branch on which the flower grows, or any portion of it. Simply cut the flower off where the calyx joins the branch, and mount it on wire, so as to form an artificial stalk. There is a special wire made for this purpose, which may be obtained from any of the principal London seedsmen. After a little practice anyone can mount flowers on wire, but Camellias require more delicacy of touch than other flowers, as they show any bruises so distinctly. Two pieces of wire are required for each flower, and they may vary in length according to the length of stalk required; but from 9 in. to 12 in. is generally sufficient. The flower is held carefully but firmly in the left hand, whilst the wires are thrust half-way through, at right angles to each other, with the right. The exact point at which the flowers should be pierced with the wires will vary with different-sized blossoms; but the object is to hold the flower together without the wire being seen. The ends of the wires are brought down under the flower, and one is wound a few times round the other, forming a very handy stalk, much better than the natural one for bouquet making. Should foliage be required, there will be no difficulty in attaching leaves to the base of the flower by means of the wires. Camellia blooms mounted in this way are usually more lasting than if cut with a piece of their own wood attached, as the petals are very apt to drop out of the calyx when taken into a warm room; but, when properly wired, the petals are held in position by the wires. Besides, when cut with a piece of wood, it is very difficult to bring the flowers to a face to display them properly, as, unlike Roses, they do not grow straight up from the ends of the shoots; but with a wire stalk they may be made to face in any direction.

Camellias at all times require a good deal of water, but especially at this season, as not only have they a large amount of foliage to support, but there is the load of rapidly swelling buds. At no season are the roots in a greater state of activity, and if not well supplied with water something must be wrong; usually it is the buds that first give way when the period of trial comes. I have occasionally come across cases where both the buds and leaves were falling through want of water, and when buds or leaves begin to fall the roots should be examined, not only on the surface, but the bottom of the ball, or, if planted out, open the border and see what sort of condition the bottom is in. When a hard ball in a pot becomes thoroughly dry, the pot should be placed in a tub or tank till all the air bubbles have done rising, then lift it out and water with more care in future. At this season onwards for the next two months there is more danger of mischief being done by withholding water

than at any other period of the year. Plants do not flag now as they do when the leaves are soft and a hot bright sun is shining; and especial care should now be given to plants growing in beds. Conservatories are often kept too warm in winter to suit the wants of Camellias, and if, in addition, they only receive a scanty supply of water, something must go wrong. A gentle dewing overhead in the morning of fine days will be beneficial, and the sponge should be used as often as possible, to keep every leaf bright and clean. Weak soft soap and water will give a gloss and polish to the plants that add much to their healthful appearance. Camellias, when well cared for, will live to a very old age, constantly increasing in value. I was in a conservatory in Worcestershire a short time since where there was a tree of the old double white that must have been much more than fifty years old. I knew it more than thirty years ago, and it was then a large old plant. It is still in robust health, and is carrying an immense number of blossom buds.

There is no doubt that Camellias planted out in a lofty house, without much artificial heat, will grow to a much larger size than is generally supposed. Good turfy loam, where it can be had, should form the basis of all borders for Camellias, and everything in the shape of leaf mould, unless thoroughly decomposed, should be rigidly excluded, as it is apt to engender fungus. I was visiting a large nursery establishment in the north some time ago, and the border of a large house, into which a great number of Camellias had been planted for cut flowers, had become so infested with fungus spores, and these had so affected the health of the plants, in spite of all that could be done, that they were at last compelled to lift the plants and pot them. This, I know, is not an isolated case. I once had to deal with a similar one. I lifted the plants out, and renewed the soil twice, and drenched both the plants and the borders frequently with soot water, until I ultimately conquered the fungus; and afterwards the plants grew amazingly, and produced very fine flowers. Although rough leaf mould, or the bits of roots and other foreign matter frequently found in peat, will engender fungus under certain conditions, yet, if the border be kept moist, it will not make much headway. It is when the border or any part of it gets dry that the fungus spores vegetate and spread so disastrously: and when the fungus reaches that stage it is very difficult to drown it out, as water will not penetrate the dry spots so long as a passage can be found in any other direction. Hence the necessity for care in watering Camellias that are growing in beds or borders. Soot water, in a weak solution, may be given with advantage at this season at every watering. It will support the foliage, imparting to it a dark green colour; and a plant with firm, healthy foliage very rarely fails to produce good crops of flowers.

E. HOBDAY.

PANSIES IN POTS.

TIME was when Pansies were much grown in pots for show purposes, to get cut blooms early in spring for April shows, and also as specimens to be shown in pots at the end of April and early in May. In this way not only were beautifully finished flowers obtained much earlier than they would be in the open ground, but excellent plants, carrying charming flowers, were also secured by the cultivator. That was a quarter of a century ago, when the Royal Horticultural Society used to offer prizes for the best twelve Pansies in 8-in. pots. At that time the culture of hardy flowers was much more followed than it is now; the bedding craze had not set in in its intensity and turned the heads of half the gardeners in this country. If people who are fond of cultivating flowers could come to realise what splendid blooms of Pansies can be had from plants well grown in pots, blooms that would be remarkable for their well-defined and rich colours, they would set about growing plants in pots. The best plants for this purpose are those grown from cuttings put in in June or July; good cuttings make good plants for pots, if, when they are rooted, the leading shoot be pinched out so as to make the plants break up well from the base of the main stem. At the time to which I have referred above the plants were potted from the cutting bed into what we used to term small 3-in. pots. We used to have three sizes of 3-in. pots in those days, the smallest being a kind of large thumb pot, and from these they were shifted into large 3-in. or $4\frac{1}{2}$ -in. pots, according to their size, and wintered in these. The great aim always was to have plants thoroughly well rooted; and, in a mixture of yellow loam, leaf mould, and rough sand they used to grow famously, and by February had masses of

healthy young roots. The blooming plants were sometimes in 6-in. and sometimes in 8-in. pots, but for blooming only, good plants and flowers can be had in 4-in. pots. When the plants were put into their blooming pots the compost used was one of fibrous, rich loam, some well-rotten manure from an old Cucumber bed, leaf mould, and sand. The roots soon ran out into the new material, and it was always found to be of great advantage for the plants to get established in the blooming pots as quickly as possible. Some care is necessary in potting. The best time to do it is early in February when the plants are fairly active. Potting should be carefully done, providing drainage according to the size of the pots, and giving a good amount at all times. The soil should not be pressed hard about the roots, as they work in much better when rather loose. The plants for exhibiting in pots used to have something like five or six leading shoots and more; the more the better, the cultivator used to think, provided they were of equal length, a matter of some importance in securing a good, symmetrically-grown plant. Given a plant with strong leading shoots, any young growths coming up from the base of the stem were cut away, so as to throw all the energy of the plant into the flower-bearing shoots. In early spring the plants do best in a slightly-raised, cold frame, so that wet can drain away. When the flowers began to open, air was freely given, but care was always taken that cold draughts did not play on the flowers, else the petals would curl. Just as the buds began to show, manure water was given twice a day, and this stimulus greatly assisted in the development of large, smooth, well-formed flowers, and beautiful they were when well finished. Whoever attempts to grow Pansies in pots must be prepared to give them plenty of attention. It is one leading condition of success; no one can grow any flower thoroughly well without making a sacrifice of time and labour; but the reward is rich and valuable, and it is especially so in the case of the Pansy. I wish some one could be induced to take up the culture of the Show Pansy in pots, and grow it as it deserves to be grown. Some old-fashioned flowers are found coming to the fore again; may be the Pansy will be found included among them.

D.

SELAGINELLAS FOR TABLE DECORATION.

Few plants excel these for table decoration, inasmuch as where a good supply of them exists a little ingenuity will find means of working them in such a variety of ways, that, although employing much the same material, a very varied series of decorations will be the result, for as a living carpet of verdant turf surpasses all other groundwork for showing off to advantage the rich and varied colours of summer flowers, so does the verdure of healthy masses of Selaginellas display in perfection the brilliant colours now so largely used in table decoration. In a moist, genial temperature, ranging from 50° to 65°, the *Selaginella denticulata* grows amazingly in a minimum of soil in tins or trays made to fit the table. Even the smallest pieces quickly become a dense mass of green; or if pyramids or circular masses be desired, wire framework of whatever form may be wanted, filled with soil and treated in the same way as the trays just alluded to, quickly becomes covered. Perhaps, however, the most serviceable mode of growing this pretty Club Moss in quantity is in small pots from 3 in. to 6 in. in diameter; and as it is a plant that will grow under a wide range of temperature, it is always advisable to have a good reserve planted out on bare, partially shaded surfaces, such as usually exist in Vineries or other fruit houses, or on the surface soil of large specimen plants in tubs, boxes, or pots, and in cool houses where it acquires a sturdy habit of growth. Under such circumstances, it is in the best possible condition for being quickly increased to any extent. Taking the desired quantity of pots and filling them with light, porous soil, a small bunch of *Selaginella* should be inserted in each; they should then be set in a shaded house or frame, where they can be kept moderately close until they have become established; afterwards, if not required for immediate use, they may be kept gently moving in any cool house or frame until within a month or six weeks of the date on which they are likely to be required, when they may be transferred to any warm forcing house, as, for instance, under Cucumbers in winter, or early forced Vines, partial shade being rather advantageous to them than otherwise. Under this treatment the pots will rapidly become circles of lovely verdure, that will of themselves, when transferred to the dining table, have a pleasing and refreshing appearance, and in connection with bright silver, either with or without flowers or fruits, cannot fail to prove satisfactory.

Where choice cut flowers are scarce a minimum quantity inserted in a groundwork of Club Moss will be set off to advantage, especially white, scarlet, or pink. A few slender Ferns or Palms, such as *Cocos Weddelliana* or the graceful *Areca*, form a simple and elegant arrangement on a carpet of living green. One of the best arrangements which I ever saw was a dessert set on a table lighted with three elegant silver candelabra, a pair of plants being put into silver hunting cups to match. The remaining surface of white cloth was covered with long sprays of *Selaginella* laid irregularly, an arrangement more effective than any kind of Fern fronds which I have yet seen.

Linton, Kent.

J. GROOM.

ABUTILON IGNEUM THE SAME AS A. INSIGNE. THROUGH the kindness of Mr. Barron, the Superintendent of the Royal Horticultural Society's Gardens, I have had an opportunity of examining a fresh specimen of the fine *Abutilon* exhibited under this name at the last meeting of the Society, and of comparing it with authentically-named species at Kew. There is no doubt whatever that it is the plant described and figured by Planchon in the "Flore des Serres," in 1850, vol. vi., part II., p. 551, under the name of *Abutilon insigne*. In 1855 it appeared in the "Botanical Magazine," plate 4340. Though comparatively an old plant, it appears to be still rare in gardens, whilst it deserves to be in every collection, for it is an exceedingly elegant and beautiful species, and very distinct from any other in cultivation. The only character in which the *Abutilon igneum* differs from the plates quoted above is the deeper, richer colour of the flowers, due, probably, to the greater vigour of the plant. Moreover, the plates quoted above differ as much from each other as either of them does from our plant. The flowers in the original plate in the "Flore des Serres" present a greater development of the white ground, and the crimson venation is of a lighter tint, whilst those in the "Botanical Magazine" figure are intermediate in colouration between the original and ours. For the information of those who have not had an opportunity of seeing *Abutilon insigne*, as it should now be named, we will briefly sketch the principal features which the cut given at p. 474 of THE GARDEN could not show. It is of compact habit, flowering when quite small, with ample leaves, and pendulous lateral and terminal racemes of bell-shaped flowers. The leaves are prominently net-veined below, the veins, as well as the young shoots, flower stalks, and calyces, being more or less densely clothed with short, stellate, brown hairs, and the polished, shining petals are of a rich crimson, with white areolations and margins, and prominent, purplish-lake veins. Another handsome species of this genus, being in gardens under two names, we take this opportunity to explain which is right. We allude to *A. megapotamicum*, perhaps better known under the name of *A. vexillarium*, given to it by Prof. Morren, who took it for an undescribed species, and, as the beautiful contrast of colours it presents very well represents the Belgian national colours, he thought the name of Standard-bearer *Abutilon* an appropriate one. The name *megapotamicum* was given in allusion to the home of this species by the great waters of the Rio Grande, in South America.

W. B. HEMSLEY.

PRIMULAS AT BIRMINGHAM.

SEEING there were not less than thirteen classes for Chinese Primulas at the late Birmingham exhibition, it is not to be wondered at that the display was not only extensive, but very attractive. Birmingham is, to a great extent, the home of the Primula, for Mr. James Tomkins, of Sparkhill nursery, there, has done good work in the way of improving this fine flower, and his Marquis of Lorne and Princess Louise—the first a rich crimson-purple flower, and the last a remarkably fine bluish-white—are standard varieties in the midland district. A dozen of Primulas—six red and six white—shown by Mr. T. Denning, gardener to J. Penton, Esq., Yardly, to which the first of the special prizes offered by Mr. T. B. Thomson, seedman, Birmingham, was awarded, I thought to be pretty well perfect as exhibition plants, because so finely and so evenly grown, but the *habitués* of the Birmingham exhibitions said they were not so good as last year. In the nurseryman's class for twelve plants, six

rad and six white—a very good arrangement, by the way, as it secures a proper contrast of colour in a group—Mr. J. Tomkins was first with admirably-grown plants, bearing splendid flowers; the dimensions, as well as the stoutness, of some of them were particularly striking, and, with but few exceptions, this fine character ran through the whole. The double varieties were well grown, but in point of effectiveness they fell far short of the single types. A large plant of a double Primula, however well grown, will be certain to have only medium-sized flowers, and the purple and cerise-red colours looked quite dull and uninteresting by gas-light. If double Primulas are to be shown, I think it should be in the form in which Mr. R. Gilbert, of Burchley, sends his plants to the meetings of the Royal Horticultural Society—plants in a state of young, vigorous development, and carrying at the most ten trusses of bloom. Then the flowers are large, bold, and fairly developed. I am tresting now of double Primulas for exhibition, not for general decorative purposes. It was at night, when the gas in the spacious Town Hall at Birmingham was fully turned on, that the Primulas shone out to full advantage; all the flowers having purple shades became intensified to rich cerise and scarlet hues, and the white and blush flowers had a glistening whiteness of star-like brilliancy. By their side dark-coloured Chrysanthemums were ineffective. Primulas are fine and striking plants for gas-light decoration, and cultivators should bear this in mind. The only thing comparable with the Primulas by night were the vermilion bracts of *Poinsettia pulcherrima*. These were splendid in hue and particularly strikingly D.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Witsenia corymbosa.—This old-fashioned plant is now seldom seen, and yet its culture is by no means difficult. It requires a cool house, good drainage, and abundance of water. It might be grown with advantage for winter flowering, its bright blue blossoms being especially attractive at this season of the year. We lately saw good examples of it in full flower in Messrs. Kollison's nursery, Tooting.

Winter-flowering Tropæolums.—Where flowers in winter are considered indispensable, this brilliant family should always have a place. Nothing with which I am acquainted in the way of winter-flowering plants can rival the Tropæolums in their own particular shades of colour, and whether used as specimens for the embellishment of the conservatory, or in a cut state for table decoration, their vivid glowing tints render them invaluable for these purposes. A very pretty and cheerful effect is obtained by training them up the rafters in a temperate house; there close to the glass they flower freely, and not only enliven the whole structure, but yield an abundance of flowers for cutting. There are both scarlet and yellow-flowered varieties, and some of each colour should be grown. The one great point to be observed in the cultivation of these plants for the production of winter bloom is to start them early into growth in order to secure size, and strength, and substance. Strike some cuttings daily in April and shift them on, using a rich compost until they get well established in their flowering pots. Subject them to full sunshine and give them plentiful supplies of water in hot weather. If they are to be trained up the roof, then they must be prepared for that purpose. The best way to effect this is to train them to some stout strings during the summer, and at housing time they may be attached to the rafters, thus effectually and at once furnishing the house with flowers and foliage. Plants thus grown possess a vast amount of flowering power, and if placed in an airy, temperate house remain fresh and green the whole winter through. These Tropæolums may also be grown as specimen plants by training them upon a hollow trellis, and if not tied in too closely they will not appear formal. Such plants associated with Chrysanthemums or plants of that kind would have a particularly bright appearance. When thus grown they must be stopped from time to time during the growing season, and the bottom portions of the trellis must be kept well furnished with shoots. The flower buds, too, should be kept picked off until the end of October, when they may be allowed to flower. For this latter purpose it is not advisable to employ seedlings; they grow too rankly. Plants from cuttings, I have found, are induced more readily to assume a shrubby habit, and they flower more abundantly. Plants that have grown in the open ground may, if not too large, be lifted and potted, but they must be taken up with good balls, or they flag too much. I once potted a number that had been growing against a wall, and they did not suffer to any extent by the removal. If they are to flower throughout the winter they must be kept growing gently. In a cold house they will stagnate and rot. Plenty of air should, however, be given on all favourable occasions, as too confined an atmosphere will induce a weak and spindly growth. —J. CORNHILL, *Byfleet*.

PLATE CLVII.

HABRANTHUS PRATENSIS FULGENS.

Drawn by NOEL HUMPHREYS.

This is the most brilliant and beautiful among new hardy plants which we have seen for many a day, and one, the peculiar splendour of which, when the plant is seen in flower in the open garden, a coloured plate fails to convey any idea of. It has been found to be quite hardy, and to bloom freely in the Rev. Mr. Nelson's garden at Aldborough, in Norfolk. Mr. Noel Humphreys visited that garden for the purpose of drawing it on the spot and as it grew in the border. It flowers at Aldborough at the end of May or beginning of June; the scapes rise about 1 ft. high, and are from one to four-flowered. It grows very freely in strong loam, improved in texture by the addition of a little leaf-mould and sand. Its propagation is too easy; for in many soils it is said to split up into offsets instead of growing to a flowering size. At Aldborough, where it does well, it makes numerous offsets. Herbert says it is from the meadows of Antuco, in South Chili, and adds that it flowers there in November. The species is, however, not well circumscribed, different writers having assigned it widely diverse limits, and it is possible that, in a revision of the species, several of the forms now referred to this name will have to be provided for elsewhere.

Goold's Artificial Manures.—Having used these manures rather extensively this season, and being desirous of eliciting the opinion of those who may have tried them, allow me to enumerate the subjects upon which I experimented, and with what results. Being specially prepared for different plants, I shall speak of the "Vine Compound" first. Having planted sixteen young Vines in July of last year, which made fair canes and ripened well, and being anxious to have what fruit they would carry, I applied this manure when the bunches began to show, and about every fortnight until the Grapes were ripe. The results were far beyond my expectations; both bunches and berries were large and well-coloured. Each Vine carried on an average six bunches, and having made good canes from the base, I am looking forward for my earliest crop from them next year. Under ordinary treatment, these Vines would have been useless for another year. Let us now take the "Fruit Compound." This I confined more particularly to Melons grown in pots. It was applied at every alternate watering after the fruit was set, and the result was three crops out of the same house of good table fruit. The plants averaged four fruits each, and occupied but a small amount of trellis. The "Hothouse Compound" I applied to Crotons, Dracænas, Marantæ, Ferns, &c., about three times in a fortnight, and with markedly good results. Crotons in particular were much benefited by it, the foliage being very highly coloured. I am now using it freely on Solanums which were lifted from the open ground, and so far they look promising; it is also recommended for hard-wooded plants, but, as yet, I have not used it on them. The "Rose Compound" I applied to Roses in the open air, and the plants so treated were more vigorous, and bore finer blooms, than those to which no compound was applied. There can be no doubt that it might be applied to pot Roses with better results. Having a climbing Rose much attacked by aphides, I mixed some of this compound with soft water and sprinkled the plant over with it, and next morning very few insects could be seen on it. I am so thoroughly convinced of the usefulness of these compounds, that I intend using them on a much more extensive scale next year. —A. HOSSACK, *Ragley, Alcester*.

Growing Flowering Plants in the Shade an Evil.—Some of our Primulas are flowering very well this autumn, others very poorly. All were treated alike, except that the best bloomers were grown fully exposed to the sun, and the worst in a frame facing the north, at the back of a shed. The growth of the latter is very soft, and I attribute their flowering indifferently to their being grown in the shade. From what I can notice regarding all winter-flowering plants I would say the more fully they are exposed to the sun during their whole growing season the better. —CAMBRIAN.

Chrysanthemums in a Cut State.—These are so useful that I find it to be a good practice to protect a few plants, when the blooms are expanding, from the inclemency of the weather. The excessive downpours of rain, high winds, and early frosts having cut short the display out of doors, more especially of the white and yellow kinds, I lifted a few plants and placed them under the protection of a glass roof, where they are affording an abundant supply of clear, unblemished flowers. —J. G.

PROPAGATING.

TAXUS ELEGANTISSIMA.—This may be increased by means of cuttings made as shown in fig. 1, and put in in August. Well drain some 6-in. pots, and fill them with finely-sifted sandy soil, consisting of yellow loam and peat in equal parts. Press the soil down firmly, and put $\frac{1}{4}$ in. of sand on the top; water through a fine-rosed pot, and, when settled, insert the cuttings firmly with a peg or dibber. Plunge the pots half-way up in a tan bed without any covering, and without surface heat. They generally take about three months to root, when they may be placed upon shelves in the greenhouse for potting off in spring. This Yew may also be increased by grafting in March. Cut the stock as shown in fig. 2, and the scion as in

Fig. 1.

Fig. 2.

Fig. 3.

Cuttings and Grafts of *Taxus elegantissima*.

fig. 3, bind them tightly together with strong thread or matting, and then place them in the grafting box, when they will be found to have united, and be ready to take out in about two months.

H. H.

A NEW MODE OF STRIKING CUTTINGS.

A PAPER was read the other day by the Rev. George Henslow, before the Linnæan Society, on the subject of "Absorption of water by leaves and the green parts of plants generally," a question which, in days gone by, much exercised the minds of our forefathers, judging by the voluminous records of experiments they made, and which for some time, strange as it may seem to us, was decided in the negative. Whatever observers who only worked in their laboratory may have settled, it is certain that cultivators, by their practice of constantly syringing moisture-loving plants, &c., showed that they were satisfied that plants did absorb moisture through their leaves and green parts generally, as well as by their roots and stems, and now time in its flight has brought up again the question merely to show how unanimous botanists, experimenters, and cultivators are on this point, namely, that a plant can absorb water more or less by all its green parts; and the well-known experiment of placing cut branches or shoots in the sun till leaves and tender shoots flag severely, and afterwards exposing them to the night dew, was cited as an instance in point, as it will be found that next morning they have quite regained their freshness. From this, now an accepted fact, it is evident that if the leaves are allowed to die, or are cut off, their power of absorption is lost to the shoot, and it suffers accordingly when placed, as we will first suppose, in water; and Mr. Henslow showed how very greatly cut flowers are helped to keep fresh

by their stems being cut rather long, and the leaves thereon left on and submerged in water. The Lilac was given as an instance of this, and it was also stated how very necessary it was to keep those leaves fresh by wiping off the mucus that collects, and thus causes decay sooner than is desirable.

This brings us to the subject of cuttings, which are usually placed in soil rather than water, and thus are apt to flag, and even die in many cases, and it is on this point that I would make a few remarks, as it seems that cultivators, influenced perhaps by those who taught that leaves did not absorb water, err in practice considerably; and, for the simplifying of the subject, I will take as examples those plants that are hardy enough to "strike" without artificial heat, as, though in many cases they are very easy to strike, the principle applies to all alike. How common a practice it is to trim off all the leaves from the lower part of a cutting, and top or dock the ends of those that are left on (a practice necessitated by the first operation), and how generally do cuttings thus treated flag terribly, whether they be put in pots or in the open border, unless a bell-glass be put over them to keep up a saturated atmosphere. A shoot, when growing on its parent plant, thrives by the circulation and elaboration of the sap, and if wounded or purposely cut, as in a layer, the descending sap speedily causes a callus to form, which in its turn puts out roots. This operation must also take place in a cutting; consequently, the quicker the circulation in a shoot the sooner roots are formed. It should therefore be our endeavour to keep up as brisk a circulation of sap as possible in the cutting, and not check the future plant by stripping it of nearly all its leaves and then, to counteract the evil effects of that operation, put a bell-glass over it, reducing evaporation, and with it the circulation in the cutting, to a minimum. How to hit the happy mean between undue evaporation on one hand, and damping off and stagnation on the other is most easily achieved by simply letting "well alone," that is, by planting the cutting with all its leaves on, and taking care that there shall be a just proportion between the buried leaves that absorb, and the exposed leaves that give off moisture, so that with a fairly moist soil the cutting shall not flag too much, or be gorged with undigested sap by having almost all its leaves buried. As in cuttings the leaves cannot be examined or spogged to avoid decay as long as possible, the soil must be open and loosely broken up, so that air may penetrate as freely as may be to the buried parts, and the leaves will then, if other conditions be suitable, last until roots are formed and give an impetus to the growth of the cutting that will be speedily noticed by any one who has tried such a plan. Shoots somewhat larger and longer than are usually taken for cuttings are the most desirable for this mode of propagation, which might be called the "rough and ready" plan, and the percentage of losses will be found reduced to *nil* in such plants as Carnations (especially the free-growing Cloves), Pinks, Mule Pinks, Roses (both Tea-scented varieties and Hybrid Perpetuals), and the variegated varieties of such things as shrubby Veronicas, especially the silver variegated *V. Andersoni*, which so often is apt to wither up or damp off when its cuttings are stripped of their leaves and put in a pot; while many persons have lost some pet Carnations by trimming off and docking the leaves of the cuttings (like a horse's tail), which, had they simply been planted as they were taken from the parent plant, but with greater length of "grass" than usual, would now adorn in number the gardens of their admirers.

Soils and situations vary so greatly that no positive rule can be given as to the depth such cuttings should be planted, but it will be found that one-third of the shoot above ground is tolerably near the mark; and it is evident that a soft-growing plant like *V. Andersoni* var. requires to be more deeply planted than a Carnation cutting, the object at heart being always to strike the happy mean between absorption and evaporation without the need for bell-glasses or any such protection.

E. H. WOODALL.

Pellæa procumbens.—This makes an excellent indoor basket plant, or it may be grown in pots or pans suspended by means of wires from the roof. It is light and graceful and pleasing in colour, its pinnæ being of a peculiar shade of green. It will succeed in any light, airy room.—S.

GARDENING FOR THE WEEK.

Roses.

Brier Stocks.—Although there can be little question that in far the greater portion of soils, Roses on their own roots for general decorative purposes are preferable to such as are budded on either dwarf or tall standards, nevertheless, for some positions, standards are useful, and by cultivating Roses in that way the advantage is offered that in the case of any new or scarce variety a larger number may by this method be grown up to a blooming state in a shorter time than by having them on their own roots. Where they are to be increased in this way, it is necessary annually to provide a sufficient number of stocks for the number intended to be budded, and in this case as in all others of propagation, it is well to be on the safe side in procuring enough, so as to allow for any that may not take, or which, even after the inserted buds have become established, may not grow away freely, for, especially where Roses are grown on the Dog Rose, the stocks of which are got from the usual source, a very great difference will be found in the progress which the plants make, a difference that in most cases may be traced to the more or less vigorous condition of the stocks, that in themselves differ very much after planting in the way in which they make roots and the strength which they consequently attain, on which latter will, in a great measure depend the progress the Roses budded upon them are able to make.

Selection of the Briers.—The above matter rests a good deal upon selecting such Briers as are suitable for the purpose; they should consist, so far as possible, of comparatively young Briers alone, rejecting all that have attained that very hard condition of the wood and rusty brown colour in the bark which is directly indicative of their being old and much less likely to form new roots freely, and grow away with the vigour necessary to support and furnish heads of a considerable size in little time. From observation in this matter, extending over a long period, I am convinced that one half the failures of Roses individually, when budded on the Dog Rose, are traceable to the stocks being too old when got in. No time should now be lost in procuring them. In carrying out the operation it is usual to cut away most of the existing roots; in fact, the stocks may generally be said, when ready for planting, to have more the appearance of an ordinary walking stick, the head of which represents the amount of root left adhering to the stock; but where young Briers, that is, such as are about of a couple of years' growth, though often springing from the base of plants much older than this, can be got they are about the best, and if more of the roots, particularly those that are the smallest, can be secured without mutilation, there is no question they will grow away much freer than when less are retained. In the case of those who grow for sale, where the stocks have often to be procured from considerable distances, and made up in bundles so as to occupy the least room, a large amount of root is out of the question, but with private growers, whose requirements are limited, there will generally be no difficulty in making a selection like that here indicated.

Planting.—With those to whom this work may happen to be new, it may be necessary to point out that above all things it is requisite in the planting of these Brier stocks to be careful not to put them in too deeply, as the Brier is a surface rooter, and deep planting is fatal to it. A very slight examination as to its roots being located so near the surface in places where it establishes itself naturally, will do more to convince any one of the fact than anything that can be said. If, in planting, the roots are covered from 2 in. to 4 in. it will be sufficient, treading the earth so as to make it firm over them. The Brier grows much better in a strong, heavy soil than in such as is light and sandy, and, in planting Brier stocks with a view to Roses being budded upon them, so far as possible, land of this description should be chosen, at the same time it must be sufficiently dry, and if not naturally so it must be drained to effect this. The stocks may be planted in rows 1 ft. apart, and 2 ft. or 3 ft. between the rows; where room can be spared, the latter distance is preferable, as it leaves more space for cleaning the ground, and the operation of budding when it has to be performed. Immediately they are planted they will be none the worse for being secured in their positions. This can be best done by procuring some long, straight Hazel or Ash rods, such as are suitable for tall Scarlet Runner sticks, or even longer if obtainable, driving a stout stake into the ground at the end of the row of stocks, and another at the opposite end of the long rod already named, which must be tied horizontally to these upright sticks. Each stock can be then easily fastened to it with a bit of tar twine, proceeding in this way till the whole are secured. If the sticks and twine thus used are of fair quality they will last well for a couple of years or so until the Roses are ready for removal, and with the limited numbers required in private establishments it is better to treat them so than to leave them loosely blowing about in the wind.

Manetti Stocks.—Where Manetti stocks are used it is well at once to get them planted similarly to the above in the places where they are to be budded. This stock will succeed in soils of a much lighter description than required for the Dog Rose. It will also bear planting somewhat deeper, but with this, as all others, it is well to avoid covering the roots too deeply. There is one advantage in using both the Brier and the Manetti stocks, that is, their giving a succession of flowers better than where one stock alone is employed.

Rose Stocks from Cuttings.—Private growers, who annually bud even a small quantity of standards or half-standards, would do well to propagate each year a sufficient number of these from cuttings. Of the Brier especially, stocks raised in this way will be found to have a great deal more active feeding roots at the time they are budded than those that are had from the ordinary sources—the hedgerows or woods. The stocks so raised will also possess the very great advantage that they can be budded just when they have attained sufficient age and strength, in which case the union of the buds with the stock will be much more natural and reciprocal than that which occurs where the hard old Brier is headed back, and the buds are inserted in the shoots which break from it.

Treatment of Stock Cuttings.—In the preparation of the cuttings, all that is required is to take a sufficient quantity of stout young shoots of the current year's growth, cutting them into lengths of about 8 in. or 10 in., having a joint for the base of each, and inserting them to about half their depth in the ground. They may be put in in rows like anything of a similar character, 3 in. or 4 in. apart in the rows, with some 15 in. or 18 in. from row to row, which will allow of enough room for hoeing. In the spring when they commence growth, all the shoots from each must be rubbed off, excepting one, so as to direct the whole of the strength into that which is retained, for which choose the one best placed and likely to make a good clean growth.

Supports to Roses permanently Planted.—It is well at this time to go over the whole stock of permanently planted standard and half-standard Roses, to see that the stakes and ties which support and hold them are sufficient for the purpose, for it is not uncommon to see them left through the winter season broken loose from the stakes and swinging about in the wind, under the impression that little harm will arise from this on account of their being denuded of leaves and no growth going on, which is anything but correct, for when the heads are swayed about, it wrenches and strains the roots immediately at the collar of the plant, and should sufficient frost occur to congeal the earth around the stems, then the bark at this point is often chafed and injured.

Periodical taking up of Standard and Half-Standard Roses.—Budded Roses, especially those that are on Brier stocks, mostly require taking up every three years or so, with a view to completely removing the suckers that they usually more or less produce, and which can only be partially got at without taking up. Where this needs to be done, no time should be lost in its completion, as the further through the winter it is delayed, the more its effects will be apparent in the reduced quantity of bloom produced by the plants next summer. Where a considerable space is occupied in the form of a border or a quarter, it is well to commence at one end, taking a row up, and going over each plant, removing not only the suckers that exist, but the strong, sappy, root-like growth from which they proceed, and which, if examined, will be found furnished with plump, prominent buds ready for pushing up aboveground when growth commences in the spring. Even those who have not had much experience in Rose growing will very easily detect the difference between these thick, fleshy sucker roots, and the real feeding fibres that have been made, the whole of which latter should be as little mutilated or broken in taking up as can be, retaining them all, in replanting spreading them well out in their natural position. Whatever manure is required should be added at the time, digging the ground well; the removal of the plants giving an opportunity for doing this deeper and much more effectually than has been possible since they were last put in. The replanting, as well as immediately staking and tying, should be carried out all through as the work proceeds, by which means the roots will not be subjected to exposure to the weather or being twisted and broken in heeling-in, as is more or less inevitable if the whole of the plants were taken up and the ground all dug before any were returned to their places. The ground can be also left in a much more satisfactory condition through not being trampled upon to any injurious extent, as is unavoidable in planting after it has all been dug over.—T. BAINES.

Indoor Plant Department.

Palms and Dracenas for Greenhouse Decoration.—Those who have not the convenience of a plant stove wherein a sufficient temperature can be maintained during the winter season to preserve

in a healthy condition such plants as require continuous artificial heat, are frequently deterred from growing many subjects which otherwise they would cultivate; for instance, Palms, from their beauty and diversity of habit, would be almost certain to find a place in their collections, were it not for the general impression that they cannot be properly developed without a high temperature and roomy houses, neither of which are required for many handsome kinds; for even the large-growing species of Palms, more than most other plants, are capable of being kept in a small yet healthy state for years by simply restricting them in pot-room. The great increase in the production of these in recent times has so far reduced the prices as to place them within the reach of all who feel disposed to possess them. They are very easily grown, but there is one essential point in connection with their well-being that it is necessary to impress upon those who have had no experience in their cultivation, and that is, the soil must never be allowed to become dry. This treatment is all the more requisite for any plant when its roots are much restricted in a small pot, but particularly with Palms, that are especially water-loving subjects. Amongst the most suitable Palms for growing in an ordinary greenhouse are the following:—*Areca Bueri*, *A. monostachya*, *Coccothrinax chilensis*, *C. Procopiana*, *C. coronata*, *Chamærops Fortunei*, *C. humilis*, *C. robusta*, *C. tomentosa*, *Seafortia elegans*, *Thrinax parviflora*, *Kentia australis*, *K. Belmoreana*, *K. Fosteriana*, *K. Canterburyana*, and *Corypha australis*. Although many of these species are of large size when fully developed, yet by managing them in the way above described, their growth can be kept within bounds. Those who have a Vinery will find that the above plants are particularly well adapted for growing under them, as they will afford the Palms the shade requisite to keep their leaves from being scorched in summer. They should be procured in 6-in. pots, and will not require for three or four years those of a larger size than 8 in. or 10 in. in diameter. If at any time the leaves assume a yellow hue they should have a few applications of manure water, which will impart to them a darker tint of green; but stimulants of this nature should not be used regularly to plants that are required to be kept in a comparatively small state, as their continued use would induce an increase in leaf growth to an extent that would necessitate larger pots than should be given them under the restricted conditions of growth to which they are subjected. There are several other plants of a like description that can with advantage be grown in a similar house; amongst which may be named the varieties of *Dracæna* that will succeed in a greenhouse through the winter, the best of which are *D. australis*, *D. cannefolia*, *D. lineata*, *D. rubra*, and *D. Veitchi*. These can be cultivated in moderate-sized pots, from 8 in. to 12 in. in diameter, in which they will prosper for several years if carefully kept free from insects, especially red spider, to which they are somewhat liable in summer, and which, if left unmolested, soon turns the leaves yellow, and causes them to fall off prematurely. Another nearly allied, very handsome plant (*Cordylina indivisa*) is a fitting companion to the above; it is a much slower grower, and never attains in a cultivated state such a height as the *Dracænas*, but must have more root room allotted to it as it increases in size than those plants, yet it should not be overpotted. A 15-in. pot is large enough for a good-sized specimen, and care must be taken never to over-water it, especially during the autumn and winter, when the roots are at rest, or it will perish. During the dull season the soil should be kept as dry as is requisite in Pine-apple culture. Corresponding care must be taken to keep the drainage perfect; and the soil used in potting should be such that will insure the water passing readily through it.

Azaleas.—These will now be fast shedding their leaves, which, if they are in the desired condition, will turn yellow before falling off. The dull season and diminished leaf surface which the plants possess will now necessitate a reduction of water; that is, the soil must now be allowed to become drier before water is given than hitherto, otherwise the fine feeding roots are liable to perish. Keep all the plants required for late flowering as cool as can be without subjecting them to injury by frost.

Hard-wooded Plants.—To these admit air on all favourable occasions, but avoid cold draughts. Keep them occasionally turned round, especially in lean-to houses, or they get one-sided. Keep the whole of the stock near the glass, by which means the plants will bear standing closer together than if they were further from the light, but on no account crowd them. Forward, as time can be found, tying and training, being careful to remove all old ligatures that otherwise may cut the shoots as they gradually thicken. Clean out all dead leaves from the plants, and remove all green Moss from the surface of the pots, but on no account resort to the practice of surface-dressing by adding fresh soil to the top of the ball; this is frequently done periodically. No practice, however, can be worse, as the nearer to the surface, even partially exposed, the thick roots

that proceed immediately from the collar of the plant are, the more likely the plants are to live long. Plants that have their surface roots buried too deeply generally go off at the collar.

Fuchsias, Calceolarias, and Cyclamens.—If pots of Fuchsias that were struck in August for flowering the ensuing spring are very full of roots, shift them into others 1 in. larger; if they are growing fast, nip out the points of the leading shoots, so as to induce the formation of side growths. See that the leaves are free from red spider, or they will turn yellow and fall off, spoiling the beauty of the plants. If these spring-blooming Fuchsias can be kept through the winter in a night temperature of 45° or 50° they will be all the better, as, so treated, they will make more growth and flower earlier than they otherwise would do; but if there is no convenience for keeping them in this way, they should be placed at the warmest end of the greenhouse. Herbaceous Calceolarias sown during summer must be shifted into larger pots as those they occupy get filled with roots; for, if allowed to become pot-bound, they will not grow freely afterwards. They require a more open description of soil than *Pelargoniums*; in addition to manure they should, therefore, have a fifth part rotten leaf-mould; the soil, too, should not be made so very hard in the pots, but only just pressed moderately firm with the fingers; the plants should also be kept much more moist at the roots than would do for *Pelargoniums*. Shrubby Calceolarias, which are so useful for flowering in pots, and, when well managed, last so much longer in bloom than the herbaceous kinds, should now receive attention; such as have grown to a considerable size, and are intended for coming into flower early in spring, ought to be placed in the pots in which they are to bloom; if the plants are large, they will bear shifting into 8-in. pots, using good rich loam, and treating them generally as advised for the herbaceous sorts. Primulas now coming into flower should be kept as near the glass as possible without touching it, as, thus situated, they will be able to bear the requisite quantity of water without being so subject to damp off as when further from the light. Give liquid manure to the earliest flowering plants every other time they need water; from 40° to 45° is a suitable heat for them at night during winter; for, thus kept, they are not nearly so liable to rot off at the collar as when grown in a lower temperature. Cyclamens will also flower satisfactorily in a house in which a similar temperature is maintained. As they will now be commencing to push up their flowers, they will be benefited by all the light that can be afforded them, for, when kept far from the glass, the flower stems often rot off at the bottom before the blossoms open.

Flower Garden.

Late-sown annuals, which are intended to stand the winter and flower early in spring, will be much benefited by a slight protection of some sort, such as a few Yew or Laurel boughs stuck amongst them; and beds of Fuchsias and other half-hardy plants (which have already been cut down by frost) should now be covered, to the depth of several inches, with tan, sawdust, or cinder-ashes. Attend very carefully now to the wants of bedding-out stock of all sorts, more particularly to that portion of it which may still occupy cold pits and frames. Frequently remove all dead and decaying leaves, and cover up whenever danger from frost is apprehended. Little water will be required at present, but where this is found to be really necessary, let it be supplied early on fine mild days, when air can be afterwards freely admitted, in order to dry the foliage, if possible, before nightfall; and, in structures in which there are means of applying fire-heat, this should be done occasionally during fine days, accompanied by abundant ventilation, to drive off as much as possible of the damp which, at this season, is so frequently injurious to such stock.

Herbaceous Plants.—Outdoor plants in bloom are very scarce during the present month, and consist chiefly of Christmas Roses, a few *Chrysanthemums*—as most of them that have not been protected have been destroyed in a great measure by frost—*Pansies*, *Laurustinuses*, *Jasminum nudiflorum*, *Cydonia japonica* (just beginning to expand), and a few others. Cut down *Chrysanthemums* when they have done flowering, and protect their roots by means of a layer of coal ashes; indeed, coal ashes are very useful for this purpose in general with herbaceous plants as a protection from frost, wet, and slugs, and they have always a neat and tidy appearance. Do not dig amongst this class of plants at present, merely cut away all decayed stems, strew some leaf soil or ashes over their crowns, clean the ground about them, and leave all undisturbed till early spring. Where any improvement is intended do not hesitate to accomplish it as long as the weather is favourable, for the more that is done in this way in winter the less will there be to do in the busy season of sowing and transplanting in spring. Many little Alpines and choice herbaceous plants are grown in frames in winter, chiefly to protect them from the excessive wet and changeableness of our climate, and

to form specimens. These pot plants only require immunity from wet, plenty of ventilation, a cool temperature, and shelter from very hard frost.

Draining Lawns and Walks.—The heavy rainfall of the present autumn has been such as, in the case of lawns and pleasure grounds, to show where any defect or deficiency in the way of drainage exists; and where work of this nature has to be done, there is no better time than the present for carrying it out. Here, as in other parts of the garden, the depth to which the drains should be cut must be regulated by the character of the land. On lawns where the soil is retentive, enough open material, such as clinkers, brick rubbish, or burnt clay should be placed over the pipes in such quantity as to fill up to within 10 in. or 12 in. of the surface. By this means water will much more quickly find its way into the drains. The necessity for removing all stagnant water, consequent upon badly drained walks, is equally pressing. It frequently happens that however well such work has been done in the first instance, the drains get choked up in the course of time by the roots of trees. Where there are indications of any defects of this kind, they should at once be remedied, in all cases putting in tiles large enough to carry the water off as fast as it falls, even during the heaviest thunder showers. Any insufficiency in this respect entails a great deal of labour by the displacement of the gravel, and the accumulation of soil and sediment upon the surface, after which a walk never looks well until the gravel is turned, or some fresh material added to the top. For drains in paths the pipes should be always laid sufficiently deep to be out of the reach of the severest and most protracted frosts; for, when ordinary unglazed pipes are used, if frozen with the moisture which they must have absorbed in them, they are certain to be destroyed. Nothing less than a depth of 12 in. or 14 in. is enough to keep them out of harm's way from this cause.

Walk Making.—It is very common, especially in small suburban gardens to see the walks so badly made in the first instance, even when enough gravel has been used, as to render them soft and uncomfortable after any considerable amount of rain has fallen. This generally arises from the gravel being spread on them without care, rough and fine being indiscriminately mixed together. Where such a state of things exists, the best way is to begin at one end, and sift the whole over again, passing it first through a 1½-in. meshed riddle, and afterwards through a second of ¾-in. mesh, putting the large stones at the bottom immediately over the drains, the second size upon them, and the fine gravel on the surface. By this means, one of the greatest comforts in a garden may be secured—an efficient path, through which the water can quickly penetrate, leaving the surface dry and pleasant to walk upon. An essential in all walk-making is to have a sufficient number of "eyes" or gratings to carry off the surface water. Where the ground is hilly, these should be placed at short intervals apart, as, when the descent is quick, there is the most danger of the gravel being washed up during heavy rains. The formation of new walks, where required, should now be proceeded with, for at no time during the whole year can such work be carried out with greater advantage than at present, before the winter frosts set in.

Clearing up and Storing Leaves.—Now that the leaves have, for the most part, fallen, means should be taken to clear up pleasure grounds for the winter. If possible, choose dry weather for sweeping lawns and gravel walks, for, not only can the work be done much more quickly when the ground is dry, but both Grass and gravel have a much better appearance than when clearing up is done during wet weather. Leaf-mould is so essential for mixing with potting soil and for other purposes, that it is always well to secure a good stock of leaves for this purpose, and such kinds as those of Oak and Beech are preferable to the softer sorts, like those of Chestnut, Plane, Elm, or Lime; but where the former cannot be had, the latter should not be rejected. In addition to their use as leaf-mould, as many as possible ought to be secured as will suffice in the spring to mix at the rate of one-half to an equal quantity of manure for hotbed making, as well as for forcing Seakale and Rhubarb during the winter. The leaves, as gathered, should be regularly stacked up in a heap in the frame ground, or some similar out-of-the-way corner, and enclosed, so as to prevent their being blown about. In gardens where leaves abound, it is much better to dig all in that lie amongst shrubs than to rake them off, as, when buried within reach of the roots of the shrubs, they materially assist them, especially if the roots of the latter are at all robbed by those of deciduous trees.

Kitchen Garden.

It is advisable to make a sowing of Cucumbers now, in order to furnish plants for potting out about the middle of next month, and if the seeds are soaked in warm water for fifteen or eighteen hours they will germinate much quicker than they otherwise would do:

place the vessel containing the seeds on or near the hot-water pipes, so as to secure a steady temperature of 85° or 90°. I have frequently soaked them thus till the seeds sprouted, when I wanted to push the plants on, and when afterwards planted in pots of warm, light soil, the plants have appeared in three or four days. Almost every grower has some favourite Cucumber for early forcing, but, for the supply of a family, Telegraph is a reliable variety. Where, as in many places, glass structures are limited, Cucumbers may be successfully grown in pots or boxes in any house in which a suitable temperature is kept up, such as one in which flowers are forced. They may be elevated on back shelves and the shoots trained over the pathway or down the rafters. Thus treated they do not obstruct light from plants underneath them. Where new Potatoes of good flavour are required early, a few selected tubers of the old Ashleaf or any other good early variety may be potted in 4½-in. pots, one tuber in each pot, and placed in a Vinery or Peach house just started. Never allow more than one shoot to grow from each tuber; more growth only tends to produce small tubers and retard maturity. When they come up, and before they become pot-bound, either plant them in a prepared hotbed, or pot them into larger pots, with the view of growing them on in the house till the crop is fit for use. I prefer the former plan, when it can be conveniently done; but a fair amount of success may be obtained by the latter method, if the pots can be placed in a light position—success or failure depending, in fact, in a great measure, upon this; have all leaves raked up and stacked in a convenient place for making hotbeds, as the season advances. Oak leaves are the best for this purpose, and most lasting. If early Radishes and Carrots are required, a hotbed may now be made up for them, composed of about equal portions of leaves and stable manure; and, when the heat has become steady, apply about 5 in. of light sandy soil, and sow early French Horn Carrots in shallow drills 6 in. apart, and afterwards scatter thinly a few Radish seeds all over the surface. The Radishes will be drawn before the Carrots require the space. Whenever severe frost sets in, and it becomes necessary to use protecting materials for Celery and other crops, the plants should always be allowed to remain covered till everything is completely thawed.

Extracts from my Diary.

December 9.—Potting another batch of Potatoes that have been previously started in the Pine stove. Pruning first Muscat-house, and washing the paint with soft soap and hot water. Finishing pruning, and nailing Pears on east and west walls. Taking up Box edgings and re-making them.

Dec. 10.—Potting a few Herbaceous Calceolarias into their flowering pots. Getting more leaves into pot Vine pit, in order to increase the bottom-heat. Collecting horse manure for Mushroom beds, and turning over a large heap to sweeten. Getting up a few more clumps of Mint for forcing. Veitch's Autumn Self-protecting Broccoli still in fine condition.

Dec. 11.—Shifting Campanulas. Putting into gentle heat a few plants of *Dielytra* and *Dentzia gracilis*. Painting Muscat Vines, lightly forking over the surface of the border, and adding a little more fresh loam to it. Fumigating Cinerarias and Cucumbers to kill green fly. Clearing all leaves and rubbish out of all the spouting; also all catchpools, so that heavy storms may pass off freely.

Dec. 12.—Getting into the forcing-pits more Lily of the Valley, Hyacinths, Narcissi, Tulips, and Cyclamens. Covering up more E-dive and Lettuce to blanch. Levelling ground in pleasure grounds, and laying down new turf. Looking over fruit room, and clearing away any fruits that are decaying.

Dec. 13.—Getting in 100 pots of Osborn's Forcing French Beans, and adding a little more earth to those already up. Forking up shrubbery borders, and getting them filled with spring flowering plants. Getting a pit filled with leaves in which to plunge Strawberry plants. Pushing on with trenching as fast as the weather will permit. Looking over the Pines, watering and tying up all that require it.

Dec. 14.—Clearing up pleasure grounds, and rolling down all gravel firmly. Looking over Grapes in bottles, removing any that are bad, and filling up the bottles where required. Thinning-out Mignonette, and tying up that which is in a more forward state. Fruit in use for dessert—Pines, Grapes, Pears, Apples, Medlars, and Nuts.—W. G. P., Dorset.

Lata Peas.—Dr. Maclean I have found to be a good Pea for late use; the last dish gathered here this season was on October 25. With me this has not been a good season for late Peas.—W. DIVERS, Wierton, near Maidstone.

THE FRUIT GARDEN.

STEEL BRUSHES FOR FRUIT TREES.

As an improvement on the old-fashioned fruit-tree scraper, Dr. Lucas, Director of the Rentlingen Pomological Institution, recommends steel brushes, made as shown in the accompanying illustrations. He has found them very efficacious in removing Moss, Lichen, American blight, &c., and dislodging the different insects which infest the bark. According to the description of tree, and part to be scrubbed, should the preference be given to one or other kind of brush. Whilst in the case of young trees the curved brush (fig. 1), with handle and

Fig. 1.

shorter wires, answers the purpose best, in that of older ones a somewhat larger brush—say 3 in. broad instead of 1½ in., by 11½ in. in length—with longer wires is found more useful; and, when it is desired to scrape the branches of tall trees, the operator has in fig. 2 a very suitable brush, a long rod being fitted into

Fig. 2.

the hole. In the brushes made by Mr. Petzhold, of Chemnitz, in Saxony—those tested by Dr. Lucas—to meet all wants or fancies, the wires vary not only in length and strength, but also in arrangement, being sometimes in clusters or circles, and sometimes in rows. The price of the brushes ranges between 3s. and 4s. T. S.

FORMING NEW RASPBERRY PLANTATIONS.

ALTHOUGH the Raspberry is not a favourite fruit for dessert, it is much valued for preserving in various ways, and for such purposes I grow it extensively. The best way of increasing the stock of Raspberries is to make plants of the young side growths or suckers. Healthy old plants always throw out quantities of them during summer, and now, just when the leaves are falling, is the time to detach them with the view of making new plantations; but, after trying them in various ways, I do not like to make permanent plantations of them just as they are taken off. Allowing them to grow in what might be termed nursery beds for one season after they are detached from the parent plants is the best way of treating them. This being decided on, before beginning to take up the suckers a piece of rich ground should be selected in which to plant them as they are taken off. They will thrive in a partially shaded spot, provided it is exposed to the sun one-half of the day. For the first year I generally plant mine in front of a wall with an east aspect, so that they get the morning sun, but none in the afternoon. Where the ground is not previously rich, a good coating of manure should be spread over it and dug in as the plants are set. Roots with a single stem to them—and this is quite enough for any young plant—may be planted 6 in. asunder in rows 15 in. or 18 in. apart. In planting, the root should be placed about 3 in. below the surface, which should be firmly trodden. When this is done properly the young plants require no support the first season. The canes formed this year should be left as they are until spring, and just before they begin to grow each should be shortened back to 6 in. from the ground. This does not weaken the plant, but rather strengthens it, as it keeps it from flowering or bearing fruit, and throws the

strength into the roots, from which the canes spring. Two, or at most three, canes are quite enough for any plant to bear during the first season; and it is well to reduce them always to this in order to give them a fair chance of being properly developed and ripened. Thick, well-ripened canes, about 4 ft. or 5 ft. high, are the kind most to be desired at the end of the season, as such will bear good crops the following year.

As soon as the leaves fall in autumn they may be planted in their permanent fruiting quarters, and this may be done throughout the winter until shortly before they start into growth. The ground to receive them should be trenched to the depth of 20 in. or 2 ft., and the whole of this depth should be well enriched with good manure. Where the ground has been properly prepared, and the after culture attended to in an ordinary way, Raspberries will bear good crops for ten or twelve years, therefore, securing good crops of fruit annually for this length of time is worth being careful in the preparation of the plantation at first. In trenching and manuring the ground the whole of it should be done before planting is begun. In planting, sometimes a row is put in one part of the garden and a row in another; but I do not approve of this plan, as it is inconvenient in more ways than one, especially as regards protecting the fruit. Half-a-dozen rows about 150 ft. long will yield a large quantity of fruit. Where the rows are together in one quarter they should be placed from 6 ft. to 8 ft. apart. In open positions the first distance is sufficient, in shady places the latter will answer the purpose. I have grown Raspberries with a stake to each root, training the stems around it, and I have also had them with the canes bent from root to root, tying them together so as to form an arch, but I now grow them nearly exclusively trained to a wood fence-like trellis. This consists of posts fixed in the ground 8 ft. apart and 5 ft. above ground, one rail being 6 in. from the top and another 3 ft. from the ground. The roots are planted along the bottom in a line with the rails 1 ft. apart. Two canes are taken from each root and tied 6 in. apart on the trellis. When a root dies a few more canes may be taken up from other roots to fill up the gap. As to pruning and training generally, it is a mistake to allow too many young canes to grow during the summer. After they are fairly above ground all the weakest should be cut away close to the ground or a little under it, leaving only those which are necessary to replace the old canes; of course where young stock is wanted shoots must be left, selecting such as come up farthest from the row, as they can be lifted without disturbing the old roots. Many injure their Raspberries by allowing the old canes, after they have done fruiting, and the younger ones for the following year, to grow into a close mass, especially in autumn, just at the time when the young canes require all the light and air available to mature their wood for bearing a full crop the following year. During September, after the fruit has been gathered, and when the canes which have produced it are beginning to wither, every one of them should be cut away and the young canes tied in their place. This is an excellent way of ripening them thoroughly, and one of the surest ways of insuring a heavy crop. Where the ground is in good order when they are planted, it is some years before they require more manure, and then it is much better to apply it as a top-dressing than to dig it in deeply about the roots. They should be top-dressed now, and in light soils it is well to put a good coating on and allow it to remain as mulching during the following summer. If it be bright weather when the fruit is ripening, it should be gathered every day, as it ripens fast and decays quickly, especially in showery weather. CAMBRIAN.

ROOT-PRUNING FRUIT TREES.

As the time has arrived for renovating fruit plantations, where such a course is thought necessary, a few observations on root-pruning, replanting, and other work of that kind may not be unacceptable. I have a row of trained Pear trees in the garden here, which, not being in a satisfactory state, are being root-pruned and replanted. The style of training is worthy of notice on account of its practical utility. The whole area of the tree is fully exposed to sun and air, while, at the same time, it is protected against the violence of rough winds and the loss of fruits sustained thereby. The kind of training in question somewhat resembles the Palmette-Verrier style; at all events, it is an attempt at working the French system in a circular

form, which is novel and much admired. The circular framework is 7 ft. 2 in. in diameter, formed of iron uprights 5 ft. 6 in. in height. These uprights, which are set in stone, have holes drilled in them at about 1 ft. apart to admit of stout iron hoops being run through them; the tops of the stones are of course only level with the surface of the ground. The tree is planted in the centre of the circle, and stands upright for about 1 ft. from the ground; the shoots are then drawn horizontally till they reach the outer side of the framework, when they are trained exactly like vertical cordons and bear their fruit on short sprays. Another plan adopted is to allow the upright shoot to grow level with the top of the trellis work, and train the branches downwards instead of upwards, but, judging by the result of five years' experience, I cannot say much for the latter plan, except from an ornamental point of view; whilst I have found the former answer admirably in every respect. Our trees are on an elevated site, and run parallel with one of the garden walks. When the roots of these trees came to be examined they were found to have been planted in a rough and ready manner, in a soil not over 2 ft. in depth, which lies on a bed of clear, yellow sand. Now, according to improved ideas of fruit growing, this would evidently be a case to be treated on its own merits, and not according to every-day practice. Modern experience would suggest that the entire body of sand be removed to a depth of from 18 in. to 2 ft. below the bottom of the natural soil, because it is a well-known fact that sand is a great absorber of moisture, and that any liquid or other water applied to the roots would filter away beyond their region in a soil which, by reason of its nature and porosity, is incapable of retention to any appreciable degree. It appeared, however, in this case that the general practice of the day had been acted upon, for I found, in addition to the sand, a thick layer of lime rubbish and broken slates laid under the roots, as if to make certain that the trees should be starved into fruit bearing. What particular virtues there is in broken slates, or to what extent they can be regarded as fertilisers, I dare not hazard an opinion. Even the retention of surface moisture was guarded against by elevating the trees above the natural ground level, which sloped to the east, and, therefore, required no artificial manipulation. The object of relating this practice is not to condemn it generally, but to show what mistaken views are sometimes entertained in regard to such matters, and how simple it is to misapply what would be very good practice under circumstances the reverse of those just referred to. Before the trees were lifted I had not anticipated such a condition of things at the root, which cleared up satisfactorily the cause of the fruit being below the ordinary standard in size, and without that substance which characterises good cultivation. The slate rubble and sand were, of course, removed, and fresh, healthy soil substituted, and the planting of the trees was so managed that the base of the bole was slightly below the ground level, leaving a cup or basin round the roots. Thus circumstanced, they will not only be benefited by natural rains, but they can also be copiously supplied with liquid manure after the crops are gathered, the object for which the operation was originally taken in hand. Opposite conditions, as regards position, soil, and subsoil, would be met by using the very means condemned in the case of light soils, sloping situations, and sandy subsoils. I have seen excellent crops of fruit obtained from soils naturally tenacious and retentive by planting the trees in lines on sloping ridges, keeping the roots on the surface, and feeding them there by means of mulchings, and by giving them supplies of liquid manure. Few cases are, however, alike in all respects, and hence the necessity for rational discrimination in carrying out projected improvements.

W. HINDS.

HARDINESS OF POT STRAWBERRIES.

PROTECTING pot Strawberries from frost is a matter upon which much stress is laid by some growers, but it has yet to be proved that the roots of such plants will not stand as much frost as the foliage without injury. Our plants are never placed in winter quarters (cold frames) till they have had two or three bites from frost. This season, about the beginning of November, they had 6° of frost and were frozen through, and for the last fourteen years I do not think there has been a season in which they have not been at times frozen hard. Yet we never missed a fine crop, nor did the plants show the least signs of injury. I remember, too, when at Dalkeith Gardens, when Mr. Thomson was there, about 1860, that all the Strawberries were housed in a long unbeated Peach case, where, during a long frost, the thermometer registered (inside) 14°. The plants for a fortnight or more were hard frozen, many pots were broken; the balls of the plants expanded, so that they stood 1 in. or more above the rims of the pots, and when the thaw came they had all to be gone over and pressed down again. Yet no fear was felt for the

plants, nor did they suffer injury; all fruited as well as usual, and this happened more than once there. Since then I have never felt any alarm about our plants getting frozen so long as they were not thawed by any artificial means. Mr. Coruhill says (p. 471) the injury is more likely to happen when the roots "become dry and frozen;" but for my part I would rather see the soil dry than wet when exposed to frost. I have always understood that frost was most destructive where there was moisture. The roots of Strawberry plants in pots are quite different from those of plants growing in the ground, which are soft and tender, comparatively, because they are deep in the ground; whereas the roots of pot plants are exposed to all the changes and vicissitudes of the weather, and are consequently proportionately harder. I do not know what success may attend your correspondent's plan of growing his Strawberries two or three years in the same pots; but I much doubt the utility of the practice. Old plants, if shaken partly out and repotted about midsummer, will produce a good crop in the autumn; but keeping them on in the same pots for one or two years for regular forcing is new to me. Old pot Strawberries, like old pot Vines that have already been forced and cropped as heavily as they will bear, are not much worth, I am afraid. Growing first-rate plants from runners every year is simply a question of layering and potting in time, anywhere, I should think, between the Land's End and John O'Groats. In our late district the plants are not potted till the first week in August, but, by the time they are housed the balls are such a mass of roots that you might play at football with them. Whether in pots or planted out, my experience is that young plants propagated the summer previously always produce the finest fruit, and I am by no means the only one who has vouched for this. Referring to the hardness of the roots again, I would ask how it is that outdoor plantations are not injured by frost? We have always planted out the greater portion of our forced plants, and, owing to the bushy nature of the roots, they rarely penetrate deeper than 9 in. or 12 in., the greater portion being close to the surface; yet the plants never suffer either from "cold, drying winds" or frost, though the roots must often be hard frozen, and they never fail to bear good crops. The permanent plantations may partially fail sometimes, but the old forced plants never do, though I do not say they are to be depended upon after the first, or at the most, the second year after planting out.

J. SIMPSON.

CLIMATE OF THE NORTH OF FRANCE.

It is stated (p. 488) "that the climate of the north of France is an extremely difficult one for the fruit grower, and, on the whole, not one whit better than that of Kent and Sussex;" and, as usual, the English cultivator gets blamed for the inferiority of our hardy fruits compared with those of the French. Though your correspondent mentions the north of France, it is evident he is speaking of Paris and its neighbourhood. I certainly did think myself at one time, from what I had read, that there was not much difference between the two climates, but a visit to the north of France last August dispelled that illusion for ever. It is admitted on all hands that the past summer in England was an early one, and it is equally certain that the summer in France has been changeable and cool. The fact was commented on in the "Times," and every Frenchman to whom I put the question told the same tale. This being so, will your correspondent explain how it was that early in August grain was all cut and housed near Paris, and the stubble actually being ploughed, when in Kent and Surrey harvest had little more than begun? how it was that in and about Paris the Horse Chestnut was yellow and ripe, and about dropping off the trees, and the Spanish Chestnut proportionally forward, while in the south of England they were only filling? And will he further explain how the Bramble and Elderberry were dead ripe in Fontainebleau Forest when both were green and only swelling in the sunny lanes not far from Dover at least a week later. I gathered and eat both at Fontainebleau, and the Brambles were very large and fine. In this part of Yorkshire neither were ripe till late in October; but, above all, will your correspondent tell us how it was that Rivers' Early York Peach was quite ripe on a north wall, in the middle of August, not far from where I gathered the Blackberries, and other later sorts very nearly ripe (I saw and ate them), and that Morello Cherries had, at the same time, been long ripe and shrivelled, while in the south of England the Peach was not ripe on south walls, and Morello Cherries just changing colour, or a little more? I might also ask how Mr. Rose Charnaux, of Thomery, manages to force early Peaches into ripeness in January for the Paris market, when English growers, in the most favoured districts dare not think of forcing their earliest Peaches for two or three months later? These and numerous other signs of a superior climate strike the stranger at a glance, and, whatever the thermometers may say, I maintain that they indicate only one thing, and that is,

that the climate of the north of France is very considerably better than ours, and that it explains as much as anything else, the difference in the quality of French and English hardy fruits.

J. SIMPSON.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

The Black Hamburgh as a Late Grape.—Mr. Stevens has two housefuls of this Grape just now ripe at Trentham, the foliage showing slightly the rich tints of autumn. The Grapes themselves are everything that one could desire, being as plump and fresh as Grapes in June. The fruit in another house is partially cut, and with this Grape Mr. Stevens seems to keep up his supplies without the use of coarser varieties.—**Geo. BOLAS.**

Fruit Trees in Autumn.—With reference to the remarks of "W. N." (p. 499) on manuring fruit trees in autumn, I would like to ask how he has proved, to his own satisfaction, that the roots of fruit trees are at work all winter, "storing vigour and strength," in order to carry the trees safely through the blooming period? Has he ever observed any difference in the size of fruit buds from the end of October to the middle of February, consequent upon the autumn applications of manure? I have always held and understood that all deciduous trees rested in winter, root and branch, and that the first signs of the roots moving was the rapid swelling of the fruit buds. Hence the practice usually followed in Vine forcing of getting root and branch to go on together. Now, as to the intentions of Nature, I think "W. N." has made another mistake. The protection to the roots during winter from the fallen leaves may be very serviceable, but what nourishment can trees at rest derive from 6 in. or 8 in. of leaves lying on the ground over their roots. Nature, I think, intends the leaves to lie all winter and rot, and, on the commencement of growth in spring, the roots to lay hold of the store of food thus provided for them, enabling them thereby to maintain their existence.—**J. KNIGHT, Reading.**

Grapes without Fire-heat.—I have seen several paragraphs in THE GARDEN lately on this subject, by which one would suppose there was some difficulty in producing good Grapes without fire-heat, but such is not my experience, though I find such to be the general impression. Some years ago I had a lean-to house, facing the east, in the north of London, in which were planted the following varieties: Muscat of Alexandria, Muscat Hamburgh, Golden Hamburgh, Black Hamburgh, and Barbarossa; they all produced good, well-ripened fruit, but the Muscats did not set well, and consequently the bunches were not always well-shaped. I now have a lean-to house facing the south-west, at Willesden. I have planted in an outside, prepared border Black Hamburgh, Muscat of Alexandria, Duke of Buccleuch, Madresfield Court, and Gros Colman, and this summer I had well-ripened bunches of Black Hamburgh, Duke of Buccleuch, Muscat of Alexandria, and Gros Colman—Madresfield Court has not come into bearing yet—without the least artificial heat. The Muscats were well set, and I had to thin out about two-thirds of the berries; they were ripe and some of them eaten the last week in August. I am careful not to give too much air in the spring, but the ventilators are often not closed in proper time. In winter the house is full of bedding plants, and last summer I had Cucumbers under the Vines.—**AN AMATEUR.**

A Prolific Bullace.—At page 435 a notice and engraving are given of a Bullace said to be very prolific in Essex, about which I should be glad to hear more particulars. In the neighbourhood in which I reside we have a very prolific Damson, which I have reason to believe had its origin very near to where I now write, and which reproduces itself to any extent by suckers, as does also one or two Bullaces of a green colour, but the black one is not so commonly met with. I have, however, heard of one in Sussex, and I once listened to an argument between a grower of this Bullace and one who patronised the Damson as regards the respective merits of each for filling the basket with good marketable fruit. The grower who upheld the black Bullace came, I think, from the neighbourhood of Mayfield, and he seemed to imply that his fruit was little known except in the district from which he came, and adduced as a proof of this being the case that a local nurseryman who had discovered its merits was propagating it largely. Now, if the Bullace you speak of readily reproduces itself by means of suckers, and is as fruitful as it is represented to be, it will be a very valuable addition to our fruit lists. On this and other matters I should like to learn a little more of the fruit of which you speak so highly, and also if it be only of local origin, and thereby likely not to succeed so well when carried away from its home, as some other fruits so treated have proved unsatisfactory.—**A RETIRED GARDENER.**

THE LATE LIVERPOOL CHRYSANTHEMUM SHOW.

It is well for the Chrysanthemum that it has the redeeming property of flowering at a season when anything in the shape of a flower is acceptable. On no other consideration but the above would this fine flower be for one moment tolerated in the painfully monotonous and conventional manner in which it was exhibited, as usual, on the above occasion. On entering that magnificent structure, St. George's Hall, the eye was immediately arrested by seeing spread over the area of the hall what appeared to be a multitude of circular shields, embossed in the most regular manner with knobs of gold, silver, or bronze—like trophies, all of one type, and all seemingly moulded by the same hand. Could they have been hung on the wall the illusion would have been perfect. These were Chrysanthemums, moulded and tortured into these everlasting circles for exhibition. Had I found on entering the hall the visitors standing on their heads the sight would have been quite as natural as the forms in which the plants were exhibited—a mechanical display of floral manufacture with only one pattern and design in the whole. Is it not possible to exhibit this flower in a more natural way than this? Could not the committee of management solve this problem by offering prizes for the Chrysanthemum grown in a natural way? Surely it is worth the trial. Certain I feel that nothing but a vitiated taste, fostered by continual example, would ever countenance these unnatural distortions, where every plant appears in a straight jacket, and every individual bloom in wire handcuffs, almost rivalling the dwarfed absurdities of China and Japan. Why should the foliage of a plant be objected to? In all the floral circles exhibited no leaves were visible; all were sedulously tucked in under the frames, forming a kind of background, on which the balls of colour stood out in ridiculous relief; the beautiful undulated foliage of the crippled plants seemed totally ignored. If there be anything rational, pleasant, or enjoyable in floriculture, let it, as far as practicable, be carried to the exhibition tent; and let it not be seen that growing plants for their own sakes in the garden is one thing, and that growing them for show is only for the sake of the exhibitors. Foliage and flowers should always go together as Nature intended them. Nature is generally profuse in her bounties. Flowers are generally produced in bunches, wreaths, festoons, and garlands, and the Chrysanthemum is one of those flowers concerning which it may be said, that "the earth brought forth by handfuls." Nevertheless, in the trained exhibition specimens it would be unpardonable to see two blooms in contact, and every individual bloom must stand at a measured distance from its neighbour with a studied kind of "don't touch me" isolation. It is a pleasing circumstance to note, that the committee of management seemed fully alive to the effect produced by the monotonous display of the Chrysanthemum as commonly exhibited, and made a praiseworthy attempt to modify it. Sorry am I, however, to put it on record that the attempt was a mistake. The body of the vast Hall was transformed into a kind of *parterre*, and five large, octangular or polygonal beds (a larger one in the centre and four smaller ones in the angles), fenced round with a neat, low railing or guard on an elevated kerb a few inches high, gave these spaces a truly gardenesque appearance. The kerb and a space about 18 in. wide were covered with green baize, which gave these compartments the appearance of having a margin of fresh turf all round, effectually neutralising the gorgeous encaustic floor. The compartments were partly filled with large Tree and other fine Ferns, among which were placed, at regular distances apart, the flat, shield-like Chrysanthemums in sixes, and this spoiled the whole. The contrast between the manufactured-looking masses of flowers and the natural, drooping, arching Ferns, was painfully violent. The Ferns seemed ashamed, as it were, of their companions. Imagine a noble *Davallia Mooreana* drooping over a gaudy Chrysanthemum. It is, to say the least of it, injudicious to associate perfection with deformity, with the idea of mitigating the latter; both are sure to suffer by the contrast. Of the cut collections of Chrysanthemums I can say but little. They were magnificent examples of the perfection to which this fine flower has been brought; but here, again, I must reiterate that gardening and exhibiting were totally distinct from each other. The blooms

here, as elsewhere, were shown in the stereotyped manner—on a white ground without a particle of foliage; handsome balls of colour, dressed, most of them, in paper filigree collars, very many of them with their centres gonged out, and stuck in tin tubes to show off their rotundity. How different all these fine blooms would have looked had a sprig or two of foliage accompanied each bloom. I never considered single bloom showing to be a means to any desirable end; and I never yet saw them exhibited in a satisfactory manner, a remark which also applies to Roses, Dablias, and other flowers. Even the *Verbena* would be enhanced by being shown along with a little of its own foliage; but at present all is bloom! bloom! bloom! It would be a curious sight to see the manufactory of these enormous blooms. What a regiment of skeleton-looking plants an exhibitor of twenty-four must have, each carrying one flower! and then talk of floral beauty! I must not omit to mention that at this great representative show of the *Chrysanthemum* in the north of England there was an attempt at variety in the form of standards; and, stiff and formal as they were, they were quite a relief to the ever-recurring flat shields. I am proud to read in *THE GARDEN* that this formality is, in some degree, modified in the south. I feel certain that these remarks will make me many enemies among exhibitors, but I trust that many will also take these observations as an attempt to elevate floral exhibitions above what too often makes them contemptible. I shall reserve for another opportunity the question, Whether such vast and gorgeous edifices as St. George's Hall are the proper places in which to hold a floral exhibition?

T. WILLIAMS.

Ormskirk.

ROSES & BOUVARDIAS IN MARKET GARDENS.

FAIRY ROSES—These are grown by thousands by several market gardeners about London. They are raised from the young tops of plants inserted in sharp sandy soil in May and June. They are placed in a warm, close, house or pit until rooted, when they are potted on in good sandy loam until they are in 5-in. pots. They are then grown in airy houses, and by the following spring they are loaded with buds and rosy-coloured blossoms, the dense masses of green leaves hiding the pots. Such plants as these find a ready sale in the markets, great numbers of them being cut up and used in bouquets, the small green leaves and buds being very effective among light-coloured flowers. During the time in which the plants are coming into bloom they are arranged on stages, receive abundance of water, and are frequently fumigated to keep down insects. Many thousands of them can be placed in a comparatively small house, and when coming into bloom they present a most striking feature. In the centre of each pot is placed a stake, to which to tie the leading shoots and thus induce the plants to assume a pyramidal, though by no means a formal, shape. They grow about 9 in. high and about as much through at the base, and they form ornamental objects for some time even in a sitting room.

MOSS ROSES.—In July these form one of the most attractive features in our flower markets, large piles, baskets, and bunches being found at every turn. The white kind, though not common, is used for bouquets, and two or three red and pink sorts are supplied in enormous quantities; indeed, there is always a great demand for Moss Roses in our markets. The old Provence Roses, too, are, during summer, very plentiful and in great demand, and buds of the White Provence are very beautiful. The common Moss Rose, so well known in our cottage gardens, is not very largely cultivated by market gardeners, the reason being that it is neither robust nor floriferous enough for market purposes. The variety most preferred is a deep red kind, which, though less mossy than the common sort, produces blooms in much greater

abundance, strong shoots bearing from eight to ten buds, all of which open well, at one time, but they are never allowed to be too much expanded before they are cut, as in that case the mossy portion would be less noticeable and the value thereby reduced. To supply the great demand for Moss Roses, many market gardeners round London devote several acres of land to their culture. They are, however, seldom all grown on one spot, but are distributed about in patches, some being in a warm border sheltered on the north by a wall, hedge, or row of fruit trees, others growing right under orchard trees, and the main crop is usually found in open quarters. This arrangement is admirable, inasmuch as it affords a lengthened season of cutting. The border plants furnish the earliest blooms. These are succeeded by those under the fruit trees; and the late blooms are furnished from plants unprotected. Moss Roses are cultivated much after the same fashion as the Raspberry, with this difference, that the old wood of the Roses bears a crop two or three years in succession before it is cut away, whilst that of the Raspberry is cut away yearly. Well established plants are, however, so productive of young growths at their bases, that it is found necessary to keep the bushes well thinned of the old wood as well as the weakest of the young shoots. Moss Roses in market gardens are grown on their own roots, and probably no form of budding or grafting on any kind of stock would give the fine results obtained from these plants. They thrive well under orchard trees, and form one of the most remunerative of under crops, for, with the shelter which the overhanging boughs afford them, frost does them but little damage, although those growing in open quarters often suffer severely from late spring frosts. The plan by which the plants are sometimes increased is to lift the old stools and strip off the outside shoots, which are freely produced, and plant them in rows 2 ft. apart each way in good soil. During the first two years after planting dwarf-growing vegetable crops are sometimes taken from between the rows, but after that time, if the Roses have done well, they require all the space. During winter, as already stated, a portion of the old wood and the weakest of the young growths are removed. Robust shoots, too, are shortened back, the soil is lightly forked over, and a good mulching of rotten manure applied. In this state the plants remain until the buds are ready for cutting, when they are gathered every other morning for market, the whole truss being removed at the same time with a few leaves attached. Some growers plant Moss Roses between bush fruit trees, but it is a bad practice, inasmuch as in a short time they form a complete thicket, much to the injury of both crops. Where no fruit bushes exist the rows are intercropped with Brussels Sprouts, Shallots, Broccoli, or some similar crop. The Rose trees after blooming are sometimes layered on both sides of the row and firmly pegged down; and, during the summer, these layers, which will have rooted, are lifted, and after being trimmed are planted in rows, as before described. By this method healthy young plants are obtained without in any way destroying the existing plantations. Moss Roses and Pheasant's-eye Narcissus are sometimes grown in rows alternately. The Narcissi are generally over before the Roses are in leaf, and thus neither crop is in any way injured. In the middle of July the streets of London are full of women selling Moss Roses which have been surrounded by a little sprig of Fern or their own leaves, and wired ready for the coat. The sale is immense, and these women gain good profits thereby. The usual price

is 1d. each, or a bunch of from eight to ten may be bought early in the morning for 6d. in the height of the Rose season.

BOUVARDIAS.—These are popular plants in our flower markets, either the plants themselves or their blooms being offered for sale during the greater part of the year. For bouquet making the white-flowered kinds are especially useful; indeed, seldom is a bouquet made which does not contain some Bouvardia blossoms. The old *B. jasminiflora* still remains one of the best kinds for market purposes. Its dwarf, compact habit of growth and its floriferous qualities, together with its easy culture, render it a favourite with everyone. One grower alone near London yearly disposes of from 20,000 to 30,000 plants of it; others grow it more for its blooms, and in that case it is grown in larger pots. The only scarlet-flowered kind grown to any extent is *B. Hogarthi*, which in habit resembles *B. jasminiflora*; it produces abundance of bright blossoms which are very effective amongst white flowers. For spring-flowering, a large white-flowered kind named *B. jasminiflora corymbiflora* is now grown to some extent. Its flowers are deliciously fragrant and much larger than those of any other kind in cultivation. Its chief value, however, is its blossoms in a cut state, for the plant is too rampant a grower ever to become a good market plant; only bushy little plants in 6-in. pots laden with blooms find favour in Covent Garden. The difference in the plants of Bouvardias as seen in Covent Garden and those usually met with in private gardens is very marked. Country growers, as a rule, use the knife too sparingly in the case of Bouvardias, and, therefore, instead of dwarf bushy specimens clothed with healthy green foliage down to the rims of the pots, as seen in the market, we find long, spindly plants with miserable-looking shrivelled-up leaves, and a few solitary sprays of flowers. I do not mean to say that all grow such miserable plants, but, as a rule, few good ones can be found in private gardens. Messrs. Low & Co., of Clapton, are the largest cultivators of Bouvardias in pots, and the way in which they grow them is as follows: In autumn old plants which have done flowering are cut down, nearly close to the pot, and placed in a moderately cool, dry temperature. After Christmas is over a little more heat is given them, and they are frequently syringed overhead; this has the effect of starting into growth a number of shoots from the bases of the plants. These, when sufficiently firm, are taken off, made into cuttings, inserted singly in 3-in. pots, and plunged in Cocoa-nut fibre on a gentle bottom-heat. These cuttings, under favourable circumstances, soon strike root, when they are potted in 5-in. and 6-in. pots in good fibrous loam and leaf-mould or rotten manure. As they advance in growth they are subjected to a cooler and more airy temperature than that in which they were struck, and when well established all the light, air, and sunshine possible are admitted to them, and they receive copious supplies of water at their roots. From these plants cuttings are taken with which to form a successional batch of plants; they are taken off when the plants have made three or four leaves, the two lower joints only being left on the plants. From these joints strong shoots are soon emitted; these when 4 in. or 5 in. long are also stopped, and this operation is carried on in the same manner for four or five times, each set of cuttings being treated in the same way. Those struck first in the year make excellent bushy-flowering plants by the following autumn, and the last taken off, which is in August and September, make good plants to bloom in the succeeding

spring. The old plants, from which the cuttings were first taken, are also shaken out and potted, and they make bushy, well-flowered plants early in the summer. In order to make large specimens, which, however, is seldom done in market gardens (except for supplying cut blooms), old plants are cut back year after year and shaken out and repotted. During summer Bouvardias are grown in cool houses or pits, and sometimes in temporary frames, but in autumn, winter, and spring a moist, airy temperature of from 50° to 55° is maintained, excepting in severe weather, when a little lower temperature does not injure them. During late years some growers plant out their Bouvardias in the open air in summer, a plan by which good plants may be obtained with less labour and expense than in the case of those grown in pots. It, however, becomes a question whether they are so valuable to the buyer as well-established pot plants, but that, with growers for market, stands for nothing. For planting out cuttings are inserted early in February, stopped in the same way as before mentioned, and, after being duly hardened off, are planted out about 2 ft. apart in well-prepared ground the first week in June. During summer they are kept well supplied with manure water, the surface soil is kept well stirred with the hoe, and sometimes a mulching of manure is applied. In the first week of September, when the shoots show bloom, the plants are carefully lifted and potted, and, after being well watered overhead and at the roots, are placed in cold frames, and kept close and shaded until re-established; after that they are again exposed to air and sunshine, and when the weather gets cold they are placed in houses or warm pits near the glass. By this means strong, bushy, well-flowered specimens are obtained during the winter months which need no staking or support in any way. Indeed, under no circumstances do market growers stake Bouvardias, beyond placing a neat deal stick in the centre of each plant, so as to support the branches in a manner to form neat, but by no means formal, conical or pyramidal-shaped plants. C. W. S.

DROUGHT-RESISTING ROSE STOCK.

I AM afraid that what I wrote lately in THE GARDEN has led some of your readers to conclusions which I certainly did not intend to suggest—viz., that the wild Portuguese Rose stock mentioned at p. 218, resists drought better than the Brier. I cannot answer for its doing so. It certainly resists the scorching heat of the sun better than the Brier does, but this is quite another matter. I will try to explain my meaning. In this part of Portugal not a drop of rain falls from June to September, and as there are no dews during these months, and plenty of hot dry winds, one can say without exaggeration that we have three months at least of absolute drought every summer, when gardens must be continually and copiously watered. Kitchen gardens, orchards, Orange and Lemon groves are irrigated. Our Rose trees are thus not exposed to positive drought; but all the watering and mulching in the world will not prevent the fiery summer sun from striking in full force on the bare Brier stocks, and that is what plays such havoc with them; and it is in this particular that we find the new stock does better. As a rule I am inclined to believe that no budded Rose stock will resist drought, however well the stock may do so in its natural unbudded state. I have a large piece of ground on a hill side, therefore naturally drained. The soil is of a stiff, red, argillous nature, and the place is planted with trees and shrubs, combined with a sort of wild garden. During summer it is positively nothing but a desolate parched up wilderness, for the plants are merely watered during the first summer or so, that is until they get a firm hold of the ground, after which no cultivation of any kind is given to them. Once the autumn rains come on the plants look up immediately. The foliage is all that can be desired. Flowers we have in abundance, and so they continue until the summer comes round again, which is in reality their time of repose. Of course many plants will not stand this rough treatment, but we have many we can fall back upon for the purpose. Let me mention the

Myrtle, Bay Laurel, Box, Pittosporums, Brooma, Arbutus, Ruscus, Brier, Manetti, and many of the old Roses, including some of the Hybrid Perpetuals, such as La Reine, which does wonderfully, on its own roots of course. Sweet Peas sow themselves and flower in profusion. Belladonna and Guernsey Lilies, Iris, Narcissus and Oxalis are quite at home. All these and many more succeed under three months of absolute drought, and a burning sun into the bargain; but I should never expect a budded Rose to stand this treatment. What is said about the constitution of modern Roses is very much to the purpose, for there can be no doubt that, however improved the flowers may be, many of the new Hybrid Perpetuals have fallen off in more than a proportionate degree as regards vigour and constitution. We ought not, therefore, to abandon the old Roses, which for many purposes are superior to the new, and I am sorry to say I meet with great difficulty in procuring them. Moreover, almost all these modern Hybrid Perpetuals are perpetuals only in name, at least in this climate. Not so the trees, they are perfectly evergreen here, and flower almost all the year round—that is I can always count on a few Tea Rose buds if I require them. I have another complaint to make: many of the new Teas are so in all but one very essential point; there is not the faintest tea scent about them. C. T.

The Guelder Rose.—This being a suitable time for planting trees and shrubs of all kinds, attention may be usefully directed to this very ornamental and effective flowering plant, which, when its merits are considered, is perhaps less extensively planted than it ought to be. It is no recent introduction; on the contrary, it has been more or less cultivated in this and other European countries for many years. It is the sterile form of the *Viburnum Opulus*, and is variously known as the *Boule de Neige*, or *Snowball tree*, *Whitewash Bush*, *Rose Elder*, *King's Crown*, &c. It is a hardy, deciduous, flowering shrub, of rapid development, and is by no means particular as to soil and situation. It also readily submits to cutting back, in cases where the plants may have attained undue dimensions, and when this is found necessary, the operation should be performed soon after the plants have ceased to flower. The flowering season is during May and June, and at that time the mixed shrubbery can hardly boast of more beautiful objects than specimens of this plant profusely loaded with large globular trusses of pure white flowers, that so well sustain its most popular name of *Snowball tree*. On close inspection it will be found that the individual blooms composing the truss or ball are entirely destitute of stamens and pistils; consequently, no seed is produced, but the plant is readily increased by means of cuttings or layers. In addition to its use as an ornamental plant for the shrubbery border, it is also found to be useful for purposes of forcing, as it can easily be induced to produce its flowers during winter and early spring, when white flowers are always so acceptable. Plants of it to be used for this purpose should be annually transplanted and kept cut into a desirable form and size, and plants intended for forcing during the ensuing winter should be lifted and potted in October, sheltered from frost in any cool structure, and introduced to the forcing house as required.—P. GRIEVE, *Culford, Bury St. Edmunds*.

Wintering Bedding Calceolarias.—The uninjured are very apt to err in the winter treatment of these plants. They should by no means be introduced into a dry, airy structure, but be kept in a brick pit, leaving air on constantly, and closing and covering them over in sharp weather. In February dip the tops in Tobacco water, to kill green fly; harden off, and plant out early in April, covering each plant with a flower-pot on frosty nights. Such treatment will ensure a hardy constitution and vigorous growth, and will reduce the ravages of the *Calceolaria* disease to a minimum.—J. CORNHILL.

Perpetual Carnations Planted Out.—I think it is not generally known that these are quite as hardy as the common Clove or exhibition Carnation—at least, as hardy as the latter. I plant out all the small plants and others I do not want to pot, and all the old plants that have been grown in pots after flowering, and I find that all stand the ordeal as well as any variety we have planted out. The tree or perpetual varieties are to the others what a summer Rose is to a hybrid perpetual. We get more or less blooms through the summer and autumn; indeed, by planting a goodly number of them, we may depend that whenever a Rosebud can be got we may have a Carnation as well; and, unlike the Rose, if the plants throw up a fine stock of buds too late to be reasonably expected to open well, we can pot them, and place them where they will open. My advice, then, is to plant plenty of the perpetual varieties.—“Field.”

NOTES FROM KEW.

HARDY SHRUB.—Quite uninjured by the wet and frosts we have lately experienced, *Elaeagnus glabra* is producing in great abundance its fragrant blossoms; these, though not showy, make the plant well worthy of mention, not only by reason of their sweet scent and numbers, but also on account of their lasting so long during the dull, late autumn season. This Japanese shrub makes a dense bush below and above, throws out yearly long, straggling shoots, which are of a deep red-brown colour because of their dense covering of rusty scales; the old leaves, however, become smooth above as they grow older, and then assume a very deep green colour.

GREENHOUSE PLANTS.—At present one of the most distinct and handsome plants for cool house decoration is *Clivia Gardenii*, a South African herb, found on tracts near the Great Fish River; it flowers very freely during the winter months, and remains a considerable time in full beauty. Its leaves are long, dark green, and strap shaped, and its stout, erect scapes bear many-flowered umbels of curved blossoms, about 2 in. in length, which are a dull orange or brick red passing into yellow and again becoming greenish near the somewhat funnel-shaped mouth. *Antholyza prealta*, another Cape plant, is also well worth growing; it has upright, sword-shaped leaves, of a pleasing light green colour, and tall stems bearing numerous orange-scarlet flowers; this plant is of the easiest cultivation, merely requiring a season of rest, like most of its relations from the same region, and to be kept free from frost. *Raphiolepis salicifolia* is a pretty Rosaceous shrub, with narrow, toothed leaves; the twigs are terminated by panicles of pleasing blossoms, the white corollas of which contrast well with the reddish calyces. Scarcely requiring more than shelter from frost, this would make a good corridor plant, valuable from its flowering at a somewhat dull season. *Malvastrum capense*, a charming South African Mallow, is in good flower; it is a neat-growing little bush (almost continually in bloom), with small leaved and white blossoms tinged with rose. *Bucklandia populnea* attains a height of about 80 ft., and is one of the finest trees of the temperate Himalayas from Nepal to Bhotan, where it grows at elevations of from 5000 ft. to 8000 ft.; it is also found on the Khasia Hills at elevations of from 4000 ft. to 6000 ft. It is quite a recent introduction to British gardens, and would make a handsome conservatory plant. It has large, heart-shaped leaves, light green with reddish veins, the under surface of the young leaves being of a warm flesh colour. Sir Joseph—then Dr.—Hooker, in his “*Journal of a Naturalist in the Himalayas*,” thus speaks of it: “A magnificent tree of *Bucklandia*, one of the most beautiful evergreens in Sikkim, grew near this village (Headon); it had a trunk 21 ft. 7 in. in girth at 5 ft. from the ground, and was unbranched for 40 ft. Ferns and the beautiful air-plant, *Coclogyne Wallichii*, grew on its branches with other Orchids, while *Clematis* and *Stauntonia* climbed the trunk.” The author adds that this superb tree, which was then a great *desideratum* in our gardens, would probably thrive in the open air in the warm west of England. Its wood is brown and not valuable as timber, but the thick, bright, glossy, evergreen foliage is particularly handsome, and so is the form of the crown. *Yucca Mooreana* is one of the few plants now in flower in Mr. Peacock's fine succulent collection exhibited in one of the octagonal compartments of the winter garden; it has large, dark green, rigid, spreading leaves, and a large panicle of white blossoms. *Gasteria Peacockii* is the only other plant of importance in bloom; it is one of the most handsome, in point of beauty of the flowers, of all the *Gasterias*. The slightly curved leaves are deeply channelled in the middle, and of a light green colour, having here and there whitish spots.

STOVE PLANTS.—*Scutellaria violacea robusta* is a very neat-habited and desirable flowering plant; it grows about 12 in. or 18 in. high, and every one of its shoots is terminated by a long, upright raceme of beautiful violet-blue blossoms. *Pitcairnia australis* deserves cultivation, even in very select collections of stove plants; it is a very handsome Chilean Bromeliad with long, glossy, light green, strap-shaped leaves, and an upright scape, bearing a fine spike of numerous brilliant scarlet blossoms, each measuring nearly 2 in. in length.—†

NOTES OF THE WEEK.

Yuccas in the Isle of Wight.—Captain Lowther has in his garden at Thornton, Ryde, a large and fine specimen of *Y. gloriosa* now in flower. It is a single plant about fourteen or fifteen years old, and it is bearing eleven spikes of flowers, not all, however, fully expanded. Its dimensions are as follows: circumference about 5 ft. from the ground, 24 ft.; girth of trunk at ground, 1 ft. 10 in.; height (highest foliage) 6 ft. 6 in.; to top of flower-stalks, 8 ft. 6 in.

New Double White Pelargonium.—What is likely to prove the best double white Pelargonium which we have yet seen is now flowering in Messrs. Carters' nursery at Forest Hill. It is of dwarf habit, and does not grow so vigorously as most of the double zonal Pelargoniums, whilst its flowers are produced very freely, and they are very double and pure white. For winter flowering it will, doubtless, prove valuable. It has not yet been named.

Cycas revoluta in Fruit.—A large specimen of this *Cycas*, which is sometimes called, but erroneously, the Sago Palm, is now fruiting freely in Mr. Laing's nursery at Forest Hill. The fruit, which is bright red, and covered with a white woolly tomentum, is produced in opposite pairs sideways on stalks of a brown tough character. The plant in question bears some hundreds of fruits, which are about as large as Chestnuts, and it is also throwing up a fine whorl of new leaves.

Adiantum palmatum.—When better known than it is, this Fern promises to be more largely grown than even *A. Farleyense*. Its pinnae resemble those of *A. Farleyense*, except that they are set wider apart, on dark, wiry stems, and are of a deep green colour. It is much hardier than *A. Farleyense*; therefore, it will be more useful for indoor decoration, and it is, moreover, on account of its less dense habit, not so likely to be affected by damp. Grown in baskets or vases, it is exceedingly effective, and it will also make an excellent pot plant for table decoration. We saw lately good examples of it in the Holloway nurseries.

Dahlia imperialis.—One of the most interesting and beautiful plants in flower at Kew at the present time is this truly Imperial Dahlia, some specimens of which are flowering freely in the Palm house. It is difficult to intelligibly describe without an artist's aid the chaste beauty of its flowers, so different are they from those of the ordinary garden varieties. The flowers, which are single, are borne in loose terminal clusters, and assume a somewhat nodding position. They measure about 6 in. across, and have many narrow pointed ray florets of a pure white colour, tinted with carmine at the base, colours which contrast finely with the bright yellow centre. The foliage, too, is handsome, being much larger and more divided than that of the ordinary Dahlia. Altogether, it is a stately plant, forming specimens from 6 ft. to 8 ft., though perhaps this is a point which deters many from growing it, as it requires the protection of glass in order to flower it, though it may be grown outside until early frosts set in. It is to be regretted that this fine plant produces its flowers so late that they cannot be enjoyed in the open air in our climate. Something, however, might possibly be done in the way of hybridising it with earlier and dwarfer species, and notably with the beautiful little *D. glabrata*, which, being of very dwarf habit, would probably infuse a dwarfer growth into the *D. imperialis*, while the colour of the flowers might not be materially affected by it as those of *glabrata* are almost pure white, varying to deep marve. A coloured illustration of this Dahlia, with descriptions of other species, will be found in Vol. XII. of THE GARDEN.—W.

Orchids in Flower at York.—In the houses devoted to Orchids, in Messrs. Ackhouse's establishment at York, I observed the other day the following kinds in flower, viz.:—*Cattleya maxima*, a considerable number of fine healthy plants, apparently all imported; their flowers varied considerably, from a light delicate pink to deep rose, the lip being white and heavily veined with deep rosy purple. They also varied in the width of the petals and labellum. Some of the varieties were extremely handsome. *Cattleya Penillii* was also in flower; it is quite distinct from *C. maxima*, being much dwarfer (4 in. to 6 in. high); it is indeed a little gem. The flowers are almost circular, of a lovely purple colour with a deep crimson lip. Another kind which attracted attention was *Oncidium Rogersi*, a species sufficient in itself to enliven any house, so bright and numerous are its blossoms. They are borne on robust, branching, arching stems from 20 in. to 30 in. long, and numbering as many as from thirty to ninety each, from 1½ in. to 2 in. in diameter. I also noticed a singularly beautiful Lady's Slipper—*Cypripedium Hartwegi*, which is a native of the West Indies. It is distinguishable from most other kinds by the large purplish bracts, which are arranged alternately throughout the entire length of the flower stem. The flowers, too, are singularly beautiful; in colour they are of an almost indescribable combination of green, yellow and cream, prettily veined with light purple. The

petals are long, slightly twisted, merging near the apex into deep purple. Pistons had been in fine condition about ten days ago, and there were still a few scattered blossoms on three or four species. I also noticed many fine masses of the true *Odontoglossum Rossi majne*, the flowers of which are white, the sepals and base of the petals being heavily blotched with chocolate pink. They have a scent resembling that of violets.—F. A. P.

Orchids Effectively Arranged.—A fine effect is produced in one of the Orchid houses in Messrs. Rollison's nursery, Tooting, by intermixing numerous well-grown flowering plants of *Lælia autumnalis* and Lady's-slippers amongst a thicket of strong spikes of *Calanthe vestita*, the whole being backed up by Vandas and similar tall-growing Orchids.

Open-air Flowers in December.—Stocks, Pansies, and, best of all, the old China Roses, are lovely here on, or sheltered by sunny walls. A plant of the old crimson China Rose is a picture, having on it over a hundred open flowers and buds. Clumps of scarlet Tritomas and feathery Pampas Grass also preserve their beauty wonderfully, although we have had a snowstorm or two and several degrees of frost.—F. W. B., Oakham.

Absorption of Moisture by the Green Parts of Plants.—In another column will be found notes of a lecture delivered by the Rev. G. Henslow on this subject. It appears that earlier experimenters were fully persuaded that leaves could and did absorb dew and rain. Duchartre, in 1857, reversed this view. Mr. Henslow now maintains, from his own experiments, that absorption does take place soon after the sun has risen, and under other predisposing circumstances; thus the common notion of cultivators is right, and the late current teaching of science wrong.

Neja gracilis.—This graceful little plant is still flowering freely in Mr. Parker's nursery at Tooting. Besides being one of the best rock plants in cultivation, it is also attractive in narrow borders, and it would probably make a good winter-flowering pot plant indoors. It blooms all through the summer and autumn, and until very severe frosts occur in winter.

Odontoglossum Warczewiczii.—This rare and pretty Orchid is now in flower in Mr. Williams' nursery at Holloway. Its blossoms appear to be intermediate between those of *O. vexillarium* and *O. Keezli*, but they are different in form to either of these kinds. It will be appreciated by Orchid growers if only for the sake of producing variety.

Primulas at Forest Hill.—Messrs. Carter & Co. have just now, considering the earliness of the season, a large and attractive display of single-flowered Primulas in their nursery at Forest Hill. The blooms are large and well varied in colour, and the plants are dwarf and bushy, some of them having very ornamental Fern-like foliage. They are the produce of seed sown early in summer, and their richly-coloured flowers serve to show the excellence of the "strain."

Zonal Pelargoniums in Winter.—The fine displays of cut blooms of zonal Pelargoniums exhibited lately at South Kensington and elsewhere by Mr. Cannell, Swanley, serve to illustrate, not only to what perfection these flowers have been brought, but also what fine displays well-managed plants of selected sorts are capable of affording at this dull season of the year. Every one who possesses a conservatory knows that in order to keep it well stocked with flowers at all seasons zonal Pelargoniums are almost indispensable. That there are now kinds which flower best in winter, and which possess a variety of colour unequalled as regards effect by those of any other class of plants at this season of the year, was fully proved by those shown by Mr. Cannell, and also by a large household of plants at the present time in a blaze of bloom in the nurseries at Swanley.

Tree Carnations.—There is just now a fine display of these in a cool house in the Pine-apple Nursery, the produce of plants struck from cuttings placed in heat ten months ago. They are in 6 in. pots, and have been out in cold frames all the summer. As their buds begin to swell, they are moved into a cool house to flower. Each plant produces from six to eight fine blooms, which are not only ornamental on the plants, but very valuable in a cut state. Considering how easily such plants can be obtained, and in such a short time, the wonder is that private growers, with only even a small house at command, do not grow these Carnations more largely than they do. Any one, indeed, possessing a small frame might have plants of these Carnations for their windows in winter. A little heat might be obtained in the frame in which to strike the cuttings by means of leaves or manure, and the plants might then remain in it until they showed bloom. Among the best kinds now in flower at Messrs. Henderson's may be mentioned: Princess of Wales, pure white; Irma, bright rosy-carmine, large and fine; Florentine, brilliant-scarlet; Angeline, white, edged and striped with pink; Miss Jolliffe, flesh-coloured; Lydia, yellow, edged and striped with carmine; Lily, white, edged and blotched with rich bluish-purple.

ANSWERS TO CORRESPONDENTS.

Black Fly on Cherry Trees.—If your correspondent (p. 501) will syringe his Morello Cherry trees with a moderately strong dose of Tobacco water the black fly will be found to quickly disappear.—W. C.

— Of all insect pests that affect fruit trees black fly is the most difficult to kill without injuring the young tender shoots it infests, and the only way I could ever accomplish its destruction with safety, as regards the trees, was by means of a decoction of Tobacco and Quassia chips with a little soda and soft soap in it, the soda being necessary on account of its oily coating, which repels water as effectually as the feathers of a duck's back. The most economical way of applying the liquid is to carry it in a light tin bowl or other broad open vessel of that kind and dip the tips of the branches in, which any expert, handy man can do at a quick rate. We always make a practice of going over ours in this way before nailing in, and if your correspondent "B. S." does likewise he will have no farther difficulty in keeping his Cherry trees clean.—S. D.

— Tobacco water is still the best and safest insecticide for black fly on trees out-of-doors. In houses and pits it is, of course, got rid of by fumigating with Tobacco paper. Paraffin when applied at a strength sufficient to kill aphides, scale, or mealy bug, will destroy the foliage of any plant with which I am acquainted; in fact, soft-wooded plants never recover from its effects. I have even known it to prove fatal to Vines when applied as a test for destroying mealy bug.—T. COWBURN.

— "B. S." will find that the following mixture will kill black fly, viz., 2 lb. of Quassia chips, 1½ lb. soft soap, and 1 lb. of sulphur; put these into a pail, and then pour over them 6 quarts of boiling water; stir the whole with a stick, and then cover it over with a sack; let it stand for a week, when it should be strained through a piece of thin shading. This dose, bottle it off and cork it down, and the longer it remains before being used the better. Of this, "B. S." should put 1½ pints into 3 gallons of clean water, and apply it to his infested Cherry trees with a syringe. I always like to apply it in the evening, and next morning give a thorough syringing with clean water. I have always found this mixture, when persevered with, to have the desired effect.—J. J., Co. Cork.

— If "B. S." will fumigate his trees that are affected with black fly two nights in succession with Griffith & Avis's Tobacco paper I will guarantee him safe immunity from this most troublesome pest. A better way still is to fumigate in the evening and again early in the morning, at least two hours before the sun has any power. Of course the house in which they are fumigated must be thoroughly filled with the fumes of the Tobacco or the cure will not be effectual.—D. THOMAS, Drayton Manor.

Paraffin Oil as an Insecticide.—Mr. Harris (p. 501) offers a valuable word of caution respecting the use of paraffin for destroying scale and mealy bug. Having on the back wall of a stove a good-sized Stephanotis, which has hitherto baffled all attempts to clear it of the above-mentioned pests, I resolved to try paraffin. The plant was accordingly well syringed with a mixture of one wineglassful of paraffin to four gallons of cold water, one man keeping it constantly agitated, while a second applied it. Both scale and bug were killed, and the plant was somewhat damaged. Nearly one-third of the leaves have since fallen off. I also tried paraffin on the old *Eranthemum pulchellum* with the same result. Epiceries do not seem to be injured by its use, but I find that one dose is not sufficient to thoroughly cleanse them from white scale.—W. M. STICKLAND, *Hopwood Hall*.

Will Rabbits Eat Jerusalem Artichokes?—My experience is that rabbits, and more especially hares, will not only eat the tops of Jerusalem Artichokes, but will scratch down and devour the tubers. During several years' experience in game-preserving districts I do not remember a single season in which this Artichoke escaped. Our remedy was to dust the tops with soot and lime, and in the autumn, as soon as the roots were fit for lifting, or before hard weather set in, to lift and store the tubers in cool cellars. Your correspondent (p. 477) will do well to follow Mr. Hobday's advice, and securely fence in the ground with galvanised wire netting, as it is surprising how hares and rabbits attack newly-planted subjects almost indiscriminately. Mr. Fish says this Artichoke "is a dainty dish," but I can nevertheless assure him that not one per cent. of the population of rural districts would accept it as a gift. For this reason its cultivation has been neglected, and it is usually consigned to some out-of-the-way corner, or used as a screen to hide dwarfier vegetables from view. Jerusalem Artichokes would, however, repay a little careful attention, as they yield abundant returns.—J. GROOM, *Linton Park*.

Clearing a Herbaceous Garden of Weeds (page 477).—The best way of dealing with weeds in a neglected herbaceous garden is to dig up the bulbs and plants carefully, and trench the whole of the ground, as, from the neglected state it is in, it must be greatly impoverished. In doing this, however, there is one thing to be avoided, and that is, bringing the subsoil to the top, the inert condition of which is always such that it takes years of aërating and exposure, with mending and top-dressing, before the roots of plants will take to it kindly. Were it not for this, it would be advisable to get rid of the weedy portion by burying it below; but if the surface be turned under and kept at a depth of from 6 in. to 9 in., there are very few weeds, except Dock, Dandelion, and such as may be picked out, that will ever find their way through again. The trenching will afford an opportunity of working in a good dressing of leaf-soil or manure, or both, according to the character of the land

to be treated; but whichever is used should be thoroughly decomposed and well incorporated during the process of digging. Herbaceous plants are such gross feeders that the greater part of them are much benefited by an overhauling of this kind occasionally, and the present is a good time to carry it out, as they may be divided or reduced in size with the greatest safety. In arranging them again it is highly important that the planter should know the different varieties, the height and size they attain, &c., to enable him to place them for effect, and afford the necessary room for their growth and future development. There are so many things that associate with herbaceous plants, and that are so well adapted for filling up vacant spaces among them, that it is always best to place the permanent plants at wide intervals, and fill up between with Gladioli and such like, which will give an additional charm to the border. The planting complete, the next thing is to afford a good mulching of leaf soil, which will not only act as a capital non-conductor in preventing frost reaching the mutilated roots and cut parts where the divisions have been made, but will also help materially in smothering weeds that will come from seeds with which the ground is stocked. Not only is the fine leaf-soil of value now and in spring for the above-named purposes, but it is of great use likewise during the summer, owing to the shade it affords and the way it intercepts the escape of moisture by evaporation when the air is hot and dry.—S. D.

Lamium striatum.—In reply to Mr. Williams (p. 502), I may state that this is an old plant. I have known it for fifteen years under this name, but it is probably inaccurate, as I find no mention of it in Loudon, though it occurs in Steudel's "Nomenclator Botanicus." I have always thought it might be a variety of *L. purpureum*, as the flowers and stem are red, and it blooms in the winter. The name *striatum* is tolerably appropriate as applied to the variegation, as it forms a band down the centre of the leaf.—J. CORNHILL.

Quickly-grown Pine-apples.—"M." (p. 499) has done well to have produced two Pine-apples weighing in the aggregate 13 lbs. 13 oz. from suckers without heat in less than four months; supposing the suckers to have been well rooted it would take more than half that time to develop such fruit, without taking into consideration the check that would be caused from separation. This reducing of the cost of fuel and the length of time usually taken to fruit Pines, will open up a new era in their culture.—M. M. P.

— Will "M." (p. 499) kindly say how long the fruit from the old stools, from which the suckers in question were taken, had been cut previous to the suckers being taken off, and what the weights of the first fruits were.—H. A. B.

Names of Fruits.—F. B. L.—Norfolk Beeding, often written Beans; a valuable late-keeping culinary Apple.

Questions.

Odontoglossum crispum.—We have a plant of this *Odontoglossum* producing two flower spikes from the apex instead of the base of the pseudo bulb. The flowers are large and well developed. Is this common?—J. C.

The Fever Gum Tree.—In the garden at Singleton, Swansea, there are numerous plants of *Eucalyptus globulus* which have stood in the open ground all the year round for several seasons. They were planted small, and have grown freely. I have a number of them, too, but as yet they are small and not worth naming. Will any of your correspondents be good enough to inform me how this or any other *Eucalyptus* would succeed planted in sand near the sea?—CAMBRIAN.

Lasting Ferns for Bouquets.—What Ferns last the best for bouquets, &c.? The British Ferns mostly fade in a few hours, and *Adiantum* and Ferns of that class are soon gone. I only know three of any lasting power, viz., *Davallia elegans*, *D. canariensis*, and *D. dissecta*; these will remain fresh a fortnight if put in water. *Nephrodium molle* and *Pteris tremula* last about three days, but most of the others, as far as my experience goes, will only do for a few hours.—W. A. S.

Currants Losing their Bloom-buds.—When I went to prune some Red Currant bushes the other day, I found some of them partially stripped of their bloom buds. Can any reader of THE GARDEN tell me what bird it is that does the mischief, and also how to remedy it? In the country I always found that it was done by bullfinches, but it cannot be them now, as we are situated right in the heart of the town, and bullfinches are such shy birds they would hardly venture where so much traffic is going on.—F. W. H., *Park Street, Yeovil*.

Salt-water-resisting Plants.—Would any readers of THE GARDEN kindly assist me by naming some shrubs and trees that would grow in an exposed place, which is at times flooded by a tidal river? The salt has hitherto destroyed anything I have planted, and ordinary Grass seeds will not grow. The soil is good and deep, but there is a soaking from the river. It is greatly exposed to north and east winds. What mixture of Grass seeds would it be advisable to use?—A. T.

Poultry Manure.—What plants or vegetables are best suited for the application of poultry manure? and how should it be employed?—SUBSCRIBER.

Field Mice in Rockwork.—I have a plague of small field mice who are working great destruction in a rockwork. How can I trap them? They refuse the ordinary baits.—H. N. ELLACOMBE, *Bitton*.

Paris Exhibition.—We learn that Mr. Lascelles, the well-known hot-house builder, 121, Bunhill Row, London, has just received the Cross of Chevalier of the Legion of Honour for his exhibits shown in classes 17, 66, and 85 at the late Exhibition. We also learn that Mr. Stephens, 171, Aldersgate Street, has carried off the highest award for his wood stains at the same exhibition.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

NEW ROSES.

THE French are a highly imaginative people. We find this quality, with which they are so abundantly gifted, cropping up every way. It shines in their romances (who but a Frenchman could have written "*Le Juif Errant?*"), and it is illustrated in the exquisite designs with which their porcelain, tapestry, and books teem. It is sometimes most enjoyable; it keeps up a pleasant system of surprise and wonder at where they could have stumbled on the conceptions which seem to them so natural. We are just the very reverse; our big city tells of practical work, theirs of beauty and gaiety. But there is one place in which I do not like the imagination to be so demonstrative, viz., in their list of new Roses. To read them, year after year, one would think that by this time there was no room left for another good Rose; that all the adjectives with which glowing descriptions could be drawn were exhausted. But, lo! another year comes round, and there is the same marvellous list. The names of the Roses are changed, but the descriptions still remain; and yet, what is the result? In a list compiled from the expressed opinions of forty-one Rose growers (twenty-five amateurs and sixteen nurserymen) of the best seventy-two Roses, we find that of the 1872 Roses, only two appear in it; of 1873, the same number; of 1875 there are six, the largest number for many years. Bearing in mind that every year there are some sixty at least new Roses advertised by the French growers, we must surely say that it is "a very small piece of bread for such an intolerable quantity of sack."

But if so, what are we to say of the last two years? that is, the Roses sent out, or rather their names, for 1876-77 and 1877-78. In each of these years there have been announced upwards of fifty varieties, and although some of our best Rosarians spoke hopefully of them, there is not one that has as yet made any mark. Of the former year I cannot recall to mind a single one of which any one has said that it would be really a desirable acquisition, nor any that has created a sensation amongst exhibitors, and yet if they were good they should by this time have done so, of those sent out the year before, such kinds as Duchess of Vallombrosa very soon asserted their position. We heard, indeed, Madame Emma All and Madame Sophie Fropot well spoken of; we have seen a bloom of them occasionally, but have not been struck by their appearance. It may be too early to judge of those of last autumn, for new Roses are so hard worked that well nigh any constitution they have is injured temporarily by the manner in which they are forced and hacked about; but, generally speaking, if there is anything really valuable, it makes a mark the first season. One, indeed—Boildieu—has been shown and certificated, and gave promise of having a fine flower, but that is the only one. I looked in vain through the boxes of new flowers, at the National Society's show at the Crystal Palace and Manchester, to see any of foreign origin that might be desirable to add to one's collection, but I failed to see any. Those to whom we are accustomed to look for information on those subjects speak favourably of Alfred K. Williams, a large Rose in the style of Horace Vernet; Edouard Dufour, in the style of Devienne-Lamy; Madame Anna de Besabrosoff (is she a Russian Mrs. Langtry? as two Roses are named after her), a light bright crimson, in the way of Annie Wood; Princess Charlotte de Trémoille, in the way of La France; Marie Verdier, like Anguste Mie, with fine petals; Madame Gabriel Linzet, clear light satin-rose, said to be distinct and good; Madame Laboulaye, light silvery-pink, in the way of Bennett's Duchess of Edinburgh; Edouard Pynaert, in the way of Antoine Ducher, deep purplish-crimson; and Grand Duke Nicolas, blood-red, shaded with vermilion, large, full, and imbricated. Time only will show whether these opinions are likely to be realised.

Similar opinions were expressed last year as to new Roses, but we were doomed to disappointment, and it may be so now.

It is refreshing to turn from these barren lists of the French raisers to those of our own country, not so redundant in quantity, or with descriptions so charged with the overflowings of an exuberant imagination, and giving promises which are never likely to be fulfilled. English Roses have to pass through an ordeal to which the French varieties are not subject; they are submitted to the consideration either of the Floral Committee of the Royal Horticultural Society, or of the judges at our great exhibitions; they are seen by most of the Rose growers in the kingdom, and, consequently, when they are put into catalogues it is easy to see whether those descriptions are justified by the recollection of the Rose growers; they are, as I have said, not so numerous. In the autumn of 1877 there were announced three new Roses by Messrs. Paul & Son, three by Mr. Charles Turner, and three by Messrs. William Paul & Son. Taking these *seriatim*, we shall find, I think, that English raisers have much cause to congratulate themselves. Mrs. Laxton, raised by that very successful hybridizer, Mr. Laxton, late of Stamford, and sent out by the Cheshunt firm, is, I believe, one of the very best Roses ever raised, and has been largely shown this season, and in every case with success; its shape is grand, an Alfred Colomb-like centre, with a grand circumference of reflexed petals; it reminds one of Alfred Colomb, Marie Baumann, and Senateur Vaisse. What more can be said? John Bright, raised at Cheshunt, is a bright glowing crimson, excessively brilliant in colour, and of a fine open-cupped shape. Robert Marnock is not equal in quality to the two preceding Roses, but is a fine garden Rose. Messrs. William Paul & Son's Rosy Morn has flowers of a delicate peach, but is not equal in quality to May Quennell, raised by Mr. Postans, but sent out from Waltham Cross; it is a fine magenta-carmine Rose shaded with crimson, very large and full, and has been seen to much advantage during the past season. Their Red Dragon is a climbing Rose of great merit. Mr. Turner sent out Penelope Mayo, raised by Mr. Davis, a fine large flower in the style of Duchesse de Caylus, with a strong, robust constitution, flowering freely in the autumn, Dean of Windsor is in the style of Oxonian, but of the colour of Comtesse d'Oxford, while Richard Laxton is a Maréchal Vaillant style of flower raised by Mr. Laxton, crimson, and a free autumnal bloomer. Thus three out of the nine are decidedly first-rate Roses, and it is just possible that some of the others may approach them next season. When we remember that we had from two of these firms in the preceding year Magna Charta and Marchioness of Exeter, we may also anticipate that in the Roses announced by them for next season we may find some real gems. Countess of Roseberry, Duchess of Bedford, Charles Darwin, Marquis of Salisbury, Harrison Weir, and Dr. Sewell have all been before the Rose-loving public, and been well received. There is one very material point in connection with English-raised Roses, and that is, that they are more likely to have a vigorous, cold-bearing constitution than those which come from France, and that in reality they do possess it. Rose lovers see the wood as it is exhibited with the blooms, and oftentimes the plant, for they are often shown as pot plants, and have also the opportunity of seeing them in the homes from whence they come (for it so happens that the three principal growers who have distinguished themselves as raisers of seedlings live contiguous to London, the centre to which all things gravitate) and note the character of the plants which they wish to procure, not that all English-raised Roses have vigorous constitutions, for I know of one which is one of the most beautiful Roses I have ever seen, but which, I fear, will never have vigour enough to enable it to be sent out.

Crowds of new varieties are announced from France, but I think the eyes of Rose lovers will, after the experience of the last two years, be turned to the Rose fields of England to find out additions to be made to their well-filled collections.

DELTA.

The Old Pink China Rose.—Mr. Hobjay (p. 496) and others may be interested in knowing that this Rose has four large beds devoted to it here, and has had for the last dozen years. The Pink

China is edged with the dark red or crimson variety. The latter is hardly so free a flowerer nor so hardy as the pink one; but the two together look well, and seldom fail to furnish a good supply of cut Roses from May to December. We are still (Dec. 4) cutting them. The beds are planted rather thickly, and a few pink Pelargoniums or Petunias are mixed with the Roses during the summer months. In very severe winters a few Spruce boughs have been laid over the beds, but in ordinary seasons even this small modicum of protection has not been given. The beds receive a slight dressing of manure every autumn, which is "pointed" rather than dug in. About April 1 all weak, exhausted, or frost-killed wood is cut out. This is all the attention which China Roses need, and they furnish unique shades of colour in a large geometrical flower garden, and are by far the most useful beds which we possess as far as cut flowers are concerned. These Roses in the bud state are really very beautiful and useful for vase or bouquet work. There is also a so-called white variety which we once had and lost; likewise fairy Roses or small representations of both colours. China Roses do remarkably well in warm and sheltered places; but the edges of our large beds were too bleak and cold for the Fairy kinds, with which it was attempted to form an outer band between the crimson China and the turf. By the way, these Fairy Roses are just the plants to match with such small Fuchsias as *Pumila microphylla*, *Venus Victorix*, &c., in small beds or borders.—D. T. Ison, *Hardwicke House, Bury St. Edmunds*

SCENTLESS ROSES.

To all who grow Roses for the beautifying of the garden and the adornment of the house, it is pleasant to hear from various sources that a growing feeling of protest is aroused against the many scentless varieties so constantly appearing at exhibitions generally. As in the tournaments of old knights contended for the sake of a smile from their chosen dame, so should we also in these modern days imitate their example, nay more, raise a crusade against those who dishonour the queen of flowers by raising and showing scentless Roses that do but mock our senses by an outward show of all that is beautiful; and thus begin a war of Roses, no longer of York and Lancaster, or of red and white, but of the sweet-scented *versus* the scentless, in which all should enlist to oppose resolutely the taste that condones any defect that is not apparent at the exhibition table—a taste that values size more than scent, indeed usually ignores the latter altogether; uniformity of shape more than that variety which we are elsewhere told is so pleasing, and even encourages rankness of growth rather than freedom of flowering, and has, to make a long story as short as may be, loaded our gardens and the lists of nurserymen with many varieties that are grown merely to be discarded. It would hardly be just to accuse exhibitors as the source of all these evils, but rather confess that the love of novelty, to which all must plead guilty, has also largely contributed, and as all true lovers of the Rose must always desire to see something more beautiful than they yet possess, the most obvious way of effecting a change so desirable, is to establish prizes for Roses in which scent shall rank as an equal qualification to those already demanded, and, in the case of new Roses, excluding them from the highest honours at shows if they lack the crowning grace of sweetness. It cannot be urged that exquisite perfume and freedom of habit are incompatible with size and shape, when such a Rose as *La France* has been for years before our eyes and noses, and those who raise new Roses should be invited by special prizes to leave no stone unturned to bring us still nearer to perfection, and, by demanding a guarantee that their beautiful novelties are sweet-scented, throw back on their hands all that are faulty in this particular. If this were done, how often should we be spared the annoyance of finding that a Rose we had admired at a show was, when grown at home, devoid of scent and scanty in blossom.

Herbaceous borders, Alpine rockeries, and wild gardens are just now the ruling taste of the day, and in the latter place we can all find beauty in the *Pæony* when its brilliant petals are bathed in June sunshine; there, then, let us place those beautiful impostors that will, in the end, bring discredit on the Rose, and reserve for our Rosery and loving care only those that really are of highest excellence; and, if we cannot refrain from showing scentless Roses, let them have a class to themselves, and then no one can complain. A list of all the scentless Roses would be instructive, in the sense of how to avoid

if some great authority would compile such an "Index expurgatorius" (for who would buy a scentless Rose?); but, in the meanwhile, a few of the head offenders may be mentioned as a guide to the unwary. Perhaps there is no greater offender than the familiar *Victor Verdier*, scentless itself, and the parent of so many scentless offspring, among which are *Comtesse d'Oxford*, *Mdlle. Eugénie Verdier*, *Hippolyte Jamain*, and many others. *Baroness Rothschild*, *Paul Néron*, Duke of Edinburgh and his descendants, are also in the same list, and *Etienne Levet* and *Marquise de Castellane*, *Mons. Noman* and *Anna Alexieff* must be added to it.

It is curious to remark that, while Tea Roses are generally considered the most powerfully scented, the new Tea Hybrids hitherto are lacking in this quality, though they may just escape the imputation of utter scentlessness; and, still more remarkable, that *Gloire de Dijon*, one of the sweetest of Roses, has not transmitted that quality to its descendants. For instance, *Madame Trifle*, *Madame Levet*, and *Tour Bertrand* are without scent, and *Belle Lyonnaise* and *Madame Bérard* are nearly so, and, as an instance to the contrary, *Maréchal Niel* itself, one of the most remarkably powerful-scented Roses, is said to have *Isabella Gray* for its parent, a Rose that is devoid of all smell. While urging the necessity of scent to the Rose, if it is to keep its place as first and foremost among flowers, the desirability of free blooming in autumn must not be overlooked; but this is just now not likely to be forgotten when the tide is setting in in favour of these Tea Hybrids, which promise so much; and, until such a combination has been achieved, till our gardens are full of new varieties surpassing all we now possess in sweetness, size, shape, colour, and freedom of bloom, let us not rest content or turn our attention to other qualifications.

E. H. WOODALL.

ROSE CUTTINGS AS ROSE STOCKS.

The closeness of affinity is an important factor in the ensuring of a sound union between the scion and the stock, and it follows that not a few Roses might form far more appropriate stocks for Roses than any sorts of Briers. Experience alone confirms this theory. Most Roses do well and live long on such stocks as *Charles Lawson*, *La Reine*, *Coupe de Hebe*, *John Hopper*, *Baronne Prevost*, and other free-rooting, vigorous-growing Roses. The old Cabbage and Provence Roses also form capital stocks for most of the Moss Roses. There is a strong similarity in the habit and mode of growth of these two classes of Roses that enables them to match well with each other. The question of Rose stocks may be said to be, as yet, in its infancy. The Brier is to the Rose what the Crab is to the Apple—a gross stock that may suit some, and destroy or deteriorate other Roses. It is high time that Rose Stocks were found having corresponding qualities to Roses as the Paradise stock to Apples. Dwarfing stocks, floriferous stocks, permanent and perpetual stocks, ought to be within reach of the rosarian. It is a question as interesting as important, to determine the cause of many premature deaths among Roses. Does, for example, the Rose kill the stock, or the stock kill the Rose? The answer is less simple than it seems. The deaths referred to, do not result from imperfect union. It is a curious fact that but very few deaths originate from this cause. The kinds take well on almost any stock—stocks of all kinds seem equally ready to welcome and form a close union with buds of every possible variety of Roses. Disease or death approaches through the tops and the bottoms; perhaps 75 per cent. of such deaths come through root failure. Nor is this greatly to be wondered at, to see the way that Briers for budding are too often treated. Torn out of old hedgerows, mostly at so much a score or hundred, tossed about in the air, conveyed often to great distances by rail, cart, or waggon, without the least protection to the roots, and finally dressed with a handbill or axe across a block, and thrust into the soil with often scarcely a root at all. Nothing but disease or death could be reasonably expected. Instead of this, however, so full of vitality are these dormant Briers that they mostly throw out a few strong shoots the following season, and these are budded in due time and take. All might, therefore, be well did the grower exercise common prudence or patience, but trade is so

brisk, or the demand for Roses so urgent, that these Roses are at once transplanted into their flowering quarters a few months after budding, and this early removal, great disturbance, and partial destruction of their roots, complete their destruction. But even with seedling Briars and Manetti stocks under better treatment, and every care being taken of their roots, the percentage of deaths among budded Roses is alarmingly high, and ought to be capable of being at once reduced one-half or two-thirds. That this high death rate among Roses arises from a bad matching of scions and stocks, seems obvious from the fact that it does not occur among Briars nor yet among Roses on their own roots. Both of these when apart are endowed with great powers of longevity. No sooner are they united than their health is enfeebled, their lives shortened. The selection of stocks with closer natural affinities and on nearer lines of consanguinity, would probably restore the health and prolong the life of many of our Roses. After all the stocks that have already been noted, for most or all of the Tea Roses, there are few better than the old pink China monthly Rose and Gloire de Dijon. The first has a thin bark, and needs careful manipulation, but, with that drawback, it forms an admirable stock, roots like a Gooseberry cutting, and grows like a weed. The present is a good time to select Rose cuttings for stocks. They may be put in of any desired length from 6 in. to 4 ft. in length. Pieces from 2 ft. to 4 ft. are the most suitable for forming stocks for standards. Taken off either with or without a heel, and about 6 in. inserted in the soil, most Roses root readily. There are few better modes than that of digging in the cuttings. If the ground be poor give it a good coating of good manure, for Roses like a rich soil even to root amount, and the vigour of the Roses will largely depend on the amount of good food the roots find to feed upon afterwards. Begin digging the ground at one end, and when a sufficient space—say 18 in. for dwarf Rose cuttings, and 3 ft. for taller ones—is turned over, run a line along the dug side of the ground and cut it down straight and even to a depth of 6 in. Should the bottom be very loose, tread it down firmly; then insert the cuttings at distances of 6 in. apart, and cover along the bottom with a little sandy compost, should such be available, if not, the soil will answer almost equally well. Place a small spadeful of fine soil against the cuttings, and tread it down firmly around them. Proceed with the digging, making up the soil to the level of the ground around the cuttings, and leaving the surface loose and smooth. Dig on to the distance for the next row, and proceed exactly as before, and so on, and so on till the cuttings are exhausted, or the ground is filled. Nothing more will be needed till next June but keeping the ground free from weeds and rubbing off all the buds as they appear but two, or at most three, of those best placed for budding. Let these be budded as soon as the wood is sufficiently developed for the purpose. This will probably happen at various times from June to September, while some of the Rose stocks may not be fit to bud the first year. Each, however, as soon as rooted, becomes a Rose bush or tree without budding, and may either be kept as such, or cut back, after a season's growth, to form a yet better, stronger stock the second season from a cutting.

D. T. FISH.

The Sickle-leaved Catchfly (*Silene falcata*).—This pretty Catchfly forms perennial tufts consisting of numerous curved, awl-shaped, hairy leaves. The flowers are borne singly on stems about 6 in. high, and are about $\frac{3}{4}$ in. across; the petals are divided into halves down to the throat, as are also the central appendages, the colour of the whole being a creamy white. It is a native of the Bithynian Mount Olympus.—W.

Japanese Primroses out of Doors in the Eastern Counties.—I see it stated in THE GARDEN (p. 500), that these Primroses thrive well in the open air in the garden of the Rev. Mr. Nelson, at Aldborough, in Norfolk. Possibly it is warm and sheltered, and we don't think Hardwicke so very cold. Charmed with the beauty of *Primula Japonica*, I propagated it largely by means of seeds and otherwise, and was rewarded with about 1,000 plants, most of which were planted out in herbaceous borders, and warm prepared nooks and corners in our large shrubberies. The result has been cruelly disappointing, not half-a-dozen of them are alive.—D. T. FISH, *Hardwicke House, Bury St. Edmund's*.

THE KITCHEN GARDEN.

FORCING FRENCH BEANS.

THERE is no other forced vegetable that requires so little labour and expense in its production as French Beans. Unlike Seakale or Asparagus there is no previous preparation required; one has only to plant the Beans in the right soil and temperature, and, under ordinary circumstances, we may look forward with certainty to gathering a crop, more or less prolific, according to the way in which the wants of the plants have been attended to. A steady, regular night temperature of about 60° there must be, and from the time the young plants break through the soil till they cease bearing from exhaustion, they must occupy a light position, and the nearer the glass the better. In the old days, before the advent of hot water, when fruit-forcing was mostly done with smoke flues, many a good crop of Beans I have seen growing in 8-in. pots on the top of the flues in the early Vineries. The red spider was kept down by placing dishes of water among the pots of Beans on the flues, and these maintained a genial atmosphere in the house, which was beneficial to the Vines as well as to the Beans. But when the longer and brighter days of March and April come, French Beans are rather a dangerous crop to have in Vineries, and it requires the greatest care to keep them free from spider, and when the first symptoms of a discoloured leaf appears, which the practised eye soon detects, out must go the whole crop. Old plants that have been some time in bearing, are more liable to spider attacks than others in robust health. This is according to a well-known natural law; insects rarely attack their prey till it has become weakened from some previous cause. If one had any choice in the matter, the best structure for French Bean forcing is a low span, or half-span-roofed house or pit, sunk 12 in. or 18 in. in the ground, having a path down the centre and beds of fermenting materials on each side. The beds of fermenting materials are not indispensable, but the soft, genial atmosphere which prevades the house in which they form a part of the arrangement imparts a vigour to the plants that is the sure precursor of a good crop. There are various ways of planting Beans. One (and I think the best way) is to plant four Beans in each 4-in. pot, and when the pots are full of roots shift on to 7-in. or 8 in. pots, dropping the balls down so that the stems are earthed up in the potting nearly to the leaves.

The soil used should be turfy loam and old manure, about two of the former to one of the latter, and should be of the same temperature as the house. This can easily be managed by placing the soil inside the house a few hours before using it. Most men have a favourite kind of Bean for forcing. Osborn's forcing is a good kind, and the fact is any kind that is early and productive in the open air will be proportionately early under glass. Some growers simply plant five Beans in the fruiting pot at once, and fill the pot about half full of soil, reserving the remaining space to be filled up after the plants have made some progress. I have seen Beans also grown in boxes, and I mention that here because there may occasionally be situations on shelves near the glass where boxes might be suitable for the last crop, as plants in boxes are less liable to suffer from heat or drought. As the plants advance in growth, a few light Hazel or Birch sprays may be placed around the edges of the pots as a support to the plants. With strong, vigorous plants that have had plenty of light this may not in all cases be necessary, but it is not much trouble, and it prevents the plants falling over. Every pod should be gathered when large enough for use. If left longer not only do they become tough and useless, but they prevent a successional crop coming on the same plants.

Beans will keep fresh for a week or so after being gathered if tied up in bundles and the stalks just inserted in water and placed in a cool room. Liquid manure may be given often to plants in bearing, as by that time the pots will be full of roots, and will be in a position to absorb and utilise strong food. Drainage is not a very important matter in French Bean forcing. One large crock over the hole in the bottom of the pot and some rough loam and manure over it will suffice. They must at all times have plenty of space.

E. HOBDAV.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Capsicum Princess of Wales.—This has been well grown by Mr. Wildsmith, of Heckfield. A large collection of it was staged at Messrs. Suttons' root show at Reading on Saturday last and attracted considerable attention. The plants were all of standard growth, their stems being about 12 in. in height, and their heads about 15 in. across, the rich yellow fruit hanging down so as to present a most effective appearance. Either for tables, sideboards, or for any ordinary decorative purpose, this Capsicum is singularly pleasing, and contrasts strikingly with the various scarlet-berried Solanums. Seed sown in March in a gentle heat will, under ordinary cultivation, produce plants loaded with golden pods in the autumn. A little heat assists the ripening and colouring, just as it is productive of similar results in the Solanum.—A. D.

Celery Free from Worms.—The fine examples of Celery lately exhibited by Mr. Pragnell, of Sherborne Castle, at South Kensington and the Agricultural Hall, serve to show what good results may be obtained when proper provision has been made for its culture and for the prevention of worms. This Celery was grown in trenches, into which had been well worked a quantity of manure prepared by having a quantity of salt and soot mixed with it some time previous to its being used. The manure is laid in a round heap and frequently turned in order to get the salt and soot thoroughly incorporated with it. It must be remembered that soil in which worms abound most is that to which unprepared raw manure has been added from time to time, and, therefore, freeing the manure from worms previous to its being used is one way of effectually keeping them from the soil. In addition to this the salt and soot promote growth to a marvellous extent. The examples alluded to were of great weight, remarkably solid, brittle, and fine flavoured, and not a leaf-stalk was worm-eaten.—S.

The Highfield Grape Tomato.—This singular hybrid, the produce of a cross between the Currant Tomato and Hathaway's Excelsior, is apparently a most valuable kind as it withstands the disease long after others have been killed off by it. I saw this new kind growing quite fresh and green on the garden walls at Highfield a few days ago, having but the shelter of a mat over each plant at night. The bunches of fruit range from 9 in. to 18 in. in length, the fruit being as large as the berries of the Gros Colman Grape and finely flavoured. It is a capital kind to stew whole and use for dressing a roast joint, with which it should be eaten. The entire stock has now passed into the hands of the Messrs. Suttons, of Reading, and, therefore, next season the variety will be doubtless widely grown.—A. D.

Late-sown Scarlet Runners.—I quite agree with what Mr. Groom says (p. 453) in reference to this subject and I cannot understand why Mr. Legge should condemn the practice of late sowing in this county. It is from the late-sowings that I generally obtain the finest Beans. I made a sowing on June 12, and gathered from the produce of it on August 23, exhibited the Beans, and won first prizes with them. I never sowed before May 12. I have seen too many bad results from sowing earlier. I always have plenty of the dwarf kinds from which to gather until the Runners come in.—J. J. C., *West Hall, Sherborne, Dorset.*

Asparagus and Salt.—I have for some time past paid very considerable attention to the cultivation of Asparagus. If any one thing is clear to me it is that no salt or brine is in any way necessary to it. The best beds I know of never get any salt at all. I write this in reference to Mr. Legge's note in *THE GARDEN* of November 23. Mr. Legge adds: "The only questions not settled—Should a bed be made raised or flat? Should there be good drainage or none? of course, supposing the ground fairly dry. Should, as at Bath years ago, large patches be cultivated? or should only single lines be planted at a distance of 18 in. between each plant?" He may rest assured that his single lines at 18 in. between each plant are far too close.—T. H.

Potatoes at the Paris Exhibition.—At the great Parisian Potato show, held at the Trocadero in October last, a remarkably fine collection of Potatoes, most of them French varieties, was exhibited by Hyacinthe Riganlt, of Groslay (Seine-et-Oise), for which the judges awarded a silver medal. The following were the most noteworthy varieties, viz., Tétart Hâtive, Reine de Mai, Feuille d'Ortie, Platte de Brest, Bonlangère, Rosee de Villers, Marjolain Hâtive, Zavier, Farinouse Ronce, Coquette, Poasée Debout, Cailland Hardy, Crapaudine, Sacoise, Violette Rouge, Bourbon Lacey, Morcesax, Cornichon, and Rognon Rose. English Potato growers, instead of adding so many worthless American varieties to their collections, had better try some of the above-named French kinds, which are far

better for table purposes than the Americans. For a table Potato there is not an American, nor very few English, that would equal the first-named French variety—Tétart Hâtive. I quite agree with what "A. D." says (p. 453), that there is not that piquancy of flavour in those white, mealy Potatoes that is found in the yellow-fleshed kinds. If a new Potato is brought out that boils mealy and white it is spoken of as a first-class variety, when, in reality, most of those white, mealy Potatoes have no more flavour than starch. Twenty years ago there was a Potato very much grown in the eastern counties known as the Old Cambridge Kidney; it boiled yellow, was moderately mealy, and had a sweet, nutty flavour. For the table there was nothing to equal it. I have been frequently asked by different people where they could get that Old Cambridge Kidney that was so much grown about twenty years ago? There are varieties exhibited now and then at the different Potato shows as the Cambridge Kidney, but not at all like the one about which I have spoken when boiled. It appears to be quite gone out of cultivation, a circumstance to be regretted, as there is not another variety in cultivation at the present time equal to it.—R. S.

Late Peas.—We find *No Plus Ultra* a very good late Pea (*Netro Sultans* I once knew a jobbing gardener term them). We had our last dish of Peas this year on November 24, and very good they were. We should have had them later had the birds been kept off. Late Peas have not, on the whole, done nearly so well this autumn as they did last year, when we had good ones and plenty of them on December 2.—M. P. S.

Telegraph Cucumber.—I find this Cucumber to be most prolific. From a single plant, in a one-light frame, I got, between June 1 and Oct. 31, sixty-seven Cucumbers of average size, and this without special preparation of any sort. The bed was made up in April, slowly because of frost. It consisted of one load of manure (not over good) and a small quantity of rotten leaves. The manure was a fortnight in preparation, and it took a month after that before the bed got into condition. On removing the plant at the end of October, it was far from exhausted, and a quantity of Gherkins, which were used for pickling, was plucked from it.—J. W., *Talbot Road, Tottenham.*

Autumn-sown Peas.—I have noticed the recommendation not to sow Peas before the new year. I have them now more than 1 in. high, thoroughly vigorous, and fear not they will be fit to pick the third week in May. As to the kind for early sowing there can be no doubt that East's Kentish Invicta lasts all, even Dickson's first and best. All must agree that in flavour a blue wrinkled Pea is superior to any other, also the Invicta possesses the qualities of being a good bearer and very hardy, never reaching the height of Sangster's No. 1.—EUGENE E. P. LEGGE, *Litton Cheney, Dorset.*

Winter Radishes in Germany.—In England Radishes are not nearly so much eaten as they should be. They would be more largely consumed if it were generally known how they should be prepared. In Switzerland and Germany Radishes are largely eaten both in summer and winter, prepared as follows: Wash them clean and wipe them dry and then with a sharp knife begin at the root end and cut in nearly to the centre of the Radish. Continue to work the knife round, cutting as thinly as possible until the base of the root is reached; then take the Radish by the small end, and, holding it base downwards, each segment will open, giving it the appearance of a large corkscrew. Then dredge the interstices with salt and allow them to remain a quarter of an hour, when by gently pressing the whole close in together a portion of the sap will flow out, thus extracting the hot flavour which to many is a cause of dislike. The flesh, so to speak, is thus rendered crisp and delicate. The culture of this root forms an important industry in many parts of Germany: Regensburg, in Bavaria, enjoying a special renown for Radishes. There they are grown to a large size, and when seen in the markets in great stacks have a somewhat similar appearance to Turnips as seen in Covent Garden. Rich ground and plenty of water are necessary for their summer culture; if not grown quickly they fail to attain that crispness which renders them so palatable.—JOHN CORNHILL, *Byfleet.*

Green Kohl Rabi.—This more than answers my expectations. We have always had some amount of trouble with Turnips. They come in a glut, and do not last long, and often when wanted for soups there are none to be found. We cannot, in fact, guarantee Turnips fit for use any and every day throughout the year; but this can be done with Kohl Rabi, for a lot of roots stored last winter lasted until we had fresh small roots from seed sown early in the spring, and thus there was no broken link. As for the root, it gives a better flavour than the Turnip, and also makes a very good vegetable; but to serve as Turnips it certainly will not do, and I am glad to see that we have a good crop of white Turnips for autumn use, for there are times when we prize them.—"Gardeners' Magazine."

NEW OR RARE PLANTS.

BEGONIA POLYPETALA.

BEGONIA POLYPETALA (Alph. D. C.); *inberosa*; scapo petiolisque albido-tomentosis; limbis ovato-acutis, erosodentatis, cordatis, supra pubescentibus, subtus dense tomentosis; floris masc. sepalis 2, petalis 9-10.

A very distinct species of the section *Huszi'a* (Prodr. XV., pars 2, p. 283), next to *B. pleiopetala* for the characters, with splendid red flowers as in *B. cinnabarina* and *B. Veitchi*. Root tuberous. Scape 40-42 cent. high, covered with a soft whitish tomentum. Petioles 18-20

Begonia polypetala.

cent. long, with soft and white hairs as the scape. Limbs ovato-pointed, cordiform, irregularly toothed, 25 cent. long and 20 broad, 7-ribbed, with nerves bifid, hairy above, white and woolly underneath. Flowers emerging out of two opposite elliptic concave bracts 18-20 mill. long. Pedicels of the male flowers 20-22 millim. long, hoary and reddish. Sepals two, ovato-elliptic, 18 mill. long, smooth and reddish inside, tomentose and rather white outside. Petals 9-10, of a fine red colour, smooth, except outside on the middle; the external ones ovato-oblong, pointed, $2\frac{1}{2}$ -3 cent. long, $1\frac{1}{2}$ broad; the internal somewhat shorter and narrower. Anthers shorter than the filaments, with a short point at the top. Bract of the female flower elliptic, 15 mill. long, reddish, somewhat white and hoary outside. Ovary tomentose, 3-winged,

with one wing larger, ascendent. Lobes 9, of an intense red colour, smooth inside, tomentose outside, the external ones ovato-acute, 2 cent. long, 6 mill. broad, the internal narrower. Style 3, ramose, with tortuous branches. Placentas 3, bipartite, bearing ovules on the whole surface.

ALPH. DE CANDOLLE.

We have received from M. Otto Fröbel, of Zurich, flowers of the annexed brilliant and very distinct *Begonia*, introduced by Messrs. Fröbel, and of which the above description has been written by M. de Candolle, of Geneva. The plant comes from the Andes of northern Peru. It is a species which in Europe grows and flowers in the winter, and will, therefore, be more welcome and more useful than one of the many kinds which are so much employed in summer. The bulbs begin to grow in the month of August, and the first flowers open in October. They open in succession until the month of January, and are during that time the most beautiful ornaments of the temperate house. One flower which was sent to us much resembled, even after its long journey from Switzerland, a blossom of the brilliant *Anemone fulgens*. Already as many as twelve such flowers had been seen on one plant at the same time in M. Fröbel's nursery. As yet the plant has not been sufficiently multiplied to allow its being offered in commerce. We purpose in due time issuing a coloured illustration of it, which will give a fair idea of a plant which is one of the best and most interesting of recent novelties.

Deherainia Smaragdina.—A most singular plant, with relatively large green flowers. It was described and first figured by Prof. Decaisne in the "Annales des Sciences Naturelles," 1876 (p. 133 plate 12) and recently a coloured plate of it has appeared in the "Botanical Magazine," 6373. This shrub (which appears to be rather a shy bloomer) though it flowered as long ago as 1870 in the Municipal Garden of Paris, Dr. Lindley imported from the tropical regions of Mexico, and it is in gardens under the names of *Posoqueria macrantha*, *Theophrasta smaragdina*, and *Jacquinia smaragdina*. Prof. Decaisne recognised in it the type of a new genus of the Theophrasteae. It is certainly more curious than beautiful, though it would interest any lover of plants who can appreciate something besides brilliant colours in the vegetable kingdom. In habit it resembles some of the Azaleas, having slender, hairy branches, with the leaves crowded towards the ends. The leaves are leathery, glossy on the upper surface, minutely toothed, especially in the upper half, and about 3 in. or 4 in. long. The position of the flowers is very anomalous, being almost concealed beneath the clusters of foliage. Individually, they are about $1\frac{1}{2}$ in. in diameter, and not unlike a green Primrose, save that the tube of the corolla is very short and the throat wide. With the exception of the yellow anthers, the flowers are quite green, a colour intensely dark in the throat. One stalked flower proceeds from the axil of each leaf, hanging down beneath it. It flowered in the Palm house at Kew in May of the present year.

Pavonia Makoyana, a beautiful Malvaceous flowering shrub, of which an illustration is given in the "Belgique Horticole," 1878, plate 3. It is allied to the equally pretty and interesting *P. Wioti*, figured in the same publication, 1875, plate 7, and since in the "Floral Magazine," plate 276. Professor Morren states that he has no doubt that this *P. Makoyana* is new to horticulturists, but he is not so certain that it is to botanists. After some research we think there is a little doubt on the latter point also, so far as this plant is concerned, but *P. Wioti* turns out to be the same as *P. multiflora* of St. Hilaire's "Flora Brasiliæ Meridionalis" (p. 239, plate 47). In habit and foliage, the two species named are very much alike, but *P. Makoyana* has five broad heart-shaped bracts forming the outer calyx, instead of numerous linear ones as in *P. multiflora*. The flowers are much rarer those of *Goethea strictiflora*, "Botanical Magazine," plate 4677, but instead of being scattered all along the branches, they are clustered at the ends, and are borne on slender stalks about 1 in. long. In colour they are of a rich rosy red, that is to say the bracts of the outer calyx, the true sepals and petals being relatively small and dull coloured. The column of stamens and styles projects about 1 in. beyond the petals, and the anthers are of a bright blue, contrasting well with the rosy-red of the floral envelopes. In

cultivation, *Pavonia Makoyana* forms a shrub 3 ft. to 5 ft. high, with straight branches, leafy chiefly at the tips, and the leaves are narrow and toothed on the margin, and about 6 in. long; a native of Brazil, introduced into cultivation by Messrs. Jacob & Makoy. The only other plant figured in the last part of the "Belgique Horticole" is *Bilbergia Saundersi*, a pretty species with red, yellow, and blue flowers and white mottled leaves margined with red; imported into this country from Brazil by Mr. W. W. Saunders about 1869, and first cultivated under the name of *B. chlorosticta*.

W. B. HEMSLEY.

TREES, SHRUBS, & WOODLANDS.

ORNAMENTAL FORESTRY.

THE beauty and picturesqueness of every locality are so largely dependent upon the disposition of its scattered trees, its groups and masses of plantation, that no landed proprietor and no forester should entirely lose sight of this, even in laying-out woodlands which are planted mainly for profit; and, though in Nature we sometimes meet with scenes of such surpassing grandeur that any attempt to brighten their effect by planting must necessarily prove futile, yet, in the majority of cases, considerable improvements in a landscape may be effected by a judicious choice of trees combined with such a mode of planting as shall be in accordance with the character of the district. Thus, the park or any other wide expanse of comparatively level, or gently undulating surface, through which the sluggish stream glides almost noiselessly, or expands into a placid lake, requires the accompaniment of rolling masses of underwood, dipping to the water's edge, and from amongst which spring up round-headed trees of various kinds, while here and there a graceful Alder, a spreading Ash with recurvate branches, or a Willow which "grows aslant the brook, and shows his hoar leaves in the glassy stream," give both beauty and variety to the scene. On the other hand, the mountain defile, through which the rapid torrent bounds from rock to rock, and above which peak rises above peak, is most befittingly clothed with the tangled thicket, the spiral-headed Larch and Spruce, the Scotch Pine, and the Mountain Ash, and when upon the slopes such groves of Fir or Pine have been so thinned out as to produce a dense canopy supported only by a few trunks of large size, the scene becomes one of solemn grandeur.

Whoever has attentively studied the effects of light and shade upon the landscape, must have remarked that when a house of any considerable size is bounded only by the skyline, or backed and flanked by open lawn and bare arable and pasture land, there is a degree of indistinctness about it which considerably lessens its effect upon the spectator, inasmuch as the whole of its surroundings participate in the strong light which should be concentrated upon the building. But when such a house is backed up by a well-selected mass of trees, planted at a proper distance to secure the desired effect, the whole building becomes boldly prominent, and if it contains lengthened horizontal lines, the breaks produced by a few trees planted directly in front of it not only increase its apparent size, but also give it an air of lightness and elegance. Similar effects may be observed upon the boles of tall trees which occupy the front lines of a dense plantation, when the sun's rays strike them in the morning or evening, according as they happen to be west or east of the observer.

Considered as the surroundings of the abodes of people of taste and refinement, trees are indeed beautiful at all seasons, yet as beauty alone satiates in time, it is only when they combine this with utility that they become in reality "a joy for ever." On account of their uniformity of colour at all seasons of the year, and also from the absence of any tints, properly so called, ever-green trees afford less real pleasure to the beholder than the deciduous kinds. During the spring most of the latter assume a certain lightness and elegance of form, as through and beyond the delicate tints with which they are clothed, the anatomy of their branches and twigs is, more or less, strikingly displayed as the winds wave them to and fro, and gleams of sunshine or dark patches of shadow alternately reveal and conceal the forms beneath. In summer they strike us by their intensity of shade, as they "hide us from day's garish eye"; in autumn

by their depth and variety of tint; and in winter by their breadth of shadow as the sun skirts the southern horizon, while at the same season, the endless ramifications and interlacings of their branches are distinctly traceable, down almost to the smallest twig, as they stand out in relief against the frosty sky or become thickly coated with rime.

The planter who combines taste with soundness of judgment will produce striking effects with few subjects, just as the Greeks of old, with four colours only, produced results in painting which far surpassed those of a later and more degenerate age, when chemistry had largely increased the number of pigments which figured on the palette. Whoever has the opportunity of conducting such planting on a large scale should bear in mind the fact that to produce grand and striking effects one or two bold and well-wooded prominences, or the same number of deep recesses, are worth scores of minor irregularities; also, that while the mistakes of the farmer, or even those of the gardener, may sometimes be seen and rectified in one short season, those of the professed improver of landscape may take years to realise and a lifetime to rectify.

In thickly-wooded districts much more immediate and, consequently, more striking effects may be produced by thinning than by planting. The judicious opening out of a large wood greatly increases its apparent extent, and this, whether it be viewed from a distance or carefully observed in passing through it; the variety and succession please, while, at the same time, they arrest the eye. Where there are also considerable irregularities of surface, the clearance of a space between the highest and the lowest ground, so as to enable the distant observer to see the trunks of the upper trees over the tops of the lower ones, and across a clear space of turf or arable land, gives greater height to the wood. But to produce the most pleasing effects, either by planting or thinning, the intricacy should be such as to avoid uniformity on the one hand and confusion on the other. The beauty of outline, whether in single trees, in groups, or in plantations on a large scale, is that which is broken rather than regularly sweeping, affording the greatest variety of forms without a constant succession. Broken ground undoubtedly admits of more ornament than that which is level, but even here too much planting produces the same result as large masses in flat districts—it loads the scene. In looking upon such I have often been reminded of a saying of the famous Apelles, who, when he saw one of his pupils painting a Helen and loading her with ornaments, remarked, "Young man, not being able to paint her beautiful, you have made her rich."

It is only by a close study of Nature that the landscape gardener can attain to anything approaching perfection in his art. To insure that harmony which is so highly essential, his principal effects must be produced by trees indigenous to the district, otherwise he will destroy that unity of character which should pervade all large compositions. Much has been said and written about the study of landscape painting as being an essential for him who aims at the improvement of real landscape. The striking effects observable in the works of our best painters are such, that while we may never have seen their exact counterparts in Nature, they often excite the wish that we could see them realised. As a suggestive monitor, or as the assistant and handmaid of Nature, Art may do much, but it must not be forgotten that under the influence of the artist's softening pencil the most picturesque scenes often assume beauties not their own, and also that the operations upon the canvas are much more under the control of the artist than those attempted upon the face of Nature, while the growth of deformity is frequently more marked, if not more rapid, than the development of beauty. The painter turns out a finished picture which time only mellows; it can be seen under only one aspect, and as it appeared at one season of the year, whereas the work of the landscape gardener has to be seen at all seasons, and judged under a variety of aspects. When, however, one observes the reckless manner in which noble prospects are sometimes broken up or frittered away by the successive dotting of single trees, or of small clumps, it is impossible not to wish that the immortal Claude had been studied and accepted as a model, for in his "Liber Veritatis," which consists of about 200 drawings, he has introduced only three or four single trees.

Happily for the present generation, the rage for disfiguring trees and shrubs, by sculpturing them into unnatural forms, has passed away; and, though for a short time, it was re-imported from Holland after the Revolution, Lord Bacon dealt a death-blow to the system when he wrote "As to the making of knots and figures, they be but toys; you may see as good sights many times in tarts. I do not like images cut out in Juniper, or other garden stuffs: they are for children." But, unfortunately, even now we have sometimes to lament the disfigurement of rural scenery by injudicious lopping and beheading; for, to the farmer's eye, the prolific, though pollarded and mutilated, Oak and Ash, and the cropped, but yielding, Willow are more valuable than the best specimens of free-growing, hedgerow timber. Undoubtedly, the finest landscape effects are to be obtained from trees which have neither been clipped into deformity nor elbowed into insignificance.

The literature of what we have called ornamental forestry is too diffuse to be of much practical value to the student; but occasionally we meet with sentences of deep import in the writings of our poets and essayists, as when Mason says, in speaking of the adornment of hilly districts:—

Rich the robe,
And ample let it flow, that Nature wears
On her throned eminence! Where'er she takes
Her horizontal march, pursue her step
With sweeping train of forest: hill to hill
Unite, with prodigality of shade.

Or the author of the "Revival":—"That most engaging feature of landscape—a portion of lawn on the slope of a hill, peeping above wood, and every way enclosed by it." And again, "Belts may be serviceable expedients for mere perambulations, but can seldom be made accordant with freedom of landscape. They absolutely deface the vicinity whenever made receptacles for a long and thin concatenation of slender stems."

A. J. BURROWS.

THE RED-BERRIED ELDER.

ALLOW me to inform Mr. Fish (p. 476), that this Elder comes quite true from seed; at least such is my experience with regard to it. I cannot, however, say whether or not the properties of the fruit are identical with those of the black-berried or common kind, but the birds devour it greedily, almost as fast as it becomes fairly coloured. If Mr. Fish can obtain ripe berries of this plant, he will, I think, find little difficulty in getting them to vegetate, but success in its growth for any length of time may not be so certain. Many years ago, when the late Sir John Nasmith was on a visit at this place, he spoke so highly of the effect produced by this plant when in fruit, at Dalwick, in Peebleshire, and at other places on Tweed-side, that plants of it were obtained and carefully planted in the shrubberies and coverts here, where for a season or two they appeared to thrive, and fruited freely. Some of the ripe berries were gathered and sown, and abundance of plants was the result, and these were in due time planted out; but they have all entirely disappeared. The common Elder is a weed here, and a rather troublesome one too; reproducing itself by means of self-sown seed where it is by no means wanted. But the red-berried variety has never done so, as far as I can ascertain, and the fact of the blackbirds, &c., being very fond of the ripe fruit does not account for this, as the passage of such seeds through the stomach of birds is not generally found to have destroyed their vitality. The plant in question, however, may be less hardy than its black-berried congener; or, perhaps, the soil or climate of this part of Suffolk may be in some way unsuited to it.

P. GRIEVE.

Culford, Bury St. Edmund's.

— The Red-berried Elder growing in Scotland, introduced and brought into notice, I believe, by the late Sir John Nasmith, though of great value as an ornamental shrub and deserving of more extensive cultivation, should be distinguished from its splendid and dazzling relative the *Sambucus racemosa*, which is to be met with in the Black Forest and on Mont Cenis, and of which Sir William Hoeker thus wrote (in a private letter to a friend):—"The plant is the 'Racemose Elder,' (*Sambucus racemosa*) a mountain plant of the middle and south of Europe. I do not wonder that your sister was struck with it in its native hills." London, the great authority for trees and shrubs, says of it, "This tree has a splendid appearance when covered with its panicles of fine large scarlet fruit." Captain S. E. Cook (a great tree lover and traveller), says that the "panicles of fruit resemble miniature bunches of Grapes of the most brilliant

scarlet," and that when in perfection, he thinks it the most beautiful wild fruit which he ever saw. "It grows freely in England," he goes on to say, "but is very seldom found in British gardens of such a size as to display its beauty. London recommends its being budded on the common Elder to give it vigour." The brilliancy of the berries is perfectly dazzling. They do not grow in the form of the Black-berried Elder, or of the Red-berried Elder alluded to in THE GARDEN, but in pointed clusters more resembling miniature bunches of Grapes. I have never met with any Nurseryman who had this shrub, but it has, I know, been raised from seed in South Wales in one locality, where it grew into a tree, bore freely, and was increased by cuttings. Nothing can exceed the beauty of this species of Elder, the colour of the berries being that of scarlet sealing-wax, while the other species or variety is of a duller crimson, and grows in a less graceful form.

A.

PRUNING TREES AND SHRUBS.

WITH much that "J. S. W." (p. 485) says on this subject I perfectly agree, but respecting some other matters on which he has not treated something may be said. The pruning of Conifers is, I know, too often performed at the wrong time, yet "J. S. W." has not alluded to it. I well remember, more than fifty years ago, being employed with others in pruning a plantation of young trees of Spruce, Silver and Scotch Firs, of some ten or twelve years' growth, on a high, bleak, and cold situation, and, the operation being performed in winter, the practice taught me at that time I never forgot, for the next winter it would have been easy to have gathered cartloads of the resin which exuded. It collected in lumps at the base of every cut branch, and showed in the most unmistakable manner that the very life blood of the plants was being drained away. This was done under the name of science, but it occurred in an age when bleeding human beings was also done under the name of science. Well, the latter has, in a great measure, been abandoned, and so ought pruning Conifers, excepting at a proper season. I have repeatedly pruned Conifers in August, and on one occasion I think I operated on the limbs of some large Cedars of Lebanon—that encroached on and overhung a walk—in the month of July, and that with the best results, there being scarcely any bleeding, and the growth the next season did not appear to have experienced the least check. Of course, many kinds of trees could not be pruned at that season, but there may possibly be even some deciduous trees which might be cut early in the autumn with advantage; there are one or two concerning which I never could fairly find out the right time to prune, and one of these is the Sycamore, which, if cut in winter, loses gallons of sap in the spring, when growth commences; and the same happened in the case of the Birch, if I recollect rightly. The common Laurel may be cut at almost any time with impunity, but, as it seldom happens that pruning improves the appearance of any shrub, it is often best to delay it until spring, when the growth which takes place soon after restores the fine appearance of the plant. For a like reason, spring is a good time to cut Ivy well back, although I have cut it pretty close in July; but then it was in a vigorous state, and speedily recovered its foliage. Some plants seem to dislike the knife more than others, and the Portugal Laurel suffers from cutting in most places, while I have seen the common one cut with shears in July, and make a fresh growth after that, which also ripened; but the situation was a favourable one, otherwise such treatment could not be generally adopted. Therefore, a knowledge of the locality as well as of the plants to be operated on must to some extent guide the pruner.

A RETIRED GARDENER.

PINUS INSIGNIS AND ITS TIMBER.

SOME interesting accounts have recently appeared in THE GARDEN on the growth of this Pine in different localities, and one of the writers on the subject, Mr. Garland, solicits information respecting the quality of the timber of this Pine, but thus far without any very satisfactory response. I am unable to speak of it as grown in Britain, but as grown in its native habitat at Monterey, on the coast of Upper California, it is of the very poorest. The entire forest of it, at the time of my stay on its borders, belonged to one gentleman who had not realised much from it, and that little was in converting it into charcoal and cutting it up into cordwood for firing, a condition in which it was shipped to the San Francisco market. The wood is very coarse, brittle, and resinous, and altogether unfit for planking. A most common sight in the forest was living trees with large pieces chopped out of them at about 4 ft. above the ground, and this had been done by the inhabitants of Monterey for firewood. As a large portion of the forest is growing on a dry, calcareo-arenaceous soil, I conclude that this Pine would do well on the chalky soils of the south of England, more

especially near the sea. It is highly ornamental, but when "S. D." writes that "Pinus Cembra comes nearest to it of any Pinus I know as regards colour and habit," I am afraid that people may think me enthusiastic. However, I would advise "S. D." to contrast the two Pines once more, and see well to it that there is no mistake as to the proper names. The ornamental character of this Pine is universally admitted, and though large plants of it have been killed in this country during exceptionally severe winters, the fact of young plants being cheap, and the all but unequalled rate at which they grow, ought to encourage people to plant again. GEO. SIMS.

Elvaston Nurseries, Borrowash, Derbyshire.

BEECH TREES AND UNDERWOOD.

It surprises one to find a man of Mr. Knight's experience defending and corroborating the absurd statements of M. Lavallée, respecting the vagaries of plants. But Mr. Knight does not quote me correctly or fairly. So far as I remember—for I cannot refer to the back numbers containing my remarks at present—I did not say the Beech was "the worst tree in the forest for injuring and destroying under-wood," as Mr. Knight puts it. What I did say was that it was "one of the worst," or something to that effect and to this statement I adhere, and I shall be much surprised if foresters of experience do not corroborate my statements, and I shall be equally surprised if Mr. Knight is able to tell me where I shall see a Beech wood or forest, of mature age and planted as thickly as our woods generally are, where under-wood thrives and flourishes under the trees or even maintains a tolerable existence—that is, where the underwood has not been recently planted. I never saw such a thing. I showed M. Lavallée's remarks to a forester near here who has had forty years experience of woods in different parts of England, and he remarked that the Beech was one of the worst trees he had to contend with where underwood had to be kept up. I have some recollection of the Floors Castle estates and neighbourhood, and I think Mr. Knight need not go far from home to convince himself of his error. One writer says that even "Grass does not grow readily under the shade of the Beech, and I rather think, also, that Mr. Heath, in his recently-issued book entitled "Our Woodland Trees," has something to say on the same subject. It is quite certain, at all events, that the Beech has a bad reputation for destroying underwood. As to the Walnut, I do not know what M. Lavallée may have "meant" in saying that "undergrowth absolutely refuses to live under the shade of the Walnut," but it was only my concern to interpret his words as I found them, and we have no reason to suppose that the writer meant anything but what he said. Let me say, in conclusion, that when speaking of the Beech destroying the undergrowth in my former letter, I said where "planted extensively," but "planted thickly" would have better expressed my meaning. Mr. Knight, I think, knows the Drumlanrig estates, in Dumfriesshire, where there are tracks of Beech plantations, under which hardly a green blade of any kind is to be seen, a statement which I have no doubt Mr. Thomson can confirm.

J. S. W.

— I have never met with underwood making good growth under Beeches, where any quantity grew together. Rhododendrons and other evergreens have been planted here under Beech trees, but they either eventually die, or only partially exist if within 20 yards or so of the trunks of the Beech. Clumps of Beech here in open, elevated spots have scarcely a vestige of herbage under them. I could point out a remarkable instance where Walnuts are planted extensively in woods, in quantities together, with underwood growing most luxuriantly, viz., Laurels, Hollies, Rhododendrons, &c., on clay in a low situation.—GEO. BOLAS.

— Permit me to corroborate "J. S. W.'s" remarks regarding this subject. I resided for several years in a chalk district in Hampshire, where Beech woods and single specimens abounded, and I cannot call to mind a single instance in which there was healthy underwood growing beneath them, that is, where the branches came anyway near the ground. On the contrary, I have seen acres of ground covered with Beech trees where there was scarcely any living vegetation beneath them. When one comes to consider the dense foliage which a healthy Beech tree bears, and also its masses of surface roots, I do not see how it could be otherwise.—H. J. CLAYTON, *Grimston Gardens, Tadcaster.*

Dynamite and Tree Roots.—We find this of great use in blowing up large tree roots. The charge of dynamite will do in a few seconds what it would otherwise take several men a whole day to do. It has, however, this drawback; it is not safe to apply it to any root, unless at a considerable distance from all buildings. In using the dynamite, it requires especial care in connecting the fuze and

cap with the dynamite, more especially if the dynamite gets frosted, as it requires to be thawed before it can be connected with the cap. Lately we have used a good deal of it in stabbing tree roots.—J. MILLER, *Clumber.*

NEW PLAN OF WATERING STREET TREES.

A good deal has been done lately in London and other towns in the way of planting trees in the streets, but I have not seen any planted hitherto with any regard to the natural requirements of the tree. The roots are placed beneath paved roads and footpaths P P, with an iron grating surrounding the stem, which is even sometimes closely surrounded by the paving stones themselves. When the water is thus drained off into the sewers, what is to become of the trees? The following method of watering them is so simple, that I cannot help thinking it must be employed somewhere, but in case it may be new to some about to plant trees below pavements, I will describe it. The water, as it runs along the gutter A on its way to the sewer grating, is drawn off by a pipe B B, which is placed slightly on an incline, and runs into the space C C round the stem of the tree below the usual iron grating I I. If the space be small, the water may be

New Plan of Watering Street Trees.

dispersed by pipes made of common drain tiles D placed radially round the tree. In this way the tree may be well supplied with water, while any very heavy fall of rain will run off into the sewers in the usual way.

HERBERT BIRKETT.

55, New York Street, Manchester.

NOTES & QUESTIONS ON TREES, SHRUBS, & WOODLANDS.

Irish Yew.—Some notes having appeared in THE GARDEN about Irish Yews opening and spreading out in an awkward manner when old, allow me to say that I used to adopt the following method of preventing this. When the plants have grown to the size which one wishes them to do, and before they show indications of opening out, let a stout wire ring or two down on the plant over the top, about the same girth as the plant. These rings can be worked in amongst and hid by the small branches. Such appliances will keep the plants perfect pillars for years.—T. WILLIAMS.

White Azaleas Out-of-doors.—Several bushes of these grow here in the open air that have evidently been out some years. I hope to make an experimental bed of various kinds next spring, as I see no reason why many other Indian Azaleas might not succeed out-of-doors besides the white one, seeing that Camellias grow well as single bushes on Grass, and that they are now covered with buds in various stages of development.—J. GROOM, *Linton, near Maidstone.*

Grouping Oaks in Parks.—Amongst all our native trees the Oak stands pre-eminent; in fact, to my mind, a park without Oaks is like an orchard without Apple trees, it is devoid of its greatest source of interest; and a wide expanse of verdure, in which the Oak has no place, always impresses me with a sense of incompleteness. The Oak amongst trees is the emblem of strength; its sturdy growth, spreading habit, and dense foliage render it both useful and ornamental. Happy are those who possess in their domains some fully-developed examples of this fine old English tree. This advantage can, however, only be enjoyed by the few. A generation is required for the proper development of the Oak, and it is this fact probably which deters the owners of newly-formed parks from planting it; but if we cannot have ancient specimens we may, by planting it in groups, obtain a very fair idea of the true beauty of the Oak. By grouping a few young trees we may effectually realise the characteristics of an aged specimen. If planted rather closely the branches soon intermingle, and the group eventually develops those features which form the charm of a large tree. When seen from a distance—and woodland scenes should be always thus judged—the individuality of each tree is scarcely distinguishable, the effect being that of a single, fully-developed, and luxuriant specimen of Oak.—J. CORNILL, *Byfleet.*

GARDEN DESTROYERS.

THE POT-HERB MOTH.

(HADENA OLERACEA.)

THE caterpillars of this common moth are frequently very destructive to culinary vegetables. They do not, however, confine their ravages to the kitchen garden, for they have a great partiality to Dahlias, and in the autumn do much damage by eating their petals and so spoiling the blossoms. As they never feed during the day they are seldom seen on the flowers until after dusk, unless they try and hide themselves among the petals, as they sometimes do; if, however, Dahlias are attacked by them they may generally be found during daylight, resting hidden under the leaves. In the kitchen garden they attack many kinds of vegetables, particularly Cabbages, Lettuces, and Turnips; they also feed on the leaves of Gooseberry and Raspberry bushes. The only way of ridding a

Pot Herb Moth (*Hadena oleracea*).

garden of these pests is by picking them by hand off the plants on which they are feeding. Their natural enemies, fortunately, are numerous. Several kinds of ichneumons lay their eggs in them, the grubs from which feed on their bodies and eventually kill them, and many kinds of birds devour them eagerly. Cold and wet weather is very hurtful to them, so that in all probability comparatively few reach maturity. The moths make their first appearance towards the middle of the month of May. They are, however, seldom seen unless search is made for them, as, during the day, they generally rest on the stems of trees, palings, or in hedges, where they get as much out of sight as possible, or are so much the colour of the substance on which they are resting that they are not noticed. It is only after dusk that they may be seen on the wing, unless they happen to be disturbed; from this it will be seen that it is almost useless to try and lessen the numbers of this insect by killing the moths. The female lays her eggs about the end of May or the beginning of June, on the leaves of the various plants which will serve the caterpillars for food. They are soon hatched, and at once begin feeding on the leaves. They increase in size very rapidly under favourable conditions of food and weather. In about a month they are fully grown; they then leave the plants on which they have been feeding, and, having buried themselves in the ground, become chrysalides, from which the moths emerge in August, from whose eggs a second brood of caterpillars soon makes its appearance. These in due course become chrysalides, in which state the insects remain during the winter and until the following May. The moth measures about $1\frac{1}{2}$ in. across the wings when fully expanded. The thorax and body are stout. The latter is of an ashy-grey colour, with a somewhat darker broken central line. The antennæ are smooth and tapering. The head, thorax, and upper wings are reddish-brown; the latter are marked with several darker streaks and irregular transverse bands, and various small white dots. Near the middle of the upper margins of the wings are two yellowish spots, the one nearer the base being small and round, the other larger and somewhat kidney-shaped. Near the outer margins of the wings there is a fine, whitish, very irregular line, the margins themselves being deeply fringed. The lower wings are of a dirty white colour, with the margin blackish. The caterpillar, when full grown, is about $1\frac{1}{2}$ in. in length and about the thickness of an ordinary quill. It has thirteen joints, including the head, eight of which—namely, the first three, the sixth, seventh, eighth, ninth, and last joints of the body—bear legs. The colour of the caterpillar varies from a greenish to a yellowish or reddish-brown dotted with white, and with a dark brown line down the middle of the back and a pale line on either

side. There is also a line on each side, just above the legs, of a bright yellow colour, on the upper margin of which is a blackish line. The chrysalis is of a bright reddish-brown.

S. G. S.

SNAIL AND SLUG TRAP.

THE trap figured below is a very simple one. It consists of a kind of pot provided with a number of holes in the side and a closely-fitting cover, the pot being plunged into the ground so that the holes are just level with the soil. The pot is glazed inside, and the cover is made to fit tightly, so as to keep the bait that is used in a fresh condition. The holes are conical, so that when once the snail enters the pot it has great difficulty in getting out again. The interior being thus kept cool and dark has a great attraction for snails, slugs, mole crickets, woodlice, and other plagues which burrow in the earth. As for the bait to be used, that depends in a great measure upon the pest which we wish to destroy. A sancer of strong-smelling stale beer, or beer mixed with vinegar, is an excellent bait for snails, slugs, and woodlice, the olfactory nerves of these

Pot trap for snails, slugs, &c.

destructive pests being particularly sensitive. Stale wine is much used in France as a bait for the mole cricket, and earwigs seem to enjoy fresh bones which have not been too well picked, stale soup, or pot liquor with great gusto. For field mice and other four-footed vermin, flour, meal, corn, or bran may be used. As a rule, the traps should be placed in a shady position, so as to keep them as cool as possible, snails, slugs, and woodlice hating light and warmth. In the case of slugs and snails the greatest harvests ought to be made in damp or wet weather, and approaching showers ought therefore to be the signal for putting fresh bait in the traps. These pots are sold by M. Pelletier, 20, Rue de la Banque, Paris, but they might be easily manufactured by boring a number of holes in a flower-pot with an old three-cornered file, the point and edges of which have been well sharpened on a grindstone. If plenty of water and silver sand be used a hole is very soon made. The cover may be formed of a flower-pot saucer, and should be fastened down with ordinary clay. C. W. QUIN.

Paraffin Oil as an Insecticide.—Some time ago Mr. Koight, of Floors, published a receipt in a contemporary which I sent to Tweed Vineyard for exterminating bag, &c., but he did not publish it correctly. I never use less than three wine-glassfuls of paraffin to four gallons of water, and it is instant death to bugs without the least injury to tender stove plants. My way of mixing and applying it is to put the oil first into a pot and fill in the water vigorously with a syringe. In applying it, one man is kept lifting a syringe full out of

the mixture and discharging it into itself, while another applies it to the plant. In two or three minutes it is syringed off again with clean water. It is only very partially effectual when mixed at the rate of one glassful to four gallons of water.—D. I.

THE FLOWER GARDEN.

ROCKERIES AND ROCK PLANTS.

IN the construction of a rockery, if bright-coloured or glaring white stones must be used, they should be coated with cement to tone down their colour. A rockery never looks so well as when timeworn and the stones are clothed with Mosses. Shakespeare says "there are sermons in stones," but new, bright-looking stones tell nothing. I was forcibly reminded of this passage in "As You Like It" when looking at the rockery at Castle Hill House, Huntingdon, some time ago. It is not large, but it is tastefully arranged in an excavation in the side of the hill, on which stood, many years ago, the old Castle of Huntingdon, and this hill or mound is all that is now left to mark its site. What makes this rockery peculiarly interesting, too, is the fact that it is mainly composed of the old stones that have been from time to time dug out of the hill. They are relics of the old Castle, many of them bearing traces of man's handiwork in the carvings with which they are adorned. Thus, this is not only a charming little rockery, it is more—it is a museum of ancient history, running back for centuries into the past. In the construction of rockeries small, narrow ridges of rocks should be avoided, as the plants growing thereon suffer so much in dry weather. It may not always be easy to exactly imitate the conditions under which Alpine plants grow naturally, but building up high, narrow masses of stone, through which wind, sun, and frost can penetrate will certainly prove a mistake, so far as the culture of Alpine vegetation is concerned. Broad masses of rockwork of moderate height will be found to be the most suitable. There should, of course, be sinuosities and variations in outline, and even a small rockery may have its apparent elevation added to, by planting on it a suitable shrub or two. The outline may often be broken and improved by planting such trailing shrubs as *Cotoneaster microphylla*, and allowing them to hang over. Several of the Berberies, such as *B. empetrifolia* and *stenophylla*, are well suited for planting on the crown of a rockery; their growth is so light and elegant scarcely anything can surpass them. Then again there are Bamboos, including such kinds as *Metake* and *Fortunei variegata*. Amongst hardy ornamental Grasses, *Eulalia japonica* should not be omitted. *Aralia japonica* and *Sieboldi* are both effective plants for rockeries. In sheltered situations, the Australian *Dracena indivisa* would, in most places south of London, stand the winter, and so would the Fan Palm (*Chamærops excelsa*). The appearance of the rockery would be very much improved by planting a few of the plants which I have named on the salient points, not in any formal order, but just one here and there. The northern side of such plants as throw a little shade, might be seized upon for planting anything that did not thrive in hot sunshine.

Alpine plants are usually propagated by division of the roots or offsets, or by seeds; the former is by far the commonest plan, and is usually performed just about the time when growth begins. The growth of most plants, of course, begins in spring, and, from February onwards propagation by division may go on as each family shows signs of moving. If propagation by cuttings be resorted to for some kinds, summer will be the best time for that operation, when the growth is soft, and they should be inserted in a prepared bed in a shady border. If it be possible, duplicates of all the choice and rare kinds should be grown in pots. A choice collection of Alpines in pots would be as interesting to people who really loved flowers and were interested in their culture, when once they had become acquainted with them, as a collection of greenhouse plants would be, and they would cost nothing for fuel and would require much less attention; 5-in. or 6-in. pots would be large enough for most of them. The pots should be plunged up to their rims out of doors in summer in ashes or new Cocoa-nut fibre. If

the latter be used, the soil will not dry quite so fast as it otherwise would do; and so, perhaps, something may be gained by less watering being required. This, however, should not make us indifferent to their wants. A good and liberal supply of water is a most important matter, and in the evenings succeeding hot days a watering overhead with a rosed pot or the hose will be found to be very beneficial in addition to a good supply of moisture at the roots. If the pots are plunged in Cocoa-nut fibre they should be placed on a good layer of ashes 3 in. or 4 in. thick to keep out worms. If, however, at any time worms have got into the pots, watering with lime-water will dislodge them without injuring the plants. Place 8 lb. or 9 lb. of new lime in a barrel of soft water; allow it to settle, and then use the water.

When autumn sets in, or before severe frost, the plants should be moved to a cold pit, and be plunged to protect the roots from frost and to keep them in an equable state as to moisture. How charming it would be to have a low house for Alpine plants in winter laid out in beds and winding paths! If the plants were plunged in Cocoa-nut fibre, very little labour would be required. With the Alpines might be associated a few of such plants as the following: *Farfugium grande*, *Bambusa Fortunei*, *Dracena indivisa*, *Chamærops excelsa*, *C. Fortunei*, several of the *Euonymus*, and other variegated shrubs of Chinese or Japanese origin. To these might be added, if space permitted, *Erica codonoides*, *E. herbacea*, and others; also a few berry-bearing plants, such as *Skimmia oblata* and *Aucubas*. Such a house would be exceedingly interesting all through the winter and spring, when the Alpines might be plunged in the open air again. The house need not be heated artificially, and should be provided with abundant means of ventilation. In summer it might be made gay with *Clematises*, *Lilies*, *Fuchsias*, and hardy plants (such as *Phloxes*, *Carnations*, &c.), that would do out of doors in winter or in frames with very slight protection during severe weather. The season for removal to the open air would, for most species, be the time for dividing and repotting them. Generally from 1 in. to 2 in. of drainage will be found to be sufficient. Over the drainage should be placed a little rough peat or loam to prevent the finer particles of soil blocking it up. In selecting the right kind of soil for the different species it may be stated as a rough sort of guide, and one that is easily remembered, that all plants having masses of fine, hair-like, fibry roots do best in peat or a compost of which peat forms a considerable part, whilst plants having strong, fleshy roots succeed best in loam or where loam preponderates. Some of the more delicate kinds should have a little grit or lime rubble mixed with the soil. When a plant is difficult to cultivate the cause may not always arise from unsuitable soil; climate, pure air, shade, and shelter, have oftentimes as much to do with the health of a plant as soil. Many Alpines—indeed most of those that give any trouble—have been brought from a situation where the air, from its altitude, is thin, cool, and pure in summer, and where in winter they are snugly covered up in a mantle of snow. Though such conditions cannot exactly be imitated with us, yet it generally happens that by shading, by simply sticking a branch over a plant during very hot days, and by affording a little shelter in winter in severe weather, a fair amount of success is obtained. In other words, success in this, as in all other matters, will be in proportion to the trouble taken to ascertain the respective wants of the plants and the efforts made to supply them with what is needful.

In some places in the country stubs and roots of old trees are plentiful about the woods; these, if gathered together and tastefully disposed, form a suitable home for Ferns and creepers. Somehow I do not like the idea of mixing stones and roots together. I have seen it done, but it does not seem natural. According to my view, the rockery and rootery should be distinct, the one garnished with Ferns and creepers, the other furnished with Alpine plants; but, although I think they should form distinct features, yet they may be appropriately placed in the same locality. Both need not fall into the same view, but a winding path may lead from one to the other, and, if there be any difference in the level of the ground, the rootery for Ferns should occupy the lowest position, and if

surrounded by lofty banks so that the light falls on the plants in a subdued manner all the better. This effect may be easily created by digging the soil out of the bottom and throwing it up to heighten the sides; but, in doing this, care should be taken to have the best soil on the top.

The following are lists of Alpine plants and hardy Ferns suitable for rock and rootworks:—

Rock Plants.

Fereries are frequently over-loaded with shade. A little shade from overhanging banks, or from trees at a little distance off is beneficial to many species, and enhances the effect, but every gleam of sunshine should not be shut out.

E. HOBDAY.

CANNAS: THEIR CULTURE AND PROPAGATION.

CANNAS deservedly occupy a high place amongst ornamental-foliaged plants adapted for the decoration of our flower gardens in summer. Their stately, massive growth renders them conspicuous in pleasure grounds, and as we now possess varieties which vary much in their leaf tints, running from glaucous green to almost crimson, and many of them being very floriferous, we find that they are alike valuable for beauty of foliage and abundance of flowers. I have remarked that Cannas are but seldom seen in villa gardens, a circumstance for which I think it is easy to assign a reason. In the first place, they are generally considered difficult to preserve during winter, and, again, they are often planted in unsuitable situations, such as in small beds in the centre of the lawn, where they not only fail to harmonise with other plants, but are apt to get beaten down by wind and rain. Their proper place is out of the direct line of sight, a sheltered corner, for instance, backed up by shrubs, where they do not present a too obtrusive appearance, suits them admirably; there they grow freely and flower finely. It must not, however, be inferred that they should be planted where they fail to get full light; it is simply shelter, not shade, that they require. If thus treated they would not fail to give satisfaction, and they would be oftener seen in small gardens than they are at present. Cannas may be successfully grown in pots, and when so treated they are often found serviceable for indoor decoration. They look well by gaslight, and where large-foliaged plants are often required some good potfuls of them should always be grown, as they may be often used in such situations where choicer kinds could hardly be employed without risk. They may be propagated either by cuttings made from shoots taken from the old stools or by seed. In order to induce the formation of suitable cuttings, the old roots must be placed upon a gentle hotbed early in March; after the roots are in position, fill in between them with some good light soil. As the plants start into growth, take off the cuttings when about 3 in. long and insert them singly in small pots, plunging them in gentle heat. They will soon root, when they may be shifted into 4-in. pots, and replaced in the hotbed. From thence they may, when fairly established, be removed to a cold frame, and so gradually inured to the full air and sun. A considerable quantity of plants may be thus worked up from a few strong stools. The seed, which is hard and round, and which gives to the plant the name of Indian shot, must be soaked in warm water for forty-eight hours before sowing, and requires a brisk bottom heat to induce a free germination. The seedlings may be treated in the same way as above described for cuttings, but this method of obtaining plants is hardly to be recommended in a general way, as they are never so strong as those obtained from cuttings. Cannas are gross feeders; they flourish best when the roots can freely ramble where they do not lack for either nourishment or moisture. In France Cannas are generally mulched with good rotten manure, the copious waterings combined with great solar heat inducing a grand

development. I have grown them to perfection in Normandy by planting them upon large raised beds, and I believe they do best when the roots are raised rather above the ordinary garden level, as the heat of the sun is better enabled to penetrate to and warm them. They must, of course, be well mulched, or there is a difficulty in saturating them in hot weather. I should recommend a trial of this method to those who may have to deal with a cold soil, as the success of sub-tropical plants depends quite as much upon the amount of warmth which they get at the root as on that experienced above ground. There need be no difficulty experienced in keeping the roots over the winter. They merely require a cool, dry place into which the frost cannot penetrate. The soil should be cleared away from the roots when lifted, and if packed away quite close they will keep in good condition and come out quite fresh when required for propagation. I have heard the assertion made that if left in the ground during the winter they will push stronger and thrive altogether better than if lifted in the autumn. That they will grow fairly well in this way I have had ocular proof, but that was on a high-lying, dry soil. In soils of a free, light character, and well drained, the roots being protected during the winter, they might be depended on to come up well again. I doubt, however, if whether, after the second year, they would not need lifting and replanting. Perhaps some of the readers of THE GARDEN may have had some experience in this particular matter. In making a selection, due regard should be paid to securing as much variety of leaf-tint and colour of flower as possible. In grouping them together in masses some knowledge of their individual growth is necessary, as they vary considerably in height and spread of foliage. The following varieties are amongst the best, and would give satisfaction:—Bihoreli, distinct, of a good habit, and floriferous; Rendatleri, a tall grower; nigricans, tall, with dark leaves; Annei; erecta, fine growth; and Warscewiczii major. There are many varieties now to choose from, and individual tastes differ, but these are all calculated to create good effects in either large or small establishments.

JOHN CORNHILL.

The Common Rhubarb in France.—The value of this plant, so prized as an esculent in this country, is differently estimated in France. There it is classed amongst plants of high decorative qualities, and has generally a post of honour assigned to it in the vicinity of the mansion. In rural districts amongst amateurs and peasant farmers, one occasionally finds a stool of Rhubarb which is highly prized for its beauty only, its esculent properties being wholly unknown to them. When the slight feeling of wonderment which one naturally feels at seeing in the flower garden a hitherto considered common vegetable wears off, one cannot but admit that it associates remarkably well with the ordinary inmates of the pleasure ground. A large stool when in flower in an isolated position has an imposing appearance, and there are plenty of situations in large grounds in this country where a few plants of Rhubarb would not appear at all out of character with the surroundings.—J. CORNHILL, *Byfleet, Weybridge.*

Lily Growing.—I am sorry to see (p. 518) that my former questions on this subject were not explicit enough to deserve an answer from "Dunedin." I will endeavour to be more definite this time, but I decline to be led into a discussion on the "personal theory," which has nothing whatever to do with my questions, which relate exclusively to certain statements of "Dunedin"; viz., that Mr. Dod was "deceiving himself and possibly others in saying that he gained a year's growth by buying large bulbs." What I say is that Mr. Dod was right, and that, practically, his advice was good. My argument, briefly formulated, is this: first, that large bulbs of such Liliæ as *auratum*, for example, produces the strongest stems and the greatest quantity of flowers. Secondly, that the bulbs grow large as they grow older up to a certain limit, and under ordinary good culture; and thirdly, that when we buy a large bulb we gain one, two, or three years' growth, just as the case may be. In other words, a three-year old bulb is better than a one-year old one, simply because it is older and consequently larger; the buyer gains two years' growth, and that growth is represented by size, greater vigour and flowering power. This, I apprehend, is all that Mr. Dod means, and this is what "Dunedin" denies, when he states that, by saying he gains a year's growth by buying a large bulb, Mr. Dod "deceives himself and possibly others." No other construction can be put upon "Dunedin's" statement, which is refuted by every-day experience.—J. S. W.

PLATE CLVIII.

EARLY SPRING-FLOWERING SQUILLS.

THE annexed illustration represents two varieties of these charming vernal gems, which have recently been added to our lists of hardy flowers. A glance at the figures will, however, show that they are but deviations from two well-known and deservedly popular types. Like them, too, they belong to the small group of Squills which flower very early. The larger kind depicted in our plate is the Taurian form of the two-leaved Squill (*Scilla bifolia*), but it differs from it in being larger in size and more robust in habit; its flowers are also larger and more numerous, and it produces several leaves, thus departing from the bifoliate character generally observed by the type, but which, by the way, is not an absolutely reliable one. This handsome variety was first brought into notice by Dr. Regel, of St. Petersburg, and it is gratifying to see it already in trade lists. The small kind shown in the plate is a minor variety of the brilliant Siberian Squill (*S. sibirica*), and much resembles the other small variety of it (*S. s. amœnula*). It is dwarfer than the type, and though it lacks its robustness, and the flowers are somewhat of a lighter shade of colour, this is compensated by its flowering at least two or three weeks earlier, thereby much enhancing its value, and placing it on the same level, as regards earliness, with *S. bifolia*. Like the type, it has a wide geographical range, but appears to be most plentiful in southern and central European Russia.

Whilst upon the subject of early Squills, it may not be out of place to mention a few other distinct and valuable kinds, though, of course, the line of demarcation between the early and the late spring-flowering varieties cannot be very tersely defined, as they merge into each other according to the season, and notably the beautiful rich blue Italian Squill (*S. italica*), which is immediately succeeded by the numerous varieties of the Spanish and English Squills, and a host of others. Taking them in point of earliness, we have the early two-leaved Squill (*S. bifolia* var. *præcox*), an extremely handsome form, much larger than the type, and one which flowers considerably earlier. Next comes the true *S. bifolia*, which is succeeded by the varieties *carnea* and *alba*, sorts that differ only as regards colour. Accompanying these are the varieties *S. candida* and *rosea*, both in every way much larger, the former with pure white, and the latter with bright rosy-pink blossoms, but apparently not so robust in habit as *S. b. var. taurica* above described. The minor variety of the Siberian Squill (*S. sibirica*) opens its blossoms along with these, and is succeeded by the type and its small variety, *amœnula*. *S. amœna*, a handsome kind from Central Europe, &c., comes next; it may be recognised from the preceding by the flowers not assuming such a nodding position, nor being so bell-shaped, and also by the darker hue and the yellowish centre.

The culture of Squills in the outdoor garden is by no means difficult. If planted at the depth of a few inches when the bulbs are at rest—that is early in the autumn—in any good garden soil, if not too heavy, and if, when once established, they are allowed to remain undisturbed for years, except perhaps giving them a slight annual top-dressing of manure, the cultivator will be annually rewarded with a display which will amply repay any trouble that may be taken with them. Some kinds, especially the many-coloured varieties of the Spanish Squill (*S. hispanica*, syn., *S. campanulata*), and the English (*S. nutans*), are admirably adapted for introducing into the wild garden by the sides of woodland walks, margins of shrubberies, &c., situations in which they form an attractive feature in spring. Some kinds again, and notably the Siberian Squill, is perfectly amenable to forcing, and associates charmingly with Lily of the Valley, Maiden-hair Fern, &c., as may be seen now and then in Covent Garden Market.

As regards propagation, offsets may be taken from established clumps during summer, and a very interesting, though somewhat slow, mode of procedure is raising them from seeds, which in some seasons are produced plentifully; by this mode many varieties of real merit, both as regards size and colour, have been obtained, and there is still ample room for further improvement in this direction.

(The plants from which our plate was prepared were furnished by Mr. Ware and Dr. Wallace.]

HARDY FLOWER GARDEN PLANTS

VALERIANA *Plu* var. *anrea*, we have found to keep its colour longest in light soil, and in a sunny exposure, but it has only been suitable for winter bedding here, as the gold colour goes off before spring flower garden plants are over. It is useful as an edging to a shrubbery border where it can be permanent, but not in a more prominent place, as it is quite uninteresting after the three months of gold colour, when it begins to grow and flower; cats, too, rub and roll themselves on the Valerian borders, and by bruising the stems, and scratching up the roots, cause the unpleasant smell of the plant to be perceptible even to any one walking past it. Travelling in Northumberland in March, 1868. I was struck by the bright colour of this Valerian in a cottage garden in the village of Ford, and on the spot secured a good patch of it; by striking the tops and cutting up the roots, I got up a fine stock for next winter's work, and from February to April it was very effective.

Mr. Ingram, to whom I sent it, however, found that it was not bright enough for Belvoir, the soil probably being too heavy for it. In the out of the way village of Eltrick (Selkirkshire) I also saw it in cottage gardens, but never in any private gardens, with the exception of those to which I sent it.

There is a very pretty gold variety of *Potentilla anserina*, the young leaves of which come up golden all through the summer, though, of course, not so bright as in spring. It makes a beautiful gold feather leaf for associating with out flowers, and lasts long in water. Here I find it to do best in a patch; it is too liable to run to make a good edging plant.

Another beautiful variegated-leaved plant is *Achillea Millefolium*; whole leaves of this come of a pure creamy white; others more or less white, but if not watched this plant is apt to go back to the green state, which the *Potentilla* never does, at least here.

It would be difficult to name a handsome bed than *Lobelia fulgens*, or others of that class, and the variegated *Tussilago Farfara* makes, in cool strong soil, and in a moist climate; such a combination is faultless: height, form, colour, all these contrast and suit.

A fourth wild plant, *Sorophularia nodosa variegata*, makes an excellent edging for a large bed; it was originally picked up by a hedge-side, Mr. James Ray, late superintendent of the Dean Cemetery, has told me. Mr. Ray knew plants well, and first introduced *Meum Athamanticum* as a hardy, fine foliaged plant about here; and most decidedly it should be meant to be permanent wherever it is planted, for there is great difficulty in getting rid of its roots, which go down 3 ft., and the least remnant of them will grow. We cut over our edgings in summer and never let them flower, thus securing good foliage late as well as early, and, as in autumn it fades into a very bright yellow, it is worth having good strong leaves to become golden. It grows under the shade of Yew trees, which few plants will do. I have seen parcels of the long tap roots for sale as a substitute for Tobacco in some of the Aberdeen markets. Going round the King's Road Nursery, a few years ago, with Mr. Harry Veitch, I picked up what I fancied was another *Meum*, the habit of which seems different from that of *M. Athamanticum*. It is more erect, thinner in growth, and has still more hair-like leaflets. It is also equally fine in colour when fading, and its erect habit shows the autumn colour to better advantage; after two examinations, however, Mr. Sadler assured me that the two were identical, and so, of course, botanically, they must be. Nevertheless, we grow them both, and separately; for cutting Mr. Veitch's is the best. I have spent long summer mornings hunting through great patches of *Meum Athamanticum* in Glen Lyon (Perthshire) where it grows abundantly by the road sides, collecting seeds in hopes of possibly finding varieties, but fruitlessly, as the seeds came up provokingly true. A variegated form would be a great acquisition; but very numerous as are the Umbelliferous tribes, at this moment I can only recall two which come variegated—viz., *Celery* and *Cow Parsnip*.

Wardie Lodge.

F. J. Hope.

NOTES AND QUESTIONS ON THE FLOWER GARDEN:

A Word or Two more about Fuchsias.—I think Mr Williams (p. 498) must have under-rated *Fuchsia microphylla*, which at one time was certainly one of the most floriferous *Fuchsias* known, and I simply called attention to it on account of its being so seldom met with. In its early days it was more grown as a pot plant than as one planted out in the flower garden. About the time when it first made its appearance the only kinds generally known were *F. gracilis*, *F. coccinea*, *F. tenella*, and *F. conica*, the last named being, I believe, the parent of all the large-growing hybrids which followed each other in such rapid succession from about 1833 to 1850. Amongst these, perhaps, the one that created the greatest stir, and certainly originated a fresh strain amongst *Fuchsias*, was the first

white one called *F. Venoe Victrix*, while for outdoor purposes, one about coeval with it, called *Riccartoni*, maintains a good position even now; and, in fact, it is the best I know of for general outdoor decoration, although some give the preference to *Corallina*. All are, however, beautiful, and well deserve to be more widely cultivated than they are.—A RETIRED GARDENER.

The Woolly Lavender (*Lavandula lanata*).—This very much resembles the ordinary garden Lavender, but it may be recognised at a glance by its blunter leaves, which are densely covered with short white down, and also by being a much dwarfer plant. The flowers are borne in the same manner, and are of the same colour and size. It is a native of Spain, and would probably require some little attention in this climate, especially during winter, as its woolly leaves would be liable to be injured by excessive moisture.—W.

Lamium striatum.—Thanks to Mr. Cornhill for kindly replying to my query respecting this Dead-Nettle. The name was new to me, and having, since my query, seen a portion of the plant, I must say that it appears new to me also. The name is a good one, and if any member of this varying family has borne the name of *striatum*, this must be the plant, as the markings are certainly more striated than maculated. I believe, however, that it will prove to be a striped-leaved variety of *L. Ævrigatum*. *L. vulgatum*, *album*, *mysorum*, *maculatum*, and *ævrigatum* are now by botanists thrown together. Need I remind Mr. Cornhill that *L. purpureum* is an annual?—THOS. WILLIAMS.

Wallflower Seed.—It is indeed remarkable that there should be just now almost a dearth in Wallflower seed. Although the spring was not severe one it was eminently destructive to the Wallflower seed crop, as a more general failure has rarely been known. Growers who looked for gallons have hardly got ounces, and have been compelled to hold over what little they have saved for their own sowings. The cause of this failure is generally attributed to the rainy time that occurred when the plants were in bloom, but it is difficult to assign an exact reason for such a deficiency. It is worthy of note that the best heads of seed were found where the plants were sheltered by trees. Another fact leads to the belief that late spring frosts may have been the cause of the mischief. *Myosotis dissitiflora* was also a very scarce crop, as, indeed, it is probable that it always will be. One or two spring frosts do the bloom so much mischief that probably one-half of its seed produce is at once affected. It is such a floral gem, however, that it will always be in request.—A. D.

Mulching with Cocoa-nut Fibre.—This is an excellent plan, especially in the case of small town gardens, where the soil is too often what it ought not to be. I have seen Cocoa-nut fibre applied in small town gardens with excellent effect for years. Its advantages are, that as soon as the beds are planted in spring, a layer of this material will keep down weeds during the whole of the summer. It does away with the cold, chilly, baked appearances so common in the case of stiff soils, and obviates the continual surface stirring, so often necessary. To hungry, sandy soils it gives body, and prevents evaporation and starvation, and, being of an absorbent character, it is nearly always warm; and lastly, its colour is so neutral, that it shows off to perfection nearly every kind of flower or plant.—THOS. WILLIAMS.

Water Lilies on Grass.—When walking around the observatory at Harvard University the other day, I came upon two little pools of water in the Grass. Water Lilies were growing in them, and around the margin the German Ivy (*Senecio scandens*) was in wild luxuriance, sending its shoots, covered with deep green glossy leaves, lither and thither among the Grass. On closer observance I found the pools to be tubs plunged to their brims in the ground and filled with water. These Lily ponds on the lawn formed part of a brilliant little flower garden; they bloomed splendidly during the summer, and some dozens of blossoms were cut from them. As Water Lilies thrive well under such circumstances, who need be without them?

Scarlet Flowers among the Grass.—A novel but pretty way of using *Tropæolum Lobbianum* is in common practice around Boston. A small flower bed, 12 in. or 14 in. in diameter, is made at the top of a bank or on the sunny slope of a lawn, and planted with these fiery *Nasturtiums*. As they advance in growth, the shoots covered with scarlet blossoms reach forth in all directions among the Grass. The Grass is not mowed, but merely swathed over with the sickle, when it overtops the *Nasturtiums*. Such brilliantly studded banks attract considerable attention.—“Rural New Yorker.”

Cannas with Gladioli.—One of the specialities of the Paris flower markets from the middle of July onwards is a combination of *Cannas* and *Gladioli* in pots. A strong clump of a bronzy-leaved *Canna* is potted with one or two bulbs of *Gladioli*, the variety *Branchleyensis* being the favourite. The pots are brought to the markets in considerable numbers and look remarkably well, the ample leafage of the *Cannas* setting off the scarlet flowers to great advantage. Occasionally we see in the same pot the bold leaves and striking flowers of the *Canna* with those of the *Gladiolus*; but, generally speaking, the flowers of the *Canna* are pinched out before they open.—“Gardeners' Magazine.”

GARDENING FOR THE WEEK.

Orchids.

The most generally useful of all Orchids are those that, in addition to their flowers lasting long on the plant or in a cut state, are abundantly plentiful, moderate in cost, and easy of cultivation to admit of their being grown in quantities so as to enable the cultivator to bring them into bloom in succession.

Dendrobium moniliforme and **D. nobile**.—Amongst Dendrobes bearing the above character, one of the first in the year that has a tendency to come into bloom is the Chinese species, *D. moniliforme*. If several plants of this are grown, and some are at once put into a brisk heat, their buds, which are now prominent, will soon expand; they will admit of more water being given to the roots in the first stages of development than the nearly allied species *D. nobile*, as *D. moniliforme* has not a disposition to produce growth from the nodes if kept comparatively moist at the root in the early stages of the flower advancement, as is the case with *D. nobile*. By keeping some of the plants cooler, that is, a few degrees warmer than the temperature of an ordinary greenhouse, they will succeed the earliest in bloom. If some plants of *D. nobile* are put similarly into a warm house, they will come on to succeed, as well as give contrast, to the first-named sort, but with these, as already intimated, no water at all should be given to the roots until the flowers are distinctly discernible. Where there is a moderate amount of atmospheric moisture it will suffice to enable the plants to make the requisite progress.

Cœlogyne cristata.—If there be a sufficient stock of *Cœlogyne cristata*, some of the plants should be put in warmer quarters, to hasten the expansion of the already advancing flower stems. This is a subject that requires an abundant supply of water at the roots, but at this time of the year, instead of giving it with the syringe, I have found it best to apply it with a spouted can; in this way, with care, it will not lodge on the bloom spikes, which are liable to damp off if moisture accumulates about them.

Lycaste Skinneri.—From this useful and easily-grown species a longer succession of flowers may be obtained, if a few of the plants are likewise placed where they will be a little warmer than the rest. Such Orchids as are in flower, especially in the East Indian or warmest compartment, should be put where they are the least likely to suffer by the condensation of moisture upon them; this will be generally found at a distance from the extreme ends or sides of the house; for the same reason no more moisture ought to be used in the atmosphere than is absolutely necessary for the well-being of those plants that are making growth.

Material for Growing Orchids in.—The peculiar nature of most Orchids is such that the material in which it is necessary to grow them artificially is very different from that required by the majority of other plants; most of them grow naturally with their roots in a great measure exposed to the air on trees or slightly-covered rocks to which they cling, with the extremities extending to the light, and decomposed vegetable matter is generally to be found within their reach; it follows, therefore, that if potted in soil at all adhesive, they very soon perish, though, on the other hand, the extremely light potting practised by some growers is not calculated to produce, nor does it actually result in, such strength of growth and flowering abilities, with a disposition to increase, as where more or less peat is employed. A sufficient quantity of peat, Sphagnum, and turfy loam for such as want it should always be got in before the close of the year to last for the next six months.

Sphagnum.—In the case of Sphagnum, with those who reside in localities where it grows, and can procure it for the trouble of collecting, enough for twelve months should be secured, as, when severe and protracted frost occurs, I have seen it so far killed, or injured, as to reduce it to a slimy mass, totally unfit for placing near the roots of any living plant. When it is got in, it is advisable to pick out all dead leaves or particles of Grass that frequently are found amongst it, and which, if used in a living state, grow in the pots and take a good deal of trouble to eradicate; and if the Grass be killed by the Moss being dried before use, as soon as it gets wet it produces mould, which, if it does no direct injury to the plants, quickens the decomposition of the material, rendering it sooner an unfit medium for the roots to penetrate. The best plan that I have found with Sphagnum is to spread it out thinly on a boarded floor, if available, and to keep it turned till it is quite dry.

Peat.—Even for the commonest Orchid, nothing but the best fibrous peat should be used. Such as is of a brown colour obtained from a dry situation occupied by the common Brake (*Fera.*) is the best, as the fibrous roots of the Fern permeate the peat so as to make

it nothing but a mass of fibre; this, with the more earthy part shaken out, and the thick portion of fleshy roots of the Fern removed, is in my opinion the only description of peat fit for Orchids. The hard, black, close peat, on which Heather grows, sometimes used, is anything but suitable. The majority of Orchid growers are not so situated as to have good Orchid peat in their own immediate neighbourhood, as in comparatively few parts of the kingdom is this to be found. When purchasing, it is much more satisfactory to obtain it by the yard than by the ton, as, in the former case, it is immaterial to both buyer and seller whether it is wet or comparatively dry.

Storage of Peat.—Good Orchid peat being dear, it is often, with a view to economising it, kept until required under cover, where it is perfectly dry. This I have found to be a mistake, as it does not go near so far, by reason that when broken into bits, more of the earthy matter becomes detached than is absolutely necessary to take away, and the fibre that has once been thoroughly dried in this way sooner decomposes than when it has been kept all along in a slightly moist condition. It is better stacked out-of-doors, like other potting soils, in a manner that will throw the greater portion of the wet off, only taking it in sufficiently long before it is required, to admit of its getting into a sort of half-dry condition.

Loam.—There are a few plants such as *Cypripedium insigne*, *Phajus*, the larger-growing *Zygopetalums*, and some others of a like character, I have found to do better in loam than peat. A sufficient quantity of this of a not too sandy description should also be procured and stored as directed for peat.

Wood for Blocks and Baskets.—For such plants as are to be grown suspended from the roof, the superiority of baskets over pots is their being so much lighter, that where used in large quantities they do not put near so great a strain on the roof timber of the house, as well as the fact that they have a much better appearance; but whatever is chosen it is of the first importance that it be of the most durable character obtainable. The branches of Maple, Acacia, and similar wood look very well, but they are soon rotten, the result of which is that the wood gets so far decomposed as to necessitate the plants being moved from it, by which their roots, which in many cases will have absolutely entered the rotten material, are, unavoidably, to a considerable extent, destroyed in the removal. Cork, in common with all other bark, is a material that the roots freely cling to, but it is alike open to a similar objection on account of its soon becoming as rotten as the wood. The best material I have ever found for use in the shape of blocks, or wherewith to make baskets, is fossil or Bog Oak, which will last very much longer than any other description of wood, with the additional advantage that its decay is gradual from the outer surface, much in the manner in which a piece of iron rusts away, and not the whole mass together, as in the case of other wood, hence the roots do not get absolutely into it. The next best material that I have met with is the heart of English Oak, quite dry before being used, cut up into lengths proportionate to the size of the baskets or blocks required, and split, not sawn, to the thickness wanted. In this way it has a much better appearance than the straight-sawn surface. In making the baskets and blocks, a sufficient quantity of which should now be prepared, copper is preferable to the galvanised wire often used, which always rusts where the outer metallic coating is displaced in bending it. For draining the baskets, as also for mixing with the potting soil, charcoal, on account of its lightness, is much better than crocks. If all such materials are now got ready, when the time for potting the principal portion—towards the latter end of winter—has arrived, it will be found that the work can be got on with very much quicker than where everything has to be prepared as it is required.—T. BAINES.

Indoor Plant Department.

Forced Flowers.—There is no season of the year wherein flowers are so deservedly prized as during the ensuing three months, when, if we except the Christmas Rose, the naked-flowered Jasmine, *Laurustinus*, and Snowdrops, there is little out of doors, in the way of flowers, to interest us. In glass structures, that are kept at an ordinary greenhouse temperature, Camellias, Primulas, *Cyclamens*, *Mignonette*, early sown *Cinerarias*, and similar plants can be had in blossom; but, in the case of those who require a good and regular supply, a house wherein a night temperature of from 60° to 65° is maintained, is indispensable. It is not necessary that such a house should be either very large or costly; but in order to be able to reap full benefit from it, as regards the production of winter flowers, it should be divided by a glass partition, so as to keep one part cooler than the other. By this simple arrangement, there is no necessity for keeping some plants warmer than they require, and others cooler than they can well bear. In the coolest division, where a night temperature of from 50° to 55° can be kept up, bulbs, such as Hyacinths, Narcissus, and Early Van Thol Tulips, may be brought on into flower

much more satisfactorily than in a stronger heat. Of that very best of all shrubs for forcing, *Deutzia gracilis*, plants that have been forced before, and that have made their growth afterwards in a little warmth, will flower earlier than they otherwise would do, and with less application of heat. The double-flowered Plum also forces well under similar treatment to that of the *Deutzia*; both will succeed better in the cooler stove temperature above-mentioned than if subjected to more heat, and the same remark also applies to *Azaleas*. The double *A. Borsig*, *Reine de Portugal*, and *Flag of Truce*, last in a cut state much longer than the single varieties, and, therefore, deserve to be generally cultivated by all who require forced flowers. In bringing all such plants into bloom in heat, the atmosphere should not be kept too moist, just enough water being used to maintain it in a general healthy condition; neither should the plants be syringed over-head too often; once a day, and that in the afternoon, is enough, for if too moist or hot, the flowers of all forced plants will not last nearly so long as those brought on slower. The plants should also from the time they are placed in the heat, be as near the light as possible. By this means the colour and substance of the flowers will be much improved, and, if required for cutting, will keep much better. In the warmer stove should be placed successional plants of *Poinsettia*, *Euphorbia jacquiniæiflora* and *E. splendens*, *Plumbago rosea*, *Sericographia Ghiesbreghtiana*, *Gesnera exoniensis* and *G. zabrina*. The two last, when well managed, are amongst the best winter-flowering plants grown; all the above are suitable for cultivation in small houses, where larger-growing plants could not be so well accommodated.

Indoor Fruit Department.

Vines.—Late Vines have now, for the most part, lost their foliage and, therefore, the fruit which may still be hanging on the plants is not so liable to decay as it was some time ago. The air, however, about them should still be kept as dry as circumstances will permit. The temperature should never be permitted to exceed 40° at any time with fire-heat, or the berries will be likely to shrivel and lose their plump appearance. Muscats are amongst the first to shrink, probably owing to their often being not quite so well matured as most other varieties. The bunches which contract most should, in all cases, be used first. Fire-heat should not be employed for their preservation, unless it be to exclude frost or at times expel damp.

Pines.—The earliest batch of Queens must be started now to fruit during the early part of May. If the whole of those first rested are too numerous to begin with, those most likely to fruit first should be selected. This state is generally indicated by the leaves being widely spread out from the centre, and the stem around which the leaves cling being very robust; plants of this description may usually be depended on. Those selected should be taken from where they are at present and have their leaves tied up, previous to the removal of a few of the lowermost ones, and all the loose soil down to the roots. This exposes part of the stem, and it will be seen that many small roots will be emitted from it. Against these a quantity of fresh loam and bones should be firmly pressed, leaving not less than 1 in. empty below the rim of the pot, that watering may be easily effected. The young roots soon take possession of the new material, and the plants derive the benefit of it when they come into fruit. After adding a quantity of fresh plunging matter, and mixing it well up with the old, the plants should be plunged 2 ft. or 3 ft. apart, and the leaves let down into the position which they occupied previous to being tied up. It will be a few days before the heat rises about the pots, and until this time no water should be given at the root. As soon as the heat rises to 80°, give a thorough watering with water heated to 85°. Do not let the heat ascend above 80° for the first fortnight. The air heat should be about 65° at night and 70° throughout the day, with fire-heat, and 80° with that of the sun. The atmosphere must constantly be kept moist; on sunny days they may be lightly sprinkled overhead with the syringe early in the afternoon. Do not open any of the ventilators until the temperature rises to 85°.—J. MUIR.

Hardy Fruit.

Pruning Fruit Trees.—It is always advisable to get the pruning of all fruit trees, except Peaches, Nectarines, and Apricots, completed as soon after the leaves are off as possible. When pruning is finished before the close of the year, time is given for the performance of other operations as they become due. Pruning at this season is certainly cold work, but it will be much more so if deferred until winter is far advanced, when there may be frost and snow, and when the work cannot be done so well as when it is carried out with comfort to the operator. Those who have not had much practice in pruning are very liable to either overdo or underdo it. In the case of bush or pyramidal Apples and Pears grown on borders of limited-sized gardens, it is generally deemed advisable to confine them to a small or medium size, and in order to accomplish this, they are often

so severely cut as to defeat the object in view, especially when the trees are young and disposed to make strong growth. In order to check too great a luxuriance of growth, those trees that are in the condition just mentioned and that were root-pruned about the end of the summer, should not be more closely pruned than will be effected by a slight shortening of the strong shoots requisite for the necessary furnishing of the trees, while those shoots that tend to overcrowd and are in the worst position should be entirely removed. Thus treated, it will be found that the root-pruning, if sufficiently and judiciously carried out, will have the effect of reducing the next summer's production of wood to not more than one-fifth of what it has previously been, in place of which the energies of the trees will be directed to the formation of quantities of fruit-bearing spurs on the shoots that have been made this and the preceding season, whereas if too much of the young wood be cut away, the full effects to be derived from the root-pruning will be rendered nugatory. Pears on the Quince stock do not make so much wood, and consequently do not require so much pruning, either roots or branches, as those grown on Pear stocks, but the fruit of many varieties is frequently not so good in quality, particularly such kinds as are at all disposed to be gritty. Apples, also, on *Paradise* stocks, will not need pruning nearly so much as when grafted on the Crab. I mention this merely for the guidance of those who are inexperienced, and who frequently cut away at every tree upon which they operate without discrimination, as if the impression existed that the fruit-bearing capabilities of a tree depended upon pruning alone, whereas pruning is only one of the means employed to induce fertility, and requires to be varied in extent according to the state of each individual tree. It is simply useless attempting to get fruit from a young tree that produces quantities of young wood by persistently cutting out the shoots at the winter pruning; the effect of this is to cause similar growth the following season. In the case of large standard trees do not overprune; on the contrary, only just thin out the weak, inner branches, so as to admit a reasonable amount of light, and allow space sufficient to prevent one branch coming in contact with the other during high winds, and thus knock off the fruit. It is no unusual occurrence for an inexperienced pruner to use the saw so freely in the case of standard trees as seriously to reduce their bearing capabilities. In small gardens, where trees of good varieties of Apples exist that are too large for the places which they occupy, or when they unduly shade the vegetable crops that have to be grown near them, rather than remove them altogether, it is frequently more desirable to head them down to within 2 ft. or 3 ft. of the ground. Soon afterwards they form moderate-sized, fruitful heads, certainly not so trim in appearance as those of young dwarf trees, but very often of much more service in filling the fruit room. Plums and Cherries, unless in damp, over-rich soil, are not usually disposed to make such rank, unfruitful growth as Pears and Apples; they, therefore, simply need their shoots regulated by cutting back any that take an undue lead and thinning out all that are not wanted to form symmetrical heads. With young Pears on walls there is frequently too much haste displayed in covering the space allotted to them, by laying in the shoots indiscriminately their whole length, instead of shortening such as require it to furnish a sufficient number to cover the wall evenly; the result of this is a waste of space and an unsightly appearance ever afterwards, with the generally additional disadvantage that a considerable portion of the base of the trees contain no bearing wood at all. In the case of young trees of this description any shoots that show a decided tendency to outgrow the rest should be cut sufficiently close to induce them to break back where additional growths are required to cover the wall; this will tend to equalise the strength by throwing more vigour into the weaker shoots. The same holds good with Cherries and Plums on walls.

Pruning Bush Fruits.—In respect to Gooseberries and Currants, advice is often given not to prune them until the winter is far advanced, so that if birds attack the buds the pruning can be afterwards so regulated as to leave the shoots on which the buds are least destroyed. A little reflection will show this to be a mistake, as in localities where sparrows and finches abound, if the trees be left to themselves, they frequently clear off the whole of the buds; and even where a portion is left, it is often on such shoots as are misplaced, and which, to preserve a shapely bush, have to be cut out. Besides, in advocating such a course of treatment the fact is lost sight of, that when buds are stripped off, especially in the case of Currants, it is not the ensuing year's crop alone that is destroyed, but also the spurs that should push for a number of years. It is much better to prune these fruits at once, and, where necessary, to take such means as will deter the birds from attacking the buds or render the latter distasteful to them. In pruning young Gooseberries, little more requires to be done than cutting out the superabundant shoots, leaving those that are best placed to form the future bushes, so as to give them

a shapely appearance. In the case of those as have attained sufficient size, a portion of the old wood should be cut out each year, leaving young shoots to take its place, and selecting, as far as possible, those that spring from near the base, so as to keep the bushes furnished properly down to the bottom. Never leave the centres of the bushes crowded, or the fruit will be deficient in both size and flavour, and avoid, however, the extreme of reducing the bushes to mere skeletons in the way practised by those who grow this fruit for exhibition, where everything is sacrificed to the production of a very limited quantity of large-sized berries. Red and White Currants only need the branches to be reduced so as to leave sufficient space without crowding. Immediately the pruning is completed, a few white threads should be run loosely over the bushes in the usual way. These, while they retain their fresh colour, will generally be found effective in scaring sparrows, but not finches; to preserve the buds from being eaten by the latter, mix lime and soot in equal quantities with water, as thick as it will pass through a syringe with a coarse rose; or it may be sprinkled on with an ordinary hand-brush. A fine sunny day, when there is enough wind to dry the mixture on thoroughly before night, should be chosen for the operation, and if that be done it will stick for a good portion of the winter in quantity sufficient to make the buds unpalatable to these feathered predators; a second dressing of the mixture should be given after the first has become inefficient; but whether the thread or the soot and lime be used, the bushes should be looked over at intervals to see that the means employed are effectual, as there is nothing more annoying than to find the season's crop destroyed as well as injury inflicted for a longer period. Black Currants require much less wood being cut out of them than the Red and White kinds; all that is required is to thin out the growths so as to prevent their getting too close, and in the case of old trees to cut a few of the branches out near the bottom each year, which will induce them to push up young shoots that will keep the bushes renewed, and to shorten the whole so as to keep them within bounds as to size. Raspberries may also be pruned at any time after the leaves are off; the number of shoots that should be retained to each stool will depend upon the age and strength of the plants, say from one or two to such as have only been a year planted, and six or eight to those that have got to full maturity, and that are strong; the length at which the shoots should be left will also depend on their strength and the method upon which they are grown; the old-fashioned practice of tying half the shoots from one stool to an equal number of another in the form of an arch with a stake driven into the ground where the bent shoots meet to which they can be fastened, has its advantages in the bearing shoots trained in this way not interfering in any way with, or being shaded by, the young growth, but grown in this way they have not such an orderly look as when the shoots are tied to wires stretched from end to end of the rows; under the latter method the shoots should not be left so long, as from their being in an upright position the lowest eyes do not usually break so well. In very many gardens there are portions of low wall unsuited for growing such fruits as require considerable space; these usually have Currants planted and trained over them; it is much better to cover part of such walls with Gooseberries, as they give variety, and in such a position they will keep for weeks when ripe, as here they are little exposed to wet and can be easily protected from birds with nets. On east or even north walls Gooseberries, as a rule, will bear well, whereas on these aspects the space is often under ordinary circumstances lost under the impression that nothing will succeed.

Kitchen Garden.

Forcing Seakale.—Where Seakale is required for use early in the ensuing month, means should at once be taken for applying heat to the roots. There are two methods by which it may be forced, viz., either by placing over the crowns, where they grow, the ordinary pots employed for the purpose, and covering them up with fermenting materials, such as leaves, fresh stable manure, or a mixture of both, or by lifting the roots and forcing them elsewhere. Where leaves can be had in sufficient quantities, these are much to be preferred to all other material, as they afford a more gentle warmth, and are not liable to get too hot, or impart a disagreeable flavour to the Kale. In forcing under pots, the whole space between them should be filled up with fermenting matter, covering the lid with which they are provided to the depth of a few inches. When the whole is complete, two or three sticks, to test the heat, should be inserted in the heating material. These ought to be frequently examined, to see that it does not get too hot, in which case the produce is forced up too quickly, which makes it thin and weak, instead of having the short, thick crowns of which well-managed Seakale consists. If the sticks feel a little warm, it is sufficient to produce Kale of 8 in. or 9 in. in length in five weeks or so from the time the material has begun to ferment.

Should there be any indication of too much heat, some of the fermenting material ought to be removed from the tops of the pots, so as to cool it. By this method of growing Seakale, the same roots will bear forcing in the beds in which they are grown for years, without replanting; but the produce is not usually so fine as when the roots are taken up and placed on a bed of leaves or other fermenting matter. For this reason, and the fact that much more can be grown on a given space—consequent upon the closer planting which the latter system admits of—it is to be preferred. Where the roots were planted as advised in spring, they will now be in a condition for taking up; and it is best to at once lift all that are likely to be required for the season, selecting the strongest crowns for forcing. Those not wanted for immediate use should be heeled in in a few inches of soil or ashes, in any place out of the reach of frost. At the time of taking up, the weakest crowns, and all the whip-thong-like pieces of roots should be placed by themselves in a little moist soil, where they will not get frozen, and be kept for replanting in spring. A bed of leaves, about 2 ft. thick, will be enough, made up so as to place on the top of it a small garden frame, or large box of any kind. In it put 10 in. of ordinary soil, and in this plant the crowns about 3 in. apart each way. On the top of the frame, or box, place a lid or shutter, and cover up the sides and top, so as to keep in warmth, and totally exclude light. By this means, Seakale can be grown in perfection. Where there is a Mushroom-house at work, the crowns may be placed in it; but, here again, especially when a considerable body of fermenting stable manure exists, the flavour is not nearly so good as when it is grown on a bed of leaves.

Rhubarb.—Where Rhubarb is required early some roots should at once be placed in a gentle heat. They may be forced like Seakale where they grow, except that much deeper pots must be used; but, in the case of Rhubarb, as well as in that of Seakale, it is preferable to take up the roots and place them in heat. Nothing is better than a slight bed of leaves on which to put them, protected by a deep temporary frame or box, covered up so as to keep in the warmth and exclude light. The roots should have a few inches of soil placed under and about between them. For the first produce some early kind, such as Linnæus, Tobolsk, or Prince Albert, should be selected, as these will come in much sooner than the later sorts. If a few roots of the Victoria, which is a later kind, but large and very productive, are at the same time put under the stage in a greenhouse, or in any similar out-of-the-way place that is kept a little warmer than the external temperature, they will come on in succession; but, in such a situation, they should be covered up to exclude light, and, in all cases, the soil that is placed round the roots should be watered as required so as to keep it a little moist.

Extracts from my Diary.

December 16.—Examining Cucumbers, stopping them where required, and picking off all useless blossoms. Making a new border for Roses 18 in. deep, and filling it with good loam and manure. Looking over Cauliflower plants, picking off all decayed leaves, and stirring the soil amongst them.

Dec. 17.—Getting into spare frames a quantity of large Endive for protection. Turning over Mushroom manure to sweeten. Covering up part of another Seakale bed. Getting manure wheeled on to the land whilst the weather is favourable, and mending Box edgings in the kitchen garden.

Dec. 18.—Getting up another lot of Snow's Winter White Broccoliⁱ and putting them in spare cold pits. Putting more Asparagus in frames and renovating the linings. Staking and tying some newly-planted trees and shrubs. Cleaning the walks and Grass in pleasant grounds. Looking over the Grape room, removing bad berries, and filling up the bottles with water where required.

Dec. 19.—Sowing Mustard and Cress and getting in another batch of French Beans. Covering up Endive and Lettuces to blanch. Lifting and root-pruning some dwarf-trained Plum trees that were growing too grossly. Rolling down all gravel walks firmly, also all the Grass when the weather will permit.

Dec. 20.—Getting into the forcing pit some more Lily of the Valley and *Deutzia gracilis*. Proceeding with the pruning of large deciduous trees. Clearing off all decayed vegetables and prunings and burning them. Getting into the Mushroom house a little more Chicory and Dandelion to force.

Dec. 21.—Looking over Pelargoniums, stopping them, and picking off dead leaves; examining Pines and watering any that require it. Looking over the fruit room, and removing any fruits that are decaying. Fruits in use for dessert:—Pines, Grapes, Pears, Apples, and Nuts.—W. G. P., *Dorset*.

THE INDOOR GARDEN.

WINTER FLOWERING BOUVARDIAS.

CAMBRIAN," and several others who have written on this subject, make the mistake of implying that because these plants will produce some flowers during winter in a greenhouse temperature, or something a little over this, that it is wrong to grow them warmer. That Bouvardias would bloom at this season with ordinary greenhouse warmth, I had already learned by subjecting them to such treatment, and this many years before the majority of those who now grow them in all probability knew the plants were in existence; but, so managed, I found that they produced little flower beyond that which was formed on the plants in the autumn, when they were taken in from the cold frames. To argue that, because they will produce a certain quantity of flowers under this treatment, it is wrong in practice

who have not the convenience or inclination to grow them warmer, and consequently are content with a slower and smaller return.

T. BAINES.

Croton Prince of Wales.—This graceful and richly-coloured species, introduced from the South Sea Islands by Mr. Williams, of the Victoria Nurseries, Holloway, is one of the handsomest and most distinct of the narrow-leaved Crotons, and one which will form a beautiful object either for the decoration of the dinner-table or as a specimen plant. It is of a free branching habit; the leaves are pendulous, arching, and slightly twisted; some of them even present a complete spiral form, ending in a small pointed elongation of the mid-rib, the edges of the leaves being always beautifully undulated. The colour of the leaf is almost entirely pale yellow, margined and mottled with bright carmine, with occasional irregular blotches of pale green, the mid-rib and petiole being bright magenta. It has

Croton Prince of Wales.

to subject them to a higher temperature, by which, as I have learned in practice, they will keep on quickly and continuously through the winter, making short growths and flowers from the axils of the leaves of four or five joints on the shoots below the top, where the first bunches are produced, is just as inconsistent as it would be to try to make it appear, that because many of the other plants which we force in a more or less high temperature through the winter, would flower to a certain extent without this, the extra heat was wrong that enables those who subject them to it to get two or three times the quantity of bloom in a given time from a given number of plants, that they will furnish under cool treatment. What I wrote on the cultivation of Bouvardias for winter flowers, was simply a short detail of the method that I had found best calculated to produce the greatest quantity of flowers from the smallest number of plants, a desideratum that most private growers find it worth while to take into consideration, and had nothing to do either for or against the practice of those

been shown on several occasions this year in excellent condition, has always attracted much attention.—S.

CULTURE OF ORCHIDS IN BASKETS.

It has often been a matter of surprise to me that baskets should not be more extensively employed than they are in Orchid culture. One of the most important points connected with their cultivation is insuring to them at all times an effective drainage. The basket, to my mind, better enables the grower to guard against excess of, or stagnant moisture at the root than any other receptacle which can be employed for them. Well as pots may be drained, they yet necessarily lack that free outlet for superabundant moisture which is characteristic of the basket. For beginners especially I feel convinced that this

method of culture is particularly recommendable, inasmuch as with them the great difficulty is to regulate the amount of water, to give enough and yet not overstep the mark. Had I any new, rare, or difficult species to deal with, I would certainly put it in a basket, and I should feel more confidence in its doing well than if it were potted. I once took under my care a collection of Orchids which had been sadly neglected, they having scarcely any root left to them. Some I potted and some were set up in baskets; the latter made by far the most satisfactory progress, making a free and healthy growth. Some of the finest *Vandas* and *Cattleyas* I ever saw were from the establishment of the Duke d'Ayen, near Paris. *Vanda snavis* was 6 ft. high, foliated to the bottom, clean, healthy, and vigorous; *Cattleya Skinneri*, had nearly 400 expanded blossoms on it. There were two plants of this species equally well bloomed and in every way admirable examples of successful culture. With these were also *Zygotetulum Mackayi* and *Miltonias* of proportionately large dimensions and manifesting the same exuberance of bloom. These plants were, without exception, in baskets, having never been grown in pots. Another large collection of *Vandas*, *Cattleyas*, *Saccolabiums*, &c., was grown exclusively in baskets, and the specimens generally were some of the largest and healthiest I ever saw. On complimenting the person in charge, he said, "This is the first and only collection of Orchids I ever had to cultivate. When my employer first took a fancy to Orchids, and placed his first acquisitions in my care, I told him frankly that I knew absolutely nothing of their culture. He, however, procured some baskets and Sphagnum, and I arranged them to the best of my ability, using nothing but a little charcoal with the Sphagnum. There (pointing out some large specimens) are the identical plants. Seeing that they grew, others were procured, and I treated them the same, and, really, I have never had any difficulty. I can see how they are when the basket of any one of them rots, or a plant needs a shift, and I scarcely ever interfere until the basket gives way; I just drop it into another basket, ram in some Sphagnum and a little turfy peat and charcoal, and the job is done. My friends say that Orchid growing is difficult. I have not taken a great amount of pains, and really do not find it so. As to watering, I am not at all particular; in hot weather I moisten them thoroughly with a rosed pot, and they enjoy it." Now, I ask, would these results have been attained if pots had been employed? Scarcely, I think; half the plants would probably have died, and the remainder have made but small progress in the hands of such an inexperienced person. Pots look well, and the plants as a Frenchman would say, "present themselves better" in a new or well-washed pot; and, for trade purposes, appearance goes a long way; but the amateur need not let such considerations influence him; his object is to grow his plants so that they will repay him by a healthy growth and abundance of bloom, and this, I believe, is more easily obtained by the employment of baskets than by using pots.

Biflect.

J. CORNHILL.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Casuarina sumatrana as a Large Specimen.—This plant is often grown for table decoration, but it is seldom seen in the form of a large specimen. In such a state, however, it forms one of the most ornamental occupants of the stove or warm greenhouse at this season of the year, its graceful, thread-like, deep green foliage being shown off to good advantage among finely-coloured *Crotons*, *Draconas*, &c. Thus circumstanced I found a fine plant of it—6 ft. high and as much through—in Messrs. Carters' nursery, at Forest Hill.—S.

Selaginellas for Table Decoration.—Like Mr. Groom, I find these Clab Mosses most useful for dinner-table decoration, especially in winter, when few cut flowers can be had. When I came here, I found a good supply of them in pots, and when required they had to be turned out and broken up to fit into certain stands—an operation which somewhat spoiled their appearance. I, therefore, tried growing them in flats of different sizes that would fit into the vases which they were afterwards intended to ornament. I bored a hole in the bottom of each flat, filled it with soil, raising it a little in the centre, and dibbled small pieces of *Selaginella* all over it; they soon formed dense little mounds, which we placed on other flats full of water.

This enabled the Moss to hang down all round, and obviated the giving of so much water on the top. When required, we place each in its respective stand at once. We keep up a succession of them, and, whenever one lot assumes a brown or withered appearance, we cast them away and supply their places with fresh plants. Small flats require a little care at first, as, on account of their holding little soil, it might easily be washed out in watering. Such a system as this is attended with the best results.—S. K., *Templepatrick*.

Adiantum Farleyense on Water Tanks.—Though liable, when syringed overhead, to be affected by damp on account of the tenderness and the dense character of its pinnae, this Fern succeeds well when placed on inverted pots in a water tank so that the bottom of the pot on which the plant is growing is just above the level of the water. In this way we find fine healthy plants of this Fern 3 ft. through in Messrs. Osborn's nursery at Fulham, where also *Anthuriums* thrive well under the same conditions.—S.

Indian Azaleas Planted Out.—Where large collections of Azaleas exist in private gardens, it is generally the practice to place them out-of-doors in summer under the shade of trees and in similar positions. A much better way, however, is to plant them out in prepared beds of soil in an open, sunny position. Thus situated, if they receive plenty of water at the roots, they will assume a much greener and healthier appearance, and will flower better than those kept in pots. Azaleas are thus treated in Messrs. Rolleson's nursery at Tooting, both large and small specimens, and, at the present time, their health, vigour, and quantity of flower buds are all that could be desired.

Training and Tying-out Specimen Plants.—This is the most favourable time of the year for looking through and putting into shape the general stock of Azaleas, Heaths, and New Holland plants. In fact, this description of work should be completed by the middle of next month, before the lengthening days, and consequent increase of work, arrive. Old, straggling specimens may now, with a little time and patience, be brought into a shapely condition. It does not, however, follow that every little branch and twig should be closely tied in so as to entirely destroy the natural habit of the plant. Training is now admitted by many good growers to have been overdone, and good taste tells us that, whilst we should so train and restrict a plant that it may be better adapted to our requirements, we should not wholly obliterate that irregularity of outline which is one of Nature's greatest charms.—J. CORNHILL.

Burnt Earth for Potting.—In many parts of Germany burnt earth is much employed for horticulture. It there often usurps the place of loam, the use of which is not generally so well known as in this country. The refuse of the garden—clay, rotten wood, lawn sweepings, &c.—is all thrown together and slowly burnt in the summer. Many kinds of plants root freely in soil thus prepared, and it is very serviceable for seed sowing, being free from weeds. It is the custom in most large establishments to annually burn a large quantity, as, even when merely employed to enrich the ordinary garden soil, it is credited with stronger renovating powers than rubbish applied in a decayed state.—J. C., *Duffield*.

Exhibition Chrysanthemums.—I do not think that Mr. Williams (page 521) need fear creating many enemies by his vigorous onslaught on the "parterre-trained" exhibition Chrysanthemums, at least, amongst the readers of THE GARDEN. The teachings of that paper have so far tended to a diverse view as to the merits of trained plants to those held by exhibitors, and generally in favour of Mr. Williams' ideas, that I believe what he has written will be received with approbation. There are a few certain plants that are, when trained in the usual exhibition style, particularly objectionable. These are the rigid pyramid Azalea, the flat flower-bed-like floral pancake seen in the zonal Pelargonium, and the formal, inverted, saucer-like Chrysanthemum. All of these plants display in their training most remarkable evidence of perverted ingenuity and industry. In no sense does either present its natural habit, the foliage is as much as possible kept out of sight, and the great effort of the grower is to bring into apical and rigid prominence every bit of bloom. Judges seem to forget that plants should have leaves as well as flowers, and are taken only by the mass of bloom presented to the eye. Could not some prizes be offered for the best untrained examples of all the above plants, showing the natural growth with the most pleasing admixture of foliage and flowers? This would, indeed, be a step in the right direction. I observed at the late Ealing Autumn Show a mode of exhibiting our Chrysanthemum blooms that I think would have gratified Mr. Williams. These were in threes of one sort cut on 9-in. stems with good foliage attached, and staged in flower pots filled with sand and Moss. This made a very pleasing class, and was by no means formal, as the flowers admitted of different degrees of elevation. A flat box of cut blooms is the most formal thing imaginable.—A. D.

THE FRUIT GARDEN.

FRUIT GROWING IN CALIFORNIA.

THE sudden development of this coast as a great fruit-producing region is so surprising even to those in its midst, and will probably in the near future so affect the world's markets, that some facts concerning it cannot fail to interest your readers. When the Americans first came to California they found little wild fruit and no orchards, except those planted by the Spanish padres around all the old Missions. These orchards consisted chiefly of seedling Apples and Pears, of Olives and Figs, with usually a Vineyard of a sweet blue Grape known since as the Mission Grape. When the mining excitement of 1849 began, the inferior fruit from these old Mission orchards brought such enormous prices, from 25 cents to 50 cents being often paid for one Apple, that great efforts were made to plant young orchards. Fruit trees, costing from 4 to 5 dollars in the nursery, were brought from Oregon as early as 1851, and often carried on muleback for hundreds of miles over mountain trails to little mining camps. The first trees which came into bearing netted large sums, Peaches being sold for 1 dollar apiece, and Plums for 25 cents. In one instance, a small orchard consisting of three-year-old trees was condemned for mining purposes, and a jury of miners appraised the trees at 100 dollars apiece. Nurseries were soon started at various points near the Bay of San Francisco, and tree-planting went on with vigour. In 1855 or 1856 some of the mining camps began to decline, and the mountainous portion of the State was comparatively deserted. By 1860 fruit had so greatly declined in value, that old and formerly valuable orchards in the mining counties were totally neglected and left to run wild. Lack of transportation and an overcrowded home market were the chief causes of this neglect. Here was a remarkable state of affairs, which few were able to realise. This State, settled by pioneers in 1849, had actually, in less than a dozen years, become overstocked with orchards, so as to pass the limits of home consumption, and yet the great thermal fruit belt, adapted to Oranges, Grapes, &c., and extending for a length of 400 miles, with an average width of 30 miles, had only an orchard here and there, whilst a vast acreage of higher lands, fit for harder fruits, was untouched and unclaimed. To many the limit of orchard planting had been passed, and in some cases young orchards were foolishly cut down. From 1860 to 1870 some railroads were built, which lessened the cost of transportation; fruit driers and canneries were established, and enough was done to convince people that dried and canned fruits would soon become a leading industry. Successful shipments were also made to the Eastern States, and have rapidly increased each year since. The planting of orchards began once more, and has gone on steadily. The old mining counties of Eldorado, Placer, Nevada, and others came to the front as fruit-producing counties, and will probably so remain. Since 1870 the fruit interests have yearly become greater. New varieties of fruit, patent driers, Apple parers, and labour-saving devices have occupied the public mind. There are a great many accidental seedlings, some of much promise. Our best autumn and winter Apples are White Winter Pearmain, Rhode Island Greening, Baldwin, Spitzenberg, Yellow Bellefleur, and Newtown Pippin. These average in price about 1 cent. per lb. The trees are healthy and yield enormously, so that they are profitable even at that price.

Clingstone Peaches are now considered better than Freestone for canning, and immense quantities are used. Late Peaches, also, and Apricots are greatly in demand. Only a few varieties of Plum, such as Coe's Golden Drop and Washington, are planted for drying, but Petite Prune d'Agen and Felleberg are favourites. Of Pears, Bartlett, Winter Nelis, and Easter Beurré are the only ones worth shipping eastwards. Cherries have never been too abundant, but the price for them is each year becoming lower, reaching 6 cents and 8 cents per lb. last season. Small fruits are wonderfully prolific, and we can have Strawberries grown in the open air every month in the year.

Dried Figs and Raisins are every year of better quality. Many failures were made at first, but now our best Raisins, dried by the blower's process, are perfect in colour and flavour,

and outsell Malagas in San Francisco. There is hardly any limit to our possible Raisin produce, and it is becoming a great industry. Dried Figs equal to the Smyrnas have never yet, to my knowledge, been produced on this coast, but tons of a second quality are made.

We have discovered within a few years that the Orange and other members of the Citrus family will thrive over more than three-fourths of the State, and in this direction also much interest is shown. The Dwarf Banana (*Musa Cavendishi*), of Florida, fruits here, and may already be seen in large fields; the Guava succeeds south of San Francisco; we are venturing, not without hopes, to raise Coffee; and our latest fruit is the Japanese Persimmon, or Diospyros Kaki, of which some 40,000 trees have, within two seasons, been disseminated, and some of the earlier importations are in bearing. The present prospect is in the highest degree encouraging for nurserymen, orchardists, and consumers. After our present Wheat era is done, our greatest wealth will remain in our Vines and trees. Indeed, our county fairs are already chiefly pomological displays, and exhibits of fine stock, rather than of grains or minerals. The variety of these displays is another marvel, eighty or ninety kinds of Apples often being exhibited, and sixty of Grapes. Our only enemies as yet have been the woolly aphid on Apple trees, and mildew on Grapes near the sea-coast, with an occasional borer; but none of these have been troublesome. An orchard here will come into full bearing in five years. Peaches often bear the third year from the bud.

Niles, Alameda, California.

CHARLES H. SHINN.

THE CLIMATE OF THE NORTH OF FRANCE AND SOUTH OF ENGLAND.

MR. SIMPSON'S questions (p. 520) are very easily answered. The passages to which he alludes are the following:—

No less important than the forest and ornamental trees were the fruit trees, particularly to France, in which the growth of hardy fruit for both home use and exportation has assumed such large proportions. . . . In England there are not a few who attribute the excellence of France in the culture of hardy fruit to the climate—the fact being that the climate of northern France is an extremely difficult one for the fruit grower, and, on the whole, not a whit better than that of Kent or Sussex. . . . There is no reason why we should not supply our own markets with the Pears we import from northern France and the Apples we import from the United States.

If Mr. Simpson had visited France in March instead of in August he would have had a very different idea of the climate. The difference between the climate of Paris and that of London is as well known to the many who pass between the two cities as the difference between the climate of Yorkshire and that of London. The question concerns hardy fruits, and anybody who holds that the climate of the south of England cannot produce these as well as that of north France, cannot know much of the climate of either. The summer heat of the south of England is ample for the development of the finest Apples and Pears, as all must know who are acquainted with good gardens in the south, or who have seen the Apples from West Park and the Pears from such market gardens as those of Mr. Dancer, at Chiswick, and Mr. Wilmot, at Isleworth. I am merely defending the climate of the south of England, but could not a very good case be made from districts very much farther north? Did not Mr. Anderson, from Oxenford Castle, near Dalkeith, send a collection of Pears to London some years ago which carried off first prizes in competition with even the same kinds of fruit grown in the south of England? I have seen enormous standard Pears of Marie Louise in cold clays in Notts, and I have seen a very fine fruit garden at Stourton, near Knaresboro, under the management of Mr. Saul. The difficulties of saving the blossom in spring are quite as great in northern France as in England. It is not certain that the greater heat of Paris in summer is beneficial to many varieties of hardy fruits. It is probable that the south of England is a little more favourable to the Apple than the climate of Paris—at least with the exception of one or two kinds. I have not seen Apple orchards near Paris in a very good state, and yet our markets are filled with Apples both from France and America. The passages which excited Mr. Simpson's remarks were written

with the view of encouraging hardy fruit culture at home, and of dispelling the common error in which Mr. Simpson seems to so fully share, viz., that the climate of the south of England is against the success of the culture of hardy fruits. It would be very easy to mention climates far worse than either it or the north of France where hardy fruits are grown to perfection. It would be also easy to name climates infinitely better than either in which the blossoms are seldom destroyed by cold, but they are very far away from us. In the remarks in question the English cultivator did not get blamed for his inferior hardy fruits, as Mr. Simpson states. One cannot, it would appear, point out one or two of the causes of our not being able to supply our own markets with a sufficiency of hardy fruits without this begging of the question. I was once talking about this question to Mr. Wood, an English nurseryman settled at Rouen, and he told me that for one fruit tree planted in England there were one thousand planted in France. We can call attention to such a fact as this without, it is to be hoped, blaming the cultivator. Mr. Simpson says:—"It is admitted on all hands that the past summer in England was an early one, and it is equally certain that the summer in France has been changeable and cool." This would seem to imply that he is not aware that the districts alluded to are under exactly the same climatic influences. A cool or a bad summer in the south of England is the same in the north of France. The question has mainly concerned Apples and Pears. With reference to Rivers' Early York Peach ripening on a wall in the middle of August, the Peaches are none the worse for being a little later. I have seen the Peach ripening as a standard, with Mr. Grieve, at Culford, and though such cases are not very much more to the point than Mr. Simpson's allusion to forcing Peaches in January, still I know from much observation on both sides of the channel that the climate of Southern England and Ireland is quite as good for wall-culture of Peaches as that of Northern France. In fact a good soil and a district not far from the sea in Southern England are conditions a little more favourable for Peach growing than the climate of Paris, provided, of course, the blossoms receive equal protection in both cases.

— Allow me to inform "J. S. W." that the climate of northern France cannot be judged by that of Paris. In the neighbourhood of that town there are plenty of Vireys; in Normandy there are none beyond Vernon. Grapes there, as here, can only be grown on walls, and even then they do not always ripen well. I resided some time in the neighbourhood of Ronen, and although the summer temperature may be somewhat higher than that with us, yet, with respect to the variability of the spring months and the severity of the winter, I found but little difference between that place and England. The growers there have to contend with spring frosts and hard weather, and I noticed, with some surprise, that the periods of heat, cold, rain, and drought corresponded pretty accurately with those experienced in this country; and yet from that region a vast amount of fruit generally flows into our markets. Why is this? Simply because their fruit culture is considered in the light of an important industry. Where one fruit tree is planted in this country twenty are planted in Normandy. Not only is this the case, but the knowledge of how to plant and care for a fruit tree is universal there, and that is one of the principal reasons why they have fruit to sell us. The question of superiority in this branch of gardening does not really rest upon the production of a little very fine fruit. We must take a broader view than that of it; we must rather look for that system which gives us a large supply of wholesome fruit, and in this respect the French are many years before us. J. CORNHILL.

Byfleet.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Chaumontel Pears—At the late autumn show of the Ealing, Acton, and Hanwell Horticultural Society, a basket of very fine Chaumontel Pears, shown by Mr. J. Hepper, gardener to C. O. Lidgard, Esq., The Elms, Acton, attracted much attention. They were gathered from a tree growing against an east wall on a gravelly subsoil—a tree that makes but little growth, but blooms and bears freely every year. To assist the tree, it is dressed with plenty of manure in winter and spring, and in summer, when the fruit is swelling off, constant supplies of liquid manure are given. The fruit has that rich, luscious, buttery flavour peculiar to this fine variety. Mr. Hepper states that when grown in this way this Pear is at its

best during the month of December, and as a dessert fruit he does not care to keep it beyond that time. He thins his crop, but allows the fruits to be removed to hang as long as possible, and then they are sent into the house for stewing, thus making them take the place of the ordinary stewing Pears, which can in that way remain long on the trees.—D.

The Best Kinds of Pine-apples.—I have this autumn had an opportunity of comparing the qualities of the following kinds of Pine-apples, all grown under precisely the same conditions, and I place them as to merit, in the following order, viz., Charlotte Rothschild, Black Jamsies, Prince Albert, Smooth Cayenne, Prickly Cayenne, and Black Prince; all were excellent, but the two first outdistanced the others by many points.—W. II.

Beurre Rance and Easter Beurre Pears.—These are two of the best Pears we have here, and as for Chaumontel we had fruit of it 19 oza. the year before last; the trees are large and on the Pear stock and trained on an east wall. The Quince stock is not adapted for these sorts, and perhaps this accounts for the failure of these kinds in some gardens in the north. It is a well-known fact that the Quince stock destroys the flavour of many Pears; one especially, Vicar of Winkfield, becomes mealy, while on its own roots it is buttery and excellent in flavour. I believe in this country that the Quince stock has done as much harm as good.—H. KNIGHT, *Floors.*

Pear Triomphe de Jodoigoe.—This Pear has gained for itself a first position with me this season. Its bearing qualities are marvellous, for, during the last nine years, it has not once failed to produce a full crop, and, though it has always been good, it has often disappointed me by rotting at the core prematurely. This season, the weather being windy, the fruit was gathered, as I thought, too soon; but, as it has turned out, such was not the case, as not a single fruit has rotted at the core, nor is the fruit shrivelled in the least, and the quality is excellent. Thus, accidentally, I have learned a valuable lesson, viz., that Pears may be left too long on the trees as well as be gathered too soon.—W. WILDSMITH.

Mulching Fruit Trees in Autumn.—I quite agree with all "W. N." says (p. 499) on this subject. A good many fruit growers appear to have a dread of the roots of their trees coming into contact with manure. This feeling seems to have been instilled into cultivators in their youth, and to have been accepted as sound doctrine—perhaps in a fuller sense than was always intended—without inquiry or experiment. All people know how difficult it is to get rid of preconceived notions that have been looked upon as truths, and no doubt this old view of manure being inimical to fruit trees has a modicum of truth in it, for it is not wise to bury manure much below the surface, but to feed them as Nature does and as your correspondent recommends, or only just beneath the surface. This is the true and rational way of manuring fruit trees.—E. HOBDAK.

Peach Pruning.—It is recommended (p. 494) never to shorten the bearing wood, that is, not to prune the current season's growth. Now, I believe it to be impossible for any one to form a good "year-after-year" fruit-bearing tree, unless the knife be judiciously applied to the previous summer's growth. If this be not attended to, the wood becomes weak and attenuated (as we too often witness), and, therefore, incapable of producing either good fruit or a satisfactory crop.—T. COWBURN, *Sunbury Park.*

Pear Van Mons. Leon Leclerc.—This is a kind that does well with us; it is not only a large, handsome, long Pear, but also one of good quality. It makes a fine addition to the dessert, and if grown on a south or west wall will generally be found to bear well. In less favourable positions it is valuable as a stewing Pear.—J. G.

Pitmaston Duchess Pear.—A dish of this splendid Pear was shown at the Town Hall, Birmingham, on November 27, by Mr. T. Stait, gardener to the Rev. Canon Evans, Solihull, and attracted much attention on account of its handsome appearance. As it is at its best in October and November, it comes in finely for exhibition purposes during the last-named month. At Preston Hall, near Maidstone, Mr. Breadley had it very fine this year, growing against a south wall, and praised it highly. This variety is said to be well adapted for growing as a pyramid or a bush tree, but not as a standard, as the fruit is too large. It is certainly a very fine exhibition Pear.—D.

Fastening Labels on Fruit Trees.—Whatever kind of label is used for naming trees, one fatal error should always be guarded against, and that is, tying the label on with wire round the main stems or principal branches, as, even if plenty of room be allowed for one or two seasons' growth, there is great danger of the wire being allowed to grow into the bark, and eventually strangling the branch. With wall trees, the best plan is to nail the label to the wall, just above the centre of the tree; and, in the case of standards, the label is more readily discernible if hung on one of the outer spurs or branches, where danger of injury is much less than in the central portions of the tree.—J. G.

PROPAGATING.

COLEUSES.—These ornamental-leaved plants are easily increased in a warm greenhouse from cuttings made as shown in fig. 1.; loam, leaf-mould, and peat soil, with a little silver sand in it form a good compost for them. In a close propagating box

Fig. 1.

they will emit roots in five or six days, but they do equally well without covering, if in a warm, humid atmosphere. They may also be increased by means of grafting, and in this way variously coloured sorts may be put on one plant. The branches may be cut as shown in fig. 2, and the scion as in fig. 3. Fit the latter neatly into the branch and tie with worsted; they

Fig. 2.

Fig. 3.

will unite in a fortnight if kept rather close in the propagating box, or under a large bell-glass or cloche that can be lifted off when required, to allow superfluous moisture to escape. They want, however, a good deal of attention, as, being so soft and full of sap, they are liable to damp off.—H. H.

AN ECONOMICAL PROPAGATING HOUSE.

My friend, Alégatière, of Lyons, the celebrated grower and raiser of Perpetual Carnations, having seen the smoke of furnaces used for heating, thought of adapting it to his propagating house, and, after several years trial, he has arrived at the conclusion that it is the most efficient and most economical way of heating it. The structure is easier to build and less expensive than any other. It is excellent for early propagation, and, once established, it requires very little work to keep it in order, and the sand used, in which to insert the cuttings, does not, like tan or manure, encourage insects. The particulars of M. Alégatière's system I therefore append, thinking they may be interesting to the readers of THE GARDEN. The pits, path, and fire-place are below the level of the ground. Of course there is a step leading to the path and fire-place, which place is covered, and can be used as a potting shed. The pit A is about 1 ft. deep; the space E, which is empty, about 2 ft. and about 3 ft. or 4 ft. in breadth. The pit A 1 is separated from the empty space under it by iron bars, on which rest large flat bricks, and on these fine sand is put, in which the cuttings are inserted. The cuttings are not covered either by bell-glasses or frames. The sand in the pit A 1 is heated by the smoke from the fire C, which circulates under the bricks and fills the empty space EE. At the top of the back part of the furnace, which is built with bricks, is an earthen pipe to lead the smoke from the fire-place to the empty space, and at the further end of the house, under the pit A 1 an

earthen pipe passes through the wall and forms there a chimney, which carries out the smoke. By this method of heating by smoke very little fuel (coal) is required, and no heat is lost. Besides, if perchance the fire should be extinguished at night, the smoke partly remains, and the bricks and the sand maintain a sufficient heat, particularly if in very cold weather the house is covered at night. The heat obtained in the sand is about 20° centigrade, or about 68° Fahrenheit, a temperature sufficient for Dahlias, Carnations, Fuchsias, Chrysanthemums, Begonias, Pelargoniums, and all herbaceous or soft-wooded plants, but it is necessary to keep the sand damp, and four or five times a day, at least, to syringe the leaves. The cuttings are put directly in the sand and not in pots, which saves room and time. The interior of the house is sufficiently warmed by the heat of the brick wall and the sand. Pit A is not heated, but is used as a receptacle for the cuttings when they are rooted and potted off singly in 2-in. pots. If thought necessary, however, pit A might be heated by hot-water pipes fixed to a saddle boiler on the top of furnace C. If the interior of the

Propagating House.

house be found too damp by the continual watering of the cuttings, an air-pipe may be introduced from the path B through the brick wall, through the bottom of the fireplace, and returned at some distance through the same brick wall in the path with several openings. All this may be done with the same fire and the same expense of fuel. This system may also be adapted to a lean-to house, of which the front is the propagating pit, and the back the receptacle for the rooted cuttings or the plants from which the cuttings should be taken.

JEAN SISLEY.

Montplaisir, Lyons.

Goold's Chemical Compounds.—Like Mr. Hassock (p. 514) I can speak favourably of these artificial manures. In appearance they are simply a white powder which dissolves immediately in water, and may either be applied in solution or scattered thinly over a damp surface and watered in directly. They are cleanly in application, and leave no bad smell, and, as pointed out by your correspondent, they are prepared to suit different classes of plants, such as Vines, Ferns, Roses, &c. I have long thought that chemists would do something more for us than has hitherto been done in this direction, and I have no doubt that, when the public confidence has been won, a considerable development may be anticipated in the manufacture of these concentrated stimulants. People who live a long distance from the manufactory do not want to pay carriage for inert matter that is of no use to them. From my own trials of five different samples of Goold's manures, I can endorse all Mr. Hassock says respecting them. The Vine compound was especially noticeable in its effects. I am not troubled with much Grape shankling, but to any one who has a bad case of it, I would strongly recommend a trial of this Vine compound, and to report the result for the benefit of your readers.—E. HOBDAY.

— I agree with Mr. Hassack as to the usefulness of Goold's manures which I have used with remarkably good results, especially in the case of Figs and Strawberries, but without a fixed quantity in a mixture of water. What quantity does Mr. Hassack put into a gallon of water with which plants in pots can be watered with safety? If correctly done the liquid form would answer much better than the practice of putting a pinch on the soil of the pot. The plant compound has a wonderful effect in increasing the size of Camellia blooms, the colours of which are also brilliant.—W. CULVERWELL, Thorpe Perrow.

ENGLISH HORTICULTURAL EXHIBITS AT THE PARIS EXHIBITION.

In your remarks upon the French exhibition allusion is made to the paucity of English horticultural exhibits, and "want of home organisation" is assigned as the probable reason of this lukewarmness on the part of our horticulturists. When arrangements were being made to forward the interests of our countrymen, and the list of Commissioners was issued, I felt truly grieved, as well as surprised, that horticulture had no special representative therein. I was then quite sure that 1878 would be but a repetition of 1867. Then, as now, there was an utter absence of home organisation, and, what was still worse, there was no one to represent or in any way aid our exhibitors on their arrival. Being stationed in the gardens the whole of that season, I had an opportunity of observing the difficulty which those who were not acquainted with French customs and the language experienced. I was the only individual there for a long time who could act as medium between Englishmen and the French officials. Now, on what a different footing did the Belgian growers stand. They had special officials, appointed by the State, to receive and convey the goods to the Exhibition, and experienced men to unpack, care for them, and pack them up again, a resident gentleman of high standing exercising constant supervision. The consequence was that trees, plants, &c., were sent in the most perfect confidence that they would be cared for whilst they were there. The contrast to me, as an Englishman, was, I admit, humiliating, and until horticulturists are made to feel that they are the objects of State consideration English culture will never be fully represented at foreign Exhibitions. Nurserymen generally cannot absent themselves for any time from their business; therefore, what was required was a competent man who would have received and aided, in any way required, exhibitors from this country; also, an influential person to forward and care for their interests. It is useless to cry over spilt milk, but, at the same time, it behoves us to take note of our shortcomings, and if, in the future, we resolve that English growth shall be worthily represented at International Exhibitions, we must see to and remedy this defect.

J. CORNHILL.

FLOWER BEDS AT THE PARIS EXHIBITION.

In reference to your remarks on horticulture at the Paris Exhibition (p. 486) allow me to add that one bedding arrangement in the grounds there struck me as being particularly chaste and effective. It was doubtless intended to show that bedding out need not be the transitory affair which it generally is. Unfortunately I did not notice the exhibitor's name, being too much taken up with the plants and their arrangement. It was a circular border some 6 ft. in width, divided into a series of ovals and diamonds, the divisional and outside lines being composed of Lavendar Cotton (*Santolina rosmarinifolia*). The diamonds of *Euonymus radicans variegatus*, with a small *Juniperus ericoides* as a centre plant; the ovals were planted with the larger foliaged variegated *Euonymus* and a centre plant of *Thuja aurea*. The angles and outside edge were filled in with *Euonymus radicans variegatus*. The simplicity, yet good effect, of the whole was very striking, and, to my mind, equal to the best carpet or any other kind of bed in the exhibition grounds, and what was still better all the plants used were hardy. Another very effective arrangement in the same grounds was a large oblong-shaped bed edged with *Festuca glauca*, and planted with purple *Petunias* and Paris Daisies—plants at present not sufficiently valued on this side of the Channel. The beautiful purple of the *Petunias*, blended with the white flowers of the Daisies, had a charming effect, and would make a handsome combination for large vases or beds.

W. W. H.

A story is sent to me about the late Mr. McNab, Curator of the Edinburgh Botanic Gardens. When Dubufe's celebrated paintings of Adam and Eve were on exhibition, Mr. McNab was taken to see them, and was asked for his opinion. "I think no great things of the painter," said the great gardener. "Why, man, Eve's a temptin' Adam wi' a pippen of a variety that waeen known until about twenty years ago!" As genuine a bit of criticism as that of the farmer who told George Morland that he had never seen eight little pigs feeding without one of them having his feet in the trough. Morland altered the picture.—"The World."

INTERNATIONAL POTATO EXHIBITION.

At the International Potato Exhibition held at the Crystal Palace in September last, about thirty new varieties of Potatoes were brought forward by exhibitors, who were anxious to obtain for them critical consideration. It was found to be impossible to deal fairly with so many in the brief space of time then at command, and hence there were no certificates awarded. The committee charged with the task of inquiring into the merits of new varieties have now made their final selection, and have awarded first-class certificates to two varieties. It must be understood, however, that a very considerable proportion of the varieties brought under their notice were of superior merit, and may, hereafter, obtain the same distinction as is now conferred on the kinds which, for the present, they consider the best. It is not alone sufficient that a new variety should look well on the exhibition table, and be well spoken of as grown in the locality in which it originated. It should, in the opinion of the committee, be characterised by general usefulness, which includes adaptation to a variety of soils, constancy in respect to form and colour, high productiveness, comparative immunity from disease, and first-rate table quality.

RADSTOCK BEAUTY.—A coloured Round, inclining to pebble shape, even, and somewhat angular, rarely attaining to large size, the skin tawny-white, smooth, and silky. The eyes are few, but conspicuous, the side eyes being of a rosy-purple colour, with arched brows of the same tint distinctly defined, the eyes of the crown or nose end clustered in a patch of a somewhat darker shade, giving to a good sample an extremely pleasing appearance. The growth is moderate, the produce mostly of smallish ware size, plentiful, and clean; the flesh fine in texture, mealy, dry, and delicately flavoured. First-class certificate.

WOODSTOCK KIDNEY.—A white Kidney, of oblong shape, extremely even and smooth, the skin tawny-white, silky; the eyes few and inconspicuous, set level with the general surface in small clusters of dots at the crown or nose end. So regular in form is this variety that a fair sample may be likened to a model turned in a lathe. The growth is moderate and compact, the tubers plentifully produced, and mostly of middling ware size, and are in the very least degree affected by disease. The flesh is yellowish, fine in texture, and of the most delicate flavour. This is, all points considered, one of the finest varieties hitherto submitted to the International Committee. First-class certificate.

Scottish Horticultural Association, Dec. 3.—Mr. L. Dow read a paper on this occasion on the "Kitchen Garden," being a continuation of a former paper on the same subject. He again urged upon the attention of young gardeners the great importance attaching to this part of their profession. Operations in the kitchen garden, such as trenching, manuring, and cropping, were first alluded to, and then a detailed account was given of his mode of cultivating the Cauliflower, Pea, Carrot, and Turnip. As regard Carrots, he approved of deep trenching and deep manuring, a dry bog being the soil best adapted for their growth. He also spoke of the leafstalks of the Swedish Turnip being a good substitute for Seakale. Mr. Robertson Munro next read a paper on "Hardy Spring Flowers," including all those that bloom from January 1 to May 1. He named the most popular kinds, and explained the treatment of those that required particular cultivation. The following are some of the plants referred to, viz., *Hellebore* of various sorts, *Snowdrops*, *Iris reticulata*, *Cyclamen Comu*, and other varieties, *Winter Aconites*, *Scillas*, *Seyrinchiums*, *Leucopiums*, *Hepaticas*, *Anemones*, *Myosotis*, *Crocuses*, *Daisies*, *Primulas* of different varieties, *Aubrietias*, *Saxifrages*, *Tulips*, &c. Messrs. Downie & Laird showed *Sibthorpia europaea variegata* in good condition; Messrs. Dickson & Co. two stands of cut blooms of *Chrysanthemums*, containing sixty-three varieties, and a fine bloom of *Thubergia laurifolia*. Mr. John Webster exhibited a new calivary Apple.

Ancient Buildings.—The Hon. Percy S. Wyndham, M.P., recently delivered a lecture on this subject at Keswick, in which he advocated the views of the Society for the Preservation of Ancient Buildings, drawing largely for his facts and illustrations from Mr. William Morris's annual report as hon. sec. of that society. As an example of a house which had never been "planned down" to uniformity he instanced with approval the seat of Sir Henry Vane, at Hutton-in-the-forest, a residence built at three different epochs. Restoration, he averred, meant "destruction accompanied by a false description of the thing destroyed."

Fungi on Leaves.—Prof. B. Frank communicates to the "Botanische Zeitung" (No. 40) an account of a few short investigations on parasitic fungi, conducted with the view of determining whether they are the cause, or merely the concomitant, of certain leaf-stains on which they occur. In the cases examined by him he succeeded in producing the stains by sowing and cultivating the fungi in question on the fresh leaves. The fungi experimented with were *Isariopsis pusilla*, and species of *Ramularia* and *Cercospora*; of none of these was the life-history at all well known.

Compulsory Destruction of Mistletoe.—In certain districts of the Rhine provinces police regulations have been issued ordering, according to "The Farmer," the destruction every year of all Mistletoe found upon fruit trees. The parasite must be removed each season by February at the latest, on pain of summary punishment. Evidently the Mistletoe enjoys but little veneration on this part of the German Empire, and the issue of an order for its destruction just at this period of the year seems strange indeed to English readers, who are just preparing to do full honour to it in connection with the approaching Christmas festivities.

NOTES OF THE WEEK.

New White-flowering Orchid.—What seems likely to prove one of the most useful Orchids that has been imported for a long time past is now in flower in Mr. Bull's nursery at Chelsea. It is a pure white form of the well-known *Lælia anceps*, than which, no plant is more prized in winter by Orchid growers. The flowers of the white kind are equally large as those of the type, and the petals and sepals are broad and wax-like, whilst the throat is well-formed and slightly tinged with green, like that seen in *Eucharis amazonica*. Altogether, it promises to be a grand addition to our list of winter-blooming Orchids.

Pitcairnia muscosa.—This greenhouse plant, now in flower in Mr. Parker's nursery, Tooting, is well worth culture on account of the bright orange-scarlet blossoms, which it produces on white, woolly stalks. Its leaves are similar to those of a Carnation, being silvery underneath. Good flowering plants may be grown in very small pots, or five or six of them placed together in pans would, when in flower, have a good effect.

Ipomæa Horsfalliæ in Small Pots.—In addition to being one of the most ornamental of stove climbers, this fine old-fashioned plant is useful and attractive when grown in small pots. We lately saw some grown in this way in Messrs. Veitch's nursery at Chelsea. They were from 15 in. to 18 in. high and bore several trusses of bright magenta blossoms, and, associated with *Ixoras* and other winter-flowering plants, they had a pleasing effect.

Stenomeson Hartwegianum.—This is a pretty little bulbous plant now in flower in the Pine-Apple Nursery. Its blossoms, which are produced in whorls on the tops of fleshy stalks about 15 in. long, are tube-shaped, drooping, and of a rich orange-scarlet colour. It lasts in flower for some time and is of importance for winter decoration. It succeeds well in a cool greenhouse.

Adiantum Capillus-Veneris on Walls.—For covering bare walls in cool houses, or for similar situations, this is one of the best of Ferns. When once established it spreads rapidly if the walls be kept moist, and soon forms a dense green cover on the sides of pathways or on the back walls of houses. We lately saw it succeeding well on the back wall of an unheated brick pit in Mr. Parker's nursery at Tooting. Where Fern fronds are in demand for cutting, too, this is an excellent way of growing them, as, when produced in a cool temperature, they are of a deeper green colour, and, being harder, last for a much longer period when cut than those produced in heat.

Schizostylis coccinea in Winter.—This fine hardy plant is largely grown at Gunnersbury for furnishing cut blooms in winter. It usually flowers too late out of doors to be of much value, but as treated at Gunnersbury a good show of blooms is secured from October till Christmas, and even longer. The plants are planted out of doors in good soil during summer, and in autumn are lifted, potted, and placed in the greenhouse. This planting and lifting retards the flowering period to some extent, and the plants are not at their best until those left out of doors are over. For the cool conservatory this *Schizostylis* is one of the best plants which can be grown for winter, and any one who practises the method here described need not fail to succeed in its culture.

Sericographis Giesbreghtiana.—Wherever neat-flowering plants are required in winter for vases, this old, but comparatively little cultivated, Acanthad should be grown. It is easily propagated, and may be grown bushy in habit and in small pots, or large specimens may, under favourable circumstances, soon be obtained. In either case, when furnished with its light, graceful, half-drooping racemes of bright crimson blossoms, it forms one of the most attractive objects in the stove at this time of the year. It is grown at Gunnersbury Park, in company with such plants as *Eranthemum pulchellum*, *Euphorbia jacquiniæflora*, and *Thyrsoanthus rutilans*.

Orchids at Chelsea.—Among other fine Orchids in bloom in Messrs. Veitch's nursery are *Cattleya exoniensis*, with eighteen large, gorgeously-coloured blossoms; the pure ivory-like *Lycaste Skinneri alba*; and *Odontoglossum Roezli album*, small plants of which are furnished with from five to six spikes, each bearing six or seven large pure white blossoms with rich yellow throats. *Pilumna fragrans* is unusually well flowered, one plant bearing seventeen fine flowers. White *Calanthes*, arranged on each side of the pathways in the houses, make quite an avenue of graceful spikes of blossom. Abundance of other popular Orchids are also flowering well in association with those just named. In Mr. Bull's nursery there is likewise a charming group of Orchids in flower, arranged effectively on low stages, and many of them are growing in pans and on blocks suspended from the roof. In the centre of the house is a large group of *Dendrobium superbiens*, bearing long, graceful flower spikes, on

some of which may be counted as many as twenty finely-coloured blossoms and buds. These are backed up by large spikes of the violet-scented *Oncidium tigrinum*, *Calanthes*, *Lælia anceps*, and similar plants. Among dwarfier plants are finely-flowered examples of the brilliant *Sophrontis grandiflora*, *Masdevallia Harryana cœrulea*, *Odontoglossum nebulosum*, in several distinct forms, *Lady's Slippers*, and the blue-flowered *Bollea cœlestis*. To these may also be added *Odontoglossum Roezi majus*, *Lycaste Skinneri*, *Dendrobium album*, and several fine varieties of *Cattleya maxima*.

Laurustinus Indoors.—These are largely grown in the form of standards and bushes in Messrs. Osborn's nursery at Fulham, for indoor decoration about Christmas. When placed in a warm greenhouse the flowers come whiter than when left out-of-doors, and a quantity of plants just opening their blossoms in the nursery referred to will be a sheet of white flowers at Christmas. When associated as they are with finely-berried *Aucubas*, *Skimmias*, and similar plants, a good display is produced with little trouble.

Calanthe Turneri.—This is grown at Gunnersbury, where it is much prized for bouquet making. When well grown, as we here find it, its flowers are produced in large numbers on strong spikes, and being of a soft white with a rich violet eye they are more effective and useful for the purpose alluded to than those of other kinds of *Calanthes*.

Celosia pyramidalis in the Conservatory.—Few plants are more easily cultivated than the crimson or magenta-flowered *Celosia*, and few are more useful or effective at this season of the year. At Syon House it is grown for mixing with *Chrysanthemums* and other plants, and the richly-coloured, feather-like plumes have a striking effect. They may either be grown singly in 6-in. pots, or five or six may be planted together in large pots, under either of which conditions they afford quantities of good material for cutting; or they make a good display in the conservatory or dwelling house for a long time under favourable conditions.

Bamboo Mats.—A sample of the Bamboo mats alluded to in THE GARDEN (p. 482) has been sent to us from Colchester by the New Plant and Bulb Company. The sample in question is stated to have been in use for three years, but it is still as good as when new. It resembles the Dutch reed mats (of which a representation will be found in THE GARDEN, Vol. XIII., p. 311), but, being made of Bamboo, they are lighter and neater. These mats are about 4 ft. 6 in. in width, and can be made of any length that may be required.

A Finely-flowered Odontoglossum Alexandræ.—There is in the gardens at Gunnersbury Park, a remarkably healthy collection of plants of this best of Orchids. Some of the flower spikes are unusually strong and promising, and one plant bears a long branching spike which produced fifty large and delicately-tinted blossoms, forty-five of which were, at the time of our visit, still in full beauty. By growing a quantity of plants of this *Odontoglossum*, some of them are in flower nearly all the year round, and moreover, nearly all of them are in some way dissimilar, either in size or tint. We also saw several *Odontoglossums* producing flower spikes from the apex of the pseudo-bulbs as well as from the base, a circumstance about which some enquiries have lately been made in THE GARDEN.

Royal Horticultural Society.—At the next meeting of the Fruit and Floral Committees at South Kensington, Messrs. Charles Lee & Son will exhibit a very interesting collection of hardy evergreen and variegated-leaved plants. Mr. Gilbert, Burghley, will again exhibit his new double *Priaculas*, and Mr. Gardiner will send a large collection of Apples from Evington Park.

Royal Caledonian Horticultural Society.—The annual meeting of this Society was held the other day in one of the ante-rooms of the Music Hall, Edinburgh, Mr. Macnochie Welwood, one of the vice-presidents, occupying the chair. After the minutes of the previous meeting had been read and confirmed, the treasurer submitted the annual financial statement, from which it appeared that the receipts had amounted to £1436 4s. 2d., and the ordinary expenditure to £1304 12s. 1d. Last year the receipts were £713 14s., and the payments £697 6s. 10½d. On this occasion the receipts included members' subscriptions received for 1877, £14 13s.; for 1878, £439 14s.; for 1879, £3 2s. 6d.—total, £457 9s. 6d.; special prizes, £18 11s.; and admission to shows, £929 18s. 2½.; while the payments included show expenses—spring show, £280 3s. 10d.; summer show, £148 1s. 10d.; autumn show, £175 8s. 10d.—total, £603 14s. 6d.; prize money—spring show, £218 14s. 6d.; summer show, £167 5s. 6d.; autumn show, £216 1s. 6d.—total, £602 1s. 6d.; and account for permanent tables, pedestals, and booths for secretary and treasurer, £195 7s. The total funds on hand at the 30th ult. were £666 3s. 10d., as compared with £534 11s. 9d. at the corresponding date of last year.

On M. Charpentier, head gardener at the Trianon at Versailles, has been conferred the rank of Chevalier of the Legion of Honour, after fifty-seven years' service.

ANSWERS TO CORRESPONDENTS.

Two Kinds of Grapes on One Vine.—The Vine from which both bunches of Grapes which I send you were cut is a West's St. Peters. The shrivelled bunches all grow on one rod, but the Vine shows no appearance of having been inarched. The sport, if sport it be, looks like Mrs. Pince's Black Muscat, but that variety has never been known to be in the Vinery.—B. W. S. [The two bunches sent are quite distinct. One is certainly West's St. Peters; the other (with shrivelled berries) has a flavour exactly resembling that of Mrs. Pince. It looks like the result of a bud or graft.]

Field Mice in a Rockery.—In reply to Mr. Ellacombe's enquiry (p. 526) permit me to say that I was troubled for years with mice in my rockery, until a cat was turned into it, when they disappeared like magic.—C. ISHAM, *Lampport Hall, Northampton.*

—Mr. Ellacombe will probably find trapping of all kinds to be ineffectual in the present instance. If he does not dislike cats, he may speedily get rid of the mice in the following manner: Place, late in the evening, some small pieces of fish (herring is best) near their runs; the cats will come in the night, when all is quiet, and, getting scent of the mice, they will frequent the spot until the mice are either caught or frightened away.—J. CORNHILL.

Rain Water.—Would this, caught in a large copper, if used for watering in a greenhouse, be injurious to the plants?—J. B. C. [No; it would be the best you could use if fresh and clean.]

Primulas Destroyed by Grubs.—I have grown a large batch of *Primula sinensis* this season, which, for health and luxuriance, I have rarely seen surpassed up to the time when they commenced to bloom, early in November, when I was much disappointed to find that the majority of the plants began to flag, and the large trusses of flowers to die down. For this I was at a loss to account, as the plants had received due attention with regard to watering, &c., and they were placed in a moderately dry and warm conservatory, where *Primulas* had hitherto done well. On examining some of them, however, at the root the other day, I found that the tap roots had been eaten, and that a grub had eaten its way into the very hearts of the plants, a circumstance which quite accounted for their failure. Having never experienced such a disaster in the case of *Primulas* before, I should be glad to know if any of your correspondents have witnessed a similar occurrence, and, if so, what means were adopted to destroy the grubs.—T. FOOTE, *Cleveland Court, Somerset* [The grub in question is no doubt that of the weevil (*Otiorhynchus sulcatus*, well known for the injury which it does to the roots of plants. It must have been introduced with the soil.—W. W. S.]

Ferns suitable for a Cool Conservatory.—I am much obliged to "S. D." (p. 433) and others who have given me lists of Ferns suitable to plant in a cool conservatory, but as I fear that some of them from their size would scarcely be adapted for my purpose, perhaps I may be allowed to give a more detailed description of the place for which they are required. It is a glass, unheated structure, forming the entrance to my residence, and so shaded that it only gets a little sun in the morning, and a little in the summer time in the evening. Nevertheless, though so shady, I find that flowers brought on in pots elsewhere, when introduced, do exceedingly well there, and remain in bloom a long time, and it is now (Dec. 2), quite gay with *Fuchsias*, *Zonal Pelargoniums*, *Primulas*, *Begonias*, *Chrysanthemums*, &c. There are two borders about 2 ft. 6 in. wide each, with a central stone path, and my idea is to plant these borders permanently with Ferns, placing my flower pots among and between them so as to conceal the pots. The place is favourably situated as to temperature; I have never known the thermometer lower than 32°. If "S. D." or any other of your correspondents, would further oblige by giving me a list of good ornamental Ferns, just suited to the above conditions, bearing in mind my restricted limits, I should be glad, and the information may be useful to others as well as to myself. I do not want British Ferns, as many of them grow in profusion in this locality.—S. CHAMP, *Bridport, Dorset.*

Wintering Orange Trees.—Will you kindly inform me which of two conservatories is most suitable for wintering large Orange trees—the one kept at a night temperature of from 45° to 50° or the other, which is not artificially heated? also a few hints as to their culture?—H. S. W. [Orange trees require more heat and more careful treatment than they generally receive in order to induce them to yield good results. During the summer months it is usual to place large Orange trees growing in pots and tubs on terrace walks and in similar positions. This is an operation which may be carried out without much injury to the plants, provided they are not placed in such positions until the middle of June, and are taken indoors again early in September, and afterwards placed in a light, airy house, the temperature of which ranges about 50° during winter and spring, instead of being crammed into an outhouse, shed, or unheated corridor, to lose their leaves and get covered with filth and insects, as is too often the case. Few plants are more ornamental than well-shaped Orange bushes laden with fruit and blossoms, and they would no doubt be more largely grown than they are at present if the conditions of their successful culture were better understood. The best soil for Oranges is that composed of two parts good turfy loam and equal parts well-decomposed manure or leaf mould, to which may be added a little road sand. Some cultivators recommend turfy loam and fresh horse manure. The soil should be made firm in the pots or tubs, good drainage should be provided, and potting of established plants will only require

to be done once in five or six years. Light, air, sun, and heat are highly necessary for the perfect growth of the Orange, although established plants will exist for years under very rough treatment. The Orange is liable to a kind of black fungus, which infests its leaves and gives them a very unhealthy appearance, but this can easily be removed by sponging with warm water and soap, and, indeed, it seldom occurs on well-cultivated plants. Green fly is destroyed by *Quassia* chips boiled in water for a quarter of an hour, at the rate of 4 oz. of chips to the gallon. The shoots may be dipped in the water when cool, or they may be syringed with it. Scale may be prevented by syringing frequently with *Quassia* water; and it may be effectually destroyed by methylated spirits of wine applied to the shoots with a brush.—S.]

Black Fly on Cherry Trees.—I have no doubt that if "B. S." will follow up any of the recommendations given him in last week's GARDEN (p. 526) he will be able to keep both black and green fly in subjection, but for outside work, cultivators will easily understand that fumigating is the least practical method of dealing with this pest. In my own experience I have found nothing better than good Tobacco juice, applied at the rate of one pint to three gallons of water. The water may be soft or hard, but I consider soft water preferable if it can be had. Stir the water and juice, so as to mix both well together, and apply them with the syringe or engine. I have tried dipping the points of the shoots in a basin containing this mixture, but I consider that to be a very slow process; if it saves a little material, it wastes a very great deal of time, and where there are a good many trees to get over, the time saved more than pays for the extra material used. I used to syringe before nailing or fastening in the young shoots, but I now fasten them in before doing so, and I consider the work much better done, as the shoots are held in position and are thus subjected to the whole force of the syringe or engine. "B. S." should examine the trees after the first syringing to see that every fly is killed, and it may be necessary to give two or more syringings at short intervals if they should again make their appearance.—JAS. FATAWEATHER, *Halstead.*

Currants losing their Bloom Buds (p. 526).—I expect that sparrows are picking the buds off "F. W. H.'s" Currant bushes. My garden, like his, is situated in the heart of this city, and my experience is that these little depredators pick the buds off my Currant and Gooseberry bushes, and also off Plum trees trained against walls. I have tried many so-called remedies to prevent them, but the one that I have used for these last few years I find to be the best and simplest, viz.: After pruning my bushes, I procure some white worsted or knitting cotton, and string it several times from side to side, and once or twice across the bushes, leaving it there. No more sparrows come near them; they seem to me to be afraid that it is a net set for them. If "F. W. H." will try this plan, I think it will answer his purpose.—J. D., *Ripon, Yorks.*

Quickly-grown Pine-apples.—In reply to "H. A. B." (p. 526), allow me to say that the fruits from the old stools were cut last April; one weighed 4 lb. 4 oz., the other 4 lb. 12 oz.—M.

Names of Plants.—T. W., *Torquay.*—*Cestrum aurantiacum*. *F. Banks.*—Apparently some species of *Lycaste*, but which we cannot say from the dead specimen sent. *W. J.*—The erect kind is *Selaginella cuspidata*: the prostrate one *S. cœsia*.

Questions.

Eucharis intermedia.—Can any of your readers instruct me how to flower this *Eucharis*? I have no difficulty with *E. amazonica*, but many cultivators inform me that they have never succeeded with *E. intermedia*.—C. E. B.

Binding Compounds.—I am desirous of forming a perpendicular bank from 8 ft. to 10 ft. high, and would be glad to be informed if there is any binding mixture suitable for that purpose. I have heard that sand and chalk make a binding compound, also ashes and chalk. I should be glad of information on the subject, also stating the best proportions. I have sand on my ground, and chalk exists in the neighbourhood.—S. F.

Lamp Heating.—I have recently heated a small greenhouse with a paraffin lamp, and I fancy the smoke or smell from it has injured the plants. Will any of your correspondents say if paraffin is injurious, and if there be any other oil better suited than paraffin for heating a small house?—A SUBSCRIBER.

Pollard Oaks.—Some Oaks of fifty years of age were becoming crowded, but as the timber was not then required, they were beheaded into poles; the stems soon sprouted from top to bottom. Is there any objection to this system? or is it to be recommended under similar circumstances?—C. I.

Pomegranates.—I have, I believe, a double Pomegranate, in the form of a bush 3 ft. high and 2½ ft. through. It came from France two years ago; it made 4½ of young wood last year, but did not flower. Would some one kindly inform me how to treat it? Should I report it now? and what soil should I use? Will it require cutting back? When ought it to flower? on old, or young wood?—C. J.

Ice Houses.—Will any reader of THE GARDEN tell me how to make an ice house? I propose digging out the clay to the depth of 3 ft. or 4 ft., and draining it; then I intend building what I have to build in bricks, covering the whole with clay and soil and planting it with shrubs. About what size should such a house be for a private family, whether it should be round or square, and what thickness of earth will be enough to cover it?—W. H. B.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

FLORAL DECORATIONS FOR CHRISTMAS DAY.

ALLOW me, once again, to offer a few suggestions relative to the floral decoration of dinner-tables on Christmas Day. A year or two ago, I wrote a similar paper on this subject for THE GARDEN, and in it I gave descriptions of two tables florally decorated—one expensively, and the other the reverse. I shall not now, however, direct particular attention to the arrangement of any vase or stand, but shall content myself with a few remarks respecting what flowers and foliage look best when subjected to artificial light, and what will last in good condition for the greatest length of time. As to the size and number of the stands to be employed, that, of course, must be regulated by the size of the tables to be decorated, and also by what the decorators may have in their possession; but, where stands are about to be purchased, I should recommend their being of the March form, with trumpet, or the trumpet with curved branches. I have myself seen and decorated many other varieties of stands, but none have looked better or, indeed, pleased me so well as these two shapes. Next to be thought of comes the material in which the flowers are to be kept fresh. This is nearly always either water, Moss, sand, or worked clay. Blooms will last longest in water, the next best material for this purpose being Moss; but I prefer silver sand well moistened, as, though, perhaps, the flowers may not retain their freshness quite so long in it as if they were in water, they retain their position better than in any other material. I need hardly say that I use sand only in flat tazzas or similar designs, as in trumpets water, of course, must be employed. At this season I prefer arrangements in white and scarlet or crimson flowers only to those composed of mixed tints; but many may be of a different opinion, so I shall not wholly limit myself to those shades. For large, bold decorations there are no two handsomer or more useful flowers grown at this season than the lovely white Arum Lily and the scarlet bracts of the Poinsettia; the latter can be obtained in different shades, from vivid scarlet to deep crimson. Large-sized blooms of white Chrysanthemums may also be employed with good effect in floral arrangements. Too many large flowers should not, however, be used, as they tend to make a stand look heavy, but when they are employed they should stand out well one from the other, and if thus placed in the bottom tazza of a stand they look very much better than smaller flowers. Next in size come Camellias, Eucharis, Gardenias, and Roses, all of which are suited for portions of stands, such as second tiers, &c., or for mixing amongst the larger kinds just enumerated. Then comes a size smaller still, viz., Pelargoniums, Carnations, half-blown Rose-buds, Narcissi, Primulas, Stephanotis, Tuberoses, Azaleas, Pan-cratiun fragrans, Neapolitan Violets, &c., all equally useful for second tiers or for specimen glasses. Lastly in the floral list come those light and elegant varieties which are suited for trumpets, and which give a light finish to the whole arrangement, viz., such flowers as those of the Lily of the Valley, Roman Hyacinth, and small Paper-white Narcissus. Many varieties of Ferns and foliage are always

obtainable, but none last so well as the old favourite, *Adiantum cucucatum*; for the edges of tazzas *Pteris serrulata* looks well and remains fresh for a long time if the fronds be of mature growth—a point which should be borne in mind with respect to all Ferns, as young fronds will not stand when cut and brought into the hot, dry air of a room. For trailers in the Fern class nothing is so effective as long sprays of *Lygodium scandens* (the creeping Fern). Having said so much for flowers and Ferns, I must not forget our old friends the Holly, Ivy, and Mistletoe, without which one could hardly realise the season, nor would the decorations be complete without them. Sprays of these plants should be interspersed through all floral arrangements on Christmas Day. For decorating the different dishes of fruit these three last-named plants will be found most effective; also the berry of the Arbutus, which looks almost like the small fruit of the Siberian Crab. Take, for instance, a dish of purple Grapes, and what will come out better against their rich deep tint than little sprigs or sprays of Golden Holly or Ivy, and the crimson berries of either the Holly or Arbutus, or the white berries of the Mistletoe. Light-coloured Grapes, again, associate well with the small-leaved Irish Ivy, the dark green, bright-leaved Holly and its scarlet berries, all of which have a charming effect at this season, and in like manner they can be adopted for decorating every kind of fruit that may be on the table, if a little forethought be given as to which combination will look best.

ANNIE HASSARD.

A GARDEN IN CENTRAL EUROPE.

IT was a pleasure to find an Englishman, who evidently possesses experience in garden matters and good taste, criticising the Imperial Gardens at Schönbrunn (p. 365). He hit off all their worst points, but if he knew the Viennese of the present day he would see some need for the "immense deserts of gravel" to which he alludes, and also for the interminable alleys, with their inevitable espaliers of Beech, Maple, and Hornbeam. The townspeople, on their holidays and festivals, flock to these really fine resorts in thousands to promenade, and for amusement and music, of which they are devoted admirers. Then, with an almost tropical sun, one can appreciate the efforts of the old planters who devised these much-abused alleys and enormous hedges. Many of my fellow cultivators can hardly imagine a good and interesting garden possible without its usual accompaniments of Laurels, American plants, Sweet Bays, Laurustinus, and Rhododendrons. Such gardens are here in Central Europe a necessity, and afford as much enjoyment to their possessors as others do of quite a different character. It may be considered heresy to say so, but our English gardens of the present day lack variety and beauty of foliage in deciduous trees and shrubs, and they are being reduced both by owners and by those in charge of them to a monotonous dead level. Every one plants the evergreens just mentioned in great quantities, and in all places, right or wrong. Thus, lightness, grace, and breadth are lost, the views are confined, and a decided heaviness and lumpiness is the result. In town gardens exclusiveness may be allowable, for we always try to shut ourselves up from our neighbours, but in the open country the case is different. Perhaps some one will have the courage to make a departure from this stereotyped style, which has greatly robbed English gardens of their charms. Foreigners are, however, delighted with them, because they see so much that is new to them in style and material, and they are especially fond of the greenness and freshness of English lawns; good turf on the Continent is costly, while in England it can be obtained with little or no care. A good garden in this part of the world is furnished with a large assortment of deciduous trees, such as Red American Oaks, Tulip trees, Maples, Chestnuts of many sorts, Limes (especially the American kinds,

which have the good property of blooming late and of retaining their freshness of foliage till late in autumn), Catalpas, Copper Beeches, Gymnocladus, Sophoras, Paulownias, American Walnuts, and Salisburia. These trees yield fine foliage in summer, and produce beautiful leaf tints in autumn. They are planted largely in groups, consisting each of five or six trees set close together, the trunks of specimens 1 ft. or more in diameter being often not more than 3 ft. or 4 ft. asunder. Individually, such trees are not regular or symmetrical, but they form charming groups for the artist and the true lover of Nature, both of whom dislike straight stems and perfectly-balanced specimens. Two or three kinds of trees may be allowed in a group for the sake of giving it character, but, as a rule, the fewer the better. A bright-berried tree, such as the Mountain Ash (yellow or red), Crabs, or Sorbus, may be added, as, in their struggle for existence, they are so graceful. Thorns are admissible, and also Buckthorns, with their beautiful orange-red fruits. Large groups are made up of the commoner kinds of Oak, Elm, Ash, and Alder, and it is only on the outsides of such groups that one finds the better kinds of plants. The Oriental Plane and Tulip trees, the American Oaks and Ailantus, are excellent subjects for the sides of walks and roads, their large foliage affording the shade so much needed when the thermometer for weeks stands at 30° of warmth (Reaumur).

Evergreen trees consist of Thuja plicata, Warreana, occidentalis, orientalis, Craigi, sinensis aurea, and Cupressus Lawsoniana. Juniperus virginiana is largely planted, not only for effect, but also for its wood, and for its fruits, which are made into a sort of jam. Associated with these may be found Taxus baccata fastigiata, drupacea, erecta, pendula, and aurea. Pinus Strobus is grand either alone or grouped with the Red Cedar and Pinus maritima, austriaca, and Cembra are also largely used in groups or as single specimens. The common green Holly was once thought to be unsuitable; it is, however, now planted out, but only in the shade, as it is found to suffer from direct sunshine, but not from 25° of cold (Reaumur). Picea nobilis and nobilis glauca, Wellingtonia, Thujopsis borealis, Thuja gigantea, Thujopsis dolabrata, Picea Nordmanniana, P. lasiocarpa and P. grandis, are all quite hardy and grow well. The three last will make excellent forest trees if seeds of them can be obtained in quantity. Abies viminalis, orientalis, americana alba, and canadensis, are also at home. With such materials as these, one can easily make an interesting and enjoyable garden. Hardy shrubs of a deciduous character are nearly as numerous as those quoted in any good English catalogue, and the best kinds are largely used, and mainly in groups of one variety on the Grass, or singly if the sort possesses a good habit and flowering properties.

Virginian; Creeper and Veitch's variety, with Aristolochia Sipho, Menispermum, Ivy, and Clematis, are made good use of here on living trees, on walls, in beds, and as edgings and hanging garlands. Sophora japonica pendula is a beautiful plant for lawn decoration, but it should be grafted at least 10 ft. from the ground. Celtis australis is an excellent plant for masses, especially when old; so is the Judas tree (Cercis Siliquastrum). Platanus striata makes a good low tree, and the same may be said of Ornus Europæa, Elæagnus angustifolia, and E. sativa, Æsculus flava, Pterocarya caucasica, and Bignonia Catalpa. Such are some of the chief plants which the climate permits the landscape gardener to use, in his imitation of Nature, on a comparatively small scale. The winter here is nearly always severe, accompanied by much snow; the summers, too, are very trying, and, unless abundance of water be at hand, gardening is most disheartening. It sometimes happens that for four months no rain falls, and then newly-planted shrubs and trees invariably die if not well watered every other day, although mulched with some retentive material. It is even found to be necessary, during hot summers, to give water regularly to plantations which have been planted twenty years.

Moravia.

SYLVESTRIS.

Honeyuckles and Clematises on Trees.—There would be some difficulty in establishing the above or similar plants in the exhausted soil around the trunks of trees, so as to enable them to grow with any degree of vigour. To overcome this procure the longest

plants you can get, and plant them in a prepared pit 4 ft. or 6 ft. from the bole of the tree; connect this pit with the tree by a trench 9 in. or 12 in. deep; plant the climber in the prepared pit, lay the long stem along the trench at bottom, cover it the whole length of the trench with a bottomless draining pipe, and turf the whole neatly over. You will thus have a trailing plant growing at a distance from the tree, but connected with it by means of an underground stem. In this way even the choicest standard Roses—too often bare and unsightly—may be ornamented with some delicate climber without detriment to the Rose.—THOMAS WILLIAMS, Ormskirk.

PROPAGATING.

SPRING PROPAGATION.

In large private establishments, and also in the majority of nurseries, it is often found impossible to secure the desired amount of plants for summer flower gardening and other purposes, by the ordinary method of autumn propagation. It frequently occurs that in hot, dry summers, such plants as Verbenas, Calceolarias, tricolor Pelargoniums, &c., fail to grow with that freedom which is necessary for the production of an abundance of healthy cuttings. If too, through some unforeseen cause, the stock of any particular plant happens to run low at housing time, there is no remedy but to resort to a speedy method of working up a stock in the spring. In the case of novelties, it is desirable to have the means of being able to quickly increase them. The wood of many plants is in a better condition in spring for cuttings than later in the season. A small propagating house heated by hot water, or a brick pit filled with tan, is indispensable for this purpose. The chief point is, the means of creating at will, and steadily maintaining a brisk, moist heat both night and day. If this accommodation can be commanded, then there will be no difficulty in rapidly increasing all the so-called soft-wooded material. Such plants as Verbenas, Celosias, Alternantheras, Cupheas, and Lobelias, will, of course, be wintered in store pots, and supposing that they have been kept perfectly cool, and are fairly healthy, they will be in good order for introducing into heat the first week in January. But here caution must be exercised not to increase the heat too suddenly, as too great a change will debilitate the plants to a serious extent. During January, the day temperature may be 55°, and that of the night 45°. As the days lengthen, the average temperature may be increased until, in March, the maximum of 70° by day and 60° by night be attained. On bright sunny days the thermometer will naturally run up much higher, when a corresponding rise of higher temperature may be given. Great caution must be exercised in giving air, as draughts of any kind are very injurious, and so is hot sunshine. The cuttings being tender, must be screened from all vicissitudes of climate. In a house devoted to propagating perennials there should be some kind of provision made for bottom-heat, which is best furnished by a hot-water pipe to be heated independently of the rest of the house. The stage on which the pots are placed should be quite close and covered with ashes, or Cocoa-nut fibre, which must be occasionally turned over and well wetted so that a gentle, dewy moisture may continually arise therefrom. About the beginning of February propagation may commence by taking off the most advanced cuttings. If a large stock be required do not cut too closely. There is nothing gained by undue haste. If the plant from which the cuttings are taken be checked at the outset it will have a vast influence on the after produce.

There are two methods of striking the cuttings; they may either be inserted in pots specially prepared for them, or they may be dibbled into a bed of sand and potted after they have become rooted. Both plans have their respective advantages, the latter requires the least amount of labour and demands less care in watering, but the former is handiest if the space be limited, as each pot may be removed to other quarters as soon as the cuttings are fairly established, where they may remain until convenience is found for potting them off. 4-in. pots are best for this purpose. They should be filled about one-third of their depth with drainage, and then to within 1 in. of the rim with free, light soil, covering the whole with

silver sand and filling the pots quite full. Verbenas are easily propagated. If only a piece of stem with a pair of leaves attached be inserted they will root all up the stem. Lobelias, Alternantheras, and many such plants do not require to be cut to a joint; they root freely up the stems if in sufficient heat. Ageratums, Centaureas, Petunias, and all such plants as are more or less of a woolly character are best cut to a joint. Spring is a good time to propagate many kinds of flowering shrubs, such as Spiræas, Lilacs, Deutzias, &c. Plants that have been forced for bloom will furnish good cuttings which will readily strike at that season. Pelargoniums of all kinds will also strike freely, but they require different treatment. They should, when inserted, be put upon a shelf near the ventilators, where they get a circulation of air around them. Do not insert them deeply, and only water them when quite dry and on fine days. All the tricolors, bronzes, and variegated kinds do well thus treated. The old plants will break again freely, and will form better material than if not headed down. The Lemon-scented Verbena will also root readily, but cuttings of it are easily affected by fluctuations of atmosphere, and, if once they flag, they inevitably damp off. Covering them with a hand-glass in the daytime will ensure them against accidents of this kind. April and May are good months to propagate the double Primulas. Place them under a hand-light in 2½-in. pots, taking the glasses off for an hour in the morning, and leaving a little air on at night. Thus treated, ninety-five per cent. may be relied on to root. Centaureas strike well from spring cuttings; the wood, then, is devoid of that wooliness for which this genus is remarkable. They make roots as freely as Verbenas. They should, however, be inserted in small pots, the roots being so brittle that they break when potted off from store pots. Fuchsias, too, should be struck in small pots, and they should not be allowed to become potbound, but should be grown on without check.

If a large quantity of any one kind of plant be required, then, as the cuttings root, they may be removed to the cooler end of the house, when they, in time, will furnish others. Considerable attention is necessary in the way of watering, as, although they must never get dry, yet excess of moisture amongst them will have to be guarded against. They will require constant supervision in the way of cutting out dead and decaying leaves, for which a small pair of sharp scissors will be found the most useful. Watering should always be performed about the middle of the day, as it is then better seen what is in need of watering, and the foliage dries before night. With respect to the admission of air, there will be need of but little, except what can be given at the top of the house; the air merely requires changing, no brisk circulation being allowable. If the front part of the house be of brickwork, a wooden flap here and there is all that is necessary, and, in the earlier period of the season, these will scarcely be needed. The main secret of success in propagating is attention; a slight amount of neglect, either in watering, shading, or ventilating will produce such effects as the initiated know full well cannot be remedied by any amount of after care. The successful propagator is generally the first at his work, and the last to leave it. I have known some who carried their attention so far as to prefer making their own fires, and attending to them themselves, the whole winter through, and it is only fair to say that they achieved great success. Propagating probably taxes the ingenuity and exercises the faculties more than any other branch of gardening, and if tedious, and causing at times some anxiety, there is intense satisfaction in finding that one's care is requited by the increase of useful plants. J. CORNHILL.

Byfleet.

Gladioli Wintered Out-of-doors.—It has been my practice for some years past to leave our Gladioli in the ground all the winter, taking them up once in three or four years and transplanting them. When the tops are dead I cut them off near the ground and give a good coating of half-decayed manure and leaves before frost sets in; this, I find, to be sufficient protection, the soil here being a light, sharp loam. I have sometimes had the early kinds damaged by late spring frosts. It is, I think, incorrect to say that bulbs taken up and dried till spring do not produce as fine spikes as those left in the ground. I know a very extensive grower and breeder o'

Gladioli, whose seedlings every year are numbered by thousands, besides a general stock; these are all taken up every year, dried, cleaned, and labelled, and yet at every exhibition at which they have been shown they have carried off most of the prizes for years past. When in full bloom, so fine and varied are they, a sight of them is one not easily to be forgotten.—W. DIVERS, *Wierton, Maidstone.*

FORWARDING EARLY CROPS.

ALTHOUGH hot-water involves much less trouble in forwarding early crops than fermenting material, yet there is no warmth so regular and congenial for the purpose as a good bed of leaves, such as those of Oak or Chestnut, which, got together before they lose their virtues, hold heat for a considerable period. To catch them at their best they should not only be collected as soon as possible after they are shed, but when they are in a moderately dry condition, for, if wet, the fermentation is either excessively violent or so imperfect as to be of little or no service unless mixed with an equal bulk of stable manure. The two combined, if turned over a few times and thoroughly sweetened by allowing the rank steam and gases to escape, form an admirable bed for forcing Asparagus, but to have this esculent in perfection during January and February, it is necessary to have it in pits, where there is a hot-water pipe running along the front, without which there is not sufficient top-heat to admit of giving air to get the heads of their proper colour and flavour. To have Asparagus really good the temperature should range between 50° and 60° according to the state of the weather, in addition to which light has great influence upon it, and it is important therefore that it be admitted as freely as can be done by having clean glass, and the covering, if any, removed from it in the morning as early as circumstances will allow.

Next to forced Asparagus, Potatoes are considered the greatest luxury in the vegetable way, and there is no plan of obtaining these so good as growing them on a gentle hotbed, as, although warmth is required for the roots, the cooler in reason the tops can be kept the better and more satisfactory will the crop be. Heat above only produces long, attenuated haulm, and more particularly is this the case if there is at any time a deficiency of air or sun to thicken and consolidate the growth and foliage, the latter of which, when under confinement, always comes thin and flimsy in texture. One advantage in growing early Potatoes is that the frame may be made to do double duty, and thus economise space, as, between the rows, Cauliflower or Lettuce may be sown and raised, or a crop of Radishes obtained and cleared off long before they can be got in the open, however favoured a border or position they may have. In order to get these well in advance of the Potatoes it is always advisable to soak the seeds a few hours in warm water before sowing, which accelerates its germination considerably, but, when this is done, it should be well timed, so as to have the bed all ready, with a proper degree of heat in the soil, otherwise the tender germs get a chill, and instead of having handsome-shaped Radishes they are all fangs and roots. Where frames are now in use, and it may, on that account, be desirable to defer making up hotbeds for Potatoes, they may be forwarded very much by placing them on end in boxes, filled with sifted leaf soil, so as to just cover the crowns of the tubers, and if then stood in any warm shed or house they will form strong shoots, round which a quantity of roots will be emitted, so that each Potato may be lifted and planted with a large ball without suffering the least check if the planting is done in a careful manner. A very good way of getting a few early is to get some large pots and place two or three tubers in each, according to their size, when they may be set in any light, airy house, where they can get a little heat, and afterwards plunged in a bed of fermenting material to finish them off. The pots at starting should only be about half filled with light soil, as they do better earthed up later on when the tops get advanced and require support to keep them erect.

Seakale may be forced to any extent with a few cartloads of leaves shot in any out-of-the-way corner by digging up the roots and plunging them therein, the bulk of ours being brought on in this manner before the leaves come into use for hotbed work, and while they would otherwise be lying idle. The plan we adopt is to pack the roots tightly in rich soil in

large pots, over which others of the same dimensions are inverted, and slightly covered to exclude the light, when the heads come slowly on, are of large size, and of most perfect whiteness and quality. The old-fashioned way of growing *Seakale*, by making huge beds of fermenting material over it in the open ground, involves so much labour that the produce is in no manner commensurate; and as fine roots, with large developed crowns, can be grown anywhere in one season from the time of planting, the wonder is that so many still go to the trouble and tolerate the litter and untidy look it occasions. Besides forcing well in a bed of leaves, as above named, *Seakale* may be brought on almost anywhere if there be heat available, as there is always near chimneys or furnaces in use, or where hot-water pipes run underground before reaching the houses they are intended to warm. Such places made the most of will yield a large supply and answer equally well for *Rhubarb*, but as the heat so obtained is of a dry nature, the soil immediately surrounding the roots should be kept well watered to prevent them from shrivelling.

A little later on, *French Beans* do far better planted out on hot beds, than they ever do with their roots confined to the limited area of a pot, however well they may be attended to, and if a pit can be made use of with a pipe for top heat, they succeed almost as satisfactorily as when planted out in the open. The steam arising from manure and leaves, impregnated as it is with ammonia, is very conducive to the health of the plants, as it not only wards off red spider, which are generally so troublesome to *Beans* grown under glass; but the leaves, no doubt, absorb some of its nutritive properties on which the roots feed likewise, when it is passing through the soil. It is a well-known fact to those who have had much to do with raising *Cucumbers* and *Melons*, that there is no place where they do so well after the turn of the year, as in a hot-bed frame, and many who grow them on trellises in houses after, prefer sowing their seed and nursing the plants on in the genial atmosphere such a situation affords. A small frame will render much good service for all purposes of this kind, and the most useful way of making it up is to have a few rough faggots at the bottom, so as to admit of driving fresh heat under by means of linings, instead of having so large a body of stuff at starting. The linings can then be added to, or renewed at pleasure, and a tolerably regular temperature thus kept up.

S. W.

A DECEMBER AFTERNOON AT KEW.

ALL who love their gardens should now and then pay a visit to Kew. The rich collections of trees and shrubs are capable of affording valuable lessons to the planter at all seasons of the year, and now that many of the hardy plants of old English gardens are coming to the fore again, where can one see them so well as at Kew? Then, again, there are the many rich collections of exotics under glass gathered together from all parts of the world, worthy, both as regards extent and keeping of a great national establishment. From an educational point of view, one of the great advantages possessed by Kew over private establishments or nurseries is the generally clear manner in which the plants are named; and the free way in which one is allowed to move about is a great boon to those who are trying to familiarise themselves with the various forms of vegetable life which are here so abundant. On a winter's day the glass houses will generally be the most attractive, and one of the most interesting of these is the large temperate house. Many of the specimens here are of large size, thus giving one an idea of their development in their native country. The *Acacias* will shortly be a special feature in the house. Already one or two of them are beginning to show colour, and the others have thrown out their globular or, in certain species, elongated heads of flower, which, during the next three months, will be masses of bright colour. Those whose memories carry them back some thirty or forty years will recollect the handsome specimens of *Acacias* that were common then in many conservatories, but which are now succeeded by plants not half so valuable or showy. Everything, however, comes to the surface in turn. *Acacias* will again be sought after, and I know of nothing so likely to hasten that time as a visit about next February to the temperate house at

Kew. The following kinds are free bloomers (and their habit of growth is so elegant that they are ornamental when not in flower), viz., *Acacia pulchella*, *armata*, *longifolia* var. *floribunda*, *grandis*, *verticillata*, *linearis*, *Drummondii*, *leprosa*, *platyptera* (now in flower), *hybrida*, *diffusa*, *vestita*, and *Riceana*. The latter is an excellent winter-blooming kind, well adapted for training up the rafters in a greenhouse. Its sprays have an elegant drooping habit, and its yellow flowers are freely produced. *Acacias* are equally at home as pot plants, or planted out in the border of a conservatory, and many of the free-growing kinds are desirable subjects with which to cover a wall or to furnish a pillar, or any other naked surface under glass. The *Polygalas* are also deserving of mention as conservatory plants. They are seldom altogether flowerless, and their bright peashaped blossoms are very pretty. The views from the galleries in both the temperate and the Palm-houses are very interesting, the vegetation looked down upon being so different from what is met with in this country in the open air. Here may be seen *Araucarias* towering up to, and in one instance actually touching the roof; wide-spreading Palms and tree Ferns, and long, slender Bamboos—in fact such a picture as is that here presented, could be found nowhere else.

In one of the circular annexes or wings at the end of the temperate house is a most interesting collection of *Aloes* and *Cacti*. It is amusing to watch the effect produced by this class of plants upon visitors who had never previously seen such an assemblage of grotesque vegetable forms. Their singular appearance seems to open up a new world to them. In the Palm-house *Strelitzia reginae* is in flower. It is an interesting old *Musad*, and its singular blue and yellow flowers, borne on long, stout stems, are at this season and onward very effective. *Tillandsia splendens*, a Bromeliaceous plant, with a marbled aspect, would form a striking object in a small collection of stove plants. At this season, when flowers are scarce, *Strobilanthes isophylla* is worthy of notice from its dwarf, bushy habit, and the profusion of pale lilac flowers which it produces. The variegated Fig (*Ficus Pearcei*) has breadth of foliage to recommend it; and as an easily-grown decorative plant for a warm conservatory, *Holcus saccharatus*, from its light, elegant growth, would give character in winter. The collection in the tropical house near the Kew Green entrance is always attractive. Beauty of form, even when destitute of bright colour, has charms for most people. But many tropical plants have brilliant-coloured leaves, and for a moderate-sized stove there is no class of plants more effective than the *Marantas*. They are not difficult to cultivate; rough, fibry peat, crushed charcoal, and sand, with plenty of drainage and abundance of moisture, form the chief requisites. The following are selected from the Kew collection, viz., *Maranta fasciata*, *Lindeniana*, *rosea lineata*, *porteaena*, *Veitchi*, *zebrina*, and *splendida*. Amongst the Ferns, at which I had only just time to glance, *Adiantum æthiopicum* seemed well worthy of notice. It has a tall, slender, elegant habit, and although introduced long ago, it is still rare.

Now, when locomotion is so easy and rapid, the impetus that Kew is capable of giving to gardening assumes an importance which it did not possess twenty or thirty years ago. One can now leave home in the country, 80 or 100 miles away, reach London by half-past ten or eleven o'clock in the forenoon, spend four or five hours at Kew, and be back home again in the evening. I look upon Kew as a large national school of gardening, and it would be an enormous advantage to country people if they could obtain admission, say by eleven o'clock in the morning, instead of the usual late hour in the day. I shall probably be told that gardeners, both amateur and professional, can already gain admittance by attending at the curator's office and inscribing their name and the object of their visit in a book. That this is a boon I do not deny, but why retain even this much of red tapeism if it can be proved to be unnecessary.

E. HODDAY.

The Weather in Ireland.—The weather here is very severe for this part of Ireland. At the present moment (seven o'clock Monday night) we register 21° of frost. We had 19° last night, 21° on Saturday, 20° on Friday, 16° on Thursday, 18° on Wednesday, 19° on Tuesday. All outdoor garden operations are at a standstill, the frost being too severe even for trenching.—J. CLEWS, *Kells, Co. Meath*.

THE INDOOR GARDEN.

ADIANTUM EDGEWORTHII.

THIS is a distinct and useful Fern, and one which thrives well in an intermediate temperature. It is closely related to *A. caudatum*, but differs from it in its pinnæ, which are more deeply cut, glaucous, and altogether more ornamental than those of *A. caudatum*. It is one of the best of basket Ferns, and it also looks well when grown in suspended pots. It is largely used by Mr. Wills for suspending amongst tall plants in decorations in which choice materials are employed,

Adiantum Edgeworthii.

and our woodcut was prepared from one of his plants. It comes from the Himalayas, China, and other parts; in fact, it is a Fern which has a wide distribution. S.

STOVE CLIMBERS.

CLIMBING or trailing plants that will bear a greenhouse or conservatory temperature are plentiful enough, but for embellishing the roof of a stove the choice of varieties is more limited. What they lack in numbers, however, is fully made up by the gorgeous display several of them make, and the great value of their flowers for cutting. Take the Bougainvilleas, for instance, the rich inflorescence of which is so telling and effective as to quite brighten up any epergne or vase they may be used in, and besides being of the most enduring character in water, when once the plants begin to bloom there is no end to the supply they afford. From one planted out and trained under the ridge where it has a straight run of 20 ft. or so, I believe I am not exaggerating when I say that any time from the end of January up to May I could cut as much as a man could fairly carry. Most of the branches generally range from 2 ft. to 5 ft. or 6 ft. long, laden throughout with lovely-coloured bracts, which, seen under a full play of light above, have a most imposing appearance. The first to bloom is *B. speciosa*, which is decidedly the most useful of them all, and should have a place in every stove; but where room is limited, the best way is to keep it in a pot, box, or tub, where its roots can be restricted and always under control, as then it is an easy matter to withhold water so as to assist in inducing a thorough ripening of the wood, without which it never flowers in the free manner it is capable of. Planted out it generally grows too rampant and requires much thinning and cutting, but with a limited larder it can be starved into subjection at will and easily kept within bounds. As plenty of light and sun is essential to success in getting this splendid climber to a high state of perfection, the best way to manage it is to train it up with a clear naked stem to the roof of the house, and run its leader along a tightly-strained wire within 9 in. or so of the glass. Any side shoots it may then form should be laid in something after the manner those of a Vine are, and it is on these the flowers appear. In order to give the plant a long season's growth, and afford plenty of time to become thoroughly mature, what pruning it requires ought to be taken in hand directly the leaf-bracts fade, when most of the shoots that have borne them may be cut away, so as to leave room for fresh ones to follow and occupy their places. It generally happens that more of these show than are required, and the best plan is to rub them out at once, especially all such as are strong, and appear likely to take the lead, as they are only robbers, and are generally very shy in blooming. Twiggy shoots, about the size of a straw or less, are the best for this, and such as these should be encouraged till they have attained sufficient length to be serviceable, when, to check further growth, water sparingly till the autumn, at which time the ball of earth may be brought to such a condition of dryness as to induce thorough rest till about Christmas, and then the plant should be gradually started again. Being naturally free-growing, any kind of soil partaking of a fibry, sandy nature, suits to pot it in, but whatever is used should not contain manurial matter, as any stimulant applied during the early stages only forces strong wood, and is only required when the feeding ground becomes exhausted, a time when, if given in the liquid form, it is of much service, and will keep a plant healthy for years. *B. glabra*, although not so useful as its congener above-named, is a very serviceable variety to succeed it, as it begins to come in just as *B. speciosa* is fading, and continues to blossom during the whole of the summer months, and, when planted out in a warm house, it may be had even as late as Christmas. The habit of this species is to produce its flowers on the young wood as it grows, and the way, therefore, to manage it is to spur it in in the spring. One advantage in growing *B. glabra* is that it does not require much heat, as, if kept dry at the root, it will winter safely in the temperature of an ordinary greenhouse, although under such conditions it becomes leafless during the winter. As a pot plant trained on a trellis it is of much value for conservatory decoration and exhibition purposes, and when shown in good condition always has great weight with the judges. *Clerodendron Balfourianum* is another stove climber of rare merit, good alike for pots or planting out, its branched cymes of creamy-white bracts, with brilliant-coloured, star-like

Aponogeton distachyon in Small Aquaria.—This interesting aquatic plant may be grown in small glass cases in dwelling-houses with good results. We lately saw a small square glass aquarium in which several plants of it in small pots were growing freely, and showing flower. The pots were submerged to a depth of 6 in. or 7 in., and their surface was covered with stones and shells, which also covered the bottom of the case. A little air at the top is necessary, and also fresh water occasionally, to ensure healthy growth.

corollas peeping from them, having a most striking and beautiful effect. Plants of this, with plenty of well-ripened wood in them, started now will soon be in flower, or young ones potted or planted out and grown on freely during the summer may be had in fine condition by the autumn. Fibry peat with a good dash of sand and free drainage suits it best, and to ripen the twining shoots which it forms, the way is to gradually withhold water till the leaves flag, and only give just sufficient to prevent them from falling till a month or so of the time they are required in bloom. Trained under the rafters of a stove and allowed to festoon therefrom, *Clerodendron Balfourianum* forms a fine ornament, and contrasts well with *Passiflora* princeps, the long racemes of deep crimson flowers of which always command admiration. This is a plant that likes strong heat, and always does best planted out where it can have plenty of root room and a tolerably rich run in which to feed. Like all the *Passifloras*, it is easily managed and not at all subject to insects of any kind; and, being of a remarkably free-blooming habit, it is one of the most desirable stove climbers than can be grown. A back wall with a trellis or a few wires strained on it is a very good position for it, as, although it thrives best under plenty of sunlight, it will succeed in a more shady situation than either of the foregoing. Another grand subject for cutting from at this season is *Euphorbia jacquiniæiflora*, which, either planted out or grown in large pots and trained within a few inches of the glass, affords an immense quantity of bloom for the flower basket, and does much to brighten up any house in which it may be cultivated. Although the individual blossoms are very small, they are so thickly set, and of such a fiery scarlet colour when exposed to full light as to be very showy, and, with the rich garniture the well-arranged leaves afford, nothing can be more effective as wreaths for ladies' hair, a purpose for which Nature seems to have specially adapted them in every way. If grown in a cool temperature, these flowers last a long time in water, and the plants, after yielding a supply for cutting, break again and send out a succession on the freshly-formed laterals. To induce them to do this freely, it is well to give them a slight rest by keeping them a little dry at the root for a time, when with slight additional heat, they soon respond and start away freely; and the same should be done again when cuttings are wanted.

Jasminum Sambac fl.-pl. is a capital wall plant that is highly deserving a place in any stove, yielding as it does the most deliciously-fragrant flowers that can be had for bouquet making, and of a size and form just suited for the work. This and *Stephanotis floribunda* are almost indispensable for the above-named purpose, but the latter, unfortunately, is very subject to mealy bug, an insect that always assails it in the most persistent manner, but now it is known that paraffin will destroy this pest without the least injury to the plant, it will be an easy matter in future to keep it free from its ravages. The best way to grow *Stephanotis* is to plant it out in a prepared bed, where it can get some bottom-heat, or place it on a large box over hot-water pipes in an angle of the house, from whence it can be run with a single stem to the roof, and there trained in a position where it can have the benefit of the full solar rays to ripen and mature the shoots, on the young ones of which the flowers are produced. Fibry loam, with plenty of drainage is a suitable soil for the *Stephanotis*, and this should be used in rough, large lumps, in which state it remains more open and lasts in better condition than such as is finer. With the *Allamandas*, the above are the principal stove climbers that are worth growing, and these last named, like most of the others, must have full exposure to get them to emit their gorgeous flowers, which under a light roof they do in a very free manner. Owing to their naturally strong habit they do not require much root room and generally do best confined in large-sized pots, instead of being planted out, unless they have an unusually large space to cover, and even then it is always advisable to have them somewhat under control. As the blossoms are all made on the young growth, an annual pruning or thinning out is necessary, the time for doing which, should in some measure be regulated by the season they are required to flower. Enforced rest during the winter, by being kept dry, prepares them for the pruning, and if this is done before starting them into growth, by giving water they will not bleed at the wounds. *Allamandas* always have the best effect with the shoots growing

somewhat loosely, as they show their blooms more effectively when hanging down in their own natural way. Strong loam is the soil most suitable, and when in full leafage they cannot well be kept too moist at the root, and if assisted occasionally with liquid manure their foliage will maintain a more pleasing green colour. A. D.

CULTURE AND PROPAGATION OF CHOROZEMAS.

SCARCELY any of the Australian plants are brighter, more useful, or more easily cultivated than these Pea-flowered, slender-growing shrubs. Being of free growth, which, when matured by full exposure, is certain to be abundantly floriferous, not much subject to insect attacks, and, thriving as they do in a conservatory where most of the ordinary hard-wooded plants would quickly die, *Chorozemas* are well worth attention. If, at any time, a specimen becomes leggy, or naked at the base, it may be pruned back, placed in a gentle heat, and it soon breaks into young growth. They are easily propagated from cuttings of half-ripened wood, in sandy soil under a bell-glass in gentle heat, and I have often rooted them without the shelter of the hell-glass. Seeds also, either imported or home-grown, soon vegetate if good, and make pretty little plants. They will succeed either in peat or loam, or in a mixture of the two, with sand added in proportion to the nature of the soil. In the matter of soil for this and many other plants, I think it is not so well to tie ourselves down too tightly to any particular compost, as all of us are more or less influenced by surrounding circumstances. There are many plants usually grown in peat that might be better grown in good loam than in inferior peat; and where the loam is good and the peat inferior or expensive, I should certainly prefer the loam. There are some plants, of course, that cannot be grown and kept in health in loam. Heaths, for instance, and other fine-rooted plants thrive only in peat. But there are a good many different kinds of loam. The best kind for New Holland plants has a bright colour and a soft, silky feel when handled, and if used in a fibrous condition, with sufficient sand added to make the water pass through freely, the growth will be firm and short-jointed, and less likely to run up weakly than when potted in a lighter compost. One of the good qualities of this race of plants is blooming freely in a small state, and their long period of duration. Young plants may be pushed on in spring in an intermediate house or a Vinery at work. All shoots showing a tendency to run away should be pinched back. In this way a good thick base will be made that will in time form a handsome specimen. Some support will be required for the slender shoots as they advance in growth, and there is nothing neater or better than thin deal sticks painted green. These can be made in bad weather, and have a little green paint rubbed over them. Not one more than is necessary to give the requisite support to the plants should be used, as in themselves they constitute no ornament. The plants must not be given too much heat in spring. After pruning, a little warmth and a closer atmosphere will be beneficial for a few weeks, but they should be cooled down early, and be placed in a sheltered situation in the open air early in July, where they may remain till the middle of September. Those plants of such kinds as *cordatum splendens*, that are started in a little heat in spring, to get the growth made early, will commence to flower in October, and will prove exceedingly valuable and reliable when other flowers are scarce. Any one having a large house to furnish and keep gay in autumn and winter should have at least half-a-dozen good-sized specimens to help out the *Chrysanthemums*, *Salvias*, and other plants. The following include some of the best kinds:—*cordatum splendens*, *Lawrenceanum*, *Henchmanni*, and *varium nanum*. The last is a dwarf kind suitable for a small house. E. HODDAY.

A Good Table Plant.—*Casuarina ericoides*, in Mr. Williams' nursery at Holloway, possesses qualities which render it one of the best of table plants. It is easily grown, of bushy habit, and its graceful, lively green, thread-like leaves make it a desirable plant for vases or for similar uses in the dwelling house. Good plants of it may be grown in 5-in. pots, or large specimens fit for conservatory decoration may be produced in a comparatively short time.—S.

PLANT-COVERED WALLS.

ALTHOUGH the plan recommended by "S" (p. 501) for covering the bare wall of a stove is a very good one, and a quick way of doing it, far better and more permanent results may be attained by building pockets to hold from half-a-peck to a peck or more of soil each. This may be done by using any light, rugged material, such as large pieces of hard locomotive coke or the clinkers from the garden furnaces, or both combined, which any handy bricklayer or man of taste can put together so as to be quite an ornament to any house. The way to set about it is first to get a sufficient number of pieces of ordinary roofing slate, of various sizes, and then rake out a joint of the wall where it is desired to have a pocket, into which the slate can be thrust, so as to form a solid foundation to build on. The best cement to use is the Roman, on account of its quick-setting properties, as within a few minutes it hardens and holds the pieces bedded in it securely in their places. To expedite the work of building, the way to manage is to place all the pieces of slate in the wall at starting, putting them at from something like 18 in. to 2 ft. 6 in. apart in irregular rows, which done, the builder should then stick a piece of clinker at the side of each against the wall, beginning at one end and working on to the others. By so doing, it affords time for each to dry and set, when the same process can be begun again and continued till the whole of the pockets are complete, which, when done, have something the appearance of huge swallows' nests. This is only the foundation, as it were, for the finishing touches have to be put in afterwards by attaching more coke or clinker, as the case may be, to give the whole a more rock-like appearance. To get the pieces to remain in their places till the cement hardens, it is an easy matter to drive a few cast nails in the wall, and run a string from one to the other so as to hold all together where arranged, and this is a great saving of time, but little difficulties of this kind can be met as they present themselves and readily overcome. Towards the top of the wall the pockets should be smaller and more numerous to hold the choicer kinds of Ferns and Mosses, Orchids, Epiphyllums, or anything of that description it is thought desirable to introduce, as there are many plants that do much better grown in this way than in pots, and have a far more natural appearance. This is especially the case with Ferns and more particularly the *Gleichenias* and the drooping varieties, such as *Goniophlebium subpetiolatum*, and others of that class, that never show off their full beauty unless in some elevated position where they depend gracefully without being hidden by others. There are many flowering plants, too, of which the same may be said, as for instance, the *Æschynanthus*, the lovely *Epiphyllums*, that beautiful winter-flowering subject *Centropogon Lucyanus*, and many others too numerous to mention. Such as these, associated with Ferns and *Lycopodiums*, have a fine effect, their bright colours showing up in pleasing contrast with the different shades of green, to which they help to give life and character. Among Orchids the *Dendrobiums*, *Oncidiums*, *Cattleyas*, and others of similar habit and hardness of constitution may be grown, and with these *Anthurium Scherzerianum*, so that, with one and the other, a wall converted to such a use is sure to commend itself and command notice. One great advantage in covering walls with imitation rock is that Ferns may be grown in places that would otherwise be bare and unsightly, as, except these, there are few plants that will do under shelves far from light, but that is just the situation where Ferns seem greatly at home, the shade there during the summer exactly suiting their requirements. Being of a moisture-loving nature, it is necessary in building the pockets to make due provision for free drainage, which may be done by leaving holes at the bottom and putting in a few crocks or cinders before filling the spaces with soil. Cork has been brought into notice for making receptacles for Ferns, but it is much more expensive than such as can be formed of clinkers or coke, besides which, when the latter are at all well put together it is in no way equal in effect, while, as to durability, there is no comparison between the two. Such hard materials are imperishable, and improve in appearance by age, as, after a time, Moss and Lichen spring up on it, and it assumes a weather-worn look. To assist in adding to this, it is a good plan to give it a touch over here and there with some of the colours used in paint, such

as any of the greens, brown umber, yellow ochre, and the back of the pockets with black, so as to make them look deeper. The above-named dry colours should be mixed with gold size which prevents water having any effect on them, so far at least as regards washing them off. I omitted to add that after the building is satisfactorily completed, the whole of the material used in its construction should be coated over with liquid cement, which not only strengthens it, but is necessary to give it an entire rock-like look. The easiest and best way of putting this on is to mix it to about the consistency of thick whitewash, and then splash it on by means of a new brush, when it will run into all the crevices and effectually hide the joints, if the work be gone over a second or third time, which is generally desirable to give the whole a good finish. S. D.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Prumbago rosea.—For this season of the year this is one of the brightest decorative plants that can be found. It will not do for cutting, as the flowers will not keep above a day or two, but the plants will stand for three weeks or a month in drawing or sitting rooms and continue flowering, provided the temperature does not fall below 40°.—W. W. H.

Abutilons for Winter Flowering.—Those in search of easily-managed winter flowering plants should procure *Abutilon* *Boule de Neige* and *A. Lemoinei*. These two varieties flower the whole winter long in an intermediate temperature and stand a long time in the warmest rooms after being cut; they are therefore also valuable as cut flowers.—W. W.

Zonal Pelargoniums for Winter Flowering.—I have for some time rather looked down upon scarlet Pelargoniums, but I must confess that my opinion concerning them has altered a good deal since I visited the other day the gardens at Narrowwater Castle, County Down, where, on the 9th of December, I saw a whole household of them, comprising all shades of colour, beautifully grown and flowered. Both trusses and tints seemed to me to be greatly superior to anything which I had seen in summer, at least so I thought. For this superiority I endeavour to account, by supposing that at this season the flowers take longer to open and come to maturity than in summer, and the colours thus become intensified. All that is necessary seems to be, plants grown freely through the summer and not allowed to flower until autumn, housing them in time in a good light house with a free circulation of air, and sufficient warmth to maintain a genial growing temperature. It struck me, in fact, that but little else is required at this dull season besides Zonal Pelargoniums and *Chrysanthemums*, which are also well grown in the gardens just alluded to.—F. SMITH, *Newry*.

Primula sinensis coccinea.—Having received a packet of seed of this *Primula* in April last, I sowed it and grew the young plants on fast, and now I have some good plants in 5-in. and 6-in. pots, several of them being beautifully in flower. This is the best and brightest *Primula* I have ever seen, and when put by the side of those strains generally sold as red, the latter won't bear comparison with *coccinea*. It is really a good *Primula*, and I would recommend all who have not got it to give it a trial. When it becomes better known it will supersede the old types of red. Another recommendation belonging to it is, it throws its flower trusses well up above the foliage.—J. C. F.

Gold's Chemical Compounds.—Allow me to inform Mr. Culverwell (p. 547) that from careful observation, I find that adding as much of these chemicals as will lie on a two-shilling piece to a gallon of water, has the desired effect, and with a little careful attention, it is astonishing how near one can guess that amount. In the case of robust-growing plants, a little more might be safely added, but I prefer a moderate quantity used oftener.—A. HOSSACK, *Ragley, Alcester*.

Iris Persica and Reticulata Indoors.—I have found these to do well treated as follows: I put from four to six roots of them in a 5-in. or 6-in. pot in August or September, and plunge them like Hyacinths till they begin to grow; then I put them into a cold pit, giving all the air possible in fine weather, and only keeping them from frost, and just previous to their blooming I bring them into the greenhouse, giving them a good place on a light, airy shelf, where they throw up strong blooms. When out of flower I replace them in the pot, encouraging the foliage so as to keep it green as long as possible. When it shows signs of turning yellow, I gradually withhold water till the soil becomes quite dry, and allow them to remain in the pots till they are wanted to start again.—J. C. F.

THE FRUIT GARDEN.

PROTECTING STRAWBERRY PLANTS IN POTS.

Mr. SIMPSON (p. 520) appears to have entirely misconstrued the meaning of my remarks upon this subject. I must therefore direct his attention to the following passages, portions of which he has so quoted as to distort their signification. In the first place I observed that I preferred "to place the plants in frames, merely covering them with the lights during heavy rains or in very severe weather;" and, again, "air should never be taken off unless the frost be very penetrating or accompanied by harsh drying winds," as biting drying air playing upon the frozen foliage is apt to cause a considerable amount of injury. It will thus be seen that I did not advocate the entire exclusion of frost; what I did recommend was the sheltering of the plants, especially when not thoroughly well rooted, from extremes of wet and cold, and I think that on this point most growers will be of my opinion. Mr. Simpson cites instances in which plants were not injured by being frozen. I could do that, too, but, at the same time, I have had practical illustration that they may, under certain circumstances, be irretrievably injured. I witnessed a striking instance of this several years ago. At housing time I placed some good plants in frames, the back and front of which were boarded; the soil having given way, there was a passage of air through the frame; a period of severe frost set in, accompanied by a searching drying wind; the pots became frozen through, and the foliage was so shrivelled that the plants did not bear one-half the crop that others did that were better cared for; while, had the frame been close, I am convinced that they would not have suffered much. This is not the only instance that has come under my notice of plants suffering from our icy winds playing continually upon them when in a hard frozen state. The fact is, that a series of mild winters have had the effect of putting many of us off our guard, and, consequently, when an exceptionally severe season comes, a considerable amount of injury is done that might have been easily prevented. Mr. Simpson draws a comparison between plants in the open ground and those in pots, and asks, "Why are not the outdoor plantations injured?" Simply because the conditions under which they are placed are very different from those of plants in pots. During the last severe winter that we experienced, I left some plants in pots out of doors on purpose to give them a trial, and the result was that by February they were killed completely root and leaf, and yet they were standing near outdoor plantations that were not injured. How does Mr. Simpson explain that? Although Strawberry plants form a quantity of fibres near the surface, they send down many feeders deep into the soil, and I cannot quite understand why plants put out in good time should not root deeper than "9 in. to 12 in." I have traced the roots of summer-planted Strawberries fully 2 ft. in depth in the winter, and these are the roots which keep up a flow of sap at all times of the year, and enable the plants to resist the extremes of heat and cold. With respect to two-year-old plants, I can only state that they give fruit equal in quality to young ones; the only difference is that they are more certain to yield a heavier crop. This has been proved here over and over again. Were it not so, they would not be grown, as growing for Covent Garden Market and supplying a gentleman's table are two different matters. Those who grow for profit are very apt to have their wits sharpened and find out that which gives the greatest returns for their labour, and know, when old and young plants have been repeatedly tried, that the balance is greatly in favour of the former. The true test of quality in a fruit is the price it commands in the market, and I have invariably found that that produced by plants two or three years old has realised quite as much as that obtained from young runners. The preference is given to old plants because they never fail in a crop; they yield better, and are, therefore, more profitable; they do not require half the care in the summer, and are more easily managed in the spring. Neither does it matter how hot, dry, or unfavourable the season may be, they may be always relied upon to be of uniform quality. I am not surprised to find that all this is new to Mr. Simpson, who has evidently pursued the old beaten track. It does not, however, follow that this is the best or only sure road, as others, to my certain knowledge, besides myself, have found out.

Bylect.

J. CORNHILL.

CLOSE PRUNING BUSH FRUITS.

MANY of us must feel indebted to "Cambrian" (p. 471) for his remarks on the pruning of Currants and Gooseberries; nevertheless, I am afraid that all kinds of Currants must not be treated alike; few, for instance would think of pruning Black Currants back to one or two eyes, and throughout my experience of thirty years I have seldom met with any one who would prune Red Currants to one or two eyes.

My mode of pruning Red Currants is to leave the leading shoots from 3 in. to 4 in. long, cutting the side shoots so as to leave them about 1 in. long, and in that space I generally find eyes sufficient for a crop to satisfy any one, and as fine in bunch and berry as could be wished for when liberally supplied with manure. As regards Gooseberries, I consider that nearly every variety should be pruned differently; take, for instance, Ironmonger; no one would think of pruning that kind closely who knows how apt the old wood is to go "blind." On that account all the spring wood possible should be retained, allowing room at the same time for plenty of light and air. The side shoots of Warrington, again, require close pruning, and from 4 in. to 5 in. are amply sufficient for the leading shoots, taking into account the drooping tendency of this variety, unless placed on very high stems, when a little more latitude might be allowed. Another variety which requires close pruning, is the yellow sulphur, but, being of a more erect habit than the last, its leading shoots may be left longer. Again, if we take Crown Bob with its long shoots and drooping habit, if not set on high stems, the weight of the crop will bend the shoots down to the ground, and thus spoil the fruit for every purpose. At the same time, this variety does not require close pruning. In this way I might go on enumerating almost any number of Gooseberries, all of which, being of different habits, would require almost in every case, a slight difference in the mode of pruning, but perhaps enough has been said. In regard to the pruning of fruit trees, almost everyone has his way of performing the operation. Here, in East Kent, we have close upon 50 acres, some close-pruned and others growing at random.

J. STEWART.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Golden Queen Grape.—Vines of this Grape in pots on their own roots do well with me. Last season I had bunches from 1 lb. to 1½ lb. in weight, of a beautiful golden colour. These won a second prize as new Grapes at the York show, in June, and, strange to say the first prize was awarded to Madresfield Court; therefore, in future, schedules should distinctly state what varieties they consider to be new. I also grafted Golden Queen on Madresfield Court in one of our late houses; it made a capital one, and this year it bore six bunches of Grapes. All went right until colouring commenced, when, instead of becoming golden, it began to spot and shrivel, so much so as to be useless, thus showing, according to my opinion, the stock to be an unsuitable one; and, in order to strengthen my views in this matter, I may mention that Mr. Wilson, gardener to Lord Lindsay, Uppington, planted it out direct from the pot in which it was received, and is rewarded with grand bunches, free from spot, as yellow as gold, and in every way satisfactory. I therefore say, grow it on its own roots, and I feel sure that there will be no disappointment.—R. CILBERT, *Burghlen*.

The Black Hamburgh as a Late Grape at Trentham.—Without in any way detracting from Mr. Stevens' skill as a Grape grower (which it would be invidious to attempt to do), I think it should be generally known that the soil at Trentham, being as it is on the red sandstone formation, is very favourable to the Hamburgh Grape; hence, partly, its keeping qualities there, as mentioned by Mr. Bolas (p. 521). My object in mentioning this is merely to prevent disappointment on the part of those who might be disposed to expect similar results in all cases. Most cultivators who have practised on various soils will, like myself, have often remarked how much better Grapes generally keep when grown on some soils than on others, all other items in their culture being equal. I have more than once seen Hamburgh Grapes grown in soil on the sandstone formation keep plump and sound until December, under ordinary treatment, while, on the other hand I have known able Grape growers not so fortunately situated as to soil try all in their power to keep them until that time and fail; and yet an ordinary observer might not have seen much difference in the fruit in the two cases, say when just ripe in September. From careful observation on this point I have always found that Hamburgh Grapes grown on the chalk and light limestone formation keep the worst. The berries individually do not seem to be so firm and pulpy as when grown on stiffer soils, though the general finish is often better.—H. J. CLAYTON, *Grinton*.

Winter Nelis Pear.—Those who are desirous of having a really good Pear to come into use at Christmas will find this variety second to none. It has always been spoken of as the best Pear out for dessert in every place in which I have been. Some fine specimens of it, imported from California, may now be seen in Covent Garden Market. The tree forms a handsome, small pyramid, is quite hardy, and an excellent bearer.—D. S. GILLET, *Weybridge*.

GARDEN DESTROYERS.

THE LIGHT-COLOURED PINE SAW FLY.

(LOPHYRUS PALLIDUS.)

THIS saw fly, when in the caterpillar or grub state, does much injury to our Coniferæ by eating the leaves of the young shoots and gnawing deep grooves in the young wood. As they are generally found together in families of from twenty to fifty individuals, it can easily be imagined that when a tree is infested by several of these families, particularly if the tree is a specimen one, it is much injured by them. The best means of destroying this insect, is by laying a sheet or white cloth under the branches on which the caterpillars are feeding and shaking them well, when the caterpillars will fall off and can be easily destroyed. If the trees are quite small, they can be picked off by hand. They are, fortunately, very subject to the attacks of several kinds of ichneumons, some species of which deposit their eggs in those of the sawfly, some in the caterpillars, and others in the chrysalis. All insectivorous birds prey upon them, so that their natural enemies reduce the numbers which attain maturity very considerably. The perfect insects are frequently found in June and July, on and flying around various Fir trees, and should always be destroyed. They make their first appearance in June, and soon

Lophyrus (Tenthredo) pallidus.

afterwards begin to lay their eggs in the leaves of Fir trees. The females are furnished with a short but very curiously made ovipositor, very similar to that of the Rose saw fly described in a previous article on that insect, as an instrument formed of two toothed plates with which, by a rapid and alternating movement of the plates, the female can very easily make an incision in a leaf or tender shrub. In this slit she deposits an egg which, passing between the two saws, is thus directed into its resting place; with each egg is deposited a drop of a frothy liquid, which, it is supposed, keeps the edges of the slit from closing; the slit is said to increase in size as the egg grows, which Reaumur states is the case, the egg, in some unknown manner, deriving nutriment from the juices of the leaf. In the course of a fortnight or three weeks the eggs hatch, and the caterpillars spread themselves over the surrounding leaves. These false caterpillars very much resemble, and are often mistaken for, the true caterpillars of butterflies or moths, but, with a little care, they can always be distinguished from them, for the false caterpillar of this species has eleven pairs of legs, whilst no true caterpillars have more than eight pairs. The heads of the latter are nearly always heart-shaped, whilst those of the former are round; they emit from their mouths, when touched, a drop of fluid having a resinous smell. They attain their full growth towards the end of August or the beginning of September; they then spin amongst the leaves where they

have been feeding a small oval cocoon, in which they pass the winter, and in which, in the following spring, they assume the chrysalis state. Dr. Leach found that one of these caterpillars remained unchanged in its cocoon for two years, but this, I imagine, was a very unusual circumstance. The saw flies leave their cocoons in June; the males differ considerably from the females both in size and colour; the former measure about 6-10ths of an inch across the wings when they are fully expanded, and are black, with the front margin of the thorax and the legs yellow; the antennæ are deeply toothed on both sides; the body is reddish-brown beneath. The females are somewhat larger than the males, and their colour is pale yellow with several reddish-brown transverse bands on the body; their antennæ are not nearly so deeply toothed as those of the males, and they are furnished at the apex of their bodies with the above-mentioned ovipositors. In both sexes the wings are transparent, but very much veined. The larvæ are about 7-10ths of an inch long when full-grown, and of a pale green or yellow colour. Some have three darker longitudinal lines, one down the back and one on either side. Their bodies consist of twelve joints, not including the head, which is reddish-brown; each joint bears a pair of legs, with the exception of the fourth. The cocoon is oval and of a grey colour; it is very small in comparison with the grub, which is obliged to lie within it in a curved position. S. G. S.

Marl as a Cultural Agent.—I was informed by an advanced cultivator some years ago that nothing refused to grow in marl. Since then I have verified the remark as being applicable to many plants. I have used it extensively in young shrubberies with forest trees, choice Coniferæ, stone fruits of all kinds, Pears, and Strawberries in pots, with advantage. Where such soil abounds, it would be found to act as an excellent dressing for old gardens which have been heavily manured. Fruits and vegetables alike would benefit from such material. Where such can be procured in quantity, it may be turned to good account by being spread over the surface of vacant plots, and afterwards dug in. When Melon soil is light marl will be found most serviceable when mixed in moderate proportion, well mixing the two together. I have not tried it for Vines, but intend making the experiment with some in pots. I suppose its action in a Vinery would be similar to that of burnt earth, which is known to suit Vines well when mixed in the borders. For Peaches it suits admirably. Two years ago (August 20) we planted two small Peach houses with suitable kinds for early and mid-season work, the plants being kept in pots till the structures were glazed, and having anything but proper treatment. A quantity of marl, lime rubbish, and bones (the latter in small proportion) was mixed with the soil, which was of very inferior quality. The trees made good root action in the border, which had been rammed very firm, but little growth was made in the branches. The following July about two dozen fruits were taken off each tree; in August, while the foliage was green and growth going on, the trees were well trimmed in and the roots half lifted. Some of them were nearly entirely lifted, and, of course, speedily replanted. No more growth was made by the shoots, which became very hard and red in colour. This season we took out of the same house 330 capital fruit within the year, and ten months from planting. The house is 33 ft. long, and the back wall and front trellis are covered with fine wood. The second house is similar to the other; it was cropped about the same as the first last year, but only 250 were taken off the trees this season; and we find that, as soon as the crop is all gathered, a number of roots will require lifting, to stop the vigour of the trees. The fibrous roots are all over the soil, a few inches from the surface, and are easily manipulated on. We never saw Strawberries in pots fruit better than when, last season, the plants were potted with a mixture of marl in the soil (which was of a very bad quality). The kinds of Strawberries which did so well were Vicomtesse Héricart du Thury as first crop, Sir Harry as second, and Oxonian as last. All the kinds were much larger than in the open ground. They kept wonderfully free from insects, and set freely in great quantity. The Oxonian grew to a large size, some berries measuring over 6 in. by 4½ in. in circumference.—M. T.

Polemonium coeruleum variegatum with White Flowers.—It would appear that there are two forms of this *Polemonium*, as some of the plants of it which I have produced white flowers, the native variety being blue-flowered. The white-flowered sort is, of course, merely a variety of the blue kind.—R. P. BROTHERTON, Tynningham.

THE FLOWER GARDEN.

LILIUM AURATUM AT HOME.

PERHAPS a few words from one who has recently visited Japan may be of interest to those who asked for information about the habitat and growth of this Lily in its native country. *Lilium auratum* is found in great abundance on the steep, partially-wooded hill-sides that form the flanks of the well-known volcanic mountain Fujiyama, and in smaller quantities throughout the district generally. The soil that covers to a varying depth the crumbling igneous rocks, consists of decomposed leaf-mould, mixed largely with the detritus of this volcanic rock, that sparkles with particles of mica, and is excessively porous and friable. This Lily, then, grows on hill-sides where there is perfect drainage, with a soil free from lime, in a climate that is both hotter and wetter than our own in summer, and is in winter dry and bright, with occasional sharp frosts of a few days duration. To imitate this in our climate, we must provide it with soil as warm and well drained as possible, and in summer (if the weather be hot and dry) supply it copiously with water that has been well aired and the chill taken off it, as sudden changes of temperature are most fatal, as will be inferred below. Another point to be noticed is that this Lily abounds at the edges of woods, where the dwarf Bamboo, that in Japan takes the place of Grass, effectually shields the stem and roots from the sun's rays, while the upper part of the stem with the broadest leaves rejoices in full sunshine. Sunstroke at the base of the stem is a fertile source of disappointment, and for this reason Lilies planted among *Rhododendrons* succeed so well in warm localities in this country. Another and frequent cause of failure arises from the bad treatment of the bulbs by the Japanese, who are in the habit of taking them up, and exposing them to the sun and air for ten days or a fortnight before packing them for exportation, a practice against which "Dunedin" has rightly remonstrated as being most injurious.

The drying up of the sap in the scales and consequent exhaustion of the bulb's vital power is the real cause of the "mop-like growth of stem roots" so often seen in late-potted bulbs that have been recently imported; because the base from whence the roots proceed has become so dried up as to be unable to push new roots. The stem in spring, when it begins to rise soon exhausts the bulb on which it feeds, and so pushes out stem roots to supply its growing wants; and it seems true that stem roots do not strengthen the bulb to any appreciable extent in storing up strength for another season, for on being taken up it is found to have dwindled to a mere nothing, not because of the stem roots, but because it lacked roots of its own. They are Nature's effort to help the stem to perfect flower and seed before death, and are the result rather than the cause of weakness and death. On healthy plants in their own country they are present to a moderate degree, and serve, probably, to strengthen the stem and prevent it from being twisted off by wind when top-heavy with its magnificent flowers; and it will never be found that a really healthy bulb, provided with abundant roots of its own pushes stem roots in any quantity. I should hardly recommend the practice of cutting off the stem roots for the reasons I have given, and it is evident that unsuitable soil will, by its coldness and wetness, destroy the bulb roots, and cause a great growth of stem roots in the same way that exposure to the air does. It may, however, be worth mentioning in case some do not know it, that the stem of the seeding Lily may be cut off below the stem roots without apparent injury to the seeds, and the bulb, thus deprived of its load, may be potted or replanted before the autumn roots (which are most valuable) have pushed. The top must, of course, be transplanted with the greatest care if perfect seeds are wished for, and if successfully performed, it will never flag, and will, in a warm autumn perfect some small offsets as well as seeds.

In Japan just now the thirst for change and improvement is even greater than in Europe, and some of the best exporters of wild or cultivated Lilies, now dip each bulb in a bucket of clay and water, "thick and slab," until by repeated coats of mud the bulb is guarded from the direct action of the air. This is a

great improvement, and with proper cultivation in warm soils, it is to be hoped that the number of failures in the management of this Lily will be lessened; but in truth it is not of as hardy a constitution as many, and in cold soils and situations it is best under glass.

E. H. W.

SCALES AND STEM ROOTS OF LILIES.

"DUNEDIN" asserts (p. 507) that the scales of imported bulbs of *Lilium auratum* are dead when received in this country from Japan, and then he goes on to say that the "cell walls which make up the tissue or fabric of the bulb remain unaltered, and perform some offices long after life has departed." This, I am sure, will be a surprising statement to many, more especially to those who have successfully used the scales of such old bulbs for propagating purposes. I once saw half a basketful of the imported bulbs of *L. auratum* which had lain all winter in a shed, and which had during that time fallen to pieces, start into growth in the spring, nearly every detached scale bearing one or more leafy bulblets. The fact is that the old scales of Lily bulbs which have flowered are not dead, any more than the old pseudo-bulbs of Orchids are dead after flowering. They may not bloom again, but they have still offices to perform, and that is the reason why Nature so persistently retains them alive. We are told that the scales of a Lily bulb that has flowered are virtually dead soon afterwards, but how about the bulbs which produce stems that do not bloom? Surely, if the mere process of flowering is so exhaustive, we ought to have conservation of energy in bulbs of the latter class, and that that is so the Dutch system of cultivating Hyacinth and other bulbs, for sale or exhibition purposes, fairly proves a system in which energy is fostered and conserved until wanted. Hence I willingly admit that flowering weakens the old bulb generally, and should the bulbs be starved in poor soil, and their roots be cramped in small pots, such bulbs may die, but I am fairly convinced that the scales of a well fed flowering bulb do not die as stated by "Dunedin"; indeed, as I have before stated, they may be used for propagating purposes with success.

I totally disagree with "Dunedin" with regard to stem roots and their functions. That they are not analogous to stem roots on forced Grape Vines is admitted, since we are told they ran down inside the pots, "completely exhausting the soil," and that is a proof that they absorb nutriment exactly like the bulb roots. If we could see *L. auratum* and *L. lancifolium* growing in their natural habitat, I have no doubt there are conditions which render stem roots helpful and desirable to them, even although other species, growing under other conditions, may not thus require them. How has "Dunedin" (p. 508) proved that "secondary roots are composed of a different tissue or organisation of parts, and that their absorbing powers are of a totally different character from ordinary roots?" and, moreover, that the sap drawn up by stem roots has no assimilated flower nourishment in it? This is a startling assertion, the confirmation of which is yet wanting. As to the "assimilated flower nourishment," surely "Dunedin" is aware that no root, of whatever description, ever yet drew up sap or nutriment, from air or soil, having any assimilated flower nourishment in it, seeing that the assimilating part of the business is invariably carried on by means of the leaves or their representatives, so that whatever is absorbed by roots of any kind must pass through the leaf tissues of the plant ere it can in any way become assimilated.

I quite agree with Mr. Baines, that the growth of Lily bulbs is, in plan, like that of all other true bulbs. What "Dunedin" calls a seed bud is simply the growing point, one or more of which every bulb and every other plant, must needs possess.

F. W. B.

— "Dunedin" (p. 508) seems to have quite missed the drift of my argument (p. 460-1) for he deprecates the introduction of extraneous matter and expresses a desire that I will in future limit myself to specific questions, and above all, state whether I am a believer in his successional bulb theory or not. I thought I had sufficiently indicated my position in regard to this latter question, but, for "Dunedin's" satisfaction permit me to say that I am a believer in the successional

bulb theory which he advocates. With regard to the first part of "Dunedin's" remarks, I have again perused my letter (p. 460-1) but must say that I fail to see wherein I have wandered from the subject as he suggests. The point which I there endeavoured to urge was, that it is not by chance that some Lilies have stem roots and others have none, and that there must be surely some wise reason for their possession by some species, and their non-possession by others, and some good end to be gained by the proper utilisation of these stem roots, and my object was to elicit, if possible, some information of a positive character from "Dunedin" as to their proper position in the economy of the Lily. So far, however, "Dunedin" has only vouchsafed to us negative replies on this point. He says in effect, that these stem roots do the bulb no good whatever, and that they do not secrete any flower-nourishing juices. Then what do they do? They cannot be there for no purpose whatever, and therefore I shall be glad if, with a view to elucidate this problem, "Dunedin" will, at his convenience, let us have his replies to the following specific questions:—

1. If stem roots, when they occur in Lilies, do not assist in nourishing the flowers, what do they nourish?

2. As it is not probable that the sap which they secrete descends before being utilised, and, as it can hardly be supposed that such sap is altogether useless, and further, as "Dunedin" asserts that it cannot, from its composition, nourish the flowers, will he say whether it is the stem or the leaves, or both, that are nourished by these stem roots?

3. If it is the stem and leaves that they nourish, is it not evident that if we throw the burden of them, as "Dunedin" counsels us to do, upon the bulb and its roots, we must do so at the expense of the flowers, or the successional bulb, or both?

4. If, as "Dunedin" states in reply to "London Stone," his method encourages the growth of bottom root offsets and small bulbules (these latter I understand to be the bud-bulbs which sometimes grow at the junction of the leaves with the stem) must their production not throw a further strain on the bulb and its roots, and also, therefore, be at the expense of the flowers, or the successional bulb, or of them both?

In speaking of stem roots, it must be understood that I mean those that are the outcome of natural growth. I am quite prepared to admit that by injudicious overfeeding they may be made to become a source of danger to the plant; that is an error in one extreme, but I hold that "Dunedin's" remedy is an error just as far in the opposite direction. The position which he occupies in this matter appears to me to be this: He has been subjecting *L. auratum* and *speciosum* to the conditions of culture which suit *L. candidum* and other non-possessors of stem roots, and under such conditions he finds the stem roots positively harmful, and looks "upon them as his greatest enemies." From this result he argues that these stem roots are a mistake and should not be there at all, and forthwith he proceeds to remove them most effectually by scraping the stem. His facts may be right enough, but I submit that his deductions from them are erroneous, for, to my mind, this result of his simply shows that he has not been treating *L. auratum* and *speciosum* as they should be treated. We all know that by certain treatment an Apple tree may be induced to run all to wood, and consequently produce no fruit; but that is not surely the fault of the Apple tree, but of the treatment. So I take it, if a certain treatment be found, as "Dunedin" maintains, to encourage the growth of these stem roots to such an extent as to be detrimental to the bulb, it is the treatment we must condemn, and the proper remedy must be not the cutting off of the stem roots but an alteration of the treatment. I venture to predict that, when the true method of treatment is worked out, these same stem roots which "Dunedin" at present looks upon as his greatest enemies he will acknowledge to be his greatest friends in the cultivation of these particular species of Lilies. The large bulb which "J. S. W." mentions (p. 461) I am sure was not systematically deprived of its stem roots, as "Dunedin" advocates.

A. S. O. N.

— When "Dunedin" has shewn us specimens grown according to his view which surpass all those that have ever been seen before, I shall begin to think, and not till then, that we Lily growers are on the wrong track. I shall, however,

require better argument than any "Dunedin" has yet adduced, before I commence to cut off even the stem roots of a Lily. If they are useless, why are they produced? Some Lilies form stem roots and others do not, but for my part I should always rejoice to see a pot well filled with healthy roots, let them come from where they like, and when I saw them crawling over the sides of the pot, and through the bottom, I should simply regard it as an eloquent sign that the pot was too small, and act accordingly. Will "Dunedin" kindly say whether it is a fact that the most vigorous-growing and largest-flowering Lilies produce the greatest number of stem roots, and whether the contrary is the case as natural vigour decreases and the flowers diminish in size, and if that be so, why? also, if it be equally a fact that the smaller-growing and smaller-flowering species, and those producing the smallest number, or no stem roots at all, go soonest to rest, and *vice versa*. To my mind, looking at the matter from Dame Nature's point of view, the answer is very simple, but what says "Dunedin"?

Newry.

T. SMITH.

— "Dunedin's" views regarding Lily growth are sometimes opposed to the practice by which the most successful cultivators have attained the best results. Before attempting to persuade Lily growers that large bulbs are not better than small ones, that destroying the stem roots in the case of such Lilies as form these will strengthen the bulbs, and that it is better to pot or transplant before the leaves are dead and have fulfilled the office which Nature has assigned them, why did not "Dunedin" take the course usually pursued, viz., that of giving us the benefit of his experience by letting us see the results of his treatment? There are many and various opportunities of doing this, and a single practical illustration, exemplified by his showing better grown Lilies under the course of treatment which he advocates than others have been able to produce by the old system, would have done more to convince us of the soundness of his practice than all the assertions that he has made. We live in an age when people believe much more in what they see than in what they hear. If "Dunedin's" assumptions respecting the nature of Lilies be correct, then the practice of those who have hitherto grown these plants must be wrong. But, to prove this, something is required stronger than mere opinions. In common with most other plants that I have grown I have, at one time or other, tried experiments with as many of the best kinds of Lilies as it occurred to me there was anything to be learned by, and amongst them was the removal of the stem roots of such as I grew in pots, both by planting so near the surface as to leave little room for the development of stem roots, and also by their actual removal as soon as they appeared. When the bulbs, too, were put in deeply, I have removed the whole of the stem roots, and the result of this treatment enables me to give unhesitating contradiction to this last of "Dunedin's" teachings, for the bulbs so disrooted neither produced the same quantity of flowers nor increased in size or in numbers by division, as plants of the same varieties similarly managed in every way, except that all the roots possible for 6 in. or 8 in. above the bulbs up the stems were freely encouraged. In answering "London Stone" (p. 508) "Dunedin" effectually demolishes the argument which he previously on the same page had set up against me; here are his words:—"It is thus that Nature has decreed, that as soon as the bloom is over, all nourishing connection between the bulbs and the stem must cease. As regards the stem, that would be left standing; it would have gone on keeping green for some weeks longer, its nourishment being supplied by its own stem roots." Further on he says, "green leaves on the stem are no proof whatever that vitality exists between the bulb and the stem." In his reply to "London Stone" he says:—"As to seeding, I leave that to the trade, for this reason, that the new or successional bulb gains in strength and size by not allowing the plant to run to seed." Now, if, as "Dunedin" in the previous breath says, "green leaves on the stem are no proof whatever that vitality exists between the bulb and the stem," how does he reconcile that statement with his immediately following assertion that the bulb is injured by allowing the stem to produce seed. If, in attempting to disprove what I maintain, viz., that the bulb is benefited by the presence of the leaves so long as these have life in them, "Dunedin" asserts

that there is no vital connection at this time between the stem and the bulb, how can the latter be injured by the production of seed which necessarily takes place subsequent to blooming? "Dunedin" says if I had "carefully examined" the stem at its junction with the bulb, I should have found it much contracted and dried up, compared with what it was above ground. The stem of any Lily is, during the whole period of its existence, much more contracted, or thinner at the base than above ground, and I have, with a view to ascertain their condition, actually severed the stems of *L. auratum* and others, two months after the flowering was over, after the leaves had fallen, but when the stems were still green above, and I have found them fresh and quite alive down to the junction, thus directly disproving what "Dunedin" asserts. He also speaks of the structural formation of Lilies, and tells us that a medium-sized *Lilium auratum* contains not less than 300,000,000 cells. To test the truth of this statement, I have to-day taken some sections from the scales of a good-sized bulb of this Lily, mounted and examined them carefully under the microscope, and I find that so far from "Dunedin" being correct in his assertion, it would take nearer half-a-peck than a single bulb to supply the number which he mentions. These Lilies, like most other soft, quick-growing vegetable forms, have much larger and consequently, fewer cells, compared with their bulk than hardwooded, slow-growing plants generally. But what has the structural details of these plants with which "Dunedin" favours us, to do with the question which strictly bears upon cultivation and nothing else? "Dunedin" has, however, brought to light one good point, namely, the advisability of moving Lilies when most at rest, a practice which I have always urged in all I have ever written connected with their treatment.

T. BAINES.

— "Dunedin's" views on the stem roots and practice of not cutting down Lilies after flowering are so entirely opposed to long experience and practice, that I should like to ask him, as he invites us to do, a question or two. He says some species throw out stem roots, others do not, but he opposes the encouragement of all stem roots. Will he have us believe that Nature throws out stem roots, not only without any good purpose to serve, but for no purpose at all? As to cutting or not cutting down the stem immediately after flowering, he says (p. 503) that as soon as the flowers have faded, the roots and scales of the old bulb will be found to be dead or dying, and that there is an entire absence of sap in the stem, but he subsequently adds that the new or successional bulb gains in strength and size by not allowing the plant to run to seed. Now this appears to me to be contradictory; one statement requires to be reconciled with the other.

E. B.

— After a careful consideration of "Dunedin's" last contribution (p. 503), I fail to see anything in it that supports his statements as to the injurious effect of stem roots on *Lilium auratum*, nor can I see the applicability of the 6-in. pots, as I stated that my Lilies were grown in boxes 15 in. deep. I should consider, even in the case quoted, that the small size of the bulb was owing to the short supply of food, and that the stem roots "being unable to elaborate flower nourishment" (p. 503), must possess most mysterious powers, for while in one place "Dunedin" denies their power of preparing sap, in another he gives a long account of their voracity, carried by them to the extent of sucking the sap from new bulbs. What, then, becomes of the sap? As to my statement "that the mop-like growth of the stem roots forms an admirable protection to the bulb" being "mere theory," why it must be patent to any one that a mass of fibres is a protection to the bulb beneath it, and, furthermore, that when the fibres decay, they must furnish food for the stool roots when carried down by the spring rains. And as at p. 113, Vol. II., Dr. Wallace states that the stem roots are sufficient in a healthy plant to enable it to flower vigorously, even after the bulb has been removed, I can only repeat that "Dunedin's" positive statement of their evil effects is "mere theory," and as unfortunate as his comparison of them to suckers from the stock of grafted Roses (p. 371)—"Rose growers wage war against suckers coming up; Lily growers should wage war against suckers going down."

LONDON STONE.

— "J. S. W." (p. 538) may rest assured that I had no intention of leading him into any discussion on the "peren-

nal theory," as there is no room for that. There is, however, plenty of room for his making experiments, in order to prove whether I am right or wrong. Had he done so, and made himself thoroughly acquainted with the organic structure and constitution of the bulbs, he would never have put such questions to me as he has done, as there is no such thing as a three-year-old bulb or a one-year-old flowering bulb, the term of the Lily's existence being only two years, when, having bloomed, it dies; and a one-year-old bulb must go on growing for another year before it is destined to bloom. DUNEDIN.

PLATE CLVI.

THE DOUBLE SCARLET AVENS.

(*GEUM COCCINEUM* FL.-PL.)

It is singular that in such a large genus as *Geum* that so few kinds produce flowers of sufficient merit to entitle them to be classed amongst garden plants; indeed, the subject of our coloured plate this week is the only showy kind belonging to the true genus. The scarlet Avens, which inhabits the Bithynian Mount Olympus, has long been a popular garden favourite, and probably the Chilean Avens (*G. chilense*) is but a mere geographical form of it, only differing in the darker colour of the blossoms, which sometimes assume a coppery hue. The double variety is a far more valuable kind than the type, as its blossoms last much longer in perfection, and are very suitable for cutting. It commences to flower in May, and produces a continuous succession of blossoms till October. There are several forms of the double kind; in some the flowers are as double as in the best sorts of *Pelargonium* whilst the inferior forms scarcely show any duplicity. It is one of the most easily managed of hardy perennials; we have seen it growing vigorously in ordinary garden soil, and it may be readily multiplied by seeds, which are freely produced, or by division, which should be done in spring. The most desirable of the other kinds in cultivation are:—

Mountain Avens (*G. montanum*—syn., *Sieversia*), of dwarf, tufted habit, with deeply lobed leaves. The flowers are large, of a yellow colour, and are borne singly on erect stalks about 1 ft. high. It inhabits high mountain pastures in various parts of Central Europe.

Creeping Avens (*G. reptans*—syn., *Sieversia*) is a trailing kind with deeply-cut foliage and erect flower stalks about 6 in. high, bearing a single blossom of the same colour, but larger than the preceding. It also inhabits the European Alps.

Three-flowered Avens (*G. triflorum*—*Sieversia*).—This very distinct kind has deeply-incised root leaves, the segments of which are also toothed. The flowers are usually borne in clusters of three, hence its name. They are rather large, reddish-purple outside, and white tinged with purple within. It is found in rocky places in various parts of North America. It was introduced about fifty years ago, but is not so common now as it should be.

Amongst the fine kinds which are not as yet in cultivation in this country may be mentioned the beautiful little *Ioy Avens* (*G. glauciale*), which is found in Siberia, principally on the Alps at the mouth of the River Hena. It is a very dwarf kind, about 1 in. or so above the surface, and is densely covered with a short, yellowish pubescence. The blossoms are yellow, and as large as those of any of the *Geums*. When introduced, this charming Alpine plant will make a desirable addition to our gardens.

Peck's Avens (*G. Pecki*—*Sieversia*).—This is another North American kind, with divided leaves and yellow flowers about the same size as the Mountain Avens.

Tall Avens (*G. elatum*) is a native of Nepal, and has divided leaves, with from four to six pairs of leaflets. The flower stems are 6 in. high, and three to four-flowered, and the blossoms are of a yellow colour. W.

[The flowers, from which our figure was prepared, were supplied by Mr. Ware, of the Hale Farm Nurseries, Tottenham.]

Michaelmas Daisies.—Any one making a plantation of Michaelmas Daisies will do well to plant the three here named, viz., *Aster linifolius*, *A. longifolius*, and *A. Amellus*; they flower in the order named, and 5° of frost does not discolour the flowers. These three

RANUNCULUS ACRIS

kinds were sent me from Mr. Parker, and are certainly the most distinct and useful. Everybody who has seen them this year has been delighted with them. These Asters are fine when allowed to grow into large clumps, forming the centres of large beds or angles of beds or borders. A dwarf kind is *A. discolor*, and, although insignificant in colour, I am beginning to fancy it, for it is still in flower and good, and when other flowers are *nil* its fanny, old-fashioned, spotted-muslin-look arouses one's attention and sympathy. Well, then, I would say to every lover of hardy plants, plant them in your next arrangement of the flower garden, and you will not begrudge the price of the plants. What *Pyrethrums* are in early summer these are late in autumn, most beautiful and valuable to the flower gardener.—H. KNIGHT, *Flours.*

NOTES AND QUESTIONS ON THE FLOWER GARDEN:

Helianthus divaricatus.—Did "G. T." (p. 452) ever see this in perfection? If so, he would have to go far to see a finer effect than it produced. I do not think I ever saw anything more striking than a group of this plant growing in a favourable position. In the southern part of Massachusetts, near Rochester, there is a small, shallow, semi-circular pond or bog along the side of the road, perhaps 50 ft. long, 4 ft. or 5 ft. from the edge, just far enough up the rising ground to be out of the way of excessive moisture; this pond is encircled with a plantation of *Helianthus divaricatus*, about 3 ft. wide, and last September, when I saw it backed up by a thick growth of *Vaccinium Prinos*, &c., it was one glowing mass of flower of the most brilliant golden-yellow, certainly exceeding any display I ever recollect seeing in any garden. The blossoms might have been counted by thousands, and were thrown well up on stems above the foliage 2 ft. to 4 ft. from the ground; they formed a mass which was truly grand.—C. M. HOVEY, *Boston.*

Cannas Out-of-doors in Winter.—In Mr. Cornhill's interesting article on Cannas, he expresses doubt whether, after the second year, Cannas would not require lifting and replanting, but he gives no reason for this view. Is it not a fact that the fine specimens of Cannas at Battersea Park have remained unmoved for many years? At present, my experience does not carry me over the second year, but there is no doubt in my mind as to the hardness of the roots, if the bed be properly prepared, and a heavy mulching be given for protection from frost. The ground requires very good and careful draining, and the bed ought, as Mr. Cornhill says, to be raised considerably above the ordinary level. With these precautions it will be found that Cannas may be wintered in the border with perfect safety. These remarks apply only to the green-leaved kinds; some of the bronze-coloured sorts seem unable to withstand a cold, wet winter, such as that of 1877-78. My experiments have been tried in a cold, clay soil and bleak situation, and the growth has been magnificent.—A. K., *Eastcott Cottage, Pinner.*

—It is a matter of some surprise that Cannas are not more largely cultivated than they are, as I quite agree with Mr. J. Cornhill that they are not at all difficult to cultivate. In fact, they are the most easily managed of all our flower garden plants. It is not necessary to have a hotbed on which to start them, as they will begin to grow quite freely in a Vinery or in any warm house. I grow a large quantity of them, and, being somewhat limited for room, my plan is to place the roots on the Vine border close to the pipes. We place them as closely together as possible, but do not cover them with anything; they start very rapidly, and when sufficiently advanced, we divide them into small pieces, and pot them in 3-in. pots. We replace them in the Vinery for a week or two, then harden them off, and plant them out at the usual time. I have tried leaving them in the borders all winter, but they do not succeed any better than those planted out early in summer. One objection to leaving them out is that if the spring be mild they start very early into growth, and, as a slight frost will discolour the leaves, they afterwards present an unsightly appearance. They may be wintered in any shed where frost does not get at them. Indeed, in this respect, they are much easier kept than *Dahlia*s.—H. HAMILL, *Hound House, Guildford.*

Japanese Primroses Out-of-doors.—The Japanese Primroses referred to as growing out-of-doors in Mr. Nelson's garden, were the varieties of *Primula cortusoides amœna* and not *P. japonica*, which, however, is, I believe, hardy in many soils. Is Mr. Fish's too light for it.—PRIMULA.

Aquilegia cœrulea hybrida.—This fine hybrid, raised by Mr. Douglas, Loxford Hall, is the result of a cross between *A. cœrulea* and *A. chrysantha*. It is exactly intermediate between the parents, the centre petals being clear sulphur yellow, and the spurs and sepals pale blue. The flowers are large and open well.—W.

GARDENING FOR THE WEEK.

Flower Garden.

Protecting Roses on Walls.—The series of mild winters that we have now had for some time is apt to throw even growers who have had some experience off their guard, and there is no doubt, from the very great increase of late years in the cultivation of Tea and Noisette Hybrid Roses, that there are great numbers of plants in most parts of the country which have attained a considerable size through having escaped the scathing effects of a severe winter, and even the destruction of their tops down to the ground level would be a severe disappointment, and cause many unsightly blanks; and, as we cannot look forward to an uninterrupted continuance of these mild winters, a little forethought in providing some slight protecting material may save many specimens upon which much store is set, especially in prominent positions on walls where their loss would be the most conspicuous. It is the more desirable to do this on account of the comparatively small amount of protection that often makes the difference between destruction and complete preservation. Many contrivances may be resorted to to afford the necessary protection, but I have never found anything better than some dry Fern with the stalks stuck in behind the shoots of the Roses, or, if the Roses are tied to wires or trellis-work it is still easier to fix in the Fern; with this, and some Spruce branches similarly put in so as to keep the Fern from blowing about, the plants will be independent of frost. This I proved years ago when plants left unprotected were killed down to the ground. It is neither necessary nor advisable to put on such covering till there is a real appearance of a more than usually low temperature. The point is to have everything in the shape of protecting material dry and ready under cover, as a very considerable space of wall may be covered in a few hours when its application appears to be necessary. In the severe winter of 1860-61, I saw a large extent of wall covered with China Roses saved up to a height of 6 ft. by fixing straw ropes horizontally across in front of the Roses. The ropes so used were tied in at intervals to the main shoots of the Roses running about 5 in. apart, with a few mats hung up in front of these. The Roses were safe up to this height, all the tops above being killed, but it was a great gain to save so much, as the portion so secured shot out vigorously, producing a fair head of bloom, and by the end of the season leaving comparatively little trace of the injury done. Where there is a greater length than can be covered to any considerable height, by the use of a number of evergreen branches of any kind, the bigger they are the better, provided they can be made to lie close to the wall and secured by any means over the collars of the plants, and as high above as can be done, so much of the plants thus protected may reasonably be expected to escape.

Dwarf Roses.—Of these, the more tender kinds in beds and borders should at once have the ground covered a few inches with old tan, litter, Furze, or Fern. Where the three latter are used, some evergreen branches laid flat on the top will prevent the material being blown about and keep the roots and collars of the plants safe, which, even should the tops be destroyed, will break out and make vigorous growth, but where in addition to this, an sufficient number of large evergreen branches can be stuck firmly in the ground, moderately close, much may be done to secure the whole of the plants. When living further north than I am now, where these more tender Roses often suffered, I had a considerable number planted on a long 6-ft.-wide bed, over which, on the approach of severe weather, I used to fix up in the form of a span roof, a lot of straw hurdles, used later on for covering Potatoes in turf pits. So sheltered, the Roses always escaped.

Standard and Half-standard Roses, of such varieties as are most susceptible of injury from cold, can often be brought safely through a severe winter by the well-known method of thrusting some Fern or Gorse in amongst the branches composing the head, tying the whole round with twine or a pliable Willow. I prefer the Gorse for this purpose to anything else, as through the changes of weather it does not lie so close and hold so much moisture as anything of a softer nature.

Protecting Roses in Pots.—Roses in pots that are intended for forcing, or bringing on into flower slowly under glass to precede the earliest in the open air, should if possible be housed, or placed in frames or cold pits; or if even loose lights can be fixed up over them, it will be better than their remaining fully exposed to rain and snow; for though such Roses may take no harm when planted out, it is a very different thing with any plant, however hardy, when its roots are confined in a pot. Under the former condition the quantity of water will in all probability do no harm, whereas those in the pots would most likely have the greater portion of their best feeding roots destroyed—a circumstance frequently not noticed at the time; yet

plants so affected are certain to be a source of disappointment, as they will neither grow nor flower anything like those that are not so injured. The pots should also be plunged sufficiently deep so as to prevent the soil being frozen, as through this cause again plants in pots, especially such as have hard woody roots, are almost certain to have the bark on these damaged by the crushing effects of the soil, expanded by being frozen, acting very differently on the earth and roots so confined, from what takes place where the roots have full liberty in the open ground.

Pruning Pot Roses.—Such pot Roses as the above should at once be pruned if not already done, and if they can have the tops dipped or washed in Tobacco-water, softened with a little Gishurst, it will destroy any living aphides, or the eggs of these most likely present though not perceptible.

Roses Grown under Glass.—By these I mean those that are kept wholly, or for perhaps nine or ten months in the year under glass, as a matter of course grown in pots, and consisting almost entirely of Tea varieties. This method of Rose growing is very different from, but often confounded with Rose forcing; for which latter purpose the Hybrid Perpetuals that are found suitable with Teas and other hybrids as well, are usually put in heat, produce a crop of flowers, and after more or less preparation by a little hardening, are again plunged out-of-doors in the summer. But it is from the Roses treated after the former method that the finest blooms, and a continuous supply for the last month in the old year, and the two first in the new must be relied upon; and the size and quantity of the flowers forthcoming during this time will be the test of the Rose-grower's ability, for if the plants are well, and skillfully managed by keeping them studiously free from mildew and aphides, with a sufficient but much reduced quantity of water to the roots during the short, sunless days of winter, and very small extent of evaporation by the almost absence of any admission of external air, but all the light possible to give, and no more moisture in the atmosphere than to keep the air from being too dry, they will keep on through this time making growth from which they will form and mature flowers. The treatment as to temperature of this description of Roses and almost all Teas becomes a study in itself that few have had an opportunity of solving so well as those who at the present day grow Roses by this method for the London market; some varieties are found not only to bear, but to absolutely require considerably more warmth than others. The practice of one of the most successful growers is to keep Niphetos almost exclusively by itself, subjecting it to a night temperature of from 50° to 55°, raising the heat by fire during the day, when there is no sun, to 65°, or a few degrees higher, using less artificial heat when there is sun to bring the thermometer up to this. So treated, with the slightest amount of air given at the top, this matchless Rose keeps on through the winter, pushing growths, and producing its long, elegant flowers with the petals as free from being crumpled as they come in the most favoured localities out-of-doors in the summer, which they will not do if grown in a lower temperature. The flesh-coloured Catherine Mermet, the rose-coloured Gonbault, the sulphur Isabella Sprunt, Madame Falcot (yellow), and the buff Safrano, which are amongst the other Teas most usually grown for the production of these winter flowers, succeed with 6° or 8° less warmth both day and night. The Hybrid China General Jacqueminot stands at the head of the high-coloured kinds that force well, and on this variety most of the growers depend for their earliest flowers of deep colour.—T. BAINES.

Auriculas.—These are now quite at rest, and it is almost the safest plan to withhold water altogether from their roots at this season of the year. I do not approve of the plants being quite dried up, but if the soil in the pots should be very moist and severe frost sets in, the expansion of the soil would cause many of the pots to crack, which would be disastrous. If there is any trace of green fly on the plants it ought to be destroyed by means of fumigation. At frequent intervals it is desirable to quite overhaul the plants, see if there be any trace of decay on the stems, and in all cases carefully remove dead and decaying leaves. Seedling plants in pots should be kept rather moist, as they will continue to appear through the ground during the winter.

Carnations and Picotees.—These ought long before this to have been potted and placed in cold frames. It is immaterial whether they are plunged in the frames or placed on a staging. Ours, at Loxford Hall, have the pots plunged in Cocoa-nut fibre refuse, and the plants are not far removed from the glass. I do not at all approve of the plants becoming very dry at the roots, even at midwinter; it gives a certain check to their growth, which future attention will not quite overcome. A few potsful of choice sorts have just arrived, as I write, from the north of England, and the soil in the pots is quite

wet, the green conferva on its surface showing that it has also been kept wet, and I never saw a healthier lot of plants. Do not be afraid to admit air freely during favourable weather, even if it be cold.

Dahlias.—Examine the roots of these occasionally, as some may become too damp and others too dry. It is a good time too to look over stakes, as all that are decayed must be replaced by new ones. Stakes usually last about two, or at the most four years. I pulled up a Rose stake that had been in the ground just about fifteen years the other day; it is quite sound. What is the reason may well be asked? I was using a number when I first came here and thought I would try the experiment of dipping the part that had to go into the ground in boiling pitch, and this is the result. I see others are also yet sound.

Hollyhocks.—These likewise require to be looked over. As much air as possible must be given to the frames, and the plants must be kept free from any decaying material. Sticks should be prepared for these as well as for Dahlias, and the ground for both should be trenched and manured. Clayey soil should always be trenched, if possible, before winter sets in, so that frosts may pulverize it. Light soils are improved by having some heavy clayey material placed on the surface, and left until it is disintegrated by frost.

Pansies and Pinks in beds will require but little attention. There let them rest for the present, except frosts uproot them when the plants may be pressed into the ground with the fingers. Pot plants in frames will require similar attention to that recommended for Auriculas, but the plants require a little more attention as regards water. If a stray slug gain admittance cease not to hunt at night with a lamp until it is destroyed. Fumigate also in order to destroy green fly which is a great pest to the Pansy.

Phloxes and Pentstemons.—Plants of these in pots may be wintered under any kind of cover that will throw off rain. The pots should be plunged just over their rims, and they will not be much injured even if exposed to severe frost. Slugs are very fond, too, of the young shoots of the Phlox just as they appear above ground. The surface of the beds out-of-doors should be mulched with rotten manure. This acts as a stimulant to the plants, and preserves them from injury.

Fyrthrums in beds require treatment very similar to the last and plants of them in pots should also be wintered in cold frames, the soil in the pots just to be kept moist.

Aquilegias, too, must not be neglected. The plants suffer from the attacks of red spider; indeed, this pest seems to cling to the Columbines through winter's cold and summer's heat. Green fly also feeds upon the leaves, and it is well that pits and frames where all such plants are kept should be fumigated during winter.

Tulips.—If the roots be not yet planted, do not delay a day longer than is necessary. I have planted a few roots this week, but would rather have put them out a month ago.—J. DOUGLAS.

Indoor Plant Department.

Conservatories.—When the earliest Chrysanthemums become unsightly they should be removed, and their places filled by such as have been treated with a view to their later flowering. These must be carefully managed so as to prolong their blooming period as much as possible; they should have a little heat at night, so as to allow of some air being admitted at the bottom, with top ventilation to allow the moisture to escape. Camellias are plants which may be induced to flower at any time of the year, yet they do not like too much forcing, for when hurried too much the buds are almost certain to drop off, especially if the atmosphere is too dry. The proper time to regulate their season of flowering is when they make their growth and set their buds; by inducing a portion of the plants to make early growth, and by keeping others later, a longer season of flower will be secured. Consequently if it happens that the bulk of these plants is flowering too much altogether, and not so early as may be required, the best plan is to at once remove part of the plants to where they can receive a little heat, and have a sufficiently moist atmosphere to accelerate their flowering, and also induce an earlier growth and disposition to come into flower earlier in future seasons. This separation of the stock is especially necessary where a considerable number of the plants are planted out, and consequently cannot be removed to regulate their time of flowering; where such is the case it is better to reserve those that are planted out for whatever time there is the greatest demand for the flowers, and to use the plants that are in pots for earlier work. That general favourite *Daphne indica* will now be opening its flowers, and tempting us to out more of them than we should do, as there is no plant with which I am acquainted that is more injured by cutting than this. No matter how vigorous and strong the plants may be, not more than half the current season's

flowers should be out, and these with as small a bit of the wood attached to them as possible. Winter-flowering Epacriæes will now be coming into bloom; most of these possess a somewhat stiff upright habit of growth; individually this may be considered a disadvantage, but in the conservatory, intermixed with numbers of other plants of bushy or pendant growth, they are of great use. Epiphyllums, now in great beauty, should be placed in prominent situations, and elevated so as to stand clear of their neighbours. Agaves, Dasyliroids, Yuccas, Cordylines, and Rhopalas might with advantage be much more extensively used in conservatory decoration than they are. Most of the species of these genera harmonise well with all kinds of blooming plants, and with little change in the materials at command they can be so altered from time to time, as to avoid that objectionable monotony of each plant being always in the same position.

Chrysanthemums.—Chrysanthemums have several properties that make them more suitable for beginners than most subjects, not the least of which is their coming in at a dull time of the year when there is little else in flower; the blooms stand long in a cut state, and when the most suitable kinds are selected, and the plants not grown too large, or spoilt by over training, they are appropriate for room decoration, where they will last for several weeks, and for which purpose their bright colours make them very attractive. They are especially suited for small gardens near towns, where the atmosphere is very frequently of such a nature as to interfere with the cultivation of more delicate subjects. They are very readily struck, and are easily managed through the subsequent stages of their growth. Neither do they suffer to the same extent as most plants by an excess of water, a kind of treatment in which the inexperienced are so liable to err—not that they are by any means indifferent to careful and attentive treatment, as is evident by the exceptionally fine condition in which they are frequently seen. With some their propagation is deferred until spring, but those that are struck from cuttings put in at the present time get their wood more fully matured, and consequently are in a condition to produce better flowers than the softer-grown, late-struck examples. We have also noticed that the late-struck plants were more liable to the attacks of mildew, owing to the softer state of the leaves. Select for cuttings the sucker-shoots that spring from the base of the old plants in preference to side-shoots from the hard wood which never grow so freely or make such good plants; they should be taken off when about 3 in. or 4 in. long, although the tops of the longer ones will answer the purpose, but are not so good. Remove two or three of the bottom leaves, cut them just below a joint, and insert them singly in 3-in. pots, with two or three pieces of crock in the bottom of each. Ordinary loam, with one-fourth sand and a sixth of sifted leaf-mould will be found to suit them admirably. As they are essentially water-loving subjects, they must never be allowed to want for it from the first day the cuttings are put in through each stage of their existence; moisten the soil as soon as the cuttings are put in; do not use bottom-heat or any heat at all, as it tends to draw them up weakly. If a few good-sized common slates be placed on the front shelf of a greenhouse or in a Vinery with 1 in. or 2 in. of sand or fine ashes on the top kept moist, and the little pots placed on this and covered with bell or hand-glasses, all they will require is the soil to be kept moist, together with a very small quantity of air for an hour or two in the daytime to dry the leaves if they show any signs of damping. Do not give any air if they do not exhibit signs of mouldiness; should this take place remove at once such as are affected. They will root in a couple of months, when the glasses can be dispensed with; in this way they will be strong and short jointed, making little top growth until they have got plenty of roots, very different from the weakly, drawn-up, newly-struck plants often seen, the bottom leaves of which are so thin and soft, as to make it impossible to preserve them through the summer, which is one of the causes to which is attributable the unsightly naked stems so often noticeable in these plants. No one needs to hesitate attempting the growth of Chrysanthemums on account of insufficient means. We have seen beautifully-managed, profusely-flowered plants struck and grown by those who had neither greenhouse nor frames, not even so much as a hand-light, by simply plunging each little pot containing a cutting into another pot 6 in. in diameter, filled with soil, and covering each with a tumbler, standing them in the window of an ordinary living room, in which they were kept until the middle of April, when they were put in larger pots and plunged under a south wall for a few weeks, after which they were placed in a more open situation. The varieties that produce the largest flowers are far from being the best adapted for amateurs, especially the kinds with incurved petals, as these largest-flowered sorts, even cultivated in the best possible manner, will not produce one-fourth the number of fully-developed blooms that the recurved kinds will. Some of the smaller incurved varieties are unsurpassed, the white Mrs. George Randle, and Mr. George Glenny, straw coloured, a sport from the last-named variety, have all the properties

to render them deserving of general cultivation. Julie Lagravère dark velvety crimson; Cardinal Antonelli, salmon-red; Annie Salter yellow, tipped with pink; and Hermine, bluish, a free flowerer, may be classed as old kinds, but where only a select lot is grown they are what I should choose as the most useful medium-sized sorts for pots. The Pomponé varieties are extremely free in flowering, and serviceable for cutting or general decorative purposes; the three forms of Cedo Nulli, white, yellow, and lilac, are all good; these, with Anrona Borealis, brown; Salmon, rose-crimson; and Mrs. Dix are six admirable kinds. Some of the true Anemone-flowered sorts, as also the Japanese varieties, are handsome and much admired by some people, but discarded by others for the somewhat ragged appearance of the flowers. I should not recommend any one to grow them without having first seen them.

Indoor Fruit Department.

Cherries.—Introduce these into some very light and airy structure, provided there is not a house expressly for Cherries, and keep it close at first, so as to induce a night temperature of 45° and a rise of 10° by day, but ventilate freely to maintain this stage. The plants are benefited by plunging the pots in a bed of leaves that will yield a heat of about 45°.

Figs.—This is a good time to shift any plants in pots or tubs that want that attention, using turfy loam, and if of a calcareous nature all the better. Top-dress old plants that have been grown for several years in pots, and water with manure-water. A few of the established plants may be put into a Vinery at work to force, or into a Pine-stove to produce a few dishes of early fruit. Should it be practicable to form a ridge of fermenting material on the floor of any of the fruit-houses for starting the Figs in, they would well repay the attention, in starting away more kindly and certainly than they otherwise would do. Endeavour to maintain an atmospheric temperature of 50°, and a bottom-heat of 75°, gradually raising the former as the plants advance. Syringe the Fig-trees every fine day.

Peaches.—All trees in pots wanting a shift should now receive attention. Those which were potted last year will only require a top-dressing of good turfy, loamy soil, mixed with a few crushed bones or well-rotted manure. If the loam is rather stiff, some burnt ashes, chalk, or old lime rubbish added will give it porosity and increase its fertility. When top-dressing, take as much of the old soil off the top of the pot as possible, and make the new soil as firm as the old ball. If the house is unheated, protect the roots from severe frosts by placing the pots in groups and covering them with litter or mats. An early house may now be started, giving it a very mild temperature at the beginning, so as not to have the blossoming period occurring before the sun has some influence in setting the fruit. From 40° to 50° is a safe range to commence with, and plenty of air should be given on all favourable occasions. For very early Peaches and Nectarines, a dozen or two of trees, grown in pots and forced in pits or low houses with a mild bottom-heat, will produce some nice fruit in April or May. When these are in blossom distribute with a feather in order to assist in setting the fruit. Syringe the trees twice a day with water of the same temperature as that of the atmosphere of the house until the flowers begin to open. The trees in the late succession houses will now want pruning, dressing, and tying to the trellises. A solution of Gishurst Compound, consisting of about five ounces to a gallon of boiling water will, if put on when cold, by syringing the trees, be an effectual cure for insects. Peach trees trained on walls will likewise be much benefited by the same application if put on with a powerful syringe or engine. When there is reason to fear that the borders inside or out are exhausted, some fresh turfy loam may be given to the roots, by opening a trench, carefully lifting their extremities, and planting them in the fresh soil after removing the old. Protect the outside borders with litter or dried Fern, and, if some wooden shutters or tarpauling are placed on the top, the roots will be kept quite safe from severe frosts or chilling snows.

Pines.—Fruit-swelling plants require a genial temperature of from 65° to 70°. Water must be given moderately, judiciously, and only to such plants as require it at the root, for a kindly atmospheric humidity goes far to answer their requirements during these short days, when we have not sufficient sun to evaporate it and dry the atmosphere. Such plants as have finished swelling, and are about to colour, should be lifted out from amongst the plants that are still swelling their fruit, and should be placed on a dry shelf or light end of the house, and allowed to colour in the best light at command. Water should be entirely withheld while the fruits are colouring, or they are liable to get diseased inside. Even ripe Pine-apples, placed under unfavourable circumstances, are apt to get discoloured and flavourless. Those that are coming into bloom, and such as are

showing fruit, require particular attention as regards the application of water and humidity, or they may produce abortive pips or swell unevenly. Those started into fruit will require, for the next six weeks, great patience, care, and perseverance, in order to induce them to swell and perfect it for early spring use. For succession-plants in every stage, maintain a regular and kindly atmosphere, and a temperature of about 60°, but not too much humidity. Little water need be applied during the short dark days, especially where fermenting material only is employed for heating. Pot on both succession-plants and suckers as required.

Strawberries.—Long before this time, these should be snugly stored in their winter quarters, either in frames or built into the sides of ridges of coal-ashes with overlapping stone flags, broad slates, or boards to throw off the wet. The main object in taking such care of the pot plants consists in preserving their crowns from frost and cold rains, which are much more injurious to these plants than to those in the open ground, and often render them abortive or "blind." Introduce a few of the most promising of them into a Peach house just started for producing fruit in late March and April. A frame, with a good depth of leaves for bottom heat, is an excellent place for starting Strawberries in. The temperature at first should be kept moderate and somewhat low, and in the humid atmosphere which the leaves afford, the plants start away much more kindly than they do in structures heated by hot water. Keen's Seedling is still one of the best for early forcing, and President and Sir J. Paxton are good successional sorts. *Éclipse* is another excellent kind for forcing; its flavour is good and it carries well. For late forcing, *Lucas*, a first-rate Belgian sort, *Rev. Mc. Radclyffe*, and *British Queen*, are useful varieties.

Vines.—Great care should be exercised as regards the temperature of the Vineries now started, which should not range higher than from 50° to 60°. When the Vines have fairly broken their buds, the temperature may be increased from 60° at night to 70° in the daytime when there is sunshine. Vines in pots, if started in the beginning of the month in a mill bottom-heat, will furnish ripe Grapes early in May; and, as late Grapes in bottles can be kept in good condition till then, with a certain number of structures, a succession of Grapes can be had all the year round. Do not force the Vines too hurriedly, however, while the days are so short, cold, and sunless; but have all in good order to go ahead as the weather becomes brighter. Prune and dress the Vines in succession-houses as soon as the Grapes are all cut, and see that the outside borders are sufficiently protected from frost.

Cucumbers.—All overbearing should be at present discouraged, in order to allow the plants to make healthy foliage and shoots, and if some weak manure water is applied to the roots, with a top-dressing of fresh turfy soil, the growths will be induced to come stronger than they otherwise would be. Avoid hard forcing in cold, dull weather, and rather than employ too much fire-heat, cover over the sashes at night with mats or straw. Should thrips or red spider put in an appearance, syringe the foliage once or twice a week in the daytime with soot-water. This will keep these pests in check, as well as act as an excellent stimulant to the roots. In Cucumber houses or pits, in which the bottom-heat is supplied by hot-water pipes, great caution will be required to see that the soil does not get too dry for the bottom roots. Should this be the case, holes must be made in places in the bed and water poured into them to moisten the sub-soil. Always use tepid water, either for syringing or applying to the roots.

Kitchen Garden.

The season has now arrived when we may expect occasional obstructions to outdoor operations, so that there should be in store and in the mind's eye plenty of work under shelter, such as looking over old stakes, re-painting and tying them up into convenient bundles, and new ones should also be prepared by sharpening and tying them in bundles of a suitable length, for the various purposes required. Clean, point, and paint all old labels, and provide new ones of various sizes, having a well-placed face for writing on. Almost any kind of wood will do for common kitchen garden labels, but common Deal is the best of all for writing on. Prepare plenty of straw mats, thatched frames, or hurdles, and have in readiness any available kind of protecting materials, so that no risk or hindrance may be experienced when frost sets in. Prepare also pegs, crooks, sticks, and stakes, litter, dry leaves, straw, haulm, and Fern, all of which will be found useful for protecting purposes. Dry dust is a most valuable protector for the crowns of plants of any kind, or for dredging Peas and Beans and other seeds when they first make their appearance above ground at this season. Dry wood-ashes should always be kept in store in old tubs, boxes, &c., for dredging Lettuce, Cauliflower, or anything else subject to canker or mildew, which many things

are, during the short dark days of winter. Nothing is so effective as dry wood-ashes for preventing such evils—but they must be dry. They answer, too, as a fertiliser for mostly every kind of plant. If there be one pursuit more than another wherein the guiding rule ought to be "Never defer until to-morrow that which can reasonably be done to-day," it is gardening; and where gardening operations are thus carried out, the faller will be the measure of success. In the vegetable department immediate attention should be paid to the removal—if not already done—of the remains of all summer crops, such as Peas, Beans, Cauliflower, and Cabbage stumps; these latter should be placed in the bottom of any ground that is being trenched, where they will slowly rot and materially assist the roots of any vegetables afterwards grown upon the space so treated. The cropping of all vegetable ground should be so arranged that a third or a fourth of the whole space can be deep-trenched every year; and, unless the subsoil is naturally bad, 1 in. or 2 in., or even more in good land, of the bottom soil should be brought to the surface each time the ground is trenched. This is of the most service in old gardens, where shallow cultivation has been practised, and the effects of incorporating a portion of the under soil with that on the surface, which has become, by length of culture, almost effate, will be found of more service than even a heavy dressing of manure without the trenching. Where there exists a deep surface soil, or the subsoil is composed of clay, we should advise the application of a good dressing of manure at the time of trenching; but when the subsoil is of an open, gravelly, or sandy character, the manure should not be applied until the ground is about to be cropped, owing to the wasteful influence of heavy rains carrying the manurial elements away. The old system of ridging up vacant vegetable ground is right in moderately light soils, but in such as are very retentive it has this drawback, especially where it has to be cropped early, that the ridges throw off the water into the alleys, which consequently get much above their share, and when the ground is levelled for cropping, the wet hollows do not for some time get dry enough to admit of early-sown seeds progressing freely. In strong, heavy soil there is nothing equal to draining efficiently in the first instance, and then digging it up roughly in autumn.

Mushrooms.—In the absence of evaporating pans or hot-water pipes, maintain a moist atmosphere in Mushroom houses by means of syringing the walls and paths, but avoid over-watering the beds. A temperature of about 60° will be quite high enough at this season. In removing exhausted beds, any flaky pieces of spawn that show signs of vitality should be saved, in order to assist in spawning the new bed. Very many of the failures in Mushroom culture arise from using old and inferior spawn. A thin covering of hay, that has been beaten with a stick to clear it of seeds and dust, should be placed over newly-made beds, and those in bearing also, for the double purpose of checking evaporation and for maintaining a steady heat. If woodlice are troublesome, pour boiling water round the edges of the beds close to the walls, after they have retired to their hiding places.

Extracts from my Diary.

December 23.—Potting a few *Vallotas*. Painting Fig trees in Fig house with a mixture of soot, sulphur, lime, and Tobacco-water, and getting them tied in. Cleaning dead leaves from Violets in frames, to prevent damp. Pruning Vines in second Muscat-house. Cleaning up the pleasure-grounds and rolling down firmly all newly-laid turf; cutting evergreens for Christmas decoration.

Dec. 24.—Putting into gentle heat a few old *Fuschias*, to supply outtings. Getting a newly-made border planted with Tea Roses. Giving early Asparagus a little warm manure-water. Looking over the Graps-room, taking out bad berries, and filling up the bottles where required with water. Washing the paint and glass in second Peach-house.

Dec. 26.—Sowing Mustard and Cress. Pruning second Peach-bons, and getting the shoots tied in. Cutting and tying in Chinese *Arbor-vitæ* hedges. Cutting down and layering some old Thorn hedges, and putting in young plants where required. Getting the Vines in second Muscat-house cleaned and painted over with competition; also forking up the border, and giving a top-dressing.

Dec. 27.—Potting 100 pots of French Beans, and earthing up a more forward lot. Getting manure on to the land whilst the weather is dry. Planting Yew hedges for protection. Getting on with the digging and trenching as fast as the weather will permit. Making another Mushroom bed, and turning over manure to sweeten.

Dec. 23.—Getting into gentle heat a few more Lily of the Valley, *Deutzias*, *Dielytras*, *Hyacinths*, *Cicorarias*, and Roses. Looking over fruit-room; also Potatoes and Onions, and removing any that are bad. Tying Mats. Making labels and cutting shreds. Fruits in use for dessert:—Pines, Grapes, Pears, Apples, and Nuts.—W. G. P., Dorset.

FERNS AND LYCOPODS IN THE TYROL.

WHERE geology is so varied as in the Tyrol we naturally look for the Ferns and Alpines to be scattered with a free hand. Indeed to study the flora of any country successfully we need in the very first instance to make ourselves acquainted with the crust of the ground which we are seeking to examine, inasmuch as the rarer and more local vegetation attaches itself to certain geological formations, and is mostly only seen to flourish on such soils and in such tracts. In the Tyrol we have the crystallised magnesian limestone known as dolomite, and this covers large tracts of country, and naturally offers us a characteristic vegetation—Phænogamous or Cryptogamous, as the case may be. Then we find also the grey granite, gneiss, porphyry, and slaty formations containing more or less of mica, and rich in plant life; even Serpentine, as we have in the Lizard in Cornwall is not wanting in the Tyrol. All these, but especially the various schists (Schiefer) offer their characteristic vegetation, and it needs but a practised and experienced eye to recognise the character of the crust by the plant-life that covers it. First let us notice

Norway a few years ago. *Cystopteris montana* grows on Alpine and sub-Alpine rocks near Salzburg and Carinthia, on the Austrian borders of Tyrol, in greater perfection than on Ben Lawers, rivalling even *P. Dryopteris* in its noble tripinnate fronds. We next have to notice *Polypodium alpestre*, which, in some of its forms, resembles our *L. Filix-femina*, but may always be distinguished, as Koch observes, by "its constant orbicular sori." It grows in moist ground, often under bushes in sub-Alpine and even Alpine tracts. The last Fern to which I shall care to refer is our Jersey one, *Grammitis leptophylla*. I have met with it in Jersey and in Corsica abundantly, always growing in sand overshadowed by moist Grassy banks, in company with *Marchantia*. Hausmann records it as found in Bavaria, on the northern borders of the Tyrol.

Hovingham Lodge, York.

PETER INCHEBALD.

Anemidietyon phyllitidis tessellata.—This handsome Fern belongs to the section known as Flowering Ferns, from the peculiarity

Anemidietyon phyllitidis tessellata.

a few of the Cryptogams that flourish on the limestone formation (Alpenkalke). In south Tyrol we find the beautiful *Nothochloa Marantæ* on warm rocks facing the south. Beyond the belt of porphyry that surrounds Botzen it is not uncommon, as Hausmann remarks, in the dolomite limestone. It shows in its fructification some affinity with our *Ceterach*, and, indeed, it was regarded by Decandolle as a *Ceterach*. Near the home of the *Nothochloa* Mr. Potter, of York, a keen and accurate observer of Alpines, found another lover of the dolomite limestone, the *Asplenium Seelosii*, an ally of *A. septentrionale*, but considered by Liebald sufficiently distinct to be regarded as a species. The Ampezzo Valley, where are the grandest dolomite peaks, abounds with two pretty little Lycopods, *Selaginella serrulata* and *S. helvetica*, fruiting as I never saw them fruit elsewhere. *S. spinulosa* assumes grand proportions in the *débris* of the valley, loving the shade of bushes more than *S. helvetica*. In deep alluvial valleys, often by the side of rivulets, rises the noble *Struthiopteris*, with its male and female fronds, a picture of beauty, as its name indeed implies. This Fern I first learned to know in

which they possess of producing their inflorescence, or rather fructification, on a separate branch, which may be taken to represent a panicle of simple flowers. The sterile branch of the frond in this *Anemidietyon* is serrate pinnate, with rather distinct oblong-lanceolate pinnae, which are some 3 in. or 4 in. long, broadish, and abruptly narrowed at the base, reticulately veined, the venation being marked by grayish lines, and the surface being also marked by longitudinal bands of deep green on each side the pale silvery centre. From the base of this sterile branch or frond spring up a pair of the contracted inflorescence-like spore-bearing panicles, which are also divided into linear pinnae, each clustered with little tufts of spore-cases. It was introduced from Brazil by M.M. Jacob-Mackoy, of Liège, from whom Mr. Williams, of Holloway, has obtained the stock. It may be recommended as a strikingly ornamental evergreen stove Fern.

Begonia Saundersi.—This, though one of the oldest, is still one of the best winter-flowering varieties of *Begonia*. Amongst several others now in bloom with me, this stands out conspicuously as the brightest.—W. H.

FLOWERING PLANTS IN MARKET GARDENS.

GARDENIAS.—The blooms of few plants are more valued in a cut state than those of the Gardenia, and although they do not now realise such high prices as formerly, on account of the increased competition and the large numbers grown, yet good prices are often made. Mr. Ladds has a house 200 ft. long and 30 ft. wide entirely devoted to their culture. The plants are permanently planted out on mounds of earth 1 ft. or so higher than the floor of the house, with the view of preventing the roots from becoming sodden through the continual heavy syringings to which the foliage is necessarily subjected in order to keep it in a healthy growing state and free from insects. The bulk of the plants are from 6 ft. to 7 ft. in height, and as much in width; they start into growth early in the year, and, from February, all through the summer, they yield a profusion of large flowers. Previous to commencing to force, the plants receive a thorough dusting overhead with a mixture of soot and guano in order to clear them of mealy bug, a pest to which Gardenias are especially subject. In that state they are allowed to remain for a few days, when the mixture is washed off the foliage by means of a powerful syringe. This treatment eradicates all insects, and, owing to forcible and frequent syringings, they are never again able to gain a footing, until the plants come fully into bloom, and syringing is necessarily discontinued. Indeed, the blooms are generally all gathered before insects of any kind can do any very serious injury to them. The guano and soot, when washed off the foliage, serve to stimulate the roots, and induce a free and healthy growth, and, although the leaves are sometimes slightly burnt by the mixture, yet it does not apparently injure the constitution of the plants. Some growers, on the other hand, cultivate them in 10-in. and 12-in. pots. They are allowed to grow from 3 ft. to 4 ft. high, and from 2 ft. to 3 ft. through at the base, and in April large houses full of such plants, well furnished with deep green, glossy foliage and loaded with fragrant, wax-like blossoms and buds, are seen in the best market gardens. Some prefer growing Gardenias in pots on account of their being more easily cleared of insects than when permanently planted out, and, moreover, they can be moved from place to place, or disposed of whenever it becomes necessary to do so. The plants grown in 6-in. pots for market are struck from cuttings inserted thickly in pots during spring, summer, and autumn; these are plunged in bottom-heat in a warm, moist atmosphere. After the cuttings have taken root, they are potted off singly into 4-in. pots, and eventually shifted into 6-in. ones, in which size they are allowed to flower. Plants from which the blooms are gathered are cut back, placed in a moist heat, and in a few weeks they break up from the bottom, and soon afterwards furnish another crop of flowers. Gardenias grown in pots, it is said, produce better-formed blooms than those planted out, and, moreover, they can be conveniently removed from place to place as required, and a few can be got into flower at a time, as becomes necessary. Cut blooms of Gardenias fetch from 10s. to 15s. per dozen when perfect in shape and colour. Plants in 6-in. pots, bearing from eight to twelve flowers, fetch from 15s. to 30s. per dozen. The best kind grown by market gardeners is *G. intermedia*; and *G. radicans* is also cultivated to some extent.

EUCHARIS AMAZONICA.—At every season of the year when they can be had the flowers of this are highly prized in the flower market. Some growers have large houses of it planted out, and others grow hundreds of it in pots. The latter method is considered to be the best, as plants

can then be got into bloom a few at a time as required. When planted out in quantity, however, and properly treated, there is always abundance of bloom to be had. Plants of it are seldom seen in the market, but during every month in the year its exquisitely-scented, wax-like blossoms from the chief white flowers for bouquets. No plant is more easily forced into bloom than this *Eucharis*, and its culture is simple and inexpensive. All that is required is to keep the stock of plants if in pots in a moderately cool house, and rather dry at their roots, and introduce a few of them into heat as they are required to bloom. If plunged in a brisk bottom-heat and kept well watered and syringed overhead they will soon throw up flower spikes. Re-potting is seldom practised, as such an operation is detrimental to the plants flowering, and sometimes they remain in the same pots for years. Liquid manure is plentifully supplied when the plants are required to flower, which makes up for the want of root-room. There is a small-flowered kind of *Eucharis* named *E. candida*, which, when plentiful, will probably be extensively grown. Its flowers are not so sweetly scented as those of *E. amazonica*, but they are more useful for small bouquets.

STEPHANOTIS FLORIBUNDA.—The flowers of this are always prized in the market, and growers can seldom get enough of them. Plants of it are usually planted out at the end of Cucumber houses or similar places, and trained over the roof. Thorough ripening of the wood is the chief point aimed at, and through this alone can abundance of flowers be obtained. When allowed plenty of room and properly treated, it is astonishing what dimensions the *Stephanotis* will attain, and what a quantity of blossom it will yield. One of the largest plants with which I am acquainted is trained lengthwise on wires, under the roof of a lean-to house 70 ft. in length. There are about thirty-five wires about 9 in. apart, giving altogether 2450 ft. or nearly half a mile of wires, to each of which are tied quite bundles of shoots. This plant, which yearly furnishes thousands of flowers, receives but little pruning, neither are the shoots ever disturbed in any way, excepting when they get very thick indeed. In February and March the old wood pushes out abundance of bloom from the axils of the leaves, and when this crop of flowers is gathered, some of the rougher or worthless wood is cut out; young growths are made freely, and in June the plant is again a sheet of blossom. If the plant gets attacked by insects, the garden engine and clear water are brought to bear upon it with such force that the insects are dislodged. This operation is repeated at frequent intervals during the time in which the plant is out of blossom, and it is considered a much more satisfactory method than that usually adopted, viz., that of unfastening the shoots from the wires, pruning them back, and sponging them, an operation which disturbs the buds and destroys a large quantity of blossom. Where trimness and order are required, the cutting back and thinning system is doubtless the best; but where the largest quantity of blossom that can be produced is aimed at, which is the case in all market gardens, the plant must be disturbed as little as possible. Sometimes in spring may be seen in Covent Garden small plants of the *Stephanotis* in 6-in. pots, bearing several clusters of blossoms, but such are never very plentiful, as the flowers almost fetch as much money as can be got for the plants. Many people have, however, often been surprised to find the *Stephanotis* flowered in such a small state as it is found here, and have wondered how such results could be attained. The plants are struck from cuttings of half-ripened wood (not points of

shoots) in autumn, or are obtained by layering a branch of a plant along a row of pots filled with soil. Such plants, when struck, have generally one joint above the pot, two leaves and two eyes. These eyes produce shoots which are encouraged to grow as much as possible until the middle of summer, when the plants are turned out-of-doors or into a pit or frame in a sunny position, in order to thoroughly ripen the wood. In autumn these shoots are cut back to firm wood and the plants are placed indoors, when they soon put forth shoots, all of which are sure to produce several clusters of blossoms. These shoots are trained round a few small stakes, and when in bloom the plants are ready for market. Such plants as are not disposed of are served in the way described the next year, when, of course, they make finer specimens. They are not allowed much pot-room as in this case they grow too long in the season, and do not ripen their wood so well, but manure water is used as a substitute for more root-room just when the plants require it. A mixture of good turfy loam, peat, and a little decomposed manure or leaf mould, to which has been added a liberal quantity of sand, forms the best compost for the *Stephanotis*. Good drainage and abundance of water when the plants are in full growth are also essential to the production of fine flowers and the perfect health of the plants.

TUBEROSES.—The flowers of the Tuberose are much sought after by London bouquet makers on account of their white, waxy appearance, their durability, and powerful perfume. Thousands of bulbs are imported yearly from France; I am acquainted with one grower who imports from 25,000 to 30,000 bulbs annually. These are divided into batches in order to obtain as long a succession of bloom as possible. The beginning of November is the time when the first batch is usually started. The bulbs are potted in small pots and placed in a warm house supplied with a good bottom-heat bed. When the shoots have attained an height of 9 in. or 10 in. the plants are potted into 6-in. pots and pushed rapidly into bloom. As the spring advances less bottom-heat as well as top-heat are required to bring the plants into bloom, and after April they are grown in pits and frames fully exposed to light and sun and abundance of air is given in fine weather. Forced plants when in bloom are placed in a cool house to harden them before being cut, in order that they may stand longer when sent to market. In the best of the season, which is from May to August, good plants often bear as many as six large and fragrant blossoms, but during dull weather two or three inferior ones only are produced. Light, rich mould, to which plenty of sand has been added is the kind of soil used for Tuberoses, but they will succeed in any good garden mould. Throughout the autumn, before *Gardenias*, *Camellias*, and other white flowers become plentiful, flowers of the Tuberose fetch high prices, and constitute one of the principal white flowers in the choicest bouquets. Nearly all the year round a good supply of Tuberoses may be obtained by good management.

C. W. S.

Hardy Variegated Plants.—May I inform Miss Hope that there is another variegated Umbellifer that must have been forgotten, viz., *Ægopodium podagraria*, decided and constant in variegation, but a sad pest, except in semi-wild places. The variegated Coltsfoot is fine, but I never could persuade it to stay at home, and, when wanted, it could scarcely be found. *Scrophularia nodosa variegata* is one of the most striking plants with which I am acquainted.—T. WILLIAMS.

— *Safrano* is one of the very best *Roses* for blooming in autumn under glass; and the same remark applies to *Souvenir de la Malmaison* in the open air.—CAMBRIAN.

THE KITCHEN GARDEN.

ASPARAGUS ALL THE YEAR ROUND.

THE accompanying extract, taken from Phillips' "History of Cultivated Vegetables," published in 1822, may possess some interest for lovers of Asparagus, but cultivators will, I fancy, fight shy of re-introducing (supposing it could be done) all the year round forcing. "Asparagus is now obtained," says Phillips, "by the attentive gardener at all seasons of the year, and the same plants are made to give two crops in the year by the following method:—Towards the end of July, especially if it be rainy weather, cut down the stalks of the plants, fork up the beds, and rake them. If it be dry, water them with the drainings of a manure heap, or with water wherein horse or cow manure has been steeped; leave the beds rather flat, instead of the usual round shape, in order that they may retain all the moisture. In ten or fourteen days the Asparagus will begin to appear; if the weather be dry, continue to water the beds two or three times a week. By this method one may cut Asparagus till about the end of September, at which time the produce of the hot-beds will be ready, so that with five or six hot-beds during the winter, one may have a regular succession of this agreeable vegetable for every month of the year. It may be observed that by cutting the beds twice a year we exhaust them; to obviate this, succeeding beds should be prepared. We are, however, of opinion that Asparagus beds do not become worn out or unproductive so soon as is generally imagined, as some of the finest Asparagus with which we have met in this country, the author recollects to have been cut from a bed at Wistburton, in Sussex, which he was then told had abundantly supplied Mr. Upperton's family for more than seventy years." No wonder that we so frequently hear complaints of young gardeners' lack of knowledge in kitchen gardening matters, seeing that a plantation of Asparagus lasts over seventy years. If such be the fact, when are they to learn, practically at least, how to make a plantation?

W. W. H.

LATE-SOWN SCARLET RUNNERS.

"J. J. C." (p. 530) seems to have quite missed the point of argument between Mr. Groom and myself, which was the fitness for table use of any kind of Runner Beans in the beginning of October. May 12 for the first sowing of Scarlet Runner Beans to me seems late, although sown at a safer time than April 23, still, a succession of crops is the great thing to be desired, nor do I consider June 12 too late to sow, provided the season permits and great care be taken as to watering judiciously. I argue that Beans sown the first or second week in May, in good ground, will continue in full bearing until the middle of September, provided all the pods be regularly picked. Of course, if seed be allowed to ripen, even partially, the Beans will cease to bloom, much as one may or deluge with water. "J. J. C." is right as to exhibition pods; there can be no doubt that Beans which have had no check from cold nights from being planted late furnish the best specimens for show, yet even then there is another thing to be considered, no spray of blossom should be allowed to bear more than one Bean. Again, some portion of the row, or rather rows, should never be gathered from; they should be reserved from the first for seed, for the first pods will be the best, owing to the plant never having been weakened and the seed ripened in the month of August. As to French Beans, commonly called dwarf Beans, their growth is easy close to a wall which will protect them from the north and east; the only difficulty that arises is perfect protection from slugs, &c. In the case of French Beans I only sow the Canadian Wonder, and the Champion in that of Scarlet Runners.

Litton Cheney, Dorset.

EUGENE E. P. LEGGE.

— I quite agree with the remarks of "J. J. C." and Mr. Groom with regard to the advisability of making two sowings of Scarlet Runner Beans. It was my practice for some years to make only one sowing, about the first or second week of May, but I found that there was always a deficiency of Beans fit for table after the beginning of September; consequently, for the last few years I have sown twice, the first on or about May 12, and again about June 8. The second sowing comes into bearing from the middle to the end of August, and gives us abundance of fresh young Beans until frost cuts them off. This year we had them up till the last week of October. Owing to the prevalence of late spring frosts for some years back there is considerable risk in sowing earlier than May 12, and I do not think it repays one to do so, as there is but little difference in the time of coming into use between those sown at that time and those which are put in earlier.

H. HAMILL.

Hound House, Guildford.

DIGGING AND BEST SPADES FOR DOING IT.

ACCORDING to my experience, a man who can dig well is generally a good workman in other respects, for, as will be freely admitted it is not every man who can dig, that is, who can handle his spade in the right fashion and do his work in a workmanlike manner. A good digger puts his spade in straight and deep, and he leaves the ground even behind him. A bad digger does quite the reverse—he pushes his spade in at an angle of 45° or thereabouts; he takes one spit thick and another thin, leaving a broken trench behind him; and he is always getting the ground either too high or too low; and it has to be put right again at a considerable loss of time. Only those who have had charge of men know how much labour is lost in this way, and yet young men not unfrequently look upon such work as beneath them, and think it of very little importance whether they have to dig or not. We hardly ever have applications from young men but they want to go into the houses at once, though in many cases they have really little or no knowledge of kitchen gardening, never having learned it properly; and they are usually behind the ordinary garden labourer as spadesmen, who are, generally, their teachers in the matter of digging. I knew of a somewhat amusing case of a young man who thought, I suppose, he was fit for anything because he had passed successfully through some examinations, both botanical and horticultural. Being afterwards employed in a large garden in Scotland, where the young men do most of the work outside as well as inside, he had among other things a good deal of digging to do, until he began to think that such work was hardly in keeping with one of his acquirements, and so one day he brought his papers and certificates over to the garden with him, and when the head gardener came round, he left his spade and presented them to him, remarking that he thought when he had examined them fully he would consider him fit for something better than such work as that in which he was then engaged. The gardener, a well-known man, looked at the papers good-naturedly, and then said, "I have no doubt that everything is true that is here stated, but you see you cannot dig—the very first work a gardener learns! Depend upon it, when you can handle your spade in a workmanlike manner, I shall not overlook you, but you surely do not expect me to put you over the heads of better workmen than yourself on the strength of these papers." The gardener, I may state, accepted no premiums, is order not to be hampered, and always put the best men first. Digging is a far more important part of a gardener's education in the north of England and in Scotland than in England generally. Of five years' apprenticeship which the writer served, three were spent in the kitchen and flower garden and two in the houses. There were about twenty young men (journeymen) in the lodge, and every one had to do his share of the spade work whatever it might be. To be able to dig deep, and straight, and even, and also to be able to reverse hands, that is, to dig right or left hand foremost in going and coming across the quarter was considered something to be proud of rather than otherwise.

Next to the man comes the tool with which he has to work. In spades after the Lyndon pattern the blade is set too much at an angle for digging, and the man in consequence has to lean himself forward in order to put it down straight into the ground. For this he is compensated a little by the extra leverage which the angle affords in turning over the spit, but he would be better off with a spade that was nearly straight, like what is called the Scotch spade, in which the shaft and blade are nearly in a line, and in digging with it the men find it is as easy to put the spade straight into the soil as not. We have tried three or four different kinds of spades, and find the men like the straight spade best. It is quite a mistake to set a spade at the same angle to the shaft as in a shovel, as the two are used for quite different purposes. And now a word as to the operation of digging itself. I speak of simple digging in contradistinction to trenching or bastard trenching, which is another thing. Most garden ground is only dug one spit deep in a season, and it becomes important that the work be done well. In the first place, a good wide opening should be taken out, that there may be plenty of room to turn over the spit and bury the manure, and in the second place the digger should not take too heavy a spit, that is, too much soil before his spade, otherwise the work will be imperfectly done; thin and deep spits turned well over and thoroughly broken up constitute good digging, and *vice versa*. Those who do digging by contract take about 6 in. or 8 in. before their spade and a proportionately shallow grip of the soil, which is simply shovelled forward anyhow, their object being to get over the ground as fast as possible, and measure so many poles or rods in a certain time. I do not agree with digging by contract, but the plan is resorted to occasionally in large gardens. Then there is "rough" or winter digging, and "fine" digging. The best plan, however, is to dig the ground roughly about this season of the year, and leave it exposed to the winter frosts, and then, when cropping time comes round, it only needs stirring with a fork and sowing or planting, as the case may be. This is the chief, if not the only, advantage of winter digging: it mellow the ground for the crops, and seeds are got in in a much shorter time when favourable weather comes than when the ground has to be dug with the spade and cropped at the same time. It is astonishing how soon the soil gets into working condition when it has been rough dug at the beginning of winter, or even later; one or two droughty days render it workable. It is not always practicable to rough dig all the ground, but an effort should be made to rough dig Onion, Potato, early Pea, Carrot, and Turnip ground, and ground for all crops that have to be got in during the most precious portion of springtime, when the days are short, and dry, favourable weather is short and uncertain. As to trenching, the gardener can never do wrong in trenching or double digging as much ground as he can find time for in summer or winter, but such work is usually done during the winter, and only rough manure is put into the

ground at such times. It is a mere waste to bury short, rotten manure in a trench, as it is almost wholly lost. All such should be dug or forked in with the top spit, so that it may come within reach of the roots at once. Weeds, dry litter, old Pea haulm, and general rough garden refuse may be trenched in, but all rich and partially rotted manure should be dug in only a spit deep. J. S.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Vick's Criterion Tomato.—This is a decided acquisition to our already numerous good kinds of Tomatoes. It is a free bearer, of moderate size, a good forcer, fine in flavour, perfectly smooth, and of the brightest red colour imaginable.—W. W.

Hardiness of Veitch's New Protecting Broccoli.—Severe frost set in here on Dec. 8, and has continued up to the present date (Dec. 16), the thermometer on one occasion having been as low as 14°; notwithstanding this, however, this Broccoli is still uninjured, the flower being so effectively protected by the foliage growing so as to completely overlap the heads.—W. W., *Heckfield*.

Asparagus and Salt.—Does "T. H." (p. 530) mean that salt is not a good manure for Asparagus, or that it is better without it? If so, my experience differs from his, as I have proved it to be the very best of all manures which I have ever used for that excellent. As to distance, the plants should be 3 ft. apart from each other, which will be more profitable than 18 in.—W. W. H.

Late Peas.—I quite agree with Mr. Divers (p. 518) as to Dr. Maclean being a good Pea for late use. We gathered here this season the last dish of it on Nov. 1, which I consider wonderful, as the weather during the latter part of the season was much against the growth of Peas. Dr. Maclean is a blue wrinkled Marrow Pea, of excellent flavour, and one which grows with us to a height of 4 ft. It is vigorous in habit and extremely productive, and we intend for the future to have it both for early and late crops.—E. W. DANCE, *Llangattock Manor, Monmouth*.

Prince of Wales Capsicum.—The Capsicum which "A. D." mentions (p. 530) was Prince, not Princess, of Wales. This correction is necessary, as there is a variety named Princess of Wales, but which, according to my opinion, is not so effective for decorative purposes.—W. WILDSMITH.

Horticultural Absurdities.—Last year we mentioned Forest Hill Cemetery, near Boston, as affording examples of very neat bedding designs; a visit to the grounds this year shows some of quite an opposite character. The amount of bedding there is something bewildering, some of it is in excellent taste, but there are things there that should never be repeated, for they "make the judicious grieve." There is one absurdity, we do not know what it is intended to represent; it is something with a handle, it may be a basket; the handle—a hollow wire frame probably—is planted with succulents, and on each side are two short pillars, which, if not barrels or casks covered with plants, might as well be, as they look like representations of those articles. It was unpleasant to see this and some other monstrosities in a place where they know how to do things better. The so-called floral designs at exhibitions are as often something to avoid as they are things to be commended. We have very little sympathy with the fashion that works flowers into broken pillars, anchors, and the like, but as this gratifies many, and affords employment to others, we do not object, so long as it is kept within bounds. At the last exhibition of the New York Horticultural Society there were liberal and extra premiums offered for works of this kind, and it brought out some strange designs. There was a pair of shoes on a cushion; the shoes were of white flowers without, and of scarlet flowers within, which looked distressingly like a red flannel lining. But why make shoes out of flowers? Why degrade these delicate creations by working them in the semblance of something that is to be trodden under foot? There were various clocks and mantelpieces, and strange affairs, unlike anything else. There was a camp fire, with a tripod, and something hanging that might have been a teapot, or may have been a tailor's goose. A greater absurdity was a fireplace, with an attempt to represent coals and flames in scarlet flowers. It becomes a question whether a society is properly educating the public taste by exhibiting such things. Of course they attracted attention, and were admired by certain people, but the persons who are pleased by such absurdities are those who would admire the old topiary work, where bears, and boars, and other horrors were clipped out of Box trees. It was a relief to turn from the numerous horticultural absurdities to one or two simple, but exquisitely neat, bouquets, not those with a silver fringe, but sufficiently beautiful without—and to the most appropriate of all the funeral designs, a plain, heavy wreath of Ivy leaves, with a few heads of ripened grain—"American Agriculturist."

Bamboo Mats.—It is stated (p. 540) that "these mats are 4 ft. 6 in. in width" only. We can supply them from 8 ft. to 10 ft. in width, and from 10 ft. to 12 ft. in length. The sample sent to you for more convenient handling was cut small.—ALEX. WALLACE, *New Plant and Bulb Company, Colchester*.

TREES, SHRUBS, & WOODLANDS.

TREES AND SHRUBS AT SOUTH KENSINGTON.

THE collection of trees and shrubs exhibited on Tuesday last at South Kensington by Messrs. Lee forcibly shows what fine effects may be produced in our gardens by means of a judicious selection and tasteful arrangement of hardy green and variegated arborescent vegetation. The plants in question embraced pyramidal Hollies 10 ft. high down to Conifers of 6 in. in height, all well arranged and not too thickly. They are to remain on view, we understand, for a week or two. They consist of the following:—

<i>Abies aurea</i> , gold	<i>Hedera arborea Rægneriana</i> , dark green
<i>Englemanni</i> , grey	<i>arboorea</i> yellow-berried, green leaf
<i>Menziessi</i> , grey	
<i>Aucuba vera foemica</i> (berried), green and red	<i>Juniperus chinensis aurea</i> , straw colour
<i>Biota argentea</i> , silver speckled	<i>drupicea</i> , bright green
<i>aurea</i> , golden bronze	<i>japonica aurea</i> , entirely gold
<i>aurea variegata</i> , gold speckled	<i>japonica argentea variegata</i> , silver blotch
<i>elegantissima</i> , bronzy gold	<i>japonica aurea variegata</i> , gold striped
<i>elegantissima picta</i> , gold, speckled with silver	<i>neaboriensis</i> , greyish green
<i>filiformis</i> , bright green	<i>virginiana argentea</i> , conspicuous white speckles
<i>perfecta</i> (new), green in winter, bright sulphur in spring	<i>virginiana columnaris</i> , dark green
<i>semper aurea</i> , golden bronze	<i>virginiana elegans</i> (Lee), dark green, suffused with cream
<i>Berberis pygmaea</i> , deep green	<i>Ligustrum coriaceum</i> , dark green
<i>Buxus nana variegata</i> , silver and green	<i>japonicum</i> , dark green
<i>Cedrus Deodara alba spica</i> , silver	<i>laevidum aureum variegatum</i> , bright gold margin
<i>Cupressus Lawsoniana alba pendula</i> , white and grey	<i>ovalifolium</i> , brightest gold margin
<i>alba spica</i> , white and grey	<i>sinense tricolor</i> , green, silver, and rose colour
<i>argentea</i> , silvery grey	<i>Osmanthus ilicifolius argenteus</i> , silver margin
<i>aurea variegata</i> , large gold blotches	<i>ilicifolius aureus</i> , dull gold margin
<i>erecta viridis</i> , bright green	<i>Prumnopitys elegans</i> , light green
<i>lutea</i> , yellow	<i>Retinospora cupressoides</i> , light brown
<i>nana glauca</i> , grey	<i>ericoides</i> , light brown
<i>ochroleuca</i> , yellowish white	<i>filifera</i> , green
<i>Cupressus macrocarpa Crippsi</i> , green, speckled with white	<i>juniperoides</i> , bluish purple
<i>sempervirens variegata</i> , green, speckled with gold	<i>obtusata nana aurea</i> , gold
<i>Elaeagnus pungens variegata</i> , golden margin	<i>pisifera lutea</i> , yellow
<i>Euonymus japonicus aureus maculatus</i> , gold in centre of leaves	<i>plumosa</i> , light greenish white
<i>Duc d'Anjou</i> , light and dark green striped	<i>plumosa alba spica</i> , tips of branches white
<i>latifolius argenteus</i> , gold and silver	<i>plumosa lutea</i> , yellow
<i>latifolius argenteus elegans</i> , bright silver	<i>squarrosa</i> , whitish grey
<i>latifolius aureus elegantissimus</i> , deep gold margin	<i>Taxodium alba spica</i> , bright silver tipped
<i>microphyllus</i> or <i>pulchellus</i> , deep green	<i>Taxus alba</i> , gold striped
<i>radicans variegatus</i> , bright silver margin	<i>elegantissima</i> , silver striped
<i>rotundifolius argenteus silver margin</i>	<i>fastigiata aurea</i> (Standish) gold
<i>G. nerium argentum compactum elegans</i> , silver striped	<i>fastigiata variegata</i> (Fisher Holmes) gold variegation
<i>Hedera arborea argentea</i> , bright silver margin	<i>gracilis pendula</i> , deep green
<i>arboorea aurea</i> , gold blotched	<i>pyramidalis variegata</i> , gold striped
<i>arboorea elegantissima</i> , silver edge	<i>Washingtoni</i> , bronze
	<i>Thuja alba spica</i> , white tipped
	<i>plicata lutea</i> , gold
	<i>Vervaneana</i> , light bronze

FINE SPECIMENS OF PINUS INSIGNIS.

"S. D." (p. 484), alluding to this Conifer, mentions the fine specimen of it which is growing at Bowood, and wonders whether it is still in existence. He will be glad to be informed that it is still alive and in robust health. When I saw it, in September last year, it struck me as being by far the most beautiful tree in the Pinetum. I should guess it to be about 60 ft. high; I girthed the stem, which I found to measure 10 ft. 2 in. at 5 ft. above the ground. Its wide-spreading branches swept the turf, and well clothed, as they were, with healthy Pea-green foliage, it formed a most striking and imposing appearance. At Mells Park, Somerset, there is a fairly good specimen, 53 ft. high, and girthing 6 ft. 2 in. at 5 ft. up

the trunk. At Dropmore the largest tree girths 9 ft. 5 in. at 5 ft. up the stem; it is about the same height as that of the one at Bowood, but not nearly so well furnished. The best specimen further north that I know of is at Eastnor Castle, but I do not know its measurements; there are also many younger trees there thriving remarkably well. *Pinus insignis*, although occupying the first rank amongst Conifers in an ornamental point of view, cannot be recommended as a tree for planting indiscriminately and in quantity with a view for use and profit, as I believe its timber will prove to be of very little value. This Pine is one of those trees that start early into growth, and it is one of the last to stop growing in autumn, invariably making a second growth late in the season. It should be planted as much as possible on dry, open, airy sites, and it will probably live longest when fully exposed; the best aspect for it being from north to south-west. In Ireland, where frosts are not usually so intense as in the north and eastern counties of England, and where the climate generally is more humid, *Pinus insignis* grows at an immense rate; indeed, nowhere have I seen it so well grown and beautiful as in some parts of the west of Ireland. G. BERRY.

Longleat.

NOTES & QUESTIONS ON TREES, SHRUBS, & WOODLANDS.

Beech Trees and Underwood.—With respect to this subject I fear it must be said that Mr. Knight's experience is singular. In this district Beeches grow like weeds, but in every case undergrowth (Moss excepted) is absent.—NORTH HANTS.

"J. S. W." is right. No practical man would ever think of planting underwood in a Beech wood. Underwood cannot be grown under the dense shade of Beech trees. Moss and Sorrel is the only vegetation that seems to thrive well under the Beech.—B.

I did not intend to have offered any remarks on the question at issue between Mr. Knight and "J. S. W.," but as "J. S. W." has appealed to me as to the condition of the undergrowth in the several large clumps of Beech here, I have to say that there is literally nothing growing under these clumps but a short, wiry, dark-coloured Cryptogam, the name of which I do not know; but immediately you get to the edge of the Beech clumps vegetation, consisting of long Grass, Ferns, &c., begins, and the Cryptogam ends. Have any of your readers observed how, under the Scotch Fir, the common Bracken and Athyriums, &c., thrive and grow close up to the boles of the trees?—D. THOMSON, *Drumlanrig.*

Mr. Knight's experience of Beech trees and underwood must be different from that of the rest of his neighbours. In our avenues here, where the trees consist of Beech, Elm, and Silver Fir, it is very easy to see where the Beech trees stand, as hardly anything will thrive under them. There is a Grass verge about 5 ft. broad on each side, and, wherever a Beech overhangs, the Grass will not grow. We have a good many Beech trees here, and if Mr. Knight will favour us with a visit I am sure we will make him welcome if he can put us upon a plan to get underwood to grow beneath them. In one Beech wood in particular we have tried almost everything, but to no purpose. No vegetation of any sort seems to thrive in it, nor am I surprised, considering the dense mass of foliage and the great quantity of roots which Beech trees throw out.—A. MCINTOSH, *Parton House, Berwickshire.*

I can point out an exception to the opinions expressed (p. 534) respecting underwood under Beeches. At Alderley Park, Cheshire, there is the finest plantation of Beeches which I ever saw, and under them grow thousands of Rhododendrons, all self sown, and it is astonishing the size which they attain; and, taking into consideration the dense canopy of foliage overhead, they flower profusely. To show that they have no great aversion to the situation, I have often found vigorous plants growing from the base of the trees. Privet in this wood also does well, and the common Yew forms handsome trees. No one can expect to grow underwood of much market value where the permanent trees occupy the whole space overhead, but such situations may be made both useful and ornamental by judiciously planting suitable shrubs; and I know of no plant so suitable for this purpose as the common Rhododendron, because, if left undisturbed, the self-sown seedlings will soon occupy every spare inch of ground; and, as is well known, game rarely injures them; and what is more pleasing in early summer than masses of these plants carpeting the ground under stately Beeches! I would recommend those who may wish to try the experiment not to procure too large plants; from 1 ft. to 2 ft. high is the most suitable size, and by allowing the leaves which fall from

the trees to remain, an excellent yearly addition to the requirements of the Rhododendron is the result.—A. HOSSACK, *Ragley, Alcester.*

Holly Berries.—These are again very scarce this season in this neighbourhood, there being no new berries, but on a few trees we have a good sprinkling of last year's fruit, which will have to do service instead of new berries. Some of the trees bloomed well, but did not set their fruit, a circumstance which I attribute to their bearing an extraordinarily heavy crop last year. This is the third time I remember having to use old berries.—W. D., *Werton, near Maidstone.*

Cerasus Watereriana.—This being the season when alterations are usually being made in gardens, let me just say to all about to plant that they should add a plant or two of this fine Cherry, as I feel assured that, as an ornamental plant, no one will be disappointed with it.—J. C. F.

The Fever Gum Tree in Surrey.—It may be interesting to know that some seedlings of *Eucalyptus globulus*, which I bought some time ago from Messrs. Cheal & Sons, Lowfield, Crawley, have flourished admirably when planted in certain selected positions. Those that were placed in low ground well drained three winters ago, in situations sheltered from the north and east, have grown rapidly, being now 24 ft. high, 5 ft. through, and 1 ft. in girth. I may add that there is one in bloom; this is 12 ft. high, and has a full west aspect, and is on much higher ground than the others. Some that were exposed to the east did not stand through the second winter.—JOHN HORNIMAN, *Croydon.*

Stuartia pentagynia.—Your illustration of *Stuartia virginica* does no more than justice to a most beautiful and valuable class of shrubs. In Great Britain, unfortunately for us, as you say, it is not quite so hardy as *S. pentagynia*. Of the latter we have plants 8 ft. high, and your illustration represents that species exactly, except as regards the arrangement and colour of the stamens and pistils. Many years ago, when *S. pentagynia* was first brought into prominent notice by its introduction into the nurseries of Messrs. Parsons, of Flushing, I published a full account of it giving its history. Its flowers, which somewhat resemble those of a large single white *Camellia*, appear in succession about the latter part of July and first half of August. When THE GARDEN of July 13 was received here it was in great perfection, and we cut a branch or two of the flowers to compare with those represented by your coloured plate. Plants of full size present a mass of these fine blossoms which cover the entire surface. *Stuartia pentagynia*, one of our handsomest native shrubs, was introduced to England nearly a century ago, and is described by London under the name of *Malachodendron ovatum*, but now called *Stuartia pentagynia*. I therefore presume that it is a well-known shrub with you, though less common than *S. virginica*, as the latter was introduced by that enthusiastic naturalist Catesby in 1741. London remarks that it was one of the plants cultivated with other American peat-earth shrubs. I have found, however, that it grows freely and vigorously in any common garden soil not too low or wet. Mr. Hemsley, in his account of *S. virginica*, makes a slight mistake in saying that the two species are natives of the "Eastern States" of North America. *S. virginica* is strictly a native of the Southern States (Florida and South Carolina), and *S. pentagynia* of the middle States (Virginia). The Eastern States comprise New England. This would not be of much importance, except to those who might compare the relative temperature of the native localities with their own; but very few of the trees and shrubs of Florida and South Carolina will survive the low winter temperature of the Eastern States.—C. M. HOVEY, *Boston, Mass.*

Blowing up Trees.—The following particulars respecting clearing land of stumps of trees may prove useful: Cost of removing thirty-six Oak stumps on the estate of Baron de Rutzen, Kobeck Park, Haverfordwest, by means of tonite or cotton powder—

	Dr.	£ s. d.	Cr.	£ s. d.
15 lb. tonits at 2s.	1 10 0	By 2 tons 14 cwt. firewood, say	1 0 0
44 detonators	0 1 6	Nett cost of breaking up and removing 36 stumps...	1 11 9
60 lb. fuse	0 1 6		
4 men 4 of a day firing, &c., at 2s. 6d. per day	0 7 6		
1 man 4 days removing the smoking wood, at 2s. 6d. p.d.	0 11 3		
		£2 11 9		£2 11 9

This was the first trial of the Baron's men after receiving instructions. By a little practice there is no doubt it could be done at the average of 8d. or 9d. per stump, which by the old method would have cost from 3s. to 4s. each.—"English Mechanic."

Cyptomera elegans.—Beautiful as this Conifer is at all seasons, it is most conspicuous now owing to the deep dark colour which it assumes in winter. We have a fine pyramidal plant of it close to the beautiful Pea-green *Pinus insignis*, and the difference between the two in point of colour is remarkable.—G.

NOTES FROM KEW.

Greenhouse Plants.—A very curious and interesting plant, and one, moreover, likely to attract attention during the festive season which approaches, is *Rhipsalis Cassytha*, a West Indian Cactacean plant, covered at present with pearly-white, Mistletoe-like berries; its blunt-ended, cylindrical branches are arranged in whorls, the branchlets being about 3 in. in length. In a state of nature, this is an epiphyte, growing from 1 ft. to 6 ft. long, and hanging from the branches of the trees; the flowers are white and are very freely produced. *Crassula lactea*, a handsome succulent introduced from the Cape of Good Hope rather more than a century ago, and not nearly so frequently seen as its merits deserve, is a most useful winter-flowering plant, of the easiest culture; it has round, fleshy leaves and large panicles of pure white blossoms, which remain a long time in perfection. This is a good habited plant, and in a well-drained loam fine examples can easily be grown, even in small-sized pots. *Astelia Banksii*, a peculiar plant from New Zealand, is worthy of note on account of its purplish, berry-like fruits, which are produced in panicles amongst the long, sedge-like leaves, green above, and silvery-white below. Scarcely any plant is more easily grown, as it will flourish in the same pot for an unlimited period, provided it can obtain an unlimited supply of water. *Strelitzia reginae*, with its large, strangely-shaped orange and azure blossoms, is one of the most gorgeous of greenhouse flowering plants. The genus was named in honour of Charlotte of Mecklenburg-Strelitz, the Queen of George the Third. All the species, of which *S. reginae* is the most handsome, are natives of the Cape of Good Hope. The fine, long-stalked, glaucous leaves of this species are, in themselves, striking. The seeds are eaten by the Kaffirs. In cultivation, recourse must be had to artificial fertilization, and even then the seeds are by no means freely produced.

Stove Plants.—Foremost in beauty amongst the tropical plants which now enliven our stoves is *Eranthemum nervosum*, an East Indian Acanthad with spikes of brilliant deep blue flowers; individually these do not last long, but, as they are very numerous, and as there is a constant succession for some time, the plant is well worthy a place in the most select collections of warm house plants. *Plumbago coccinea superba* makes a beautiful decorative object, its fine green leaves setting off to great advantage the long spikes of deep scarlet flowers; in habit, &c., this much resembles the old *Plumbago rosea*, but the colour of the blossoms is much more decided, and a couple of shades deeper. One of the very best of winter-flowering stove climbers is the West African *Clerodendron splendens*; it is a short-jointed, half-bushy climber of neat habit, and has fine, bold, deep glossy-green foliage. Where a rafters can be spared, few plants will better repay growing, particularly if planted out, as, under such conditions, its clusters of fine crimson blossoms are produced in great profusion. *Tillandsia bulbosa*, from Trinidad, is a Bromeliad, uniting both peculiarity of growth and of structure with floral beauty. It is an epiphyte merely requiring to be attached to a piece of wood and hung up in the moist orchid house. The leaves are Rush-like and spirally twisted, much resembling those of the spiral variety of the common Rush, *Juncus communis*, which passes in some nurseries as *J. spiralis*; their bases form a bulb-like mass, hence the name. The spike is short-stalked, and the colour of the flowers is outvied by the bright scarlet of the upper leaves.

Orchids.—*Lælia anceps* is a Mexican Orchid of great beauty. In habit it is far more graceful than any of the Cattleyas, on account of the length of its slender, sooty stems, from the points of which the flowers swing. The extreme delicacy of texture of petals and sepals, and the rich glowing purple of the lip, can scarcely be surpassed. *L. autumnalis* somewhat resembles, at first sight, *L. anceps*, but a closer inspection proves the two to be quite distinct in pseudo-bulbs, scapes, and flowers. *Mastdevallia polyactis*, a lovely little plant, is one of the freest-flowering of all; the cup-shaped bases of its blossoms are thickly covered with small purple dots on a white ground, the tails being yellow. About half-a-dozen flowers are borne on each of the stalks, and these overtop the leaves. *Dendrochilum glumaceum*, with its long drooping spikes of small, ivory-white, very fragrant flowers, is a very elegant and graceful plant and one of the most desirable of Orchids. *Odontoglossum Pescatorei* has fine spikes of lovely blossoms, which are of the purest white, with the exception of the bases of the small lobes of the lip, and these are purple spotted; the little ridges of the same organ are yellow. The *Medusa's Head* Orchis, *Cirrhopetalum Medusæ*, a native of Singapore, is one of the strangest of Orchids; it has short, leathery leaves, and rather shortly-stalked, dense spikes of peculiarly-formed spotted blossoms, the two lateral sepals of which are prolonged into long streamers. These give the idea of a head with long dishevelled hair, hence the name. *Epidendrum paniculatum racemosum*, though possessing no gaudy coloration to recommend it, is still a pretty

plant; it has leafy stems, about 1 ft. or 2 ft. high, and arching spikes of flowers, the sepals of which are much reflexed and of a Pea-green colour; the two petals are reduced to whitish, thread-like processes, the lip and long column are white, the former being spotted with crimson-purple.—†

ANSWERS TO CORRESPONDENTS.

Lasting Ferns for Bouquets.—"W. A. S." (p. 526) will find that *Oxychium lucidum* is one of the best Ferns for cutting, as it not only has very elegantly divided fronds, that render it suitable for bouquet work, but it is very lasting in water when used in a perfectly mature state. To have this and others in the latter condition, they should be grown well up to the light, where they can have plenty of air to thicken and harden them, as much of their enduring powers depend on this; thin, flimsy fronds withering almost as soon as they are removed from the plants. *Davallia* are mostly lasting, but the best of them all for bouquets is *D. bullata*, unfortunately a deciduous variety, and, therefore, only available for use during the summer.—S. D.

Field Mice in a Rockery.—If Mr. Ellacombe (p. 526) will bait his mousetraps with the kernel of the Barcelona Nut—the common Nut of the shops—I think he will quickly stop the ravages of field mice. Three years ago I had a pit full of valuable varieties of Ferns nearly ruined by them. They bit out the centres of the crowns. It is incredible what an amount of mischief a pair of them will do in a short time, on account of their propensity for nibbling often without eating. Finding none of the usual trap enticements effectual, it occurred to me that Nuts formed a large proportion of their natural food, and which they store up for winter. I tried them and speedily caught the mice. These Nuts appear to be an irresistible allurement. I have since used them for all kinds of mice with a like result.—J. M., *Charmouth, Dorset.*

Paraffin as an Insecticide.—My experience with this oil certainly does not tally with that of your correspondents (p. 526.) We have on the roof of the stove here, a large plant of *Stephanotis* which was infested with mealy bug, and I syringed it with a mixture of one wineglassful of paraffin to four gallons of cold water, keeping the same well mixed by driving every alternate syringe-full back into the pail again. The bug was destroyed and not a leaf was injured. Large plants of *Gardenias* were treated in a similar manner, and with equally good results.—WILLIAM THOMPSON, *Warrenpoint, Co. Down.*

Salt-water Resisting Plants.—"A. T." (p. 526) cannot do better than plant the Tamarisk and Sea Buckthorn largely, as they will grow where washed by salt water, and the first is a very beautiful evergreen, having branches that hang over in graceful sprays, and in colour and form quite equal in appearance to many Fern fronds, and as useful as most of them for cutting to dress with flowers during the winter. The evergreen Oak succeeds uncommonly well quite close to the sea, and appears to enjoy the saline matter in the air; but whether it would grow in soils occasionally soaked with salt water, I know not, although I think it quite likely it would, if kept from them till they got their roots well down and became thoroughly established. Could not something be done by throwing up an embankment, or raising the ground into large mounds before planting, so as to get it above the general level? as then *Pinus Laricio* and *P. austriaca*, with other hardy Conifers and other trees might be made to succeed, and form quite a feature in the landscape.—S. D.

Fruit Trees Losing their Blossom Buds (pp. 526, 550).—The plan recommended by "J. D." will not, I think, prove effective in preventing all birds from picking off the buds of fruit bushes, Pear and Cherry trees, &c. In this part there are some kinds of these depredators that appear to hold in contempt all such devices. Nor will soot and lime mixed with water alone, as recommended by another correspondent, meet the evil complained of by "F. W. H.," for should it happen to have been applied just before a heavy shower of rain, most of it will have been washed off the trees in a few hours. There is one remedy, however, which I have never once known to fail, viz., the ordinary Vine-stem wash, either used as it is with a brush, or diluted and then applied with a syringe. If this cannot be had, I find the following mixture to act as well, and I have never lost a crop when it has been used twice or three times, say from December to the period when the buds have expanded. To a good-sized pail of soft water add about a quart of soot, $\frac{1}{2}$ lb. of soft soap, one quart of lime, a little sulphur and Tobacco water, and a handful of clay well dissolved. Strain all through a piece of coarse muslin or a fine sieve. Should the mixture not pass freely through the syringe, add a little more water, but the thicker it can be used the better.—C. F., *Merlwood.*

Currants Losing their Bloom Buds.—As "F. W. H." (p. 526) lives, as he says, quite in the heart of a town, I have no doubt that sparrows are the depredators which have taken the buds out of his Currants, as they are quite as clever at that work as bullfinches, although by many they have the credit of being harmless. Where their numbers are few, and they can get vegetable food, besides a full supply of Corn, they may be so, but near towns they are an intolerable nuisance, making, as they do, as soon as Peas are through the ground, a regular onslaught on their tender tops, and dividing attention afterwards between these and Gooseberry and Currant buds, bushes of which, if left to themselves, they entirely strip in a very short time. Till I adopted the plan of syringing hot lime on them I seldom had a crop, as shooting, where there

are large numbers of them, is of little avail. Bullfinches may, however, soon be settled by the use of powder and shot, as, except in rural districts, where there are plenty of woods, it is seldom that more than a pair or two are seen together, but even these do a great deal of mischief in a very quiet manner. Reverting to the protection of the bushes by means of limewash, the best way I have ever found for preparing and using it is to get some large fresh lumps, say a bushel or so if there are many trees to go over, and put them in a large tub of warm water, where they will elake in a very short time, when, after the wash so obtained is strained through a fine sieve to take out the lumps, it is ready for use, and may be quickly syringed on by a Read's or other syringe, having a jet instead of a rose, as any one skilled in the use of that implement can easily guide and disperse the stream and distribute it regularly over the plants intended to be covered. By applying the lime quite fresh it adheres the better, and, if put on when it can dry and set quickly it will remain till the buds, in their rapid swelling during the spring, cause it to crack and gradually fall off. Not only is a dressing of this kind of great value to keep off birds, but it entirely destroys all Moss, Lichen, or insects with which the bark may be infested, and soon restores it to a clean and healthy condition. It is therefore worth doing for this alone, and when the ground is fresh pointed over after to get rid of that scattered about, its appearance on the bushes is not at all objectionable.—S. D.

Stocks for Vines.—Will Lady Downs make a good stock on which to work the Alicante?—M. I. B. [We should not choose such a stock for the variety in question, but if you have no other it would answer fairly well.—S.]

American Blight.—What should I do to destroy or prevent what is known as American blight, which has attacked my Apple trees very badly this season?—S. W. [Scrub the affected parts with paraffin mixed with water at the rate of a wineglassful to the gallon; afterwards put a composition of clay and cow manure over the cankered parts.—S.]

Names of Plants.—C. E. O.—*Cymbidium giganteum.*

Names of Fruits.—H. G. E., *Macartney.*—61, Marie Louise; 62, Catillac; 63, unknown. W. M.—Apparently mostly French varieties not in general cultivation in this country; 32 is Blesheim Orange; others unknown. S., *Frimley.*—120 is a wild, worthless variety.

Questions.

Charcoal Burning.—Will some one kindly give me a few hints in reference to burning charcoal for horticultural purposes? I have a quantity of Alder which I am anxious to convert into charcoal.—J. J.

Tea-scented Roses Out of doors.—Can any of your readers inform me whether these Roses would stand the winter planted here (Wimbledon) in a bed $4\frac{1}{2}$ ft. wide from a wall 12 ft. high, which would protect them from the north and east, while the house, at a distance of 15 ft., would protect them from the north-west? The soil is a very suitable one for Rose.—F. D. L.

Pteroma macrantha grandiflora.—I had a plant of this some three or four years ago, and it flowered well with me in a young state, but I lost it in moving. I have had three plants since from different nurserymen, but cannot get them to flower, although I have kept them in an intermediate house of the same temperature as that in which I kept the first. I understand that there is a true kind and others that do not come true having been raised from seed. Where can I get the true kind? A few hints as to culture would also be acceptable. The tips of the leaves have with me a tendency to curl up and turn brown.—E. B.

Roman Hyacinths.—Are these generally later this year than usual? Mine came out soon after October 21, about the 23rd, I think; they had very little forcing, and were potted on July 29. Cyclamens, I think, are unusually forward this year. I had Camellias, too, by September 23.—M. P. S.

Winter Coverings for Ferns.—Is it a good plan to cover up Ferns (outdoor ones) with sawdust, to protect the most delicate from the cold? Would not Oak wood sawdust be the worst to put on?—A. H. M.

Begonias from Leaf Cuttings.—Would Mr. Hassock please to give a few more details of his experience in raising tuberous Begonias from leaf cuttings? He says the leaf must have the stalk attached. Are we to understand that it must have the whole stalk with the embryo bud at its base, or merely a portion to steady the cutting in the soil? If the latter and if the leaf forms a bulb, as doubtless it will if it develops into a plant, does your correspondent know from actual experience that the bulb so formed will not be blind, and refuse to vegetate the following year? I find cuttings taken from the flowering branches, if cut at a leaf which has had a flower at its base, will root and flower the first year, but the bulbs they form have no eyes, and are worthless the second year. Will the leaf cuttings not be equally unsatisfactory?—T. B.

MR. E. BENNETT, of Rabley, late gardener to the Marquis of Salisbury, at Hatfield, has, we understand, taken the large forcing establishment known as the Holly Bank Nursery, Potter's Bar, lately in the occupation of Mr. John Monro, and which he intends to work in conjunction with his home nursery.

NOTES OF THE WEEK

Snowdrops on Grass.—The best position in which to show the full beauty of these, our earliest spring flowers, to advantage is not in beds or borders, but on turf under deciduous trees, where, as a rule, the Grass is thin and mowing is reduced to a minimum. Here may be seen large beds of Snowdrops already showing the tips of their snowy petals under wide-spreading Limes and similar trees, and, as they have evidently remained unmolested for years, they promise to make an early and beautiful display. This is a good time to procure bulbs of Snowdrops, which, after being dibbled into the ground, will take care of themselves.—J. GROOM, *Linton, near Maidstone.*

Carnations at Slough.—Of these, large quantities are grown in Mr. Turner's nursery for winter blooming. They are struck from cuttings in spring, and grown on in 5-in. pots in cold frames during the summer. As they show bloom in winter, they are moved to a lean-to house and placed on stair-like stages, and by this means, a good display of bloom is kept up in the house all through the winter. Several hundred plants are just opening their blossoms, which, we need scarcely say, are most valuable at this dull season of the year. Among other good kinds were *A. Alegatiero*, brilliant crimson, *Sir Garnet Wooley*, a yellow ground kind with a scarlet edge, *Souvenir de la Malmaison*, pink, and *La Belle*, white.

Melons in Covent Garden.—There is in Covent Garden Market just now an abundance of the white and green-skinned Spanish Melons. They arrive in large boxes fitted inside with square partitions, each large enough to hold one fruit, the vacant space being filled up with sawdust. They are neither so large nor so good as those imported earlier in the year, but at this season any kind of fruit which is at all eatable is welcome.

Effective Grouping in Winter.—One of the most striking effects which we have witnessed under glass for a long time may now be seen in Mr. Turner's nursery, Slough. It consists of *Calanthes*, *Polisettias*, and *Euphorbia jacquinioides* placed alternately on greenhouse stages with Maiden-hair Ferns, the latter interspersed so as to hide the pots. The *Euphorbias* are managed so that they could be used with good effect for table decoration; they are grown in the form of standards about 6 in. or 8 in. high, having heads consisting of from four to six graceful arching sprays well clothed with bright scarlet blossoms.

Browallia elata in Winter.—This is one of the most useful of old-fashioned plants for winter blooming. It is grown in quantity by Mr. Turner, of Slough, and at the present time, it is one mass of bright blue blossoms and very effective, associated as it is with well-grown *Bonvardias*, *Gardenias*, &c. Cut sprays of it are also useful in bouquets, as in a cut state they stand well for some time. The plants of it here are raised from seed sown in spring, and grown on liberally through the summer in good, sandy soil in houses or pits. Bushy plants of this *Browallia* are much more easily obtained than similar examples of *Eranthemum pulchellum*, a plant usually grown to supply blue flowers in winter, and the latter, when cut, last but a very short time in perfection.

Lachenalia pendula splendens.—Mr. Hooper has brought us a handsome flowering spike of this large and beautiful *Lachenalia*, grown by Mr. Barker, of Littlehampton. It is a very useful addition to this extremely interesting group of winter-flowering plants.

Botanical Society of Edinburgh.—At a meeting of this Society, held the other evening in St. Andrew's Square, a letter was read from the Rev. D. Lauderborough, Killmaruock, in which he gave an interesting account of the growth of New Zealand and Japanese plants planted by him in the open air at Corrie and Brodick, Isle of Arran. Tree Ferns were growing luxuriantly, and *Dicksonia antarctica*, with a girth of stem of 22 in., had fronds 5½ ft. long and 22 in. broad. The other sub-tropical Tree Ferns were *D. squarrosa* and *Cyathea medullaris*. A *Desfontainia epinosa* was 6 ft. in height, and flowered beautifully every summer. There were also three different varieties of *Eucalyptus*, from 16 ft. to 24 ft. in height, though only planted in 1872.

National Rose Society.—The annual meeting of this Society was held, as announced (by permission of the Horticultural Club, at their rooms, Arundel Street, Strand), on Thursday, the 12th inst., the Hon. and Rev. J. T. Boscawen in the chair; it was largely attended, many of our best Rosarians being present. The treasurer's account, showing a balance in hand of £25 16s. 10d., was read, passed, and ordered to be printed; the thanks of the meeting were given to Mr. W. Scott, the hon. treasurer, for the able manner in which he had fulfilled the duties of his office. The dates recom-

mended by the General Committee for the exhibitions of 1879 were agreed to, viz., the Crystal Palace on June 28, and Manchester on July 12. Mr. McIntosh was appointed by acclamation as vice-president, and committees and officers for the ensuing year were elected. Amongst the important matters decided on were that exhibitors who are not members of the Society must pay an entrance fee of 5s., that the highest number of Roses which members would be required to exhibit for the year should be thirty-six, and (although this was done at the dinner) that a die should be made and medals offered from year to year at the various Rose shows in the kingdom as funds would permit. A subscription was entered into for this purpose, and was liberally responded to.

SOCIETIES AND EXHIBITIONS:

ROYAL HORTICULTURAL SOCIETY.

DECEMBER 17.

OWING to the severity of the weather on this occasion, plants of a tender character were but sparingly represented. The chief features were the fine collection of hardy green and variegated trees and shrubs from Messrs. C. Lee & Son, Hammersmith, and brilliant stands of cut blooms of zonal *Pelargoniums* from Mr. Cancell, Swanley.

First-class Certificates were awarded to—

Primula Earl of Beaconsfield (Gilbert).—An attractive double rosy-flowered kind, which will be very useful for winter decorations.

Lælia anceps alba (Bull).—A striking white-flowered variety of this well-known Orchid (alluded to last week, p. 549).

Apple Dr. Hogg (Ford).—A large kitchen Apple of excellent quality, having a clear yellow skin, like that of the *White Calville*, and a good keeper.

Miscellaneous Plants.—Amongst Mr. Cancell's *Pelargoniums* the following were well represented, viz., H. Jacoby, dark crimson; Lizzie Brooks, a large scarlet kind with a white eye; Belle of Surrey, salmon and white; S. Holden, brilliant rosy-pink; Dr. Denny, bluish-purple; D. Thomson, large velvety crimson; Rienzi, orange-scarlet; Circulator, pinkish-salmon; The Shah, scarlet; Louisa, violet-pink; Titania, crimson-magenta; and Miss Gladstone, white with a salmon eye. The white, salmon, and striped kinds of *Vesuvius* were also shown in quantity, and attracted much attention. Mr. W. Bull, King's Road, Chelsea, sent flowering examples of *Lælia anceps*; and Mr. C. Green, gardener to Sir G. Macleay, Pendell Court, Bletchingly, showed *Æchmea Weilbacki*; also the curious *Bilbergia nutans* and *Grevillea fasciculata*, to both of which latter botanical commendations were awarded. A striking group of *Cyclamen*, contributed by Mr. Smith, Ealing Dean, was remarkable for the dwarf compact habit of the plants, their varied marbled leaves, and their profusion of pure white or vivid purple-magenta-coloured blossoms. Mr. Hepper, The Elms, Acton, exhibited a seedling *Solanum*, having a pendulous habit. Mr. George, Putney Heath, showed a new rosy-pink seedling *Abutilon* named *Rose Queen*; and Mr. Thomson, Crystal Palace, Sydenham, sent cut sprays of *Eucalyptus globulus*, bearing numbers of fruit buds. Mr. Gilbert, Burghley, contributed various double Chinese *Primulas* of an attractive character. Their names were—*Marchioness of Exeter*, blush; *Earl of Beaconsfield*, rose; *Mrs. A. F. Barrow*, white, large and fine; and *White Lady*.

The Gold Flora medal was recommended to be given to Messrs. Lee & Son, Hammersmith, for an extensive and tastefully arranged collection of hardy shrubs for winter gardening, the names of which are given in another column. Mr. Noble, Bagshot, furnished plants of *Thunopsis borealis*, aureo-variegata, which were very effective, on account of their alternate yellow and green foliage. Mr. Hoins, gardener to F. A. Philbrick, Esq., Regent's Park, contributed a fine plant of *Sophronitis* grown on a large piece of cork. It bore nearly forty expanded blossoms and many more buds were being thrown up. The same exhibitor also sent a flowering plant of *Odontoglossum Warszewiczii*.

Fruit.—Mr. A. Killeck, Mount Pleasant, Langley, contributed a collection of kitchen and dessert Apples, all sound and finely coloured. Among the most noticeable kinds were excellent fruit of the *New Hawthornden*, *Tibbet's Incomparable*, *Golden Noble*, *Beauty of Kent*, *Blenheim Orange*, *Hanwell Sourcing*, *Court Pendu Plat*, *Wellington*, and *Royal Russet*. A remarkably fine collection of Apples was also contributed by Mr. W. Gardiner, Ellington Park, Stratford-on-Avon. It contained finely-coloured fruits of *Red Rover*, *Blenheim Orange*, *Adam's Pearmain*, *Pear's Pearmain*, *Lord Duncan*, *Golden Winter Pearmain*, *Winter Quoining*, and *Annie Elizabeth*. Mr. L. N. Dancer, Little Linton, showed seedling Apples of excellent quality, cooked and uncooked. Mr. D. Wilson, Castle Hill, South Molton, contributed two grand smooth *Cayenne Pines*, weighing together nearly 16 lbs. They were well ripened and perfect in shape. Mr. Douglas, Loxford Hall, sent bunches of *Royal Vineyard* and *Golden Queen Grapes*, the berries of the latter being affected with some disease, while those of the former, grown, we believe, in the same house, were sound and good.

Mr. Gilbert, Burghley, sent a brace of *Taylor's Montrose Cucumber Despatch*, apparently a fine winter kind; the same exhibitor also sent examples of a new Cabbage, which looked remarkably tender and good. Mr. Iggulden, gardener to R. B. W. Baker, Esq., Orsett Hall, exhibited fine examples of *Trophy Tomato*.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

THE INDOOR GARDEN.

PLANT ARRANGEMENT IN STOVES.

WITHIN the last quarter of a century the internal arrangements of our stoves have been much altered, but not for the better. Where we used to see abundance of well-grown flowering plants, requiring great care combined with skilful culture in their management, we now see nearly all the space filled with what are termed fine-foliaged plants, the largest portion of them consisting of Palms, interspersed with Crotons. A few Palms, and the most distinct and good species of Crotons, should find a place in our plant stores certainly, and, in most cases, there will be room for a few other plants, but Palms and Crotons ought only to be introduced in sufficient numbers to be a relief to the flowering plants. The question may be asked at the outset, What is the best form of house in which to grow the plants and show them off to the best advantage? In order to have well-furnished specimens, and also to maintain them in the best condition, the span-roofed form of house is certainly the best, with the ends looking to the south and north. The half-span form likewise answers very well, and is also adapted for the culture of plants. In each of these forms of houses the staging may be fixed all round; the best, because the most lasting, is that formed of slate or some sort of stone slabs. In the centre there ought to be a pit to contain some fermenting material, the best being tan, used fresh from the pits. Lean-to houses may also be utilised for stove plants; in these the arrangement of the pit and stages would depend upon circumstances and the size of the house. There is so much moisture generated in plant stoves that the best arrangement for the stages is iron supports for the slabs just mentioned. If a very large house has to be kept in good condition, houses of a smaller size ought to be constructed as auxiliaries thereto, in which to grow some of the plants up to a flowering state and to place others in after they have done flowering. If the house be nearly filled with fine-foliaged plants, the labour attendant on their management is much reduced, inasmuch as long as the plants are kept in good health they may remain in the house all the year round. Owing to the desire of late years for fine-foliaged plants, and especially for those of recent introduction, many of our fine old flowering stove plants have fallen into the background. It is very undesirable, however, that this should be continued; on the contrary, some of the weediest of the fine-foliaged plants should be discarded, and room made for plants that can be admired for their sweetness and beauty. Amongst stove-flowering plants already introduced, there is ample material to keep up a grand display all the year round. Many fancy that Orchids cannot be grown well in a plant stove, but the reverse of this is the case. A very few species of Orchids alone will suffice to keep a good-sized plant stove gay all the year round, and it will be found that Orchids do not require so much care as *Ixoras* and similar plants, and that they are not so likely to get into bad condition. A few of the Orchids that may generally be obtained at a cheap rate, and which are best adapted for culture in a miscellaneous collection of plants, are the following, viz.:—*Dendrobium nobile*, an ornamental plant which holds a very high position, and one the flowers of which are well adapted for bouquets or vase decoration; its culture is by no means difficult, and a succession of flowers may be had from it from November until the end of June. *D. Wardianum*, a species adapted for hanging-baskets, should also find a place in mixed collections. These two are the best for our purpose. *Calanthes* come next; the deciduous species for winter-flowering comprise *C. Veitchii*,

a noble plant, the colours of which range from pale rose to rich deep rose, and almost crimson. *C. vestita* in variety, and *C. Turneri* are also good. These produce a grand display of flowers in November, December, and January. *C. veratrifolia*, a chastely beautiful, pure white evergreen species lasts in flower from May to the end of July. Then we must have a few of the best of the *Cattleyas*. *C. Mossiae*, in rich variety, is the best for our purpose, and the allied *Lælia purpurata* will give the greatest satisfaction. These will flower from the end of April to the end of June. *Cœlogyne cristata* is a charming plant, easily grown, most useful for cutting, and, when the flowers are tastefully associated with delicate Fern fronds, they are much prized for placing in ladies' hair; they are of the purest white, with a yellow blotch at the base of the lip, and they may be had throughout the early spring months. *Cypripedium barbatum* is a plant that should not be omitted, its quaint flowers lasting a long time in beauty. *Lælia autumnalis* and *L. anceps* are useful for autumn and winter flowering, and if the new white form of *L. anceps* should become common, it will be a most welcome introduction. *Lycaste Skinneri* does well in an ordinary stove, but the cool *Odontoglossum* will not, nor can the *Masdevallias* be recommended for that purpose. A few of the easiest grown *Oncidiums* give a plentiful supply of cut flowers during the summer months. Orchids are preferred to most other flowering plants, because as they increase in size they also increase in value, and can always be disposed of with advantage.

Let us now advert to a few of the best winter-flowering stove plants, and foremost amongst these stands *Eucharis amazonica*, which, though it produces its handsome white flowers in winter, will do so under good management at any season; the same plant will flower two and even three times a year. In striking contrast to this we have *Euphorbia jacquiniæflora*, the wreaths of small bright scarlet flowers of which enliven our stoves during the three dreariest months of the year. Almost as welcome at midwinter is the old *Eranthemum pulchellum*, the bright blue flowers of which are abundantly produced. *Pentas carnea* gives us a plentiful supply of rose-coloured flowers, and is a plant that is easily grown. *Plumbago rosea*, an East Indian species, is a charming plant for large stoves, remaining, as it does, gay all the winter. To these must be added *Epiphyllum truncatum* and other fine forms of it, all of which flower in winter. *Medinilla magnifica* is a gorgeous plant for spring flowering, and one which grows most freely, but it requires a large house in which to develop its beauty. *Poinsettias* are too well known to need any comment, and *Linum trigynum* is a choice old plant, which is grown in some gardens by the hundred. If kept free from red spider, and well managed in summer, its bright yellow flowers will be produced in abundance during the winter.

Spring and summer-flowering plants are abundant. Who would be without the *Stephanotis floribunda*, the gorgeous *Dipladenias*, and *Ixoras*, with white, bright red, orange, and salmon-coloured flowers? all these should find a prominent place in stoves, both large and small. *Francisæas*, too, with their handsome purple blossoms, give additional charms to any group of stove plants. A few choice fine-foliaged plants are quite necessary amongst such flowering plants as these, but we want selections not collections of them. One looks forward to the flowering of choice stove plants with intense interest; and, whether they last for a longer or shorter period in beauty, their charming and varied tints are always appreciated. With a fine-foliaged plant the case is different; whatever may be their merits, their appearance alters but little from month to month or from year to year. They have a place, and that is sparingly intermixed amongst flowering plants, but on no account should they be encouraged at the expense of flowering plants, which no stove should lack in any month of the year.

Loxford, Ilford.

J. DOUGLAS.

Medinilla magnifica.—This highly ornamental stove plant thrives remarkably well in the Fulham nurseries. I noticed plants of it the other day in 8 in. or 9 in. pots, which promised to flower well. They were thickly furnished with deep glossy green leaves, 2 ft. in length, and nearly 1 ft. in breadth.—S.

FRAMES AND THEIR USES.

FRAMES of some sort are indispensable adjuncts to a garden. However well adapted houses may be for the growth of plants in a general way, there are some families of them which, at a certain period of their existence, require a somewhat different treatment from that which can be accorded them in such structures. Seed sowing, propagating, and the culture of the so-called florists' flowers, can hardly be freely and perfectly carried on without their aid. A good, well-heated, brick pit, with light sashes, is a great boon to the plant grower. Somehow this is what one rarely sees in gardens; ranges of frames are erected, and then, for the want of a little additional outlay, which the provision of sufficient heating power would incur, their utility is greatly impaired. A small, conical boiler, with just a flow and return pipe, will suffice for all ordinary purposes. When the object is merely to exclude frost, I would prefer a conical boiler to any form of saddle, as it can be banded up, and may be relied on to burn steadily for ten or twelve hours without attention. Pits in which plants are to be wintered, should have the sides cemented and the bottom concreted, otherwise the moisture, continually soaking in, keeps up a state of atmospheric humidity around the plants which is often fatal to their well being. If a depth of 3 ft. can be secured, it will be all the better, as this will allow room for tall-growing plants, such as Azaleas, Camellias, Acacias, &c. The smaller plants can, of course, be accommodated by bringing them up near the glass upon shelves. For frames of this description, lights 6 ft. by 4 ft. are necessary, but they should not much exceed these dimensions or they cannot well be pulled off. Although it is far preferable that pits should be heated, yet it does not necessarily follow that plants cannot be preserved in health therein through the winter without this convenience. With care, and by giving some attention to the nature and peculiarities of each plant, or family of plants, really satisfactory results may be achieved. Some of the best Cinerarias, Calceolarias, and Primulas I ever saw, were grown in cold frames the whole winter through. The winter, even for Germany, was very severe, but by the plan adopted not a leaf was injured. There were four rows of frames, covered with 5 ft. by 4 ft. lights. The space between each row of frames was but 3 ft., and this was filled up with leaves trodden down firmly. The lights were covered with straw mats, on which wooden shutters were laid, each one overlapping the other, so that no wet could penetrate. When the thermometer registered 10° of frost, some litter was laid upon the boards, and on wet mornings, the mats were carried into an open shed close by, so that they could always be put on dry. The sashes could not, of course, be pulled off, they were provided with a handle at each end by which they were lifted off one on to the other for watering and other purposes. The great merit of this arrangement was, that it secured perfect immunity from frost; a certain amount of warmth was stored up in them, so that there were few days when they could not be uncovered.

When frames are insufficiently protected, frost gets into them, and they must then remain sealed up for days together. There is no way of examining them, and damp and decaying leaves work sad havoc. If, on the contrary, sufficient covering is afforded to preserve the temperature some degrees above freezing, it will allow of light being admitted at a much earlier period of the day. Cleanliness with respect to plants thus preserved is of the first importance; many fail through not attaching sufficient weight to this point. In damp or rainy weather they should be looked through every two or three days, picking off and clearing away the smallest portion of decaying matter. Pelargoniums, particularly the bicolor, tricolor, and variegated sections, especially require regular supervision in this matter. Their wood is of a more tender, juicy nature than that of the Zonals, and one or two rotten leaves will suffice, if allowed to remain, to completely ruin a good plant. Now and then, the whole contents of the frames should be rearranged, turning each plant round, thus equalising the light, clearing the surface of each pot, and clearing out all decayed matter from the pit. Plants stored in pits require much less water than those which stand in houses, as they rest upon a cool, moist bottom and do not get any great circulation of air around them. There is, therefore, not that necessity for immediate watering, as when the pot is placed on a dry stage

near hot pipes. It should be a rule to water as little as possible in damp, rainy weather. The soil may then remain dry for a week without injury resulting therefrom; in fact, Pelargoniums should always be on the point of flagging before being watered. Do not aim at preserving their foliage in a growing condition, as this will keep them in such a succulent state that they will be extremely susceptible to rot. In watering, too, it must be remembered that half the quantity of water required in summer will suffice to moisten the soil through when everything is cold and evaporation is extremely sluggish. This fact is too often lost sight of, and, as much water is given to a plant at rest, as is required when the functions are active. This treatment, especially in plants of a succulent nature, surcharges the tissues with sap, and renders them an easy prey to a period of atmospheric humidity. There is a certain class of plants, which, making growth in the winter, are not amenable to the above described treatment. Such are Cyclamens, Cinerarias, Calceolarias, which must not stand dry any time together, or they fail to grow in a satisfactory manner. They must be the honoured guests, and have assigned to them the lightest and best positions in the frame, for they have to continue their growth and perfect their flower buds when the days are at their shortest. Camellias and Azaleas having flower buds must not be kept long in a dry state, or the quality of the bloom will be much impaired.

Ventilation must be punctually attended to, by lifting up the lights on mild days; in still foggy weather, however, they are best closed. Frames for general purposes to be employed in the spring and summer months are better and handier if of smaller dimensions, 4 ft. by 3 ft. being quite large enough; they are then easily manipulated from the front of the frame. For pricking off seedlings and hardening off shedding plants, such frames are invaluable. They are well adapted for the summer growth of Primulas, Cyclamens, Bouvardias, &c., and in the autumn they may be used for storing away Strawberry plants, wintering choice Pansies, &c., there will, in fact, be found a use for them every month in the year, and they will prove of equal value to both the amateur and large grower. Those who do not deal in specialities, but desire as much variety as may be possible, should have their frames erected in compartments; the requirements of each kind of plant may then be better and more easily regulated. Pits which have been used for wintering plants in, may be turned to account in the spring, by filling them up with good soil and planting Cucumbers, Tomatoes, Chillies, &c. Indeed, with a little forethought and management, the cold frame may be found to be the source of a no small amount of profit and pleasure.

Byfleet.

J. CORNHILL.

Centropogon Lucyanus.—At this season of the year this is one of the most useful and showy stove or warm-house plants which we have. It is a valuable plant for cutting from, and useful for conservatory embellishment, as it stands a long time in bloom in a heat of from 45° to 50°, and it associates well with Cyclamens, Primulas, and similar plants.—J. C. F.

New Paraffin Insecticide.—I have read with interest the various communications in THE GARDEN on the use of paraffin oil as an insecticide, and have tried it in a small way with fair success. I found, however, a difficulty in keeping the oil and water mixed during the using, not having, as "D. I." (p. 535) has, "one man to keep on syringing into the tub while another applies the mixture;" and as I am a chemist primarily and amateur gardener secondarily, I set to work to devise a remedy, and this, I think, I have done in the production of a cream containing 50 % of paraffin oil, which will mix readily with any proportion of water, and will keep mixed during the using. It may be applied either with a brush or syringe, or preferably with a "spray apparatus." The mixture contains neither soap nor alkali, nor anything that can possibly injure the most delicate plant, excepting what the paraffin oil may do; it is purely vegetable.—ROBT. PARKINSON, Aldermanbury, Bradford.

Paraffin Oil as an Insecticide.—Having frequently of late seen paraffin oil recommended as an insecticide, and having also seen a caution or two administered against its excessive use, I may just state that I have dressed Ixoras, Gardenias, Crotonas, and Stephanotis with pure paraffin oil, not adulterated with water at all, without any evil results. The plants in question are healthy and vigorous, and have not lost a leaf, although the operation was performed three months ago.—J. PERKS, St. John's, Worcester.

RODRIGUEZIA (GOMEZA) RECURVA.

THIS graceful Brazilian Orchid, of which the accompanying is an illustration, appears to best advantage when grown as at the Pine-apple Nursery. The plant from which our sketch was taken was planted nearly two years ago in the outer shell of the Para or Brazil Nut (*Bertholletia excelsa*), and by the manner in which its roots have penetrated the porous shell, and its unusual vigour, it seems to enjoy its position. Each shell (which contains from twenty to twenty-four Nuts) is about the size of that of a Cocoa-nut, but much thicker, cup-shaped, and as neatly finished as if it were turned on a lathe. In shells of this kind numbers of Orchids are grown in the nursery in question, and very handsome they look, so much so, indeed, that it is evident that a greater variety, both as regards material and shape of baskets and blocks, might be introduced into Orchid houses with advantage. *Rodriguezia recurva*, like most other Orchids from Brazil, thrives well in a rather dry temperature of 60° in winter, water being given

Rodriguezia growing in a Brazil Nut-shell.

sparingly after growth has been completed and while flowering, and very liberally when the plant is making its growth.

WINTERING PELARGONIUMS.

SOME of your correspondents who have written upon this subject, appear to entertain widely different views with respect to the treatment which Pelargoniums, taken up in autumn from the open ground and potted, should receive. The Pelargonium family is a large one, and embraces various distinct types of growth. One has only to remark the difference in the growth and foliage of a nosegay and that of a tricolor, to become thoroughly alive to this fact. It will therefore follow that the treatment which perfectly agrees with one kind may not be the best that can be adopted for another. As far as my experience goes, I have found that strong-growing kinds of the *Stella* and *Tom Thumb* types may be relied upon to succeed under a somewhat rough and ready treatment. If simply cut back, crammed into pots and pans, and carefully and rather sparingly watered, they will make root, break again, and in all respects thrive satisfactorily when placed in a cold, light, well-ventilated house. If a little fire heat be given in damp weather, just to create a buoyancy

in the air, fine, strong plants may be looked for in the spring, and these old plants are, to my mind, preferable to plants raised from cuttings, inasmuch as they come into flower, and create an effect earlier in the season. With the silver variegated varieties I have found more care needful: if cut back too far they are liable to rot. They have not the power of drawing up sap which the *Zonals* possess. The best plan is to pot them as they are taken up, retaining as much leaf as possible, and cut them back early in the spring. As this section is of comparatively slow growth two-year old plants are the most serviceable, and the cuttings taken off in the spring will make excellent plants for next year. In the bronze and tricolor sections we have to deal with a tribe of plants which, owing to a delicate constitution, are more difficult to preserve in vigour through the winter than the kinds just named. They make a comparatively small amount of root, are very sappy when taken up, and it therefore frequently occurs that large portions of them die off or come out in the spring in such a debilitated state that they are but of little use for flower garden decoration. This is mainly owing to the torpid state of the root, a confirmation of which may easily be obtained by comparing them with established plants. With respect to these varieties, I would always like to plunge the pots for two or three weeks in a mild bottom-heat, merely protecting them from frost and heavy rains; this would promote the formation of a quantity of fresh fibre, without in any way exerting or enfeebling the plant itself. When placed in winter quarters, they would then be found to possess sufficient vigour to carry them through that dull season. This is very different treatment from shutting them up in a warm house, which must, more or less, unfit them for a residence in a cold structure. As regards the general potting of Pelargoniums in autumn, much will depend upon the time at which it is done. A plant taken up by the beginning of October will stand a much better chance than if it remained in the ground a fortnight longer. Generally speaking, this work is put off until late in the season, merely for the sake of an extra week of battered faded blooms. The plants are kept in the beds when they should be establishing themselves in pots. The value of that fortnight is scarcely realised; there is still sufficient heat in the soil to induce root action, and the plants get established before the period of stagnation arrives. Tricolors should be taken up by October 1, and if all the variegated kinds be potted at that time they would be much the better for it. If then placed on a dry stage in a light, airy house, they will get rid of much superfluous sap, and will thus be in better condition than they otherwise would be to resist atmospheric humidity. J. CORNHILL.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Roman Hyacinths.—These are the most useful flowers which any one just now could possess. Two months ago we bought a quantity of bulbs of them; all were potted in 6-in. pots in some good loam, leaf soil, and a little sand, four bulbs being put into a pot. For one month they stood in a frame under 4 in. of coal ashes, they were then removed to a glass covered pit in which there was a day temperature of 70° and a night one of 60°. Here, with plenty of water at the root, they are now in full bloom, white as snow and very fragrant. After the first spike has been cut nearly every bulb is throwing up a second one.—CAMBRIAN.

Schizostylis coccinea Planted Out and in Pots.—The following fact with regard to the planting out of *Schizostylis coccinea* may possibly be found of practical use:—Early last summer (it might have been in June) a few potsful which had bloomed in a cold conservatory the previous winter, and which had been left neglected in their blooming pots, were divided and repotted in very rich soil and kept well watered. The rest of the stock, which had been planted out as usual, were taken up in autumn and also carefully potted, but the effect of this late putting was not only to retard the bloom (which may often be an advantage) but also to turn the leaves prematurely yellow, and the flowers were neither so fine nor have they lasted so long as those which were kept in their pots, than which nothing could have been more satisfactory.—K. L. D., *Ashmore*.

Frame Protectors.—I find nothing to keep frost out of cold frames so well as spreading dry hay over the lights to the depth of 3 in.—CAMBRIAN.

Crassula lactea.—This, grown in round pans, in Messrs. Veitch's nursery, is a useful indoor plant at this time of year. The pans, though not drained, answer well, due attention being paid to watering. At the present time, large plants of this *Crassula* form quite attractive objects in the greenhouses at Chelsea, laden, as they are, with abundance of spikes of white sweet-scented blossoms.—S.

TREES, SHRUBS, & WOODLANDS.

FINE SPECIMENS OF WELLINGTONIA.

ABOUT twenty-five years ago this Conifer was introduced into England; it was, I think, in 1853 that Mr. Lobb sent or brought seeds of it home. Perhaps some of your readers can remember when the first seedlings were distributed throughout the country, and where the [first and earliest Wellingtonias were planted? if so, it would be very interesting to know what progress in growth these trees have made in the quarter of a century during which they have been on trial. The tallest tree with which I am acquainted is at Orton Hall, Huntingdonshire; it now measures 50 ft. high, girths 5 ft. 10 in. at 5 ft. up the stem, and is 17 ft. in diameter of spread of branches at the base. This tree unfortunately lost its leader a few years ago, or it would probably have been 2 ft. or 3 ft. higher. There are some other specimens at the same place that measure within 1 ft. or so of the height of the one just mentioned. The next highest tree, I believe, is growing in the nursery at Longleat; this was planted, as nearly as I can ascertain, twenty-two years ago; it is now 47 ft. high, and girths 5 ft. 11 in. at 5 ft. above the ground; the average spread of its branches is 21 ft., and the butt contains 20 ft. of timber. At Strathfield says there is the best grown and most perfect specimen of the Wellingtonia that I have ever seen, but it is not quite so tall as the two just mentioned. It has, however, a wider spread of branches and a thicker stem than either of them; its height is 45 ft., girth of butt at 5 ft. above the base 7 ft. 3 in., and the diameter of spread of branches is 24 ft. Another remarkably well-grown and handsome Wellingtonia is growing in the flower garden at Witley Court; it has even a thicker butt than the Strathfieldsaye tree; its height is 40 ft., its girth at 5 ft. up the stem is exactly 8 ft., and its spread of branches at the base 22 ft. The two latter are by far the handsomest Wellingtonias with which I am acquainted; neither of them presents that stiff, prim, clipped-yew-like outline that one has been often accustomed to see Wellingtonias present, but broken and irregular forms. Their branches of luxuriant foliage seem to drop, so to speak, into massive flakes, not unlike those of an aged silver Fir. I am pleased to be able to note this, to me, apparently new feature, for I was never an admirer of the stiff habit of the Wellingtonia in its comparatively young stages of growth. There are probably some few larger trees than those which I have mentioned. I know there was a particularly fine specimen at Lamorbey Park, Kent, but I have not got its present measurements. Will some of your readers kindly supply them? It is rather premature to form a decided opinion as to the quality, durability, and commercial value of the timber of this tree, but this we do know, that it is a robust, hardy tree, and as free a grower as the Larch in similar situations. I, however, may safely venture to predict that it will never be so good and useful a timber-producing tree as the Larch has proved itself to be.

Longleat.

GEORGE BERRY.

FALLACIES CONCERNING WOODLAND TREES.

IN the reviewer of "Our Woodland Trees," by Mr. Heath, in the "Saturday Review" has quoted his author correctly, some of Mr. Heath's observations on the subject of trees are open to criticism. First we are told that the Holly is produced from an acorn, which will surprise those who are in the habit of decorating their rooms with Holly-berries at Christmas. Next it is stated that "it is well for a sylvan street or garden planter to know," that the Holly "is a difficult tree to transplant, because its roots descend deep, and are apt to be injured in removal;" and we further infer from the reviewer's comments, that Mr. Heath considers the drip of the Beech detrimental to vegetation, and that the English Elm is one of the latest trees "in succumbing to autumnal influences," a fact of which the reviewer says we have abundant evidence in the general deep green tint at the end of October. These discoveries, amongst others of a similar nature, no doubt are, according to the "Saturday Review," the result of a "careful survey of the characteristic features" of each species of tree in our woodlands. Now, it is well known that there are always people, themselves uninformed in such matters, who would rather be guided by such pleasant if not very accurate writers as Mr. Heath, than by a practical forester. The writer in the "Re-

view" is himself one of this sort—one who likes to imbibe his knowledge as children take medicine, in something pleasant to the taste—even though he should lose by the process. "For a friend," he says, "who shall take us with him afield while we sit in our library chair, and set us a dreaming of summer and autumn rambles, and who instructs at the same time that he entertains and interests the would-be learner just entering on a *terra incognita*, commend us to an enthusiast like Mr. Heath." If, however, the above extracts from "Our Woodland Trees" be a sample of the author's careful observation in such matters, we doubt his being a safe guide, and one fails to see that the "fact" of Mr. Heath having been "professionally tied to London since manhood, enhances his claims to our attention." The very worst observers are those who only get glimpses of nature by fits and starts. They may note a few permanent features, but that is about all. I do not think a careful or habitual observer of trees, would call a Holly- berry an "acorn," and I am quite sure no one possessing much acquaintance with trees or tree planting, would describe the Holly as a tree "difficult to transplant, because its roots descend deep and are apt to be injured in removal." I wonder what kind of tree can be transplanted without injury to its roots, be it young or old. But as a matter of fact the Holly is not difficult to transplant, nor does it send its roots "down deep." If it be transplanted at the proper season—that is, late in spring or early in the autumn—I do not know a tree that is more likely to stand the operation. I have moved many large Hollies up to thirty and thirty-five years of age, and I do not remember ever losing a single tree, and provided you get good balls of soil with the trees, you may transplant them any month in the year. This is not a matter of opinion but of every-day experience. As a rule the main roots of Holly spread out horizontally, and make such a mass of small fibrous roots quite close to the surface of the ground, that one could hardly put a penknife into the soil without cutting them, and when the trees are lifted such sorts come away like a mat, and this is the habit of nearly all dense and close-growing twiggy trees like the Holly—the roots correspond to the branches. In trees that have grown where they stand from seed, one may find occasionally a tap-root going down, but the lateral and fibrous roots are always sufficient to preserve the life of the tree in transplanting, and give it a good start. Out of fifty Hollies, young and old, which we moved last spring, we have not lost one. With regard to the lateness of the Elm in "succumbing to autumnal influences," which means, I suppose, that it is late in shedding its leaves, I confess to being as surprised at such a statement as I am at the assertion regarding the "deep green tint of the leaves at the end of October." I never witnessed such a phenomenon, but, after dry summers, followed by autumn frosts, I have more than once seen the leaves in a fine old Elm avenue being swept up in September, and the trees are generally leafless early in October. The leaves of the Elm are of a rusty brown hue by August, and are brown rather than green by September; but, unless winds prevail, I admit that portions of the leaves often remain on the trees long after they have succumbed to autumn influences and are quite dead. The Oak and the Beech are the trees most remarkable for retaining their leaves till late in the year, sometimes till near the new year. As to drip from the leaves of the Beech being "detrimental to vegetation," foresters, while acknowledging that underwood does not thrive under the Beech, account for the fact by a less far-fetched reason. It is simply the dense and long-continued shade of the Beech that kills undergrowth, but that only happens when many Beech trees are planted together. Thickly-planted Beech woods contain little or no undergrowth, but almost anything will grow under the drip of the branches of Beech trees standing in the open park, where the light reaches the trunk all round. Under a thick plantation of Planee underwood thrives just about as ill as under the Beech, and, if anything, I think the Scotch Fir is about as destructive to undergrowth as either. In all woods the undergrowth is just healthy and luxuriant according to the amount of light it receives—a fact which should guide planters of cover. It is a sufficient commentary on the reviewer's knowledge of his subject that he has little else than praise to bestow upon "Our Woodland Trees," and that the erroneous statements we have pointed out are commended as particularly instructive and worth knowing by those engaged in planting.

W. S.

Quercus Daimyo.—Allow me to direct the attention of those who are interested in ornamental trees to this exceptionally fine foliaged Oak. It is the largest-leaved Oak which I have ever seen. A tree of it in my possession has borne leaves during the past season from 10 in. to 14 in. in length and about 5 in. in width at the widest part, and it seems to be a robust grower. This being comparatively a newly-introduced Oak, and probably not known to many planters I venture to strongly recommend it as an ornamental tree, far sur-

passing in size *Q. macrophylla* and *Q. nobilis*, although these are both remarkable for their handsome foliage; the latter particularly is a brilliant tree in autumn, its leaves when dying off assuming rich tints. While speaking of Oaks, permit me to mention two more well worth growing, viz., *Q. Tauza splendens* and *Q. purpurascens*; the former has fine foliage, and the latter bright reddish-purple young shoots.—G. B.

TREES THAT THRIVE IN INDIFFERENT SOIL.

IN some alterations which I have recently had in hand in Surrey, I had an opportunity of seeing the ability of a few plants, not only to live, but to thrive well, in pure clay. I do not mean the heavy, retentive soil of a stiff, stubborn, tenacious character, that often is designated clay, but the real, genuine yellow article, devoid of stones and without a particle of sand or anything in the shape of loam near it. The position was on the side of a hill, through which a road had been cut, after which the slopes thus formed had been trenched over and at once planted with a variety of subjects such as are usually found at the present day in shrubberies. What was the intention or expectations of the planter as to the result of his work it would be difficult to guess, unless he was acting upon the idea I have before this heard expressed, that "one good killer was worth two good growers." At all events, very few of the trees and shrubs planted were able to live; common Laurels scarcely grew at all, and their leaves were almost the colour of those of the new yellow Dogwood; others consisted of Portugal Laurels, Anoubas, Bays, Berberis Aquifolium, B. Darwini, evergreen Oaks, Arbutus, Tree Box, Hollies, Cotoneaster Simonsii, *C. microphylla*, Hypericums, Spruce Firs, Cedars, Cypresses, Junipers, Yews, and Pinuses. Amongst the whole of these and others there were none that thrived, except Thuja Lobbi, *Cryptomeria elegans*, and the double Firze (*Ulex europæus fl. pl.*). The Thujas made shoots 18 in. long in a season, and evinced little dislike to the ungenial soil in which their roots were placed beyond carrying foliage of a somewhat paler tint than when grown on good ground. The Firze grew and appeared as healthy as if on a dry, loamy bank. The *Cryptomerias* also made very fair headway, and their foliage all the year round was of so intense a reddish-purple hue as I have never seen approached, even in the autumn or winter, in any other place. So remarkable was this, that at first sight the trees looked as if they were dead. Could this tree be induced to assume this colour in company with others possessing the usual shades of green, where these latter succeeded well, it would be still more valuable for contrast than it now is. It is scarcely necessary to say that it is by no means advisable to plant either trees or shrubs in such unkindly material as the above without its being first well aerated and some soil of a better description added to it; but it is something to know that there are a few plants that appear to thrive in defiance of the stubborn nature of the medium in which their roots are placed; I traced some of the roots of the Firze, and they had penetrated straight down into the clay to a depth of over 4 ft. T. BAINES.

NOTES & QUESTIONS ON TREES, SHRUBS, & WOODLANDS.

Clothing Naked Stems of *Araucaria imbricata*.—Having two specimens of this, with handsome heads, but bare stems to a height of 6 ft. or 7 ft., it occurred to me that possibly variegated Ivy or Japanese honeysuckle might be induced to grow over them and to make them ornamental. The effect has been all that could be desired. The variegated Ivy has been allowed to completely cover the stem, whilst the Honeysuckle has been kept in bush form by clipping; and it forms a very desirable setting for the trees.—W. W. H.

Elongation of Tree Trunks.—The "College Quarterly" says that experiments made at the Iowa Agricultural College show that the popular notion that the trunks of trees elongate is entirely erroneous. Tacks were driven into the trunks of various trees, and the distance between them accurately measured. At the end of the season they were found to have neither increased nor decreased their distances. In the experiment tree trunks were selected of all ages, from one year up to five or six, and in no case was there any change whatever noticeable.

Hydrangeas Planted Out.—I would strongly recommend any one who has Hydrangeas too large for pot culture, to plant them out after all danger of severe frost is over in rich, deeply cultivated soil. Here the soil is generally stiff and clayey, resting on broken soft stone, and the Hydrangea with us forms a beautiful flowering shrub, which is very effective during the late summer and autumn months. I may remark that many of the plants produce blue flowers,

about which much controversy has been held, but which to me appears to be entirely owing to the character of the soil in which they are planted. As the Hydrangeas submit to lifting and replanting as freely as a Dahlia root, I see no reason why any one resident, even in the coldest districts, might not have a Hydrangea bed by storing the plants in a cellar during winter, and replanting them in April. They would repay that attention equally as well as many of our ordinary bedding plants.—J. GROOM, *Linton, near Maidstone.*

Beech Trees and Underwood.—I think I quoted "J. S. W." rightly, but it matters little, for he says underwood does not live under the Beech, and I say it does, and thrives just as well as under any other tree. It has, as "J. S. W." says, "the bad reputation for destroying underwood," no doubt. Ten or twelve years ago it was generally thought that nothing would grow under Beech trees here, and I was determined to try, and, I may say, that we have succeeded beyond our expectations in getting Rhododendrons chiefly, Yews, Laurels, &c., to grow in luxuriant masses under them, and I invite "J. S. W.," or any other interested in such matters, to come and see for themselves. We have acres covered with large Beech trees, under which, during the last ten years, thousands of evergreens have been planted, and are still being planted, as time permits. Last year we thinned from other places upwards of 2,000 large Rhododendrons, and planted them on bare spots under Beech trees, and I could show "J. S. W." great masses, that were planted years before in a similar manner, having growth 3 ft. long in one season from suckers from the bottom of these Rhododendrons. It is evident "J. S. W." has not been through the Floors estate for ten years, or, if he has, Beeches and underwood could not have been in his head at the time, or he would have seen for himself huge Beech trees under which the most luxuriant masses of evergreens may be found. I wish to dispel the "bad reputation" the Beech has, and for those similarly situated to plant as we have done here, and they will not be disappointed. I may say that thousands of Rhododendrons have been purchased and planted, chiefly under Beech, on these "bad reputation" spots, which are now the admiration of every one who sees them, for we are on a non-calcareous soil. Of course, in chalky districts and on calcareous soils Rhododendrons would not grow, but I have no doubt Box would thrive, and so would Yew, I believe. On any of our soils Rhododendrons will thrive, and this doubtless accounts for their luxuriant appearance. "J. S. W." corrects a phrase, "planted thickly" for "planted extensively," but planted thickly and not thriving in after years with underwood is as bad and as fatal as the trees themselves planted thickly, or like human beings huddled together in a locality they die of disease and want of nourishment eventually.—H. KNIGHT, *Floors.*

—If any more testimony is wanted to confirm the statements of "J. S. W." respecting this matter let me add mine. Altogether, here and elsewhere, I have seen some hundreds of acres of ground covered with Beech trees, but, as yet, I have never seen any undergrowth under them worth the name.—CAMBERIAN.

—It is said that "there is no rule without an exception," and Alderley Park, Cheshire (p. 571) is certainly the exception this time. Unfortunately, I am too far away from the place, or I would like to see the underwood in question. I have tried repeatedly in a soil where Rhododendrons grow freely to get them to thrive under Beeches, but every attempt has ended in failure. Hence, my astonishment at their growth at Alderley, and more particularly at flowering profusely.—NORTH HANTS.

Pinus insignis and other Conifers.—No doubt *P. insignis* is rather tender, but it ought to be largely planted wherever it will stand, for it is the greenest of all Pines, and also one of the most free-growing and perfect in habit. Our finest specimens of it were killed by the severe winter of 1859-60; but we planted a few more, and they have stood all the severities of the harsh winters and springs of East Anglia ever since, not, however, quite unaided. In very severe weather, a little long straw has been tied on the tips and allowed to hang loosely in long sprays till the weather moderated. This has proved sufficient to save the trees from getting even browned, which, of course, would greatly impair their beauty. Next to this the green variety of *Abies Douglasii* is perhaps our most verdant Conifer. I am pleased to be able to endorse all that "S. D." (p. 484) so forcibly says of the merits of this fine Spruce; also of *Pinus austriaca* and *Picea Nordmanniana* and *P. cephalonica*. *P. Pinsapo* also does remarkably well here; but these Silver Firs are somewhat singular. For instance, there seems little constitutional difference, one would suppose, between such plants as *Picea Nordmanniana*, *P. nobilis*, *P. grandis*, and *P. Webbiana*; and yet, while the first grows here like a weed, the others only consent to live, and *P. Webbiana* hardly that. On visiting other places one finds other varieties thriving well, and such sorts as *P. Pinsapo* and *P. Nordmanniana* stunted and unhealthy. The influences of local climate and soil on

trees are among those matters that require new and fuller investigation. Planters and improvers would also do well to make careful note of the trees and shrubs that do best in any given neighbourhood before proceeding to plant extensively. Locality, after all, often proves the most powerful factor in determining ultimate results.—D. T. FISH.

Robinia pseud-acacia angustifolia elegans is a graceful narrow-leaved variety, very ornamental, and suitable for town or suburban gardens. Its small elegant leaves are almost Fern-like.—G. B.

Aralia spinosa.—This handsome-foliaged shrub or dwarf tree deserves notice on account of its late blooming, and also for retaining its large compound leaves until autumn frosts warn it that winter is approaching. I consider it far superior to its near relation *Dimorphanthus manschuricus*. This latter sheds its leaves a month or six weeks earlier than the former, which is, to my thinking, a faulty property in shrubs or trees that are planted for ornament. What should be encouraged in planting is the selection of plants that bloom late and do not drop their leaves early. Spring and summer flowering shrubs are plentiful enough. *Aralia spinosa* bears its huge panicked inflorescence on the points of its principal shoots of the current season's growth. It is seen to the best advantage on a sloping Grassy bank.—G. B.

Eucalypti the Tallest Trees in the World.—The tallest accurately measured Sequoia (*Wellingtonia*) standing in the Calaveras Grove, California, measures 325 ft., and there is no positive evidence that any trees of this genus ever exceeded that height. Of late years, explorations in Gippsland, Victoria, have brought to light some marvellous specimens of Eucalyptus, and the State Surveyor of Forests measured a fallen tree on the banks of the Watts River, and found it to be 435 ft. from the roots to the top of the trunk. The crest of this tree was broken off, but the trunk at the fracture was 9 ft. in circumference, and the height of the tree when growing was estimated to have been more than 500 ft. This tree, however, was dead, though there is no doubt that it was far loftier than the tallest Sequoia. Near Fernshaw, in the Dandenong district, Victoria, there has recently been discovered a specimen of the Almond Leaf Gum (*Eucalyptus amygdalina*) measuring 350 ft. from the ground to the first branch, and 450 ft. to the topmost twig. This tree would over-top the tallest living Sequoia by 125 ft. Its girth is 80 ft., which is less than that of many Sequoias, but, as far as height is concerned, it must be considered the tallest living tree in the world.—“Scientific American.”

Cedars at Lebanon.—Here I am at last, realising one of the dreams of my boyhood, under the trees that I have always resolved to visit whenever an opportunity should occur. I had made up my mind to be disappointed, but, on the contrary, am agreeably surprised with the Cedar grove. Certainly there is no forest, and amidst lofty mountains, rising around in a magnificent amphitheatre, the grove from a short distance appears but a small plantation, a mere patch in the valley of bare mountain sides; but on nearer approach the grove rapidly assumes larger proportions, and on actually entering the wood and passing under the huge trunks and limbs of these ancient timber trees one realises that it is the remains of a vast forest, and can quite imagine oneself in the depths of widely extended woods. Thousands of seeds from the fallen cones are germinating after the equinoctial thunderstorms, but as fast as they appear above the ground the young plants are devoured by goats and destroyed, otherwise the whole valley might speedily be covered with Cedar trees. I enclose specimen of a young Cedar. I have written an appeal for aid to enclose a space around the Cedars for the propagation of young plants.—“Gardeners' Chronicle.”

The Golden Oak (*Quercus concordia*).—I speak of this Oak, not because there are no other golden Oaks, but because it is golden *par excellence*. Developing leaves somewhat late, and continuing green still later, mid-August arrives before the golden colour in this Oak is fully matured. It forms, consequently, a remarkably fine autumnal tree—one of the trees that brighten up a landscape when foliage generally has commenced to fade. Then, not only is this colour rich in August, but, with a persistency scarcely seen elsewhere, the same colours linger on, and even become intensified during September. Indeed, what the Purple Beech is to June, the Golden Oak is to early autumn; also, like the Purple Beech, its great charm lies in its solid colour. For this reason, as well as for the contrast of colours, certain unnamed varieties of the Purple Beech, that seem to don extra purples in autumn, group with this Oak most effectively. The colour of *Quercus concordia* is a clear gold, which is suffused or spread over the entire leaf, not mingled or variegated with green, like so many golden-leaved plants. In other ways the Golden Oak is quite as satisfactory. Vigorous of growth for an Oak, its leaves are large and enduring in winter as well as in summer. In fact, its reputation must always increase, if the possession of permanent variegation and solid beauty and endurance afford any title to admiration. Unfortunately for its rapid growth into popularity, it belongs to the slow-growing class of Oaks, none of which propagate with readiness and ease, except from seed. As a variegated plant, however, the Golden Oak must be grafted, if its rich colour is to be retained. It will not, therefore, soon be common or sold at the price of Silver Maples.—“Country Gentleman.”

PLATE CLVII.

YELLOW CARNATIONS AND PICOTEEES.

THE perpetual flowering section of Carnations and Picotees rank amongst the most valuable of winter-flowering plants. Who would not be proud of a bouquet of them about Christmas? Indeed, I have proved most conclusively that from a collection of only three or four dozen plants one can have flowers all the year round. Who can name another plant, with the exception of the Rose, of such exquisite beauty and delicate perfume, that will flower so continuously as this? Until very recently we had no yellow ground Picotees worth naming amongst the perpetual flowering kinds, and, indeed, until the advent of Ascot Yellow and Prince of Orange, yellow ground Picotees were not worth growing; hence they remained in obscurity up to the year 1873. Prince of Orange is far in advance even of Ascot Yellow as regards freedom of growth, and is the only one that I have been able to retain in our collection with ordinary care. Its clear yellow, crimson-edged flowers, full and of the largest size, are singularly attractive. In the autumn of 1877, when visiting the Slough Nurseries, Mr. Turner pointed out a batch of 250 seedlings from Prince of Orange which were so promising that both of us expected some startling results, and our most sanguine hopes have been fully realised. Most of the seedlings from this source flowered in 1878, and amongst them are many distinct and handsome varieties. Of these the first selection was exhibited at Regent's Park on July 10. I took the following notes of them at the time:—*Ne Plus Ultra*, a clear yellow flower of large size, petals broad, and edged with reddish scarlet, the ground slightly barred with the same colour. *Sultana*, also a very large full flower of a reddish buff colour flaked with scarlet. *Lady Roseberry*, clear primrose. These received first-class certificates. Others consisted of *Princess Marguerite*, pale yellow, edged and flaked with scarlet. *Dove*, a very large flower, yellow, streaked with scarlet, and *Lightning*, a showy and distinct flower; all good. Subsequently to this, the National Carnation and Picotee Society awarded first-class certificates to *Ophir*, a fine yellow self, and *Lord Beaconsfield*, a kind with well formed flowers of a reddish buff colour, edged with crimson. To these may be added *Eleanor*, primrose, edged and flaked with red. *Henry Tait*, also yellow, with flakes of red, and heavily edged. These, so far, are the cream of the collection, and every one of them ought to be grown.

To have blooms of the best quality in winter, it is necessary to start propagating very early; the small side growths should be slipped off in January; and this applies especially to varieties of the Prince of Orange type, which do not come so early into bloom as the others. Indeed, those raised from pipings about the end of January will not be likely to be in flower until early in the following year. The pots containing the pipings should be plunged in just a little bottom-heat in a forcing pit; they are apt to damp off if covered closely with a handlight or bell-glass, and are not likely to root freely if quite exposed. I usually place a square of glass over them, which arrests evaporation sufficiently to prevent any of them from shrivelling. Future results will depend on the care and skill devoted to their culture. They must be carefully potted off into small pots, keeping them quite close to the glass when they are in a warm house. The best time for repotting them is when the pots are fairly well filled with roots. The soil should be good, friable, turfy loam, and almost any kind of loam will answer, light, medium or heavy, all of which I have tried with success. Add to four parts of the loam one of leaf-mould and one of rotten stable manure, with a little sand. During summer I place the plants out-of-doors in a sunny position, taking care to fasten the main stems, as the plants advance in growth, to suitable supports. About the end of September the pots should be moved into a greenhouse for the winter. It is not unlikely that the leaves may have become affected with green fly, and if so, the plants will not succeed until it is destroyed by fumigating with Tobacco smoke.

The old yellow Picotees are not adapted for borders; rough, wet, and changeable weather in winter would kill most of them. King of the Yellows is one of the best for borders; it is Clove-scented, and is the only pure yellow that has been proved

to succeed out-of-doors under ordinary border treatment. Of other colours we have *Bride*, white; *Mrs. Matthews*, white, very sweet; *Elysian Beauty*, rose; *Princess Alice*, white; *Hindoo*, crimson; *Cremorne*, purple; *Sentinel*, scarlet; *Prince Arthur*, rich dark purple; *Elegant*, *Coroner*, and *Fire-eater*; all of which are hardy and do not require much care.

J. DOUGLAS.

HUNT'S PATENT AUTOMATIC VENTILATOR.

THE importance of a good and economical self-acting ventilator, adapted to horticultural structures, has long been recognised; hence the many attempts which have been made from time to time to construct one, all of which, however, have proved to be practically useless, either because too delicate or too complicated machinery has been employed, or else because the cost of erection has been too great to be consistent with the purpose for which they were intended. I am well aware that self-acting ventilators are generally looked upon with indifference, and are thought to belong rather to fancy than to practical gardening; and after an inspection of the imperfect methods which have hitherto been in use, this is not surprising; but the simplicity and completeness of Mr. Hunt's system will, I venture to think, secure for it a more favourable and lasting impression. This apparatus is no toy; on the contrary, it is likely to prove most useful. In designing it, Mr. Hunt appears to have studied the requirements of cultivators in

Patent Automatic Ventilator.

respect to ventilation most thoroughly, as he can insure the ventilators opening and shutting at any desired temperature, not by a sudden jerk or movement, but in the most gradual, precise, and regular manner, in proportion to the increase or decrease of temperature in the house. For instance, supposing the temperature of the house to be 40° , and he wished the ventilators to open slightly when it reaches 45° , and so to continue to open gradually with the increase of temperature till the desired maximum of, say 65° , is attained, and to close in the same regular manner with the decrease of temperature, so as to shut when the minimum of 45° is again reached, he can not only secure this result, but feel perfectly assured that the process will be repeated in the same gradual, precise, and proportionate manner, as often as any variation of the temperature of the house occurs. He can, moreover, at a moment's notice, simply re-adjust the apparatus so as to secure ventilation at a lower or higher degree, or at any reasonable range of temperature which may be required.

As a large portion of a gardener's time and attention is occupied, in the spring season especially, in regulating ventilators, it will, I think, be readily admitted that if this can be done so correctly (as Mr. Hunt guarantees it can) by his apparatus, it deserves to be favourably received, especially by amateurs, who are often compelled to leave their greenhouses, and Cucumber frames unattended for hours, and too often find on their return, instead of healthy specimens,

scorched leaves and shrivelled fruit. To them it would be a source of pleasure and satisfaction to reflect that in their absence the requirements of their plants and fruits were being duly attended to, with the nicest regularity and precision, by a silent, inexpensive, trustworthy help. I may mention that in the accompanying sketch the apparatus is purposely drawn too large in proportion to the house, in order to make it more easily understood. The principle upon which it acts is by compressed air. It consists of four parts, viz., an air pump, a zinc or cast iron receiver, an india-rubber bellows, and connecting pipe with valve. It is so ingeniously arranged as to make every stroke of the pump, whether in forcing air into, or withdrawing it from the receiver, represent a definite number of degrees of heat, so that as expansion or contraction of the air in the receiver takes place, by the varying temperature of the house, the necessary motive power is obtained for raising the lights. It is most exact and regular, very inexpensive, and comparatively everlasting.

The question of cost will naturally arise, and this, of course, will vary according to the size of the house and other circumstances, but, judging from the simplicity and plainness of the apparatus, I should say it ought to be erected at a price which would induce every one who possesses a greenhouse to adopt it.

T. CHALLIS.

Wilton House, Salisbury.

GARDENING FOR THE WEEK.

Indoor Plant Department.

Lachenalias.—The earliest potted bulbs of these ought now to be showing bloom, and in order to have the stems of these sufficiently firm to stand erect without support, they should be placed on shelves in cold pits or frames close up to the glass; or, better still, plunged in cinder ashes, as then their roots are kept in a more uniform state of moisture. Any attempt at forcing *Lachenalias* is sure to end in failure and disappointment, as the slightest artificial heat, unless attended with an abundance of fresh air, draws them up and gives them a very weedy appearance. The best way of getting them into bloom early is to start a part of the stock immediately after they have had a fair rest, and let them come slowly and naturally on in any cold frame till they begin to show flower, when they can at once be removed to the greenhouse, where they will then last a long time in perfection. *Lachenalias* seldom get anything like a sufficient supply of water, and, like most other bulbous-rooted plants, get ripened off much too quickly, the effect of which is to sadly diminish their blooming capacity. If properly drained, water can scarcely be given them too frequently after the flower stems make their appearance, and up to the time when they begin to die away, after which the soil should be kept in a healthy, moist state till the leaves show symptoms of ripening, when they may be slowly and gradually dried off. As the pots will now be well filled with roots, liquid manure will be of the greatest assistance to them, and this should be continued at alternate waterings till they have ceased blooming.

Ixias, Sparaxis, Babianas, &c.—For pot cultivation there are few bulbous plants more beautiful or generally useful than *Ixias*, *Sparaxis*, and *Babianas*, all of which are alike valuable either for greenhouse decoration or supplying cut flowers. Although perfectly distinct in appearance, they require the same treatment, and should be potted in rich, sandy soil, and kept close under cover of a cold frame or pit plunged in coal ashes, where all the attention they require till they get into leaf is to preserve them from frost and vermin; 6-in. pots are quite large enough for them, and in these from six to twelve bulbs should be planted, according to the strength and size of the different varieties. If the soil be in a moderately moist condition as it should be at the time of potting, no water will be required till they have started well into growth, and even then it must be given but sparingly. All the above are nearly hardy, and any small bulbs there may be on hand can be planted on dry, sunny borders, in light, sandy soil, close under walls, and will be found most useful for cutting after those in pots in the greenhouse are over.

Bedding Plants.—Tubers of *Dahlias* and bulbs of *Gladioli*, &c., should be stored in convenient places beyond the reach of frost; and this should also be carefully excluded from structures containing bedding plants, which should always, if well rooted, be kept as cool and quiet as possible, as it is by no means advisable to encourage growth in the absence of light and air. Nothing, however, is so inimical to bedding plants at the present season as damp; every possible care, therefore, must be taken to prevent, as far as this can be done, drip

from the roofs of such houses or pits which may contain them. All dead and decaying leaves, &c., must be removed whenever necessary, and every opportunity taken which the state of the weather may afford to admit fresh air, to render the plants as hardy as possible. There may also be found leisure now to take a rough estimate of the stock on hand of the various kinds of plants required for the ensuing season, and this should be compared with the list of requirements, which should have been made during the last summer or autumn; and whenever a deficiency is shown, a preparation for increasing such varieties should be made early during the ensuing year. But little, if any, advantage is likely to be gained by attempting to propagate bedding plants during the dull dark days of mid-winter. During dry or frosty weather, get, as soon as possible, a fertilising compost prepared, ready to be applied to the flower beds and borders as soon as the spring-flowering plants and bulbs are removed. It is necessary to enrich as much as possible the soil of such beds, to enable them to successfully produce two crops during each season; and it should also be borne in mind that many kinds of summer bedding plants are exceedingly gross feeders. This compost should be frequently turned during frosty weather; frost is of itself a powerful fertiliser, and fresh surfaces can hardly be too frequently exposed to its action.

Winter-resting Orchids.—There are few matters connected with the cultivation of Orchids in which beginners in their growth are more liable to make mistakes than in their treatment when at rest. Even those who have had lengthened practice in the culture of Orchids, are continually experiencing difficulties in this respect through the influx of new species from different altitudes, and that grow naturally under conditions more or less different from those of the greater portion of the kinds in cultivation. The limited number of houses, or divisions of houses, that are at the disposal of most growers, which enable them to vary the temperature and regulate the state of the atmosphere, are far from being proportionate to the widely different conditions as respect warmth and moisture that the plants are found to exist in naturally during their season of rest; consequently it entails the necessity of giving what I may term a compromising sort of treatment as to both temperature and the state of the atmosphere in regard to moisture, to which the plants are perforce obliged to be made to submit, in the various compartments at command for their cultivation. To stop growth in such kinds as naturally rest during our winters, it is not only necessary to lower the temperature, but also to withhold moisture to a considerable extent from the atmosphere, and likewise to keep them more or less dry at the root, for, independent of the necessity, in the case of many species, for a prolonged rest to insure their flowering, it is requisite to take the means for securing such to maintain their proper period of growth, otherwise they would commence so far before their time, that the development of the season's growth would be completed whilst yet the weather was hot and the days long, thereby rendering it a difficult matter to submit them to the treatment essential to the cessation of growth that accompanies the resting process. Hence the obligation of withholding water from the roots, and it is on this point principally that a very considerable amount of knowledge and experience is required to vary this drying condition of the roots so as to meet the needs of the different families and individual species of families, for if we take, for instance, even a very limited number of the plants usually found occupying either the warmest or intermediate temperatures devoted to Orchids, it is found necessary to vary the drying conditions to which the roots are subjected in a marked degree, otherwise almost irreparable injury would be the result. I have often found an impression existing in the minds of many who have had some practice in the cultivation of Orchids, that a severe drying-up process was almost universally necessary to induce them to flower, than which no greater mistake can be committed, and I will here remark, as I have frequently done before when touching on this subject, that in all the different species of Orchids that require to be kept for a time, during their season of rest, dry at the root, their ability to benefit by this will not alone depend upon what they are subjected to in their native countries, but quite as much upon the condition under which they have been grown, not only during the last, but preceding seasons; for, according to the solidity and robust stout-textured state of the leaves and pseudo-bulbs, especially the leaves of such as are evergreen, will they bear any lengthened drying up of the roots without shrivelling to an extent that will cause premature destruction to a greater or less degree of the leaves.

—T. BAINES.

Flower Garden.

Planting new Hedges with various Materials.—The present is a good time for preparing the ground, and planting Beech, Privet, or Quick, and where such work has to be done no time should be lost in carrying it out. In the case of Holly, Yew, or any other evergreen, the planting should either have been done earlier in the

autumn, or had better be deferred until spring. In the formation of a hedge, it frequently becomes a question of what to plant. There is nothing equal in appearance to green Holly, nor is there anything that makes a more impervious fence when it gets sufficiently large, if the land be dry, either naturally or made so by draining; even if of a poor sandy character, if plentifully manured, Holly will grow fast after the first or second year, when it has made plenty of roots and got established; White Thorn or Quick stands next in point of merit, where afforded similar treatment as to a dry bed and plenty of manure, but it does not make so much progress if the soil be too sandy. Beech will succeed in almost any place where there is no stagnant water, or the opposite extreme of being excessively dry; the worst of Beech in a garden is it causes a continual litter for some weeks in the spring, as when kept cut it does not shed its leaves in the autumn, although for shelter this is an advantage. For screens or divisional hedges such as those already alluded to, there are many plants that may be used; where an evergreen to grow up quickly is required, nothing surpasses the oval-leaved Privet (*Ligustrum ovalifolium*); it will grow doubly as fast as the old variety, and is stout enough to support itself against the strongest winds when allowed to grow to a height of 8 ft. or 9 ft., and kept cut into not more than 2½ ft. through at the base; whereas, the ordinary Privet would be useless so treated, unless some strong-growing plant, like Quick or Beech, were planted with it. The objection to common Privet is, that when used mixed, as at one time was customary, in winter one part of the hedge is green whilst the other is naked; but, for appearance, in screens of this kind Holly again has no equal. American or Chinese Arbor-vitæ, *Cupressus Lawsoniana*, and other kindred plants, make a screen at once, but have the fault of getting bare in time, unless allowed to extend to greater breadth than is often consistent with the purposes for which they are wanted. In all localities where they will grow freely, and can be permitted to attain a considerable breadth, and where there is no particular hurry in getting them to a good height in a short time, *Rhododendrons* are very suitable, and always look well; there are now almost unlimited quantities of seedlings little inferior for general effect to the named varieties that can be had cheap, and when in flower make a good display. Where not wanted to grow above 5 ft. in height, *Pyrus japonica* makes a good hedge, but it should not be trimmed in too closely; it is very effective when in bloom, especially if the blush and the crimson varieties be planted alternately.

Hardy Fruit.

Figs, except in the most favoured southern and western counties, or near the coast, should be lousened from the walls, the branches carefully drawn together with a piece of strong cord or stout straw ropes, and the whole covered with clean straw, encircling the branches thus bound together 5 in. or 6 in. in thickness, commencing near the bottom of the trees. Straw thus put on will not only protect from frost the young fruits that are formed, but will likewise throw off rain, for, should it become wet through to the branches, and afterwards get severely frozen, the trees would be in a worse condition than if no protecting material was used at all. To prevent the rain thus penetrating the straw to a depth that will do harm, the branches, when the covering is completed, should be placed in nearly an upright position. There are several advantages in getting pruning done early, especially in the case of such fruits as are grown on walls, the first of which is, that when completed it gives an opportunity for preparing the soil for whatever vegetable crops are grown on the borders. But, in digging the ground occupied by the roots of good fruitful trees, the fact should never be lost sight of, that the fruit should be the principal consideration, and that there should be no interference with the roots so as to injure them; for this reason the spade ought never to be used in digging fruit-borders; but the work should invariably be done with a fork instead, and even this should be used so as not to cause injury, especially to the small feeding roots that, in the case of trees in a good condition, usually lie near the surface. Where it is the intention to plant or remove Gooseberries and Currants the sooner such work is done now the better if the weather be mild, but do not plant anything when the ground is erusted with frost, as in the operation the frozen soil gets in contact with the roots, which is by no means calculated to benefit them; the ground should be well dug before it is planted, even if it has been under vegetable crops before. These fruits (except Black Currants, which like shade) are best grown on good open ground; they will, however, succeed between Apple and Pear trees, if the latter are not planted too closely. In such situations they frequently bear well when the crop in more open places gets cut off by spring frosts; the ground round these, and any trees that are newly planted, should be mulched as far as their roots extend with half-rotten manure. Raspberries should also be planted; for this fruit the ground should be well

enriched by digging into it a good dressing of manure previous to planting; existing plantations of this fruit should be pruned and tied, and, where stakes are used, renewing such as are decayed; few crops require or will better pay for a liberal use of manure than Raspberries. Even old plantations of them that have become weak can frequently be brought round by enriching the ground and otherwise bestowing on them judicious cultivation. One of the principal things to be observed in the case of the Raspberry is never to use a spade amongst them; the greater portion of the roots lie near the surface, and if the spade be employed in digging quantities of them necessarily get injured; even fork culture should not be too deep. Strawberries should now be cleared of runners and the ground should be slightly forked over; these, like Raspberries, are surface rooters, and should never have the spade used among them. If the beds are getting old and the ground poor a dressing of manure may be forked in.

Kitchen Garden.

Vegetable Forcing.—Sow successions of French Beans once every six weeks in 8-in. pots half filled with rich soil, and keep them in the Pinery, early Vinery, or other forcing house at work. Earth up the plants before they come into flower, and syringe occasionally to keep them clean from red spider. Sow Mustard and Cress every week or ten days, as required, in any house having a temperature above 45°. Keep up a succession of Chervil by wintering some roots in pots or boxes in any of the forcing houses.

Endive, Lettuce, and Cauliflower.—Plants of these in frames and under handlights or cloches should now be well attended to, giving them plenty of air when the weather is mild, but guarding against their getting wet, as they are less likely to suffer from severe frost, when the soil in which they are growing is dry on the surface, than they otherwise would be. When frozen those in frames should have a mat thrown over the glass when the sun comes upon it, as the effects of being suddenly thawed are most disastrous. Handlights and cloches ought to be similarly protected on the south side by means of litter or evergreen branches stuck in the soil so as to screen the plants. Cauliflowers and Lettuces at the foot of south walls may be protected by placing boards before them in a slanting position, propped up so as not to allow them to touch the plants. Endive covered with boards for blanching should, during frosty weather, be completely covered over with several inches of litter, for, if frozen, it will decay. The boards previously recommended to be used in this way will be found much better than slates or tiles, both of which are sometimes employed for blanching it, as wood, being a non-conductor, will ward off frost when tiles or slates would admit it to spoil the Endive.

Protecting Celery.—Care should be taken that Celery is not subjected to much frost, or it will not keep so long, however firm and solid the variety may be; for covering material use Pea haulm, which, if put under cover when pulled up and kept dry until required, is very useful for such protecting purposes; if in a neighbourhood where it is plentiful, the common Brake is a good material, if not, stable litter may be used; but whatever is employed will be found much more effectual if not in absolute contact with the tops of the Celery. To prevent this, take some stout pieces of old Pea sticks and push them down in the rows betwixt the plants, then take some of the longest and straightest of the Pea sticks, or such as have been used for Runner Beans, and tie them lengthways to the upright stick, a few inches above the tops of the Celery; on these place the litter or other material, letting it hang well over the sides like thatch; this will be the best way of protecting it from frost, and costs little more in additional labour than simply placing the material upon the tops of the Celery. Winter and spring Broccoli is frequently saved from being killed in severe frosts by the slight protection afforded by laying old Pea sticks down moderately close upon them, as these break the full force of the cutting frosty wind. During severe frosts, or when there is an appearance of snow, cover Parsley with shutters or boards, if no frames are at hand, not allowing the covering material to absolutely touch it.

Extracts from my Diary.

December 30.—Covering up Vine borders with long litter, using just sufficient to keep out frost. Planting border with Early Mazagan Beans. Pruning Mrs. Pince Vines. Turning over leaves and long manure for making hotbeds. Cutting all the Lady Downes Grapes with about 6 in. or 8 in. of wood attached to the bunches and putting them in bottles in the Grape room.

Dec. 31.—Sowing four rows of Sutton's Ringleader, four rows of William the First, one row of Dr. Hogg, and one row of Unique Peas. Preparing pit for Ash-leaved Kidney Potatoes, and turning out a crop that had been brought forward in pots. Washing the paint in

one of the Vineries with soft soap and hot water. Glon Morcean, No Plus Meuris, and Easter Bearré Pears now plentiful and good.

January 1.—Potting off Tomato cuttings. Getting Strawberries plunged in leaves to start them. Tying pot Vines which have broken satisfactorily up to the wires. Spawning a new Mushroom bed and moulding it over 2 in. thick. Getting on with digging and trenching as fast as the weather will permit. Turning over a large heap of manure to rot, adding 20 lb. of salt and one bushel of soot to the load.

Jan. 2.—Sowing Cucumber and Melon seeds. Painting the Vines in one of the houses with composition and tying up the Vines, afterwards forking over the surface of the border lightly and giving it a little top-dressing. Looking over the Grapes in bottles, removing any bad berries, and filling up the bottles where required with water.

Jan. 3.—Getting 100 pots of French Beans in and earthing up a more forward lot; also a few pots of Potatoes. Covering up Endive and Lettuces to blanch. Getting manure on to the land whenever the weather is dry. Filling another four-light pit with leaves in which to plunge Strawberries.

Jan. 4.—Putting in cuttings of Chrysanthemums. Getting on with the pruning and nailing of Pears and Plums on walls. Manuring and forking the ground amongst Gooseberries and Currants. Emptying a four-light pit and refilling it with leaves and manure for early Melons. Examining fruit room, and removing any fruits that are beginning to rot. Cleaning kitchen garden walks. Fruit in use for dessert.—Pines, Grapes, Pears, Apples, and Nuts.—W. G. P., Dorset.

THE LIBRARY.

THE WILD SPORTS AND NATURAL HISTORY OF THE HIGHLANDS.*

Wild sports and wilder country are not within the ordinary range of our commentary, but the work above named is of a merit so exceptional and a charm so rare that we cannot forbear to say a few words in its praise. Depending solely upon its attraction as a book, it had already passed through several editions before the happy thought of calling the pencil to the aid of the pen came to the mind of its publisher. A more artistic rendering of the scenes and incidents which the author describes the pen could not well achieve; while the life-like portraits of the wild creatures, the pursuit of which has led Mr. St. John through so many untrodden scenes of grandeur and beauty, are veritable triumphs of the pencil—a pencil guided by no unpractised hand. The engravings are the most delicate that we have seen for many a day. All who care about books would rejoice at the thought of such engraving being always available for the illustration of good books. Unhappily, of late years, our book engraving has been generally far from being either "fine" or artistic. The book is beautifully printed by Clarke, of Edinburgh, and is in all ways such as one expects from Albermarle Street.

LOVERS of Orchids will be glad to know that the figures of Orchids prepared for the "Requiem Botanicum" will be published after a long delay. Indeed, one part, constituting Part II. of the second volume of the work named, has recently appeared, and contains figures of twenty-four new or little known species. Of course they can hardly be called new now, as most of them were drawn from living plants several years ago. Part I. of this volume, also wholly devoted to Orchids, as the complete volume will be, appeared in 1869, and the third and concluding part is promised shortly. The majority of the species represented in the part before us are what, for want of a more expressive phrase, is termed of botanical interest only, having small and inconspicuous flowers, although *Trihopilia rostrata*, *Lycaste leucantha*, *Maxillaria nivalis*, *Zygopetalum rostratum*, *Chondrorhyncha fimbriata*, and *Stanhopea platyceras* are attractive and ornamental Orchids.

Something to Look Forward to!—The Countess of Strathbrooke, in a recent number of "Vanity Fair," in discussing the affairs of the agricultural labourer, writes as follows:—"If every man who had passed an honest and good life in his parish, and had not received relief in his youth, on arriving at the age of three score and ten years, should receive without doubt or hesitation, as his right, a sort of pension, two shillings a week and a stone of flour weekly, in recognition of his past labours, for the rest of his life, the labourer would be a happy man."

* "The Wild Sports and Natural History of the Highlands." By Charles St. John. London: John Murray, 1873.

THE FRUIT GARDEN.

FIGS AND FIG CULTURE.

WITHIN the last twenty-five years there has been a great extension of Fig culture in gardens under glass, for it is only in favourable localities in the south that the Fig can be grown out-of-doors. Its culture is, however, far from being so common or so well understood as either the Vine or the Peach, though, as a dessert fruit, the Fig will certainly bear comparison with the Peach; besides, it is a more wholesome fruit, and is much appreciated as dessert. Had it been cultivated more extensively, we should, in all probability, have had a greater number of varieties to choose from. As it is, the list is a meagre one—that is, of sorts known and cultivated with us. A few new sorts have been added within recent years, but, with these exceptions, the choice is hardly more extensive than it was when London wrote about fifty years ago. We rather suspect there are good varieties here and there in the country which are not generally known to cultivators. It is not so many years ago since the Ruby Castle Fig was introduced to public notice; and it is a good, most prolific, and large variety, well adapted for forcing, bearing two or three crops in the season even more readily than the Brown Turkey. Then there is the Castle Kennedy, which is doubtless an old variety under a new name, as I do not think Mr. Fowler claims to give the history of it farther than that he found it at Castle Kennedy when he went there; yet it was quite new to Fig growers in this country when it was sent out about twenty years ago, or less. There need to be a Fig grown—and it is grown yet, for anything we know—at Clumber, the Duke of Newcastle's, of the most delicious flavour we ever tasted, and also of good size. It was shown to us by Mr. Tegg when he was there, but was unfamiliar to us, and we know most of those in cultivation. The varieties recently added to our lists are Pugnassata, Royal Vineyard, Grizzly Boarjassotte, Negro Largo, and Osborn's Prolific. The first and third sorts named are moderate bearers, and the fruit of medium size and excellent flavour. Grizzly Boarjassotte is much superior to the Brown Turkey in the last respect. Of the Royal Vineyard we cannot speak from experience. The Negro Largo promises, however, to be a very strong-growing and fruitful variety. We notice that young plants of it here, only potted in spring and not restricted at the root, are showing fruit freely. The plant is quite as strong a grower as the Castle Kennedy, and produces very large leaves—two certain signs of fruit, for which the Negro Largo has a reputation. We are assured by Messrs. Veitch that it is an excellent sort for pot culture. Among other varieties hardly known in this country, otherwise than by description as large and good, are the Black Genoa, Black Bourjassotte, Bordeaux, Large White Genoa—the description of which might stand for the Castle Kennedy—Violette Grosse, and the three Argenteuil sorts, Black Dauphine, Dauphine d'Argenteuil, and Violette Dauphine. Of course every Fig grower knows the Brown Turkey and the Brunewick. Without going particularly into the culture of the Fig here, we would just observe that we do not consider the pot and pinching system the way to secure the best results. It is no doubt the best plan in small houses or pits, or under early forcing; but large and fine fruit, or great and certain crops, can only be had from trees that are grown out freely, and from which one or at most two crops only are taken in the season. Many sorts, indeed, like the Castle Kennedy, will not submit to pot culture. They are almost barren under treatment that the Brown Turkey will bear with impunity, but will bear well if allowed to develop their branches naturally. We have known the Castle Kennedy to do grandly in an orchard house where it was planted out to grow in tree form. We should imagine that in large and lofty houses no one need have any difficulty in having plenty of Figs of good size and quality who will take a little care to keep the roots of the trees within bounds, and do no more to the tops in the way of pruning than thinning the branches out where too crowded.—“Field.”

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

A Few Good Apples.—This being a good time for planting, a select list of Apples that produce the best crops may not be unacceptable. Of dessert kinds we have had good crops of King of the Pippins, Ribston Pippin, Cox's Orange Pippin, Barcelona Pearmain, Golden Knob, Sturmer Pippin, Court of Wick, Blenheim Orange, Ashmead's Kernel, Gravenstein, Soarlet Nonpareil, Kerry Pippin, Court Pendu Plat, and Reinette du Canada. Of kitchen Apples our heaviest croppers have been Keswick Codlin, Cellini, Lord Suffield, Stone Apple or Loddington Seedling, Cox's Pomona, New Hawthornden, Winter Queening, Wellington, Beauty of Kent, Norfolk Beefing,

Graham's Pyle Russet, Northern Greening, and French Crab. I may remark that Apple trees attain a great size in this neighbourhood, and that the majority of them are standards, which, in some cases, are alternated with closely-pruned, bush-trained trees. Fancy kinds of training and fancy sorts are not much sought after. The Loddington Seedling, or Stone Apple, has only recently been brought prominently into notice hereabouts, its unfailing crops and the ready sale that its fruit commands having made it a favourite. The original trees in an adjoining orchard have been celebrated for their produce for years. The Wellington is also thought highly of here, and the beautiful dessert Apple Golden Knob is a gem amongst Kentish Apples, lasting as it does in good condition until quite late in the spring.—J. G., *Linton, near Maidstone.*

The Black Hamburg as a Late Grape.—Mr. Clayton (p. 558) attributes Mr. Stevens' success in growing the Black Hamburg as a late Grape to the fact of the soil being on the red sandstone. At the time when the statement was made, I had 300 Bunches of Black Hamburg still on the Vines in perfect condition. They were grown in an orchard house without heat. The Vines which produced them are planted in the natural soil of the district, which, like Trentham, must be favourable to the Black Hamburg, *i.e.*, if Mr. Clayton be right in his supposition that the soil is the chief agent in the matter.—G. A. PASSINGHAM, *Milton, Cambridge.*

Permanent Copings and Insects on Wall Trees.—My experience is decidedly against the use of any kind of permanent coping for wall trees, as I find that trees planted under an overhanging roof of any kind, are very liable to the attacks of scale and similar pests, the presence of which more than outweighs the advantage derived from the protection given to the trees during the flowering season.—J. G.

Keeping Grapes.—I have to-day (December 21), filled our Grape room, and regret that it is not larger that we might harvest all, as, from past experience, I believe they keep best when out thus early. Some two or three years ago circumstances over which I had no control prevented their being harvested till the sap had become active, and the consequence was that as soon as they were put in water many of the berries cracked, and the whole kept very badly. Last year they were out about this date, and we had Lady Downes plump and fresh in the month of June.—W. WILDSMITH, *Heckfield.*

Robert's Variety of Gros Guillaume Grape.—In a circular which I have received, it is asserted that the Gros Guillaume Grape growing at Charleville is a distinct variety from that generally cultivated. Being rather sceptical on this point, I, in common with many of the readers of THE GARDEN, would like to know the origin of the Charleville variety. This the authors of the circular ought to have given, for if it really can be proved to be a distinct kind, it will doubtless be advantageous to them.—W. W.

Preserving Soft Fruit.—The following will be found to be a good way of preserving such fruits as Gooseberries, Cherries, Currants, Plums, Apricots, Damsons, and Peaches:—After filling the bottles with fruit, place them in a fish kettle in cold water, packed closely with soft hay to prevent them from shifting. After the fruit is cooked, take them out, fill them with boiling water and cork them at once, but not permanently; let them stand till cold, then uncork and fill up with salad oil; then cork and tie down tightly, and seal them closely. Treated in this way, the fruit will keep for years; in fact, I have known a Melon to have been over twenty years in the bottle, and taken out fresh. I may mention that the coarse wax should be used; have it boiling in a pan, and dip the bottles in till the corks are covered, which will take or three dipings at least. But, to be thoroughly successful, the fruit ought to be in the best possible condition, thoroughly sound, and only use one sort in a bottle; for instance, if two or more sorts of Gooseberries are used in one bottle they never keep satisfactorily.—“Journal of Horticulture.”

A Fruit Lesson.—By the thoughtful courtesy of Mr. C. Downing (and the consent of the writer) we are permitted to print the following interesting and suggestive paragraphs of a private letter to Mr. Downing from Mr. J. L. Moultrie, Union Springs: “As you are a lover of good fruit, you will excuse my egotism in giving a few items of personal experience. The opinion was generally entertained by the people here that this locality was unsuited for the successful production of good fruit. My belief was that all that was necessary was to procure such varieties as were adapted to the soil and climate; so I planted the Taunton, Horse Apple, and a few other kinds, and of Pears the Bartlett, Duchesse d'Angoulême, &c., just inside the fence on the public highway. I did not expect these trees to benefit me, for I knew that travellers would pull the fruit. The result was as I expected—the sight of these trees laden with the handsome fruit had more influence in making my neighbours plant for themselves than all I could have written in ten years.—“New York Tribune.”

ICE HOUSES.

FIG. 1 represents an ice house belonging to Mr. D. G. Mitchell, made picturesque by the roof and ends being of rough slabs. The main part of the ice room is below the surface of the ground, and it may be constructed of stones or timber. An ice house like this, or even one of greater pretensions, may have its appearance improved by the free use of climbers; these answer not only as an embellishment, but serve a useful end in breaking the force of the sun's rays and keeping the building much cooler than it would be under full exposure.

Fig. 1.—Rustic Ice House:

Fig. 2 illustrates an ice house that can be quickly erected at a very slight outlay for materials, and at the cost of only a few hours' labour. The size is determined by the length of the planks or boards to be used. Nine posts, rough sawn or hewn, of suitable height are provided, and two put up at each corner, as in fig. 2, resting upon a block of wood or a stone, or set in the ground. At one side of the front the ninth post is placed to serve as one side of the door, the bottom planks all around are nailed to the posts, which may be more firmly secured in place by cleats connecting those at each corner; the front posts are 1 ft. or so longer than the others to permit of a shed roof. A plate of light scantling secures the top in its place. Now it is ready for the ice. First, put on the ground a layer of sawdust, shavings, or cut hay, so that it will be at least 6 in. deep when firmly packed down. Then put in the first tier of ice, keeping the blocks 1 ft. away from the plank wall; fill the space solidly with the sawdust or other packing material (a fig. 3); then the second tier of ice. Next put in position more planks and so on, until the house is filled,

Fig. 2.—Cheap Ice House.

storing the ice and carrying up the wall together, and filling in between with sawdust, &c., as the work progresses. The planks need only be slightly nailed to keep them up when the ice is removed, as they will be held in position by the posts without and the pressure from within. A door (b) is made by simply using two lengths of plank on the front side, as indicated by the posts in fig. 3. When the house is full a thick layer of the packing material is also put on top of the ice. Drainage is secured by placing the structure on sloping ground. A roof of slabs, thatch, or anything to keep out rain is sufficient.—“American Agriculturist.”

— The simplest and readiest made forms of ice houses are square, beginning small at the bottom and gradually increasing in size to the

top where the spring of the arch commences. One of the size of from 6 ft. to 8 ft. at the bottom to 12 ft. or so above, and 14 ft. or 15 ft. deep would, if the ice be well stored and properly broken, afford an ample supply for any ordinary establishment. Ice houses are usually made egg-shaped, with the small end downwards, but there is no particular advantage in that form, and one thing against such houses is that they are more difficult and expensive to make. A square answers all purposes equally well, if made in the way just named, as all that is required is that the ice as it melts can gradually sink and press tightly against the lining of straw provided as a packing to keep away the air. If the situation where the house is to be built be wet, the bricks should be bedded in cement to prevent any drainage from the land getting through the joints; and, to take away the water that flows from the melting ice, an efficient drain must be provided leading to the bottom in such a way that no air can pass in, or it will cause much waste. In forming an ice house the great thing is to keep as much of it below the general level as the nature of the ground will admit, for this reason, when carting and storing the ice there is not a tithe of the labour required to get it in in a well-like receptacle as there is when it has to be lifted and thrown up with shovels. To aid the filling, the passage communicating with the house should be made to slope inwards, along which the ice will slide with a push, and its own impetus and weight will cause it to run together in a solid mass, if well broken at the time of filling. I always find this is much better and more quickly done as it is thrown into the carts; by doing so, each holds more, and in that way a saving is effected. From 2 ft. to 3 ft. of earth on the top of the arch is quite sufficient to keep out the heat and support common Laurel or evergreen Oak, either of which forms a dense shade;

Fig. 3.—Ground Plan of Fig. 2.

but if, in addition to these a few Firs or other tall-growing trees be planted on the sunny side, or the house made so as to have the shelter of some already established, it will be all the better. S. D.

Russia Grass.—This Grass has of late become so popular for garden uses that the demand for it greatly exceeds the supply, and it has risen in price from about 8s. to 2s. per lb. On its first introduction there were great prejudices displayed against it; but its many excellences—softness of texture, toughness, adaptability for the finest work, and absence of waste—made its use universal, and hence its present high price. Immense demands have been made upon it for the tying of Violets, Wallflowers, and other bunch market flowers, but if its cost increases so rapidly market growers will have again to revert to the Russian bast mats. It is somewhat singular that through all the many years that Russian mats have been used and cut up for tying purposes it should not have occurred to any one to import the bast in its ordinary form in quantity.—A. D.

The Weather in Nottinghamshire.—The frost during the past week has been at times very severe. On the 12th we had 15° of frost, and on the 15th 19° were registered here. Severe frost also still continues; this morning (the 23rd) 12° were registered, with the barometer rising, so that it is likely to continue. We have a long south wall here, protected with Rendle's new system of glazing, and the severe frost of the last week or two seems to have had no effect, through contraction, of causing any breakage in the panes. I believe it will be found in hothouses, or in glass-covered walls, glazed on this system, that the glass is quite safe from the contraction or expansion of the rafters, if of iron, in all kind of weathers. Another great advantage is the freedom from drip, if the squares are properly placed and fastened according to the directions of the patentee. In the strongest gales of wind the glass-covered wall here has stood their fury without any of the panes being shifted.—W. TILLERY, *Wellbeck.*

ANSWERS TO CORRESPONDENTS.

Stocks for Vines.—"M. J. B." (p. 573) may graft Alicantes on Lady Downes without any fear of unsatisfactory results. I grafted a house of Lady Downes with Alicantes five years ago, and, on comparing its contents with those of another house of Alicantes on their own roots, I find that those grafted on the Lady Downes are fully the best.—J. SMITH, *Waterdale*.

Winter Coverings for Ferns.—I would recommend "A. H. M." (p. 573) to use Cocoa-nut fibre refuse in lieu of sawdust for covering his Ferns; the latter soon gets sodden and generates fungi, but the former never, and it is equally efficient as a protector.—W. W.

Ferns Suitable for a Cool Conservatory.—It is very evident from the description Mr. Champ now gives (p. 550) of his conservatory, and the space he has in it, that many of the Ferns, the names of which I gave, would be unsuited to his purpose. I now give an amended list of varieties, none of which will, I think, grow too large for him, viz., *Cyrtium falcatum*, *Lomaria chilensis*, *L. magellanica*, *Asplenium oxyphyllum*, *A. lucidum*, *Davallia canariensis*, *D. novæ-zeelandiæ*, *Lastrea opaca*, *L. Standishi*, *Oncidium lucidum*, *Phlebotidium Bellardieri*, *P. areolatum*, *Polystichum flexum*, *Pteris cretica alba-lineata*, and *Platynerium alciorne*. The above are all fine distinct kinds, that will stand the temperature of an unheated structure well, and always have a bright cheerful-looking appearance.—S. D.

—*Phymatodes vulgaris*, a handsome Fern with dark green leathery fronds succeeds remarkably well in a cold greenhouse. Being somewhat slow in growth, it is suited to a small house.—K. L. D., *Ashmore*.

Leaf Cuttings of Tuberos-rooted Begonias.—In reply to "T. B." (p. 573), allow me to say that the method which I adopt in preparing leaf cuttings of these Begonias is not, as he supposes, cutting off the leafstalk with an eye at the base, but simply leaving about two-thirds of the stalk adhering to the leaf, and inserting the same in the soil, leaving the whole of the leaf exposed on the surface. As regards his second query, will they not be worthless for another year? I beg to remind him that the two cases from which he draws his conclusions are different. Cuttings made from flowering shoots generally produce blind tubers, but not always, while leaf cuttings form not only a tuber, but eyes, a fact which I have proved, and I have no hesitation in recommending "T. B." to give the method a fair trial.—A. HOSSACK.

Calanthes in Small Pans.—In THE GARDEN (p. 410), the advantage of growing *Calanthes* in small pans is alluded to. As everyone interested in the growth of Orchids will be anxious to carry out any plan proved to be successful by such highly skilful growers as Messrs. Veitch, perhaps you will say how many bulbs should be put in a 5-in. pan, whether or not the usual compost is used, whether little or any drainage is put in so shallow a pan as 1½ in., and whether the strong-growing *C. Veitchii* will succeed in a pan as well as *C. vestita*? As *Pleiones* are also surface-rooting plants, would not the same plan answer for them?—C. B. P. [The *Calanthes* in question are placed in the pans in March and started into growth. They are kept near the glass and receive abundance of water all through the growing season. A little piece of hollow crock is placed on each of the four holes in the bottom of the pan, which is filled with turfy loam, peat, broken crocks, and silver sand. All kinds of *Calanthes* do equally well under these conditions. Messrs. Veitch also grow *Dendrobium*, *Sophranitis grandiflora*, Indian *Crocuses* (*Pleiones*), and many other surface-rooting Orchids in this way with the greatest success.—S.]

Binding Compositions (p. 550).—No mixture of chalk and sand, or any other materials of that nature, are of any use to form a perpendicular bank 8 ft. or 10 ft. high, for, however well and firmly they may be compressed together, they are sure to crumble down from the action of the weather. If your correspondent resides in the neighbourhood of large ironworks or a dockyard, he will be able to obtain plenty of clinkers or huge hurrs for the carting, and these roughly cemented together, with cavities left between so as to admit of planting Ferns, if the face of the bank is shady, might be made exceedingly ornamental. With a southern or any other aspect hosts of things would be just at home, especially any of a succulent nature, such as *Mesembryanthemum*, *Portulacas*, and others of that class, that would droop over the rock and be quite a blaze of bloom in the sun. *Tropæolum*, too, Ivy-leaved *Pelargonium*, the lovely trailing *Lithospermum prostratum*, *Sedum*, *Daphne Cneorum*, *Ambretias*, *Vitadenia triloba*, and others of a similar character, would be quite a feature, and associate well with the foregoing. To give any, or the whole, of these a better chance of getting sufficient moisture, instead of the bank being perpendicular it should gradually fall back from the bottom, so that any rain that falls may soak into the soil for the benefit of the plants. If the bank is wanted as a barrier against cattle or as a boundary, and its ornamental appearance is not a consideration, the next cheapest thing to do with it is to form a concrete facing 1 ft. or so thick, which, if well done, is equal to a brick wall for durability, and answers all purposes as a means of protection. Small stones, sifted free from gravel, are the best material to make it of, and if these are mixed with about one-tenth of their bulk with good Portland cement, and gradually sprinkled with water while doing so, the mass will set as hard as a rock. The proper way to make a wall with this material is to have stout, smooth planks that can be bolted together so as to leave a cavity between the width the concrete is wanted, into which cavity it should be thrown in quickly that the whole may set together at one time without showing a

joint. So strong and durable are walls made in this manner that hereabouts, near the sea coast, where shingle is plentiful, houses are built with concrete and faced with cement after, which is marked out to look like blocks, and a great advantage, besides their cheapness, is that they are impervious to damp, which cannot be said of bricks such as we see turned out now-a-days. Ivy clings tenaciously to the concrete when left rough and unfaced, and your correspondent may therefore quickly cover any he puts up with this evergreen, which at all seasons has a pleasing and cheerful appearance, and more particularly if a few of the variegated varieties are used to mix with it.—S. D.

Names of Plants.—IV. E. P.—1. *Sericographis Ghiesbreghtiana*; 2. *Libonia floribunda*; 3. *Goldfussia isophylla*; 4. *Gymnogramma Massoni*; 5. *Coccoloba platyclada*.

Books.—*Alpine*—Hopppus' "Tree Measurer."

Questions.

Nettles Under Trees.—I have many acres of Nettles growing under large trees. Can any of your readers tell me the best way of getting rid of them?—E. F.

Substitutes for Asphalt.—Can any of your correspondents kindly tell me of an easy and inexpensive way of laying garden paths with coal tar and other materials as a cheap and durable substitute for asphalt? We are very badly off here for good gravel, and, as my house is in a dip, my paths retain the moisture.—H. M.

The Mountain Avens.—Is not "W." wrong (p. 562) in calling the Mountain Avens a *Geum*? The true Mountain Avens is *Dryas octopetala* a British species with white flowers to be found in the north and in Wales and Ireland. It grows here freely on rockwork, but does not flower profusely.—J. R. DROOP, *Stamford Hill*.

Brown Cjs Lettuces.—Where salads are required in winter these Lettuces are invaluable, as they are of such a hardy character that in ordinary winters one may insure a supply by utilising sheltered positions for late crops, which continue to grow, except during very severe weather; and if the means of affording protection be at hand, they retain their flavour better than plants lifted and stored in a close atmosphere. Dry Fern fronds are perhaps the best possible covering which can be given them, as they exclude frost without altogether depriving the plants of air.—J. GROOM, *Linton, near Maidstone*.

Rose-coloured Water Lily.—In the province of Nerike, in Sweden, there grows a lovely rose-coloured variety of our common Water Lily (*Nymphaea alba*). The outer petals of the Lily are rosy-red and the inner petals carmine-red. From what Dr. Fries, of Upsala, told me, it is chiefly to be seen in a sheet of water in the province of Nerike, where it flowers year after year. I first saw it in the Botanical Gardens at Christians, and on inquiry I learned from Professor Schübeler that it had come originally from Nerike. Nothing, save the colour, shows any variation from the normal condition of our Water Lily. What agency, chemical or otherwise, can have brought about the change it may be difficult to conceive. The colour is fixed and permanent, even after transplantation. Transmutation of colour from blue to pink and from pink to white is not very unfrequent in our native vegetation, but reversion from white to pink is assuredly rare and difficult of explanation. The cups, as I saw them, were large and well expanded, and in colour they had the appearance of a fine full rose on the water rather than of a Lily.—PETER INCHBALD, *Hovingham Lodge, York*.

The Willow and Malaria.—The cultivation of the Willow is, in your issue of October 25, recommended by one of your correspondents for districts affected with malaria. His statements on the subject being fully borne out by my own experience in the well-known malaria regions about Ephesus, I beg, through your columns, to call thereto the attention of the authorities in Cyprus. Before the *Eucalyptus* was ever heard of in Asia Minor, I had seen the bark of the Willow used as a febrifuge. I had remarked the easy and inexpensive reproduction of this tree, its quick growth in damp places, its excellent qualities for fuel and for agricultural implements, and its great advantages for strengthening the banks of capricious streams, and had thence taken every opportunity after the winter floods to stick Willow cuttings along the banks of streams and in other damp places in my property; also to scatter Plane tree seeds in marshy spots. The result has been that, whereas twenty years ago the full-grown trees in this neighbourhood might have been counted, a luxuriant growth of Willows and Plane trees marks my place, fuel is abundant, fever is steadily decreasing, the meandering propensities of the streams are checked, my neighbours have to come to me for agricultural implements, and I have not far to go for timber for rough purposes.—ERR. D. VAN LENNER, Swedish Consul, *Mahazik, near Smyrna*, in "Times." [The above is interesting as showing that other free-growing trees that are hardy are as useful as the *Eucalyptus*, which is not hardy.]

Notice to Correspondents.—Many communications are unavoidably left over this week.

NOTES OF THE WEEK

Gardening in Winter at Vienna.—At present the winter here is very severe, the thermometer sometimes being down to 0° Fahrenheit. Garden work out-of-doors is at a standstill. We could not open some of our cold frames for a week on account of the snow and cold. We grow here great numbers of Russian Violets in frames during the winter on purpose to have them in flower from November to March; some notes about their cultivation I shall have much pleasure in sending you hereafter. I also hope to send you a few remarks concerning our spring hedging out with perennial plants. We use different kinds of Wallflower, *Myosotis*, *Silene*, *Iberis*, *Aubrietia*, *Antirrhinum*, and *Delphinium*, with the view of having plenty of flowers from April, to the end of May. About this time of the year, when the earth is frozen hard, we transplant large specimen Conifers with good balls; the soil round the trees is taken out, leaving round the stem a ball of several feet in diameter, which, in a day or two becomes frozen so hard that in transplanting there is no fear of breaking it.—LOUIS JEROPATSC, *Imperial Gardens, Laxenbourg.*

New Amaryllises.—There will shortly be a good display of these in Mr. Ley's nursery, Croydon. The bulbs were imported from Peru. Numbers of them are throwing up flower spikes, and it may be reasonably hoped that some improved kinds will be found among them.

Sophronitis grandiflora.—This charming winter-flowering Orchid appears to be becoming plentiful, judging by the large importations of it which have recently been made. The back of one of the houses in Mr. Ley's nursery, Croydon, is furnished with neat little plants of it fastened on small pieces of wood. These are being grown on for flowering next winter. Considering how easy this plant may be cultivated, and in almost any way, either in pans, pots, baskets, or on blocks of wood or cork, it can hardly be too plentiful.

Plants in Bloom at Christmas.—It may be interesting to know what plants I have in flower at the present time for Christmas decoration. They consist of Lilies of the Valley in quantity, double Poinsettias, as well as some 600 of the old variety enlivened by a few plants of the white kind, *Euphorbia jacquiniædora*, Arum Lilies (*Callas*), Roman Hyacinths, Van Thol Tulips, *Eucharie amazonica* and candida, white and red Azaleas, *Lapageria alba*, *Bonvardias*, *Camellias*, *Persian Lilacs*, and *Chrysanthemums*.—H. VERTIGANS, *Chad Valley Nurseries, Birmingham.*

Musa Ensete in the Conservatory.—This noble plant is not so often grown in the conservatory as it probably would be, were it not that it is generally understood that it requires more heat than can, as a rule, be afforded in such a structure. This, however, is a mistaken notion, in proof of which we have only to allude to the fine specimen of this *Musa* in the large conservatory in Messrs. Henderson's nursery at Pine-apple Place. The plant in question was planted out from a pot two years ago last autumn, when it was about 4 ft. or 5 ft. high. The house is never kept warmer than is necessary to effectually exclude frost and expel damp, and yet this plant thrives admirably. Its dimensions at the present time are as follows: height, 25 ft.; circumference of stem at its base, 5½ ft.; circumference of stem at the part from which the leaves issue, 3 ft.; length of stem, 6 ft. 3 in. The number of leaves is fourteen, each of which is 13½ ft. long and 3 ft. wide. It is a noble specimen, and forms a striking object associated with finely-grown examples of various kinds of *Araucarias*, large spreading Palms, massive *Cordylines*, variegated New Zealand Flax, *Camellias*, and similar plants.

Orchid House and Fernery Combined.—One of the most attractive and interesting Orchid houses which we have seen, is that belonging to Mr. Philbrick, Regent's Park. It is a low lean-to, in which the pathway is sunk several feet below the ground level. The back wall, which is covered with virgin cork, is literally clothed with Ferns, Club Mosses, green trailing *Tradescantia*, and similar plants. A pathway runs through the centre of the house, formed of red bricks laid loosely so that water may stand in the apertures and give off moisture. The walls on each side which support the stages are also covered with Ferns, Grasses, and Mosses, and on the back stage, here and there, straight lines are broken by means of rustic work formed of cork and clothed with Ferns. A glass case for *Todeas* in one corner also gives an additional interest to the house, which at present contains a few pansful of *Sophronitis grandiflora*, growing on arch-shaped pieces of cork from 12 in. to 18 in. long, and from 9 in. to 12 in. wide. The plants of *Sophronitis* are dotted about on the cork when very small, but by good culture they rapidly increase, and at the present time one piece of cork covered with plants bears forty fully expanded brilliant scarlet blossoms, and there are many buds yet to open. These being suspended from the roof, among the

graceful fronds of Ferns, and associated with large, arching, finely-flowered spikes of *Odontoglossum*, a really fine effect is produced—a much better one, indeed, than that often found in more pretentious houses.

Tillandsia zebrina at Anerley.—Plants of this *Tillandsia* will shortly form a striking feature in Mr. Wills' nursery, Anerley. They are grown in 6-in. pots, and each plant is furnished with large, broad, zebra-marked leaves, and fine, long, sword-like spikes of brilliant blossoms. In the conservatory or dwelling house at this season of the year such plants would have a fine effect, and on that account they might well be grown more extensively than they are in private gardens.

Fine-leaved Plants in Winter.—The large collection of these in Mr. Wills' nursery at Anerley serves to show what excellent effects may be produced in winter by means of such materials alone. Here we find whole houses full of finely-grown *Crotons* representing nearly every possible shade of colour; *Dracænas*, with which several houses are packed, possess sparkling tints of crimson, rose, salmon, scarlet, and purple, whilst to white-edged sorts several new kinds have been added. Variegated Pines, fine specimens of *Yucca filamentosa variegata*, together with Pitcher Plants, Palms, and many other interesting plants render a visit to this nursery at any time of the year highly interesting.

HORTICULTURE AT THE PARIS EXHIBITION AND ABOUT PARIS.

At the Exhibition nothing struck one more than the Grass lawn in front of the Trocadero. It surpassed anything of the kind I ever saw; the purity of the Grasses and the density and greenness of the sward were marvellous, yet it was only laid down from seed last spring, though one would imagine it had been laid down for years. Carter, Sutton, and Webb—all English houses—supplied the seeds for the whole, or nearly the whole, of the grounds, and I noticed that one of these firms had used a good proportion of Clover among their seeds, which greatly improved the appearance of the sward, making it both much denser and greener. There can be little doubt about the advantage of using a goodly proportion of Clover in laying down lawns from seed. On some soils the plant can only be retained with difficulty for any length of time, while in others it grows spontaneously, on the red sandstone particularly, and forms the best part of the sward. The Trocadero grounds were worth going a long way to look at if for no more than just to see what can be done in so short a time by using good seed, and plenty of it, and high culture. It appeared as if the Grass had been richly dressed at intervals, and the frequent clippings of the machine had been left as a mulching, which, no doubt, protected it considerably, while the bottom was thin and exposed to the hot, dry sunshine. Cultivators generally prefer to lay down lawns with turf at once, which is certainly the speediest plan, but it is not the way to get a fine sward, which can only be secured by preparing and cleaning the ground thoroughly, and sowing seed, taking care to procure the latter from a good source, for all samples are not alike pure and clean. There was one piece of Grass in front of the Trocadero that formed a contrast to the others by its coarseness. The mistake generally made in laying down lawns is that the ground is not enriched enough, nor enough of seed used. Without attempting to criticise the laying out of the Trocadero grounds, which are undulating, sloping down to the river Seine, we may state that they were planted with considerable taste, and not overlaid with flowers or flower beds. The shining, white limestone of which the Trocadero Palace is built, as, indeed, all the city of Paris is, could not have been better relieved than by an open expanse of fresh, green Grass, and this the artist seemed to have realised. Standing in front of the Palace, and looking away over the Exhibition proper, and the city beyond spread out before one like a vast panorama, the eye fell back with a sense of relief upon the fresh green lawn beneath. The bit of ornamental gardening just immediately in front of the Trocadero, on each side of the cascade after the Versailles style, is worth alluding to. This consisted of two panels, perhaps some 60 or 80 yards long and less than half as wide. In ninety-nine cases in a hundred such a tempting piece of ground would, in England, have been filled in with a number of flower beds, and so frittered away to a considerable extent, but in this case that mistake was avoided.

A border of mixed bedding plants, annuals, perennials, and sub-tropical plants, with a goodly sprinkling of the inevitable Paris Daisy, ran round each panel a few feet from the gravel, and the centre was left quite vacant—a panel of green Grass only, about the size of a small bowling green, without a speck of colour upon it; and one sees, considering the circumstances, that this arrangement was the best that could have been adopted. We thought, at least, that the panel of beautiful green Grass, so intensely green, was more effective than any arrangement of flower beds could have been. "How beautiful the Grass looks!" was an exclamation often heard from spectators who were constantly promenading the corridors of the Trocadero. The narrow flower border before mentioned was very effectively planted, and the narrow and very exactly kept line of *Pyrethrum Golden Feather*, which ran round the border, gave just the necessary finish to the picture. I saw a similar arrangement elsewhere in Paris in some of the gardens and small squares. There was no carpet bedding in the Exposition grounds so well done, after its style, as that in Hyde Park, but some of the groups of miscellaneous bedding was very effective. The beds of China Asters were grand, and we saw them planting these out at the fortnightly exhibit in full flower—grand plants 12 in. or 15 in. high, with flowers about 6 in. across. They appeared to have been raised in sharp soil, and were not put out of pots, but had been lifted from the ground, and had only small balls of soil to them, but plenty of roots. I found out afterwards that the fine pot plants of Asters I saw in the markets, and in the shop windows had been similarly prepared, and they looked perfectly fresh. Two or three colours were put in a pot. They make gay window plants, and large quantities are sold. The Zinnias, too, were really magnificent, and were permanently planted; but the most effective, and, to us, novel beds in the grounds were the *Celosias*, a crimson kind, in habit like *Celosia aurea*, but much dwarfed. They were put out in pots, and each plant was a beautiful little specimen, about 12 in. high and as much through, and extraordinarily well flowered. They would have been considered grand objects for conservatory decoration in England, and I do not remember ever to have seen such shapely and dwarf specimens, those grown in English gardens being generally rather leggy. The *Coleus Verschaffeltii* is much used as a bedding plant in and about Paris, and grows in the most rampant fashion. The growth of this plant alone exhibits the difference of climate between Paris and London. In Hyde Park this summer the *Coleus* has done well, but the plants were stunted and dwarf compared with those in Paris, which looked more like stove-grown specimens, only that the colour of the foliage was more intense than one ever sees it in a stove in this country. In a mixed bed which we saw in front of Rose Charnoux's house at Thomery, the *Coleus* threatened to overtop everything else. In the Exposition grounds there were also grand beds of *Begonias* of the *Sedeni* and *Veitchii* types, and some of the common kinds were bedded out extensively and were growing like weeds. Next to the lawn, however, the trees, deciduous and evergreen, planted around the Trocadero attracted most attention. There were many species, all planted in spring, I believe, and all growing luxuriantly.

Every tree must have been planted with great care. The rockeries which skirted the grounds in some places and shut out undesirable prospects were wonderfully well furnished, considering the short time, and great pains had been taken to encourage the Ivy to grow over the rocks, and well it had responded to generous treatment. Altogether, the gardening round the Trocadero Palace and on the opposite side of the Seine beyond was a wonderfully successful effort, and we felt sorry that the call upon our time in other respects allowed us little more than time just to race through the grounds; hence our meagre and but half-digested observations on some topics. Among peculiar exhibits which we saw in the Exhibition may be mentioned the dwarfed, if ancient, specimens of trees and plants from Japan. At first sight, to an English gardener, these looked the most miserable rubbish that one ever cast eyes upon; and although one, on looking a little more closely at such examples of prolonged starvation, may come to regard them as physiological curiosities, we cannot indulge in any very complimentary reflections on horticulturists who have spent generations in cultivating such idiotic productions. None of the specimens could be said to be healthy; they were stunted and miserable-looking in the extreme, at the very last gasp of existence, in fact. There was one venerable *Cycas revoluta* which may be taken as an example of the lot. It had a stem, which, judging from its height, girth, and wrinkled look, may have been centuries old. From this gnarled trunk protruded an abortive attempt at growth in the shape of about three fronds 4 in. or 5 in. long, proportionately broad, and of a sickly yellow colour. The soil in the pot seemed to have been squeezed out in the course of time during which this ancestral specimen had been growing and increasing in girth, and when we saw it it looked as if it would soon be subsisting on nothing but the pot. I left this exhibition soon, and felt no desire to go back again.

Among horticultural buildings and appliances there was nothing very remarkable. All the plant houses requiring shade were shaded on the French plan, that is, by a kind of light Venetian blind. This is made of thin laths strung together, about $\frac{1}{4}$ in. apart and painted green, and the blind is rolled or pulled up and down by cords. In some cases they are used inside, but generally on the outside of the roof, and make an excellent and not too dense a shade. I am inclined to entertain a good opinion of this method of shading, though Mr. Stanton, of Park Place, assured me that he had tried the plan, but found the blinds exceedingly troublesome and very inconvenient to work when used inside, which I could well believe. French horticulturists, however, seem to get on with them well enough. I rather liked, too, the light copper pipes with which some of the houses were heated. They were thin and light, and equal in capacity to our 4-in. iron pipes, but not nearly so heavy and clumsy. They are more expensive than iron pipes, but not proportionately so, owing to their thinness and lightness, and they are very durable. Numbers of copper boilers of various shapes and sizes for heating by hot water were also exhibited, but all, without exception, were inferior in design to those supplied by English makers at home. J. S. W.

END OF VOL. XIV.
